If too many values are specified for an effect, the extra ones are ignored; if too few are specified, the remaining ones are set to 0. If no random effects are specified, the vertical bar can be omitted; otherwise, it must be present. If a SUBJECT effect is used in the **RANDOM** statement, then the coefficients specified for the effects in the **RANDOM** statement are equitably distributed across the levels of the SUBJECT effect. You can use the **E** option to see exactly what **L** matrix is used.

The **SUBJECT** and **GROUP** options in the **CONTRAST** statement are useful for the case where a **SUBJECT=** or **GROUP=** variable appears in the **RANDOM** statement, and you want to contrast different subjects or groups. By default, **CONTRAST** statement coefficients about random effects are distributed equally across subjects and groups.

PROC HPMIXED handles missing level combinations of CLASS variables similarly to the way PROC GLM does. Both procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, PROC HPMIXED does not delete missing level combinations for random-effects parameters because linear combinations of the random-effects parameters are always estimable. These conventions can affect the way you specify your **CONTRAST** coefficients.

The **CONTRAST** statement computes the statistic

$$F = \frac{\begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}' \mathbf{L}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})^{-1}\mathbf{L}' \begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}}{r}$$

where  $r = \text{rank}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})$  and approximates its distribution with an  $F$  distribution. In this expression,  $\hat{\mathbf{C}}$  is an estimate of the generalized inverse of the coefficient matrix in the mixed model equations.

The numerator degree of freedom in the  $F$  approximation is  $r = \text{rank}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})$ , and the denominator degree of freedom is taken from the “Type III Tests of Fixed Effects” table and corresponds to the final effect you list in the **CONTRAST** statement. You can change the denominator degrees of freedom by using the **DF=** option.

You can specify the following *options* in the **CONTRAST** statement after a slash (/).

#### **CHISQ**

requests that  $\chi^2$  tests be performed in addition to any  $F$  tests. A  $\chi^2$  statistic equals its corresponding  $F$  statistic times the associate numerator degree of freedom, and this same degree of freedom is used to compute the  $p$ -value for the  $\chi^2$  test. This  $p$ -value will always be less than that for the  $F$  test, as it effectively corresponds to an  $F$  test with infinite denominator degrees of freedom.

#### **DF=number**

specifies the denominator degrees of freedom for the  $F$  test. The default is the denominator degrees of freedom taken from the “Type III Tests of Fixed Effects” table and corresponds to the final effect you list in the **CONTRAST** statement.

#### **E**

requests that the **L** matrix coefficients for the contrast be displayed. The name of this “L Matrix Coefficients” table is “Coef.”

**GROUP** *coeffs*

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, **CONTRAST** statement coefficients about random effects are distributed equally across groups. If you enter a multi-row contrast, you can also enter multiple rows for the **GROUP** coefficients. If the number of **GROUP** coefficients is less than the number of contrasts in the **CONTRAST** statement, the **HPMIXED** procedure cycles through the **GROUP** coefficients. For example, the following two statements are equivalent:

```
contrast 'Trt @ x=0.4 and 0.5' trt 1 -1 0 | x 0.4,
 trt 1 0 -1 | x 0.4,
 trt 1 -1 0 | x 0.5,
 trt 1 0 -1 | x 0.5 /
 group 1 -1, 1 0 -1, 1 -1, 1 0 -1;

contrast 'Trt @ x=0.4 and 0.5' trt 1 -1 0 | x 0.4,
 trt 1 0 -1 | x 0.4,
 trt 1 -1 0 | x 0.5,
 trt 1 0 -1 | x 0.5 /
 group 1 -1, 1 0 -1;
```

**SINGULAR=***number*

tunes the estimability checking. If  $\mathbf{v}$  is a vector, define  $\text{ABS}(\mathbf{v})$  to be the largest absolute value of the element of  $\mathbf{v}$  with the largest absolute value. If  $\text{ABS}(\mathbf{K}' - \mathbf{K}'\mathbf{T})$  is greater than  $c \cdot \text{number}$  for any row of  $\mathbf{K}'$  in the contrast, then  $\mathbf{K}$  is declared nonestimable. Here  $\mathbf{T}$  is the Hermite form matrix  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$ , and  $c$  is  $\text{ABS}(\mathbf{K}')$  except when it equals 0, and then  $c$  is 1. The value for *number* must be between 0 and 1; the default is 1E-4.

**SUBJECT** *coeffs*

sets up random-effect contrasts between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, **CONTRAST** statement coefficients about random effects are distributed equally across subjects. Listing subject coefficients for multiple row **CONTRASTS** follows the same rules as for **GROUP** coefficients.

---

**EFFECT Statement**

**EFFECT** *name=effect-type (variables </ options>);*

The **EFFECT** statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “[GLM Parameterization of Classification Variables and Effects](#)” on page 383 in Chapter 19, “[Shared Concepts and Topics](#).”

You can specify the following *effect-types*:

- COLLECTION** is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.
- LAG** is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                             |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 46.4 summarizes the *options* available in the EFFECT statement.

**Table 46.4** EFFECT Statement Options

| Option                             | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Collection Effects Options</b>  |                                                                                                                                                      |
| DETAILS                            | Displays the constituents of the collection effect                                                                                                   |
| <b>Lag Effects Options</b>         |                                                                                                                                                      |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                        |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                            |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                           |
| PERIOD=                            | Names the variable that defines the period                                                                                                           |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                            |
| <b>Multimember Effects Options</b> |                                                                                                                                                      |
| NOEFFECT                           | Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                            |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                      |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                               |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                             |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                              |
| <b>Spline Effects Options</b>      |                                                                                                                                                      |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                              |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                    |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                              |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

The HPMIXED procedure does not support the SPLIT or SEPARATED option in spline effects and poly effects.

## ESTIMATE Statement

```
ESTIMATE 'label' contrast-specification <(divisor=n)>
 <, 'label' contrast-specification <(divisor=n)>> <, ... > </ options > ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. As in the **CONTRAST** statement, the basic element of the ESTIMATE statement is the *contrast-specification*, which consists of **MODEL** and **RANDOM** effects and their coefficients. Specifically, a *contrast-specification* takes the form

```
< fixed-effect values ... > < | random-effect values ... >
```

Based on the *contrast-specifications* in your ESTIMATE statement, PROC HPMIXED constructs the matrix  $L' = [K' M']$ , as in the **CONTRAST** statement, where **K** is associated with the fixed effects and **M** is associated with the G-side random effects.

PROC HPMIXED then produces for each row *l* of  $L'$  an approximate *t* test of the hypothesis  $H: l\phi = 0$ , where  $\phi = [\beta' \gamma']'$ . Results from all ESTIMATE statement are combined in the “Estimates” ODS table.

Note that multi-row estimates are permitted. Unlike the **CONTRAST** statement, you need to specify a *'label'* for every row of the multi-row estimate, since PROC HPMIXED produces one test per row.

PROC HPMIXED selects the degrees of freedom to match those displayed in the “Type III Tests of Fixed Effects” table for the final effect you list in the ESTIMATE statement. You can modify the degrees of freedom by using the **DF=** option. If you select **DDFM=NONE** and do not modify the degrees of freedom by using the **DF=** option, PROC HPMIXED uses infinite degrees of freedom, essentially computing approximate *z* tests.

If PROC HPMIXED finds the fixed-effects portion of the specified estimate to be nonestimable, then it displays “Non-est” for the estimate entry.

The construction of the **L** matrix for an ESTIMATE statement follows the same rules as listed under the **CONTRAST** statement.

Table 46.5 summarizes the options available in the ESTIMATE statement.

**Table 46.5** ESTIMATE Statement Options

| Option    | Description                                      |
|-----------|--------------------------------------------------|
| ALPHA=    | Specifies the confidence level                   |
| CL        | Constructs <i>t</i> -type confidence limits      |
| DF=       | Specifies the degrees of freedom                 |
| DIVISOR=  | Specifies values to divide the coefficients      |
| E         | Displays the matrix coefficients                 |
| GROUP     | Sets up random-effect contrasts between groups   |
| SINGULAR= | Tunes the estimability checking                  |
| SUBJECT   | Sets up random-effect estimates between subjects |

You can specify the following *options* in the ESTIMATE statement after a slash (/).

**ALPHA=number**

requests that a *t*-type confidence interval be constructed with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1 exclusively; the default is 0.05. If **DDFM=NONE** and you do not specify degrees of freedom with the **DF=** option, PROC HPMIXED uses infinite degrees of freedom, essentially computing a *z* interval.

**CL**

requests that *t*-type confidence limits be constructed. If **DDFM=NONE** and you do not specify degrees of freedom with the **DF=** option, PROC HPMIXED uses infinite degrees of freedom, essentially computing a *z* interval. The confidence level is 0.95 by default.

**DF=number**

specifies the degrees of freedom for the *t*-test. The default is the denominator degrees of freedom taken from the “Type III Tests of Fixed Effects” table and corresponds to the final effect you list in the ESTIMATE statement.

**DIVISOR=value-list**

specifies a list of values by which to divide the coefficients so that fractional coefficients can be entered as integer numerators. If you do not specify *value-list*, a default value of 1.0 is assumed. Missing values in the *value-list* are converted to 1.0.

If the number of elements in *value-list* exceeds the number of rows of the estimate, the extra values are ignored. If the number of elements in *value-list* is less than the number of rows of the estimate, the last value in *value-list* is copied forward.

If you specify a row-specific divisor as part of the specification of the estimate row, this value multiplies the corresponding divisor implied by the *value-list*. For example, the following statement divides the coefficients in the first row by 8, and the coefficients in the third and fourth row by 3:

```
estimate 'One vs. two' A 2 -2 (divisor=2),
 'One vs. three' A 1 0 -1 ,
 'One vs. four' A 3 0 0 -3 ,
 'One vs. five' A 1 0 0 0 -1 / divisor=4,.,3;
```

**E**

requests that the matrix coefficients be displayed. For ODS purposes, the name of this “L Matrix Coefficients” table is “Coef.”

**GROUP coeffs**

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, ESTIMATE statement coefficients about random effects are distributed equally across groups. If you enter a multi-row estimate, you can also enter multiple rows for the GROUP coefficients. If the number of GROUP coefficients is less than the number of contrasts in the ESTIMATE statement, the HPMIXED procedure cycles through the GROUP coefficients. For example, the following two statements are equivalent:

```

estimate 'Trt 1 vs 2 @ x=0.4' trt 1 -1 0 | x 0.4,
 'Trt 1 vs 3 @ x=0.4' trt 1 0 -1 | x 0.4,
 'Trt 1 vs 2 @ x=0.5' trt 1 -1 0 | x 0.5,
 'Trt 1 vs 3 @ x=0.5' trt 1 0 -1 | x 0.5 /
 group 1 -1, 1 0 -1, 1 -1, 1 0 -1;

estimate 'Trt 1 vs 2 @ x=0.4' trt 1 -1 0 | x 0.4,
 'Trt 1 vs 3 @ x=0.4' trt 1 0 -1 | x 0.4,
 'Trt 1 vs 2 @ x=0.5' trt 1 -1 0 | x 0.5,
 'Trt 1 vs 3 @ x=0.5' trt 1 0 -1 | x 0.5 /
 group 1 -1, 1 0 -1;

```

**SINGULAR=number**

tunes the estimability checking as documented for the **SINGULAR=** in the **CONTRAST** statement.

**SUBJECT coeffs**

sets up random-effect estimates between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, **ESTIMATE** statement coefficients about random effects are distributed equally across subjects. Listing subject coefficients for an **ESTIMATE** statement with multiple rows follows the same rules as for **GROUP** coefficients.

## ID Statement

**ID variables ;**

The **ID** statement specifies which variables from the input data set are to be included in the **OUT=** data sets from the **OUTPUT** statement. If you do not specify an **ID** statement, then all variables are included in these data sets. Otherwise, only the variables you list in the **ID** statement are included. Specifying an **ID** statement with no variables prevents any variables from being included in these data sets.

## LSMEANS Statement

**LSMEANS fixed-effects </ options > ;**

The **LSMEANS** statement computes least squares means (LS-means) of fixed effects. As in the **GLM** procedure, LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as classification and subclassification arithmetic means are to balanced designs. The **L** matrix constructed to compute them is the same as the **L** matrix formed in **PROC GLM**; however, the standard errors are adjusted for the covariance parameters in the model.

Each LS-mean is computed as  $L'\hat{\beta}$ , where **L** is the coefficient matrix associated with the least squares mean and  $\hat{\beta}$  is the estimate of the fixed-effects parameter vector. The approximate standard errors for the LS-mean is computed as the square root of  $L'(X'\hat{V}^{-1}X)^{-1}L$ .

LS-means can be computed for any effect in the **MODEL** statement that involves **CLASS** variables. You can specify multiple effects in one **LSMEANS** statement or in multiple **LSMEANS** statements, and all **LSMEANS** statements must appear after the **MODEL** statement. As in the **ESTIMATE** statement, the **L**

matrix is tested for estimability, and if this test fails, PROC HPMIXED displays “Non-est” for the LS-means entries.

Assuming the LS-mean is estimable, PROC HPMIXED constructs an approximate  $t$  test to test the null hypothesis that the associated population quantity equals zero. By default, the denominator degrees of freedom for this test are the same as those displayed for the effect in the “Type III Tests of Fixed Effects” table (see the section “TEST Statement” on page 3692).

Table 46.6 summarizes the options available in the LSMEANS statement.

**Table 46.6** LSMEANS Statement Options

| Option        | Description                                          |
|---------------|------------------------------------------------------|
| ALPHA=        | Specifies the confidence level                       |
| CL            | Constructs $t$ -type confidence limits               |
| CORR          | Displays the estimated correlation matrix            |
| COV           | Displays the estimated covariance matrix             |
| DF=           | Specifies the degrees of freedom                     |
| DIFF or PDIFF | Displays the differences of the LS-means             |
| E             | Displays the matrix coefficients for LSMEANS effects |
| SINGULAR=     | Tunes the estimability checking                      |
| SLICE=        | Partitions interaction LSMEANS effects               |

You can specify the following *options* in the LSMEANS statement after a slash (/).

**ALPHA=number**

requests that a  $t$ -type confidence interval be constructed for each of the LS-means with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**CL**

requests that  $t$ -type confidence limits be constructed for each of the LS-means. If **DDFM=NONE**, then PROC HPMIXED uses infinite degrees of freedom for this test, essentially computing a  $z$  interval. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

**CORR**

displays the estimated correlation matrix of the least squares means as part of the “Least Squares Means” table.

**COV**

displays the estimated covariance matrix of the least squares means as part of the “Least Squares Means” table.

**DF=number**

specifies the degrees of freedom for the  $t$  test and confidence limits. The default is the denominator degrees of freedom taken from the “Type III Tests of Fixed Effects” table corresponding to the LS-means effect. For these **DDFM=** methods, degrees of freedom are determined separately for each test; see the **DDFM=** option on page 3679 for more information.

**DIFF**<=*difftype*>

**PDIFF**<=*difftype*>

requests that differences of the LS-means be displayed. You can specify the following values for the optional *difftype*.

**DIFF=ALL** requests all pairwise differences; it is the default.

**DIFF=ANOM** requests differences between each LS-mean and the average LS-mean, as in the analysis of means (Ott 1967). The average is computed as a weighted mean of the LS-means, with the weights being inversely proportional to the diagonal entries of the  $L(X'X)^{-1}L'$  matrix. When a **WEIGHT** statement is specified, then the preceding matrix is replaced with  $L(X'WX)^{-1}L'$  where **W** is the diagonal matrix that contains the weights. If LS-means are nonestimable, this design-based weighted mean is replaced with an equally weighted mean. Note that the ANOM procedure in SAS/QC software implements both tables and graphics for the analysis of means with a variety of response types. For one-way designs and normally distributed data, the **DIFF=ANOM** computations are equivalent to the results of **PROC ANOM**.

**DIFF=CONTROL** requests differences with a control; by default, the control is the first level of each of the specified LSMEANS effects. To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the **CONTROL** keyword. For example, if the effects A, B, and C are classification variables, each having two levels, 1 and 2, the following LSMEANS statement specifies the (1,2) level of A\*B and the (2,1) level of B\*C as controls:

```
lsmeans A*B B*C / diff=control('1' '2' '2' '1');
```

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

**CONTROL** produces two-tailed tests and confidence limits.

**DIFF=CONTROLL** requests one-tailed results and tests whether the noncontrol levels are significantly smaller than the control. The upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing.

**DIFF=CONTROLU** requests one-tailed results and tests whether the noncontrol levels are significantly larger than the control. The upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

The differences of the LS-means are displayed in a table titled “Differences of Least Squares Means.” The table name is “Diffs.”

**E**

requests that the matrix coefficients for all LSMEANS effects be displayed. The name of this “Matrix Coefficients” table is “Coef.”

**PDIFF**

is the same as the **DIFF** option. See the description of the **DIFF** option on page 3677.

**SINGULAR=number**

tunes the estimability checking as documented for the **SINGULAR=** in the **CONTRAST** statement.

**SLICE=fixed-effect****SLICE=(fixed-effects)**

specifies effects by which to partition interaction LSMEANS effects. This can produce what are known as tests of simple effects (Winer 1971). For example, suppose that **A\*B** is significant, and you want to test the effect of **A** for each level of **B**. The appropriate LSMEANS statement is

```
lsmeans A*B / slice=B;
```

This statement tests for the simple main effects of **A** for **B**, which are calculated by extracting the appropriate rows from the coefficient matrix for the **A\*B** LS-means and by using them to form an *F* test.

The **SLICE=** option produces *F* tests that test the simultaneous equality of cell means at a fixed level of the slice effect (Schabenberger, Gregoire, and Kong 2000).

The **SLICE=** option produces a table titled “Tests of Effect Slices.” The table name is “Slices.”

## MODEL Statement

**MODEL** *dependent* = < *fixed-effects* > < / *options* > ;

The **MODEL** statement names a single dependent variable and the fixed effects, which determine the **X** matrix of the mixed model. The specification of effects is the same as in the GLM procedure; however, unlike PROC GLM, you do not specify random effects in the **MODEL** statement. The **MODEL** statement is required.

An intercept is included in the fixed-effects model by default. If no fixed effects are specified, only this intercept term is fit. The intercept can be removed by using the **NOINT** option.

You can specify the following *options* in the **MODEL** statement after a slash (/).

**ALPHA=number**

requests that a *t*-type confidence interval be constructed for each of the fixed-effects parameters with confidence level  $1 - \textit{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**CL**

requests that *t*-type confidence limits be constructed for each of the fixed-effects parameter estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

**DDF=value-list**

enables you to specify your own denominator degrees of freedom for the fixed effects. The *value-list* specification is a list of numbers or missing values (.) separated by commas. The degrees of freedom should be listed in the order in which the effects appear in the “Type III Tests of Fixed Effects” table. If you want to retain the default degrees of freedom for a particular effect, use a missing value for its location in the list. For example, the following statement assigns 3 denominator degrees of freedom to **A** and 4.7 to **A\*B**, while those for **B** remain the same:

```
model Y = A B A*B / ddf=3, ., 4.7;
```

**DDFM=RESIDUAL | NONE**

specifies the method for computing the denominator degrees of freedom for the tests of fixed effects resulting from the MODEL, CONTRAST, ESTIMATE, LSMEANS, and TEST statements.

The DDFM=RESIDUAL option performs all tests by using the residual degrees of freedom,  $n - \text{rank}(\mathbf{X})$ , where  $n$  is the number of observations used. It is the default degrees of freedom method.

DDFM=NONE specifies that no denominator degrees of freedom be applied. PROC HPMIXED then essentially assumes that infinite degrees of freedom are available in the calculation of  $p$ -values. The  $p$ -values for  $t$  tests are then identical to  $p$ -values derived from the standard normal distribution. In the case of  $F$  tests, the  $p$ -values equal those of chi-square tests determined as follows: if  $F_{obs}$  is the observed value of the  $F$  test with  $l$  numerator degrees of freedom, then

$$p = \Pr\{F_{l,\infty} > F_{obs}\} = \Pr\{\chi_l^2 > lF_{obs}\}$$

**NOINT**

requests that no intercept be included in the model. An intercept is included by default.

**SOLUTION | S**

requests that a solution for the fixed-effects parameters be produced. Using notation from the section “Model Assumptions” on page 3693, the fixed-effects parameter estimates are  $\hat{\beta}$  and their approximate standard errors are the square roots of the diagonal elements of  $(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-}$ .

Along with the estimates and their approximate standard errors, a  $t$  statistic is computed as the estimate divided by its standard error. The degree of freedom for this  $t$  statistic matches the one appearing in the “Type III Tests of Fixed Effects” table under the effect containing the parameter. The “Pr > |t|” column contains the two-tailed  $p$ -value corresponding to the  $t$  statistic and associated degrees of freedom.

**ZETA=number**

tunes the sensitivity in forming Type III functions. Any element in the estimable function basis with an absolute value less than *number* is set to 0. The default is 1E–8.

**NLOPTIONS Statement**

```
NLOPTIONS < options >;
```

For more information about the NLOPTIONS, see the section “NLOPTIONS Statement” on page 482 in Chapter 19, “Shared Concepts and Topics.”

If you choose TECH=NEWRAP, then the default value of LSPRECISION is 0.4 in the HPMIXED procedure.

**OUTPUT Statement**

```
OUTPUT < OUT=SAS-data-set >
 < keyword< (keyword-options) > < =name >> ...
 < keyword< (keyword-options) > < =name >> < / options >;
```

The OUTPUT statement creates a data set that contains predicted values and residual diagnostics, computed after fitting the model. By default, all variables in the original data set are included in the output data set.

You can use the ID statement to select a subset of the variables from the input data set to be added to the output data set.

For example, suppose that the data set Scores contains the variables score, machine, and person. The following statements fit a model with fixed machine and random person effects and save the predicted and residual values to the data set igaussout:

```
proc hpmixed data = Scores;
 class machine person score;
 model score = machine;
 random person;
 output out=igaussout pred=p resid=r;
run;
```

You can specify the following *options* in the OUTPUT statement before the slash (/).

#### OUT=SAS data set

specifies the name of the output data set. If the OUT= option is omitted, the procedure uses the DATA*n* convention to name the output data set.

#### keyword <(keyword-options)> <=name>

specifies a statistic to include in the output data set and optionally assigns the variable the name name. You can use the *keyword-options* to control which type of a particular statistic to compute. The *keyword-options* can take on the following values:

- BLUP                uses the predictors of the random effects in computing the statistic.
- NOBLUP            does not use the predictors of the random effects in computing the statistic.

The default is to compute statistics by using BLUPs. For example, the following two OUTPUT statements are equivalent:

```
output out=out1 pred=predicted lcl=lower;
output out=out1 pred(blup)=predicted lcl(blup)=lower;
```

If a particular combination of keyword and keyword options is not supported, the statistic is not computed and a message is produced in the SAS log.

A *keyword* can appear multiple times in the OUTPUT statement. Table 46.7 lists the keywords and the default names assigned by the HPMIXED procedure if you do not specify a *name*. In this table, *y* denotes the response variable.

**Table 46.7** Keywords for Output Statistics

| Keyword   | Options | Description                            | Expression                                                                                | Name   |
|-----------|---------|----------------------------------------|-------------------------------------------------------------------------------------------|--------|
| PREDICTED | BLUP    | Linear predictor                       | $\hat{\eta} = \mathbf{x}'\hat{\boldsymbol{\beta}} + \mathbf{z}'\hat{\boldsymbol{\gamma}}$ | Pred   |
|           | NOBLUP  | Marginal linear predictor              | $\hat{\eta}_m = \mathbf{x}'\hat{\boldsymbol{\beta}}$                                      | PredPA |
| STDERR    | BLUP    | Standard deviation of linear predictor | $\sqrt{\text{Var}[\hat{\eta} - \mathbf{z}'\boldsymbol{\gamma}]}$                          | StdErr |

Table 46.7 (continued)

| Keyword  | Options | Description                                          | Expression                                               | Name       |
|----------|---------|------------------------------------------------------|----------------------------------------------------------|------------|
|          | NOBLUP  | Standard deviation of marginal linear predictor      | $\sqrt{\widehat{\text{Var}}[\widehat{\eta}_m]}$          | StdErrPA   |
| RESIDUAL | BLUP    | Residual                                             | $r = y - \widehat{\eta}$                                 | Resid      |
|          | NOBLUP  | Marginal residual                                    | $r_m = y - \widehat{\eta}_m$                             | ResidPA    |
| PEARSON  | BLUP    | Pearson-type residual                                | $r / \sqrt{\widehat{\text{Var}}[y \boldsymbol{\gamma}]}$ | Pearson    |
|          | NOBLUP  | Marginal Pearson-type residual                       | $r_m / \sqrt{\widehat{\text{Var}}[y]}$                   | PearsonPA  |
| STUDENT  | BLUP    | Studentized residual                                 | $r / \sqrt{\widehat{\text{Var}}[r]}$                     | Student    |
|          | NOBLUP  | Studentized marginal residual                        | $r_m / \sqrt{\widehat{\text{Var}}[r_m]}$                 | StudentPA  |
| LCL      | BLUP    | Lower prediction limit for linear predictor          |                                                          | LCL        |
|          | NOBLUP  | Lower confidence limit for marginal linear predictor |                                                          | LCLPA      |
| UCL      | BLUP    | Upper prediction limit for linear predictor          |                                                          | UCL        |
|          | NOBLUP  | Upper confidence limit for marginal linear predictor |                                                          | UCLPA      |
| VARIANCE | BLUP    | Conditional variance of response variable            | $\widehat{\text{Var}}[y \boldsymbol{\gamma}]$            | Variance   |
|          | NOBLUP  | Marginal variance of response variable               | $\widehat{\text{Var}}[y]$                                | VariancePA |

You can use the following shortcuts to request statistics: PRED for PREDICTED, STD for STDERR, RESID for RESIDUAL, VAR for VARIANCE.

You can specify the following options of the OUTPUT statement after the slash (/).

### ALLSTATS

requests that all statistics are computed. If you do not use a keyword to assign a name, the HPMIXED procedure uses the default name.

### ALPHA=*number*

determines the coverage probability for two-sided confidence and prediction intervals. The coverage probability is computed as  $1 - \textit{number}$ . The value of *number* must be between 0 and 1 inclusively; the default is 0.05.

### NOMISS

requests that records from the input data set be written to the output data only for those observations that were used in the analysis. By default, the HPMIXED procedure produces output statistics for all observations in the input data set.

**NOUNIQUE**

requests that names not be made unique in the case of naming conflicts. By default, the HPMIXED procedure avoids naming conflicts by assigning a unique name to each output variable. If you specify the NOUNIQUE option, variables with conflicting names are not renamed. In that case, the first variable added to the output data set takes precedence.

**NOVAR**

requests that variables from the input data set not be added to the output data set. This option ignores ID statement but does not apply to variables listed in a BY statement.

---

**PARMS Statement**

**PARMS** <(value-list)... > </options> ;

The PARMS statement specifies initial values for the covariance parameters, or it requests a grid search over several values of these parameters. You must specify the values in the order in which they appear in the “Covariance Parameter Estimates” table.

The *value-list* specification can take any of several forms:

|                        |                                                                                                           |
|------------------------|-----------------------------------------------------------------------------------------------------------|
| $m$                    | a single value                                                                                            |
| $m_1, m_2, \dots, m_n$ | several values                                                                                            |
| $m$ to $n$             | a sequence where $m$ equals the starting value, $n$ equals the ending value, and the increment equals 1   |
| $m$ to $n$ by $i$      | a sequence where $m$ equals the starting value, $n$ equals the ending value, and the increment equals $i$ |
| $m_1, m_2$ to $m_3$    | mixed values and sequences                                                                                |

You can use the PARMS statement to input known parameters. Suppose the three variance components are known to be 2, 1, and 3. The SAS statements to fix the variance components at these values are as follows:

```
proc hpmixed noprofile;
 class Family Gender;
 model Height = Gender;
 random Family Family*Gender;
 parms (2) (1) (3) / noiter;
run;
```

The NOPROFILE option in the PROC HPMIXED statement suppresses profiling the residual variance parameter during its calculations, thereby enabling its value to be held at 3 as specified in the PARMS statement.

If you specify more than one set of initial values, PROC HPMIXED performs a grid search of the likelihood surface and uses the best point on the grid for subsequent analysis. Specifying a large number of grid points can result in long computing times. The grid search feature is also useful for exploring the likelihood surface.

The results from the PARMS statement are the values of the parameters on the specified grid (denoted by CovP1–CovPn), the residual variance (possibly estimated) for models with a residual variance parameter, and various functions of the likelihood.

The name of the “Parameter Search” table is “ParmSearch.”

You can specify the following *options* in the PARMs statement after a slash (/).

**HOLD=***value-list*

#### **HOLD**

specifies which parameter values **PROC HPMIXED** should hold to equal the specified values. To hold all parameters, you can use the second form without giving the *value-list*. For example, the following statement constrains the first and third covariance parameters to equal 5 and 2, respectively.

Specifying the HOLD= option implies the **NOPROFILE** option in the **PROC HPMIXED** statement:

```
parms (5) (3) (2) (3) / hold=1,3;
```

**LOWERB=***value-list*

enables you to specify lower boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that **PROC HPMIXED** uses for the covariance parameters, and each number corresponds to the lower boundary constraint. A missing value instructs **PROC HPMIXED** to use its default constraint, and if you do not specify numbers for all of the covariance parameters, **PROC MIXED** assumes the remaining ones are missing.

#### **NOITER**

requests that no optimization iterations be performed and that **PROC HPMIXED** use the best value from the grid search to perform inferences. By default, iterations begin at the best value from the PARMs grid search. This option is ignored when you specify the **HOLD=** option.

If a residual variance is profiled, the parameter estimates can change from the initial values you provide as the residual variance is recomputed. To prevent an update of the residual variance, combine the **NOITER** option with the **NOPROFILE** option in the **PROC HPMIXED** statements, as in the following program:

```
proc hpmixed noprofile;
 class A B C rep mp sp;
 model y = A | B | C;
 random rep mp sp;
 parms (180) (200) (170) (1000) / noiter;
run;
```

Specifying the **NOITER** option in the PARMs statement has the same effect as specifying **TECHNIQUE=NONE** in the **NLOPTIONS** statement.

Notice that the **NOITER** option can be useful if you want to obtain the starting values **HPMIXED** computes. The following statements produce the starting values:

```
proc hpmixed noprofile;
 class A B;
 model y = A;
 random int / subject=B;
 parms / noiter;
run;
```

**PARMSDATA=SAS-data-set**

**PDATA=SAS data set**

reads in covariance parameter values from a SAS data set. The data set should contain the numerical variable ESTIMATE or the numerical variables Covp1–Covp $q$ , where  $q$  denotes the number of covariance parameters.

If the PARMSDATA= data set contains multiple sets of covariance parameters, the HPMIXED procedure evaluates the initial objective function for each set and commences the optimization step by using the set with the lowest function value as the starting values. For example, the following SAS statements request that the objective function be evaluated for three sets of initial values:

```
data data_covp;
 input covp1-covp4;
 datalines;
180 200 170 1000
170 190 160 900
160 180 150 800
;
proc hpmixed;
 class A B C rep;
 model yield = A;
 random rep B C;
 parms / pdata=data_covp;
run;
```

Each set comprises four covariance parameters.

The order of the observations in a data set with the numerical variable Estimate corresponds to the order of the covariance parameters in the “Covariance Parameter Estimates” table.

The PARMSDATA= data set must contain at least one set of covariance parameters with no missing values.

If the HPMIXED procedure is processing the input data set in BY groups, you can add the BY variables to the PARMSDATA= data set. If this data set is sorted by the BY variables, the HPMIXED procedure matches the covariance parameter values to the current BY group. If the PARMSDATA= data set does not contain all BY variables, the data set is processed in its entirety for every BY group and a message is written to the log. This enables you to provide a single set of starting values across BY groups, as in the following statements:

```
data data_covp;
 input covp1-covp4;
 datalines;
180 200 170 1000
;
proc hpmixed;
 class A B C rep;
 model yield = A;
 random rep B C;
 parms / pdata=data_covp;
 by year;
run;
```

The same set of starting values is used for each value of the year variable.

**UPPERB=value-list**

enables you to specify upper boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC HP MIXED uses for the covariance parameters, and each number corresponds to the upper boundary constraint. A missing value instructs PROC HP MIXED to use its default constraint, and if you do not specify numbers for all of the covariance parameters, PROC HP MIXED assumes that the remaining ones are missing.

---

## RANDOM Statement

**RANDOM** *random-effects* </ options > ;

The RANDOM statement defines the random effects in the mixed model. It can be used to specify traditional variance component models (as in the VARCOMP procedure) and to specify random coefficients. The random effects can be classification or continuous. Multiple RANDOM statements are possible. Random effects specified in a RANDOM statement could be correlated with each other for certain types of covariance structures (see the TYPE= option on page 3686). It is, however, assumed that random effects specified using different RANDOM statements are not correlated.

Using notation from the section “Model Assumptions” on page 3693, the purpose of the RANDOM statement is to define the  $\mathbf{Z}$  matrix of the mixed model, the random effects in the  $\boldsymbol{\gamma}$  vector, and the structure of  $\mathbf{G}$ . The  $\mathbf{Z}$  matrix is constructed exactly like the  $\mathbf{X}$  matrix for the fixed effects, and the  $\mathbf{G}$  matrix is constructed to correspond to the effects constituting  $\mathbf{Z}$ . The structure of  $\mathbf{G}$  is defined by using the TYPE= option described on page 3686.

You can specify INTERCEPT (or INT) as a random effect. PROC HP MIXED does not include the intercept in the RANDOM statement by default, as it does in the MODEL statement.

You can specify the following *options* in the RANDOM statement after a slash (/).

**ALPHA=number**

requests that a  $t$ -type confidence interval with confidence level  $1 - \text{number}$  be constructed for the predictors of random effects in this statement. The value of *number* must be between 0 and 1 exclusively; the default is 0.05. Specifying the ALPHA= option implies the CL option.

**CL**

requests that  $t$ -type confidence limits be constructed for each of the predictors of random effects in this statement. The confidence level is 0.95 by default; this can be changed with the ALPHA= option. The CL option implies the SOLUTION option.

**GROUP=effect**

defines an effect specifying heterogeneity in the covariance structure of  $\mathbf{G}$ . All observations having the same level of the group effect have the same covariance parameters. Each new level of the group effect produces a new set of covariance parameters with the same structure as the original group. You should exercise caution in defining the group effect, because strange covariance patterns can result from its misuse. Also, the group effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

Continuous variables are permitted as arguments to the GROUP= option. PROC HPMIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of groups and also prevents the production of a large “Class Levels Information” table.

### NOFULLZ

eliminates the columns in  $\mathbf{Z}$  corresponding to missing levels of random effects involving CLASS variables. By default, these columns are included in  $\mathbf{Z}$ . It is sufficient to specify the NOFULLZ option in any RANDOM statement.

### SOLUTION

requests that the solution for the random-effects parameters be produced. Using notation from the section “Model Assumptions” on page 3693, these estimates are the empirical best linear unbiased predictors (BLUPs)  $\hat{\boldsymbol{\gamma}} = \hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})$ . They can be useful for comparing the random effects from different experimental units and can also be treated as residuals in performing diagnostics for your mixed model.

The numbers displayed in the SE Pred column of the “Solution for Random Effects” table are not the standard errors of the  $\hat{\boldsymbol{\gamma}}$  displayed in the Estimate column; rather, they are the standard errors of predictions  $\hat{\boldsymbol{\gamma}}_i - \boldsymbol{\gamma}_i$ , where  $\hat{\boldsymbol{\gamma}}_i$  is the  $i$ th BLUP and  $\boldsymbol{\gamma}_i$  is the  $i$ th random-effect parameter.

### SUBJECT=effect

identifies the subjects in your mixed model. Complete independence is assumed across subjects; thus, for the RANDOM statement, the SUBJECT= option produces a block-diagonal structure in  $\mathbf{G}$  with identical blocks. The  $\mathbf{Z}$  matrix is modified to accommodate this block-diagonality. In fact, specifying a subject effect is equivalent to nesting all other effects in the RANDOM statement within the subject effect.

Continuous variables are permitted as arguments to the SUBJECT= option. PROC HPMIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects and also prevents the production of a large “Class Levels Information” table.

### TYPE=covariance-structure

specifies the structure of the covariance matrix  $\mathbf{G}$  for random effects. The default structure is VC.

If you want different covariance structures in different parts of  $\mathbf{G}$ , you must use multiple RANDOM statements with different TYPE= options.

Valid values for *covariance-structure* are listed in Table 46.8. Examples are shown in Table 46.9.

**Table 46.8** Covariance Structures

| Structure | Description            | Parameters | $(i, j)$ element                              |
|-----------|------------------------|------------|-----------------------------------------------|
| AR(1)     | Autoregressive(1)      | 2          | $\sigma^2\rho^{ i-j }$                        |
| CHOL      | Cholesky root          | $t(t+1)/2$ | $l_{ij}$                                      |
| CS        | Compound symmetry (CS) | 2          | $\sigma_1 + \sigma^2 1(i=j)$                  |
| CSH       | Heterogeneous CS       | $t+1$      | $\sigma_i\sigma_j[\rho 1(i \neq j) + 1(i=j)]$ |

**Table 46.8** *continued*

| Structure | Description              | Parms        | (i, j) element                                                  |
|-----------|--------------------------|--------------|-----------------------------------------------------------------|
| UC        | Uniform correlation (UC) | 2            | $\sigma^2[\rho 1(i \neq j) + 1(i = j)]$                         |
| UCH       | Heterogeneous UC         | $t + 1$      | $\sigma_i \sigma_j [\rho 1(i \neq j) + 1(i = j)]$               |
| UN        | Unstructured             | $t(t + 1)/2$ | $\sigma_{ij}$                                                   |
| VC        | Variance components      | $q$          | $\sigma_k^2 1(i = j)$<br>and $i, j$ correspond to $k$ th effect |

In Table 46.8,  $t$  is the overall dimension of the covariance matrix, and  $1(A)$  equals 1 when  $A$  is true and 0 otherwise. For example,  $1(i = j)$  equals 1 when  $i = j$  and equals 0 otherwise. TYPE=UCH is the same as TYPE=CSH.

Table 46.9 lists some examples of the structures in Table 46.8.

**Table 46.9** Covariance Structure Examples

| Description                | Structure | Example                                                                                                                                                                                                                                                                                                                                                                                            |
|----------------------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| First-order autoregressive | AR(1)     | $\sigma^2 \begin{bmatrix} 1 & \rho & \rho^2 & \rho^3 \\ \rho & 1 & \rho & \rho^2 \\ \rho^2 & \rho & 1 & \rho \\ \rho^3 & \rho^2 & \rho & 1 \end{bmatrix}$                                                                                                                                                                                                                                          |
| Cholesky root              | CHOL      | $\begin{bmatrix} l_{11} & 0 & 0 & 0 \\ l_{21} & l_{22} & 0 & 0 \\ l_{31} & l_{32} & l_{33} & 0 \\ l_{41} & l_{42} & l_{43} & l_{44} \end{bmatrix} \begin{bmatrix} l_{11} & l_{21} & l_{31} & l_{41} \\ 0 & l_{22} & l_{32} & l_{42} \\ 0 & 0 & l_{33} & l_{43} \\ 0 & 0 & 0 & l_{44} \end{bmatrix}$                                                                                                |
| Compound symmetry          | CS        | $\begin{bmatrix} \sigma^2 + \sigma_1 & \sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma^2 + \sigma_1 & \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma^2 + \sigma_1 & \sigma_1 \\ \sigma_1 & \sigma_1 & \sigma_1 & \sigma^2 + \sigma_1 \end{bmatrix}$                                                                                                                                       |
| Uniform correlation        | UC        | $\sigma^2 \begin{bmatrix} 1 & \rho & \rho & \rho \\ \rho & 1 & \rho & \rho \\ \rho & \rho & 1 & \rho \\ \rho & \rho & \rho & 1 \end{bmatrix}$                                                                                                                                                                                                                                                      |
| Heterogeneous UC           | UCH       | $\begin{bmatrix} \sigma_1^2 & \sigma_1 \sigma_2 \rho & \sigma_1 \sigma_3 \rho & \sigma_1 \sigma_4 \rho \\ \sigma_2 \sigma_1 \rho & \sigma_2^2 & \sigma_2 \sigma_3 \rho & \sigma_2 \sigma_4 \rho \\ \sigma_3 \sigma_1 \rho & \sigma_3 \sigma_2 \rho & \sigma_3^2 & \sigma_3 \sigma_4 \rho \\ \sigma_4 \sigma_1 \rho & \sigma_4 \sigma_2 \rho^2 & \sigma_4 \sigma_3 \rho & \sigma_4^2 \end{bmatrix}$ |
| Unstructured               | UN        | $\begin{bmatrix} \sigma_1^2 & \sigma_{21} & \sigma_{31} & \sigma_{41} \\ \sigma_{21} & \sigma_2^2 & \sigma_{32} & \sigma_{42} \\ \sigma_{31} & \sigma_{32} & \sigma_3^2 & \sigma_{34} \\ \sigma_{41} & \sigma_{42} & \sigma_{43} & \sigma_4^2 \end{bmatrix}$                                                                                                                                       |

Table 46.9 continued

| Description         | Structure    | Example                                                                                                                              |
|---------------------|--------------|--------------------------------------------------------------------------------------------------------------------------------------|
| Variance components | VC (default) | $\begin{bmatrix} \sigma_A^2 & 0 & 0 & 0 \\ 0 & \sigma_A^2 & 0 & 0 \\ 0 & 0 & \sigma_B^2 & 0 \\ 0 & 0 & 0 & \sigma_B^2 \end{bmatrix}$ |

The variances and covariances in the formulas that follow in the TYPE= descriptions are expressed in terms of generic random variables  $\xi_i$  and  $\xi_j$ . They represent random effects for which the  $\mathbf{G}$  matrices are constructed.

The following list provides some further information about these covariance structures:

TYPE=AR(1) specifies a first-order autoregressive structure,

$$\text{Cov}[\xi_i, \xi_j] = \sigma^2 \rho^{|i-j|}$$

The values  $i$  and  $j$  are derived for the  $i$ th and  $j$ th observations, respectively. For example, in the following statements the values correspond to the class levels for the time effect of the  $i$ th and  $j$ th observation within a particular subject:

```
proc hpmixed;
 class time patient;
 model y = x x*x;
 random time / sub=patient type=ar(1);
run;
```

PROC HPMIXED imposes the constraint  $|\rho| < 1$  for stationarity.

TYPE=CHOL specifies an unstructured variance-covariance matrix parameterized through its Cholesky root. All diagonal values are constrained to be positive. This parameterization guarantees a positive definite covariance matrix. For example, a  $2 \times 2$  unstructured covariance matrix can be written as

$$\text{Var}[\boldsymbol{\xi}] = \begin{bmatrix} \sigma_1^2 & \sigma_{21} \\ \sigma_{21} & \sigma_2^2 \end{bmatrix}$$

Without imposing constraints on the three parameters, there is no guarantee that the estimated variance matrix is positive definite. Even if  $\sigma_1^2$  and  $\sigma_2^2$  are nonzero, a large value for  $\sigma_{21}$  can lead to a negative eigenvalue of  $\text{Var}[\boldsymbol{\xi}]$ . The Cholesky root of a positive definite matrix  $\mathbf{A}$  is a lower triangular matrix  $\mathbf{L}$  such that  $\mathbf{LL}' = \mathbf{A}$ . The Cholesky root of the above  $2 \times 2$  matrix can be written as

$$\mathbf{L} = \begin{bmatrix} l_{11} & 0 \\ l_{21} & l_{22} \end{bmatrix}$$

The elements of the unstructured variance matrix are then simply  $\sigma_1^2 = l_{11}^2$ ,  $\sigma_{21} = l_{21}l_{11}$ , and  $\sigma_2^2 = l_{21}^2 + l_{22}^2$ . Similar operations yield the generalization to covariance matrices of higher orders.

For example, the following statements model the covariance matrix of each subject as an unstructured matrix:

```

proc hpmixed;
 class sub;
 model y = x;
 random time / sub=patient type=chol;
run;

```

The HPMIXED procedure constrains the diagonal elements of the Cholesky root to be positive. This guarantees that the structure is positive definite.

TYPE=CS specifies the compound-symmetry structure, which has constant variance and constant covariance

$$\text{Cov}[\xi_i, \xi_j] = \begin{cases} \sigma^2 + \sigma_1 & i = j \\ \sigma_1 & i \neq j \end{cases}$$

Under compound-symmetry, the  $\mathbf{G}$  matrix is of form  $\sigma^2\mathbf{I} + \sigma_1\mathbf{J}$ . The variance parameter  $\sigma^2$  is constrained to be positive, and the covariance parameter  $\sigma_1$  is constrained to be greater than  $-\sigma^2/t$  where  $t$  is the dimension of the structure. This guarantees the structure is positive definite. The compound-symmetry structure arises naturally with nested random effects, such as when a subsampling error is nested within an experimental error.

TYPE=CSH specifies the heterogeneous compound-symmetry structure. This structure has a different variance parameter for each diagonal element, and it uses the square roots of these parameters in the off-diagonal entries. In Table 46.8,  $\sigma_i^2$  is the  $i$ th variance parameter that satisfies  $\sigma_i^2 > 0$ , and  $\rho$  is the correlation parameter that satisfies  $\rho > -1/(t-1)$ , where  $t$  is the dimension of the structure. This guarantees that the structure is positive definite.

TYPE=UC specifies the uniform correlation structure, which has constant variance and constant correlation

$$\text{Cov}[\xi_i, \xi_j] = \begin{cases} \sigma^2 & i = j \\ \sigma^2\rho & i \neq j \end{cases}$$

Under uniform correlation, the  $\mathbf{G}$  matrix is of form  $\sigma^2[(1-\rho)\mathbf{I} + \rho\mathbf{J}]$ . The variance  $\sigma^2$  is constrained to be positive, and the correlation  $\rho$  is constrained to be greater than  $-1/(t-1)$ , where  $t$  is the dimension of the structure. This guarantees the structure is positive definite. This structure is equivalent to the compound-symmetry structure with a better numerical property in terms of optimization.

The uniform correlation structure arises frequently in agriculture and animal sciences.

TYPE=UCH specifies the heterogeneous uniform correlation structure. This structure has a different variance parameter for each diagonal element, and it uses the square roots of these parameters in the off-diagonal entries. In Table 46.8,  $\sigma_i^2$  is the  $i$ th variance parameter that satisfies  $\sigma_i^2 > 0$ , and  $\rho$  is the correlation parameter that satisfies  $\rho > -1/(t-1)$ , where  $t$  is the dimension of the structure. This guarantees that the structure is positive definite.

TYPE=UN specifies a completely general (unstructured) covariance matrix parameterized directly in terms of variances and covariances. The variances are constrained to be

positive, and the covariances are unconstrained. In addition, this structure is internally constrained to be positive definite.

**TYPE=VC** specifies standard variance components and is the default structure for the **RANDOM** and **REPEATED** statements. In the **RANDOM** statement, a distinct variance component is assigned to each effect. In the **REPEATED** statement, this structure is usually used only with the **GROUP=** option to specify a heterogeneous variance model.

## REPEATED Statement

**REPEATED** *repeated-effect* </ options > ;

The **REPEATED** statement defines the repeated effect and the residual covariance structure in the mixed model. The residual variance-covariance matrix is denoted as **R**. The *repeated-effect* is required and consists entirely of classification variables. The levels of the *repeated-effect* must be different for each observation within a subject in order to avoid the singular **R** matrix. The **SUBJECT=** option is required. The data set must be grouped by subject effect.

Table 46.10 summarizes the options available in the **REPEATED** statement.

**Table 46.10** Summary of **REPEATED** Statement Options

| Option                                      | Description                                                                                 |
|---------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction of Covariance Structure</b> |                                                                                             |
| <b>GROUP=</b>                               | Defines an effect that specifies heterogeneity in the residual covariance structure         |
| <b>SUBJECT=</b>                             | Identifies the subjects in the residual covariance structure                                |
| <b>TYPE=</b>                                | Specifies the residual covariance structure (the default is VC)                             |
| <b>Statistical Output</b>                   |                                                                                             |
| <b>R=</b>                                   | Displays blocks of the estimated <b>R</b> matrix                                            |
| <b>RC=</b>                                  | Display the Cholesky root (lower) of blocks of the estimated <b>R</b> matrix                |
| <b>RCI=</b>                                 | Displays the inverse Cholesky root (lower) of blocks of the estimated <b>R</b> matrix       |
| <b>RCORR=</b>                               | Displays the correlation matrix that corresponds to blocks of the estimated <b>R</b> matrix |
| <b>RI=</b>                                  | Displays the inverse of blocks of the estimated <b>R</b> matrix                             |

You can specify the following *options* in the **REPEATED** statement after a slash (/).

**GROUP=effect**

**GRP=effect**

defines an effect that specifies heterogeneity in the residual covariance structure. All observations that have the same level of the **GROUP** effect have the same covariance parameters. Each new level of the **GROUP** effect produces a new set of covariance parameters with the same structure as the original

group. You should exercise caution in defining the GROUP effect, because strange covariance patterns can result with its misuse. Also, the GROUP effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

Continuous variables are permitted as arguments to the GROUP= option. PROC HPMIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

**R<=value-list>**

requests that blocks of the estimated **R** matrix be displayed. The first block determined by the **SUBJECT=** effect is the default displayed block.

The *value-list* indicates the subjects for which blocks of **R** are to be displayed. For example, the following statement displays block matrices for the first, third, and fifth persons:

```
repeated time / type=un subject=person r=1,3,5;
```

See the **PARMS** statement for the possible forms of *value-list*.

**RC<=value-list>**

displays the Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as for the **R=** option.

**RCI<=value-list>**

displays the inverse Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as for the **R=** option.

**RCORR<=value-list>**

displays the correlation matrix that corresponds to blocks of the estimated **R** matrix. The *value-list* specification is the same as for the **R=** option.

**RI<=value-list>**

produces the inverse of blocks of the estimated **R** matrix. The *value-list* specification is the same as for the **R=** option.

**SUBJECT=effect**

**SUB=effect**

identifies the subjects in your mixed model. Complete independence is assumed across subjects; therefore, the **SUBJECT=** option produces a block-diagonal structure in **R** with identical blocks. The **SUBJECT=** option is required. The data set must be grouped by **SUBJECT=** effect. When the **SUBJECT=** effect consists entirely of classification variables, the blocks of **R** correspond to observations that share the same level of that effect. These blocks are sorted according to this effect as well.

Continuous variables are permitted as arguments to the **SUBJECT=** option. PROC HPMIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

If you want to model nonzero covariance among all of the observations in your data, specify `SUBJECT=INTERCEPT` to treat the data as if they are all from one subject. However, be aware that in this case PROC HPMIXED manipulates an **R** matrix with dimensions equal to the number of observations.

**TYPE=covariance-structure**

specifies the structure of the residual variance-covariance matrix **R**. The `SUBJECT=` option defines the blocks of **R**, and the `TYPE=` option specifies the structure of these blocks. PROC HPMIXED supports the following structures: `TYPE=AR(1)`, `TYPE=CHOL`, `TYPE=UN`, and `TYPE=VC`. The default structure is `VC`. See the description in the section “[RANDOM Statement](#)” on page 3685 for more information about these covariance structure types.

## TEST Statement

**TEST** *fixed-effects* *</ options >* ;

The TEST statement performs a hypothesis test on the fixed effects. You can specify multiple effects in one TEST statement or in multiple TEST statements, and all TEST statements must appear after the `MODEL` statement.

You can specify the following *options* in the TEST statement after a slash (/).

**HTYPE=value-list**

indicates the type of hypothesis test to perform on the specified effects. Valid entries for values in the *value-list* are 3, corresponding to a Type III test. The default value is 3. The ODS table name is “Tests3” for the Type III test.

**E**

requests that matrix coefficients associated with test types be displayed for specified effects.

**E3 | EIII**

requests that Type III matrix coefficients be displayed if a Type III test is performed.

**CHISQ**

requests that  $\chi^2$  tests be performed in addition to any *F* tests. A  $\chi^2$  statistic equals its corresponding *F* statistic times the associate numerator degree of freedom, and this same degree of freedom is used to compute the *p*-value for the  $\chi^2$  test. This *p*-value will always be less than that for the *F* test, because it effectively corresponds to an *F* test with infinite denominator degrees of freedom.

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement replaces **R** with  $\mathbf{W}^{-1/2}\mathbf{R}\mathbf{W}^{-1/2}$ , where **W** is a diagonal matrix containing the weights. Observations with nonpositive or missing weights are not included in the resulting PROC HPMIXED analysis. If a WEIGHT statement is not included, all observations used in the analysis are assigned a weight of 1.

If a computation in PROC MIXED involves  $\mathbf{R}$ , then the WEIGHT statement replaces  $\mathbf{R}$  with  $\mathbf{W}^{-1/2}\mathbf{R}\mathbf{W}^{-1/2}$ . For example, the covariance matrix  $\mathbf{V}$  for the observations usually have the form  $\mathbf{V} = \mathbf{Z}\mathbf{G}\mathbf{Z}' + \mathbf{R}$ ; therefore, with the WEIGHT statement, this becomes  $\mathbf{V} = \mathbf{Z}\mathbf{G}\mathbf{Z}' + \mathbf{W}^{-1/2}\mathbf{R}\mathbf{W}^{-1/2}$ .

## Details: HPMIXED Procedure

### Model Assumptions

The following sections provide an overview of the approach used by the HPMIXED procedure for likelihood-based analysis of linear mixed models with sparse matrix technique. Additional theory and examples are provided in Littell et al. (1996); Verbeke and Molenberghs (1997, 2000); Brown and Prescott (1999).

The HPMIXED procedure fits models generally of the form

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

Models of this form contain both fixed-effects parameters,  $\boldsymbol{\beta}$ , and random-effects parameters,  $\boldsymbol{\gamma}$ ; hence, they are called *mixed models*. See Henderson (1990) and Searle, Casella, and McCulloch (1992) for historical developments of the mixed model. Note that the matrix  $\mathbf{Z}$  can contain either continuous or dummy variables, just like  $\mathbf{X}$ .

So far this is the same general form of model fit by the MIXED procedure. The difference between the models handled by the two procedures lies in the assumptions about the distributions of  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$ . For both procedures a key assumption is that  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$  are normally distributed with

$$\begin{aligned} E \begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} &= \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix} \\ \text{Var} \begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} &= \begin{bmatrix} \mathbf{G} & \mathbf{0} \\ \mathbf{0} & \mathbf{R} \end{bmatrix} \end{aligned}$$

The two procedures differ in their assumptions about the variance matrices  $\mathbf{G}$  and  $\mathbf{R}$  for  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$ , respectively. The MIXED procedure allows a variety of different structures for both  $\mathbf{G}$  and  $\mathbf{R}$ ; while in HPMIXED procedure,  $\mathbf{R}$  is always assumed to be of the form  $\mathbf{R} = \mathbf{I}\sigma^2$ , and the structures available for modeling  $\mathbf{G}$  are only a small subset of the structures offered by the MIXED procedure.

Estimates of fixed effects and predictions for random effects are obtained by solving the so-called *mixed model equations*:

$$\begin{bmatrix} \mathbf{X}'\mathbf{X}/\sigma^2 & \mathbf{X}'\mathbf{Z}/\sigma^2 \\ \mathbf{Z}'\mathbf{X}/\sigma^2 & \mathbf{Z}'\mathbf{Z}/\sigma^2 + \mathbf{G}^{-1} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\mathbf{y}/\sigma^2 \\ \mathbf{Z}'\mathbf{y}/\sigma^2 \end{bmatrix}$$

Let  $\mathbf{C}$  denote the coefficient matrix of the mixed model equations:

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}'\mathbf{X}/\sigma^2 & \mathbf{X}'\mathbf{Z}/\sigma^2 \\ \mathbf{Z}'\mathbf{X}/\sigma^2 & \mathbf{Z}'\mathbf{Z}/\sigma^2 + \mathbf{G}^{-1} \end{bmatrix}$$

Under the assumptions given previously for the moments of  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$ , the variance of  $\mathbf{y}$  is  $\mathbf{V} = \mathbf{ZGZ}' + \mathbf{I}\sigma^2$ . You can model  $\mathbf{V}$  by setting up the random-effects design matrix  $\mathbf{Z}$  and by specifying covariance structures for  $\mathbf{G}$ . Let  $\boldsymbol{\theta}$  be a vector of all unknown parameters in  $\mathbf{G}$ . Then the general form of the restricted likelihood function for the mixed models that the HPMIXED procedure can fit is

$$L(\boldsymbol{\theta}, \sigma^2) = -2 \log l = (n - p) \log(2\pi) + \log |\mathbf{C}| + \log |\mathbf{G}| + n \log(\sigma^2) + \mathbf{y}'\mathbf{P}\mathbf{y}$$

where

$$\mathbf{P} = \mathbf{V}^{-1} - \mathbf{V}^{-1}\mathbf{X}(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}$$

and  $p$  is the rank of  $\mathbf{X}$ . The HPMIXED procedure minimizes  $L(\boldsymbol{\theta}, \sigma^2)$  over all unknown parameters in  $\boldsymbol{\theta}$  and  $\sigma^2$  by using nonlinear optimization algorithms.

## Computing and Maximizing the Likelihood

In computing the restricted likelihood function given previously, the determinants of the matrices  $\mathbf{C}$  and  $\mathbf{G}$  can be obtained effectively by using Cholesky decomposition. The quadratic term  $\mathbf{y}'\mathbf{P}\mathbf{y}$  can be expressed in terms of solutions of mixed model equations as follows:

$$\mathbf{y}'\mathbf{P}\mathbf{y} = \frac{1}{\sigma^2} \left( \mathbf{y}'\mathbf{y} - \begin{bmatrix} \hat{\boldsymbol{\beta}}' & \hat{\boldsymbol{\gamma}}' \end{bmatrix} \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{Z}'\mathbf{y} \end{bmatrix} \right)$$

By default, the HPMIXED procedure profiles out the residual variance  $\sigma^2$  from the parameter vector  $\boldsymbol{\theta}$ . Let  $\boldsymbol{\theta}^*$  be the new parameter vector such that  $\theta_i^* = \theta_i/\sigma^2$ . The profiled objective function becomes

$$L(\boldsymbol{\theta}^*, \sigma^2) = (n - p) \log(2\pi) + \log |\mathbf{C}^*| + \log |\mathbf{G}^*| - (r_C - r_G - n) \log(\sigma^2) + (n - p)$$

where  $\mathbf{C}^* = \mathbf{C}\sigma^2$  and  $\mathbf{G}^* = \mathbf{G}\sigma^2$  are the profiled versions of  $\mathbf{C}$  and  $\mathbf{G}$ ,  $r_C$  and  $r_G$  are the ranks of  $\mathbf{C}$  and  $\mathbf{G}$ . Minimizing analytically for  $\sigma^2$  yields

$$\hat{\sigma}^2 = \frac{1}{n - p} \left( \mathbf{y}'\mathbf{y} - \begin{bmatrix} \hat{\boldsymbol{\beta}}' & \hat{\boldsymbol{\gamma}}' \end{bmatrix} \begin{bmatrix} \mathbf{X}'\mathbf{y} \\ \mathbf{Z}'\mathbf{y} \end{bmatrix} \right)$$

Optimizing the likelihood calls for derivatives with respect to the parameters. The first and second derivatives of the log-likelihood function  $L$  with respect to scalar variance components  $\theta_i$  and  $\theta_j$  are

$$\frac{\partial L}{\partial \theta_i} = \text{tr} \left( \frac{\partial \mathbf{V}}{\partial \theta_i} \mathbf{P} \right) - \mathbf{y}'\mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_i} \mathbf{P}\mathbf{y}$$

and

$$\frac{\partial^2 L}{\partial \theta_i \partial \theta_j} = -\text{tr} \left( \frac{\partial \mathbf{V}}{\partial \theta_i} \mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_j} \mathbf{P} \right) + 2\mathbf{y}'\mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_i} \mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_j} \mathbf{P}\mathbf{y}$$

The default quasi-Newton method of optimization for the HPMIXED procedure requires only first derivatives of the log likelihood, and these are readily derived by solving the mixed model equations. For example, when  $\mathbf{G} = \mathbf{I}\sigma_a^2$ , the first derivative of the log likelihood with respect to the parameter  $\sigma_a^2$  can be computed as follows:

$$\frac{\partial L}{\partial \sigma_a^2} = \frac{q}{\sigma_a^2} - \frac{\text{tr}(\mathbf{C}^{aa})}{\sigma_a^4} - \frac{\hat{\boldsymbol{\gamma}}'\hat{\boldsymbol{\gamma}}}{\sigma_a^4}$$

where  $q$  is the size of  $\boldsymbol{\gamma}$  vector and  $\mathbf{C}^{aa}$  is the part of the  $g$ -inverse of the mixed model equation coefficient matrix  $\mathbf{C}$  corresponding to the random effect  $\boldsymbol{\gamma}$ .

The second derivative of the log likelihood needs to be computed only if you specify certain nondefault optimization techniques in the NLOPTIONS statement, namely TECH=NEWRAP, TECH=NRRIDG, or TECH=TRUREG; see “NLOPTIONS Statement” on page 482 in Chapter 19, “Shared Concepts and Topics,” for more information about optimization techniques. For these second-derivative-based optimization techniques, the HPMIXED procedure does not actually use the true second derivative matrix, or *observed information matrix*, as defined earlier. Instead, it uses an alternative matrix that is more efficient to compute for large problems and that can be more stable. This alternative is called the *average information matrix*, and it is defined as follows. The expected value of the second derivative is

$$\mathbf{E}\left(\frac{\partial^2 L}{\partial \theta_i \partial \theta_j}\right) = \text{tr}\left(\frac{\partial \mathbf{V}}{\partial \theta_i} \mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_j} \mathbf{P}\right)$$

It is this trace that is computationally inefficient to evaluate. But if you average the expected information matrix defined by this formula with the observed information matrix defined by the preceding formula for the true second derivative, then the trace term cancels, leaving just a quadratic expression in  $\mathbf{y}$ . This quadratic expression defines the average information (Johnson and Thompson 1995) with respect to  $\theta_i$  and  $\theta_j$ :

$$\text{AI}(\theta_i, \theta_j) = \mathbf{y}' \mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_i} \mathbf{P} \frac{\partial \mathbf{V}}{\partial \theta_j} \mathbf{P} \mathbf{y}$$

---

## Computing Starting Values by EM-REML

The EM-REML algorithm (Dempster, Laird, and Rubin 1977) iteratively alternates between an expectation step and a maximization step to maximize the restricted log likelihood. The algorithm is based on augmenting the observed data  $\mathbf{y}$  with the unobservable random effects  $\boldsymbol{\gamma}$ , leading to a simplified form for the log likelihood. For example, if  $\mathbf{G} = \mathbf{I}\sigma_a^2$  then given the realized values  $\tilde{\boldsymbol{\gamma}}$  of the unobservable random effects  $\boldsymbol{\gamma}$ , the REML estimate of  $\sigma_a^2$  satisfies

$$\hat{\sigma}_a^2 = \frac{\tilde{\boldsymbol{\gamma}}' \tilde{\boldsymbol{\gamma}}}{q - \sigma^2 / \sigma_a^2 \text{tr}(\mathbf{C}^{aa})}$$

This corresponds to the maximization step of EM-REML. However, the true realized values  $\tilde{\boldsymbol{\gamma}}$  are unknown in practice. The expectation step of EM-REML replaces them with the conditional expected values  $\hat{\boldsymbol{\gamma}}$  of the random effects, given the observed data  $\mathbf{y}$  and initial values for the parameters. The new estimate of  $\sigma_a^2$  is used in turn to recalculate the conditional expected values, and the iteration is repeated until convergence.

It is well known that EM-REML is generally more robust against a poor choice of starting values than general nonlinear optimization methods such as Newton-Raphson, though it tends to converge slowly as it approaches the optimum. The Newton-Raphson method, on the other hand, converges much faster when it has a good set of starting values. The HPMIXED procedure, thus, employs a scheme that uses EM-REML initially in order to get good starting values, and after a few iterations, when the decrease in log likelihood has significantly slowed down, switching to a more general nonlinear optimization technique (by default, quasi-Newton).

## Sparse Matrix Techniques

A key component of the HPMIXED procedure is the use of sparse matrix techniques for computing and optimizing the likelihood expression given in the section “Model Assumptions” on page 3693. There are two aspects to sparse matrix techniques, namely, sparse matrix storage and sparse matrix computations. Typically, computer programs represent an  $N \times M$  matrix in a dense form as an array of size  $NM$ , making row-wise and column-wise arithmetic operations particularly efficient to compute. However, if many of these  $NM$  numbers are zeros, then correspondingly many of these operations are unnecessary or trivial. Sparse matrix techniques exploit this fact by representing a matrix not as a complete array, but as a set of nonzero elements and their location (row and column) within the matrix. Sparse matrix techniques are more efficient if there are enough zero-element operations in the dense form to make the extra time required to find and operate on matrix elements in the sparse form worthwhile.

The following discussion illustrates sparse techniques. Let the symmetric matrix  $\mathbf{C}$  be the matrix of mixed model equations of size  $5 \times 5$ .

$$\mathbf{C} = \begin{bmatrix} 8.0 & 0 & 0 & 2.0 & 0 \\ 0 & 4.0 & 3.0 & 0 & 0 \\ 0 & 3.0 & 5.0 & 0 & 0 \\ 2.0 & 0 & 0 & 7.0 & 0 \\ 0 & 0 & 0 & 0 & 9.0 \end{bmatrix}$$

There are 15 elements in the upper triangle of  $\mathbf{C}$ , though eight of them are zeros. The row and column indices and the values of seven nonzero elements are listed as follows:

$$\begin{array}{c|cccccc} i & 1 & 1 & 2 & 2 & 3 & 4 & 5 \\ j & 1 & 4 & 2 & 3 & 3 & 4 & 5 \\ C_{ij} & 8.0 & 2.0 & 4.0 & 3.0 & 5.0 & 7.0 & 9.0 \end{array}$$

The most elegant scheme to store these seven elements is to store them in a hash table with row and column indices as a hash key. However, this scheme is not efficient as the number of non-zero elements gets very large. The classical and widely used scheme, and the one the HPMIXED procedure employs, is the  $(\mathbf{i}_c, \mathbf{j}_c, c)$  format, in which the nonzero elements are stored contiguously row by row in the vector  $c$ . To identify the individual nonzero elements in each row, you need to know the column index of an element. These column indices are stored in the vector  $\mathbf{j}_c$ ; that is, if  $c(k) = C_{ij}$ , then  $\mathbf{j}_c(k) = j$ . To identify the individual rows, you need to know where each row starts and ends. These row starting positions are stored in the vector  $\mathbf{i}_c$ . For instance, if  $C_{ij}$  is the first nonzero element in the row  $i$  and  $c(k) = C_{ij}$ , then  $\mathbf{i}_c(i) = k$ . The row  $i$  ending position is one less than  $\mathbf{i}_c(i + 1)$ . Thus, the number of nonzero elements in the row  $i$  is  $\mathbf{i}_c(i + 1) - \mathbf{i}_c(i)$ , these elements in the row  $i$  are stored consecutively starting from the position  $k_i = \mathbf{i}_c(i)$

$$c(k_i), c(k_i + 1), c(k_i + 2), \dots, c(k_{i+1} - 1)$$

and the corresponding columns indices are stored consecutively in

$$\mathbf{j}_c(k_i), \mathbf{j}_c(k_i + 1), \mathbf{j}_c(k_i + 2), \dots, \mathbf{j}_c(k_{i+1} - 1)$$

For example, the seven nonzero elements in matrix  $\mathbf{C}$  are stored in  $(\mathbf{i}_c, \mathbf{j}_c, c)$  format as

|       |     |     |     |     |     |     |     |
|-------|-----|-----|-----|-----|-----|-----|-----|
| $i_c$ | 1   | 3   | 5   | 6   | 7   | 8   |     |
| $j_c$ | 1   | 4   | 2   | 3   | 3   | 4   | 5   |
| $c$   | 8.0 | 2.0 | 4.0 | 3.0 | 5.0 | 7.0 | 9.0 |

Note that since matrices are stored row by row in the  $(i_c, j_c, c)$  format, row-wise operations can be performed efficiently but it is inefficient to retrieve elements column-wise. Thus, this representation will be inefficient for matrix computations requiring column-wise operations. Fortunately, the likelihood calculations for mixed models can usually avoid column-wise operations.

In mixed models, sparse matrices typically arise from a large number of levels for fixed effects and/or random effects. If a linear model contains one or more large CLASS effects, then the mixed model equations are usually very sparse. Storing zeros in mixed model equations not only requires significantly more memory but also results in longer execution time and larger rounding error. As an illustration, the example in the “Getting Started: HPMIXED Procedure” on page 3658 has 3506 mixed model equations. Storing just the upper triangle of these equations in a dense form requires  $(1 + 3506) \times 3506/2 = 6,147,771$  elements. However, there are only 60,944 nonzero elements—less than 1% of what dense storage requires.

Note that as the density of the mixed model equations increases, the advantage of sparse matrix techniques decreases. For instance, a classical regression model typically has a dense coefficient matrix, though the dimension of the matrix is relatively small.

The HPMIXED procedure employs sparse matrix techniques to store the nonzero elements in the mixed model equations and to compute a sparse Cholesky decomposition of these equations. A reordering of the mixed model equations is required in order to keep the minimum memory consumption during the factorization. This reordering process results in a different  $g$ -inverse from what is produced by most other SAS/STAT procedures, for which the  $g$ -inverse is defined by sequential sweeping in the order defined by the model. If mixed model equations are singular, this different  $g$ -inverse produces a different solution of mixed model equations. However, estimable functions and tests based on them are invariant to the choice of  $g$ -inverse, and are thus the same for the HPMIXED procedure as for other procedures.

---

## Hypothesis Tests for Fixed Effects

Unlike most other SAS/STAT procedures for analyzing general linear models, the HPMIXED procedure does not by default provide  $F$  tests for the fixed effects. This is because, for the large mixed model problems that the HPMIXED procedure is designed to address, such tests are often computationally prohibitive to compute. The computation of Type III tests first constructs the Hermite matrix of the mixed model coefficient matrix  $\mathbf{C}$  and then forms the  $\mathbf{L}$  coefficient matrix to obtain the  $F$  value as follows:

$$F = \frac{\begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}' \mathbf{L}' (\mathbf{L}\hat{\mathbf{C}}^{-1}\mathbf{L}')^{-1} \mathbf{L} \begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}}{r}$$

where  $r = \text{rank}(\mathbf{L}\hat{\mathbf{C}}^{-1}\mathbf{L}')$ . The coefficient matrix  $\mathbf{L}$  corresponding to fixed effects with many levels can be very large and dense, making them very difficult to work with. At the same time, Type III tests for effects with many levels are relatively unlikely to be statistically useful.

For this reason, you must use the TEST statement in PROC HPMIXED to specifically ask for Type III tests for any effects for which you want to compute them. An example of this is given in the section “Getting Started: HPMIXED Procedure” on page 3658.

---

## Default Output

The following sections describe the output PROC HPMIXED produces by default. This output is organized into various tables, and they are discussed in order of appearance.

### Model Information

The “Model Information” table describes the model, some of the variables it involves, and the method used in fitting it. It also lists the method for computing the degrees of freedom.

The name of the “Model Information” table is “ModelInfo.”

### Class Level Information

The “Class Level Information” table lists the first 20 levels of every variable specified in the CLASS statement. You should check this information to make sure the data are correct. You can adjust the order of the CLASS variable levels with the ORDER= option in the PROC HPMIXED statement. The name of the “Class Level Information” table is “ClassLevels.”

### Dimensions

The “Dimensions” table lists the sizes of relevant matrices. This table can be useful in determining CPU time and memory requirements. The name of the “Dimensions” table is “Dimensions.”

### Number of Observations

The “Number of Observations” table shows the number of observations read from the data set and the number of observations used in fitting the model.

### Descriptive Statistics

The “Descriptive Statistics” table lists simple statistics such as means and standard deviations for the dependent variable, for each covariate in the MODEL statement, and for the weight variable in the WEIGHT statement.

### Iteration History

The “Iteration History” table describes the optimization of the residual log likelihood. The function to be minimized (the *objective function*) is  $-2l$ .

The name of the “Iteration History” table is “IterHistory.”

### Covariance Parameter Estimates

The “Covariance Parameter Estimates” table contains the estimates of the parameters in **G** and **R**. Their values are labeled in the “Cov Parm” table along with Subject and Group information if applicable. The estimates are displayed in the Estimate column.

The name of the “Covariance Parameter Estimates” table is “CovParms.”

## Convergence Status

The “Convergence Status” table contains a status message that describes the reason the optimization terminated. The message is also written to the log. The name of the “Convergence Status” table is “ConvergenceStatus.” You can query the nonprinting numeric variable `Status` to check for a successful optimization. This is useful in batch processing, or when processing BY groups, such as in simulations. Successful optimizations are indicated by the value 0 for the `Status` variable.

## Fit Statistics

The “Fit Statistics” table provides some statistics about the estimated mixed model.

In addition, the “Fit Statistics” table lists three information criteria: AIC, AICC, and BIC, all in smaller-is-better form. Expressions for these criteria are described under the `IC=` option on page 3664.

The name of the “Model Fitting Information” table is “FitStatistics.”

---

## ODS Table Names

Each table created by PROC HP MIXED has a name associated with it, and you must use this name to reference the table when using ODS statements. These names are listed in Table 46.11.

**Table 46.11** ODS Tables Produced by PROC HP MIXED

| Table Name        | Description                                                      | Required Statement / Option                      |
|-------------------|------------------------------------------------------------------|--------------------------------------------------|
| CholR             | Cholesky root of blocks of the estimated <b>R</b> matrix         | REPEATED / RC                                    |
| ClassLevels       | Level information from the CLASS statement                       | Default output                                   |
| Coef              | <b>L</b> matrix coefficients                                     | E option in TEST, CONTRAST, ESTIMATE, or LSMEANS |
| Contrasts         | Results from the CONTRAST statements                             | CONTRAST                                         |
| ConvergenceStatus | Convergence status                                               | Default                                          |
| CovParms          | Estimated covariance parameters                                  | Default output                                   |
| DiffS             | Differences of LS-means                                          | LSMEANS / DIFF (or PDIFF)                        |
| Dimensions        | Dimensions of the model                                          | Default output                                   |
| Estimates         | Results from ESTIMATE statements                                 | ESTIMATE                                         |
| FitStatistics     | Fit statistics                                                   | Default                                          |
| InvCholR          | Inverse Cholesky root of blocks of the estimated <b>R</b> matrix | REPEATED / RCI=                                  |
| InvR              | Inverse of blocks of the estimated <b>R</b> matrix               | REPEATED / RI=                                   |
| IterHistory       | Iteration history                                                | Default output                                   |
| LSMeans           | LS-means                                                         | LSMEANS                                          |
| MMEq              | Mixed model equations                                            | PROC HP MIXED MMEQ                               |
| ModelInfo         | Model information                                                | Default output                                   |

Table 46.11 (continued)

| Table Name         | Description                                                           | Required Statement / Option     |
|--------------------|-----------------------------------------------------------------------|---------------------------------|
| NObs               | Number of observations read and used                                  | Default output                  |
| OptInfo            | Optimization information                                              | Default output                  |
| OverallANOVA       | ANOVA table for model without random effect                           | Default output for fixed models |
| ParameterEstimates | Fixed-effects solution                                                | MODEL / SOLUTION                |
| ParmSearch         | Parameter search values                                               | PARMS                           |
| R                  | Blocks of the estimated <b>R</b> matrix                               | REPEATED / R=                   |
| RCorr              | Correlation matrix from blocks of the estimated <b>R</b> matrix       | REPEATED / RCORR=               |
| SimpleStatistics   | Descriptive statistics for dependent variable and covariate variables | PROC HPMIXED SIMPLE             |
| Slices             | Tests of LS-means slices                                              | LSMEANS / SLICE=                |
| SolutionR          | Random-effect solution vector                                         | RANDOM / SOLUTION               |

## Examples: HPMIXED Procedure

### Example 46.1: Ranking Many Random-Effect Coefficients

In analyzing models with random effects that have many levels, a frequent goal is to estimate and rank the predicted values of the coefficients corresponding to these levels. For example, in mixed models for animal breeding, the predicted coefficient of the random effect for each animal is referred to as the *estimated breeding value* (EBV) and animals with relatively high EBVs are chosen for breeding. This example demonstrates the use of the HPMIXED procedure for computing EBVs and their precision. Although other mixed modeling tools in SAS/STAT can potentially compute EBVs, PROC HPMIXED is particularly suited for the large, sparse matrix calculations involved. The typical performance of the HPMIXED procedure and other tools for this problem is also discussed.

The data for this problem are generated by simulation. Suppose you are considering analyzing EBVs for animals on 15 farms, with about 100 animals of 5 different species on each farm. The following DATA step simulates data with this structure, where about 40 observations of the response variable Yield are made per animal:

```
%let NFarm = 15;
%let NAnimal = %eval(&NFarm*100);
data Sim;
 keep Species Farm Animal Yield;
 array BV{&NAnimal};
 array AnimalSpecies{&NAnimal};
 array AnimalFarm{&NAnimal};
 do i = 1 to &NAnimal;
```

```

BV {i} = sqrt(4.0)*rannor(12345);
AnimalSpecies{i} = 1 + int(5 *ranuni(12345));
AnimalFarm {i} = 1 + int(&NFarm*ranuni(12345));
end;
do i = 1 to 40*&NAnimal;
 Animal = 1 + int(&NAnimal*ranuni(12345));
 Species = AnimalSpecies{Animal};
 Farm = AnimalFarm {Animal};
 Yield = 1 + Species
 + Farm
 + BV{Animal}
 + sqrt(8.0)*rannor(12345);
 output;
end;
run;

```

In this simulation, the true breeding value for each animal (BV1–BV1500) has a variance component of 4.0, while the level of background variance is 8.0.

In this type of experiment, the effect of Species and the interaction between Species and Farm are typically modeled as fixed effects, while the effect of Animal is modeled as a random effect. The following statements use the HPMIXED procedure to compute predictions for the Animal random effect and save them to the data set EBV. This data set is then sorted and the 10 animals with the highest EBVs are displayed.

```

ods listing close;
proc hpmixed data=Sim;
 class Species Farm Animal;
 model Yield = Species Farm*Species;
 random Animal/cl;
 ods output SolutionR=EBV;
run;
ods listing;

proc sort data=EBV;
 by descending estimate;
run;
proc print data=EBV(obs=10) noobs;
 var Animal Estimate StdErrPred Lower Upper;
run;

```

The preceding statements close the ODS listing destination for the duration of the PROC HPMIXED run. This avoids displaying the long random-effects solution table, since only the top few EBVs are of interest. [Output 46.1.1](#) displays the EBVs of the top 10 animals, along with their precision and confidence bounds.

**Output 46.1.1** Estimated Breeding Values: Top 10 Animals

| Animal | Estimate | StdErr<br>Pred | Lower  | Upper  |
|--------|----------|----------------|--------|--------|
| 1294   | 5.9703   | 0.6317         | 4.7321 | 7.2085 |
| 1219   | 5.0081   | 0.6396         | 3.7544 | 6.2618 |
| 1054   | 4.9452   | 0.5874         | 3.7939 | 6.0966 |
| 758    | 4.9340   | 0.6196         | 3.7195 | 6.1485 |
| 986    | 4.9329   | 0.5767         | 3.8025 | 6.0633 |
| 1150   | 4.7444   | 0.5806         | 3.6064 | 5.8824 |
| 962    | 4.6651   | 0.5794         | 3.5294 | 5.8008 |
| 225    | 4.5294   | 0.6137         | 3.3266 | 5.7322 |
| 1252   | 4.5012   | 0.5686         | 3.3868 | 5.6157 |
| 1033   | 4.4971   | 0.6080         | 3.3054 | 5.6889 |

Notice that animal 1294 is ranked as the top animal based on its EBV, but the precision of this estimate, as measured by the standard error of prediction, is lower than that of other animals.

You can also use PROC MIXED and PROC GLIMMIX to compute EBVs, but the performance of these general mixed modeling procedures for this specialized kind of data and model is quite different from that of PROC HPMIXED. The MIXED and GLIMMIX procedures are engineered to have good performance properties across a broad class of models and analyses, a class much broader than what PROC HPMIXED can handle. The HPMIXED procedure, on the other hand, can have better performance, in terms of both memory and run time, for certain specialized models and analyses, of which the current example is one.

For this example, an equivalent PROC GLIMMIX approach can take twice as long to complete, and PROC MIXED three times as long. Precise relative timings are not feasible, since those of the MIXED and GLIMMIX procedures are sensitive to the speed of disk access for writing to and reading from the utility file that holds the underlying matrices. But the results on any system would be similar: for the limited class of models to which it applies, the sparse matrix representation that the HPMIXED procedure employs should provide better computational performance than a dense representation, in terms of both run time and memory use.

Moreover, for a given analysis, if the size of the problem is increased in such a way that the underlying matrices become sparser, the relative performance of PROC HPMIXED gets even better. As an illustration of this, [Output 46.1.2](#) shows relative performance of the three procedures for simulated data as the number of farms increases. For this plot, each additional farm adds 500 levels of the Animal random effect to the model—a substantial number.

**Output 46.1.2** Comparing Mixed Model Tools for Increasingly Sparse Problems

The vertical axis in [Output 46.1.2](#) measures run time, but the units are omitted: relative performance is what counts, and that is expected to be fairly invariant to machine architecture. The output shows that while the performance of the MIXED and GLIMMIX procedures is relatively competitive with PROC HPMIXED for up to 3000 or 4000 animals, both procedures' relative performance decreases as the number of animals increases into the tens of thousands.

As a caveat, note that PROC HPMIXED can be *inefficient* relative to PROC MIXED and PROC GLIMMIX for models and data that are not sparse, because it can take many times longer to invert a large, dense matrix by sparse techniques. For example, [Output 46.1.3](#) shows relative performance of the three procedures for simulated data like the preceding, but where the fixed part of the model consists of an increasing number of continuous covariates and is thus dense.

**Output 46.1.3** Comparing Mixed Model Tools for Increasingly Dense Problems

As before, the HPMIXED procedure is more efficient than the MIXED and GLIMMIX procedures for few covariates, but when the fixed-effect calculations dominate the run time, PROC HPMIXED rapidly becomes relatively inefficient as the size of the dense fixed-effect matrix increases. Also note that while PROC MIXED is more efficient than PROC GLIMMIX for small to moderate numbers of covariates, PROC GLIMMIX has the best performance as the number of covariates get very large.

### Example 46.2: Comparing Results from PROC HPMIXED and PROC MIXED

This example revisits the mixed model problem from the section “Getting Started: MIXED Procedure” on page 4884, in Chapter 59, “The MIXED Procedure,” with the data set shown in the following statements:

```
data heights;
 input Family Gender$ Height @@;
 datalines;
1 F 67 1 F 66 1 F 64 1 M 71 1 M 72 2 F 63
2 F 63 2 F 67 2 M 69 2 M 68 2 M 70 3 F 63
3 M 64 4 F 67 4 F 66 4 M 67 4 M 67 4 M 69
;
```

The response variable Height measures the heights (in inches) of 18 individuals. The individuals are classified according to Family and Gender. The following statements fit a mixed model with random effects for Family and the Family\*Gender interaction with the MIXED procedure:

```
proc mixed;
 class Family Gender;
 model Height = Gender / s;
 random Family Family*Gender / s;
run;
```

The “Iteration History” and “Fit Statistics” tables for the optimization in PROC MIXED are shown in Output 46.2.1. The MIXED procedure converges after six iterations and achieves a -2 restricted log likelihood of 71.02246.

**Output 46.2.1** Iteration History and Fit Statistics: MIXED Procedure

| The Mixed Procedure |             |                          |            |  |
|---------------------|-------------|--------------------------|------------|--|
| Iteration History   |             |                          |            |  |
| Iteration           | Evaluations | -2 Res Log Like          | Criterion  |  |
| 0                   | 1           | 74.11074833              |            |  |
| 1                   | 2           | 71.51614003              | 0.01441208 |  |
| 2                   | 1           | 71.13845990              | 0.00412226 |  |
| 3                   | 1           | 71.03613556              | 0.00058188 |  |
| 4                   | 1           | 71.02281757              | 0.00001689 |  |
| 5                   | 1           | 71.02245904              | 0.00000002 |  |
| 6                   | 1           | 71.02245869              | 0.00000000 |  |
| Fit Statistics      |             |                          |            |  |
|                     |             | -2 Res Log Likelihood    | 71.0       |  |
|                     |             | AIC (smaller is better)  | 77.0       |  |
|                     |             | AICC (smaller is better) | 79.0       |  |
|                     |             | BIC (smaller is better)  | 75.2       |  |

Output 46.2.2 displays the covariance parameter estimates and the solutions for the fixed and random effects. Because the fixed-effect model contains a classification effect (Gender) and an intercept, the  $X'X$  matrix is singular. Only two fixed-effect parameters can be estimated in this model. The MIXED procedure, relying on a sweep operation in the order in which effects enter the model, determines that the last column of the  $X'X$  matrix is a linear function of previous columns. Consequently, the coefficient for the second level of the Gender variable is zero.

**Output 46.2.2** Parameter Estimates and Solutions: MIXED Procedure

| Covariance Parameter Estimates |        |          |                |              |         |         |         |

| Family*Gender                  | M      | 3        | -1.1429        | 1.1409       | 10      | -1.00   | 0.3401  |
| Family*Gender                  | F      | 4        | 0.8320         | 1.0933       | 10      | 0.76    | 0.4642  |
| Family*Gender                  | M      | 4        | -0.6053        | 1.0810       | 10      | -0.56   | 0.5878  |

The “Type 3 Tests of Fixed Effects” table in [Output 46.2.3](#) is produced by the MIXED procedure by default.

**Output 46.2.3** Test of Gender Effect

| Type 3 Tests of Fixed Effects |        |        |         |        |
|-------------------------------|--------|--------|---------|--------|
| Effect                        | Num DF | Den DF | F Value | Pr > F |
| Gender                        | 1      | 3      | 7.95    | 0.0667 |

The same linear mixed model is fit with the HPMIXED procedure with the following statements:

```
proc hpmixed;
 class Family Gender;
 model Height = Gender / s;
 random Family Family*Gender / s;
 test gender;
run;
```

Output 46.2.4 displays the “Iteration History” and “Fit Statistics” tables. The HPMIXED procedure, with its default quasi-Newton algorithm, achieves the same  $-2$  restricted log likelihood as the MIXED procedure (71.02246; see Output 46.2.1).

**Output 46.2.4** Iteration History and Fit Statistics: HPMIXED Procedure

| The HPMIXED Procedure    |             |                    |            |              |  |

A number of points are noteworthy in comparing the results from the procedures. The covariance parameter estimates are the same, yet the solutions for the fixed effects differ. In fact, both solutions are correct. Solving a sparse system of linear equations requires reordering of the mixed model equations to minimize memory consumption in the factorization process. As a consequence, the order in which singularities are detected can differ from the order in which effects enter the model. Mathematically, the two sets of solutions simply correspond to different choices for the generalized inverse in solving a singular linear system. See the sections “Generalized Inverse Matrices” on page 46 and “Linear Model Theory” on page 55, in Chapter 3, “Introduction to Statistical Modeling with SAS/STAT Software,” for more information about the role and importance of generalized inverses in linear model analysis.

Although the two sets of solutions for the fixed effects correspond to different choices of generalized inverses, many important results are invariant to the choice of the  $g$ -inverse. For example, the solutions for the random effects in Output 46.2.5 and Output 46.2.2 are identical. Also, the test for the Gender effect yields the same  $F$  value in both analyses (compare Output 46.2.6 and Output 46.2.3). However, note that the  $p$ -values associated with both  $F$  tests and  $t$  tests differ between the two procedures. This is due to their different default methods for computing the degrees of freedom. For this model, the HPMIXED procedure use the residual method to determine the denominator degrees of freedom for tests of fixed effects, whereas the MIXED procedure uses the containment method. The containment method is order-dependent, and thus not available in the HPMIXED procedure.

**Output 46.2.6** Parameter Estimates and Solutions: HPMIXED Procedure

| Type III Tests of Fixed Effects |           |           |         |        |
|---------------------------------|-----------|-----------|---------|--------|
| Effect                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Gender                          | 1         | 16        | 7.95    | 0.0123 |

## Example 46.3: Using PROC GLIMMIX for Further Analysis of PROC HPMIXED Fit

The HPMIXED procedure handles only a subset of the analyses of the GLIMMIX procedure. However, you can use the HPMIXED procedure to accelerate your GLIMMIX procedure analyses for large problems. The idea is to use PROC HPMIXED to maximize the likelihood and produce parameter estimates more quickly than PROC GLIMMIX, and then to pass these parameter estimates to PROC GLIMMIX for some further analysis that is not available within PROC HPMIXED.

This example revisits the mixed model problem from the section “Getting Started: HPMIXED Procedure” on page 3658 to illustrate how to obtain the covariance estimates from the HPMIXED procedure and, in turn, how to use these estimates in PROC GLIMMIX’s PARMs statement. The following statements again simulate data from animals of different species on different farms:

```

data Sim;
 keep Species Farm Animal Yield;
 array AnimalEffect{3000};
 array AnimalSpecies{3000};
 array AnimalFarm{3000};
 do i = 1 to 3000;
 AnimalEffect{i} = sqrt(4.0)*rannor(12345);
 AnimalSpecies{i} = 1 + int(5*ranuni(12345));
 AnimalFarm{i} = 1 + int(10*ranuni(12345));
 end;
 do i = 1 to 40000;
 Animal = 1 + int(3000*ranuni(12345));
 Species = AnimalSpecies{Animal};
 Farm = AnimalFarm{Animal};
 Yield = 1 + Species + int(Farm/2) + AnimalEffect{Animal}
 + sqrt(8.0)*rannor(12345);
 output;
 end;
run;

```

Note that in the preceding DATA step program, certain pairs of farms are simulated to have the same effect on yield. Suppose that your goal is to determine which farms are significantly different. While the HPMIXED procedure has an LSMEANS statement, it has no options for multiple comparisons. The following statements first use the HPMIXED procedure to obtain the covariance estimates, saving them in the SAS data set HPMEstimate. Then the GLIMMIX procedure is executed with the PARMs statement to initialize the parameter values from the data set HPMEstimate and with the HOLD= and NOITER options to prevent

further optimization iterations. The LSMEANS statement is used in PROC GLIMMIX to perform multiple comparisons of the LS-means for farms, and the results are displayed as a so-called diffogram.

```
proc hpmixed data=Sim;
 class Species Farm Animal;
 model Yield = Farm|Species;
 random Animal;
 test Species Species*Farm;
 ods output CovParms=HPMEstimate;
run;

ods graphics on;
proc glimmix data=Sim;
 class Species Farm Animal;
 model Yield = Farm|Species;
 random int/sub=Animal;
 parms /pdata=HPMEstimate hold=1,2 noiter;
 lsmeans Farm / pdiff=all plot=diffplot;
run;
```

The iteration histories for the two procedures are shown in [Output 46.3.1](#) and [Output 46.3.2](#). Whereas PROC HPMIXED requires several iterations in order to converge, PROC GLIMMIX “converges” to the same value in one step, with no iteration since the options `HOLD=` and `NOITER` are used.

**Output 46.3.1** Iteration History for the HPMIXED Procedure

| The HPMIXED Procedure |             |                    |             |              |  |
|-----------------------|-------------|--------------------|-------------|--------------|--|

| Iteration             | Evaluations | Objective Function | Change      | Max Gradient |  |
| 0                     | 4           | 202516.66891       | .           | 0.841954     |  |
| 1                     | 6           | 202516.66887       | 0.00004385  | 0.000641     |  |
| 2                     | 1           | 202516.66887       | -0.00000000 | 0.000641     |  |

**Output 46.3.2** Iteration History for the GLIMMIX Procedure

| The GLIMMIX Procedure |          |             |                    |        |              |
|-----------------------|----------|-------------|--------------------|--------|--------------|
| Iteration History     |          |             |                    |        |              |
| Iteration             | Restarts | Evaluations | Objective Function | Change | Max Gradient |
| 0                     | 0        | 4           | 202516.66887       | .      | 0            |

The graphical multiple-comparisons analysis for the LS-means of farms is shown in [Output 46.3.3](#). It confirms the pairwise equalities between farm effects with which the data were simulated.

**Output 46.3.3** LS-Means Plot of Pairwise Farm Differences

For more information about the interpretation of the LS-means difference plot, see the section “ODS Graphics” on page 3115, in Chapter 41, “The GLIMMIX Procedure.”

## Example 46.4: Mixed Model Analysis of Microarray Data

Microarray experiments are an advanced genomic technique used in the discovery of new treatments for diseases. Microarray analysis allows for the detection of tens of thousands of genes in a single DNA sample. A microarray is a glass slide or membrane that has been spotted or “arrayed” with DNA fragments or oligonucleotides representing specific genes. The response of the gene detected by a spot is proportional to the intensity of fluorescence associated with that spot. These gene responses can indicate associations with disease conditions, but they can also be affected by systematic biases and different treatments such as sex and genotypes. Statistical models for microarray data attempt to assess the significance and magnitude of gene effects across treatments while adjusting for these systematic biases and to evaluate the significance of differences between treatments.

There are two statistical approaches frequently used in mixed model analysis for microarray data. The first approach is to fit multiple gene-specific models to data normalized for systematic biases (Wolfinger et al. 2001; Gibson and Wolfinger 2004). This approach is based on assuming that

the biases are independent from the gene effects. If this assumption is untenable, then a second approach fits a single model that combines both the systematic biases and the gene effects (Kerr, Martin, and Churchill 2000; Churchill 2002; Littell et al. 2006). When the number of genes is very large, several hundreds to tens of thousands, this is an analysis for which the sparse matrix approach implemented in the HPMIXED procedure is well suited.

The following SAS statements simulate a microarray experiment with a so-called loop design structure, which is commonly used in such studies. There are 500 genes, each gene occurs in 6 arrays, and each array has 2 dyes.

```

%let narray = 6;
%let ndye = 2;
%let nrow = 4;
%let ngene = 500;
%let ntrt = 6;
%let npin = 4;
%let ndip = 4;
%let no = %eval(&ndye*&nrow*&ngene);
%let tno = %eval(&narray*&no);

data microarray;
 keep Gene MArray Dye Trt Pin Dip log2i;
 array PinDist{&tno};
 array DipDist{&tno};
 array GeneDist{&tno};

 array ArrayEffect{&narray};
 array ArrayGeneEffect{%eval(&narray*&ngene)};
 array ArrayDipEffect{%eval(&narray*&ndip)};
 array ArrayPinEffect{%eval(&narray*&npin)};

 do i = 1 to &tno;
 PinDist{i} = 1 + int(&npin*ranuni(12345));
 DipDist{i} = 1 + int(&ndip*ranuni(12345));
 GeneDist{i} = 1 + int(&ngene*ranuni(12345));
 end;

 igene = 0;
 idip = 0;
 ipin = 0;
 do i = 1 to &narray;
 ArrayEffect{i} = sqrt(0.014)*rannor(12345);
 do j = 1 to &ngene;
 igene = igene+1;
 ArrayGeneEffect{igene} = sqrt(0.0017)*rannor(12345);
 end;
 do j = 1 to &ndip;
 idip = idip + 1;
 ArrayDipEffect{idip} = sqrt(0.0033)*rannor(12345);
 end;
 do j = 1 to &npin;
 ipin = ipin + 1;
 ArrayPinEffect{ipin} = sqrt(0.037)*rannor(12345);
 end;
 end;

```

```

 end;
end;

i = 0;
do MArray = 1 to &narray;
 do Dye = 1 to &ndye;
 do Row = 1 to &nrow;
 do k = 1 to &ngene;
 if MArray=1 and Dye = 1 then do;
 Trt = 0;
 trtc = 0;
 end;
 else do;
 if trtc >= &no then trtc = 0;
 if trtc = 0 then do;
 Trt = Trt + 1;
 if Trt >= &ntrt then do;
 Trt = 0;
 trtc = 0;
 end;
 end;
 trtc = trtc + 1;
 end;
 i = i + 1;
 Pin = PinDist{i};
 Dip = DipDist{i};
 Gene = GeneDist{i};
 a = ArrayEffect{MArray};
 ag = ArrayGeneEffect{(MArray-1)*&ngene+Gene};
 ad = ArrayDipEffect{(MArray-1)*&ndip+Dip};
 ap = ArrayPinEffect{(MArray-1)*&npin+Pin};
 log2i = 1 +
 + Dye
 + Trt
 + Gene/1000.0
 + Dye*Gene/1000.0
 + Trt*Gene/1000.0
 + Pin
 + a
 + ag
 + ad
 + ap
 + sqrt(0.02)*rannor(12345);
 output;
 end;
 end;
 end;
end;
run;

```

A linear mixed model for fitting the log intensity data  $Y_{ijkmnr}$  from such a design is described by Littell et al. (2006) as follows:

$$Y_{ijkmnr} =$$

|                       |                        | <b>Fixed Effects</b>  |
|-----------------------|------------------------|-----------------------|
|                       | $\mu$                  | Overall mean          |
| +                     | $\lambda_i$            | Gene                  |
| +                     | $\tau_j$               | Treatment             |
| +                     | $\delta_k$             | Dye                   |
| +                     | $(\tau\lambda)_{ij}$   | Treatment-by-gene     |
| +                     | $(\delta\lambda)_{ik}$ | Dye-by-gene           |
| +                     | $p_r$                  | Pin                   |
| <b>Random Effects</b> |                        |                       |
| +                     | $a_m$                  | Microarray            |
| +                     | $(a\lambda)_{im}$      | Microarray-by-gene    |
| +                     | $d(a)_{mn}$            | Dip-within-microarray |
| +                     | $(ap)_{mr}$            | Microarray-by-pin     |
| +                     | $e_{ijkmnr}$           | Residual noise        |

You can use the HPMIXED procedure with the following statements to fit this model:

```
proc hpmixed data=microarray;
 class marray dye trt gene pin dip;
 model log2i = dye trt gene dye*gene trt*gene pin;
 random marray marray*gene dip(marray) pin*marray;
 test trt;
run;
```

The “Dimensions” table shown in [Output 46.4.1](#) indicates that this is a very large model, with 4512 columns in  $\mathbf{X}$  matrix and 3054 columns in  $\mathbf{Z}$  matrix. It will be computationally very inefficient to fit this model by using dense matrix methods; the sparse matrix approach of the HPMIXED procedure is of critical importance.

**Output 46.4.1** Mixed Model Dimensions

| <b>The HPMIXED Procedure</b> |      |
|------------------------------|------|
| <b>Dimensions</b>            |      |
| G-side Cov. Parameters       | 4    |
| R-side Cov. Parameters       | 1    |
| Columns in X                 | 4513 |
| Columns in Z                 | 3054 |
| Subjects (Blocks in V)       | 1    |

The  $p$ -value in [Output 46.4.2](#) indicates that there are significant differences between treatments.

**Output 46.4.2** Type III Tests of Fixed Effects

| Type III Tests of Fixed Effects |           |           |         |        |
|---------------------------------|-----------|-----------|---------|--------|
| Effect                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Trt                             | 5         | 20497     | 370005  | <.0001 |

**Example 46.5: Repeated Measures**

The following data are from Pothoff and Roy (1964) and consist of growth measurements for 11 girls and 16 boys at ages 8, 10, 12, and 14. Some of the observations are suspect (for example, the third observation for person 20); however, all of the data are used here for comparison purposes.

The analysis strategy employs a linear growth curve model for the boys and girls in addition to a variance-covariance model that incorporates correlations for all of the observations that arise from the same person. The PROC HPMIXED statements to fit an unstructured variance matrix are as follows:

```
data pr;
 input Person Gender $ y1 y2 y3 y4;
 y=y1; Time=1; Age=8; output;
 y=y2; Time=2; Age=10; output;
 y=y3; Time=3; Age=12; output;
 y=y4; Time=4; Age=14; output;
 drop y1-y4;
 datalines;
1 F 21.0 20.0 21.5 23.0
2 F 21.0 21.5 24.0 25.5
3 F 20.5 24.0 24.5 26.0
4 F 23.5 24.5 25.0 26.5
5 F 21.5 23.0 22.5 23.5
6 F 20.0 21.0 21.0 22.5
7 F 21.5 22.5 23.0 25.0
8 F 23.0 23.0 23.5 24.0
9 F 20.0 21.0 22.0 21.5
10 F 16.5 19.0 19.0 19.5
11 F 24.5 25.0 28.0 28.0
12 M 26.0 25.0 29.0 31.0
13 M 21.5 22.5 23.0 26.5
14 M 23.0 22.5 24.0 27.5
15 M 25.5 27.5 26.5 27.0
16 M 20.0 23.5 22.5 26.0
17 M 24.5 25.5 27.0 28.5
18 M 22.0 22.0 24.5 26.5
19 M 24.0 21.5 24.5 25.5
20 M 23.0 20.5 31.0 26.0
21 M 27.5 28.0 31.0 31.5
22 M 23.0 23.0 23.5 25.0
23 M 21.5 23.5 24.0 28.0
24 M 17.0 24.5 26.0 29.5
```

```

25 M 22.5 25.5 25.5 26.0
26 M 23.0 24.5 26.0 30.0
27 M 22.0 21.5 23.5 25.0
;

proc hpmixed data=pr;
 class Person Gender Time;
 model y = Gender Age Gender*Age;
 test Gender Age Gender*Age;
 repeated Time / type=un subject=Person r;
run;

```

The **MODEL** statement first lists the dependent variable *Y*. The fixed effects are then listed after the equal sign. The variable *Gender* requests a different intercept for the girls and boys, *Age* models an overall linear growth trend, and *Gender\*Age* makes the slopes different over time. It is actually not necessary to specify *Age* separately, but doing so enables PROC HPMIXED to carry out a test for heterogeneous slopes.

The **REPEATED** statement contains a *repeated-effect* *Time*. The **TYPE=UN** option models the covariance as an unstructured block for each **SUBJECT=Person**. Each of the 27 subjects has a maximum of four observations. Therefore, the **R** matrix is block diagonal with 27 blocks, each block consisting of identical 4×4 unstructured matrices. The 10 parameters of these unstructured blocks make up the covariance parameters estimated by restricted maximum likelihood. The **R=** option requests that the first block of **R** be displayed.

The results from this analysis are shown in [Output 46.5.1](#) through [Output 46.5.5](#).

#### Output 46.5.1 Repeated Measures Analysis

| The HPMIXED Procedure    |    |
|--------------------------|----|
| Dimensions               |    |
| G-side Cov. Parameters   | 0  |
| R-side Cov. Parameters   | 10 |
| Columns in X             | 6  |
| Columns in Z per Subject | 0  |
| Subjects (Blocks in V)   | 27 |

In [Output 46.5.1](#), the 10 covariance parameters result from the 4 × 4 unstructured blocks of **R**. There is no **Z** matrix for this model.

#### Output 46.5.2 Repeated Measures Analysis (continued)

| Cov Parm                       | Subject | Estimate |
| UN(1,1)                        | Person  | 5.4252   |
| UN(2,1)                        | Person  | 2.7092   |
| UN(2,2)                        | Person  | 4.1906   |
| UN(3,1)                        | Person  | 3.8411   |
| UN(3,2)                        | Person  | 2.9745   |
| UN(3,3)                        | Person  | 6.2632   |
| UN(4,1)                        | Person  | 2.7151   |
| UN(4,2)                        | Person  | 3.3137   |
| UN(4,3)                        | Person  | 4.1332   |
| UN(4,4)                        | Person  | 4.9862   |

The “Covariance Parameter Estimates” table in [Output 46.5.4](#) lists the 10 estimated covariance parameters in order; note their correspondence to the first block of **R** displayed in [Output 46.5.3](#). The parameter estimates are labeled according to their location in the block in the Cov Parm column, and all of these estimates are associated with Person as the subject effect.

**Output 46.5.5** Repeated Measures Analysis (*continued*)

| Type III Tests of Fixed Effects |           |           |         |        |
|---------------------------------|-----------|-----------|---------|--------|
| Effect                          | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Gender                          | 1         | 104       | 1.08    | 0.3011 |
| Age                             | 1         | 104       | 102.35  | <.0001 |
| Age*Gender                      | 1         | 104       | 7.40    | 0.0076 |

The “Type III Tests of Fixed Effects” table in [Output 46.5.5](#) displays Type III tests for all of the fixed effects. These tests are partial in the sense that they account for all of the other fixed effects in the model.

Since the different levels of the repeated effect represent different years, it is natural to try fitting a time series model to the data within each subject. To obtain time series structures in **R**, you can replace **TYPE=UN** with **TYPE=AR(1)** to obtain the first-order autoregressive covariance matrices. For example, the statements to fit an AR(1) structure are as follows:

```
proc hpmixed data=pr;
 class Person Gender Time;
 model y = Gender Age Gender*Age;
 repeated Time / type=ar(1) sub=Person r;
run;
```

The estimated AR(1) structure covariance matrix of the first block of **R** is shown in [Output 46.5.6](#)

**Output 46.5.6** Repeated Measures Analysis

### Overview: INBREED Procedure

The INBREED procedure calculates the covariance or inbreeding coefficients for a pedigree. PROC INBREED is unique in that it handles very large populations.

The INBREED procedure has two modes of operation. One mode carries out analysis on the assumption that all the individuals belong to the same generation. The other mode divides the population into nonoverlapping generations and analyzes each generation separately, assuming that the parents of individuals in the current generation are defined in the previous generation.

PROC INBREED also computes averages of the covariance or inbreeding coefficients within sex categories if the sex of individuals is known.

## Getting Started: INBREED Procedure

This section demonstrates how you can use the INBREED procedure to calculate the inbreeding or covariance coefficients for a pedigree, how you can control the analysis mode if the population consists of nonoverlapping generations, and how you can obtain averages within sex categories.

For you to use PROC INBREED effectively, your input data set must have a definite format. The following sections first introduce this format for a fictitious population and then demonstrate how you can analyze this population by using the INBREED procedure.

### The Format of the Input Data Set

The SAS data set used as input to the INBREED procedure must contain an observation for each individual. Each observation must include one variable identifying the individual and two variables identifying the individual's parents. Optionally, an observation can contain a known covariance coefficient and a character variable defining the gender of the individual.

For example, consider the following data:

```
data Population;
 input Individual $ Parent1 $ Parent2 $
 Covariance Sex $ Generation;
 datalines;
Mark George Lisa . M 1
Kelly Scott Lisa . F 1
Mike George Amy . M 1
. Mark Kelly 0.50 . 1
David Mark Kelly . M 2
Merle Mike Jane . F 2
Jim Mark Kelly 0.50 M 2
Mark Mike Kelly . M 2
;
```

It is important to order the pedigree observations so that individuals are defined before they are used as parents of other individuals. The family relationships between individuals cannot be ascertained correctly unless you observe this ordering. Also, older individuals must precede younger ones. For example, 'Mark' appears as the first parent of 'David' at observation 5; therefore, his observation needs to be defined prior to observation 5. Indeed, this is the case (see observation 1). Also, 'David' is older than 'Jim', whose observation appears after the observation for 'David', as is appropriate.

In populations with distinct, nonoverlapping generations, the older generation (parents) must precede the younger generation. For example, the individuals defined in Generation=1 appear as parents of individuals defined in Generation=2.

PROC INBREED produces warning messages when a parent cannot be found. For example, 'Jane' appears as the second parent of the individual 'Merle' even though there are no previous observations defining her own parents. If the population is treated as an overlapping population, that is, if the generation grouping is ignored, then the procedure inserts an observation for 'Jane' with missing parents just before the sixth observation, which defines 'Merle' as follows:

```
Jane . . . F 2
Merle Mike Jane . F 2
```

However, if generation grouping is taken into consideration, then ‘Jane’ is defined as the last observation in Generation=1, as follows:

```
Mike George Amy . M 1
Jane . . . F 1
```

In this latter case, however, the observation for ‘Jane’ is inserted after the computations are reported for the first generation. Therefore, she does not appear in the covariance/inbreeding matrix, even though her observation is used in computations for the second generation (see [Figure 47.2](#)).

If the data for an individual are duplicated, only the first occurrence of the data is used by the procedure, and a warning message is displayed to note the duplication. For example, individual ‘Mark’ is defined twice, at observations 1 and 8. If generation grouping is ignored, then this is an error and observation 8 is skipped. However, if the population is processed with respect to two distinct generations, then ‘Mark’ refers to two different individuals, one in Generation=1 and the other in Generation=2.

If a covariance is to be assigned between two individuals, then those individuals must be defined prior to the assignment observation. For example, a covariance of 0.50 can be assigned between ‘Mark’ and ‘Kelly’ since they are previously defined. Note that assignment statements must have different formats depending on whether the population is processed with respect to generations (see the section “[DATA= Data Set](#)” on page 3731 for further information). For example, while observation 4 is valid for nonoverlapping generations, it is invalid for a processing mode that ignores generation grouping. In this latter case, observation 7 indicates a valid assignment, and observation 4 is skipped.

The latest covariance specification between any given two individuals overrides the previous one between the same individuals.

---

## Performing the Analysis

To compute the covariance coefficients for the overlapping generation mode, use the following statements:

```
proc inbreed data=Population covar matrix init=0.25;
run;
```

Here, the DATA= option names the SAS data set to be analyzed, and the COVAR and MATRIX options tell the procedure to output the covariance coefficients matrix. If you omit the COVAR option, the inbreeding coefficients are output instead of the covariance coefficients.

Note that the PROC INBREED statement also contains the INIT= option. This option gives an initial covariance between any individual and unknown individuals. For example, the covariance between any individual and ‘Jane’ would be 0.25, since ‘Jane’ is unknown, except when ‘Jane’ appears as a parent (see [Figure 47.4](#)).

**Figure 47.1** Analysis for an Overlapping Population

| The INBREED Procedure   |         |         |        |        |        |        |        |
|-------------------------|---------|---------|--------|--------|--------|--------|--------|
| Covariance Coefficients |         |         |        |        |        |        |        |

| Number of Individuals   |         |         |        | 11     |        |        |        |

In the previous example, PROC INBREED treats the population as a single generation. However, you might want to process the population with respect to distinct, nonoverlapping generations. To accomplish this, you need to identify the generation variable in a CLASS statement, as shown by the following statements:

```
proc inbred data=Population covar matrix init=0.25;
 class Generation;
run;
```

Note that, in this case, the covariance matrix is displayed separately for each generation (see Figure 47.5).

**Figure 47.2** Analysis for a Nonoverlapping Population

| <b>Individual</b>              | <b>Parent1</b> | <b>Parent2</b> | <b>David</b>                 | <b>Merle</b> | <b>Jim</b>  | <b>Mark</b> |
| <b>David</b>                   | <b>Mark</b>    | <b>Kelly</b>   | 1.2500                       | 0.3047       | 0.8125      | 0.5859      |
| <b>Merle</b>                   | <b>Mike</b>    | <b>Jane</b>    | 0.3047                       | 1.1250       | 0.3047      | 0.4688      |
| <b>Jim</b>                     | <b>Mark</b>    | <b>Kelly</b>   | 0.8125                       | 0.3047       | 1.2500      | 0.5859      |
| <b>Mark</b>                    | <b>Mike</b>    | <b>Kelly</b>   | 0.5859                       | 0.4688       | 0.5859      | 1.1250      |
|                                |                |                | <b>Number of Individuals</b> | <b>4</b>     |             |             |

You might also want to see covariance coefficient averages within sex categories. This is accomplished by indicating the variable defining the gender of individuals in a GENDER statement and by adding the AVERAGE option to the PROC INBREED statement. For example, the following statements produce the covariance coefficient averages shown in Figure 47.3:

```

proc inbreed data=Population covar average init=0.25;
 class Generation;
 gender Sex;
run;

```

**Figure 47.3** Averages within Sex Categories for a Nonoverlapping Generation

---

## Syntax: INBREED Procedure

The following statements are available in the INBREED procedure:

```

PROC INBREED < options > ;
 BY variables ;
 CLASS variable ;
 GENDER variable ;
 MATINGS individual-list1 / mate-list1 < , ... , individual-listn / mate-listn > ;
 VAR variables ;

```

The PROC INBREED statement is required. Items within angle brackets (< >) are optional. The syntax of each statement is described in the following sections.

---

## PROC INBREED Statement

```

PROC INBREED < options > ;

```

The PROC INBREED statement invokes the INBREED procedure. [Table 47.1](#) summarizes the options available in the PROC INBREED statement.

**Table 47.1** PROC INBREED Statement Options

| Option                                  | Description                                                               |
|-----------------------------------------|---------------------------------------------------------------------------|
| <b>Specify Data Sets</b>                |                                                                           |
| DATA=                                   | Names the SAS data set                                                    |
| OUTCOV=                                 | Names an output data set to contain the inbreeding coefficients           |
| <b>Control Type of Coefficient</b>      |                                                                           |
| COVAR                                   | Specifies that all coefficients output consist of covariance coefficients |
| SELFDIAG                                | Includes an individual's self-mating kinship coefficient                  |
| <b>Control Displayed Tables</b>         |                                                                           |
| AVERAGE                                 | Produces a table of averages of coefficients                              |
| IND                                     | Displays the individuals' inbreeding coefficients                         |
| MATRIX                                  | Displays the inbreeding coefficient matrix                                |
| <b>Specify Default Covariance Value</b> |                                                                           |
| INIT=                                   | Specifies the covariance value                                            |
| <b>Suppress Output</b>                  |                                                                           |

---

**AVERAGE****A**

produces a table of averages of coefficients for each pedigree of offspring. The AVERAGE option is used together with the **GENDER** statement to average the inbreeding/covariance coefficients within sex categories.

**COVAR****C**

specifies that all coefficients output consist of covariance coefficients rather than inbreeding coefficients.

**DATA=SAS-data-set**

names the SAS data set to be used by **PROC INBREED**. If you omit the DATA= option, the most recently created SAS data set is used.

**IND****I**

displays the individuals' inbreeding coefficients (diagonal of the inbreeding coefficients matrix) for each pedigree of offspring.

If you also specify the **COVAR** option, the individuals' covariance coefficients (diagonal of the covariance coefficients matrix) are displayed.

**INDL**

displays individuals' coefficients for only the last generation of a multiparous population.

**INIT=COV**

specifies the covariance value *cov* if any of the parents are unknown; a value of 0 is assumed if you do not specify the INIT= option.

**MATRIX****M**

displays the inbreeding coefficient matrix for each pedigree of offspring.

If you also specify the **COVAR** option, the covariance matrices are displayed instead of inbreeding coefficients matrices.

**MATRIXL**

displays coefficients for only the last generation of a multiparous population.

**NOPRINT**

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS). For more information on ODS, see Chapter 20, "Using the Output Delivery System."

**OUTCOV=SAS-data-set**

names an output data set to contain the inbreeding coefficients. When the **COVAR** option is also specified, covariance estimates are output to the OUTCOV= data set instead of inbreeding coefficients.

**SELFDIAG**

includes an individual's self-mating kinship coefficient instead of the individual's inbreeding coefficient on the diagonal of the matrix in the OUTCOV= data set when the COVAR option is not specified.

**BY Statement**

**BY** *variables* ;

You can specify a BY statement with PROC INBREED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the INBREED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

**CLASS Statement**

**CLASS** *variable* ;

To analyze the population within nonoverlapping generations, you must specify the variable that identifies generations in a CLASS statement. Values of the generation variable, called *generation numbers*, must be integers, but generations are assumed to occur in the order of their input in the input data set rather than in numerical order of the generation numbers. The name of an individual needs to be unique only within its generation.

When the **MATRIXL** option or the **INDL** option is specified, each generation requires a unique generation number in order for the specified option to work correctly. If generation numbers are not unique, all the generations with a generation number that is the same as the last generation's are output.

**GENDER Statement**

**GENDER** *variable* ;

The GENDER statement specifies a variable that indicates the sex of the individuals. Values of the sex variable must be character beginning with ‘M’ or ‘F’, for male or female. The GENDER statement is needed only when you specify the AVERAGE option to average the inbreeding/covariance coefficients within sex categories or when you want to include a gender variable in the OUTCOV= data set.

PROC INBREED makes the following assumptions regarding the gender of individuals:

- The first parent is always assumed to be the male. See the section “VAR Statement” on page 3730.
- The second parent is always assumed to be the female. See the section “VAR Statement” on page 3730.
- If the gender of an individual is missing or invalid, this individual is assumed to be a female unless the population is overlapping and this individual appears as the first parent in a later observation.

Any contradictions to these rules are reported in the SAS log.

---

## MATINGS Statement

**MATINGS** *individual-list1 / mate-list1 <, ..., individual-listn / mate-listn>* ;

You can specify the MATINGS statement with PROC INBREED to specify selected matings of individuals. Each individual given in *individual-list* is mated with each individual given in *mate-list*. You can write multiple mating specifications if you separate them by commas or asterisks. The procedure reports the inbreeding coefficients or covariances for each pair of mates. For example, you can use the following statement to specify the mating of an individual named ‘David’ with an individual named ‘Jane’:

```
matings david / jane;
```

---

## VAR Statement

**VAR** *individual parent1 parent2 <covariance>* ;

The VAR statement specifies three or four variables: the first variable contains an individual’s name, the second variable contains the name of the individual’s first parent, and the third variable contains the name of the individual’s second parent. An optional fourth variable assigns a known value to the covariance of the individual’s first and second parents in the current generation.

The first three variables in the VAR statement can be either numeric or character; however, only the first 12 characters of a character variable are recognized by the procedure. The fourth variable, if specified, must be numeric.

If you omit the VAR statement, then the procedure uses the first three unaddressed variables as the names of the individual and its parents. (Unaddressed variables are those that are not referenced in any other PROC INBREED statement.) If the input data set contains an unaddressed fourth variable, then it becomes the covariance variable.

---

## Details: INBREED Procedure

---

### Missing Values

A missing value for a parent implies that the parent is unknown. Unknown parents are assumed to be unrelated and not inbred unless you specify the `INIT=` option.

When the value of the variable identifying the individual is missing, the observation is not added to the list of individuals. However, for a multiparous population, an observation with a missing individual is valid and is used for assigning covariances.

Missing covariance values are determined from the `INIT=cov` option, if specified. Observations with missing generation variables are excluded.

If the gender of an individual is missing, it is determined from the order in which it is listed on the first observation defining its progeny for an overlapping population. If it appears as the first parent, it is set to 'M'; otherwise, it is set to 'F'. When the gender of an individual cannot be determined, it is assigned a default value of 'F'.

---

### DATA= Data Set

Each observation in the input data set should contain necessary information such as the identification of an individual and the first and second parents of an individual. In addition, if a `CLASS` statement is specified, each observation should contain the generation identification; and, if a `GENDER` statement is specified, each observation should contain the gender of an individual. Optionally, each observation might also contain the covariance between the first and the second parents. Depending on how many statements are specified with the procedure, there should be enough variables in the input data set containing this information.

If you omit the `VAR` statement, then the procedure uses the first three *unaddressed variables* in the input data set as the names of the individual and his or her parents. Unaddressed variables in the input data set are those variables that are not referenced by the procedure in any other statements, such as `CLASS`, `GENDER`, or `BY` statements. If the input data set contains an unaddressed fourth variable, then the procedure uses it as the covariance variable.

If the individuals given by the variables associated with the first and second parents are not in the population, they are added to the population. However, if they are in the population, they must be defined prior to the observation that gives their progeny.

When there is a `CLASS` statement, the functions of defining new individuals and assigning covariances must be separated. This is necessary because the parents of any given individual are defined in the previous generation, while covariances are assigned between individuals in the current generation.

Therefore, there could be two types of observations for a multiparous population:

- one to define new individuals in the current generation whose parents have been defined in the previous generation, as in the following, where the missing value is for the covariance variable:

```
Mark George Lisa . M 1
Kelly Scott Lisa . F 1
```

- one to assign covariances between two individuals in the current generation, as in the following, where the individual's name is missing, 'Mark' and 'Kelly' are in the current generation, and the covariance coefficient between these two individuals is 0.50:

```
. Mark Kelly 0.50 . 1
```

Note that the observations defining individuals must precede the observation assigning a covariance value between them. For example, if a covariance is to be assigned between 'Mark' and 'Kelly', then both of them should be defined prior to the assignment observation.

## Computational Details

This section describes the rules that the INBREED procedure uses to compute the covariance and inbreeding coefficients. Each computational rule is explained by an example referring to the fictitious population introduced in the section "Getting Started: INBREED Procedure" on page 3722.

### Coancestry (or Kinship Coefficient)

To calculate the inbreeding coefficient and the covariance coefficients, use the degree of relationship by descent between the two parents, which is called *coancestry* or *kinship coefficient* (Falconer and Mackay 1996, p.85), or *coefficient of parentage* (Kempthorne 1957, p.73). Denote the coancestry between individuals X and Y by  $f_{XY}$ . For information on how to calculate the coancestries among a population, see the section "Calculation of Coancestry" on page 3733.

### Covariance Coefficient (or Coefficient of Relationship)

The covariance coefficient between individuals X and Y is defined by

$$\text{Cov}(X, Y) = 2f_{XY}$$

where  $f_{XY}$  is the coancestry between X and Y. The covariance coefficient is sometimes called the *coefficient of relationship* or the *theoretical correlation* (Falconer and Mackay (1996, p.153); Crow and Kimura (1970, p.134)). If a covariance coefficient cannot be calculated from the individuals in the population, it is assigned to an initial value. The initial value is set to 0 if the INIT= option is not specified or to *cov* if INIT=*cov*. Therefore, the corresponding initial coancestry is set to 0 if the INIT= option is not specified or to  $\frac{1}{2}\text{cov}$  if INIT=*cov*.

## Inbreeding Coefficients

The inbreeding coefficient of an individual is the probability that the pair of alleles carried by the gametes that produced it are identical by descent (Falconer and Mackay (1996, Chapter 5), Kempthorne (1957, Chapter 5)). For individual X, denote its inbreeding coefficient by  $F_X$ . The inbreeding coefficient of an individual is equal to the coancestry between its parents. For example, if X has parents A and B, then the inbreeding coefficient of X is

$$F_X = f_{AB}$$

## Calculation of Coancestry

Given individuals X and Y, assume that X has parents A and B and that Y has parents C and D. For nonoverlapping generations, the basic rule to calculate the coancestry between X and Y is given by the following formula (Falconer and Mackay 1996, p.86):

$$f_{XY} = \frac{1}{4}(f_{AC} + f_{AD} + f_{BC} + f_{BD})$$

And the inbreeding coefficient for an offspring of X and Y, called Z, is the coancestry between X and Y:

$$F_Z = f_{XY}$$

**Figure 47.4** Inbreeding Relationship for Nonoverlapping Population

For example, in Figure 47.4, ‘Jim’ and ‘Mark’ from Generation 2 are progenies of ‘Mark’ and ‘Kelly’ and of ‘Mike’ and ‘Kelly’ from Generation 1, respectively. The coancestry between ‘Jim’ and ‘Mark’ is

$$f_{\text{Jim,Mark}} = \frac{1}{(f_{\text{Mark,Mike}} + f_{\text{Mark,Kelly}} + f_{\text{Kelly,Mike}} + f_{\text{Kelly,Kelly}})}$$

From the covariance matrix for Generation=1 in [Figure 47.4](#) and the relationship that coancestry is half of the covariance coefficient,

$$f_{\text{Jim,Mark}} = \frac{1}{4} \left( \frac{0.4688}{2} + \frac{0.5}{2} + \frac{0.25}{2} + \frac{1.125}{2} \right) = 0.29298$$

For overlapping generations, if X is older than Y, then the [basic rule](#) can be simplified to

$$F_Z = f_{XY} = \frac{1}{2} (f_{XC} + f_{XD})$$

That is, the coancestry between X and Y is the average of coancestries between older X with younger Y's parents. For example, in [Figure 47.5](#), the coancestry between 'Kelly' and 'David' is

$$f_{\text{Kelly,David}} = \frac{1}{2} (f_{\text{Kelly,Mark}} + f_{\text{Kelly,Kelly}})$$

**Figure 47.5** Inbreeding Relationship for Overlapping Population

This is so because ‘Kelly’ is defined before ‘David’; therefore, ‘Kelly’ is not younger than ‘David’, and the parents of ‘David’ are ‘Mark’ and ‘Kelly’. The covariance coefficient values  $\text{Cov}(\text{Kelly}, \text{Mark})$  and  $\text{Cov}(\text{Kelly}, \text{Kelly})$  from the matrix in Figure 47.5 yield that the coancestry between ‘Kelly’ and ‘David’ is

$$f_{\text{Kelly}, \text{David}} = \frac{1}{2} \left( \frac{0.5}{2} + \frac{1.125}{2} \right) = 0.40625$$

The numerical values for some initial coancestries must be known in order to use these rule. Either the parents of the first generation have to be unrelated, with  $f = 0$  if the `INIT=` option is not specified in the `PROC INBREED` statement, or their coancestries must have an initial value of  $\frac{1}{2} \text{cov}$ , where `cov` is set by the `INIT=` option. Then the subsequent coancestries among their progenies and the inbreeding coefficients of their progenies in the rest of the generations are calculated by using these initial values.

Special rules need to be considered in the calculations of coancestries for the following cases.

**Self-Mating**

The coancestry for an individual X with itself,  $f_{XX}$ , is the inbreeding coefficient of a progeny that is produced by self-mating. The relationship between the inbreeding coefficient and the coancestry for self-mating is

$$f_{XX} = \frac{1}{2}(1 + F_X)$$

The inbreeding coefficient  $F_X$  can be replaced by the coancestry between X's parents A and B,  $f_{AB}$ , if A and B are in the population:

$$f_{XX} = \frac{1}{2}(1 + f_{AB})$$

If X's parents are not in the population, then  $F_X$  is replaced by the initial value  $\frac{1}{2}cov$  if  $cov$  is set by the INIT= option, or  $F_X$  is replaced by 0 if the INIT= option is not specified. For example, the coancestry of 'Jim' with himself is

$$f_{\text{Jim},\text{Jim}} = \frac{1}{2}(1 + f_{\text{Mark},\text{Kelly}})$$

where 'Mark' and 'Kelly' are the parents of 'Jim'. Since the covariance coefficient  $\text{Cov}(\text{Mark},\text{Kelly})$  is 0.5 in Figure 47.5 and also in the covariance matrix for GENDER=1 in Figure 47.4, the coancestry of 'Jim' with himself is

$$f_{\text{Jim},\text{Jim}} = \frac{1}{2}\left(1 + \frac{0.5}{2}\right) = 0.625$$

When INIT=0.25, then the coancestry of 'Jane' with herself is

$$f_{\text{Jane},\text{Jane}} = \frac{1}{2}\left(1 + \frac{0.25}{2}\right) = 0.5625$$

because 'Jane' is not an offspring in the population.

**Offspring and Parent Mating**

Assuming that X's parents are A and B, the coancestry between X and A is

$$f_{XA} = \frac{1}{2}(f_{AB} + f_{AA})$$

The inbreeding coefficient for an offspring of X and A, denoted by Z, is

$$F_Z = f_{XA} = \frac{1}{2}(f_{AB} + f_{AA})$$

For example, ‘Mark’ is an offspring of ‘George’ and ‘Lisa’, so the coancestry between ‘Mark’ and ‘Lisa’ is

$$f_{\text{Mark,Lisa}} = \frac{1}{2}(f_{\text{Lisa,George}} + f_{\text{Lisa,Lisa}})$$

From the covariance coefficient matrix in [Figure 47.5](#),  $f_{\text{Lisa,George}} = 0.25/2 = 0.125$ ,  $f_{\text{Lisa,Lisa}} = 1.125/2 = 0.5625$ , so that

$$f_{\text{Mark,Lisa}} = \frac{1}{2}(0.125 + 0.5625) = 0.34375$$

Thus, the inbreeding coefficient for an offspring of ‘Mark’ and ‘Lisa’ is 0.34375.

### **Full Sibs Mating**

This is a special case for the basic rule given at the beginning of the section “[Calculation of Coancestry](#)” on page 3733. If X and Y are full sibs with same parents A and B, then the coancestry between X and Y is

$$f_{XY} = \frac{1}{4}(2f_{AB} + f_{AA} + f_{BB})$$

and the inbreeding coefficient for an offspring of A and B, denoted by Z, is

$$F_Z = f_{XY} = \frac{1}{4}(2f_{AB} + f_{AA} + f_{BB})$$

For example, ‘David’ and ‘Jim’ are full sibs with parents ‘Mark’ and ‘Kelly’, so the coancestry between ‘David’ and ‘Jim’ is

$$f_{\text{David,Jim}} = \frac{1}{4}(2f_{\text{Mark,Kelly}} + f_{\text{Mark,Mark}} + f_{\text{Kelly,Kelly}})$$

Since the coancestry is half of the covariance coefficient, from the covariance matrix in [Figure 47.5](#),

$$f_{\text{David,Jim}} = \frac{1}{4}\left(2 \times \frac{0.5}{2} + \frac{1.125}{2} + \frac{1.125}{2}\right) = 0.40625$$

**Unknown or Missing Parents**

When individuals or their parents are unknown in the population, their coancestries are assigned by the value  $\frac{1}{2}cov$  if *cov* is set by the INIT= option or by the value 0 if the INIT= option is not specified. That is, if either A or B is unknown, then

$$f_{AB} = \frac{1}{2}cov$$

For example, ‘Jane’ is not in the population, and since ‘Jane’ is assumed to be defined just before the observation at which ‘Jane’ appears as a parent (that is, between observations 4 and 5), then ‘Jane’ is not older than ‘Scott’. The coancestry between ‘Jane’ and ‘Scott’ is then obtained by using the [simplified basic rule](#) (see the section “[Calculation of Coancestry](#)” on page 3733):

$$f_{\text{Scott},\text{Jane}} = \frac{1}{2} (f_{\text{Scott},\cdot} + f_{\text{Scott},\cdot})$$

Here, dots (·) indicate Jane’s unknown parents. Therefore,  $f_{\text{Scott},\cdot}$  is replaced by  $\frac{1}{2}cov$ , where *cov* is set by the INIT= option. If INIT=0.25, then

$$f_{\text{Scott},\text{Jane}} = \frac{1}{2} \left( \frac{0.25}{2} + \frac{0.25}{2} \right) = 0.125$$

For a more detailed discussion on the calculation of coancestries, inbreeding coefficients, and covariance coefficients, see Falconer and Mackay (1996); Kempthorne (1957); Crow and Kimura (1970).

**OUTCOV= Data Set**

The OUTCOV= data set has the following variables:

- a list of BY variables, if there is a **BY** statement
- the generation variable, if there is a **CLASS** statement
- the gender variable, if there is a **GENDER** statement
- `_Type_`, a variable indicating the type of observation. The valid values of the `_Type_` variable are ‘COV’ for covariance estimates and ‘INBREED’ for inbreeding coefficients.
- `_Panel_`, a variable indicating the panel number used when populations delimited by BY groups contain different numbers of individuals. If there are  $n$  individuals in the first BY group and if any subsequent BY group contains a larger population, then its covariance/inbreeding matrix is divided into panels, with each panel containing  $n$  columns of data. If you put these panels side by side in increasing `_Panel_` number order, then you can reconstruct the covariance or inbreeding matrix.

- `_Col_`, a variable used to name columns of the inbreeding or covariance matrix. The values of this variable start with 'COL', followed by a number indicating the column number. The names of the individuals corresponding to any given column  $i$  can be found by reading the individual's name across the row that has a `_Col_` value of 'COL $i$ '. When the inbreeding or covariance matrix is divided into panels, all the rows repeat for the first  $n$  columns, all the rows repeat for the next  $n$  columns, and so on.
- the variable containing the names of the individuals, that is, the first variable listed in the `VAR` statement
- the variable containing the names of the first parents, that is, the second variable listed in the `VAR` statement
- the variable containing the names of the second parents, that is, the third variable listed in the `VAR` statement
- a list of covariance variables `Col1–Col $n$` , where  $n$  is the maximum number of individuals in the first population

The functions of the variables `_Panel_` and `_Col_` can best be demonstrated by an example. Assume that there are three individuals in the first BY group and that, in the current BY group (`Byvar=2`), there are five individuals with the following covariance matrix.

| COV                 | 1        | 2        | 3                   | 4        | 5        |
|---------------------|----------|----------|---------------------|----------|----------|
| 1                   | Cov(1,1) | Cov(1,2) | Cov(1,3)            | Cov(1,4) | Cov(1,5) |
| 2                   | Cov(2,1) | Cov(2,2) | Cov(2,3)            | Cov(2,4) | Cov(2,5) |
| 3                   | Cov(3,1) | Cov(3,2) | Cov(3,3)            | Cov(3,4) | Cov(3,5) |
| 4                   | Cov(4,1) | Cov(4,2) | Cov(4,3)            | Cov(4,4) | Cov(4,5) |
| 5                   | Cov(5,1) | Cov(5,2) | Cov(5,3)            | Cov(5,4) | Cov(5,5) |
| _____ Panel 1 _____ |          |          | _____ Panel 2 _____ |          |          |

Then the `OUTCOV=` data set appears as follows.

| Byvar | _Panel_ | _Col_ | Individual | Parent | Parent2 | Col1     | Col2     | Col3     |
|-------|---------|-------|------------|--------|---------|----------|----------|----------|
| 2     | 1       | COL1  | 1          |        |         | Cov(1,1) | Cov(1,2) | Cov(1,3) |
| 2     | 1       | COL2  | 2          |        |         | Cov(2,1) | Cov(2,2) | Cov(2,3) |
| 2     | 1       | COL3  | 3          |        |         | Cov(3,1) | Cov(3,2) | Cov(3,3) |
| 2     | 1       |       | 4          |        |         | Cov(4,1) | Cov(4,2) | Cov(4,3) |
| 2     | 1       |       | 5          |        |         | Cov(5,1) | Cov(5,2) | Cov(5,3) |
| 2     | 2       |       | 1          |        |         | Cov(1,4) | Cov(1,5) | .        |
| 2     | 2       |       | 2          |        |         | Cov(2,4) | Cov(2,5) | .        |
| 2     | 2       |       | 3          |        |         | Cov(3,4) | Cov(3,5) | .        |
| 2     | 2       | COL1  | 4          |        |         | Cov(4,4) | Cov(4,5) | .        |
| 2     | 2       | COL2  | 5          |        |         | Cov(5,4) | Cov(5,5) | .        |

Notice that the first three columns go to the first panel (`_Panel_=1`), and the remaining two go to the second panel (`_Panel_=2`). Therefore, in the first panel, 'COL1', 'COL2', and 'COL3' correspond to individuals 1, 2, and 3, respectively, while in the second panel, 'COL1' and 'COL2' correspond to individuals 4 and 5, respectively.

---

## Displayed Output

The INBREED procedure can output either covariance coefficients or inbreeding coefficients. Note that the following items can be produced for each generation if generations do not overlap.

The output produced by PROC INBREED can be any or all of the following items:

- a matrix of coefficients
- coefficients of the individuals
- coefficients for selected matings

---

## ODS Table Names

PROC INBREED assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 47.2. For more information on ODS, see Chapter 20, "Using the Output Delivery System."

**Table 47.2** ODS Tables Produced by PROC INBREED

| ODS Table Name           | Description                               | Statement | Option            |
|--------------------------|-------------------------------------------|-----------|-------------------|
| AvgCovCoef               | Averages of covariance coefficient matrix | GENDER    | COVAR and AVERAGE |
| AvgInbreedingCoef        | Averages of inbreeding coefficient matrix | GENDER    | AVERAGE           |
| CovarianceCoefficient    | Covariance coefficient table              | PROC      | COVAR and MATRIX  |
| InbreedingCoefficient    | Inbreeding coefficient table              | PROC      | MATRIX            |
| IndividualCovCoef        | Covariance coefficients of individuals    | PROC      | IND and COVAR     |
| IndividualInbreedingCoef | Inbreeding coefficients of individuals    | PROC      | IND               |
| MatingCovCoef            | Covariance coefficients of matings        | MATINGS   | COVAR             |

## Examples: INBREED Procedure

### Example 47.1: Monoecious Population Analysis

The following example shows a covariance analysis within nonoverlapping generations for a monoecious population. Parents of generation 1 are unknown and therefore assumed to be unrelated. The following statements produce [Output 47.1.1](#) through [Output 47.1.3](#):

```
data Monoecious;
 input Generation Individual Parent1 Parent2 Covariance @@;
 datalines;
1 1 . . . 1 2 . . . 1 3 . . .
2 1 1 1 . 2 2 1 2 . 2 3 2 3 .
3 1 1 2 . 3 2 1 3 . 3 3 2 1 .
3 4 1 3 . 3 . 2 3 0.50 3 . 4 3 1.135
;

title 'Inbreeding within Nonoverlapping Generations';
proc inbreed ind covar matrix data=Monoecious;
 class Generation;
run;
```

**Output 47.1.1** Monoecious Population Analysis, Generation 1

**Output 47.1.3** *continued*

|                       |   |
|-----------------------|---|
| Number of Individuals | 4 |
|-----------------------|---|

Note that, since the parents of the first generation are unknown, off-diagonal elements of the covariance matrix are all 0s and on-diagonal elements are all 1s. If there is an `INIT=cov` value, then the off-diagonal elements would be equal to `cov`, while on-diagonal elements would be equal to  $1 + cov/2$ .

In the third generation, individuals 2 and 4 are full siblings, so they belong to the same family. Since PROC INBREED computes covariance coefficients between families, the second and fourth columns of inbreeding coefficients are the same, except that their intersections with the second and fourth rows are reordered. Notice that, even though there is an observation to assign a covariance of 0.50 between individuals 2 and 3 in the third generation, the covariance between 2 and 3 is set to 1.135, the same value assigned between 4 and 3. This is because families get the same covariances, and later specifications override previous ones.

---

## Example 47.2: Pedigree Analysis

In the following example, an inbreeding analysis is performed for a complicated pedigree. This analysis includes computing selective matings of some individuals and inbreeding coefficients of all individuals. Also, inbreeding coefficients are averaged within sex categories. The following statements produce [Output 47.2.1](#):

```
data Swine;
 input Swine_Number $ Sire $ Dam $ Sex $;
 datalines;
3504 2200 2501 M
3514 2521 3112 F
3519 2521 2501 F
2501 2200 3112 M
2789 3504 3514 F
3501 2521 3514 M
3712 3504 3514 F
3121 2200 3501 F
;

title 'Least Related Matings';
proc inbreed data=Swine ind average;
 var Swine_Number Sire Dam;
 matings 2501 / 3501 3504 ,
 3712 / 3121;
 gender Sex;
run;
```

Note the following from [Output 47.2.1](#):

- Observation 4, which defines `Swine_Number=2501`, should precede the first and third observations where the progeny for 2501 are given. PROC INBREED ignores observation 4 since it is given out of order. As a result, the parents of 2501 are missing or unknown.

- The first column in the “Inbreeding Averages” table corresponds to the averages taken over the on-diagonal elements of the inbreeding coefficients matrix, and the second column gives averages over the off-diagonal elements.

---

---

## Overview: KDE Procedure

The KDE procedure performs univariate and bivariate kernel density estimation. Statistical *density estimation* involves approximating a hypothesized probability density function from observed data. *Kernel density estimation* is a nonparametric technique for density estimation in which a known density function (the *kernel*) is averaged across the observed data points to create a smooth approximation. PROC KDE uses a Gaussian density as the kernel, and its assumed variance determines the smoothness of the resulting estimate. See Silverman (1986) for a thorough review and discussion.

You can use PROC KDE to compute a variety of common statistics, including estimates of the percentiles of the hypothesized probability density function. You can produce a variety of plots, including univariate and bivariate histograms, plots of the kernel density estimates, and contour plots. You can also save kernel density estimates into SAS data sets.

---

## Getting Started: KDE Procedure

The following example illustrates the basic features of PROC KDE. Assume that 1000 observations are simulated from a bivariate normal density with means (0, 0), variances (10, 10), and covariance 9. The SAS DATA step to accomplish this is as follows:

```
data bivnormal;
 seed = 1283470;
 do i = 1 to 1000;
 z1 = rannor(seed);
 z2 = rannor(seed);
 z3 = rannor(seed);
 x = 3*z1+z2;
 y = 3*z1+z3;
 output;
 end;
 drop seed;
run;
```

The following statements request a bivariate kernel density estimate for the variables x and y, with contour and surface plots:

```
ods graphics on;
proc kde data=bivnormal;
 bivar x y / plots=(contour surface);
run;
ods graphics off;
```

The contour plot and the surface plot of the estimate are displayed in [Figure 48.1](#) and [Figure 48.2](#), respectively. Note that the correlation of 0.9 in the original data results in oval-shaped contours. These graphs are produced by specifying the `PLOTS=` option in the `BIVAR` statement with ODS Graphics enabled. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the KDE procedure, see the section “[ODS Graphics](#)” on page 3767.

**Figure 48.1** Contour Plot of Estimated Density

**Figure 48.2** Surface Plot of Estimated Density

The default output tables for this analysis are shown in Figure 48.3.

**Figure 48.3** Default Bivariate Tables

| The KDE Procedure           |                |
|-----------------------------|----------------|
| Inputs                      |                |
| Data Set                    | WORK.BIVNORMAL |
| Number of Observations Used | 1000           |
| Variable 1                  | x              |
| Variable 2                  | y              |
| Bandwidth Method            | Simple Normal  |
|                             | Reference      |

Figure 48.3 continued

| Controls             |        |        |
|----------------------|--------|--------|
|                      | x      | y      |
| Grid Points          | 60     | 60     |
| Lower Grid Limit     | -11.25 | -10.05 |
| Upper Grid Limit     | 9.1436 | 9.0341 |
| Bandwidth Multiplier | 1      | 1      |

The “Inputs” table lists basic information about the density fit, including the input data set, the number of observations, and the variables. The bandwidth method is the technique used to select the amount of smoothing in the estimate. A simple normal reference rule is used for bivariate smoothing.

The “Controls” table lists the primary numbers controlling the kernel density fit. Here a  $60 \times 60$  grid is fit to the entire range of the data, and no adjustment is made to the default bandwidth.

---

## Syntax: KDE Procedure

The following statements are available in the KDE procedure:

```

PROC KDE < options > ;
 BIVAR variable-list < / options > ;
 UNIVAR variable-list < / options > ;
 BY variables ;
 FREQ variable ;
 WEIGHT variable ;

```

The PROC KDE statement invokes the procedure. The BIVAR statement requests that one or more bivariate kernel density estimates be computed. The UNIVAR statement requests one or more univariate kernel density estimates. You can specify any number of BIVAR and UNIVAR statements.

---

## PROC KDE Statement

```

PROC KDE < options > ;

```

The PROC KDE statement invokes the procedure. It also specifies the input data set.

```

DATA=SAS-data-set

```

specifies the input SAS data set to be used by PROC KDE. The default is the most recently created data set.

## BIVAR Statement

The BIVAR statement computes bivariate kernel density estimates. Table 48.1 summarizes the options available in the BIVAR statement.

**Table 48.1** BIVAR Statement Options

| Option      | Description                                                                                             |
|-------------|---------------------------------------------------------------------------------------------------------|
| BIVSTATS    | Produces a table for each density estimate                                                              |
| BWM=        | Specifies the bandwidth multiplier                                                                      |
| GRIDL=      | Specifies the lower grid limit                                                                          |
| GRIDU=      | Specifies the upper grid limit                                                                          |
| LEVELS      | Requests a table of levels for contours of the bivariate density                                        |
| NGRID=      | Specifies the number of grid points associated with each variable                                       |
| NOPRINT     | Suppresses output tables                                                                                |
| OUT=        | Specifies the name of the output data set                                                               |
| PERCENTILES | Requests that a table of percentiles be computed                                                        |
| PLOTS=      | Requests one or more plots                                                                              |
| UNISTATS    | Produces a table for each density estimate containing standard univariate statistics and the bandwidths |

The basic syntax for the BIVAR statement specifies two variables:

```
BIVAR v1 <(v-options)> v2 <(v-options)> </ options> ;
```

This statement requests a bivariate kernel density estimate for the variables v1 and v2. The *v-options* optionally specified in parentheses after a variable name apply only to that variable, and override corresponding global *options* specified following a slash (/).

You can specify a list of more than two variables:

```
BIVAR v1 <(v-options)> v2 <(v-options)> ... vN <(v-options)> </ options> ;
```

This statement requests a bivariate kernel density estimate for each distinct pair of variables in the list. For example, if you specify

```
bivar x y z;
```

then a bivariate kernel density estimate is computed for each of the variable pairs (x, y), (x, z), and (y, z).

Alternatively, you can specify an explicit list of variable pairs, with each pair enclosed in parentheses:

```
BIVAR (v1 v2)(v3 v4)...(vN-1 vN)</ options> ;
```

(You can also specify *v-options* following a variable name appearing in an explicit pair, but they are omitted here for clarity.) This statement requests a bivariate kernel density estimate for each pair of variables. For example, if you specify

```
bivar (x y) (y z);
```

then bivariate kernel density estimates are computed for (x, y) and (y, z).

**NOTE:** The VAR statement supported by PROC KDE in SAS 8 and earlier releases is now obsolete. The VAR statement has been replaced by the UNIVAR and the BIVAR statements, which enable you to produce multiple kernel density estimates with a single invocation of the procedure.

You can specify the following options in the BIVAR statement. As noted, some options can be used as *v-options*.

### **BIVSTATS**

produces a table for each density estimate containing the covariance and correlation between the two variables.

### **BWM=number**

specifies the bandwidth multiplier applied to each variable in each kernel density estimate. The default value is 1. Larger multipliers produce a smoother estimate, and smaller ones produce a rougher estimate. To specify different bandwidth multipliers for different variables, specify BWM= as a *v-option*.

### **GRIDL=number**

specifies the lower grid limit applied to each variable in each kernel density estimate. The default value for a given variable is the minimum observed value of that variable. To specify different lower grid limits for different variables, specify GRIDL= as a *v-option*.

### **GRIDU=number**

specifies the upper grid limit applied to each variable in each kernel density estimate. The default value for a given variable is the maximum observed value of that variable. To specify different upper grid limits for different variables, specify GRIDU= as a *v-option*.

### **LEVELS**

#### **LEVELS=numlist**

requests a table of levels for contours of the bivariate density. The contours are defined in such a way that the density has a constant level along each contour, and the volume enclosed by each contour corresponds to a specified percent. In other words, the contours correspond to slices or levels of the density surface taken along the density axis. You can specify the percents used to define the contours. The default values are 1, 5, 10, 50, 90, 95, 99, and 100. The “Levels” table also provides the minimum and maximum values for each contour along the directions of the two data variables.

### **NGRID=number**

#### **NG=number**

specifies the number of grid points associated with each variable in each kernel density estimate. The default value is 60. To specify different numbers of grid points for different variables, specify NGRID= as a *v-option*.

### **NOPRINT**

suppresses output tables produced by the BIVAR statement. You can use the NOPRINT option when you want to produce graphical output only.

### **OUT=SAS-data-set**

specifies the name of the output data set in which kernel density estimates are saved. This output data set contains the following variables:

- `var1`, whose value is the name of the first variable in a bivariate kernel density estimate
- `var2`, whose value is the name of the second variable in a bivariate kernel density estimate
- `value1`, with values corresponding to grid coordinates for the first variable
- `value2`, with values corresponding to grid coordinates for the second variable
- `density`, with values equal to kernel density estimates at the associated grid point
- `count`, containing the number of original observations contained in the bin corresponding to a grid point

## PERCENTILES

**PERCENTILES**=*numlist*

requests that a table of percentiles be computed for each BIVAR variable. You can specify a list of percentiles to be computed. The default percentiles are 0.5, 1, 2.5, 5, 10, 25, 50, 75, 90, 95, 97.5, 99, and 99.5.

**PLOTS**=*plot-request*< (*options*)> | **ALL** | **NONE**

**PLOTS**=(*plot-request*< (*options*)> < . . . *plot-request*< (*options*)> >)

requests one or more plots of the bivariate data and kernel density estimate. When you specify only one plot request, you can omit the parentheses around the plot request.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc kde data=octane;
 bivar Rater Customer / plots=all;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

By default, if ODS Graphics is enabled and you do not specify the PLOTS= option, then the BIVAR statement creates a contour plot. If you specify the PLOTS= option, you get only the requested plots.

The following *plot-requests* are available.

### ALL

produces all bivariate plots.

### CONTOUR

produces a contour plot of the bivariate density estimate.

### CONTOURSCATTER

produces a contour plot of the bivariate density estimate overlaid with a scatter plot of the data.

**HISTOGRAM** < (*view-options*)>

produces a bivariate histogram of the data. The following *view-options* can be specified:

**ROTATE=angle**

rotates the histogram *angle* degrees, where  $-180 < angle < 180$ . By default, *angle* = 54.

**TILT=angle**

tilts the histogram *angle* degrees, where  $-180 < angle < 180$ . By default, *angle* = 20.

**HISTSURFACE <(view-options)>**

produces a bivariate histogram of the data overlaid with a surface plot of the bivariate kernel density estimate. The following *view-options* can be specified:

**ROTATE=angle**

rotates the histogram and kernel density surface *angle* degrees, where  $-180 < angle < 180$ . By default, *angle* = 54.

**TILT=angle**

tilts the histogram and kernel density surface *angle* degrees, where  $-180 < angle < 180$ . By default, *angle* = 20.

**NONE**

suppresses all plots, including the contour plot that is produced by default when ODS Graphics is enabled and the PLOTS= option is not specified.

**SCATTER**

produces a scatter plot of the data.

**SURFACE <(view-options)>**

produces a surface plot of the bivariate kernel density estimate. The following *view-options* can be specified:

**ROTATE=angle**

rotates the kernel density surface *angle* degrees, where  $-180 < angle < 180$ . By default, *angle* = 54.

**TILT=angle**

tilts the kernel density surface *angle* degrees, where  $-180 < angle < 180$ . By default, *angle* = 20.

**UNISTATS**

produces a table for each density estimate containing standard univariate statistics for each of the two variables and the bandwidths used to compute the kernel density estimate. The statistics listed are the mean, variance, standard deviation, range, and interquartile range.

---

## UNIVAR Statement

**UNIVAR** *variable* <(v-options)> <... variable <(v-options)>> </ options> ;

The UNIVAR statement computes univariate kernel density estimates. You can specify various *v-options* for each variable by enclosing them in parentheses after the variable name. You can also specify global *options* among the UNIVAR statement options following a slash (/). Global *options* apply to all the variables specified in the UNIVAR statement. However, individual variable *v-options* override the global *options*.

**NOTE:** The VAR statement supported by PROC KDE in SAS 8 and earlier releases is now obsolete. The VAR statement has been replaced by the UNIVAR and BIVAR statements, which enable you to produce multiple kernel density estimates with a single invocation of the procedure.

Table 48.2 summarizes the options available in the UNIVAR statement.

**Table 48.2** UNIVAR Statement Options

| Option      | Description                                                                                    |
|-------------|------------------------------------------------------------------------------------------------|
| BWM=        | Specifies a bandwidth multiplier                                                               |
| GRIDL=      | Specifies a lower grid limit                                                                   |
| GRIDU=      | Specifies an upper grid limit                                                                  |
| METHOD=     | Specifies the method used to compute the bandwidth                                             |
| NGRID=      | Specifies a number of grid points                                                              |
| NOPRINT     | Suppresses output tables produced                                                              |
| OUT=        | Specifies the output SAS data set containing the kernel density estimate                       |
| PERCENTILES | Requests that a table of percentiles                                                           |
| PLOTS=      | Requests plots of the univariate kernel density estimate                                       |
| SJPIMAX=    | Specifies the maximum grid value in determining the Sheather-Jones plug-in bandwidth           |
| SJPIMIN=    | Specifies the minimum grid value in determining the Sheather-Jones plug-in bandwidth           |
| SJPINUM=    | Specifies the number of grid values used in determining the Sheather-Jones plug-in bandwidth   |
| SJPITOL=    | Specifies the tolerance for termination of the bisection algorithm                             |
| UNISTATS    | Produces a table for each variable containing standard univariate statistics and the bandwidth |

You can specify the following options in the UNIVAR statement. As noted, some options can be used as *v-options*.

**BWM=number**

specifies a bandwidth multiplier used for each kernel density estimate. The default value is 1. Larger multipliers produce a smoother estimate, and smaller ones produce a rougher estimate. To specify different bandwidth multipliers for different variables, specify BWM= as a *v-option*.

**GRIDL=number**

specifies a lower grid limit used for each kernel density estimate. The default value for a given variable is the minimum observed value of that variable. To specify different lower grid limits for different variables, specify GRIDL= as a *v-option*.

**GRIDU=number**

specifies an upper grid limit used for each kernel density estimate. The default value for a given variable is the maximum observed value of that variable. To specify different upper grid limits for different variables, specify GRIDU= as a *v-option*.

**METHOD=SJPI | SNR | SNRQ | SROT | OS**

specifies the method used to compute the bandwidth. Available methods are Sheather-Jones plugin (SJPI), simple normal reference (SNR), simple normal reference that uses the interquartile range (SNRQ), Silverman's rule of thumb (SROT), and oversmoothed (OS). See the section “[Bandwidth Selection](#)” on page 3765 and see Jones, Marron, and Sheather (1996) for a description of these methods. SJPI is the default method.

**NGRID=number****NG=number**

specifies a number of grid points used for each kernel density estimate. The default value is 401. To specify different numbers of grid points for different variables, specify NGRID= as a *v-option*.

**NOPRINT**

suppresses output tables produced by the UNIVAR statement. You can use the NOPRINT option when you want to produce graphical output only.

**OUT=SAS-data-set**

specifies the output SAS data set containing the kernel density estimate. This output data set contains the following variables:

- var, whose value is the name of the variable in the kernel density estimate
- value, with values corresponding to grid coordinates for the variable
- density, with values equal to kernel density estimates at the associated grid point
- count, containing the number of original observations contained in the bin corresponding to a grid point

**PERCENTILES****PERCENTILES=numlist**

requests that a table of percentiles be computed for each UNIVAR variable. You can specify a list of percentiles to be computed. The default percentiles are 0.5, 1, 2.5, 5, 10, 25, 50, 75, 90, 95, 97.5, 99, and 99.5.

**PLOTS=plot-request | ALL | NONE****PLOTS=(plot-request < . . . plot-request >)**

requests plots of the univariate kernel density estimate. When you specify only one plot request, you can omit the parentheses around the plot request.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc kde data=channel;
 univar length / plots=histdensity;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The following table shows the available *plot-requests*.

| Keyword        | Description                                                              |
|----------------|--------------------------------------------------------------------------|
| ALL            | produces all plots                                                       |
| DENSITY        | univariate kernel density estimate curve                                 |
| DENSITYOVERLAY | overlaid univariate kernel density estimate curves                       |
| HISTDENSITY    | univariate histogram of data overlaid with kernel density estimate curve |
| HISTOGRAM      | univariate histogram of data                                             |
| NONE           | suppresses all plots                                                     |

By default, if you ODS Graphics is enabled and you do not specify the PLOTS= option, then the UNIVAR statement creates a histogram overlaid with a kernel density estimate. If you specify the PLOTS= option, you get only the requested plots.

If you specify more than one variable in the UNIVAR statement, the DENSITYOVERLAY keyword overlays the density curves for all the variables on a single plot. The other keywords each produce a separate plot for every variable listed in the UNIVAR statement.

**SJPIMAX=number**

specifies the maximum grid value in determining the Sheather-Jones plug-in bandwidth. The default value is two times the oversmoothed estimate.

**SJPIMIN=number**

specifies the minimum grid value in determining the Sheather-Jones plug-in bandwidth. The default value is the maximum value divided by 18.

**SJPINUM=number**

specifies the number of grid values used in determining the Sheather-Jones plug-in bandwidth. The default is 21.

**SJPITOL=number**

specifies the tolerance for termination of the bisection algorithm used in computing the Sheather-Jones plug-in bandwidth. The default value is 0.001.

**UNISTATS**

produces a table for each variable containing standard univariate statistics and the bandwidth used to compute its kernel density estimate. The statistics listed are the mean, variance, standard deviation, range, and interquartile range.

## Examples

Suppose you have the variables x1, x2, x3, and x4 in the SAS data set MyData. You can request a univariate kernel density estimate for each of these variables with the following statements:

```
proc kde data=MyData;
 univar x1 x2 x3 x4;
run;
```

You can also specify different bandwidths and other options for each variable. For example, the following statements request kernel density estimates that use Silverman's rule of thumb (SROT) method for all variables:

```
proc kde data=MyData;
 univar x1 (bwm=2)
 x2 (bwm=0.5 ngrid=100)
 x3 x4 / ngrid=200 method=srot;
run;
```

The option NGRID=200 applies to the variables x1, x3, and x4, but the *v-option* NGRID=100 is applied to x2. Bandwidth multipliers of 2 and 0.5 are specified for the variables x1 and x2, respectively.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC KDE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the KDE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## FREQ Statement

**FREQ** *variable* ;

The FREQ statement specifies a variable that provides frequencies for each observation in the DATA= data set. Specifically, if  $n$  is the value of the FREQ variable for a given observation, then that observation is used  $n$  times. If the value of the FREQ variable is missing or is less than 1, the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

---

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement specifies a variable that weights the observations in computing the kernel density estimate. Observations with higher weights have more influence in the computations. If an observation has a nonpositive or missing weight, then the entire observation is omitted from the analysis. You should be cautious in using data sets with extreme weights, because they can produce unreliable results.

---

## Details: KDE Procedure

---

### Computational Overview

The two main computational tasks of PROC KDE are automatic bandwidth selection and the construction of a kernel density estimate once a bandwidth has been selected. The primary computational tools used to accomplish these tasks are binning, convolutions, and the fast Fourier transform. The following sections provide analytical details on these topics, beginning with the density estimates themselves.

---

### Kernel Density Estimates

A weighted univariate kernel density estimate involves a variable  $X$  and a weight variable  $W$ . Let  $(X_i, W_i)$ ,  $i = 1, 2, \dots, n$ , denote a sample of  $X$  and  $W$  of size  $n$ . The weighted kernel density estimate of  $f(x)$ , the density of  $X$ , is as follows:

$$\hat{f}(x) = \frac{1}{\sum_{i=1}^n W_i} \sum_{i=1}^n W_i \varphi_h(x - X_i)$$

where  $h$  is the bandwidth and

$$\varphi_h(x) = \frac{1}{\sqrt{2\pi}h} \exp\left(-\frac{x^2}{2h^2}\right)$$

is the standard normal density rescaled by the bandwidth. If  $h \rightarrow 0$  and  $nh \rightarrow \infty$ , then the optimal bandwidth is

$$h_{\text{AMISE}} = \left[ \frac{1}{2\sqrt{\pi}n \int (f'')^2} \right]^{1/5}$$

This optimal value is unknown, and so approximations methods are required. For a derivation and discussion of these results, see Silverman (1986, Chapter 3) and Jones, Marron, and Sheather (1996).

For the bivariate case, let  $\mathbf{X} = (X, Y)$  be a bivariate random element taking values in  $R^2$  with joint density function

$$f(x, y), (x, y) \in R^2$$

and let  $\mathbf{X}_i = (X_i, Y_i)$ ,  $i = 1, 2, \dots, n$ , be a sample of size  $n$  drawn from this distribution. The kernel density estimate of  $f(x, y)$  based on this sample is

$$\begin{aligned} \hat{f}(x, y) &= \frac{1}{n} \sum_{i=1}^n \varphi_{\mathbf{h}}(x - X_i, y - Y_i) \\ &= \frac{1}{nh_X h_Y} \sum_{i=1}^n \varphi\left(\frac{x - X_i}{h_X}, \frac{y - Y_i}{h_Y}\right) \end{aligned}$$

where  $(x, y) \in R^2$ ,  $h_X > 0$  and  $h_Y > 0$  are the bandwidths, and  $\varphi_h(x, y)$  is the rescaled normal density

$$\varphi_h(x, y) = \frac{1}{h_X h_Y} \varphi\left(\frac{x}{h_X}, \frac{y}{h_Y}\right)$$

where  $\varphi(x, y)$  is the standard normal density function

$$\varphi(x, y) = \frac{1}{2\pi} \exp\left(-\frac{x^2 + y^2}{2}\right)$$

Under mild regularity assumptions about  $f(x, y)$ , the mean integrated squared error (MISE) of  $\hat{f}(x, y)$  is

$$\begin{aligned} \text{MISE}(h_X, h_Y) &= E \int (\hat{f} - f)^2 \\ &= \frac{1}{4\pi n h_X h_Y} + \frac{h_X^4}{4} \int \left(\frac{\partial^2 f}{\partial X^2}\right)^2 dx dy \\ &\quad + \frac{h_Y^4}{4} \int \left(\frac{\partial^2 f}{\partial Y^2}\right)^2 dx dy + O\left(h_X^4 + h_Y^4 + \frac{1}{n h_X h_Y}\right) \end{aligned}$$

as  $h_X \rightarrow 0$ ,  $h_Y \rightarrow 0$  and  $n h_X h_Y \rightarrow \infty$ .

Now set

$$\begin{aligned} \text{AMISE}(h_X, h_Y) &= \frac{1}{4\pi n h_X h_Y} + \frac{h_X^4}{4} \int \left(\frac{\partial^2 f}{\partial X^2}\right)^2 dx dy \\ &\quad + \frac{h_Y^4}{4} \int \left(\frac{\partial^2 f}{\partial Y^2}\right)^2 dx dy \end{aligned}$$

which is the asymptotic mean integrated squared error (AMISE). For fixed  $n$ , this has a minimum at  $(h_{\text{AMISE}_X}, h_{\text{AMISE}_Y})$  defined as

$$h_{\text{AMISE}_X} = \left[ \frac{\int \left(\frac{\partial^2 f}{\partial X^2}\right)^2}{4n\pi} \right]^{1/6} \left[ \frac{\int \left(\frac{\partial^2 f}{\partial X^2}\right)^2}{\int \left(\frac{\partial^2 f}{\partial Y^2}\right)^2} \right]^{2/3}$$

and

$$h_{\text{AMISE}_Y} = \left[ \frac{\int \left(\frac{\partial^2 f}{\partial Y^2}\right)^2}{4n\pi} \right]^{1/6} \left[ \frac{\int \left(\frac{\partial^2 f}{\partial Y^2}\right)^2}{\int \left(\frac{\partial^2 f}{\partial X^2}\right)^2} \right]^{2/3}$$

These are the optimal asymptotic bandwidths in the sense that they minimize MISE. However, as in the univariate case, these expressions contain the second derivatives of the unknown density  $f$  being estimated, and so approximations are required. See Wand and Jones (1993) for further details.

## Binning

Binning, or assigning data to discrete categories, is an effective and fast method for large data sets (Fan and Marron 1994). When the sample size  $n$  is large, direct evaluation of the kernel estimate  $\hat{f}$  at any point would involve  $n$  kernel evaluations, as shown in the preceding formulas. To evaluate the estimate at each point of a grid of size  $g$  would thus require  $ng$  kernel evaluations. When you use  $g = 401$  in the univariate case or  $g = 60 \times 60 = 3600$  in the bivariate case and  $n \geq 1000$ , the amount of computation can be prohibitively large. With binning, however, the computational order is reduced to  $g$ , resulting in a much quicker algorithm that is nearly as accurate as direct evaluation.

To bin a set of weighted univariate data  $X_1, X_2, \dots, X_n$  to a grid  $x_1, x_2, \dots, x_g$ , simply assign each sample  $X_i$ , together with its weight  $W_i$ , to the nearest grid point  $x_j$  (also called the bin center). When binning is completed, each grid point  $x_i$  has an associated number  $c_i$ , which is the sum total of all the weights that correspond to sample points that have been assigned to  $x_i$ . These  $c_i$ s are known as the *bin counts*.

This procedure replaces the data  $(X_i, W_i)$ ,  $i = 1, 2, \dots, n$ , with the smaller set  $(x_i, c_i)$ ,  $i = 1, 2, \dots, g$ , and the estimation is carried out with these new data. This is so-called *simple binning*, versus the finer *linear binning* described in Wand (1994). PROC KDE uses simple binning for the sake of faster and easier implementation. Also, it is assumed that the bin centers  $x_1, x_2, \dots, x_g$  are equally spaced and in increasing order. In addition, assume for notational convenience that  $\sum_{i=1}^n W_i = n$  and, therefore,  $\sum_{i=1}^g c_i = n$ .

If you replace the data  $(X_i, W_i)$ ,  $i = 1, 2, \dots, n$ , with  $(x_i, c_i)$ ,  $i = 1, 2, \dots, g$ , the weighted estimator  $\hat{f}$  then becomes

$$\hat{f}(x) = \frac{1}{n} \sum_{i=1}^g c_i \varphi_h(x - x_i)$$

with the same notation as used previously. To evaluate this estimator at the  $g$  points of the same grid vector  $grid = (x_1, x_2, \dots, x_g)'$  is to calculate

$$\hat{f}(x_i) = \frac{1}{n} \sum_{j=1}^g c_j \varphi_h(x_i - x_j)$$

for  $i = 1, 2, \dots, g$ . This can be rewritten as

$$\hat{f}(x_i) = \frac{1}{n} \sum_{j=1}^g c_j \varphi_h(|i - j|\delta)$$

where  $\delta = x_2 - x_1$  is the increment of the grid.

The same idea of binning works similarly with bivariate data, where you estimate  $\hat{f}$  over the grid matrix  $grid = grid_X \times grid_Y$  as follows:

$$grid = \begin{bmatrix} \mathbf{x}_{1,1} & \mathbf{x}_{1,2} & \dots & \mathbf{x}_{1,g_Y} \\ \mathbf{x}_{2,1} & \mathbf{x}_{2,2} & \dots & \mathbf{x}_{2,g_Y} \\ \vdots & & & \\ \mathbf{x}_{g_X,1} & \mathbf{x}_{g_X,2} & \dots & \mathbf{x}_{g_X,g_Y} \end{bmatrix}$$

where  $\mathbf{x}_{i,j} = (x_i, y_j)$ ,  $i = 1, 2, \dots, g_X$ ,  $j = 1, 2, \dots, g_Y$ , and the estimates are

$$\hat{f}(\mathbf{x}_{i,j}) = \frac{1}{n} \sum_{k=1}^{g_X} \sum_{l=1}^{g_Y} c_{k,l} \varphi_h(|i - k|\delta_X, |j - l|\delta_Y)$$

where  $\delta_X = x_2 - x_1$  and  $\delta_Y = y_2 - y_1$  are the increments of the grid.

## Convolutions

The formulas for the binned estimator  $\hat{f}$  in the previous subsection are in the form of a convolution product between two matrices, one of which contains the bin counts, the other of which contains the rescaled kernels evaluated at multiples of grid increments. This section defines these two matrices explicitly, and shows that  $\hat{f}$  is their convolution.

Beginning with the weighted univariate case, define the following matrices:

$$\begin{aligned}\mathbf{K} &= \frac{1}{n}(\varphi_h(0), \varphi_h(\delta), \dots, \varphi_h((g-1)\delta))' \\ \mathbf{C} &= (c_1, c_2, \dots, c_g)'\end{aligned}$$

The first thing to note is that many terms in  $\mathbf{K}$  are negligible. The term  $\varphi_h(i\delta)$  is taken to be 0 when  $|i\delta/h| \geq 5$ , so you can define

$$l = \min(g-1, \text{floor}(5h/\delta))$$

as the maximum integer multiple of the grid increment to get nonzero evaluations of the rescaled kernel. Here  $\text{floor}(x)$  denotes the largest integer less than or equal to  $x$ .

Next, let  $p$  be the smallest power of 2 that is greater than  $g + l + 1$ ,

$$p = 2^{\text{ceil}(\log_2(g+l+1))}$$

where  $\text{ceil}(x)$  denotes the smallest integer greater than or equal to  $x$ .

Modify  $\mathbf{K}$  as follows:

$$\mathbf{K} = \frac{1}{n}(\varphi_h(0), \varphi_h(\delta), \dots, \varphi_h(l\delta), \underbrace{0, \dots, 0}_{p-2l-1}, \varphi_h(l\delta), \dots, \varphi_h(\delta))'$$

Essentially, the negligible terms of  $\mathbf{K}$  are omitted, and the rest are *symmetrized* (except for one term). The whole matrix is then padded to size  $p \times 1$  with zeros in the middle. The dimension  $p$  is a highly composite number—that is, one that decomposes into many factors—leading to the most efficient fast Fourier transform operation (see Wand 1994).

The third operation is to pad the bin count matrix  $\mathbf{C}$  with zeros to the same size as  $\mathbf{K}$ :

$$\mathbf{C} = (c_1, c_2, \dots, c_g, \underbrace{0, \dots, 0}_{p-g})'$$

The convolution  $\mathbf{K} * \mathbf{C}$  is then a  $p \times 1$  matrix, and the preceding formulas show that its first  $g$  entries are exactly the estimates  $\hat{f}(x_i)$ ,  $i = 1, 2, \dots, g$ .

For bivariate smoothing, the matrix  $\mathbf{K}$  is defined similarly as

$$\mathbf{K} = \begin{bmatrix} \kappa_{0,0} & \kappa_{0,1} & \dots & \kappa_{0,l_Y} & \mathbf{0} & \kappa_{0,l_Y} & \dots & \kappa_{0,1} \\ \kappa_{1,0} & \kappa_{1,1} & \dots & \kappa_{1,l_Y} & \mathbf{0} & \kappa_{1,l_Y} & \dots & \kappa_{1,1} \\ \vdots & & & & & & & \\ \kappa_{l_X,0} & \kappa_{l_X,1} & \dots & \kappa_{l_X,l_Y} & \mathbf{0} & \kappa_{l_X,l_Y} & \dots & \kappa_{l_X,1} \\ \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} & \mathbf{0} & \mathbf{0} & \dots & \mathbf{0} \\ \kappa_{l_X,0} & \kappa_{l_X,1} & \dots & \kappa_{l_X,l_Y} & \mathbf{0} & \kappa_{l_X,l_Y} & \dots & \kappa_{l_X,1} \\ \vdots & & & & & & & \\ \kappa_{1,0} & \kappa_{1,1} & \dots & \kappa_{1,l_Y} & \mathbf{0} & \kappa_{1,l_Y} & \dots & \kappa_{1,1} \end{bmatrix}_{p_X \times p_Y}$$

where  $l_X = \min(g_X - 1, \text{floor}(5h_X/\delta_X))$ ,  $p_X = 2^{\text{ceil}(\log_2(g_X + l_X + 1))}$ , and so forth, and  $\kappa_{i,j} = \frac{1}{n} \varphi_h(i\delta_X, j\delta_Y)$   $i = 0, 1, \dots, l_X$ ,  $j = 0, 1, \dots, l_Y$ .

The bin count matrix  $\mathbf{C}$  is defined as

$$\mathbf{C} = \begin{bmatrix} c_{1,1} & c_{1,2} & \dots & c_{1,g_Y} & 0 & \dots & 0 \\ c_{2,1} & c_{2,2} & \dots & c_{2,g_Y} & 0 & \dots & 0 \\ \vdots & & & & & & \\ c_{g_X,1} & c_{g_X,2} & \dots & c_{g_X,g_Y} & 0 & \dots & 0 \\ 0 & 0 & \dots & 0 & 0 & \dots & 0 \\ \vdots & & & & & & \\ 0 & 0 & \dots & 0 & 0 & \dots & 0 \end{bmatrix}_{p_X \times p_Y}$$

As with the univariate case, the  $g_X \times g_Y$  upper-left corner of the convolution  $\mathbf{K} * \mathbf{C}$  is the matrix of the estimates  $\hat{f}(\text{grid})$ .

Most of the results in this subsection are found in Wand (1994).

## Fast Fourier Transform

As shown in the last subsection, kernel density estimates can be expressed as a submatrix of a certain convolution. The fast Fourier transform (FFT) is a computationally effective method for computing such convolutions. For a reference on this material, see Press et al. (1988).

The *discrete Fourier transform* of a complex vector  $\mathbf{z} = (z_0, \dots, z_{N-1})$  is the vector  $\mathbf{Z} = (Z_0, \dots, Z_{N-1})$ , where

$$Z_j = \sum_{l=0}^{N-1} z_l e^{2\pi i l j / N}, \quad j = 0, \dots, N-1$$

and  $i$  is the square root of  $-1$ . The vector  $\mathbf{z}$  can be recovered from  $\mathbf{Z}$  by applying the *inverse discrete Fourier transform* formula

$$z_l = N^{-1} \sum_{j=0}^{N-1} Z_j e^{-2\pi i l j / N}, \quad l = 0, \dots, N-1$$

Discrete Fourier transforms and their inverses can be computed quickly using the FFT algorithm, especially when  $N$  is *highly composite*; that is, it can be decomposed into many factors, such as a power of 2. By the *discrete convolution theorem*, the convolution of two vectors is the inverse Fourier transform of the element-by-element product of their Fourier transforms. This, however, requires certain periodicity assumptions, which explains why the vectors  $\mathbf{K}$  and  $\mathbf{C}$  require zero-padding. This is to avoid *wrap-around* effects (see Press et al. 1988, pp. 410–411). The vector  $\mathbf{K}$  is actually mirror-imaged so that the convolution of  $\mathbf{C}$  and  $\mathbf{K}$  will be the vector of binned estimates. Thus, if  $S$  denotes the inverse Fourier transform of the element-by-element product of the Fourier transforms of  $\mathbf{K}$  and  $\mathbf{C}$ , then the first  $g$  elements of  $S$  are the estimates.

The bivariate Fourier transform of an  $N_1 \times N_2$  complex matrix having  $(l_1 + 1, l_2 + 1)$  entry equal to  $z_{l_1 l_2}$  is the  $N_1 \times N_2$  matrix with  $(j_1 + 1, j_2 + 1)$  entry given by

$$Z_{j_1 j_2} = \sum_{l_1=0}^{N_1-1} \sum_{l_2=0}^{N_2-1} z_{l_1 l_2} e^{2\pi i(l_1 j_1 / N_1 + l_2 j_2 / N_2)}$$

and the formula of the inverse is

$$z_{l_1 l_2} = (N_1 N_2)^{-1} \sum_{j_1=0}^{N_1-1} \sum_{j_2=0}^{N_2-1} Z_{j_1 j_2} e^{-2\pi i(l_1 j_1 / N_1 + l_2 j_2 / N_2)}$$

The same discrete convolution theorem applies, and zero-padding is needed for matrices  $\mathbf{C}$  and  $\mathbf{K}$ . In the case of  $\mathbf{K}$ , the matrix is mirror-imaged twice. Thus, if  $S$  denotes the inverse Fourier transform of the element-by-element product of the Fourier transforms of  $\mathbf{K}$  and  $\mathbf{C}$ , then the upper-left  $g_X \times g_Y$  corner of  $S$  contains the estimates.

---

## Bandwidth Selection

Several different bandwidth selection methods are available in PROC KDE in the univariate case. Following the recommendations of Jones, Marron, and Sheather (1996), the default method follows a plug-in formula of Sheather and Jones.

This method solves the fixed-point equation

$$h = \left[ \frac{R(\varphi)}{nR(\hat{f}_g''(h)) \left( \int x^2 \varphi(x) dx \right)^2} \right]^{1/5}$$

where  $R(\varphi) = \int \varphi^2(x) dx$ .

PROC KDE solves this equation by first evaluating it on a grid of values spaced equally on a log scale. The largest two values from this grid that bound a solution are then used as starting values for a bisection algorithm.

The simple normal reference rule works by assuming  $\hat{f}$  is Gaussian in the preceding fixed-point equation. This results in

$$\begin{aligned} h &= \hat{\sigma} [4/(3n)]^{1/5} \\ &= 1.06 \hat{\sigma} n^{-1/5} \end{aligned}$$

where  $\hat{\sigma}$  is the sample standard deviation.

Alternatively, the bandwidth can be computed using the interquartile range,  $Q$ :

$$\begin{aligned} h &= 1.06 \hat{\sigma} n^{-1/5} \\ &\approx 1.06 (Q/1.34) n^{-1/5} \\ &\approx 0.785 Q n^{-1/5} \end{aligned}$$

Silverman's rule of thumb (Silverman 1986, Section 3.4.2) is computed as

$$h = 0.9 \min[\hat{\sigma}, Q/1.34] n^{-1/5}$$

The oversmoothed bandwidth is computed as

$$h = 3\hat{\sigma} [1/(70\sqrt{\pi n})]^{1/5}$$

When you specify a WEIGHT variable, PROC KDE uses weighted versions of  $Q_3$ ,  $Q_1$ , and  $\hat{\sigma}$  in the preceding expressions. The weighted quartiles are computed as weighted order statistics, and the weighted variance takes the form

$$\hat{\sigma}^2 = \frac{\sum_{i=1}^n W_i (X_i - \bar{X})^2}{\sum_{i=1}^n W_i}$$

where  $\bar{X} = (\sum_{i=1}^n W_i X_i) / (\sum_{i=1}^n W_i)$  is the weighted sample mean.

For the bivariate case, Wand and Jones (1993) note that automatic bandwidth selection is both difficult and computationally expensive. Their study of various ways of specifying a bandwidth matrix also shows that using two bandwidths, one in each coordinate's direction, is often adequate. PROC KDE enables you to adjust the two bandwidths by specifying a multiplier for the default bandwidths recommended by Bowman and Foster (1993):

$$\begin{aligned} h_X &= \hat{\sigma}_X n^{-1/6} \\ h_Y &= \hat{\sigma}_Y n^{-1/6} \end{aligned}$$

Here  $\hat{\sigma}_X$  and  $\hat{\sigma}_Y$  are the sample standard deviations of  $X$  and  $Y$ , respectively. These are the optimal bandwidths for two independent normal variables that have the same variances as  $X$  and  $Y$ . They are, therefore, conservative in the sense that they tend to oversmooth the surface.

You can specify the BWM= option to adjust the aforementioned bandwidths to provide the appropriate amount of smoothing for your application.

## ODS Table Names

PROC KDE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 48.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

**Table 48.3** ODS Tables Produced in PROC KDE

| ODS Table Name       | Description                | Statement      | Option      |
|----------------------|----------------------------|----------------|-------------|
| BivariateStatistics  | Bivariate statistics       | BIVAR          | BIVSTATS    |
| Controls             | Control variables          | default        |             |
| Inputs               | Input information          | default        |             |
| Levels               | Levels of density estimate | BIVAR          | LEVELS      |
| Percentiles          | Percentiles of data        | BIVAR / UNIVAR | PERCENTILES |
| UnivariateStatistics | Basic statistics           | BIVAR / UNIVAR | UNISTATS    |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

## ODS Graph Names

PROC KDE assigns a name to each graph it creates using the Output Delivery System (ODS). You can use these names to reference the graphs when using ODS. The names are listed in Table 48.4.

**Table 48.4** Graphs Produced by PROC KDE

| ODS Graph Name     | Plot Description                                                                    | Statement | PLOTS= Option  |
|--------------------|-------------------------------------------------------------------------------------|-----------|----------------|
| BivariateHistogram | Bivariate histogram of data                                                         | BIVAR     | HISTOGRAM      |
| ContourPlot        | Contour plot of bivariate kernel density estimate                                   | BIVAR     | CONTOUR        |
| ContourScatterPlot | Contour plot of bivariate kernel density estimate overlaid with scatter plot        | BIVAR     | CONTOURSCATTER |
| DensityPlot        | Univariate kernel density estimate curve                                            | UNIVAR    | DENSITY        |
| DensityOverlayPlot | Overlaid univariate kernel density estimate curves                                  | UNIVAR    | DENSITYOVERLAY |
| HistogramDensity   | Univariate histogram overlaid with kernel density estimate curve                    | UNIVAR    | HISTDENSITY    |
| Histogram          | Univariate histogram of data                                                        | UNIVAR    | HISTOGRAM      |
| HistogramSurface   | Bivariate histogram overlaid with surface plot of bivariate kernel density estimate | BIVAR     | HISTSURFACE    |

Table 48.4 (continued)

| ODS Graph Name | Plot Description                                  | Statement | PLOTS= Option |
|----------------|---------------------------------------------------|-----------|---------------|
| ScatterPlot    | Scatter plot of data                              | BIVAR     | SCATTER       |
| SurfacePlot    | Surface plot of bivariate kernel density estimate | BIVAR     | SURFACE       |

## Bivariate Plots

You can specify the PLOTS= option in the BIVAR statement to request graphical displays of bivariate kernel density estimates.

**PLOTS=** *option1* < *option2* . . . >

requests one or more plots of the bivariate kernel density estimate. The following table shows the available plot *options*.

| Option         | Description                                                                   |
|----------------|-------------------------------------------------------------------------------|
| ALL            | all available displays                                                        |
| CONTOUR        | contour plot of bivariate density estimate                                    |
| CONTOURSCATTER | contour plot of bivariate density estimate overlaid with scatter plot of data |
| HISTOGRAM      | bivariate histogram of data                                                   |
| HISTSURFACE    | bivariate histogram overlaid with bivariate kernel density estimate           |
| NONE           | suppresses all plots                                                          |
| SCATTER        | scatter plot of data                                                          |
| SURFACE        | surface plot of bivariate kernel density estimate                             |

By default, if ODS Graphics is enabled and you do not specify the PLOTS= option, then the BIVAR statement creates a contour plot. If you specify the PLOTS= option, you get only the requested plots.

## Univariate Plots

You can specify the PLOTS= option in the UNIVAR statement to request graphical displays of univariate kernel density estimates.

**PLOTS=** *option1* < *option2* . . . >

requests one or more plots of the univariate kernel density estimate. The following table shows the available plot *options*.

| Option         | Description                                                              |
|----------------|--------------------------------------------------------------------------|
| ALL            | all available displays                                                   |
| DENSITY        | univariate kernel density estimate curve                                 |
| DENSITYOVERLAY | overlaid univariate kernel density estimate curves                       |
| HISTDENSITY    | univariate histogram of data overlaid with kernel density estimate curve |
| HISTOGRAM      | univariate histogram of data                                             |
| NONE           | suppresses all plots                                                     |

By default, if ODS Graphics is enabled and you do not specify the PLOTS= option, then the UNIVAR statement creates a histogram overlaid with a kernel density estimate. If you specify the PLOTS= option, you get only the requested plots.

### Binning of Bivariate Histogram

Let  $(X_i, Y_i)$ ,  $i = 1, 2, \dots, n$ , be a sample of size  $n$  drawn from a bivariate distribution. For the marginal distribution of  $X_i$ ,  $i = 1, 2, \dots, n$ , the number of bins ( $\text{Nbins}_X$ ) in the bivariate histogram is calculated according to the formula

$$\text{Nbins}_X = \text{ceil}(\text{range}_X / \text{width}_X)$$

where  $\text{ceil}(x)$  denotes the smallest integer greater than or equal to  $x$ ,

$$\text{range}_X = \max_{1 \leq i \leq n} (X_i) - \min_{1 \leq i \leq n} (X_i)$$

and the optimal bin width is obtained, following Scott (1992, p. 84), as

$$\text{width}_X = 3.504 \hat{\sigma}_X (1 - \hat{\rho}^2)^{3/8} n^{-1/4}$$

Here,  $\hat{\sigma}_X$  and  $\hat{\rho}$  are the sample variance and the sample correlation coefficient, respectively. When you specify a WEIGHT variable, PROC KDE uses weighted versions of  $\hat{\sigma}_X$  and  $\hat{\rho}$  in the preceding expressions.

Similar formulas are used to compute the number of bins for the marginal distribution of  $Y_i$ ,  $i = 1, 2, \dots, n$ . Further details can be found in Scott (1992).

Notice that if  $|\hat{\rho}| > 0.99$ , then  $\text{Nbins}_X$  is calculated as in the univariate case (see Terrell and Scott 1985). In this case  $\text{Nbins}_Y = \text{Nbins}_X$ .

---

## Examples: KDE Procedure

---

### Example 48.1: Computing a Basic Kernel Density Estimate

This example illustrates the basic functionality of the UNIVAR statement. The effective channel length (in microns) is measured for 1225 field effect transistors. The channel lengths are saved as values of the variable length in a SAS data set named channel; see the file *kdex1.sas* in the SAS Sample Library. These statements create the channel data set:

```
data channel;
 input length @@;
 datalines;
0.91 1.01 0.95 1.13 1.12 0.86 0.96 1.17 1.36 1.10
0.98 1.27 1.13 0.92 1.15 1.26 1.14 0.88 1.03 1.00
0.98 0.94 1.09 0.92 1.10 0.95 1.05 1.05 1.11 1.15
1.11 0.98 0.78 1.09 0.94 1.05 0.89 1.16 0.88 1.19

... more lines ...

2.13 2.05 1.90 2.07 2.15 1.96 2.15 1.89 2.15 2.04
1.95 1.93 2.22 1.74 1.91
;
```

The following statements request a kernel density estimate of the variable length:

```
ods graphics on;
proc kde data=channel;
 univar length;
run;
```

Because ODS Graphics is enabled, PROC KDE produces a histogram with an overlaid kernel density estimate by default, although the PLOTS= option is not specified. The resulting graph is shown in [Output 48.1.1](#). For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the KDE procedure, see the section “[ODS Graphics](#)” on page 3767.

**Output 48.1.1** Histogram with Overlaid Kernel Density Estimate

The default output tables for this analysis are the “Inputs” and “Controls” tables, shown in [Output 48.1.2](#).

**Output 48.1.2** Univariate Inputs Table

| The KDE Procedure           |                |
|-----------------------------|----------------|
| Inputs                      |                |
| Data Set                    | WORK.CHANNEL   |
| Number of Observations Used | 1225           |
| Variable                    | length         |
| Bandwidth Method            | Sheather-Jones |
|                             | Plug In        |

**Output 48.1.2** *continued*

| Controls             |        |
|----------------------|--------|
|                      | length |
| Grid Points          | 401    |
| Lower Grid Limit     | 0.58   |
| Upper Grid Limit     | 2.43   |
| Bandwidth Multiplier | 1      |

The “Inputs” table lists basic information about the density fit, including the input data set, the number of observations, the variable used, and the bandwidth method. The default bandwidth method is the Sheather-Jones plug-in.

The “Controls” table lists the primary numbers controlling the kernel density fit. Here the default number of grid points is used and no adjustment is made to the default bandwidth.

---

## Example 48.2: Changing the Bandwidth

Continuing with [Example 48.1](#), you can specify different bandwidth multipliers that determine the smoothness of the kernel density estimate. The following statements show kernel density estimates for the variable `length` by specifying two different bandwidth multipliers with the `BWM=` option:

```
proc kde data=channel;
 univar length (bwm=2) length (bwm=0.25);
run;
ods graphics off;
```

[Output 48.2.1](#) shows an oversmoothed estimate because the bandwidth multiplier is 2. [Output 48.2.2](#) is created by specifying `BWM=0.25`, so it is an undersmoothed estimate.

**Output 48.2.1** Histogram with Oversmoothed Kernel Density Estimate

**Output 48.2.2** Histogram with Undersmoothed Kernel Density Estimate

---

### Example 48.3: Changing the Bandwidth (Bivariate)

Recall the analysis from the section “Getting Started: KDE Procedure” on page 3748. Suppose you would like a slightly smoother estimate. You could then rerun the analysis with a larger bandwidth:

```
ods graphics on;
proc kde data=bivnormal;
 bivar x y / bwm=2;
run;
```

The BWM= option requests bandwidth multipliers of 2 for both x and y. With ODS Graphics enabled, the BIVAR statement produces a contour plot, as shown in [Output 48.3.1](#).

**Output 48.3.1** Contour Plot of Estimated Density with Additional Smoothing

### Multiple Bandwidths

You can also specify multiple bandwidths with only one run of the KDE procedure. Notice that by specifying pairs of variables inside parentheses, a kernel density estimate is computed for each pair. In the following statements the first kernel density is computed with the default bandwidth, but the second kernel density specifies a bandwidth multiplier of 0.5 for the variable *x* and a multiplier of 2 for the variable *y*:

```
proc kde data=bivnormal;
 bivar (x y) (x (bwm=0.5) y (bwm=2));
run;
ods graphics off;
```

The contour plot of the second kernel density estimate is shown in [Output 48.3.2](#).

**Output 48.3.2** Contour Plot of Estimated Density with Different Smoothing for x and y

---

### Example 48.4: Requesting Additional Output Tables

This example illustrates how to request output tables with summary statistics in addition to the default output tables. Using the same data as in the section “Getting Started: KDE Procedure” on page 3748, the following statements request univariate and bivariate summary statistics, percentiles, and levels of the kernel density estimate:

```
proc kde data=bivnormal;
 bivar x y / bivstats levels percentiles unistats;
run;
```

The resulting output is shown in [Output 48.4.1](#).

**Output 48.4.1** Bivariate Kernel Density Estimate Tables

| The KDE Procedure           |                            |        |
|-----------------------------|----------------------------|--------|
| Inputs                      |                            |        |
| Data Set                    | WORK.BIVNORMAL             |        |
| Number of Observations Used | 1000                       |        |
| Variable 1                  | x                          |        |
| Variable 2                  | y                          |        |
| Bandwidth Method            | Simple Normal<br>Reference |        |

| 99      | 0.02608  | -0.53       | 0.16        | -0.67       | 0.30        |
| 100     | 0.02629  | -0.19       | -0.19       | -0.35       | -0.35       |

The “Univariate Statistics” table contains standard univariate statistics for each variable, as well as statistics associated with the density estimate. Note that the estimated variances for both  $x$  and  $y$  are fairly close to the true values of 10.

The “Bivariate Statistics” table lists the covariance and correlation between the two variables. Note that the estimated correlation is equal to its true value to two decimal places.

The “Percentiles” table lists percentiles for each variable.

The “Levels” table lists contours of the density corresponding to percentiles of the bivariate data, and the minimum and maximum values of each variable on those contours. For example, 5% of the observed data have a density value less than 0.0030. The minimum  $x$  and  $y$  values on this contour are  $-7.10$  and  $-7.14$ , respectively (the Lower for  $x$  and Lower for  $y$  columns), and the maximum values are  $7.07$  and  $6.77$ , respectively (the Upper for  $x$  and Upper for  $y$  columns).

You can also request “Percentiles” or “Levels” tables with specific percentiles:

```
proc kde data=bivnormal;
 bivar x y / levels=2.5, 50, 97.5
 percentiles=2.5, 25, 50, 75, 97.5;
run;
```

The resulting “Percentiles” and “Levels” tables are shown in [Output 48.4.2](#).

**Output 48.4.2** Customized Percentiles and Levels Tables

## Example 48.5: Univariate KDE Graphics

This example uses data from the section “[Getting Started: KDE Procedure](#)” to illustrate the use of ODS Graphics. The following statements request the available univariate plots in PROC KDE:

```
ods graphics on;
proc kde data=bivnormal;
 univar x / plots=(density histogram histdensity);
 univar x y / plots=densityoverlay;
run;
ods graphics off;
```

Graphs are requested by specifying the `PLOTS=` option in the `UNIVAR` statement with ODS Graphics enabled. [Output 48.5.1](#), [Output 48.5.2](#), and [Output 48.5.3](#) show the kernel density estimate, histogram, and histogram with kernel density estimate overlaid, respectively, produced by the first `UNIVAR` statement.

**Output 48.5.1** Kernel Density Estimate

Output 48.5.2 Histogram

**Output 48.5.3** Histogram with Overlaid Kernel Density Estimate

Output 48.5.4 shows the plot produced by the second UNIVAR statement, in which the kernel density estimates for x and y are overlaid.

**Output 48.5.4** Overlaid Kernel Density Estimates

For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the KDE procedure, see the section “ODS Graphics” on page 3767.

---

## Example 48.6: Bivariate KDE Graphics

This example illustrates the available bivariate graphics in PROC KDE. The octane data set comes from Rodriguez and Taniguchi (1980), where it is used for predicting customer octane satisfaction by using trained-rater observations. The variables in this data set are Rater and Customer. Either variable might have missing values. See the file *kdex3.sas* in the SAS Sample Library. The following statements create the octane data set:

```
data octane;
 input Rater Customer;
 label Rater = 'Rater'
 Customer = 'Customer';
 datalines;
94.5 92.0
94.0 88.0
94.0 90.0
93.0 93.0

... more lines ...

88.0 84.0
.H 90.0
;
```

The following statements request all the available bivariate plots in PROC KDE:

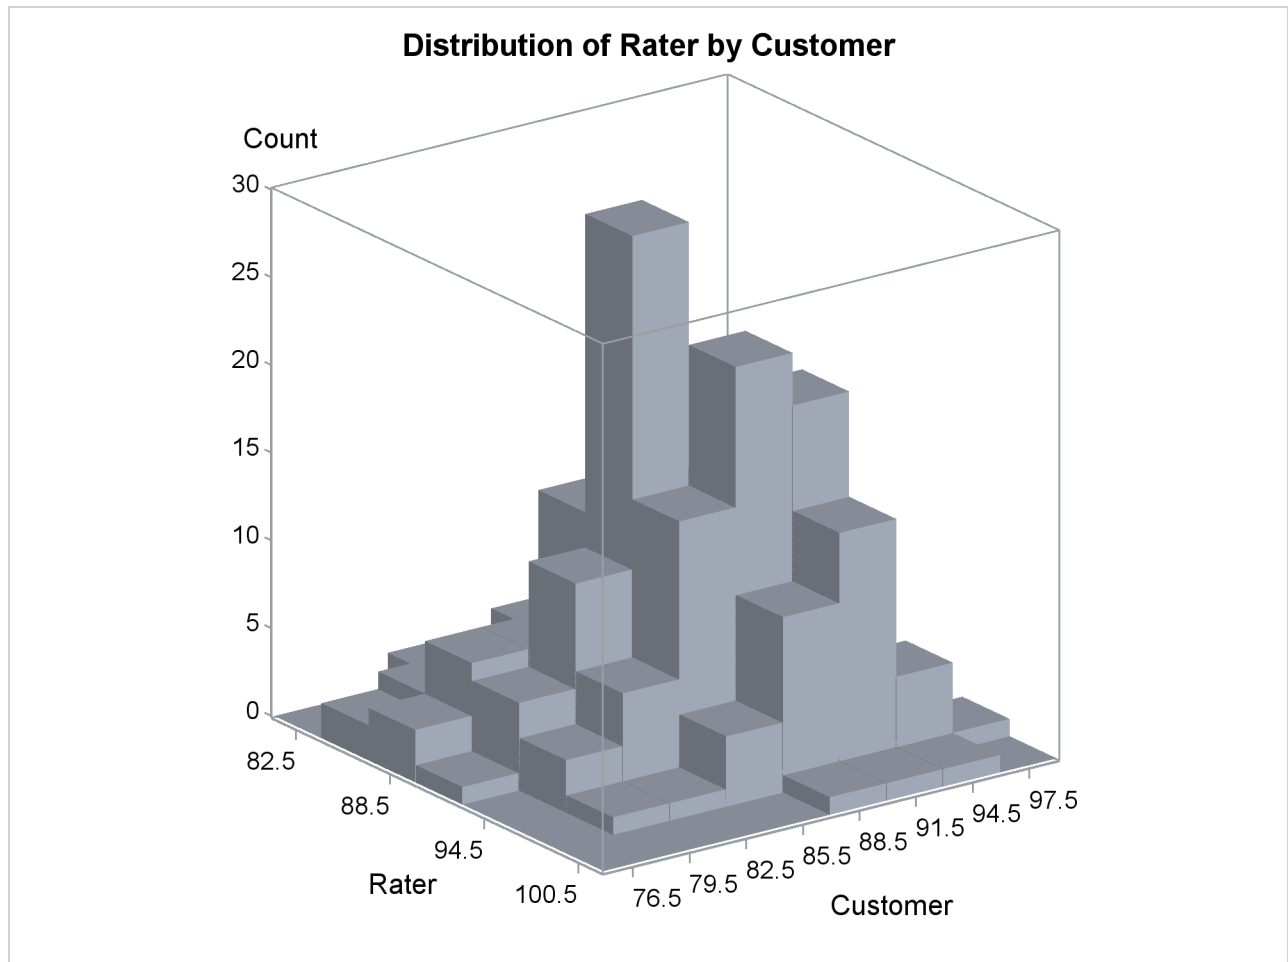

```
ods graphics on;
proc kde data=octane;
 bivar Rater Customer / plots=all;
run;
ods graphics off;
```

Output 48.6.1 shows a scatter plot of the data, Output 48.6.2 shows a bivariate histogram of the data, Output 48.6.3 shows a contour plot of bivariate density estimate, Output 48.6.4 shows a contour plot of bivariate density estimate overlaid with a scatter plot of data, Output 48.6.5 shows a surface plot of bivariate kernel density estimate, and Output 48.6.6 shows a bivariate histogram overlaid with a bivariate kernel density estimate. These graphical displays are requested by specifying the **PLOTS=** option in the **BIVAR** statement with ODS Graphics enabled. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the KDE procedure, see the section “ODS Graphics” on page 3767.

Output 48.6.1 Scatter Plot

**Output 48.6.2** Bivariate Histogram

Output 48.6.3 Contour Plot

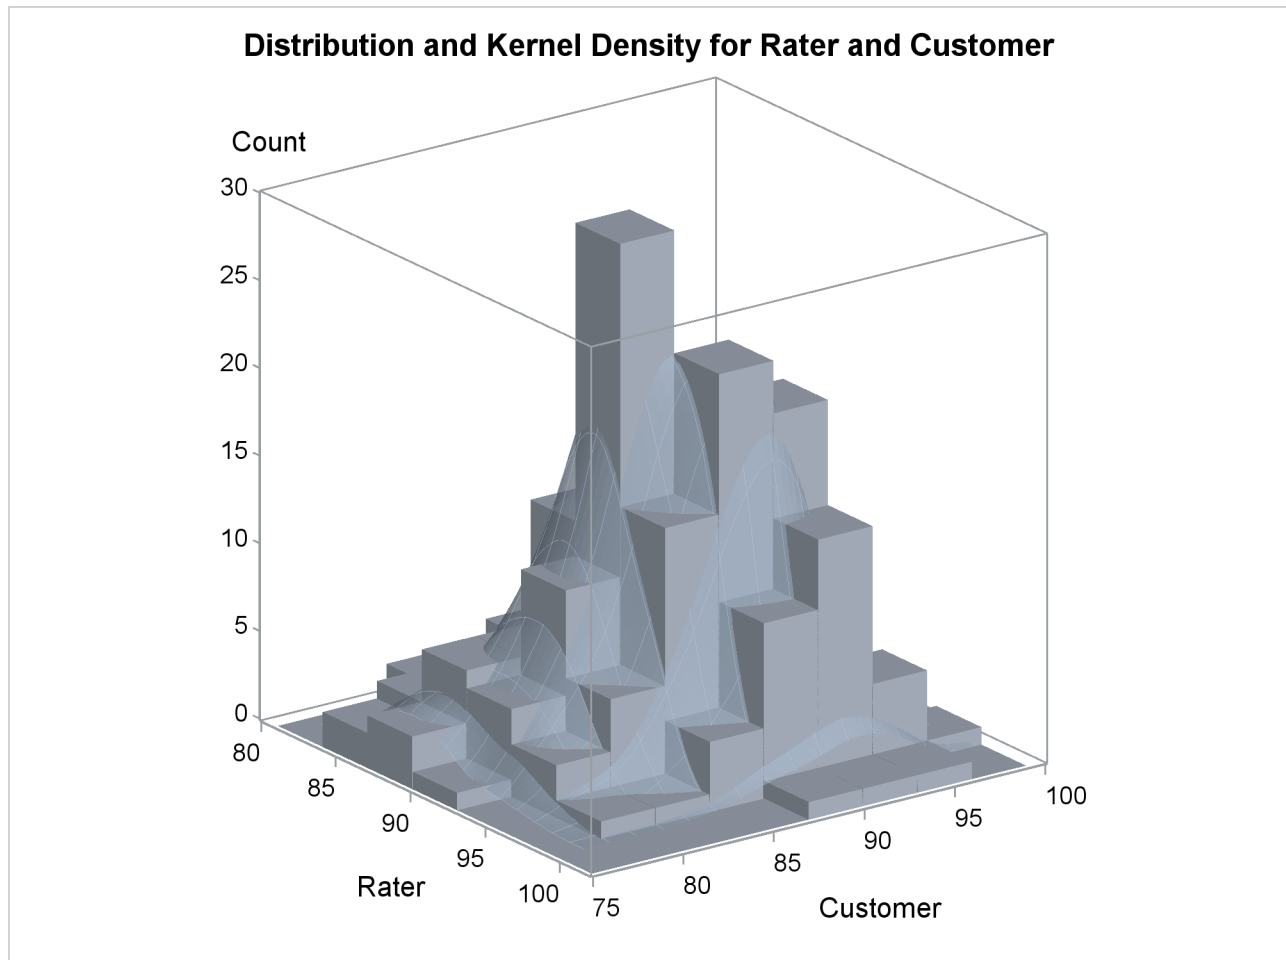

**Output 48.6.4** Contour Plot with Overlaid Scatter Plot

Output 48.6.5 Surface Plot

**Output 48.6.6** Bivariate Histogram with Overlaid Surface Plot

## Overview: KRIGE2D Procedure

The KRIGE2D procedure performs ordinary kriging in two dimensions. PROC KRIGE2D can handle anisotropic and nested semivariogram models. Eight semivariogram models are supported: the Gaussian, exponential, spherical, power, cubic, pentaspherical, sine hole effect, and Matérn models. A single nugget effect is also supported. You can specify the correlation model by naming the form and supplying the associated parameters, or by using the contents of an item store file that was previously created by PROC VARIOGRAM.

You can specify the locations of kriging predictions in a **GRID** statement, or they can be read from a SAS data set. The grid specification is most suitable for a regular grid; the data set specification can handle any irregular pattern of points.

Local kriging is supported through the specification of a radius around a grid point or the specification of the number of nearest neighbors to use in the kriging system. When you perform local kriging, a separate kriging system is solved at each grid point by using a neighborhood of the data point established by the radius or number specification.

The KRIGE2D procedure writes the kriging predictions and associated standard errors for each grid to an output data set. When you perform local kriging, PROC KRIGE2D writes the neighborhood information for each grid point to an additional, optional data set. The KRIGE2D procedure does not produce any displayed output.

The KRIGE2D procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For more information about the graphics available in PROC KRIGE2D, see the section “ODS Graphics” on page 3845.

---

## Introduction to Spatial Prediction

Many activities in science and technology involve measurements of one or more quantities at given spatial locations, with the goal of predicting the measured quantities at unsampled locations. Application areas include reservoir prediction in mining and petroleum exploration, in addition to modeling in a broad spectrum of fields (for example, environmental health, environmental pollution, natural resources and energy, hydrology, and risk analysis). Often, the unsampled locations are on a regular grid, and the predictions are used to produce surface plots or contour maps.

The preceding tasks fall within the scope of *spatial prediction*, which, in general, is any prediction method that incorporates spatial dependence. The study of these tasks involves naturally occurring uncertainties that cannot be ignored. Stochastic analysis frameworks and methods are often used to account for these uncertainties. Hence, the terms *stochastic spatial prediction* and *stochastic modeling* are also used to characterize this type of analysis.

A popular method of spatial prediction is *ordinary kriging*, which produces both predicted values and associated standard errors. Ordinary kriging requires the complete specification (the form and parameter values) of the spatial dependence that characterizes the spatial process. For this purpose, models for the spatial dependence are expressed in terms of the distance between any two locations in the spatial domain of interest. These models take the form of a covariance or semivariance function.

Spatial prediction, then, involves two steps. First, you model the covariance or semivariance of the spatial process. These measures are typically not known in advance. This step involves computing an empirical estimate, in addition to determining both the mathematical form and the values of any parameters for a theoretical form of the dependence model. Second, you use this dependence model to solve the kriging system at a specified set of spatial points, resulting in predicted values and associated standard errors.

The KRIGE2D procedure performs the second of these steps by using ordinary kriging of two-dimensional data.

This introduction concludes with a note on terminology. You might commonly encounter the terms *estimation* and *prediction* used interchangeably by experts in different fields; this could be a source of confusion. A precise statistical vernacular uses the term *estimation* to refer to inferences about the value of fixed but unknown parameters, whereas *prediction* concerns inferences about the value of random variables—see, for example, Cressie (1993, p. 106). In light of these definitions, kriging methods are clearly predictive techniques, since they are concerned with making inferences about the value of a spatial random field at observed or unobserved locations. The SAS/STAT suite of procedures for spatial analysis and prediction (VARIOGRAM, KRIGE2D, and SIM2D) follows the statistical vernacular in the use of the terms *estimation* and *prediction*.

## Getting Started: KRIGE2D Procedure

### Spatial Prediction Using Kriging, Contour Plots

After an appropriate semivariogram model is chosen, a number of choices are involved in producing the kriging surface. In order to illustrate these choices, you use the theoretical semivariogram model that was fitted to the coal seam thickness data empirical semivariogram in “Theoretical Semivariogram Model Fitting” on page 8571 in the VARIOGRAM procedure. This model is Gaussian,

$$\gamma_z(h) = c_0 \left[ 1 - \exp\left(-\frac{h^2}{a_0^2}\right) \right]$$

with a scale of  $c_0 = 7.4599$  (that is, the model sill) and a range of  $a_0 = 30.1111$ , based on the weighted least squares fitting results in the PROC VARIOGRAM example.

The first choice is whether to use local or global kriging. Local kriging uses only data points in the neighborhood of a grid point, and you choose this type of analysis by specifying a data search radius around the grid point. Global kriging uses all data points.

The most important consideration in this decision is the spatial covariance structure. Global kriging is appropriate when the correlation range  $\epsilon$  is approximately equal to the length of the spatial domain. The correlation range  $\epsilon$  is the distance  $r_\epsilon$  (also known as *effective* or *practical* range) at which the covariance is 5% of its value at zero. That is,

$$C_Z(r_\epsilon) = 0.05C_Z(0)$$

For a Gaussian model,  $r_\epsilon$  is  $\sqrt{3}a_0 \approx 52,000$  feet. The data points are scattered uniformly throughout a  $100 \times 100$  ( $10^6$  ft<sup>2</sup>) area. Hence, the linear dimension of the data is nearly double the  $r_\epsilon$  range. This indicates that local kriging rather than global kriging is appropriate because data that are farther away than  $r_\epsilon$  essentially add to the computational burden without significant contribution to the prediction. The following DATA step inputs the thickness data set `thick`, which is available from the `Sashelp` library. In the `thick` data set, thickness is represented by the `Thick` variable.

```

Local kriging is performed by using only data points within a specified radius of each grid point. In this example, a radius of 60,000 feet is used. Other choices involved in local kriging are the minimum and maximum number of data points in each neighborhood (around a grid point). The minimum number is left at the default value of 20; the maximum number defaults to all observations in the data set within the specified radius.

The last step in contouring the data is to define the prediction grid point (node) locations. The prediction grid is typically rectangular, and you decide on the grid points population and spacing based on your available data in addition to your application needs. A convenient area that encompasses all the data points is a square of side length 100,000 feet. In the present analysis, a distance of 2,500 feet between nodes in the prediction grid is selected to obtain a smooth contour plot. Based on this choice, you obtain predictions on a square grid with 41 nodes on each side, which yields a total of 1681 grid points.

You can visualize the outcome of your analysis by using the **PLOTS** option in the **PROC KRIGE2D** statement. By default, **PROC KRIGE2D** produces one plot that displays the kriging prediction and its corresponding standard error at each output grid point. The locations of the Thick observations are displayed too, as outlines in the default plot. You can also ask for a plot of the thick data set observations and their values by specifying the **OBSERV** option in the **PLOTS** option.

The kriging analysis with the **KRIGE2D** procedure requires that you provide the prediction parameters in the **PREDICT** statement. You use the **VAR=** option to specify that you want to use the Thick variable in the kriging system, and the **RADIUS=** option to specify the radius of the local kriging regression. In this scenario you want to consider for your predictions all the neighboring data within a radius of 60,000 feet from each prediction location. You can specify more than one **PREDICT** statements; for example, you can do this when you want predictions for different variables in your **DATA=** data set.

The coordinates of your variable are specified in the **COORDINATES** statement. The **MODEL** statement contains the parameters that describe your data spatial correlation. Namely, the **FORM=** option specifies the model type, based on its mathematical form. The **SCALE=** and **RANGE=** options specify the model sill and range, respectively. You can specify more than one **MODEL** statement for the same **PREDICT** statement in order to obtain predictions based on different correlation models.

When you use the **RADIUS=** option to perform local kriging, as in the present example, it is suggested that the radius parameter be at least as large as your model range, so that you include data points that can contribute to your prediction.

Eventually, you specify the region of predictions with the **GRID** statement. The following SAS statements compute the kriged surface by using the preceding options and grid choice:

```
ods graphics on;

proc krige2d data=thick;
 coordinates xc=East yc=North;
 predict var=Thick radius=60;
 model scale=7.4599 range=30.1111 form=gauss;
 grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;

ods graphics off;
```

The table in Figure 49.1 shows the number of observations read and used in the kriging prediction. This table provides you with useful information in case you have missing values in the input data.

**Figure 49.1** Number of Observations for the thick Data Set

| Spatial Prediction With Kriging |    |
|---------------------------------|----|
| The KRIGE2D Procedure           |    |
| Dependent Variable: Thick       |    |
| Number of Observations Read     | 75 |
| Number of Observations Used     | 75 |

Figure 49.2 shows some general information about the kriging analysis. This includes the count of the output grid points. You have specified the `RADIUS=` option; therefore you also see that local kriging is requested. Because this is a local analysis, the table also displays the parameters related to the neighborhood search around the grid points.

**Figure 49.2** Kriging Analysis Information

| Kriging Information        |                   |
|----------------------------|-------------------|
| Prediction Grid Points     | 1681              |
| Type of Analysis           | Local             |
| Neighborhood Search Radius | 60                |
| Minimum Neighbors          | 20                |
| Maximum Neighbors          | All Within Radius |

The covariance model parameters, including the effective range of the Gaussian model you specified, are shown in Figure 49.3.

**Figure 49.3** Kriging Covariance Model Information

| Spatial Prediction With Kriging  |           |
|----------------------------------|-----------|
| The KRIGE2D Procedure            |           |
| Dependent Variable: Thick        |           |
| Prediction: Pred1, Model: Model1 |           |
| Covariance Model Information     |           |
| Type                             | Gaussian  |
| Sill                             | 7.4599    |
| Range                            | 30.1111   |
| Effective Range                  | 52.153955 |
| Nugget Effect                    | 0         |

Figure 49.4 shows a map of the kriging prediction contours based on the Thick observations in the specified spatial domain. The prediction error is displayed as a surface in the background.

**Figure 49.4** Contour Plot of Kriged Coal Seam Thickness

Note the locations of the observed data in Figure 49.4. The figure suggests that the Thick sampling locations are not ideally spread around the prediction area; however, there are no extended areas lacking measurements.

Based on the spatial distribution of the Thick data and the range  $r_\epsilon$  of your covariance model, you can roughly see that for each prediction location there are at least several neighboring data points that contribute to the prediction value. Except perhaps for the nodes close to the boundaries of the prediction grid, you can then expect the prediction errors to be reasonably low compared to the predicted Thick values.

The kriging outcome in Figure 49.4 indicates that the standard errors are smaller in the neighborhoods where data are available. The size of these neighborhoods depends on the range of the specified covariance model that characterizes the spatial continuity of the domain, and on the prediction radius, if one is specified as in this example. The standard errors tend to increase toward the borders of the prediction area, beyond which no observations are available.

## Syntax: KRIGE2D Procedure

The following statements are available in the KRIGE2D procedure:

```

PROC KRIGE2D options ;
 BY variables ;
 COORDINATES | COORD coordinate-variables ;
 GRID grid-options ;
 ID variable ;
 PREDICT | PRED | P predict-options ;
 MODEL model-options ;
 RESTORE restore-options ;

```

The **PREDICT** and **MODEL** statements are hierarchical; the **PREDICT** statement is followed by a **MODEL** statement. If more than one **MODEL** statement is given, only the last one is used for the analysis. The **MODEL** statement following a **PREDICT** statement uses the variable and neighborhood specifications in that **PREDICT** statement.

You must specify at least one **PREDICT** statement and one **MODEL** statement. You must supply a single **COORDINATES** statement to identify the  $x$  and  $y$  coordinate variables in the input data set. You must also specify a single **GRID** statement to include the grid information.

Table 49.1 outlines the options available in PROC KRIGE2D classified by function.

**Table 49.1** Options Available in the KRIGE2D Procedure

| Task                                                                  | Statement    | Option   |
|-----------------------------------------------------------------------|--------------|----------|
| <b>Data Set Options</b>                                               |              |          |
| Specifies input data set                                              | PROC KRIGE2D | DATA=    |
| Specifies grid data set                                               | GRID         | GDATA=   |
| Specifies labels for individual grid points or in 1-D                 | GRID         | LABEL    |
| Specifies model data set                                              | MODEL        | MDATA=   |
| Writes kriging predictions and standard errors                        | PROC KRIGE2D | OUTEST=  |
| Writes neighborhood information for each grid point                   | PROC KRIGE2D | OUTNBHD= |
| Specifies plot display and options                                    | PROC KRIGE2D | PLOTS    |
| <b>Declaring the Role of Variables</b>                                |              |          |
| Specifies variables to define analysis subgroups                      | BY           |          |
| Specifies variable with observation labels                            | ID           |          |
| Specifies the variables to be predicted (kriged)                      | PREDICT      | VAR=     |
| Specifies the $x$ and $y$ coordinate variables in the DATA= data set  | COORDINATES  | XC= YC=  |
| Specifies the $x$ and $y$ coordinate variables in the GDATA= data set | GRID         | XC= YC=  |
| <b>Controlling the Prediction</b>                                     |              |          |
| Specifies the number of grid points in one-dimensional cases          | GRID         | NPTS=    |

Table 49.1 *continued*

| Task                                                        | Statement | Option      |
|-------------------------------------------------------------|-----------|-------------|
| <b>Controlling Kriging Neighborhoods</b>                    |           |             |
| Specifies the radius of a neighborhood for all grid points  | PREDICT   | RADIUS=     |
| Specifies the number of neighbors for all grid points       | PREDICT   | NUMPOINTS=  |
| Specifies the maximum of neighbors for all grid points      | PREDICT   | MAXPOINTS=  |
| Specifies the minimum of neighbors for all grid points      | PREDICT   | MINPOINTS=  |
| Specifies the action when maximum not met                   | PREDICT   | NODECREMENT |
| Specifies the action when minimum not met                   | PREDICT   | NOINCREMENT |
| <b>Controlling the Semivariogram Model</b>                  |           |             |
| Specifies an angle for an anisotropic model                 | MODEL     | ANGLE=      |
| Specifies a type with a functional form                     | MODEL     | FORM=       |
| Specifies an item store with correlation information        | RESTORE   | IN=         |
| Specifies a nugget effect                                   | MODEL     | NUGGET=     |
| Allows power exponent values outside [0,2)                  | MODEL     | POWNOBOUND  |
| Specifies a range parameter                                 | MODEL     | RANGE=      |
| Specifies a minor-major axis ratio for an anisotropic model | MODEL     | RATIO=      |
| Specifies a scale parameter                                 | MODEL     | SCALE=      |
| Specifies model and parameters from an item store           | MODEL     | STORESELECT |

## PROC KRIGE2D Statement

**PROC KRIGE2D** *options* ;

The PROC KRIGE2D statement invokes the KRIGE2D procedure. Table 49.2 summarizes the options available in the PROC KRIGE2D statement.

Table 49.2 PROC KRIGE2D Statement Options

| Option        | Description                                                               |
|---------------|---------------------------------------------------------------------------|
| DATA=         | Specifies input data set                                                  |
| IDGLOBAL      | Uses ascending observation numbers as observation labels across BY groups |
| IDNUM         | Uses observation number as observation labels                             |
| NOPRINT       | Suppresses the normal display of results                                  |
| OUTEST=       | Writes kriging predictions and standard errors                            |
| OUTNBHD=      | Writes neighborhood information for each grid point                       |
| PLOTS         | Specifies plot display and options                                        |
| PREDICTION    | Produces the kriging prediction plot                                      |
| SEMIVARIOGRAM | Produces the semivariogram used for the kriging prediction                |
| SINGULARMSG=  | Controls the number of warning messages displayed for a singular matrix   |

You can specify the following options in the PROC KRIGE2D statement.

**DATA=SAS-data-set**

specifies a SAS data set that contains the  $x$  and  $y$  coordinate variables and the **VAR=** variables in the **PREDICT** statement.

**IDGLOBAL**

specifies that ascending observation numbers be used across **BY** groups for the observation labels in the appropriate output data sets and the **OBSERVATIONS** plot, instead of resetting the observation number in the beginning of each **BY** group. The **IDGLOBAL** option is ignored if no **BY** variables are specified. Also, if you specify the **ID** statement, then the **IDGLOBAL** option is ignored unless you also specify the **IDNUM** option in the **PROC KRIGE2D** statement.

**IDNUM**

specifies that the observation number be used for the observation labels in the appropriate output data sets and the **OBSERVATIONS** plot. The **IDNUM** option takes effect when you specify the **ID** statement; otherwise, it is ignored.

**NOPRINT**

suppresses the normal display of results. The **NOPRINT** option is useful when you want only to create one or more output data sets with the procedure. **NOTE:** This option temporarily disables the Output Delivery System (ODS); see the section “**ODS Graphics**” on page 3845 for more information.

**OUTEST=SAS-data-set**

**OUTE=SAS-data-set**

specifies a SAS data set in which to store the kriging predictions, standard errors, and grid location. For details, see the section “**OUTEST=SAS-data-set**” on page 3843.

**OUTNBHD=SAS-data-set**

**OUTN=SAS-data-set**

specifies a SAS data set in which to store the neighborhood information for each grid point. Information is written to this data set only if one or more **PREDICT** statements have options that specify local kriging. For details, see the section “**OUTNBHD=SAS-data-set**” on page 3844.

**PLOTS** < (*global-plot-option*) > < = *plot-request* < (*options*) > >

**PLOTS** < (*global-plot-option*) > < = (*plot-request* < (*options*) > < ... *plot-request* < (*options*) > > >

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=observ
plots=(observ(out1) prediction)
plots=(prediction(fill=pred line=se obs=grad) prediction(fill=se))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc krige2d data=thick;
 coordinates xc=East yc=North;
 predict var=thick r=60;
 model scale=7.4599 range=30.1111 form=gauss;
 grid x=0 to 100 by 10 y=0 to 100 by 10;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

If ODS Graphics is enabled but you omitted the PLOTS option or have specified PLOTS=ALL, then PROC KRIGE2D produces a default plot for each MODEL statement of every PREDICT statement that you specify. The default PROC KRIGE2D plot displays a contour plot of the kriging prediction and the gradient of the kriging prediction standard error at every location of the prediction grid, in addition to empty circles that indicate the observation locations. See Figure 49.4 for an example of the default KRIGE2D plot.

The following *global-plot-option* is available:

#### ONLY

suppresses the default plot. Only plots that are specifically requested are displayed.

The following individual *plot-requests* and *plot options* are available:

#### ALL

produces all appropriate plots. You can specify other *options* with ALL. For example, to request the default plot and an additional plot of the predictions, specify PLOTS=(ALL PREDICTION).

#### EQUATE

specifies that all appropriate plots be produced in a way that the axes coordinates have equal size units.

#### NONE

suppresses all plots.

**OBSERVATIONS** <(observations-plot-options)>

**OBSERV** <(observations-plot-options)>

**OBS** <(observations-plot-options)>

produces the observed data plot. Only one observations plot is created if you specify the OBSERVATIONS option more than once within a PLOTS option.

The OBSERVATIONS option has the following suboptions:

**GRADIENT**

specifies that observations be displayed as circles colored by the observed measurement.

**LABEL** < (*label-option*) >

labels the observations. The label is the ID variable if the ID statement is specified; otherwise, it is the observation number. The *label-option* can be one of the following:

**EQ=number**

specifies that labels show for any observation whose value is equal to the specified *number*.

**MAX=number**

specifies that labels show for observations with values smaller than or equal to the specified *number*.

**MIN=number**

specifies that labels show for observations with values equal to or greater than the specified *number*.

If you specify multiple instances of the OBSERVATIONS option and you specify the LABEL suboption in any of those, then the resulting observations plot displays the observations labels. If more than one *label-option* is specified in multiple LABEL suboptions, then the prevailing *label-option* in the resulting OBSERVATIONS plot emerges by adhering to the choosing order: MIN, MAX, EQ.

**OUTLINE**

specifies that observations be displayed as circles with a border but with a completely transparent fill.

**OUTLINEGRADIENT**

is the same as OBSERVATIONS(GRADIENT) except that a border is shown around each observation.

**SHOWMISSING**

specifies that observations with missing values be displayed in addition to the observations with nonmissing values. By default, missing values locations are not shown on the plot. If you specify multiple instances of the OBSERVATIONS option and you specify the SHOWMISSING suboption in any of those, then the resulting observations plot displays the observations with missing values.

If you omit any of the GRADIENT, OUTLINE, and OUTLINEGRADIENT suboptions, the OUTLINEGRADIENT is the default suboption. If you specify multiple instances of the OBSERVATIONS option or multiple suboptions for OBSERVATIONS, then the resulting observations plot honors the last specified GRADIENT, OUTLINE, or OUTLINEGRADIENT suboption.

**PREDICTION** < (*prediction-plot-options*) >**PRED** < (*prediction-plot-options*) >

specifies that the kriging prediction plot be produced. You can specify the PREDICTION option multiple times in the same PLOTS option to request instances of plots with the following *prediction-plot-options*:

**ALPHA=number**

specifies a parameter to obtain the confidence level for constructing confidence limits based on the prediction standard error. The value of *number* must be between 0 and 1, and the confidence level is  $1 - \text{number}$ . The default is ALPHA=0.05; this corresponds to the confidence level of 95%, or about 1.96 times the prediction standard error. The ALPHA= suboption is used only for prediction plots in one dimension, and it is incompatible with the FILL and LINE suboptions.

**CLONLY**

specifies that only the confidence limits be shown in a prediction plot without the predicted values. This suboption can be useful for identifying confidence limits when the prediction standard error is small at the prediction locations. CLONLY is used only for prediction plots in one dimension, and it is incompatible with the FILL and LINE suboptions.

**CONNP**

specifies that grid points that you provide as individual prediction locations be connected with a line on the area map. This suboption is ignored when you have a single grid point, a prediction grid in two dimensions, or when you also specify the NOMAP suboption. The CONNP suboption is incompatible with the FILL and LINE suboptions.

**FILL=NONE | PRED | SE**

produces a surface plot for either the predicted values or the standard errors. FILL=SE is the default. However, if you omit the FILL suboption, the behavior depends on the LINE suboption as follows: If you specify LINE=NONE or entirely omit the LINE suboption, then the FILL suboption is set to its default value. If LINE=PRED or LINE=SE, then the FILL suboption is set to the same value as the LINE suboption.

**LINE=NONE | PRED | SE**

produces a contour line plot for either the predicted values or the standard errors. LINE=PRED is the default. However, if you omit the LINE suboption the behavior depends on the FILL suboption as follows: If you specify FILL=NONE or entirely omit the FILL suboption, then the LINE suboption is set to its default value. If FILL=PRED or FILL=SE, then the LINE suboption is set to the same value as the FILL suboption.

**NOMAP**

specifies that the prediction plot be produced without a map of the domain where you have observations. The NOMAP suboption is used in the case of prediction in one dimension or at individual points. It is incompatible with the FILL and LINE suboptions.

**OBS=obs-options**

produces an overlaid scatter plot of the observations in addition to the specified contour plots. The following *obs-options* are available:

**GRAD**

specifies that observations be displayed as circles colored by the observed measurement. The same color gradient displays the prediction surface and the observations. Observations where the prediction is close to the observed values have similar colors—the greater the contrast between the color of an observation and the surface, the larger the prediction standard error is at that point.

**LINEGRAD**

is the same as OBS=GRAD except that a border is shown around each observation. This option is useful for identifying the location of observations where the standard errors are small, because at these points the color of the observations and the color of the surface are indistinguishable.

**NONE**

specifies that no observations be displayed.

**OUTL**

specifies that observations be displayed as circles with a border but with a completely transparent fill.

OBS=NONE is the default when you specify a grid in two dimensions, and OBS=LINEGRAD is the default used in the area map when you have a grid in one dimension. However, the default PROC KRIGE2D plot for a surface grid displays the observations locations as outlines.

**SHOWD**

specifies that the horizontal axis in scatter plots of linear prediction grids show the distance between grid points instead of the grid points' coordinates. When the area map is displayed, the prediction locations are also connected with a line. In all other grid configurations the SHOWD suboption is ignored, and it is incompatible with the FILL and LINE suboptions.

**SHOWP**

specifies that the grid points in band plots of linear prediction grids be shown as marks on the band plot. In all other grid configurations the SHOWP suboption is ignored, and it is incompatible with the FILL and LINE suboptions.

**TYPE=BAND | SCAT**

requests a particular type of plot when you have a linear grid, regardless of the default PREDICTION plot behavior in this case. The TYPE suboption is incompatible with the FILL and LINE suboptions.

If you specify multiple instances of the ALPHA, FILL, LINE, OBS, or TYPE suboptions in the same PREDICTION option, then the resulting predictions plot honors the last value specified for any of the suboptions. Any combination where you specify FILL=NONE and LINE=NONE is not available. When the prediction grid is in two dimensions, only the FILL, LINE, and OBS suboptions apply. If you specify incompatible suboptions in the same PREDICTION plot, then the plot instance is skipped.

The PREDICTION option produces a surface or contour line plot for grids in two dimensions and a band plot or scatter plot with error bars for grids in one dimension or individual points. In two dimensions the plot illustrates the predicted values and prediction error at each grid point.

By default, when you specify a linear grid with fewer than 10 points, PROC KRIGE2D produces a PREDICTION scatter plot for each one of the prediction grid points. For 10 or more points in a linear grid, the PREDICTION plot is a band plot of the predicted means and the confidence limits at the 95% confidence level. You can override the default behavior in linear grids with the TYPE suboption. Prediction at individual locations always produces a PREDICTION scatter plot.

In cases of prediction in one dimension or at individual points, an area map is produced that shows the observations and the grid points. Band plots of linear grids display the grid points as a line on the map. When you specify individual prediction locations, the grid points are indicated with marks on the area map. The area map appears on the side of the prediction band plot or scatter plot, unless you specify the NOMAP suboption. You can also label the individual grid points or the ends of linear grid segments with the LABEL option of the GRID statement.

**SEMIVARIOGRAM** < (*semivar-plot-option*) >

**SEMIVAR** < (*semivar-plot-option*) >

specifies that the semivariogram used for the kriging prediction be produced. You can use the following *semivar-plot-option*:

**MAXD=number**

specifies a positive value for the upper limit of the semivariogram horizontal axis of distance. The SEMIVARIOGRAM plot extends by default to a distance that depends on the correlation model range. You can use the MAXD= option to adjust the default maximum distance value for the plot.

The SEMIVARIOGRAM option produces a plot for each correlation model that you specify for your prediction tasks. In an anisotropic case, the plot is not produced if you assign different anisotropy angles for different model components. The only exception is when you specify zonal components at right angles with the nonzonal model components. Also, the SEMIVARIOGRAM option is ignored for models that consist of purely zonal components.

**SINGULARMSG=number**

**SMSG=number**

controls the number of warning messages displayed for a singular matrix. When local kriging is performed, a separate kriging system is solved for each grid point. Anytime a singular matrix is encountered, a warning message is displayed up to a total of *number* times. The default is SINGULARMSG=10.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC KRIGE2D to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the KRIGE2D procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## COORDINATES Statement

**COORDINATES** | **COORD** *coordinate-variables* ;

The following two options specify the names of the variables in the **DATA=** data set that contains the values of the  $x$  and  $y$  coordinates of the data.

Only one COORDINATES statement is allowed, and it is applied to all **PREDICT** statements. In other words, it is assumed that all the **VAR=** variables in all **PREDICT** statements have the same  $x$  and  $y$  coordinates.

This is not a limitation. Since each **VAR=** variable is processed separately, observations for which the current **VAR=** variable is missing are excluded. With the next **VAR=** variable, the entire data are read again, this time excluding missing values in this next variable. Hence, a single run of PROC KRIGE2D can be used for variables measured at different locations without overlap.

**XCOORD=** (*variable-name*)

**XC=** (*variable-name*)

specifies the name of the variable that contains the  $x$  coordinate of the data locations in the **DATA=** data set.

**YCOORD=** (*variable-name*)

**YC=** (*variable-name*)

specifies the name of the variable that contains the  $y$  coordinate of the data locations in the **DATA=** data set.

---

## GRID Statement

**GRID** *grid-options* </ option > ;

The GRID statement specifies the grid of spatial locations for kriging predictions. The grid specification is applied to all **PREDICT** and **MODEL** statements. Specify the grid in one of the following three ways:

- Specify the  $x$  and  $y$  coordinates explicitly for a grid in two dimensions.
- Specify the NPTS= option in addition to the  $x$  and  $y$  coordinates to define a grid of individual points or in one dimension.
- Specify the coordinates by using a SAS data set for a grid of individual points or in one dimension.

The GRID statement has the following *grid-options*:

**NPTS=number**

**NPTS=ALL**

controls specification of a grid in one dimension or a grid of individual prediction locations.

When you specify the NPTS=*number* option and the coordinates of two points in the GRIDDATA= data set or in both the X= and Y= options, you request a linear prediction grid. Its direction is across the line defined by the specified points. The grid size is equal to the *number* of points that you specify in the NPTS= option, where  $number \geq 2$ .

When you specify the NPTS=ALL option and the coordinates for any number of points in the GRIDDATA= data set or in each of the X= and Y= options, the KRIGE2D procedure performs prediction only at the specified individual locations. Use the NPTS=ALL option to examine a set of individual points anywhere on the XY plane or to specify a custom grid in one dimension.

If the number of  $x$  coordinates and the number of  $y$  coordinates in the X= and Y= options, respectively, are different, then the NPTS= option is ignored; in that case, a two-dimensional grid is used according to the specified X= and Y= options.

If you specify a prediction grid with any number of points other than two in the GRIDDATA= data set, then the option NPTS=ALL has the same effect as omitting the NPTS= option.

**X=number**

**X= $x_1, \dots, x_m$**

**X= $x_1$  to  $x_m$**

**X= $x_1$  to  $x_m$  by  $\delta x$**

specifies the  $x$  coordinate of the grid locations.

**Y=number**

**Y= $y_1, \dots, y_m$**

**Y= $y_1$  to  $y_m$**

**Y= $y_1$  to  $y_m$  by  $\delta y$**

specifies the  $y$  coordinate of the grid locations.

Use the X= and Y= options of the GRID statement to specify a grid in one or two dimensions, or a grid of individual prediction locations.

For example, the following two GRID statements are equivalent.

```
grid x=1,2,3,4,5 y=0,2,4,6,8,10;
```

```
grid x=1 to 5 y=0 to 10 by 2;
```

In the following example, the first GRID statement produces a grid in two dimensions. The second statement produces predictions only for the four individual points at the locations (1,0), (2,5), (3,7), and (4,10) on the XY plane.

```
grid x=1 to 4 y=0,5,7,10;
```

```
grid x=1 to 4 y=0,5,7,10 npts=all;
```

In the next example, the first GRID statement specifies a 2-by-2 grid in two dimensions. The second GRID statement specifies a linear grid of eight points. The grid is in the direction of the line defined by the specified points (2,8) and (3,5) on the XY plane and it extends between these two points.

```
grid x=2,3 y=8,5;
```

```
grid x=2,3 y=8,5 npts=8;
```

The last example shows a GRID statement that specifies a linear grid made of seven points across the Y axis. In this case, the syntax is sufficient to fully define a linear grid without the NPTS= option.

```
grid x=5 y=3 to 9;
```

To specify grid locations from a SAS data set, you must provide the name of the data set and the variables that contain the values of the  $x$  and  $y$  coordinates.

**GRIDDATA=***SAS-data-set*

**GDATA=***SAS-data-set*

specifies a SAS data set that contains the  $x$  and  $y$  grid coordinates. Use the GRIDDATA= option of the GRID statement to specify a grid in one dimension or a grid of individual prediction locations.

**XCOORD=** (*variable-name*)

**XC=** (*variable-name*)

specifies the name of the variable that contains the  $x$  coordinate of the grid locations in the **GRID-DATA=** data set.

**YCOORD=** (*variable-name*)

**YC=** (*variable-name*)

specifies the name of the variable that contains the  $y$  coordinate of the grid locations in the **GRID-DATA=** data set.

You can specify the following option in the GRID statement after a slash (/):

**LABEL** < (*suboption*) > = (*character-list*)

specifies labels to tag grid points in prediction plots when you use grids in one dimension. You can specify one or more such labels as quoted strings in the *character-list*.

When the number of labels in the *character-list* exceeds the number of points in your grid, the labels in the list are used sequentially and any labels in excess are ignored. When the number of labels in the *character-list* is smaller than the number of points in your grid, the behavior is as follows:

- If an area map is included in the prediction plot, then blank labels are assigned to the remaining nonlabeled grid points on the map.
- For the prediction band and scatter plots, the coordinates of nonlabeled grid points are automatically assigned as their labels.

If the grid points are collinear and the horizontal axis displays distance, then two labels appear by default in the prediction plot. These are assigned to the first and the last points of the grid to help identify the ends of the linear grid segment on the plot map. This label pair is shown only when the plot includes an area map. Specifically, the two labels appear when you request prediction band plots, or prediction scatter plots for which you specify the **PREDICTION(SHOWD)** suboption, if applicable. The two labels do not appear if you specify explicitly the **NOMAP** suboption in the **PLOTS=PRED** option.

The two labels have default values, unless you choose to specify your own labels with the **LABEL=** option. If you specify more than two labels in the *character-list* under these conditions, then only the first and last labels in the list are used; any additional labels in between are ignored.

The **LABEL=** option has the following *suboption*:

#### **ALL**

specifies that all individual points in the grid be assigned sequentially the labels you specify in the **LABEL(ALL)=** option when the **PREDICTION(SHOWD)** suboption is applicable and specified in a prediction scatter plot. In all other cases, the **ALL** suboption is ignored.

The **ALL** suboption enables you to override the default behavior when the **PREDICTION(SHOWD)** suboption is specified (the default behavior is to display labels only for the first and last grid points). As a result, you can use the **ALL** suboption to label grid points regardless of whether you specify the **NOMAP** suboption in the **PLOTS=PRED** option.

The **LABEL=** option is ignored when you produce prediction plots of grids in two dimensions.

---

## **ID Statement**

**ID** *variable* ;

The **ID** statement specifies which variable to include for identification of the observations in the **OUTNBHD=** output data set. The **ID** statement variable is also used for the labels and tool tips in the **OBSERVATIONS** plot and the tool tips in the **PREDICTION** plot.

In the **KRIGE2D** procedure you can specify only one **ID** variable in the **ID** statement. If no **ID** statement is given, then **PROC KRIGE2D** uses the observation number in the data sets and the plots.

## PREDICT Statement

**PREDICT** | **PRED** | **P** *predict-options* ;

You can specify the following options in a PREDICT statement.

**MAXPOINTS=number**

**MAXP=number**

**MAX=number**

specifies the maximum number of data points in a neighborhood. You specify this option in conjunction with the **RADIUS=** option. When the number of data points in the neighborhood formed at a given grid point by the **RADIUS=** option is greater than the **MAXPOINTS=** value, the **RADIUS=** value is decreased just enough to honor the **MAXPOINTS=** value unless you specify the **NODECREMENT** option. The default is to include all data points within the specified **RADIUS=** value. Neighborhoods with very large numbers of data points might lead to unnecessarily slow execution times and potential lack of memory issues, depending on the problem setup and your computational resources. In that case, you could use the **MAXPOINTS=** option to set a cap for your neighborhood size. For details about numerical considerations, see the section “[Computational Resources](#)” on page 3843. Unless the **RADIUS=** option is also specified, when the **MAXPOINTS=** and **NUMPOINTS=** options are specified in the same **PREDICT** statement the **MAXPOINTS=** option is ignored.

**MINPOINTS=number**

**MINP=number**

**MIN=number**

specifies the minimum number of data points in a neighborhood. You specify this option in conjunction with the **RADIUS=** option. When the number of data points in the neighborhood formed at a given grid point by the **RADIUS=** option is less than the **MINPOINTS=** value, the **RADIUS=** value is increased just enough to honor the **MINPOINTS=** value unless you specify the **NOINCREMENT** option. The default is **MINPOINTS=20**. When enough data are available, you might improve prediction if you increase this value. When the **MINPOINTS=** and **NUMPOINTS=** options are specified in the same **PREDICT** statement, the **MINPOINTS=** option is set to the value of **NUMPOINTS=**.

**NODECREMENT** | **NODECR**

requests that the **RADIUS=** value not be decremented when the **MAXPOINTS=** value is exceeded at a grid point. This option is relevant only when you specify both a **RADIUS=** value and a **MAXPOINTS=** value. In this case, when the number of points in the neighborhood constructed from the **RADIUS=** specification is greater than the **MAXPOINTS=** value, the **RADIUS=** value is decremented enough to honor the **MAXPOINTS=** value, and the kriging system is solved for this grid point. If you specify the **NODECREMENT** option, no decrementing is done, prediction is skipped at this grid point, and a message is written to the log.

**NOINCREMENT** | **NOINCR**

requests that the **RADIUS=** value not be incremented when the **MINPOINTS=** value is not met at a grid point. This option is relevant only when you specify both a **RADIUS=** value and a **MINPOINTS=** number. In this case, when the number of points in the neighborhood constructed from the **RADIUS=** specification is less than the **MINPOINTS=** value, the **RADIUS=** value is incremented enough to honor the **MINPOINTS=** value, and the kriging system is solved for this grid point. If you specify the **NOINCREMENT** option, no incrementing is done, prediction is skipped at this grid point, and a message is written to the log.

**NUMPOINTS=***number*

**NPOINTS=***number*

**NPTS=***number*

**NP=***number*

specifies the exact size of a neighborhood. This option is incompatible with all other **PREDICT** statement options that control the neighborhood; it must appear by itself. In particular, if you specify both **NUMPOINTS=** and the **RADIUS=** option in the same **PREDICT** statement, then **RADIUS=** is honored, instead. In this event the value of the **MINPOINTS=** option is set to **NUMPOINTS=**, and the value of the **MAXPOINTS=** option is set to default, regardless of whether these options have been specified or not. If you specify any of the **MINPOINTS=** or **MAXPOINTS=** option without the **RADIUS=** option in the same **PREDICT** statement as **NUMPOINTS=**, then the **NUMPOINTS=** option is honored.

**RADIUS=***number*

**R=***number*

specifies the radius to use in a local kriging regression. When you specify this option, a separate kriging system is solved at each grid point by finding the neighborhood of this grid point that consists of all data points within the distance specified by the **RADIUS=** value. Thus, you can avoid unnecessary computational burden in your analysis by specifying the **RADIUS=** value to include data points situated within the extent of your problem's spatial correlation. For additional control on the neighborhood, see the **MAXPOINTS=** and **MINPOINTS=** options. When you specify the **RADIUS=** and **NUMPOINTS=** options in the same **PREDICT** statement, then **RADIUS=** is honored.

**VAR=** *variable-name*

specifies the single numeric variable used in the kriging system.

---

## MODEL Statement

**MODEL** *model-options* ;

The **MODEL** statement specifies details about the correlation model that you use in the kriging system for prediction. The specified model is used in the kriging system defined by the most previous **PREDICT** statement. You can specify a semivariogram or covariance model in three ways:

- You specify the required parameters **SCALE**, **RANGE**, **FORM**, and **SMOOTH** (if you specify the **MATERN** form), and possibly the optional parameters **NUGGET**, **ANGLE**, and **RATIO**, explicitly in the **MODEL** statement.
- You specify an **MDATA=** data set. This data set contains variables that correspond to the required parameters **SCALE**, **RANGE**, **FORM** and **SMOOTH** (if you specify the **MATERN** form), and optionally variables for the **NUGGET**, **ANGLE**, and **RATIO** parameters.
- You can specify an input item store in the **RESTORE** statement. The item store contains one or more correlation models for one or more direction angles. You can specify these models in the **STORESELECT** option of the **MODEL** statement to perform a prediction task.

The three methods are mutually exclusive: you specify all parameters explicitly, they are all read from the `MDATA=` data set, or you select a model and its parameters from an input item store.

Table 49.3 summarizes the options available in the MODEL statement.

**Table 49.3** MODEL Statement Options

| Option      | Description                                                                      |
|-------------|----------------------------------------------------------------------------------|
| ANGLE=      | Specifies the angle of the major axis                                            |
| FORM=       | Specifies the functional form (type)                                             |
| MDATA=      | Specifies the input data set containing parameter values                         |
| NUGGET=     | Specifies the nugget effect for the model                                        |
| POWNOBOUND  | Allows values for the power model exponent parameter outside the range of [0, 2) |
| RANGE=      | Specifies the range parameter                                                    |
| RATIO=      | Specifies the ratio of the length of the minor axis                              |
| SCALE=      | Specifies the scale parameter                                                    |
| SINGULAR=   | Gives the singularity criterion for solving kriging systems                      |
| SMOOTH=     | Specifies the smoothness parameter                                               |
| STORESELECT | Uses the information from an input item store                                    |

You can use the following *model-options* with the MODEL statement:

**ANGLE=***angle*

**ANGLE=**(*angle1*, ..., *anglek*)

specifies the angle of the major axis for anisotropic models, measured in degrees clockwise from the N-S axis. The default is ANGLE=0.

In the case of a nested semivariogram model with  $k$  nestings, you have the following two ways to specify the anisotropy major axis: you can specify only one *angle* which is then applied to all nested forms, or you can specify one angle for each of the  $k$  nestings.

**NOTE:** The syntax makes it possible to specify different angles for different forms of the nested model, but this practice is rarely used.

**FORM=***form*

**FORM=**(*form1*, ..., *formk*)

specifies the functional form (type) of the semivariogram model. Use the syntax with the single *form* to specify a non-nested model. Use the syntax with forms *form<sub>i</sub>*,  $i = 1, \dots, k$ , to specify a nested model with  $k$  structures. Each of the forms can be any of the following:

**CUBIC | EXPONENTIAL | GAUSSIAN | MATERN |  
PENTASPHERICAL | POWER | SINEHOLEEFFECT | SPHERICAL**

**CUB | EXP | GAU | MAT | PEN | POW | SHE | SPH**

Usage examples follow.

For example, the syntax

```
FORM=GAU
```

specifies a model with a single Gaussian structure. Also, the syntax

```
FORM= (EXP , SHE , MAT)
```

specifies a nested model with an exponential, a sine hole effect, and a Matérn structure. Finally

```
FORM= (EXP , EXP)
```

specifies a nested model with two structures both of which are exponential.

**NOTE:** In the documentation, models are named either by using their full names or by using the first three letters of their structures. Also, the names of different structures in a nested model are separated by a hyphen (-). According to this convention, the previous examples illustrate how to specify a GAU, an EXP-SHE-MAT, and an EXP-EXP model, respectively, with the FORM= option.

All the supported model forms have two parameters specified by the SCALE= and RANGE= options, except for the MATERN model which has a third parameter specified by the SMOOTH= option. A FORM= value is required, unless you specify the MDATA= option or the STORESELECT option.

Computation of the MATERN covariance is numerically demanding. As a result, predictions that use Matérn covariance structures can be time-consuming.

See the section “Theoretical Semivariogram Models” on page 3823 for details about how the FORM= forms are determined.

#### **MDATA=SAS-data-set**

specifies the input data set that contains parameter values for the covariance or semivariogram model. The MDATA= option cannot be combined with any of the FORM= or STORESELECT options.

The MDATA= data set must contain variables named SCALE, RANGE, and FORM, and it can optionally contain variables NUGGET, ANGLE, and RATIO. If you specify the MATERN form, then you must also include a variable named SMOOTH in the MDATA= data set.

The FORM variable must be a character variable, and it can assume only the values allowed in the explicit FORM= syntax described previously. The RANGE, SCALE and SMOOTH variables must be numeric. The optional variables ANGLE, RATIO, and NUGGET must also be numeric if present.

The number of observations present in the MDATA= data set corresponds to the level of nesting of the covariance or semivariogram model. For example, to specify a non-nested model that uses a spherical covariance, an MDATA= data set might be given by the following statement:

```
data mdl;
 input scale range form $;
 datalines;
 25 10 SPH
run;
```

The PROC KRIGE2D statement to use the `MDATA=` specification is of the form shown in the following:

```
proc krige2d data=...;
 predict var=...;
 model mdata=mdl;
run;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```
proc krige2d data=...;
 predict var=...;
 model scale=25 range=10 form=sph;
run;
```

The following `MDATA=` data set is an example of an anisotropic nested model:

```
data mdl;
 input scale range form $ nugget angle ratio;
 datalines;
 20 8 SPH 5 35 0.7 .
 12 3 MAT 5 0 0.8 2.8
 4 1 GAU 5 45 0.5 .
 ;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```
proc krige2d data=...;
 predict var=...;
 model scale=(20,12,4) range=(8,3,1) form=(SPH,MAT,GAU)
 angle=(35,0,45) ratio=(0.7,0.8,0.5) nugget=5 smooth=2.8;
run;
```

This example is somewhat artificial in that it is usually hard to detect different anisotropy directions and ratios for different nestings by using an empirical semivariogram. **NOTE:** The NUGGET variable value is the same for all nestings. This is always the case; the nugget effect is a single additive term for all models. For further details, see the section “[The Nugget Effect](#)” on page 3830.

The example also shows that if you specify a MATERN form in the nested model, then the SMOOTH variable must be specified for all nestings in the `MDATA=` data set. You simply specify the SMOOTH value as missing for nestings other than MATERN.

#### **NUGGET=***number*

specifies the nugget effect for the model. The nugget effect is due to a discontinuity in the semivariogram as determined by plotting the sample semivariogram. For details, see the section “[The Nugget Effect](#)” on page 3830 and Chapter 102, “[The VARIOGRAM Procedure.](#)” For models without any nugget effect, this option is left out; the default is `NUGGET=0`.

**POWNOBOUND**

specifies that values for the power model exponent parameter outside the range of  $[0, 2)$  be allowed. The POWNOBOUND option applies only when you specify a power form in the MODEL statement.

Power models yield permissible covariance models only when the exponent parameter is nonnegative and less than 2. By default, PROC KRIGE2D produces an error if you specify a negative power exponent or one that is equal to or larger than 2 in the RANGE= option of the MODEL statement.

See the section “[The Power Semivariogram Model](#)” on page 3828 for more details about the power model form and its exponent parameter.

**RANGE=range****RANGE=(range1, ..., rangek)**

specifies the range parameter in semivariogram models. If you have anisotropy, you must specify the range of the major anisotropy axis, or the range of the minor anisotropy axis for any zonal components. In the case of a nested semivariogram model with  $k$  nestings, you must specify a range for each nested structure.

The range parameter has units of distance, and it is related to the correlation scale for the underlying spatial process.

**NOTE:** If you specify this parameter for a power model, then it does not correspond to a range. For power models, the parameter you specify in the RANGE option is a dimensionless power exponent whose value must range within  $[0, 2)$  so that the power model is a valid semivariance function. See also the POWNOBOUND option of the MODEL statement.

See the section “[Theoretical Semivariogram Models](#)” on page 3823 for details about how the RANGE= values are determined.

**RATIO=ratio****RATIO=(ratio1, ..., ratiok)**

specifies the ratio of the length of the minor axis to the length of the major axis for anisotropic models. The value of the RATIO= option must be between 0 and 1. An exception is the case of zonal anisotropy, where the ratio of zonal components must be designated by a very large number for the RATIO= option. For further details, see the section “[Zonal Anisotropy](#)” on page 3835.

In the case of a nested semivariogram model with  $k$  nestings, you can specify a ratio for each nesting. The default is RATIO=1.

**SCALE=scale****SCALE=(scale1, ..., scalek)**

specifies the scale parameter in semivariogram models. In the case of a nested semivariogram model with  $k$  nestings, you must specify a scale for each nesting.

The scale parameter is the multiplicative factor in all supported models; it has the same units as the variance of the VAR= variable in the preceding PREDICT statement.

In power models the SCALE= parameter does not correspond to a sill because the power model has no sill. Instead, PROC KRIGE2D uses the SCALE= option to designate the slope (or scaling factor) in power model forms. The power model slope has the same variance units as the VAR= variable.

See the section “[Theoretical Semivariogram Models](#)” on page 3823 for details about how the SCALE= values are determined.

**SINGULAR=number**

gives the singularity criterion for solving kriging systems. The larger the value of the SINGULAR= option, the easier it is for a kriging system to be declared singular. The default is SINGULAR=1E-7. See the section “[Ordinary Kriging](#)” on page 3840 for more detailed information.

**SMOOTH=smooth****SMOOTH=(smooth1, ..., smoothm)**

specifies the smoothness parameter  $\nu > 0$  in the Matérn type of semivariance structures. The special case  $\nu = 0.5$  is equivalent to the exponential model, whereas  $\nu \rightarrow \infty$  gives the Gaussian model.

When you specify  $m$  different MATERN forms in the **FORM=** option, you must also provide  $m$  smoothness values in the SMOOTH option. If you must specify more than one smoothness value, the values are assigned sequentially to the MATERN nestings in the order the nestings are specified. If you specify more smoothness values than necessary, then values in excess are ignored.

**STORESELECT(ssel-options)****SSEL(ssel-options)**

specifies that information from an input item store be used for the prediction. You cannot combine the STORESELECT option with any of the **FORM=** or **MDATA=** options. The STORESELECT option has the following *ssel-options*:

**TYPE=field-type**

specifies whether to perform isotropic or anisotropic prediction. You can choose the *field-type* from one of the following:

**ISO**

specifies an isotropic field for the prediction.

**ANIGEO | GEO**

specifies a field with geometric anisotropy for the prediction.

**ANIZON(zonal-form1, ..., zonal-formn)****ZON(zonal-form1, ..., zonal-formn)**

specifies a field with zonal anisotropy for the prediction. Each *zonal-formi*,  $i = 1, \dots, n$ , can be any of the following:

**CUB | EXP | GAU | MAT | PEN | POW | SHE | SPH**

Each *zonal-formi*,  $i = 1, \dots, n$ , is a structure in the purely zonal component of the correlation model in the direction angle of the minor anisotropy axis. For this reason, when you specify the TYPE=ANIZON suboption you must also specify the nonzonal component of the correlation model in the **MODEL=** suboption of the STORESELECT option.

Assume the nonzonal component has  $k$  structures; these are common across all directions and each one has the same scale in all directions. In that sense, you use the TYPE=ANIZON suboption to specify only the  $n$  zonal anisotropy structures of an input store ( $k + n$ )-structure nested model in the direction angle of the minor anisotropy axis.

Given this specification,  $k + n$  must be up to the maximum number of nested model structures that is supported by the item store. See also the **MODEL=** suboption of the STORESELECT option.

In conclusion, you can use an input item store for prediction with zonal anisotropy if you know that every structure in the nonzonal model component has the same scale across all directions. When this condition does not apply for the item store models, specify the model parameters explicitly in the **MODEL** statement. For more details, see the examples in the section “[Zonal Anisotropy](#)” on page 3835.

Computation of the MATERN covariance is numerically demanding. As a result, predictions that use Matérn covariance structures can be time-consuming.

If you omit the **TYPE=** option, the default behavior is **TYPE=ISO** when the input item store contains information for only one angle or for the omnidirectional case. If you specify an item store with information for more than one direction, then the default behavior is **TYPE=ANIGEO**.

When you specify **TYPE=ISO** to request isotropic analysis in the presence of an item store with information for multiple directions, you must specify the **ANGLEID=** suboption of the **STORESELECT** option with one argument. This argument specifies which of the direction angles information to use for the isotropic analysis.

When you indicate the presence of anisotropy with the **TYPE=ANIGEO** or **TYPE=ANIZON** suboptions of the **STORESELECT** option, the following conditions apply:

- You must specify the **ANGLEID=** suboption of the **STORESELECT** option to designate the major and minor anisotropy axes. See the **ANGLEID=** suboption of the **STORESELECT** option for details.
- – For **TYPE=ANIGEO**, ensure that you have the same scale in all anisotropy directions.
- – For **TYPE=ANIZON**, ensure that the nonzonal component scale is the same in all anisotropy directions.

If you import a nested model, these rules also apply to each one of the nested structures.

- Model ranges in the major anisotropy axis must be longer than ranges in the minor anisotropy axis.
- Any Matérn covariance structure must maintain its smoothness parameter value in all anisotropy directions.

**ANGLEID=***angleid1*

**ANGLEID=**(*angleid1*, *angleid2*)

specifies which direction angles in the input item store be used for prediction. The angles are identified by the corresponding number in the **AngleID** column of the “Store Models Information” table, or by the **AngleID** parameter in the table title when you specify the **INFO(DETAILS)** option in the **RESTORE** statement.

If you request isotropic prediction in the **TYPE=** suboption of the **STORESELECT** option and the item store has omnidirectional contents or information about only one angle, then the **ANGLEID=** option is ignored. The prediction input comes from the omnidirectional information. In the case of a single angle, you still perform isotropic prediction and the model parameters are provided by the model in the single direction angle in the item store. However, if the item store contains information for more than one angle, then you must specify one angle ID in *angleid1*. The model information from the corresponding angle is then used in your isotropic prediction.

When you specify an anisotropic prediction in the **TYPE=** option of the **STORESELECT** option, you need to have information about two perpendicular direction angles. One of them is the

major and the other is the minor anisotropy axis. You must always specify the major anisotropy axis angle ID in *angleid1* and the minor anisotropy axis angle ID in *angleid2*. This means that the range parameters of the model forms in the angle designated by the *angleid1* need to be larger than the corresponding ranges of the forms in the angle designated by the *angleid2*. Conveniently, if the item store has only two angles, then you only need to specify the ID *angleid1* of the major anisotropy axis angle. If the item store has only one angle, then you cannot perform anisotropic prediction with input from the item store.

**NOTE:** You can perform geometric anisotropic analysis even if the item store does not contain information about a direction that is perpendicular to the one specified by *angleid1*. This is possible due to the geometry of the ellipse. In particular, when you specify the major axis with *angleid1* and an angle ID for a second direction with a corresponding smaller range, then PROC KRIGE2D automatically computes the minor anisotropy axis range and the necessary range ratio parameter.

Anisotropic analysis is not possible when you specify instances of the same angle in the input item store. It is possible that PROC VARIOGRAM produces an item store in which two or more directions can be the same if their corresponding correlation models were obtained for different angle tolerances or bandwidths in the VARIOGRAM procedure. Consequently, you cannot specify anisotropic prediction if the input store contains only two angles that are the same or if you specify *angleid1* and *angleid2* that correspond to equal angles.

**MODEL=***form*

**MODEL=**(*form1*, . . . , *formk*)

specifies the theoretical semivariogram model selection to use for the prediction. Use any combination of one, two, or three forms to describe a model in the input item store because up to three nested structures are supported. Each *form<sub>i</sub>*,  $i = 1, \dots, k$ , can be any of the following:

**CUB | EXP | GAU | MAT | PEN | POW | SHE | SPH**

Computation of the MATERN covariance is numerically demanding. As a result, predictions that use Matérn covariance structures can be time-consuming.

All fitted models that are stored in the input item store contain information about their component parameters and also about the nugget effect if any. The KRIGE2D procedure retrieves this information when you make a model selection in the MODEL= option, and you do not need to individually specify a nugget effect or any other parameter of the model.

By default, the model that is ranked first among the models for a given angle in the item store is used for the prediction task. If more than one model is available in the item store, then you can specify the MODEL= option to use a different model for the prediction.

In an anisotropic prediction, the default selection is the model that is ranked first in the direction angle of the major anisotropy axis. If you specify the TYPE=ANIGEO option, then a model that consists of identical structures needs to be present in the selected minor anisotropy axis angle in the item store. If you specify the TYPE=ANIZON option, then a model with the exact same first  $k$  structures must be present in the selected minor anisotropy axis angle, and it must feature at least one more structure as a zonal component. The zonal component is specified separately in the TYPE=ANIZON suboption of the STORESELECT option. Consequently, remember that in zonal anisotropy the MODEL= suboption designates only the nonzonal component of the correlation model in the minor anisotropy axis direction. In all, if there are  $k$  common structures

and  $n$  structures in the purely zonal component, then  $k + n$  must be up to the maximum number of nested model structures that is supported by the item store.

In comparison to the other two ways of specifying a correlation model in PROC KRIGE2D, the STORESELECT option is quite different because you can avoid explicit specification of all parameter values of a model. When you specify the STORESELECT option, then the corresponding scale, range, nugget effect, and smoothness (if appropriate) parameter values are invoked as saved attributes of the model that you select from the item store.

In the case of anisotropy, you specify the angles indirectly with the ANGLEID= option of the STORESELECT option, and the ratios are computed implicitly by using the selected model ranges. Explore how to specify valid anisotropical models imported from an input item store with the two examples that follow.

In the first example, assume the input item store InStoreGeo contains exponential models in the angles  $\theta_1 = 0^\circ$ ,  $\theta_2 = 45^\circ$ , and  $\theta_3 = 90^\circ$ . You know in advance that all models have the same scale  $c_1 = c_2 = c_3$  across these directions and that the respective ranges are  $a_1 = 15$ ,  $a_2 = 20$ , and  $a_3 = 25$  in distance units. Hence, you have a case of geometric anisotropy where the major anisotropy axis is in the direction of angle  $\theta_3$  and the minor anisotropy axis is in the direction of angle  $\theta_1$ . The following statements in PROC KRIGE2D use the information in the item store InStoreGeo to perform simulation under the assumption of geometric anisotropy:

```
proc krig2d data=...;
 restore in=InStoreGeo;
 predict var=...;
 model storeselect(model=exp type=anigeo angleid=(3,1));
run;
```

For the second example, assume a case of zonal anisotropy. Consider the input item store InStoreZon, which contains models in the two angles,  $\theta_1 = 30^\circ$  and  $\theta_2 = 120^\circ$ . Specifically, in  $\theta_1$  you have an exponential-spherical model: the exponential structure has scale  $c_{1E} = 3$  and range  $a_{1E} = 10$ ; the spherical structure has scale  $c_{1S} = 1$  and range  $a_{1S} = 6$ . In direction  $\theta_2$  you have an exponential model with scale  $c_{1E} = 3$  and range  $a_{1E} = 12$ . Hence, the zonal anisotropy major axis is in the direction of the lowest total variance, which is in angle  $\theta_2$ ; then, the minor axis is in the direction of angle  $\theta_1$ . The following statements in PROC KRIGE2D use the information in the store InStoreZon to perform prediction under the assumption of zonal anisotropy:

```
proc krig2d data=...;
 restore in=InStoreZon;
 predict var=...;
 model storeselect(model=exp type=anizon(sph) angleid=(2,1));
run;
```

---

## RESTORE Statement

**RESTORE IN=store-name** </option> ;

The RESTORE statement specifies an item store that provides spatial correlation model input for the PROC KRIGE2D prediction tasks. An item store is a binary file defined by the SAS System. You cannot mod-

ify the contents of an item store. The KRIGE2D procedure can use only item stores created by PROC VARIOGRAM.

Item stores enable you to use saved correlation models without having to repeat specification of these models in the **MODEL** statement. In principle, an item store contains the chosen model from a model fitting process in PROC VARIOGRAM. If more than one model form is fitted, then all successful fits are included in the item store. In this case, you can choose any of the available models to use for prediction with the **STORESELECT(MODEL=)** option in the **MODEL** statement. Successfully fitted models might include questionable fits, which are so flagged when you specify the **INFO** option to display model names.

The *store-name* is a usual one- or two-level SAS name, as for SAS data sets. If you specify a one-level name, then the item store resides in the WORK library and is deleted at the end of the SAS session. Since item stores are often used for postprocessing tasks, typical usage specifies a two-level name of the form *libname.membername*.

When you specify the **RESTORE** statement, the default output contains some general information about the input item store. This information includes the store name, label (if assigned), the data set that was used to create the store, **BY** group information, the procedure that created the store, and the creation date.

You can specify the following option in the **RESTORE** statement after a slash (/):

**INFO** < ( *info-options* ) >

specifies that additional information about the input item store be printed. This information is provided in two ODS tables. One table displays the variables in the item store, in addition to the mean and standard deviation for each of them. These statistics are based on the observations that were used to produce the store results. The second table shows the model on top of the list of all fitted models for each direction angle in the item store. The **INFO** option has the following *info-options*:

**DETAILS**

**DET**

specifies that more detailed information be displayed about the input item store. This option produces the full list of models for each direction angle in the item store, in addition to the model equivalence class. For more information about classes of equivalence, see the section “Classes of Equivalence” on page 8634 in the VARIOGRAM procedure. The **DETAILS** option is ignored if the input item store contains information about a single fitted model.

**ONLY**

specifies that only information about the input item store without any prediction tasks be displayed.

When you specify an input item store with the **RESTORE** statement in PROC KRIGE2D, all the **DATA=** input data set variables must match input item store variables. If there are **BY** groups in the input **DATA=** set or in the input **RESTORE** variables, then PROC KRIGE2D handles the different cases as follows:

- If both PROC KRIGE2D has **BY** groups and the **RESTORE** statement has **BY** groups, then the analysis variables must match. This matching assumes implicitly that in each **BY** group of PROC KRIGE2D and the item store, the corresponding set of observations and correlation model comes from the same random field. This assumption is valid if you use the same data set, first in PROC VARIOGRAM to fit a model and save it in the item store, and then in PROC KRIGE2D to perform predictions with the resulting correlation models.

- If PROC KRIGE2D has BY groups but the item store does not, then the item store is accepted only if the procedure and the item store analysis variables match. In this case, the same item store model choice iterates across the BY groups of the input data. You are advised to proceed with caution: each BY group in the input DATA= set corresponds to a different realization of a random field. Hence, by using the same correlation model for prediction purposes, you implicitly assume that all these different realizations are instances of the same random field.
- If PROC KRIGE2D has no BY groups but the item store does, then the item store is rejected.

---

## Details: KRIGE2D Procedure

---

### Theoretical Semivariogram Models

Consider a stochastic spatial process represented by the stationary spatial random field (SRF)  $\{Z(s), s \in D \subset \mathcal{R}^2\}$  (Christakos 1992). The VARIOGRAM procedure computes the empirical (also known as sample or experimental) semivariance of  $Z(s)$ . Prediction of the spatial process  $Z(s)$  at unsampled locations by techniques such as ordinary kriging requires a theoretical semivariogram or covariance.

When you use PROC VARIOGRAM and PROC KRIGE2D to perform spatial prediction, you must determine a suitable theoretical semivariogram based on the sample semivariogram. Various methods exist to fit semivariogram models, such as least squares, maximum likelihood, and robust methods (Cressie 1993, section 2.6). You can use PROC VARIOGRAM to perform automated fitting of a semivariogram model with weighted or ordinary least squares. A different approach is manual fitting, in which a theoretical semivariogram is chosen based on visual inspection of the empirical estimate; see, for example, Hohn (1988, p. 25).

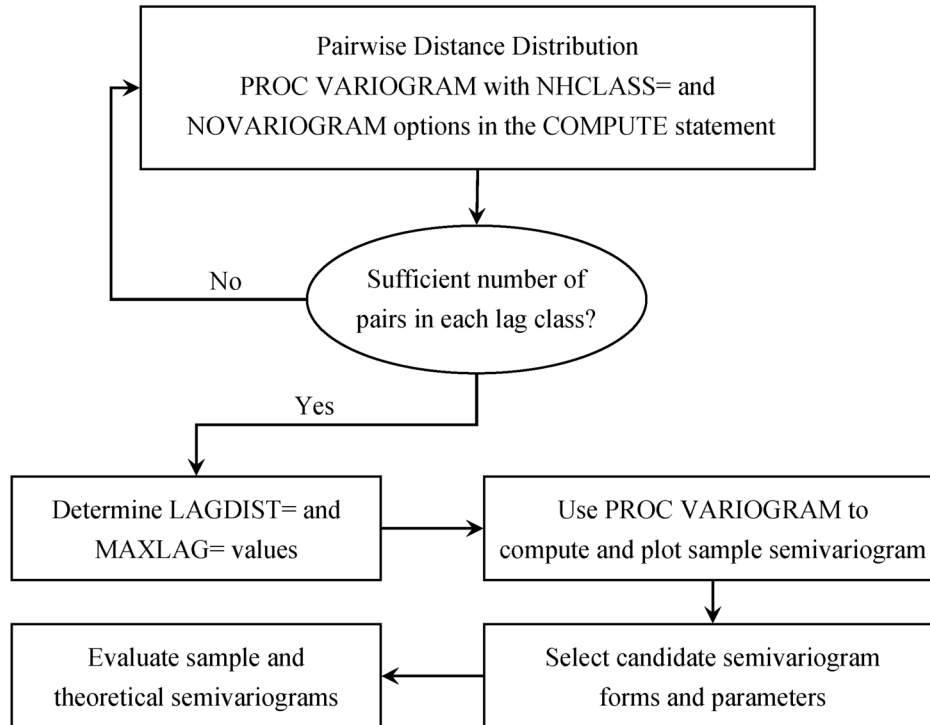

In some cases, a plot of the experimental semivariogram suggests that a single theoretical model is inadequate. Nested models, anisotropic models, and the nugget effect increase the scope of theoretical models available. All of these concepts are discussed in this section. The specification of the final theoretical model is provided by the syntax of PROC KRIGE2D.

Figure 49.5 shows the general flow of investigation. The empirical semivariogram is computed after a suitable choice is made for the LAGDISTANCE= and MAXLAGS= options in PROC VARIOGRAM, and possibly the NDIR= option or the DIRECTIONS statement for computations in more than one directions. Potential theoretical models (which can also incorporate nesting, anisotropy, and the nugget effect) are then plotted against the empirical semivariogram and evaluated. A suitable theoretical model is found by using the methodology presented in the section “[Examples: VARIOGRAM Procedure](#)” on page 8648 in the VARIOGRAM procedure.

Eight theoretical models are supported by PROC KRIGE2D: the Gaussian, exponential, Matérn, spherical, cubic, pentaspherical, sine hole effect and power models. See also the section “[Theoretical Semivariogram Models](#)” on page 8608 in the VARIOGRAM procedure. These eight model forms are now examined in more detail: the Gaussian, exponential, and Matérn forms are examined as one group; the spherical, cubic, and pentaspherical as a second group; and the remaining power and sine hole effect models are examined individually. For comparison purposes, the axes in the forms’ illustrations are kept the same across the plots, and the corresponding parameters of the different forms have the same values.

In PROC KRIGE2D the parameters  $a_0$  and  $c_0$  for all forms correspond to the **RANGE=** and **SCALE=** options, respectively, in the **MODEL** statement. For all model forms, the dimension of  $c_0$  is the same as the dimension of the variance of the spatial process  $Z(s)$ . For all forms but the power model, the dimension of  $a_0$  is length with same units as the distance  $h$  in the semivariance  $\gamma_z(h)$ . See the section “The Power Semivariogram Model” on page 3828 for more details about interpretation of the power model  $a_0$  parameter.

**Figure 49.5** Flowchart for Semivariogram Selection

### The Gaussian Semivariogram Model

The form of the Gaussian model is

$$\gamma_z(h) = c_0 \left[ 1 - \exp\left(-\frac{h^2}{a_0^2}\right) \right]$$

The shape is displayed in Figure 49.6, using range  $a_0 = 1$  and scale  $c_0 = 4$ .

The vertical line at  $h = r_\epsilon = \sqrt{3}a_0$  shows the *effective* (or *practical*) range as defined by Deutsch and Journel (1992) or the *range*  $\epsilon$  defined by Christakos (1992). The effective range is the  $h$ -value where the covariance is approximately 5% of its value at zero. Alternatively, the stationarity assumption implies that the effective range is the  $h$  value where the semivariance is approximately 5% of the sill value, as shown in Figure 49.6.

In the Gaussian model the semivariance  $\gamma_z(h)$  approaches the sill asymptotically at  $c_0$ .

### The Exponential Semivariogram Model

The form of the exponential model is

$$\gamma_z(h) = c_0 \left[ 1 - \exp\left(-\frac{h}{a_0}\right) \right]$$

The shape is displayed in Figure 49.6, using range  $a_0 = 1$  and scale  $c_0 = 4$ .

The vertical line at  $h = r_\epsilon = 3a_0$  is the *effective* (or *practical*) *range* or the *range*  $\epsilon$  (that is, the  $h$ -value where the covariance is approximately 5% of its value at zero).

As in the Gaussian model, the sill in this example is at 4.0 variance units (corresponding to  $c_0 = 4$ ) and is approached asymptotically.

The major distinguishing feature of the Gaussian and exponential forms is the shape in the neighborhood of the origin  $h = 0$ , as Figure 49.6 illustrates. In general, small lags are important in determining an appropriate theoretical form based on an empirical semivariogram.

### The Matérn Semivariogram Model

The form of the Matérn model is

$$\gamma_z(h) = c_0 \left[ 1 - \frac{2}{\Gamma(\nu)} \left( \frac{h\sqrt{\nu}}{a_0} \right)^\nu K_\nu \left( 2 \frac{h\sqrt{\nu}}{a_0} \right) \right]$$

where  $\nu > 0$  is the smoothness factor parameter. Figure 49.6 shows an example of the Matérn form, where range  $a_0 = 1$ , scale  $c_0 = 4$ , and  $\nu = 1.5$ .

The Matérn semivariance  $\gamma_z(h)$  is a class of semivariance models that emerge for different values of the smoothing parameter  $\nu$ . The Matérn form reaches its sill value  $c_0$  asymptotically.

The Gaussian and exponential semivariances are two frequently used members of the Matérn class of semivariances. In particular, the exponential semivariance model is derived from the Matérn class of models for  $\nu = 0.5$ . Also, when  $\nu \rightarrow \infty$  then the Matérn semivariance gives the Gaussian model. In Figure 49.6 the selected value of  $\nu = 1.5$  places the Matérn form in between the Gaussian and the exponential. The Matérn semivariance typically begins to look and behave as the Gaussian for values of  $\nu > 10$ .

**Figure 49.6** Gaussian, Exponential, and Matérn Semivariograms with Parameters  $a_0 = 1$ ,  $c_0 = 4$ , and  $\nu = 1.5$

### The Spherical Semivariogram Model

The form of the spherical model is

$$\gamma_z(h) = \begin{cases} c_0 \left[ \frac{3}{2} \frac{h}{a_0} - \frac{1}{2} \left( \frac{h}{a_0} \right)^3 \right] & \text{for } h \leq a_0 \\ c_0 & \text{for } h > a_0 \end{cases}$$

The shape is displayed in Figure 49.7, using range  $a_0 = 1$  and scale  $c_0 = 4$ .

The vertical line at  $h = 1$  shows the range  $a_0$  of the model.

In the case of the spherical model,  $\gamma_z(h)$  actually reaches the sill value at  $c_0$ , unlike the Gaussian and exponential types where the sill is a horizontal asymptote.

### The Cubic Semivariogram Model

The form of the cubic model is

$$\gamma_z(h) = \begin{cases} c_0 \left[ 7 \left( \frac{h}{a_0} \right)^2 - \frac{35}{4} \left( \frac{h}{a_0} \right)^3 + \frac{7}{2} \left( \frac{h}{a_0} \right)^5 - \frac{3}{4} \left( \frac{h}{a_0} \right)^7 \right] & \text{for } h \leq a_0 \\ c_0 & \text{for } h > a_0 \end{cases}$$

The cubic form shape is displayed in Figure 49.7, using range  $a_0 = 1$  and scale  $c_0 = 4$ .

The vertical line at  $h = 1$  shows the range  $a_0$  of the model.

Similarly to the spherical model, the cubic model,  $\gamma_z(h)$  reaches the sill value at  $c_0$  and maintains this value after a distance  $h$  equal to the model range.

## The Pentaspherical Semivariogram Model

The form of the pentaspherical model is

$$\gamma_z(h) = \begin{cases} c_0 \left[ \frac{15}{8} \frac{h}{a_0} - \frac{5}{4} \left( \frac{h}{a_0} \right)^3 + \frac{3}{8} \left( \frac{h}{a_0} \right)^5 \right] & \text{for } h \leq a_0 \\ c_0 & \text{for } h > a_0 \end{cases}$$

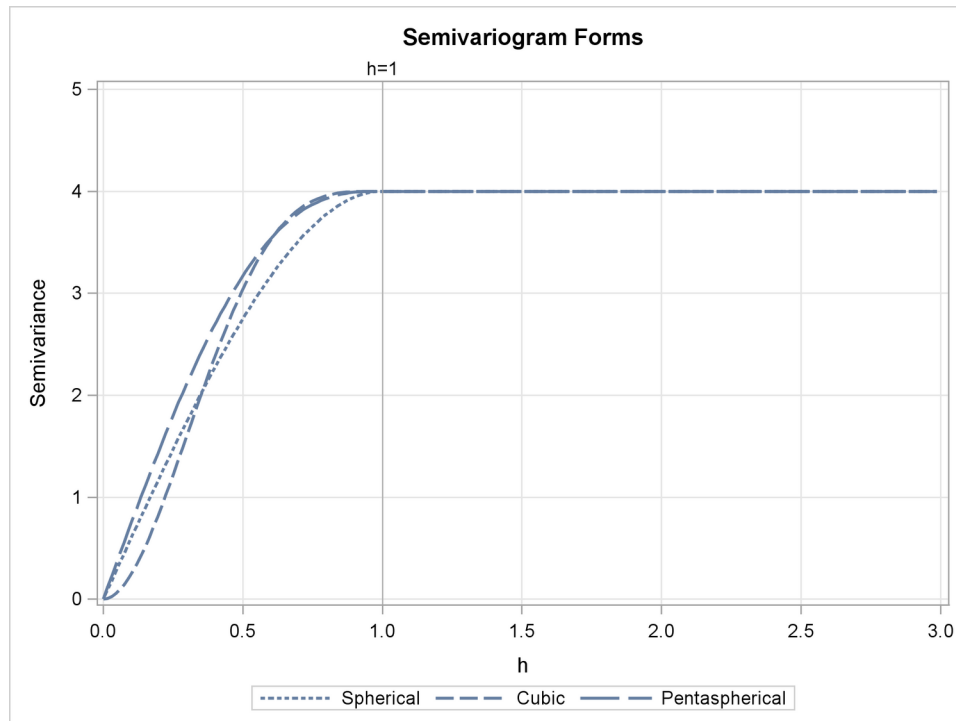

The pentaspherical form shape is displayed in [Figure 49.7](#), using range  $a_0 = 1$  and scale  $c_0 = 4$ .

The vertical line at  $h = 1$  shows the range  $a_0$  of the model.

The pentaspherical semivariance behaves like the spherical and cubic semivariances, in that  $\gamma_z(h)$  increases with distance until it reaches the sill value  $c_0$  at the distance  $h$  equal to the model range  $a_0$ .

[Figure 49.7](#) accents the differences in the behavior of the featured semivariances. Specifically, the cubic and pentaspherical forms reach the sill value faster than the spherical form. Also, the spherical and pentaspherical forms exhibit a more linear behavior at distances close to the origin  $h = 0$ .

**Figure 49.7** Spherical, Cubic, and Pentaspherical Semivariograms with Parameters  $a_0 = 1$  and  $c_0 = 4$

## The Sine Hole Effect Semivariogram Model

The form of the sine hole effect model is

$$\gamma_z(h) = c_0 \left[ 1 - \frac{\sin(\pi h/a_0)}{\pi h/a_0} \right]$$

[Figure 49.8](#) shows an example of the sine hole effect form, where range  $a_0 = 1$  and scale  $c_0 = 4$ .

The vertical line at  $h = 1$  shows the range  $a_0$  of the model.

The sine hole effect semivariance  $\gamma_z(h)$  increases with distance. It has the distinct characteristic that it reaches the sill at a distance  $h = a_0$  equal to the model range and then it oscillates around the sill value with a decreasing amplitude as it moves to higher values of  $h$ .

### The Power Semivariogram Model

The form of the power model is

$$\gamma_z(h) = c_0 h^{a_0}$$

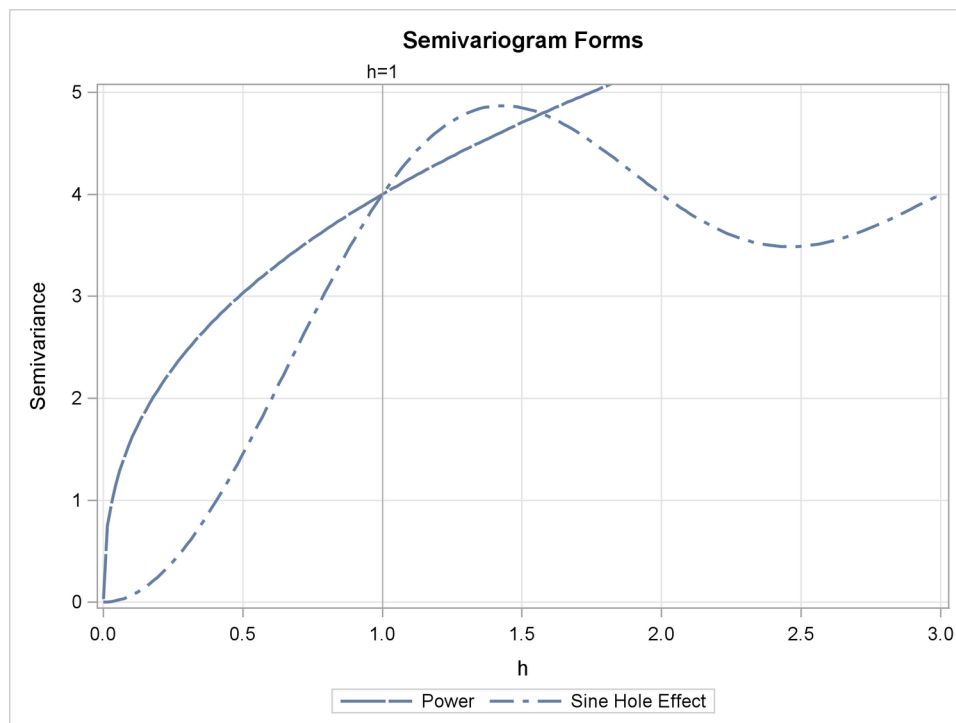

For this model, the parameter  $a_0$  is known as the power exponent. This is a dimensionless quantity which must range within  $0 \leq a_0 < 2$  so that the power model is a permissible semivariance model.

The KRIGE2D procedure enables you to specify power exponent values that are outside this range when you also explicitly specify the **POWNOBOUND** option in the **MODEL** statement. However, parameter values equal to or greater than 2 can result in singular covariance matrices or negative prediction errors.

For the special case of  $a_0 = 1$  the form yields a straight line. In this case the power model reduces to the linear model. The parameter  $c_0$  designates the slope of the power form and has dimensions of the variance as in the other models.

The power model has no sill; this differentiates it from the rest of the models presented earlier. Spatial correlation that is described by a power model indicates that the stochastic process variance increases constantly with distance. The shape of the power model with  $a_0 = 0.4$  and  $c_0 = 4$  is displayed in [Figure 49.8](#).

**Figure 49.8** Sine Hole Effect Semivariogram with Range  $a_0 = 1$  and Scale  $c_0 = 4$ , and Power Semivariogram with Exponent  $a_0 = 0.4$  and Slope  $c_0 = 4$

For comparison purposes, [Figure 49.9](#) displays all eight semivariance forms that you can use with PROC

KRIGE2D. The figure displays a composition of the different forms with the parameter values selected earlier throughout this section. Depending on the empirical semivariogram, these models provide you with flexibility to select an appropriate theoretical semivariance model for prediction.

**Figure 49.9** Semivariogram Forms Used in PROC KRIGE2D

### Nested Models

For a given set of spatial data, a plot of an experimental semivariogram might not seem to fit any of the individual theoretical models. In such a case, you might obtain a more accurate fit if you consider your covariance model to be the sum of two or more covariance structures. Such covariance models are called *nested* models. Nesting is common in geologic applications where correlations can exist at different length scales. At small lag distances  $h$ , the smaller scale correlations dominate, while the large scale correlations dominate at larger lag distances.

Nested models are permissible covariances if they are the sum of permissible models. Therefore, you can include in a sum any combination of the models presented in the preceding subsections and produce permissible covariance models. As an illustration, consider two semivariogram models: an exponential and a spherical,

$$\gamma_{z,1}(h) = c_{0,1} \exp\left(-\frac{h}{a_{0,1}}\right)$$

and

$$\gamma_{z,2}(h) = \begin{cases} c_{0,2} \left[ \frac{3}{2} \frac{h}{a_{0,2}} - \frac{1}{2} \left( \frac{h}{a_{0,2}} \right)^3 \right], & \text{for } h \leq a_{0,2} \\ c_{0,2}, & \text{for } h > a_{0,2} \end{cases}$$

with  $c_{0,1} = 1$ ,  $a_{0,1} = 2.5$ ,  $c_{0,2} = 2$ , and  $a_{0,2} = 1$ . If both of these correlation structures are present in a spatial process  $\{Z(s), s \in D\}$ , then the semivariance  $\gamma_z(h)$  of this process can be expressed as

$$\gamma_z(h) = \gamma_{z,1}(h) + \gamma_{z,2}(h)$$

In this case, the experimental semivariogram  $\gamma_z(h)$  for the process  $Z(s)$  resembles the semivariogram of the sum of  $\gamma_{z,1}(h)$  and  $\gamma_{z,2}(h)$ . This is illustrated in Figure 49.10.

The sum of  $\gamma_{z,1}(h)$  and  $\gamma_{z,2}(h)$  in Figure 49.10 does not resemble any *single* theoretical semivariogram; however, its shape at  $h = 1$  is similar to a spherical form. The asymptotic approach to a sill at three variance units, along with the shape around  $h = 0$ , indicates an exponential structure. The sill value  $c_0$  of the sum is the sum of the individual sills  $c_{0,1} = 1$  and  $c_{0,2} = 2$ . In general, a nested model has a sill equal to the sum of the sills of its nested structures plus the nugget effect, if present.

See Hohn (1988, p. 38ff) for further examples of nested correlation structures.

**Figure 49.10** Sum of Exponential and Spherical Structures at Different Scales

## The Nugget Effect

For all the semivariogram models considered previously, the following property holds:

$$\gamma_z(0) = \lim_{h \downarrow 0} \gamma_z(h) = 0$$

However, a plot of the experimental semivariogram might indicate a discontinuity at  $h = 0$ ; that is,  $\gamma_z(h) \rightarrow c_n > 0$  as  $h \rightarrow 0$ , while  $\gamma_z(0) = 0$ . The quantity  $c_n$  is called the *nugget effect*; this term is from mining

geostatistics where nuggets literally exist, and it represents variations at a much smaller scale than any of the measured pairwise distances—that is, at distances  $h \ll h_{min}$ , where

$$h_{min} = \min_{i,j} h_{ij} = \min_{i,j} |s_i - s_j|$$

Nonzero nugget effects have been associated with conceptual and theoretical difficulties; see Cressie (1993, section 2.3.1) and Christakos (1992, section 7.4.3) for details. There is no *practical* difficulty, however; you simply visually extrapolate the experimental semivariogram as  $h \rightarrow 0$ . The importance of availability of data at small lag distances is again illustrated.

As an example, an exponential semivariogram with a nugget effect  $c_n$  has the form

$$\gamma_z(h) = c_n + \sigma_0^2 \left[ 1 - \exp\left(-\frac{h}{a_0}\right) \right], h > 0$$

and

$$\gamma_z(0) = 0$$

where the factor  $\sigma_0^2$  is called the *partial sill* and the sill  $c_0 = c_n + \sigma_0^2$ .

This is illustrated in Figure 49.11 for the parameters  $a_0 = 1$ ,  $\sigma_0^2 = 4$ , and nugget effect  $c_n = 1.5$ .

You can specify the nugget effect in PROC KRIGE2D with the **NUGGET=** option in the **MODEL** statement. It is a separate, additive term independent of direction; that is, it is isotropic. The way to approximate an anisotropic nugget effect is described in the following section.

**Figure 49.11** Exponential Semivariogram Model with a Nugget Effect  $c_n = 1.5$

## Anisotropic Models

In all of the theoretical models considered previously, the lag distance  $h$  is entered as a scalar value. This implies that the correlation between the spatial process at two point pairs  $P_1, P_2$  is dependent *only* on the separation distance  $h = |P_1 P_2|$ , not on the orientation of the vector  $\mathbf{h}$ . A spatial process described by an SRF  $\{Z(\mathbf{s}), \mathbf{s} \in D \subset \mathcal{R}^2\}$  with this property is called isotropic, as is the associated covariance or semivariogram.

However, real spatial phenomena often show directional effects. Particularly in geologic applications, measurements along a particular direction might be highly correlated, while typically the perpendicular direction shows little or no correlation. Such processes are called anisotropic; see, for example, Journel and Huijbregts (1978, section III.B.4).

When the correlation structure varies across different directions, you need different models for each direction so that you can account correctly for the continuity within the SRF. The following subsections describe how techniques are applied to override the anisotropy effects for computational purposes. First, characteristics of anisotropy are examined.

The semivariogram sill is a measure of the process variability; hence the direction of the highest continuity is perpendicular to the direction where the highest sill occurs. If the sill is the same in all directions, then the direction with the highest range indicates highest continuity. The directions in which the spatial process  $\{Z(\mathbf{s}), \mathbf{s} \in D\}$  is most and least correlated are called the *major* and *minor* axis of anisotropy, respectively.

In some cases, these directions are known a priori. This can occur in mining applications where the geology of a region is known in advance. In most cases however, nothing is known about possible anisotropy. Depending on the amount of data available, using several directions is usually sufficient to determine the presence of anisotropy and to find the approximate major and minor axis directions; see the discussion in the section “Anisotropy” on page 8616 in the VARIOGRAM procedure documentation. You can find a detailed example of anisotropy investigation in the section “[Example 102.2: An Anisotropic Case Study with Surface Trend in the Data](#)” on page 8658 in the VARIOGRAM procedure documentation.

After you explore an anisotropic process and you identify the minor and major axis directions, you can compute the *anisotropy factor* parameter  $R$  which is defined as

$$R = \frac{a_0^{min}}{a_0^{max}}$$

where  $a_0^{min}$  is the semivariogram range in the direction of the minor axis and  $a_0^{max}$  is the semivariogram range in the direction of the major axis.

There are two types of anisotropy, depending on which semivariogram characteristics change in different directions. These types are the *geometric* and the *zonal* anisotropy, and either or both can be present. Both are examined in detail in the following subsections.

## Geometric Anisotropy

Geometric anisotropy is the simplest type of anisotropy. It occurs when the same sill (or scale) parameter  $c_0$  is present in all directions but the range  $a_0$  changes with direction. In geometric anisotropy the covariance model uses the same forms in all directions.

Therefore, geometric anisotropy features one single sill value, and depending on the direction the semivariogram reaches the sill within a different distance. This is illustrated in Figure 49.12, where an anisotropic exponential semivariogram is plotted. Assume that the two curves displayed in this figure have the same sill  $c_0 = 1.5$  and are generated using the ranges  $a_{0,1} = 3$  in the direction  $\theta_1 = 30^\circ$  (effective range is  $r_{\epsilon,1} = 9$ ) and  $a_{0,2} = 1$  in the direction  $\theta_2 = 120^\circ$  (effective range is  $r_{\epsilon,2} = 3$ ).

As you can see from the figure, the ratio of the shorter to longer range is  $R = 1/3$ . The anisotropy factor  $R$  is the value to use in the `RATIO=` parameter in the `MODEL` statement in PROC KRIGE2D. When you model geometric anisotropy  $R \leq 1$ . In fact, isotropy is a partial case of geometric anisotropy for which  $a_0^{min} = a_0^{max}$  and  $R = 1$ .

**Figure 49.12** Geometric Anisotropy with Major Axis in the Direction  $\theta_1 = 30^\circ$

The values of the `RANGE=` and `ANGLE=` parameters in the `MODEL` statement in PROC KRIGE2D are set based on the major anisotropy axis characteristics. Specifically, the `RANGE=` parameter is the value of the major axis range  $a_0^{max} = a_{0,1}$ , and the `ANGLE=` parameter is the angle  $\theta_1$  of the major axis measured clockwise from north (angles measured in this way are also known as *azimuths*). You can then specify the following `MODEL` statement in PROC KRIGE2D to approximate the covariance structure:

```
model form=exp range=3 scale=1.5 angle=30 ratio=0.3333;
```

If you use a nested model, provide the type for each one of the nested structures with the `FORM=` option, and assign the individual `SCALE=` parameters so that they add up to the total sill (include in the sum the nugget effect, if present). In the typical case, all of your nested structures have the same anisotropy axes. This means that you specify the same `ANGLE=` parameter value for all structures. Each structure likely has its own values for the `RANGE=` and `RATIO=` parameters depending on the degree of its contribution to the nested model.

The terminology associated with geometric anisotropy is that of ellipses. To see how this comes about, consider the following hypothetical set of calculations. Let  $\{Z(s), s \in D \subset \mathcal{R}^2\}$  be a geometrically anisotropic process, and assume sufficient data points are present to calculate an experimental semivariogram at a large number of angle classes  $\theta \in \{0, \delta\theta, 2\delta\theta, \dots, 180^\circ\}$ . At each of these angles  $\theta$ , the experimental semivariogram is plotted and the range  $a_0$  is recorded. A diagram in polar coordinates  $(a_0, \theta)$  yields an ellipse with the major axis  $a_0^{max}$  in the direction of the largest  $a_0$  and the minor axis  $a_0^{min}$  perpendicular to it. For the example in Figure 49.12, the ellipse is shown in Figure 49.13(a). Its major axis has size  $a_0^{max}$  situated at angle  $\theta_1$  clockwise from north, and the minor axis has size  $a_0^{min}$  oriented at angle  $\theta_2$  clockwise from north.

The KRIGE2D procedure handles geometric anisotropy by applying a reversible transformation in two steps that converts geometric anisotropy into isotropic conditions.

The first step is to align your coordinates axes with the anisotropy ellipse axes. Specifically, you choose to rotate by an angle  $\varphi$  the standard Cartesian orientation of the  $(x, y)$  coordinates system shown in Figure 49.13(a) so that the Y axis coincides with the ellipse minor axis. The rotation result is illustrated in Figure 49.13(b). The second step is to elongate the minor axis so its length equals that of the major axis of the ellipse. You can see the result in Figure 49.13(c). The computational details are shown in the following.

**Figure 49.13** Transformation Applied to Geometric Anisotropy

The transformation angle  $\varphi$  is measured in standard Cartesian orientation counterclockwise from the X axis (east). If the major axis azimuth is  $\theta_1$ , then the Cartesian system of  $(x, y)$  needs to be rotated by  $\varphi = 90^\circ - \theta_1$  so that the Y axis can coincide with the ellipse minor axis; see Figure 49.13(a).

Let us call the ellipse major axis  $X'$  and the minor axis  $Y'$ . The transformation that converts any coordinates in the  $(x, y)$  system into  $(x', y')$  coordinates in terms of  $\varphi$  is given by the matrix:

$$\mathbf{H} = \begin{pmatrix} \cos(\varphi) & \sin(\varphi) \\ -\sin(\varphi) & \cos(\varphi) \end{pmatrix}$$

The elongation of the minor axis in the second step is performed with the matrix:

$$\mathbf{D}_R = \begin{pmatrix} 1 & 0 \\ 0 & 1/R \end{pmatrix}$$

**NOTE:** These two steps are sequential and their order cannot be reversed. For any point pair  $P_1$  and  $P_2$  with respective coordinates  $\mathbf{s}_1 = (x_1, y_1)$  and  $\mathbf{s}_2 = (x_2, y_2)$  in the  $(x, y)$  axes, their distance is given by

$$|P_i P_j|_{(x,y)} = h = \sqrt{(\delta x)^2 + (\delta y)^2}$$

where the distance components  $\delta x = x_2 - x_1$  and  $\delta y = y_2 - y_1$ . Based on the previous, the corresponding distances  $\delta x'$  and  $\delta y'$  in the  $(x', y')$  coordinates system are given by the vector:

$$\begin{pmatrix} \delta x' \\ \delta y' \end{pmatrix} = \mathbf{D}_R \mathbf{H} \begin{pmatrix} \delta x \\ \delta y \end{pmatrix} = \begin{pmatrix} \cos(\varphi) & \sin(\varphi) \\ -\sin(\varphi)/R & \cos(\varphi)/R \end{pmatrix} \begin{pmatrix} \delta x \\ \delta y \end{pmatrix}$$

The transformed interpair distance is then:

$$|P_i P_j|_{(x',y')} = h' = \sqrt{(\delta x')^2 + (\delta y')^2}$$

As a result, the original anisotropic semivariogram in Figure 49.12 that was a function  $\gamma(\mathbf{h}) = \gamma(h, \theta)$  of both  $h$  and  $\theta$  is then transformed to an equivalent function  $\hat{\gamma}(h')$  only of  $h'$ :

$$\hat{\gamma}(h') = \gamma(\mathbf{h})$$

This single isotropic semivariogram  $\hat{\gamma}(h')$  is then used for kriging purposes.

The two steps used by PROC KRIGE2D in the previous analysis can also be performed in a different manner. For instance, you might equivalently choose to rotate the  $(x, y)$  Cartesian coordinates so that the  $Y$  axis coincides with the ellipse major axis, rather than with the minor axis as was shown earlier. Also, you might prefer to compress the major axis rather than elongating the short one. In any case, you need to perform the appropriate computations for the transformation of your choice.

## Zonal Anisotropy

In zonal anisotropy, the sill (or scale) parameter  $c_0$  is different for different directions. It is not possible to transform such a structure into an isotropic semivariogram. Instead, nesting and geometric anisotropy are used together to approximate zonal anisotropy.

When the scale varies with direction, the lowest scale (that is, the lowest variance) naturally corresponds to the maximum continuity direction. The same direction has the longest range, as also discussed in the section “Geometric Anisotropy” on page 3833.

A varying scale with direction can be interpreted as having one or more model components whose individual contributions to the total variance differ with direction. For each such component, its contribution (scale) ranges between zero and a maximum value. This makes it unlikely that you can describe a natural process with a pure zonal model, because doing so would imply zero continuity in the direction of zero contribution; see also Chilès and Delfiner (1999, p. 96).

In a simple case of zonal anisotropy, a model includes one zonal component. The zonal component makes its highest contribution in a direction perpendicular to the maximum continuity direction, and it contributes zero to the maximum continuity direction. This is necessary; otherwise, there would be a direction with a total scale less than the scale in the maximum continuity direction. Following a similar reasoning, the zonal component's direction of maximum contribution cannot coincide with the one of maximum continuity. In the general case, there can be multiple zonal components, each making its highest contribution in a different direction.

The following describes how to deal with zonal anisotropy in your analysis; see also Goovaerts (1997, p. 96) and Deutsch and Journel (1992, pp. 27–32). If you start with an empirical semivariogram, you can investigate zonal anisotropy by identifying whether a maximum and a minimum scale exist in two specific directions. If they exist, typically these two directions might be perpendicular. Then proceed to identify the zonal component that causes the difference in scale by fitting the empirical semivariogram. You represent zonal component as an additional nested structure in the direction of maximum total scale.

If the minimum and maximum sills are not in perpendicular directions, then you might be seeing the combined effects of multiple zonal components in different directions. In that case you might be able to approximate the continuity behavior by assuming a single zonal component in the direction that is perpendicular to the one of maximum continuity. Alternatively, you might decide to investigate a more elaborate configuration for the model components. In this case, you need to maintain a geometrical anisotropy part across all directions and add zonal components in an appropriate way to match your empirical semivariance in different directions.

After you have a theoretical semivariance model with zonal anisotropy, the next step is to include zonal components in your prediction or simulation analysis. In PROC KRIGE2D you can specify zonal components either explicitly or with the use of results previously saved in item stores produced by the VARIOGRAM procedure.

Specifying a zonal component explicitly in the **MODEL** statement has the following implications:

- The **RANGE=** parameter for the zonal component refers to the range value in the direction of maximum zonal contribution, unlike the case of ranges specified for nonzonal components that refer to the direction of maximum continuity.
- The anisotropy factor  $R$  in the **RATIO=** parameter for the zonal component should be specified as a large positive value to designate zero contribution in the perpendicular direction.

To explain the previous point, remember that  $R$  is defined as  $R = a_0^{min}/a_0^{max}$ . Its value specifies how much to elongate the minor anisotropy axis to make it equal to the major anisotropy axis, in order to transform geometric anisotropy into isotropy. Intuitively, an infinite  $R$  value makes it impossible for the minor axis to become as large as the major axis. This is equivalent to having a very large major anisotropy axis; hence, it indicates a very large range across the major axis direction. Indeed, you can consider a zero zonal contribution in the major anisotropy axis as a very large range of the zonal component along this direction. The particular range is so large that the zonal component practically never reaches its scale along this direction, and this is interpreted as zero contribution.

In the case where you specify zonal anisotropy by using the contents of an item store, you only need to specify the geometric anisotropy components in the `SSEL(MODEL=)` option, and the zonal components as suboptions of the `SSEL(TYPE=ANIZON)` option. Then, the KRIGE2D or SIM2D procedure checks whether the item store contains models that are suitable to use, based on your specifications.

The following two examples illustrate different instances of zonal anisotropy and how to specify the corresponding covariance model parameters in PROC KRIGE2D.

### Example 1

The first example shows that if you can model the direction with the highest sill as a nested model, then you can treat the case as a composition of geometric anisotropy and an additional structure that acts only in the direction of the increased sill.

Consider a spatial process in which the fitting of theoretical models in your experimental semivariogram produces a correlation structure like the one shown in Figure 49.14. In the direction  $\theta_1 = 40^\circ$ , the covariance model has a single exponential structure  $\gamma_1(\mathbf{h}) = \text{Exp}(a_{0,1E}, c_{0,1E})$  with range  $a_{0,1E} = 2$  and sill  $c_{0,1E} = 1.5$ . In the direction  $\theta_2 = 130^\circ$ , the covariance model  $\gamma_2(\mathbf{h}) = \text{Exp}(a_{0,2E}, c_{0,2E}) + \text{Sph}(a_{0,2S}, c_{0,2S})$  has two nested structures: an exponential structure with range  $a_{0,2E} = 0.5$  and sill  $c_{0,2E} = 1.5$  and a spherical structure with range  $a_{0,2S} = 1$  and sill  $c_{0,2S} = 0.5$ .

Figure 49.14 Zonal Anisotropy in Two Directions

The total sill in the direction  $\theta_2$  of highest variance is the sum of the nested structures' sills  $c_{0,2E} + c_{0,2S} = 2$ . You can consider that your process is characterized by a geometrically anisotropic exponential structure with common sill  $c_{0,E} = 1.5$  across all directions and major axis range  $a_{0,1E} = 2$ , and by a spherical structure which is a zonal anisotropy component that contributes only in the  $\theta_2$  direction. Based on the remarks in this section, the `RATIO=` parameter for the exponential structure is  $R_E = 0.5/2 = 0.25$ , whereas for the spherical structure you choose a large value, such as  $R_S = 10^8$ .

Then, you can approximate this structure in PROC KRIGE2D by specifying the two structures with the following `MODEL` statement:

```

model form=(exp,sph) range=(2,1) scale=(1.5,0.5)
 angle=(40,130) ratio=(0.25,1e8);

```

You can handle more elaborate cases in a similar way, where the covariance models in different directions might all be nested models. Your goal is to model the continuity by starting with a sum of isotropic or geometrically anisotropic structures whose total sill is the lowest sill in all directions. Then, in each of the directions with higher sills you add a zonal anisotropy component to the corresponding sum to compensate for the increased variability in that direction.

### Example 2

The second example provides important perspective about the physics of zonal anisotropy analysis. It is an extreme case of the general guidelines for zonal anisotropy. You examine what happens when each of the directions is modeled with a single-form, non-nested model, and the sills for these models are clearly different.

Consider a spatial process with a continuity description almost identical to the one in the previous example. In the direction  $\theta_1 = 40^\circ$ , the covariance model has again a single exponential structure  $\gamma_1(\mathbf{h}) = \text{Exp}(a_{0,1E}, c_{0,1E})$  with range  $a_{0,1E} = 2$  and sill  $c_{0,1E} = 1.5$ . However, this time in the direction  $\theta_2 = 130^\circ$  you have fit the experimental semivariogram by using a single exponential structure  $\gamma_2(\mathbf{h}) = \text{Exp}(a_{0,2E}, c_{0,2E})$  with range  $a_{0,2E} = 1$  and sill  $c_{0,2E} = 2$ . These models are shown in Figure 49.15.

Figure 49.15 Zonal Anisotropy in Two Directions

In this case you have a simplified situation with a single covariance structure in each direction, and the two structures have different scale parameter values. This is a case of zonal anisotropy in which all directions have no shared component. Hence, you have a case with two pure zonal components, where both structures can be practically approximated by specifying two models with large **RATIO=** values. You could then use the following **MODEL** statement in PROC KRIGE2D to describe the covariance in this example:

```
model form=(exp,exp) range=(2,1) scale=(1.5,2)
 angle=(40,130) ratio=(1e8,1e8);
```

The semivariogram of the specified model is accurately shown in Figure 49.15, because the angles  $\theta_1$  and  $\theta_2$  are perpendicular and each component has a contribution to all directions except for the one that is perpendicular to its angle. In the general case,  $\theta_1$  and  $\theta_2$  might not be perpendicular; hence the maximum and minimum scale values can be different from those displayed in Figure 49.15.

In general, avoid configurations with pure zonal components. Correlation models with pure zonal components might imply zero continuity along some direction, which is a very unlikely occurrence in natural processes. For that reason, in similar cases try to use the analysis illustrated in the previous example. In particular, try to model the highest sill direction as a nested structure (such that it contains a geometrical anisotropy component whose cumulative sill is equal to the lower sill) and a zonal anisotropy component that accounts for the sill difference.

### Anisotropic Nugget Effect

Isotropic nugget effects can be approximated with nested models, where one of the nested structures has a very small range. Applying a geometric anisotropy specification to this nested structure results in an anisotropic nugget effect.

---

## Details of Ordinary Kriging

### Introduction

Three common characteristics are often observed with spatial data (that is, data indexed by their spatial locations):

- (i) slowly varying, large-scale variations in the measured values
- (ii) irregular, small-scale variations
- (iii) similarity of measurements at locations close together

As an illustration, consider a hypothetical example in which an organic solvent leaks from an industrial site and spreads over a large area. Assume the solvent is absorbed and immobilized into the subsoil above any groundwater level, so you can ignore any time dependence.

To find the areal extent and the concentration values of the solvent, you need measurements. Although the problem is inherently three-dimensional, if you measure total concentration in a column of soil or take a depth-averaged concentration, it can be handled reasonably well with two-dimensional techniques.

You usually assume that measured concentrations are higher closer to the source and decrease at larger distances from the source. On top of this smooth variation, measured concentrations typically have small-scale variations, due perhaps to the inherent variability of soil properties.

You also tend to suspect that measurements made close together yield similar concentration values, while measurements made far apart can have very different values.

These physically reasonable qualitative statements have no explicit probabilistic content. A number of numerical smoothing techniques, such as inverse distance weighting and splines, make use of large-scale variations and “close distance-close value” characteristics of spatial data to interpolate the measured concentrations for contouring purposes.

While characteristics (i) and (iii) are handled by such smoothing methods, characteristic (ii), the small-scale residual variation in the concentration field, is not accounted for.

There can be situations, due to the use of the prediction map or the relative magnitude of the irregular fluctuations, where you cannot ignore these small-scale irregular fluctuations. In other words, the smoothed or predicted values of the concentration field alone are not a sufficient characterization; you also need the possible spread around these contoured values.

## Spatial Random Fields

One method of incorporating characteristic (ii) into the construction of a contour map is to model the concentration field as a spatial random field (SRF). The mathematical details of SRF models are given in a number of texts, such as Cressie (1993) and Christakos (1992). The mathematics of SRFs is formidable. However, under certain simplifying assumptions, it produces classical linear predictors with very simple properties, enabling easy implementation for prediction purposes. These predictors, primarily ordinary kriging (OK), give both a prediction and a standard error of prediction at unsampled locations. This allows the construction of a map of both predicted values and level of uncertainty about the predicted values.

The key assumption in applying the SRF formalism is that the measurements come from a single realization of the SRF. However, in most geostatistical applications, the focus is on a single, unique realization. This is unlike most other situations in stochastic modeling in which there will be future experiments or observational activities (at least conceptually) under similar circumstances. This renders many traditional ideas of statistical inference ambiguous and somewhat counterintuitive.

Additional logical and methodological problems could stand in the way of applying a stochastic model to a unique but partly unknown natural process; see the introduction in Matheron (1971) and Cressie (1993, section 2.3). These difficulties have resulted in attempts to frame the prediction problem in a completely deterministic way (Isaaks and Srivastava 1988; Journel 1985). Also, some issues with kriging, and with spatial prediction methods in general, are related to the necessary assumption of ergodicity of the spatial process. This assumption is required to estimate the covariance or semivariogram from sample data. Details are provided in Cressie (1993, pp. 52–58).

Despite these difficulties, ordinary kriging remains a popular and widely used tool in modeling spatial data, especially in generating surface plots and contour maps. An abbreviated derivation of the OK predictor for point prediction and the associated standard error is discussed in the following section. Full details are given in Journel and Huijbregts (1978); Christakos (1992); Cressie (1993).

## Ordinary Kriging

Denote the SRF by  $Z(\mathbf{s})$ ,  $\mathbf{s} \in D \subset \mathcal{R}^2$ . Following the notation in Cressie (1993), the following model for  $Z(\mathbf{s})$  is assumed:

$$Z(\mathbf{s}) = \mu + \varepsilon(\mathbf{s})$$

Here,  $\mu$  is the fixed, unknown mean of the process, and  $\varepsilon(\mathbf{s})$  is a zero mean SRF, which represents the variation around the mean.

In most practical applications, an additional assumption is required in order to estimate the covariance  $C_z$  of the  $Z(\mathbf{s})$  process. This assumption is second-order stationarity:

$$C_z(\mathbf{s}_1, \mathbf{s}_2) = E[\varepsilon(\mathbf{s}_1)\varepsilon(\mathbf{s}_2)] = C_z(\mathbf{s}_1 - \mathbf{s}_2) = C_z(\mathbf{h})$$

This requirement can be relaxed slightly when you are using the semivariogram instead of the covariance. In this case, second-order stationarity is required of the differences  $\varepsilon(\mathbf{s}_1) - \varepsilon(\mathbf{s}_2)$  rather than  $\varepsilon(\mathbf{s})$ :

$$\gamma_z(\mathbf{s}_1, \mathbf{s}_2) = \frac{1}{2}E[(\varepsilon(\mathbf{s}_1) - \varepsilon(\mathbf{s}_2))^2] = \gamma_z(\mathbf{s}_1 - \mathbf{s}_2) = \gamma_z(\mathbf{h})$$

By performing local kriging, the spatial processes represented by the previous equation for  $Z(\mathbf{s})$  are more general than they appear. In local kriging, at an unsampled location  $\mathbf{s}_0$ , a separate model is fit using only data in a neighborhood of  $\mathbf{s}_0$ . This has the effect of fitting a separate mean  $\mu$  at each point, and it is similar to the *kriging with trend* (KT) method discussed in Journel and Rossi (1989).

Given the  $N$  measurements  $Z(\mathbf{s}_1), \dots, Z(\mathbf{s}_N)$  at known locations  $\mathbf{s}_1, \dots, \mathbf{s}_N$ , you want to obtain a prediction of  $Z$  at an unsampled location  $\mathbf{s}_0$ . When the following three requirements are imposed on the predictor  $\hat{Z}$ , the OK predictor is obtained:

- (i)  $\hat{Z}$  is linear in  $Z(\mathbf{s}_1), \dots, Z(\mathbf{s}_N)$
- (ii)  $\hat{Z}$  is unbiased
- (iii)  $\hat{Z}$  minimizes the mean square prediction error  $E[(Z(\mathbf{s}_0) - \hat{Z}(\mathbf{s}_0))^2]$

Linearity requires the following form for  $\hat{Z}(\mathbf{s}_0)$ :

$$\hat{Z}(\mathbf{s}_0) = \sum_{i=1}^N \lambda_i Z(\mathbf{s}_i)$$

Applying the unbiasedness condition to the preceding equation yields

$$E[\hat{Z}(\mathbf{s}_0)] = \mu \Rightarrow \sum_{i=1}^N \lambda_i E[Z(\mathbf{s}_i)] = \mu \Rightarrow \sum_{i=1}^N \lambda_i \mu = \mu \Rightarrow \sum_{i=1}^N \lambda_i = 1$$

Finally, the third condition requires a constrained linear optimization that involves  $\lambda_1, \dots, \lambda_N$  and a Lagrange parameter  $2m$ . This constrained linear optimization can be expressed in terms of the function  $L(\lambda_1, \dots, \lambda_N, m)$  given by

$$L = E \left[ \left( Z(\mathbf{s}_0) - \sum_{i=1}^N \lambda_i Z(\mathbf{s}_i) \right)^2 \right] - 2m \left( \sum_{i=1}^N \lambda_i - 1 \right)$$

Define the  $N \times 1$  column vector  $\boldsymbol{\lambda}$  by

$$\boldsymbol{\lambda} = (\lambda_1, \dots, \lambda_N)'$$

and the  $(N + 1) \times 1$  column vector  $\lambda_0$  by

$$\lambda_0 = (\lambda_1, \dots, \lambda_N, m)' = \begin{pmatrix} \lambda \\ m \end{pmatrix}$$

The optimization is performed by solving

$$\frac{\partial L}{\partial \lambda_0} = \mathbf{0}$$

in terms of  $\lambda_1, \dots, \lambda_N$  and  $m$ .

The resulting matrix equation can be expressed in terms of either the covariance  $C_z(\mathbf{h})$  or semivariogram  $\gamma_z(\mathbf{h})$ . In terms of the covariance, the preceding equation results in the matrix equation

$$\mathbf{C}\lambda_0 = \mathbf{C}_0$$

where

$$\mathbf{C} = \begin{pmatrix} C_z(\mathbf{0}) & C_z(s_1 - s_2) & \cdots & C_z(s_1 - s_N) & 1 \\ C_z(s_2 - s_1) & C_z(\mathbf{0}) & \cdots & C_z(s_2 - s_N) & 1 \\ & & \ddots & & \\ C_z(s_N - s_1) & C_z(s_N - s_2) & \cdots & C_z(\mathbf{0}) & 1 \\ 1 & 1 & \cdots & 1 & 0 \end{pmatrix}$$

and

$$\mathbf{C}_0 = \begin{pmatrix} C_z(s_0 - s_1) \\ C_z(s_0 - s_2) \\ \vdots \\ C_z(s_0 - s_N) \\ 1 \end{pmatrix}$$

The solution to the previous matrix equation is

$$\hat{\lambda}_0 = \mathbf{C}^{-1}\mathbf{C}_0$$

Using this solution for  $\lambda$  and  $m$ , the ordinary kriging prediction at  $r_0$  is

$$\hat{Z}(s_0) = \lambda_1 Z(s_1) + \cdots + \lambda_N Z(s_N)$$

with associated prediction error the square root of the variance

$$\sigma_z^2(s_0) = C_z(\mathbf{0}) - \lambda' \mathbf{c}_0 + m$$

where  $\mathbf{c}_0$  is  $\mathbf{C}_0$  with the 1 in the last row removed, making it an  $N \times 1$  vector.

These formulas are used in the best linear unbiased prediction (BLUP) of random variables (Robinson 1991). Further details are provided in Cressie (1993, pp. 119–123).

Because of possible numeric problems when solving the previous matrix equation, Deutsch and Journel (1992) suggest replacing the last row and column of 1s in the preceding matrix  $\mathbf{C}$  by  $C_z(0)$ , keeping the 0 in the  $(N + 1, N + 1)$  position and similarly replacing the last element in the preceding right-hand vector  $\mathbf{C}_0$  with  $C_z(0)$ . This results in an equivalent system but avoids numeric problems when  $C_z(0)$  is large or small relative to 1.

---

## Computational Resources

To generate a predicted value at a single grid point by using  $N$  data points, PROC KRIGE2D must solve the kriging system

$$C\lambda_0 = C_0$$

where the dimensions of  $C$  are  $(N + 1) \times (N + 1)$  and the right-hand-side  $C_0$  has one column.

Holding the matrix and vector associated with this system in core requires approximately  $8N^2/2$  bytes. The CPU time used in solving the system is proportional to  $N^3$ . For large  $N$ , this time dominates the  $O(N^2)$  time to compute the elements of the covariance matrix  $C$  from the specified covariance or semivariogram model.

For local kriging, the kriging system is set up and solved for each grid point. Part of the setup process involves determining the neighborhood of each grid point. A fast K-D tree algorithm determines neighborhoods. For  $G$  grid points, the dominant CPU time factor is setting up and solving the  $G$  kriging systems. The  $N$  in the algorithm of the section “[Ordinary Kriging](#)” on page 3840 is the number of data points in a given neighborhood, and it can differ for each grid point.

In global kriging, the entire input data set and all grid points set up and solve the single system

$$C\lambda_0 = C_0$$

Again  $C$  has dimensions  $(N + 1) \times (N + 1)$ , but  $\lambda_0$  and  $C_0$  now have  $G$  columns, where  $G$  is the number of grid points. Memory requirements are approximately  $8[(N^2/2) + GN]$  bytes. The CPU time used in solving the system is still dominated by the  $N^3$  factorization of the left-hand side.

---

## Output Data Sets

The KRIGE2D procedure produces two data sets: the `OUTEST=SAS-data-set` and the `OUTNBHD=SAS-data-set`. These data sets are described as follows.

### **OUTEST=SAS-data-set**

The `OUTEST=` data set contains the kriging predictions and the associated standard errors. The `OUTEST=` data set contains the following variables:

- ESTIMATE, which is the kriging prediction for the current variable.
- GXC, which is the  $x$  coordinate of the grid point at which the kriging prediction is made.
- GYC, which is the  $y$  coordinate of the grid point at which the kriging prediction is made.
- LABEL, which is the label for the current `PREDICT/MODEL` combination that produces the kriging prediction. If you do not specify a label, default labels of the form `Predj.Modelk` are used.
- NPOINTS, which is the number of points used in the prediction. This number varies for each grid point if local kriging is performed.

- STDERR, which is the standard error of the kriging predict.
- VARNAME, which is the variable name.

### OUTNBHD=SAS-data-set

When you specify the **RADIUS=** option or the **NUMPOINTS=** option in the **PREDICT** statement, local kriging is performed. Local kriging is simply ordinary kriging at a given grid location, using only those data points in a neighborhood defined by the **RADIUS=** value or the **NUMPOINTS=** value.

The **OUTNBHD=** data set contains one observation for each data point in each neighborhood. Hence, this data set can be large. For example, if the grid specification results in 1,000 grid points and each grid point has a neighborhood of 100 points, the resulting **OUTNBHD=** data set contains 100,000 points.

The **OUTNBHD=** data set contains the following variables:

- **GXC**, which is the  $x$  coordinate of the grid point.
- **GYC**, which is the  $y$  coordinate of the grid point.
- **ID**, which is the ID variable value or observation. number of the current data point
- **LABEL**, which is the label for the current **PREDICT/MODEL** combination. If you do not specify a label, default labels of the form *Predj.Modelk* are used.
- **NPOINTS**, which is the number of points used in the prediction.
- **RADIUS**, which is the radius used for each neighborhood.
- **VALUE**, which is the value of the variable at the current data point.
- **VARNAME**, which is the variable name of the current variable.
- **XC**, which is the  $x$  coordinate of the current data point.
- **YC**, which is the  $y$  coordinate of the current data point.

If no **ID** statement is specified, then the corresponding observation number is assigned to the variable **ID**, instead.

---

## Displayed Output

In addition to the output data sets, the **KRIGE2D** procedure produces output objects as well. The **KRIGE2D** procedure output objects are the following:

- a default “Number of Observations” table that displays the number of observations read from the input data set and the number of observations used in the analysis.
- a map that shows the spatial distribution of the observations of the current **VAR=** variable in the **PREDICT** statement. The observations are displayed by default with circled markers whose color indicates the **VAR=** value at the corresponding location.

- a default table for each **PREDICT** statement that sums up basic information about the kriging analysis.
- a default table for each **MODEL** statement that shows the covariance model parameters for the corresponding **PREDICT** statement.
- plots of the kriging prediction and the prediction standard error at each point of the specified output grid or at specified individual locations. The **KRIGE2D** procedure produces by default a plot of the kriging prediction and the corresponding prediction error for each **MODEL** statement of every **PREDICT** statement that you specify. You can produce more of these plots with styles that you can specify by using the available suboptions of the **PLOTS=PREDICTION** option.
- a “Store Info” table with basic information about the input item store. This table is produced by default when you specify the **RESTORE** statement.
- a “Store Variables Information” table that describes the analysis variables of an input item store. The table is produced by default when you specify an item store with the **RESTORE** statement.
- a “Store Models Information” table with detailed information about the models and direction angles that are contained in an input item store. The table is produced by default when you specify an item store with the **RESTORE** statement.

---

## ODS Table Names

Each table created by PROC KRIGE2D has a name associated with it, and you must use this name to reference the table when using ODS Graphics. These names are listed in [Table 49.4](#).

**Table 49.4** ODS Tables Produced by PROC KRIGE2D

| ODS Table Name                 | Description                                                         | Statement | Option         |
|--------------------------------|---------------------------------------------------------------------|-----------|----------------|
| <a href="#">KrigInfo</a>       | Kriging analysis general information                                | PROC      | Default output |
| <a href="#">ModelInfo</a>      | Parameters of the covariance model used in current kriging analysis | PROC      | Default output |
| <a href="#">NObs</a>           | Number of observations read and used                                | PROC      | Default output |
| <a href="#">StoreInfo</a>      | Input item store identity information                               | RESTORE   | Default output |
| <a href="#">StoreModelInfo</a> | Input item direction angles and models information                  | RESTORE   | INFO           |
| <a href="#">StoreVarInfo</a>   | Input item store variables and their statistics                     | RESTORE   | INFO           |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the **ODS GRAPHICS ON** statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

For additional control of the graphics that are displayed, see the PLOTS option in the section “PROC KRIGE2D Statement” on page 3801.

## ODS Graph Names

PROC KRIGE2D assigns a name to each graph it creates by using ODS Graphics. You can use these names to reference the graphs when using ODS Graphics. You must also specify the PLOTS= option indicated in Table 49.5.

**Table 49.5** Graphs Produced by PROC KRIGE2D

| ODS Graph Name   | Plot Description                                                                                                    | Statement | Option           |
|------------------|---------------------------------------------------------------------------------------------------------------------|-----------|------------------|
| ObservationsPlot | Scatter plot of observed data and colored markers indicating observed values                                        | PROC      | PLOTS=OBSERV     |
| PredictionPlot   | Contour plots of the kriging prediction, surface of the prediction error, and outlines of the observation locations | PROC      | PLOTS=PREDICTION |
| Semivariogram    | Plots of the semivariogram models used for all prediction tasks                                                     | PROC      | PLOTS=SEMIVAR    |

## Examples: KRIGE2D Procedure

### Example 49.1: Spatial Prediction of Pollutant Concentration

The example in the section “Example 102.1: Aspects of Semivariogram Model Fitting” on page 8648 in the VARIOGRAM procedure investigates fitting of a theoretical model to describe spatial correlation in a study of 138 simulated arsenic logarithm concentration ( $\log As$ ) observations. These observations form the `logAsData` data set, which is treated as actual data for illustration in the examples.

In this example, you use the `logAsData` data set and the semivariogram analysis results to predict the `logAs` variable values across space in a specified square region of size 500 km  $\times$  500 km. Your goal is to answer scientific questions in your analysis by means of your prediction results. This application highlights the impact of the correlation model choice on predictions. The example in section “Example 49.2: Investigating the Effect of Model Specification on Spatial Prediction” on page 3856 examines additional aspects of this impact.

The World Health Organization (WHO) standard for maximum arsenic concentration in drinking water is 10  $\mu\text{g}/\text{lt}$ . Assume that you want to answer the following question: In what percentage of the study area does the Arsenic concentration exceed the WHO regulatory standard?

First, you read the `logAsData` data set with the following DATA step:

```

title 'Spatial Prediction of Log-Arsenic Concentration';

data logAsData;
 input East North logAs @@;
 label logAs='log(As) Concentration';

;

```

For prediction of the logAs values in the specified area, assume a rectangular grid of nodes with an equal spacing of 5 km between neighboring nodes in the north and east directions. This produces a total of  $101 \times 101 = 10201$  prediction locations.

In the section “[Example 102.1: Aspects of Semivariogram Model Fitting](#)” on page 8648 in the VARIOGRAM procedure, you saved the selected fitted model that resulted from the correlation analysis into the SemivAsStore item store as shown in the following statements:

```
ods graphics on;

proc variogram data=logAsData plots=none;
 store out=SemivAsStore / label='LogAs Concentration Models';
 compute lagd=5 maxlag=40;
 coord xc=East yc=North;
 model form=auto (mlist=(exp,gau,mat) nest=1 to 2);
 var logAs;
run;
```

In the KRIGE2D procedure you specify the name of the item store you want to use for prediction input in the **IN=** option of the **RESTORE** statement. You request use of the selected model for prediction by specifying the **STORESELECT** option in the **MODEL** statement.

The **INFO** option of the **RESTORE** statement produces a table with information about the selected fitted model in the item store. To review all models in the input item store, specify the two **INFO** option suboptions. In particular, specify the **DET** suboption to request details about all additional fitted models that are included in the item store and the **ONLY** suboption to suppress prediction and produce only the tables about the item store, as shown in the following statements:

```
proc krige2d data=logAsData outest=pred plots=none;
 restore in=SemivAsStore / info(det only);
 coordinates xc=East yc=North;
 predict var=logAs;
 model storeselect;
 grid x=0 to 500 by 5 y=0 to 500 by 5;
run;
```

PROC KRIGE2D produces a table with general information about the input item store identity, as shown in [Output 49.1.1](#).

**Output 49.1.1** PROC KRIGE2D and Input Item Store General Information

| Spatial Prediction of Log-Arsenic Concentration |                            |
|-------------------------------------------------|----------------------------|
| The KRIGE2D Procedure                           |                            |
| Correlation Model Item Store Information        |                            |
| Input Item Store                                | WORK.SEMIVASSTORE          |
| Item Store Label                                | LogAs Concentration Models |
| Data Set Created From                           | WORK.LOGASDATA             |
| By-group Information                            | No By-groups Present       |
| Created By                                      | PROC VARIOGRAM             |
| Date Created                                    | 07JUN12:11:31:33           |

The second table in [Output 49.1.2](#) itemizes the variables in the item store and displays the sample mean and standard deviation of their data set of origin. Hence, the values shown in [Output 49.1.2](#) refer to the observations in the logAsData data set.

**Output 49.1.2** Variables in the Input Item Store

| Item Store Variables |          |               |
|----------------------|----------|---------------|
| Variable             | Mean     | Std Deviation |
| logAs                | 0.084309 | 1.527707      |

The table in [Output 49.1.3](#) presents all the correlation models fitted to the arsenic logarithm logAs empirical semivariance that are saved in the SemivAsStore item store.

**Output 49.1.3** Angle and Models Information in the Input Item Store

| Item Store Models For logAs |         |
|-----------------------------|---------|
| Class                       | Model   |
| 1                           | Gau-Gau |
|                             | Gau-Mat |
| 2                           | Exp-Gau |
| 3                           | Exp-Mat |
| 4                           | Mat     |
| 5                           | Gau     |
| 6                           | Exp     |
|                             | Exp-Exp |
|                             | Mat-Exp |
|                             | Gau-Exp |

According to [Output 49.1.3](#), the Gaussian-Gaussian model is the selected model for the empirical semivariance fit based on the specific weighted least squares fit and ranking criteria. In the section “[Example 102.1: Aspects of Semivariogram Model Fitting](#)” on page 8648 in the VARIOGRAM procedure, it is noted that all fitted models in the first five equivalence classes produce very similar semivariograms, and this is likely to lead to similar results in prediction analysis. For comparison purposes, you choose to examine the selected model, in addition to the exponential model in the SemivAsStore item store. As shown in [Output 49.1.3](#), the exponential model is one of the least well-fit models based on the criteria used for the specific fit. You are interested in comparing the predictions from each one of these two models, and you examine their impact on your analysis.

The default item store model selection is the model on top of the list in [Output 49.1.3](#). Hence, you specify the `STORESELECT` option in the `MODEL` statement without any suboptions, and it invokes the Gaussian-Gaussian model from the SemivAsStore item store. You assign the label `SELMODEL` to the corresponding `MODEL` statement.

You also specify a second **MODEL** statement with the label **EXPMODEL** to request prediction based on the exponential correlation form. In this case you specify the **STORESELECT(MODEL=)** option in the **MODEL** statement to request the desired form.

You omit the **INFO** option from the **RESTORE** statement. You specify the **PRED** and the **SEMIVAR** options in the **PLOTS** option of the **PROC KRIGE2D** statement to produce plots of the predicted values and the semivariance model, respectively, for each **MODEL** statement. You request that the prediction output be saved in the **Pred** output data set.

You satisfy the preceding requests by specifying the following statements:

```
proc krige2d data=logAsData outest=Pred plots(only)=(pred semivar);
 restore in=SemivAsStore;
 coordinates xc=East yc=North;
 predict var=logAs;
 SelModel: model storeselect;
 ExpModel: model storeselect(model=exp);
 grid x=0 to 500 by 5 y=0 to 500 by 5;
run;
```

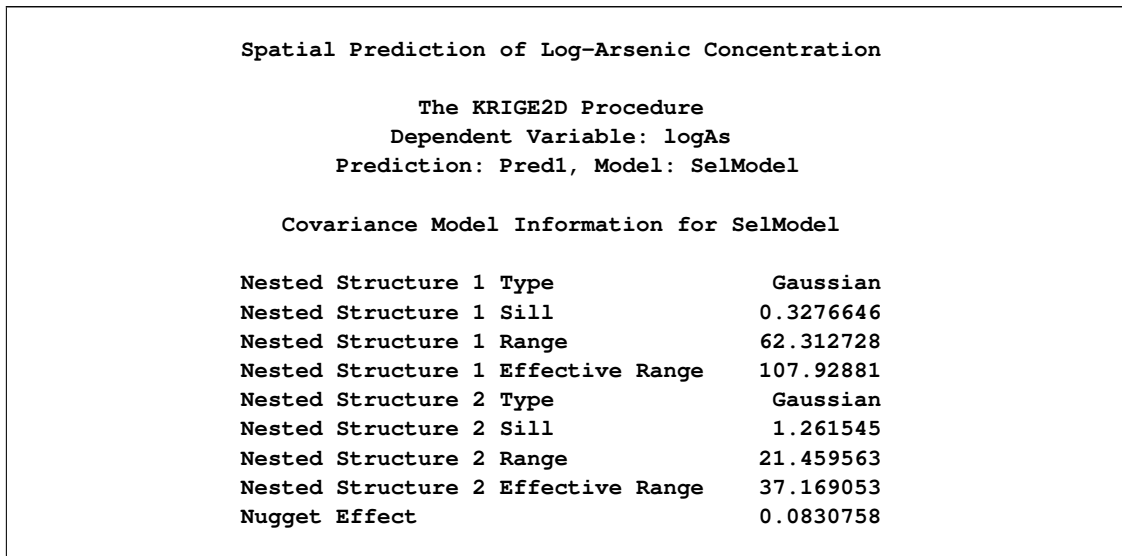

When you run these statements, in addition to the input item store information table, **PROC KRIGE2D** also produces the number of observations table and general kriging process information, as shown in [Output 49.1.4](#).

**Output 49.1.4** Number of Observations and Kriging Information Tables

**PROC KRIGE2D** first uses the Gaussian-Gaussian model. The table in [Output 49.1.5](#) shows the saved parameter values of the fitted Gaussian-Gaussian model in the **SemivAsStore** item store. **PROC KRIGE2D** uses these parameters for the prediction based on the selected model.

**Output 49.1.5** Information about the Gaussian-Gaussian Model

The semivariogram of the Gaussian-Gaussian model with the parameters shown in [Output 49.1.5](#) is depicted in [Output 49.1.6](#).

**Output 49.1.6** Gaussian-Gaussian Semivariogram Model Used in Kriging Predictions

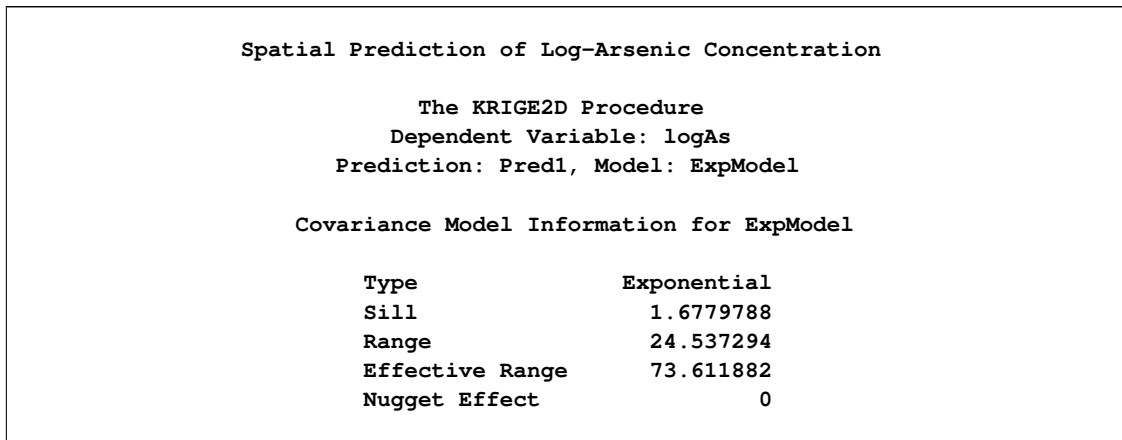

Output 49.1.7 is a map of the kriging prediction of the arsenic concentration values  $\log As$  in the specified domain. The prediction error surface shows a naturally increasing error as you move farther away from the observation locations. Interestingly, kriging predicts a small area of increased arsenic concentration values located in the central-eastern part of the domain. The WHO threshold of  $10 \mu\text{g}/\text{lt}$  for the maximum allowed arsenic concentration in water translates into about 2.3 in the log scale, and the particular area exhibits values in excess of 3. Due to the suggested violation of the WHO standard, this particular area is very likely to be the focus of further environmental risk analysis.

**Output 49.1.7** Predicted Arsenic Logarithm Values with Gaussian-Gaussian Covariance

Next, PROC KRIGE2D performs prediction with the exponential model. The model parameters are also read from the SemivAsStore item store and are shown in Output 49.1.8.

**Output 49.1.8** Information about the Exponential Model

Output 49.1.9 illustrates the semivariogram of the nested exponential model where its parameter values are those shown in Output 49.1.8.

**Output 49.1.9** Exponential Semivariogram Model Used in Kriging Predictions

The prediction plot for the exponential model is shown in [Output 49.1.10](#). Prediction values and spatial patterns are similar overall to those of the Gaussian-Gaussian case. Clearly, although both models predict the same basic characteristics for the arsenic logarithm concentration distribution, the exponential model suggests a more limited spatial variability in closely neighboring locations. The lack of a nugget effect in the exponential model justifies this behavior. Also, the exponential model predictions seem less inclined to deviate farther away from the near-zero mean than the Gaussian-Gaussian model predictions. The prediction error reaches about the same upper values for both models, though its low values are slightly smaller in the exponential model.

**Output 49.1.10** Predicted Arsenic Logarithm Values with Exponential Covariance

In the following two-step computation, you proceed to compute the percentage of the study area where the arsenic concentration exceeds the WHO regulatory standard according to your predictions. First, a DATA step marks the arsenic predicted values in excess of the WHO concentration threshold of  $10 \mu\text{g}/\text{lt}$  and saves the outcome into an indicator variable `OverLimit`. The DATA step input is the prediction `Pred` output data set, where the logarithm arsenic prediction is stored in the estimate variable. The DATA step also transforms the arsenic logarithm values back into arsenic concentration values to compare them to the threshold value. You use the following statements:

```

data AsOverLimit;
 set Pred;
 OverLimit = (exp(estimate) > 10) * 100;
run;

```

The second step uses the MEANS procedure to express the selected nodes population, where the WHO arsenic concentration limit violation occurs, as a percentage of the entire domain area. You study the results of each correlation model separately by specifying the BY statement in the PROC MEANS. The BY variable is the Label variable in the AsOverLimit and Pred data sets. You need to sort the AsOverLimit data prior to using PROC MEANS. You run the following statements:

```

proc sort data=AsOverLimit;
 by Label;
run;
proc means data=AsOverLimit mean;
 var OverLimit;
 by label;
 label Overlimit="Percent above WHO threshold";
run;

ods graphics off;

```

The Gaussian-Gaussian model prediction produces the result in [Output 49.1.11](#). The analysis suggests a minimal occurrence of excessive arsenic concentration in drinking water in about 0.43% of the study region.

#### **Output 49.1.11** Violation of Arsenic Concentration Threshold Using Gaussian-Gaussian Model

```

 Spatial Prediction of Log-Arsenic Concentration
----- Label for the PREDICT/MODEL combination=Pred1.SelModel -----

 The MEANS Procedure

Analysis Variable : OverLimit Percent above WHO threshold

 Mean

 0.4313303

```

The exponential model predicts that the WHO arsenic concentration threshold is exceeded in about 0.27% of the domain, as shown in [Output 49.1.12](#). Although this is still a minimal occurrence of the threshold violation across the region, the exponential model estimates the impact to be at about two thirds of the Gaussian-Gaussian model percentage.

**Output 49.1.12** Violation of Arsenic Concentration Threshold Using Exponential Model

```

 Spatial Prediction of Log-Arsenic Concentration
----- Label for the PREDICT/MODEL combination=Pred1.ExpModel -----
 The MEANS Procedure
 Analysis Variable : OverLimit Percent above WHO threshold

 Mean

 0.2744829

```

The results in [Output 49.1.11](#) and [Output 49.1.12](#) suggest that it might not be possible to provide a unique answer about the area percentage that is affected by increased arsenic concentration. You chose to examine two different correlation models whose performance is relatively similar, and they provide impact estimates that differ by about 37%.

You might conclude that the answer to the initial question about the percentage value lies in the neighborhood of the results given by the two correlation models. Further analysis with more models is necessary to validate this assumption. It is important to note that apart from the continuity model choice, additional factors contribute to this investigation. Such factors could be the use of local instead of global kriging, or even going back to the empirical semivariogram computation stage and repeating the analysis for different possible spatial continuity empirical estimates. A sensible approach to tackle this analysis would be to investigate the range of the impact suggested by all candidate correlation models and to proceed by defining the best and worst case scenarios for the size of the affected area.

Eventually, when it comes to using your findings, it is important to account for the subjective nature of stochastic analysis and multiple possible answers to your questions. In that sense, some scientific questions might be more sensible than others to interpret your results correctly. For instance, you might want to investigate only whether the adversely affected domain percentage is below 1%, rather than attempting to provide a specific value for it. Then, you might consider the preceding findings sufficient, despite any fluctuations in the estimated percentage. In a different scenario, the areas with high pollutant concentration could be populated. Hence, any local health standard violation is probably unacceptable, and it can be crucial that you provide solid and more detailed assessment in that case.

The section “[Example 85.3: Risk Analysis with Simulation](#)” on page 7423 in the SIM2D procedure investigates a different aspect of this study and offers additional perspective about spatial analysis.

---

## **Example 49.2: Investigating the Effect of Model Specification on Spatial Prediction**

It is generally believed that spatial prediction is robust against model specification, while the standard error computation is not so robust. This example investigates the effect of using these different models on the prediction and associated standard errors.

In the section “[Theoretical Semivariogram Model Fitting](#)” on page 8571 in the VARIOGRAM procedure, a particular theoretical semivariogram is fitted to the coal seam thickness data empirical semivariogram. The chosen semivariogram is Gaussian with a scale (sill) of  $c_0 = 7.2881$  and a range of  $a_0 = 30.6239$ .

Another possible model choice could be the spherical semivariogram. First, use a DATA step to input the thickness data:

```

```

Fitting of the Gaussian model is performed in the section “[Theoretical Semivariogram Model Fitting](#)” on page 8571 in the VARIOGRAM procedure, and the fitting parameters are saved in the SemivStoreGau item store with the following statements:

```

ods graphics on;

proc variogram data=thick noprint;
 store out=SemivStoreGau / label='Thickness Gaussian Model';
 compute lagd=7 maxlag=10;
 coord xc=East yc=North;
 model form=gau;
 var Thick;
run;

```

For prediction with the saved Gaussian model, you use the following statements to run the KRIGE2D procedure with input from the SemivStoreGau item store. You invoke the item store with the **RESTORE** statement. The **STORESELECT** option in the **MODEL** statement that specifies that you want to use the selected model in the item store as input for your prediction.

```
proc krige2d data=thick outest=pred1 noprint;
 restore in=SemivStoreGau;
 coordinates xc=East yc=North;
 predict var=Thick r=60;
 model storeselect;
 grid x=0 to 100 by 10 y=0 to 100 by 10;
run;
```

Then, you run the KRIGE2D procedure by using a spherical model. Start by using the VARIOGRAM procedure to fit a spherical model to the thick data set empirical semivariogram. You specify the **STORE** statement again in PROC VARIOGRAM to save the spherical model estimated parameters in an item store with the name SemivStoreSph. You use the following statements:

```
proc variogram data=thick plots(only)=fit;
 store out=SemivStoreSph / label='Thickness Sph Model';
 compute lagd=7 maxlag=10;
 coord xc=East yc=North;
 model form=sph;
 var Thick;
run;
```

The VARIOGRAM procedure fits the spherical model successfully, and the estimated parameters for this fit are shown in [Output 49.2.1](#).

**Output 49.2.1** Spherical Model Fitting Parameter Estimates

| Effect of Model Specification on Prediction |          |                     |    |         |                   |

| Nugget                                      | 0        | 0                   | 8  | .       | .                 |
| Scale                                       | 7.1914   | 0.2827              | 8  | 25.44   | <.0001            |
| Range                                       | 63.2351  | 4.1050              | 8  | 15.40   | <.0001            |

The fit summary is displayed in [Output 49.2.2](#). When compared to the corresponding result in the section “[Theoretical Semivariogram Model Fitting](#)” on page 8571 in the VARIOGRAM procedure, the goodness-of-fit criteria indicate a worse statistical fit for the spherical model compared to the Gaussian.

**Output 49.2.2** Spherical Model Fit Summary

| Fit Summary |              |          |
|-------------|--------------|----------|
| Model       | Weighted SSE | AIC      |
| Sph         | 52.26791     | 23.14336 |

Output 49.2.3 suggests an acceptable fit of the spherical model to the thick data set. Obviously, the fit of the spherical model in the sensitive area near the semivariogram origin is less faithful to the empirical semivariance than the Gaussian model. The following analysis explores the consequence in the kriging prediction of this discrepancy.

**Output 49.2.3** Fitted Spherical and Empirical Thick Semivariogram

For the next step, you run the KRIGE2D procedure by using the spherical model parameters stored in the SemivStoreSph item store. You use the following statements:

```

proc krige2d data=thick outest=pred2 noprint;
 restore in=SemivStoreSph;
 coordinates xc=East yc=North;
 predict var=Thick r=60;
 model storeselect;
 grid x=0 to 100 by 10 y=0 to 100 by 10;
run;

```

Eventually, you compare the prediction results and errors of the two models. You use a DATA step to compute the relative difference of the predicted values and the prediction error for each one of the Gaussian and the spherical models. You store the prediction relative difference in the `prdRelDif` variable and the prediction relative error in the `stdRelDif` variable. You save the output in the `compare` data set with the following statements:

```

data compare;
 merge pred1(rename=(estimate=g_prd stderr=g_std))
 pred2(rename=(estimate=s_prd stderr=s_std));
 prdRelDif = ((g_prd-s_prd) / s_prd) * 100;
 stdRelDif = ((g_std-s_std) / s_std) * 100;
run;

```

The MEANS procedure uses the `compare` data set to produce statistics about the prediction relative difference and error for each one of the `prdRelDif` and `stdRelDif` variables with the following statements:

```

proc means data=compare;
 var prdRelDif stdRelDif;
run;

ods graphics off;

```

Output 49.2.4 shows that on average the predicted values are very close for the two semivariogram models. The mean relative difference in the prediction values is close to zero with a low standard deviation, whereas the relative difference values fluctuate with an absolute maximum of about 5%.

However, note that the mean relative standard error is about -96%. According to the definition of the `stdRelDif` variable, the high negative value indicates that the prediction error difference between the two models is very close to the spherical model prediction error. Hence, the prediction standard error of the spherical model is substantially larger than that of the Gaussian model. In fact, the prediction relative error never gets smaller than about 66% for the two models, where the negative sign in the Minimum and Maximum columns in Output 49.2.4 means that the prediction error is always greater for the spherical model.

**Output 49.2.4** Comparison of Gaussian and Spherical Models

| Effect of Model Specification on Prediction |     |             |           |             |             |

## Example 49.3: Data Quality and Prediction with Missing Values

Kriging methods depend primarily on your data. The quantity and quality of your observations are important factors in minimizing prediction errors and increasing accuracy in your prediction analysis.

A typical aspect of data quality is measurement accuracy. In principle, the accuracy level of your data is not a parameter in kriging prediction; kriging assumes by definition that your data are perfectly accurate (hard) measurements. Whether you accept this assumption depends on your application. For example, an instrumentation error of  $\pm 1\%$  in the data values might be regarded as considerable in one case, whereas the same level of uncertainty might be trivial within a different framework. Your experience and judgment are crucial when you consider whether observations in a data set might be too noisy for kriging predictions to be useful.

A second aspect of data quality involves the spatial arrangement of your observations. You need to have a sufficient number of observations in order to perform spatial prediction. Also, a key element in minimizing prediction errors is an adequate sampling density. Interpretation of the expressions “sufficient number” and “adequate sampling” is again case-specific. In any event, you want enough measurements so that you can deduce the underlying spatial correlation in the working domain; see also the discussion in the section “Choosing the Size of Classes” on page 8623 in the VARIOGRAM procedure.

This example focuses on the effects of different sampling densities on the prediction analysis. The demonstration is a slight variation of the example in the section “Getting Started: KRIGE2D Procedure” on page 3795. Specifically, you use the same correlation structure and prediction grid. However, the thick data set, is modified as follows: three values in the central area of the grid are assumed missing, namely the observation values at locations  $s_1 = (x_1, y_1) = (55.8, 50.5)$ ,  $s_2 = (x_2, y_2) = (52.8, 68.9)$ , and  $s_3 = (x_3, y_3) = (52.9, 32.7)$ . These locations have been selected so that an extended area without observations is created in the domain. The following DATA step is the input for the modified thick data set:

```

**NOTE:** Here you assume prior knowledge of the correlation structure model, because its parameters are based on the complete thick data set. A covariance model extracted from the incomplete set with the missing values would be a covariance model coming from a different data set; hence, it is likely to have different parameters.

After you define the modified data set, you run PROC KRIGE2D and request the **OBSERVATIONS** plot with the **SHOWMISSING** suboption. You also request two instances of the **PREDICTION** plot: one that displays the prediction surface and contours, and another that plots the kriging standard error surface and contours. In both of these **PREDICTION** plots you specify that the observations be shown as gradient markers with outlines. The following statements compute the kriged predictions and produce the requested graphics:

```

proc krige2d data=thick outest=predictions
 plots(only)=(observ(showmissing)
 pred(fill=pred line=pred obs=linegrad)
 pred(fill=se line=se obs=linegrad));
 coordinates xc=East yc=North;
 predict var=Thick r=60;
 model scale=7.4599 range=30.1111 form=gauss;
 grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;

ods graphics off;

```

The number of observations table indicates the three missing values in [Output 49.3.1](#).

#### Output 49.3.1 Number of Observations for the Modified thick Data Set

| Kriging Prediction in the Presence of Missing Values |    |
|------------------------------------------------------|----|
| The KRIGE2D Procedure                                |    |
| Dependent Variable: Thick                            |    |
| Number of Observations Read                          | 75 |
| Number of Observations Used                          | 72 |

Output 49.3.2 is a scatter plot of the modified observed data. The `SHOWMISSING` suboption produces marks in the observations plot that conveniently indicate the locations  $s_1$ ,  $s_2$ , and  $s_3$  of the missing values. Consequently, Output 49.3.2 displays an extended area with no observed Thick values in the central part of the domain.

**Output 49.3.2** Scatter Plot of the Observations Spatial Distribution

Predictions at grid points with few neighboring data points rely heavily on the underlying covariance structure. The covariance model has a range of about 30,000 feet, which suggests that within this range a grid point might have no data neighbors at all and still obtain a prediction value on the basis of the correlation structure alone. This type of behavior is demonstrated in the Output 49.3.3, which shows a circular region in the center of the plot that has no data points. Predictions at the nodes in this area are mostly influenced by the covariance structure.

You can see the impact of this effect on the predictions if you compare the prediction contours in the Output 49.3.3 to the ones in Figure 49.4. Despite the contribution of the neighboring Thick data values to the predictions within the area of no observations, the outcome is clearly altered by the absence of observations at the locations  $s_1$ ,  $s_2$ , and  $s_3$ .

**Output 49.3.3** Surface Plot and Contours of Kriged Coal Seam Thickness

A noticeable difference is also apparent in the plot of the prediction standard errors. [Output 49.3.4](#) displays these errors, and you can compare it to the standard error surface in [Figure 49.4](#). The comparison shows a slight difference in the color gradient within the area of the missing data values. [Output 49.3.4](#) uses standard error contours to enhance the effect of this difference.

The lack of information from the removed data results in an increase of the prediction uncertainty at the grid nodes that are most remotely situated from any observation in the central part of the domain. According to [Output 49.3.4](#), the standard error at these nodes is almost comparable to the error observed near the borders of the domain, where the nodes of the prediction grid have relatively fewer data neighbors than other nodes in the domain.

**Output 49.3.4** Surface Plot and Contours of Prediction Standard Errors

On a side note, **PREDICTION** plots display only observations with nonmissing values, as the plots in Output 49.3.3 and Output 49.3.4 demonstrate.

## Overview: LATTICE Procedure

The LATTICE procedure computes the analysis of variance and analysis of simple covariance for data from an experiment with a lattice design. PROC LATTICE analyzes balanced square lattices, partially balanced square lattices, and some rectangular lattices.

In balanced square lattices, the number of treatments is equal to the square of the number of units per block. Incomplete blocks are grouped to form mutually orthogonal replications. The number of replicates in the basic plan is always 1 plus the number of units per block.

Partially balanced square lattices are similar to balanced lattices, although the number of replicates can vary. Partially balanced designs are constructed of the replicates in the basic plan, but not all replicates are included the same number of times, and some might not be included at all.

In rectangular lattices, there are  $k$  units per block and  $k(k+1)$  treatments. As in square lattices, blocks are grouped to form mutually orthogonal replicates in the basic plan. PROC LATTICE can analyze simple rectangular lattices (two orthogonal replications) and triple rectangular lattices (three orthogonal replications). The experiment can include several repetitions of the basic plan.

The LATTICE procedure determines from the data set which type of design has been used. It also checks to see whether the design is valid and displays an appropriate message if it is not.

## Getting Started: LATTICE Procedure

An example of a balanced square design is an experiment to investigate the effects of nine diets on the growth rate of pigs.

In some breeds of pigs, past experience has shown that a large part of the total variation in growth rates between animals can be attributed to the litter. Therefore, this experiment is planned so that litter differences do not contribute to the intrablock error.

First, the pigs are separated into sets of three litter-mates. Each block is assigned two sets of the three litter-mates. In a given block, one pig from each set receives a diet. Therefore, the experimental unit is a pair of pigs feeding in a particular pen on one of the nine diets. The response variable, growth rate, is the sum of the growth rates for the two pigs in a particular pen. To get the adjusted diet mean per pig, the adjusted treatment mean for the pen must be divided by 2.

The special numeric SAS variables named Group, Block, Treatment, and Rep must be used to define the design. In this example, the Treatment variable ranges from 1 to 9 and indicates the particular diet. The Block variable is 1, 2, or 3 and indicates the pen containing the two pigs. The Group variable ranges from 1 to 4 and specifies which replication within the basic plan includes the experimental unit. In this example, you would not use the Rep variable since the entire basic plan is not replicated.

You can use the following DATA step and PROC LATTICE statement to analyze this experiment. The response variable is Weight.

```

title 'Examining the Growth Rate of Pigs';

data Pigs;
 input Group Block Treatment Weight @@;
 datalines;
1 1 1 2.20 1 1 2 1.84 1 1 3 2.18 1 2 4 2.05 1 2 5 0.85
1 2 6 1.86 1 3 7 0.73 1 3 8 1.60 1 3 9 1.76
2 1 1 1.19 2 1 4 1.20 2 1 7 1.15 2 2 2 2.26 2 2 5 1.07
2 2 8 1.45 2 3 3 2.12 2 3 6 2.03 2 3 9 1.63
3 1 1 1.81 3 1 5 1.16 3 1 9 1.11 3 2 2 1.76 3 2 6 2.16
3 2 7 1.80 3 3 3 1.71 3 3 4 1.57 3 3 8 1.13
4 1 1 1.77 4 1 6 1.57 4 1 8 1.43 4 2 2 1.50 4 2 4 1.60
4 2 9 1.42 4 3 3 2.04 4 3 5 0.93 4 3 7 1.78
;

proc lattice data=Pigs;
 var Weight;
run;

```

The SAS code produces the output shown in [Figure 50.1](#).

**Figure 50.1** Output from Example LATTICE Procedure

| Total                             | 35 | 5.9609         | 0.1703      |

| Additional Statistics for Weight |         |
|----------------------------------|---------|
| Variance of Means in Same Block  | 0.04593 |
| LSD at .01 Level                 | 0.6259  |
| LSD at .05 Level                 | 0.4543  |
| Efficiency Relative to RCBD      | 120.55  |

| Adjusted Treatment Means for Weight |        |
|-------------------------------------|--------|
| Treatment                           | Mean   |
| 1                                   | 1.8035 |
| 2                                   | 1.7544 |
| 3                                   | 1.9643 |
| 4                                   | 1.7267 |
| 5                                   | 0.9393 |
| 6                                   | 1.8448 |
| 7                                   | 1.3870 |
| 8                                   | 1.4347 |
| 9                                   | 1.5004 |

Diet 3 yields the highest mean growth rate at 1.9643 pounds for the two pigs (0.9822 per pig), while diet 5 has the lowest rate at 0.9393 (0.4696 per pig). The efficiency of the experiment relative to a randomized complete block design is 120.55 percent, so using the lattice design increased precision, producing more accurate estimates of the treatment effects. The different elements of the LATTICE procedure's output are discussed in the "Displayed Output" on page 3872 section.

---

## Syntax: LATTICE Procedure

The following statements are available in the LATTICE procedure:

```
PROC LATTICE < options > ;
 BY variables ;
 VAR variables ;
```

Three specific numeric SAS variables, Group, Block, and Treatment, *must* be present in the data set to which PROC LATTICE is applied. For compatibility with previous releases, the variable Treatment can alternatively be named Treatmnt. A fourth numeric variable named Rep must be present when the design involves repetition of the entire basic plan. (See the “[Input Data Set](#)” on page 3871 section for more information.)

Every numeric variable other than Group, Block, Treatment, or Rep in the input SAS data set may be considered a response variable. A VAR statement tells PROC LATTICE that only the variables listed in the VAR statement are to be considered response variables. If the VAR statement is omitted, then all numeric variables, excluding Group, Block, Treatment, and Rep, are considered response variables. PROC LATTICE performs an analysis for each response variable.

---

## PROC LATTICE Statement

```
PROC LATTICE < options > ;
```

The PROC LATTICE statement invokes the LATTICE procedure.

### **DATA=SAS-data-set**

names the SAS data set to be used by PROC LATTICE. If you omit the DATA= option, the most recently created SAS data set is used.

### **COVARIANCE**

#### **COV**

calculates sums of products for every possible pair of response variables. A sum of products is given for each source of variation in the analysis of variance table. For each pair of response variables, the one appearing later in the data set (or in the VAR statement) is the covariable.

---

## BY Statement

```
BY variables ;
```

You can specify a BY statement with PROC LATTICE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the NOTSORTED or DESCENDING option in the BY statement for the LATTICE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement specifies the response variables. If you do not include a VAR statement, all numeric variables in the data set are considered response variables (except Group, Block, Treatment, and Rep).

---

## Details: LATTICE Procedure

---

### Input Data Set

Four numeric SAS variables, Group, Block, Treatment, and Rep, are used in the input data set to define the lattice design. The Group, Block, and Treatment variables are required in the data set to which PROC LATTICE is applied. For compatibility with previous releases, the third variable can alternatively be named Treatmnt. The Rep variable must be present when the design involves repetition of the entire basic plan.

|           |                                                                                                                                                                                                                                              |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Group     | specifies which orthogonal replication in the basic plan includes the experimental unit. Values of Group must be $1, 2, \dots, n$ , where $n$ is the number of replicates in the basic plan.                                                 |
| Block     | specifies the block in which the experimental unit is present. Values of Block must be $1, 2, \dots, m$ , where $m$ is the number of blocks in a replication.                                                                                |
| Treatment | specifies which treatment was applied to the experimental unit. Values of Treatment must be $1, 2, \dots, i$ , where $i$ is the number of treatments in a replication.                                                                       |
| Rep       | specifies which repetition of the basic plan includes the experimental unit. Values of Rep must be $1, 2, \dots, p$ , where $p$ is the number of replications of the entire basic plan. Thus, the experiment has a total of $np$ replicates. |

---

### Missing Values

If a value of Group, Block, Treatment, or Rep is missing, the analysis is not performed and an appropriate error message is displayed.

If a value of a response variable is missing, this entire variable is dropped from the analysis. If other response variables exist that do not have missing values, they are analyzed.

---

## Displayed Output

For each response variable, PROC LATTICE displays the following

- an “Analysis of Variance” table and related statistics, including the following as separate sources of variations:
  - Replications
  - Blocks within Replications (adjusted for treatments)
  - Treatments (unadjusted)
  - Intra-block Error
  - Randomized Complete Block Error

The Blocks within Replications sum of squares is further broken down into “Component A” and “Component B.” If there is no repetition of the basic plan, the Component B sum of squares is the same as the Blocks within Replications sum of squares. If there is repetition of the basic plan, the Component A sum of squares reflects the variation among blocks that contain the same treatments.

The source of variation called Randomized Complete Block Error is the sum of the Blocks within Replications sum of squares and the Intra-block Error sum of squares. It is the appropriate error term if the experimental design is a randomized complete block design, with the replications filling the roles of complete blocks.

- two values for the Variance of Means. For some lattice designs, these are only approximations. The first value is applicable when the two treatments appear in the same block; the other (when it appears) applies when the two treatments never appear in the same block (a possibility in partially balanced and rectangular designs).
- an Average of Variance. Except with small designs, it is sufficient to use this average variance of means for tests between treatments (whether the two treatments appear in the same block or not); see Cochran and Cox (1957).
- the Least Significant Differences (LSDs) at the 0.01 and 0.05 levels of significance, based on the Average of Variance
- Efficiency Relative to RCBD, the efficiency of the lattice design relative to a randomized complete block design. The efficiency is the ratio of the randomized complete block mean squared error to the effective error variance; see Cochran and Cox (1957).
- the Adjusted Treatment Means. These are adjusted for blocks if the relative precision is greater than 105%.

When you specify the COVARIANCE option, PROC LATTICE produces sums of products and the mean product for each source of variation in the analysis of variance table.

## ODS Table Names

PROC LATTICE assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 50.1. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 50.1** ODS Tables Produced by PROC LATTICE

| ODS Table Name    | Description              | PROC LATTICE Option |
|-------------------|--------------------------|---------------------|
| ANOVA             | Analysis of variance     | default             |
| AdjTreatmentMeans | Adjusted treatment means | default             |
| Statistics        | Additional statistics    | default             |

## Example: LATTICE Procedure

### Example 50.1: Analysis of Variance through PROC LATTICE

In the following example, from Cochran and Cox (1957, p. 406), the data are yields (Yield) in bushels per acre of 25 varieties (Treatment) of soybeans. The data are collected in two replications (Group) of 25 varieties in five blocks (Block) containing five varieties each. This is an example of a partially balanced square lattice design.

```
data Soy(drop=plot);
 do Group = 1 to 2;
 do Block = 1 to 5;
 do Plot = 1 to 5;
 input Treatment Yield @@;
 output;
 end;
 end;
 end;
 datalines;
 1 6 2 7 3 5 4 8 5 6 6 16 7 12 8 12 9 13 10 8
 11 17 12 7 13 7 14 9 15 14 16 18 17 16 18 13 19 13 20 14
 21 14 22 15 23 11 24 14 25 14 1 24 6 13 11 24 16 11 21 8
 2 21 7 11 12 14 17 11 22 23 3 16 8 4 13 12 18 12 23 12
 4 17 9 10 14 30 19 9 24 23 5 15 10 15 15 22 20 16 25 19
;

proc print data=Soy;
 id Treatment;
run;

proc lattice data=Soy;
run;
```

The results from these statements are shown in [Output 50.1.1](#) and [Output 50.1.2](#).

**Output 50.1.1** Displayed Output from PROC PRINT

| Treatment | Group | Block | Yield |
|-----------|-------|-------|-------|
| 1         | 1     | 1     | 6     |

The efficiency of the experiment relative to a randomized complete block design is 174.34%. Precision is gained using the lattice design via the recovery of intra-block error information, enabling more accurate estimates of the treatment effects. Variety 8 of soybean had the lowest adjusted treatment mean (6.7483 bushels per acre), while variety 11 of soybean had the highest adjusted treatment mean (23.5511 bushels per acre).

## Overview: LIFEREG Procedure

The LIFEREG procedure fits parametric models to failure time data that can be uncensored, right censored, left censored, or interval censored. The models for the response variable consist of a linear effect composed of the covariates and a random disturbance term. The distribution of the random disturbance can be taken from a class of distributions that includes the extreme value, normal, logistic, and, by using a log transformation, the exponential, Weibull, lognormal, log-logistic, and three-parameter gamma distributions.

The model assumed for the response  $y$  is

$$y = \mathbf{X}\boldsymbol{\beta} + \sigma\epsilon$$

where  $y$  is a vector of response values, often the log of the failure times,  $\mathbf{X}$  is a matrix of covariates or independent variables (usually including an intercept term),  $\boldsymbol{\beta}$  is a vector of unknown regression parameters,  $\sigma$  is an unknown scale parameter, and  $\epsilon$  is a vector of errors assumed to come from a known distribution (such as the standard normal distribution). If an offset variable  $O$  is specified, the form of the model is  $y = \mathbf{X}\boldsymbol{\beta} + O + \sigma\epsilon$ , where  $O$  is a vector of values of the offset variable  $O$ . The distribution might also depend on additional shape parameters. These models are equivalent to accelerated failure time models when the log of the response is the quantity being modeled. The effect of the covariates in an accelerated failure time model is to change the scale, and not the location, of a baseline distribution of failure times.

The LIFEREG procedure estimates the parameters by maximum likelihood with a Newton-Raphson algorithm. PROC LIFEREG estimates the standard errors of the parameter estimates from the inverse of the observed information matrix.

The accelerated failure time model assumes that the effect of independent variables on an event time distribution is multiplicative on the event time. Usually, the scale function is  $\exp(\mathbf{x}'_c\boldsymbol{\beta}_c)$ , where  $\mathbf{x}'_c$  is the vector of covariate values (not including the intercept term) and  $\boldsymbol{\beta}_c$  is a vector of unknown parameters. Thus, if  $T_0$  is an event time sampled from the baseline distribution corresponding to values of zero for the covariates,

then the accelerated failure time model specifies that, if the vector of covariates is  $\mathbf{x}_c$ , the event time is  $T = \exp(\mathbf{x}'_c \boldsymbol{\beta}_c) T_0$ . If  $y = \log(T)$  and  $y_0 = \log(T_0)$ , then

$$y = \mathbf{x}'_c \boldsymbol{\beta}_c + y_0$$

This is a linear model with  $y_0$  as the error term.

In terms of survival or exceedance probabilities, this model is

$$\Pr(T > t \mid \mathbf{x}_c) = \Pr(T_0 > \exp(-\mathbf{x}'_c \boldsymbol{\beta}_c) t)$$

The probability on the left-hand side of the equal sign is evaluated given the value  $\mathbf{x}_c$  for the covariates, and the right-hand side is computed using the baseline probability distribution but at a scaled value of the argument. The right-hand side of the equation represents the value of the baseline survival function evaluated at  $\exp(-\mathbf{x}'_c \boldsymbol{\beta}_c) t$ .

Models usually have an intercept parameter and a scale parameter. In terms of the original untransformed event times, the effects of the intercept term and the scale term are to scale the event time and to raise the event time to a power, respectively. That is, if

$$\log(T_0) = \mu + \sigma \log(T_\epsilon)$$

then

$$T_0 = \exp(\mu) T_\epsilon^\sigma$$

Although it is possible to fit these models to the original response variable by using the NOLOG option, it is more common to model the log of the response variable. Because of this log transformation, zero values for the observed failure times are not allowed unless the NOLOG option is specified. Similarly, small values for the observed failure times lead to large negative values for the transformed response. The NOLOG option should be used only if you want to fit a distribution appropriate for the untransformed response, such as the extreme value instead of the Weibull. If you specify the normal or logistic distributions, the responses are not log transformed; that is, the NOLOG option is implicitly assumed.

Parameter estimates for the normal distribution are sensitive to large negative values, and care must be taken that the fitted model is not unduly influenced by them. Large negative values for the normal distribution can occur when fitting the lognormal distribution by log transforming the response, and some response values are near zero. Likewise, values that are extremely large after the log transformation have a strong influence in fitting the Weibull distribution (that is, the extreme value distribution for log responses). You should examine the residuals and check the effects of removing observations with large residuals or extreme values of covariates on the model parameters. The logistic distribution gives robust parameter estimates in the sense that the estimates have a bounded influence function.

The standard errors of the parameter estimates are computed from large sample normal approximations by using the observed information matrix. In small samples, these approximations might be poor. See Lawless (2003) for additional discussion and references. You can sometimes construct better confidence intervals by transforming the parameters. For example, large sample theory is often more accurate for  $\log(\sigma)$  than  $\sigma$ . Therefore, it might be more accurate to construct confidence intervals for  $\log(\sigma)$  and transform these into confidence intervals for  $\sigma$ . The parameter estimates and their estimated covariance matrix are available in an output SAS data set and can be used to construct additional tests or confidence intervals for the parameters. Alternatively, tests of parameters can be based on log-likelihood ratios. See Cox and Oakes (1984) for a

discussion of the merits of some possible test methods including score, Wald, and likelihood ratio tests. Likelihood ratio tests are generally more reliable for small samples than tests based on the information matrix.

The log-likelihood function is computed using the log of the failure time as a response. This log likelihood differs from the log likelihood obtained using the failure time as the response by an additive term of  $\sum \log(t_i)$ , where the sum is over the uncensored failure times. This term does not depend on the unknown parameters and does not affect parameter or standard error estimates. However, many published values of log likelihoods use the failure time as the basic response variable and, hence, differ by the additive term from the value computed by the LIFEREG procedure.

The classic Tobit model also fits into this class of models but with data usually censored on the left. The data considered by Tobin (1958) in his original paper came from a survey of consumers where the response variable is the ratio of expenditures on durable goods to the total disposable income. The two explanatory variables are the age of the head of household and the ratio of liquid assets to total disposable income. Because many observations in this data set have a value of zero for the response variable, the model fit by Tobin is

$$y = \max(\mathbf{x}'\boldsymbol{\beta} + \epsilon, 0)$$

which is a regression model with left censoring, where  $\mathbf{x}' = (1, \mathbf{x}'_c)$ .

Bayesian analysis of parametric survival models can be requested by using the BAYES statement in the LIFEREG procedure. In Bayesian analysis, the model parameters are treated as random variables, and inference about parameters is based on the posterior distribution of the parameters, given the data. The posterior distribution is obtained using Bayes' theorem as the likelihood function of the data weighted with a prior distribution. The prior distribution enables you to incorporate knowledge or experience of the likely range of values of the parameters of interest into the analysis. If you have no prior knowledge of the parameter values, you can use a noninformative prior distribution, and the results of the Bayesian analysis will be very similar to a classical analysis based on maximum likelihood. A closed form of the posterior distribution is often not feasible, and a Markov chain Monte Carlo method by Gibbs sampling is used to simulate samples from the posterior distribution. See Chapter 7, "[Introduction to Bayesian Analysis Procedures](#)," for an introduction to the basic concepts of Bayesian statistics. Also see the section "[Bayesian Analysis: Advantages and Disadvantages](#)" on page 132 for a discussion of the advantages and disadvantages of Bayesian analysis. See Ibrahim, Chen, and Sinha (2001) and Gilks, Richardson, and Spiegelhalter (1996) for more information about Bayesian analysis, including guidance in choosing prior distributions.

For Bayesian analysis, PROC LIFEREG generates a Gibbs chain for the posterior distribution of the model parameters. Summary statistics (mean, standard deviation, quartiles, HPD and credible intervals, correlation matrix) and convergence diagnostics (autocorrelations; Gelman-Rubin, Geweke, Raftery-Lewis, and Heidelberger and Welch tests; and the effective sample size) are computed for each parameter, as well as the correlation matrix of the posterior sample. Trace plots, posterior density plots, and autocorrelation function plots that are created using ODS Graphics are also provided for each parameter.

The LIFEREG procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, "[Statistical Graphics Using ODS](#)."

---

## Getting Started: LIFEREG Procedure

The following examples demonstrate how you can use the LIFEREG procedure to fit a parametric model to failure time data.

Suppose you have a response variable  $y$  that represents failure time; a binary variable, `ensor`, with `ensor=0` indicating censored values; and two linearly independent variables,  $x_1$  and  $x_2$ . The following statements perform a typical accelerated failure time model analysis. Higher-order effects such as interactions and nested effects are allowed in the independent variables list, but they are not shown in this example.

```
proc lifereg;
 model y*censor(0) = x1 x2;
run;
```

PROC LIFEREG can fit models to interval-censored data. The syntax for specifying interval-censored data is as follows:

```
proc lifereg;
 model (begin, end) = x1 x2;
run;
```

You can also model binomial data by using the *events/trials* syntax for the response, as illustrated in the following statements:

```
proc lifereg;
 model r/n=x1 x2;
run;
```

The variable  $n$  represents the number of trials, and the variable  $r$  represents the number of events.

---

## Modeling Right-Censored Failure Time Data

The following example demonstrates how you can use the LIFEREG procedure to fit a model to right-censored failure time data.

Suppose you conduct a study of two headache pain relievers. You divide patients into two groups, with each group receiving a different type of pain reliever. You record the time taken (in minutes) for each patient to report headache relief. Because some of the patients never report relief for the entire study, some of the observations are censored.

The following DATA step creates the SAS data set `headache`:

```
data Headache;
 input Minutes Group Censor @@;
 datalines;
11 1 0 12 1 0 19 1 0 19 1 0
19 1 0 19 1 0 21 1 0 20 1 0
21 1 0 21 1 0 20 1 0 21 1 0
20 1 0 21 1 0 25 1 0 27 1 0
30 1 0 21 1 1 24 1 1 14 2 0
16 2 0 16 2 0 21 2 0 21 2 0
23 2 0 23 2 0 23 2 0 23 2 0
```

```

25 2 1 23 2 0 24 2 0 24 2 0
26 2 1 32 2 1 30 2 1 30 2 0
32 2 1 20 2 1
;

```

The data set `Headache` contains the variable `Minutes`, which represents the reported time to headache relief; the variable `Group`, the group to which the patient is assigned; and the variable `Censor`, a binary variable indicating whether the observation is censored. Valid values of the variable `Censor` are 0 (no) and 1 (yes). Figure 51.1 shows the first five records of the data set `Headache`.

**Figure 51.1** Headache Data

|  | Obs | Minutes | Group | Censor |
|--|-----|---------|-------|--------|
|  | 1   | 11      | 1     | 0      |
|  | 2   | 12      | 1     | 0      |
|  | 3   | 19      | 1     | 0      |
|  | 4   | 19      | 1     | 0      |
|  | 5   | 19      | 1     | 0      |

The following statements invoke the LIFEREG procedure:

```

proc lifereg data=Headache;
 class Group;
 model Minutes*Censor(1)=Group;
 output out=New cdf=Prob;
run;

```

The CLASS statement specifies the variable `Group` as the classification variable. The MODEL statement syntax indicates that the response variable `Minutes` is right censored when the variable `Censor` takes the value 1. The MODEL statement specifies the variable `Group` as the single explanatory variable. Because the MODEL statement does not specify the DISTRIBUION= option, the LIFEREG procedure fits the default type 1 extreme-value distribution by using  $\log(\text{Minutes})$  as the response. This is equivalent to fitting the Weibull distribution.

The OUTPUT statement creates the output data set `New`. In addition to containing the variables in the original data set `Headache`, the SAS data set `New` also contains the variable `Prob`. This new variable is created by the CDF= option to contain the estimates of the cumulative distribution function evaluated at the observed response.

The results of this analysis are displayed in the following figures.

**Figure 51.2** Model Fitting Information from the LIFEREG Procedure

| The LIFEREG Procedure    |               |        |
|--------------------------|---------------|--------|
| Model Information        |               |        |
| Data Set                 | WORK.HEADACHE |        |
| Dependent Variable       | Log(Minutes)  |        |
| Censoring Variable       | Censor        |        |
| Censoring Value(s)       | 1             |        |
| Number of Observations   | 38            |        |
| Noncensored Values       | 30            |        |
| Right Censored Values    | 8             |        |
| Left Censored Values     | 0             |        |
| Interval Censored Values | 0             |        |
| Number of Parameters     | 3             |        |
| Name of Distribution     | Weibull       |        |
| Log Likelihood           | -9.37930239   |        |
| Class Level Information  |               |        |
| Name                     | Levels        | Values |
| Group                    | 2             | 1 2    |

Figure 51.2 displays the class level information and model fitting information. There are 30 uncensored observations and 8 right-censored observations. The log likelihood for the Weibull distribution is  $-9.3793$ . The log-likelihood value can be used to compare the goodness of fit for nested models with different covariates, but with the same distribution.

**Figure 51.3** Model Fit Statistics from the LIFEREG Procedure

| Fit Statistics                     |         |
|------------------------------------|---------|
| -2 Log Likelihood                  | 18.759  |
| AIC (smaller is better)            | 24.759  |
| AICC (smaller is better)           | 25.464  |
| BIC (smaller is better)            | 29.671  |
| Fit Statistics (Unlogged Response) |         |
| -2 Log Likelihood                  | 199.747 |
| Weibull AIC (smaller is better)    | 205.747 |
| Weibull AICC (smaller is better)   | 206.453 |
| Weibull BIC (smaller is better)    | 210.660 |

Figure 51.3 displays fit statistics for the model. The “Fit Statistics” table displays statistics based on the maximum extreme-value log likelihood fit by using  $\log(\text{Minutes})$  as the response. These statistics are useful

in comparing the fit of a different model when the fit criteria from the model that you compare is also based on the log likelihood using  $\log(\text{Minutes})$  as the response. The “Fit Statistics (Unlogged Response)” table is based on the maximum Weibull log likelihood using Minutes as the response. The AIC, BIC, and AICC statistics in this table can be used to compare models with different covariates, in addition to models with different distributions, as long as the fit statistics for the models that you compare use Minutes as the response.

**Figure 51.4** Model Parameter Estimates from the LIFEREG Procedure

| Analysis of Maximum Likelihood Parameter Estimates |     |          |                |                       |         |            |            |
|----------------------------------------------------|-----|----------|----------------|-----------------------|---------|------------|------------|
| Parameter                                          | DF  | Estimate | Standard Error | 95% Confidence Limits |         | Chi-Square | Pr > ChiSq |
| Intercept                                          | 1   | 3.3091   | 0.0589         | 3.1938                | 3.4245  | 3161.70    | <.0001     |
| Group                                              | 1 1 | -0.1933  | 0.0786         | -0.3473               | -0.0393 | 6.05       | 0.0139     |
| Group                                              | 2 0 | 0.0000   | .              | .                     | .       | .          | .          |
| Scale                                              | 1   | 0.2122   | 0.0304         | 0.1603                | 0.2809  |            |            |
| Weibull Shape                                      | 1   | 4.7128   | 0.6742         | 3.5604                | 6.2381  |            |            |

The table of parameter estimates is displayed in Figure 51.4. Both the intercept and the slope parameter for the variable group are significantly different from 0 at the 0.05 level. Because the variable group has only one degree of freedom, parameter estimates are given for only one level of the variable group (group=1). However, the estimate for the intercept parameter provides a baseline for group=2.

The resulting model is as follows:

$$\log(\text{minutes}) = \begin{cases} 3.30911843 - 0.1933025 & \text{for group} = 1 \\ 3.30911843 & \text{for group} = 2 \end{cases}$$

Note that the Weibull shape parameter for this model is the reciprocal of the extreme-value scale parameter estimate shown in Figure 51.4 ( $1/0.21219 = 4.7128$ ).

The following statements produce a graph of the cumulative distribution values versus the variable Minutes.

```
proc sgplot data=New;
 scatter x=Minutes y=Prob / group=Group;
 discretelegend;
run;
```

Figure 51.5 displays the estimated cumulative distribution function values contained in the output data set New for each group.

**Figure 51.5** Plot of the Estimated Cumulative Distribution Function

## Bayesian Analysis of Right-Censored Data

Nelson (1982) describes a study of the lifetimes of locomotive engine fans. This example shows how to use PROC LIFEREG to carry out a Bayesian analysis of the engine fan data. In this example, a lognormal distribution is used to model the engine lifetimes, but other survival time distributions, such as the Weibull, can also be used.

The following SAS statements create the SAS data set `Fan`. This data set contains a censoring indicator variable and right-censored survival times for the 70 locomotive engine fans in the study.

```
data Fan;
 input Lifetime Censor@@;
 datalines;
 450 0 460 1 1150 0 1150 0 1560 1
 1600 0 1660 1 1850 1 1850 1 1850 1
 1850 1 1850 1 2030 1 2030 1 2030 1
 2070 0 2070 0 2080 0 2200 1 3000 1
 3000 1 3000 1 3000 1 3100 0 3200 1
 3450 0 3750 1 3750 1 4150 1 4150 1
 4150 1 4150 1 4300 1 4300 1 4300 1
 4300 1 4600 0 4850 1 4850 1 4850 1
 4850 1 5000 1 5000 1 5000 1 6100 1
 6100 0 6100 1 6100 1 6300 1 6450 1
 6450 1 6700 1 7450 1 7800 1 7800 1
 8100 1 8100 1 8200 1 8500 1 8500 1
 8500 1 8750 1 8750 0 8750 1 9400 1
 9900 1 10100 1 10100 1 10100 1 11500 1
 ;
```

Some of the fans had not failed at the time the data were collected, and the unfailed units have right-censored lifetimes. The variable `Lifetime` represents either a failure time or a censoring time. The variable `Censor` is equal to 0 if the value of `Lifetime` is a failure time, and it is equal to 1 if the value is a censoring time.

The following SAS statements specify a Bayesian analysis that uses a lognormal model for the engine lifetimes. There are no covariates, so the model is an intercept-only model. The `OUTPOST=` option saves the samples from the posterior distribution in the SAS data set `Post` for further processing.

```
ods graphics on;
proc lifereg data=Fan;
 model Lifetime*Censor(1)= / dist=lognormal;
 bayes seed=1 outpost=Post;
run;
ods graphics off;
```

The `SEED=` option is specified to maintain reproducibility; no other options are specified in the `BAYES` statement. By default, a uniform prior distribution is assumed for the intercept coefficient. The uniform prior is a flat prior on the real line with a distribution that reflects ignorance of the location of the parameter, placing equal probability on all possible values the regression coefficient can take. Using the uniform prior in the following example, you would expect the Bayesian estimates to resemble the classical results of maximizing the likelihood. If you can elicit an informative prior on the regression coefficients, you should use the `COEFFPRIOR=` option to specify it. A default noninformative gamma prior is used for the lognormal scale parameter  $\sigma$ .

You should make sure that the posterior distribution samples have achieved convergence before using them for Bayesian inference. If you do not specify additional options, `PROC LIFEREG` produces by default three convergence diagnostics: autocorrelations of the posterior sample, effective sample size, and the Geweke statistic. See the section “[Assessing Markov Chain Convergence](#)” on page 139 for information about assessing the convergence of the chain of posterior samples. Trace plots, posterior density plots, and autocorrelation function plots that are created using `ODS Graphics` are also provided for each parameter. See the section “[Visual Analysis via Trace Plots](#)” on page 139 for help in interpreting these plots.

The “Analysis of Maximum Likelihood Parameter Estimates” table in Figure 51.6 summarizes maximum likelihood estimates of the lognormal intercept and scale parameters.

**Figure 51.6** Maximum Likelihood Estimates from the LIFEREG Procedure

| The LIFEREG Procedure                              |    |          |                |                       |         |
|----------------------------------------------------|----|----------|----------------|-----------------------|---------|
| Bayesian Analysis                                  |    |          |                |                       |         |
| Analysis of Maximum Likelihood Parameter Estimates |    |          |                |                       |         |
| Parameter                                          | DF | Estimate | Standard Error | 95% Confidence Limits |         |
| Intercept                                          | 1  | 10.1432  | 0.5211         | 9.1219                | 11.1646 |
| Scale                                              | 1  | 1.6796   | 0.3893         | 1.0664                | 2.6453  |

Since no prior distribution for the intercept was specified, the default uniform improper distribution shown in the “Uniform Prior for Regression Coefficients” table in Figure 51.7 is used.

Noninformative prior distributions are appropriate if you have no prior knowledge of the likely range of values of the parameters, and if you want to make probability statements about the parameters or functions of the parameters. Refer, for example, to Ibrahim, Chen, and Sinha (2001) for more information about choosing prior distributions.

The default noninformative gamma prior distribution for the lognormal scale parameter is shown in the “Independent Prior Distributions for Model Parameters” table in Figure 51.7.

**Figure 51.7** Noninformative Prior Distributions

| The LIFEREG Procedure                                |                    |                 |       |               |       |
|------------------------------------------------------|--------------------|-----------------|-------|---------------|-------|
| Bayesian Analysis                                    |                    |                 |       |               |       |
| Uniform Prior for Regression Coefficients            |                    |                 |       |               |       |
| Parameter                                            | Prior              |                 |       |               |       |
| Intercept                                            | Constant           |                 |       |               |       |
| Independent Prior Distributions for Model Parameters |                    |                 |       |               |       |
| Parameter                                            | Prior Distribution | Hyperparameters |       |               |       |
| Scale                                                | Gamma              | Shape           | 0.001 | Inverse Scale | 0.001 |

By default, posterior mode estimates of the model parameters are used as the starting value for the simulation. These are listed in the “Initial Values of the Chain” table in Figure 51.8.

**Figure 51.8** Markov Chain Initial Values

| Initial Values of the Chain |      |           |         |
|-----------------------------|------|-----------|---------|
| Chain                       | Seed | Intercept | Scale   |
| 1                           | 1    | 10.0501   | 1.59544 |

Summary statistics for the posterior sample are displayed in the “Fit Statistics,” “Descriptive Statistics for the Posterior Sample,” “Interval Statistics for the Posterior Sample,” and “Posterior Correlation Matrix” tables in Figure 51.9. Since noninformative prior distributions were used, these results are consistent with the maximum likelihood estimates shown in Figure 51.6.

**Figure 51.9** Posterior Sample Summary Statistics

| Fit Statistics                      |           |                     |                       |              |         |         |

| Scale                               | 0.8297    |                     | 1.0000                |              |         |         |

By default, PROC LIFEREG computes three convergence diagnostics: the lag1, lag5, lag10, and lag50 autocorrelations; the Geweke diagnostic; and the effective sample size. These are displayed in [Figure 51.10](#). There is no indication that the Markov chain has not converged. See the section “[Assessing Markov Chain Convergence](#)” on page 139 for more information about convergence diagnostics and their interpretation.

**Figure 51.10** Posterior Sample Summary Statistics

| Scale                      | 1805.0  | 5.5400               | 0.1805     |         |

Summary statistics of the posterior distribution samples are produced by default. However, these statistics might not be sufficient for carrying out your Bayesian inference. The samples from the posterior distribution saved in the SAS data set Post created with the OUTPOST= option can be used for further analysis.

Trace, autocorrelation, and density plots for the three model parameters shown in Figure 51.11 and Figure 51.12 are useful in diagnosing whether the Markov chain of posterior samples has converged. These plots show no evidence that the chain has not converged. See the section “Visual Analysis via Trace Plots” on page 139 for more information about interpreting these types of diagnostic plots.

**Figure 51.11** Diagnostic Plots

Figure 51.12 Diagnostic Plots

The fraction failing in the first 8000 hours of operation might be a quantity of interest. This kind of information could be useful, for example, in determining whether to improve the reliability of the engine components due to warranty considerations. The following SAS statements compute the mean and percentiles of the distribution of the fraction failing in the first 8000 hours from the posterior sample data set Post:

```
data Prob;
 set Post;
 Frac = ProbNorm((log(8000) - Intercept) / Scale);
 label Frac= 'Fraction Failing in 8000 Hours';
run;

proc means data = Prob(keep=Frac) n mean p10 p25 p50 p75 p90;
run;
```

The mean fraction of failures in the first 8000 hours, shown in Figure 51.13, is about 0.24, which could be used in further analysis of warranty costs. The 10th percentile is about 0.16 and the 90th percentile is about 0.32, which gives an assessment of the probable range of the fraction failing in the first 8000 hours.

**Figure 51.13** Fraction Failing in 8000 Hours

## Syntax: LIFEREG Procedure

The following statements are available in the LIFEREG procedure:

```

PROC LIFEREG < options > ;
 BAYES < options > ;
 BY variables ;
 CLASS variables ;
 ESTIMATE < 'label' > estimate-specification < (divisor=n) >
 < , ... < 'label' > estimate-specification < (divisor=n) > > < / options > ;
 EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
 INSET < keyword-list > < / options > ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect < 'label' > values < (divisor=n) >
 < , ... < 'label' > values < (divisor=n) > > < / options > ;
 MODEL response = < effects > < / options > ;
 OUTPUT < OUT=SAS-data-set > < keyword=name ... keyword=name > < options > ;
 PROBPLOT < / options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 TEST < model-effects > < / options > ;
 WEIGHT variable ;

```

The MODEL statement is required; it specifies both the variables that are used in the regression part of the model and the distribution that is used for the error (random) component of the model. Each invocation of the LIFEREG procedure can use only one MODEL statement. If multiple MODEL statements are present, only

the last is used. You can specify main effects and interaction terms in the MODEL statement, as in the GLM procedure. You can specify initial values in the MODEL statement or in an INEST= data set. If no initial values are specified, the starting estimates are obtained by ordinary least squares. The CLASS statement determines which explanatory variables are treated as categorical. The WEIGHT statement identifies a *variable* with values that are used to weight the observations. Observations with zero or negative weights are not used to fit the model, although predicted values can be computed for them. The OUTPUT statement creates an output data set that contains predicted values and residuals.

The ESTIMATE, EFFECTPLOT, LSMEANS, LSMESTIMATE, SLICE, STORE, and TEST statements are common to many procedures. Summary descriptions of functionality and syntax for these statements are also given after the PROC LIFEREG statement in alphabetical order, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

---

## PROC LIFEREG Statement

**PROC LIFEREG** < options > ;

The PROC LIFEREG statement invokes the LIFEREG procedure. Table 51.1 summarizes the options available in the PROC LIFEREG statement.

**Table 51.1** PROC LIFEREG Statement Options

| Option   | Description                                                                |
|----------|----------------------------------------------------------------------------|
| COVOUT   | Writes the estimated covariance matrix to the OUTEST= data set             |
| DATA=    | Specifies the input SAS data set                                           |
| GOUT=    | Specifies a graphics catalog                                               |
| INEST=   | Specifies an input SAS data set that contains initial estimates            |
| NAMELEN= | Specifies the length of effect names                                       |
| NOPRINT  | Suppresses the display of the output                                       |
| ORDER=   | Specifies the sort order for the levels of the classification variables    |
| OUTEST=  | Specifies an output SAS data set                                           |
| PLOTS=   | Controls graphics created by ODS Graphics                                  |
| XDATA=   | Specifies a SAS input data containing values for the independent variables |

You can specify the following *options* in the PROC LIFEREG statement.

### COVOUT

writes the estimated covariance matrix to the OUTEST= data set if convergence is attained.

### DATA=*SAS-data-set*

specifies the input SAS data set used by PROC LIFEREG. By default, the most recently created SAS data set is used.

### GOUT=*graphics-catalog*

specifies a graphics catalog in which to save graphics output.

**INEST=SAS-data-set**

specifies an input SAS data set that contains initial estimates for all the parameters in the model. See the section “[INEST= Data Set](#)” on page 3945 for a detailed description of the contents of the INEST= data set.

**NAMELEN=*n***

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

**NOPRINT**

suppresses the display of the output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “[Using the Output Delivery System.](#)”

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This option applies to the levels for all classification variables, except when you use the (default) ORDER=FORMATTED option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The ORDER= option can take the following values:

| Value of ORDER=  | Levels Sorted By                                                                                                                       |
|------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>      | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b> | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>      | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>  | Unformatted value                                                                                                                      |

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**OUTEST=SAS-data-set**

specifies an output SAS data set containing the parameter estimates, the maximized log likelihood, and, if the COVOUT option is specified, the estimated covariance matrix. See the section “[OUTEST= Data Set](#)” on page 3946 for a detailed description of the contents of the OUTEST= data set.

**PLOTS=NONE | PROBLOT**

specifies options that control graphics created by ODS Graphics.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc lifereg plots=probplot;
 model y = x;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The following plot requests are available.

- NONE suppresses any plots created by ODS Graphics specified in other LIFEREG statements, such as the BAYES or PROBPLOT statement.
- PROBPLOT creates a default probability plot based on information in the MODEL statement. If a PROBPLOT option is also specified, the probability plot specified in the PROBPLOT statement is created, and this option is ignored.

#### **XDATA=SAS-data-set**

specifies an input SAS data set that contains values for all the independent variables in the MODEL statement and variables in the CLASS statement for probability plotting. If there are covariates specified in a MODEL statement and a probability plot is requested with a PROBPLOT statement, you specify fixed values for the effects in the MODEL statement with the XDATA= data set. See the section “XDATA= Data Set” on page 3947 for a detailed description of the contents of the XDATA= data set.

---

## **BAYES Statement**

**BAYES** < options > ;

The BAYES statement requests a Bayesian analysis of the regression model by using Gibbs sampling. The Bayesian posterior samples (also known as the chain) for the regression parameters are not tabulated. The Bayesian posterior samples (also known as the chain) for the model parameters can be output to a SAS data set.

Table 51.2 summarizes the options available in the BAYES statement.

**Table 51.2** BAYES Statement Options

| <b>Option</b>              | <b>Description</b>                                                                 |
|----------------------------|------------------------------------------------------------------------------------|
| <b>Monte Carlo Options</b> |                                                                                    |
| <b>INITIAL=</b>            | Specifies initial values of the chain                                              |
| <b>INITIALMLE</b>          | Specifies that maximum likelihood estimates be used as initial values of the chain |

Table 51.2 (continued)

| Option                                                | Description                                                      |
|-------------------------------------------------------|------------------------------------------------------------------|
| METROPOLIS=                                           | Specifies the use of a Metropolis step                           |
| NBI=                                                  | Specifies the number of burn-in iterations                       |
| NMC=                                                  | Specifies the number of iterations after burn-in                 |
| SEED=                                                 | Specifies the random number generator seed                       |
| THINNING=                                             | Controls the thinning of the Markov chain                        |
| <b>Model and Prior Options</b>                        |                                                                  |
| COEFFPRIOR=                                           | Specifies the prior of the regression coefficients               |
| EXPONENTIALSCALEPRIOR=                                | Specifies the prior of the exponential scale parameter           |
| GAMMASHAPEPRIOR=                                      | Specifies the prior of the three-parameter gamma shape parameter |
| SCALEPRIOR=                                           | Specifies the prior of the scale parameter                       |
| WEIBULLSCALEPRIOR=                                    | Specifies the prior of the Weibull scale parameter               |
| WEIBULLSHAPEPRIOR=                                    | Specifies the prior of the Weibull shape parameter               |
| <b>Summary Statistics and Convergence Diagnostics</b> |                                                                  |
| DIAGNOSTICS=                                          | Displays convergence diagnostics                                 |
| PLOTS=                                                | Displays diagnostic plots                                        |
| STATISTICS=                                           | Displays summary statistics of the posterior samples             |
| <b>Posterior Samples</b>                              |                                                                  |
| OUTPOST=                                              | Names a SAS data set for the posterior samples                   |

The following list describes these options and their suboptions.

**COEFFPRIOR=UNIFORM | NORMAL** <(normal-options)>

**CPRIOR=UNIFORM | NORMAL** <(option)>

**COEFF=UNIFORM | NORMAL** <(option)>

specifies the prior distribution for the regression coefficients. The default is COEFFPRIOR=UNIFORM. The available prior distributions are as follows:

**NORMAL**<(normal-option)>

specifies a normal distribution. The *normal-options* include the following:

**CONDITIONAL**

specifies that the normal prior, conditional on the current Markov chain value of the location-scale model precision parameter  $\tau = \frac{1}{\sigma^2}$ , is  $N(\boldsymbol{\mu}, \tau^{-1}\boldsymbol{\Sigma})$ , where  $\boldsymbol{\mu}$  and  $\boldsymbol{\Sigma}$  are the mean and covariance of the normal prior specified by other normal options.

**INPUT= SAS-data-set**

specifies a SAS data set that contains the mean and covariance information of the normal prior. The data set must have a `_TYPE_` variable to represent the type of each observation and a variable for each regression coefficient. If the data set also contains a `_NAME_` variable, the values of this variable are used to identify the covariances for the `_TYPE_='COV'` observations; otherwise, the `_TYPE_='COV'` observations are assumed to be in the same order as the explanatory variables in the MODEL statement. PROC LIFEREG reads the

mean vector from the observation with `_TYPE_='MEAN'` and reads the covariance matrix from observations with `_TYPE_='COV'`. For an independent normal prior, the variances can be specified with `_TYPE_='VAR'`; alternatively, the precisions (inverse of the variances) can be specified with `_TYPE_='PRECISION'`.

**RELVAR<=c>**

specifies the normal prior  $N(\mathbf{0}, c\mathbf{J})$ , where  $\mathbf{J}$  is a diagonal matrix with diagonal elements equal to the variances of the corresponding ML estimator. By default,  $c = 10^6$ .

**VAR<=c>**

specifies the normal prior  $N(\mathbf{0}, c\mathbf{I})$ , where  $\mathbf{I}$  is the identity matrix.

If you do not specify an option, the normal prior  $N(\mathbf{0}, 10^6\mathbf{I})$ , where  $\mathbf{I}$  is the identity matrix, is used. See the section “[Normal Prior](#)” on page 3949 for more details.

**UNIFORM**

specifies a flat prior—that is, the prior that is proportional to a constant ( $p(\beta_1, \dots, \beta_k) \propto 1$  for all  $-\infty < \beta_i < \infty$ ).

**DIAGNOSTICS=ALL | NONE | (keyword-list)**

**DIAG=ALL | NONE | (keyword-list)**

controls the number of diagnostics produced. You can request all the following diagnostics by specifying `DIAGNOSTICS=ALL`. If you do not want any of these diagnostics, specify `DIAGNOSTICS=NONE`. If you want some but not all of the diagnostics, or if you want to change certain settings of these diagnostics, specify a subset of the following keywords. The default is `DIAGNOSTICS=(AUTOCORR ESS GEWEKE)`.

**AUTOCORR <(LAGS= numeric-list)>**

computes the autocorrelations of lags given by `LAGS= list` for each parameter. Elements in the list are truncated to integers and repeated values are removed. If the `LAGS=` option is not specified, autocorrelations of lags 1, 5, 10, and 50 are computed for each variable. See the section “[Autocorrelations](#)” on page 152 for details.

**ESS**

computes Carlin’s estimate of the effective sample size, the correlation time, and the efficiency of the chain for each parameter. See the section “[Effective Sample Size](#)” on page 152 for details.

**GELMAN <(gelman-options)>**

computes the Gelman and Rubin convergence diagnostics. You can specify one or more of the following *gelman-options*:

**NCHAIN=number**

**N=number**

specifies the number of parallel chains used to compute the diagnostic, and must be 2 or larger. The default is `NCHAIN=3`. If an `INITIAL=` data set is used, `NCHAIN` defaults to the number of rows in the `INITIAL=` data set. If any number other than this is specified with the `NCHAIN=` option, the `NCHAIN=` value is ignored.

**ALPHA=***value*

specifies the significance level for the upper bound. The default is ALPHA=0.05, resulting in a 97.5% bound.

See the section “[Gelman and Rubin Diagnostics](#)” on page 145 for details.

**GEWEKE** <(geweke-options)>

computes the Geweke spectral density diagnostics, which are essentially a two-sample  $t$  test between the first  $f_1$  portion and the last  $f_2$  portion of the chain. The default is  $f_1 = 0.1$  and  $f_2 = 0.5$ , but you can choose other fractions by using the following *geweke-options*:

**FRAC1=***value*

specifies the fraction  $f_1$  for the first window.

**FRAC2=***value*

specifies the fraction  $f_2$  for the second window.

See the section “[Geweke Diagnostics](#)” on page 146 for details.

**HEIDELBERGER** <(heidel-options)>

computes the Heidelberg and Welch diagnostic for each variable, which consists of a stationarity test of the null hypothesis that the sample values form a stationary process. If the stationarity test is not rejected, a halfwidth test is then carried out. Optionally, you can specify one or more of the following *heidel-options*:

**SALPHA=***value*

specifies the  $\alpha$  level ( $0 < \alpha < 1$ ) for the stationarity test.

**HALPHA=***value*

specifies the  $\alpha$  level ( $0 < \alpha < 1$ ) for the halfwidth test.

**EPS=***value*

specifies a positive number  $\epsilon$  such that if the halfwidth is less than  $\epsilon$  times the sample mean of the retained iterates, the halfwidth test is passed.

See the section “[Heidelberg and Welch Diagnostics](#)” on page 148 for details.

**MCSE****MCERROR**

computes the Monte Carlo standard error for each parameter. The Monte Carlo standard error, which measures the simulation accuracy, is the standard error of the posterior mean estimate and is calculated as the posterior standard deviation divided by the square root of the effective sample size. See the section “[Standard Error of the Mean Estimate](#)” on page 153 for details.

**RAFTERY**<(raftery-options)>

computes the Raftery and Lewis diagnostics that evaluate the accuracy of the estimated quantile ( $\hat{\theta}_Q$  for a given  $Q \in (0, 1)$ ) of a chain.  $\hat{\theta}_Q$  can achieve any degree of accuracy when the chain is allowed to run for a long time. A stopping criterion is when the estimated probability  $\hat{P}_Q = \Pr(\theta \leq \hat{\theta}_Q)$  reaches within  $\pm R$  of the value  $Q$  with probability  $S$ ; that is,  $\Pr(Q - R \leq \hat{P}_Q \leq Q + R) = S$ . The following *raftery-options* enable you to specify  $Q$ ,  $R$ ,  $S$ , and a precision level  $\epsilon$  for the test:

**QUANTILE | Q=value**

specifies the order (a value between 0 and 1) of the quantile of interest. The default is 0.025.

**ACCURACY | R=value**

specifies a small positive number as the margin of error for measuring the accuracy of estimation of the quantile. The default is 0.005.

**PROBABILITY | S=value**

specifies the probability of attaining the accuracy of the estimation of the quantile. The default is 0.95.

**EPSILON | EPS=value**

specifies the tolerance level (a small positive number) for the stationary test. The default is 0.001.

See the section “[Raftery and Lewis Diagnostics](#)” on page 149 for details.

**EXPSCALEPRIOR=GAMMA<(options)> | IMPROPER****ESCALEPRIOR=GAMMA<(options)> | IMPROPER****ESCPRIOR=GAMMA<(options)> | IMPROPER**

specifies that Gibbs sampling be performed on the exponential distribution scale parameter and the prior distribution for the scale parameter. This prior distribution applies only when the exponential distribution and no covariates are specified.

A gamma prior  $G(a, b)$  with density  $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$  is specified by EXPSCALEPRIOR=GAMMA, which can be followed by one of the following *gamma-options* enclosed in parentheses. The hyperparameters  $a$  and  $b$  are the shape and inverse-scale parameters of the gamma distribution, respectively. See the section “[Gamma Prior](#)” on page 3949 for more details. The default is  $G(10^{-4}, 10^{-4})$ .

**RELSHAPE<=c>**

specifies independent  $G(c\hat{\alpha}, c)$  distribution, where  $\hat{\alpha}$  is the MLE of the exponential scale parameter. With this choice of hyperparameters, the mean of the prior distribution is  $\hat{\alpha}$  and the variance is  $\frac{\hat{\alpha}}{c^2}$ . By default,  $c=10^{-4}$ .

**SHAPE=a****ISCALE=b**

when both specified, results in a  $G(a, b)$  prior.

**SHAPE=c**

when specified alone, results in a  $G(c, c)$  prior.

**ISCALE=c**

when specified alone, results in a  $G(c, c)$  prior.

An improper prior with density  $f(t)$  proportional to  $t^{-1}$  is specified with EXPSCALEPRIOR=IMPROPER.

**GAMMASHAPEPRIOR=NORMAL<(options)>****GAMASHAPEPRIOR=NORMAL<(options)>****SHAPE1PRIOR=NORMAL<(options)>**

specifies the prior distribution for the gamma distribution shape parameter. If you do not specify any options in a gamma model, the  $N(0, 10^6)$  prior for the shape is used. You can specify MEAN= and VAR= or RELVAR= options, either alone or together, to specify the mean and variance of the normal prior for the gamma shape parameter.

**MEAN=*a***

specifies a normal prior  $N(a, 10^6)$ . By default,  $a=0$ .

**RELVAR=<=*b*>**

specifies the normal prior  $N(0, bJ)$ , where  $J$  is the variance of the MLE of the shape parameter. By default,  $b=10^6$ .

**VAR=*c***

specifies the normal prior  $N(0, c)$ . By default,  $c=10^6$ .

**INITIAL=*SAS-data-set***

specifies the SAS data set that contains the initial values of the Markov chains. The INITIAL= data set must contain all the variables of the model. You can specify multiple rows as the initial values of the parallel chains for the Gelman-Rubin statistics, but posterior summaries, diagnostics, and plots are computed only for the first chain. If the data set also contains the variable `_SEED_`, the value of the `_SEED_` variable is used as the seed of the random number generator for the corresponding chain.

**INITIALMLE**

specifies that maximum likelihood estimates of the model parameters be used as initial values of the Markov chain. If this option is not specified, estimates of the mode of the posterior distribution obtained by optimization are used as initial values.

**METROPOLIS=YES****METROPOLIS=NO**

specifies the use of a Metropolis step to generate Gibbs samples for posterior distributions that are not log concave. The default value is METROPOLIS=YES.

**NBI=*number***

specifies the number of burn-in iterations before the chains are saved. The default is 2000.

**NMC=*number***

specifies the number of iterations after the burn-in. The default is 10000.

**OUTPOST=*SAS-data-set*****OUT=*SAS-data-set***

names the SAS data set that contains the posterior samples. See the section “[OUTPOST= Output Data Set](#)” on page 3951 for more information. Alternatively, you can create the output data set by specifying an ODS OUTPUT statement as follows:

```
ODS OUTPUT POSTERIORSAMPLE=SAS-data-set
```

**PLOTS<(global-plot-options)>=*plot-request*****PLOTS<(global-plot-options)>=*(plot-request < ...plot-request>)***

controls the display of diagnostic plots. Three types of plots can be requested: trace plots, autocorrelation function plots, and kernel density plots. By default, the plots are displayed in panels unless the global plot option UNPACK is specified. Also, when specifying more than one type of plots, the plots are displayed by parameters unless the global plot option GROUPBY is specified. When you specify only one plot request, you can omit the parentheses around the plot request. For example:

```
plots=none
plots(unpack)=trace
plots=(trace autocorr)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc lifereg;
 model y=x;
 bayes plots=trace;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The global plot options are as follows:

#### **FRINGE**

creates a fringe plot on the X axis of the density plot.

#### **GROUPBY=PARAMETER**

#### **GROUPBY=TYPE**

specifies how the plots are grouped when there is more than one type of plot.

#### **GROUPBY=TYPE**

specifies that the plots be grouped by type.

#### **GROUPBY=PARAMETER**

specifies that the plots be grouped by parameter.

GROUPBY=PARAMETER is the default.

#### **LAGS=*n***

specifies that autocorrelations be plotted up to lag *n*. If this option is not specified, autocorrelations are plotted up to lag 50.

#### **SMOOTH**

displays a fitted penalized B-spline curve for each trace plot.

#### **UNPACKPANEL**

#### **UNPACK**

specifies that all paneled plots be unpacked, meaning that each plot in a panel is displayed separately.

The plot requests include the following:

**ALL**

specifies all types of plots. PLOTS=ALL is equivalent to specifying PLOTS=(TRACE AUTO-CORR DENSITY).

**AUTOCORR**

displays the autocorrelation function plots for the parameters.

**DENSITY**

displays the kernel density plots for the parameters.

**NONE**

suppresses all diagnostic plots.

**TRACE**

displays the trace plots for the parameters. See the section “[Visual Analysis via Trace Plots](#)” on page 139 for details.

**SCALEPRIOR=GAMMA**< (*options*) >

specifies that Gibbs sampling be performed on the location-scale model scale parameter and the prior distribution for the scale parameter.

A gamma prior  $G(a, b)$  with density  $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$  is specified by SCALEPRIOR=GAMMA, which can be followed by one of the following *gamma-options* enclosed in parentheses. The hyperparameters  $a$  and  $b$  are the shape and inverse-scale parameters of the gamma distribution, respectively. See the section “[Gamma Prior](#)” on page 3949 for details. The default is  $G(10^{-4}, 10^{-4})$ .

**RELSHAPE**<=*c*>

specifies independent  $G(c\hat{\sigma}, c)$  distribution, where  $\hat{\sigma}$  is the MLE of the scale parameter. With this choice of hyperparameters, the mean of the prior distribution is  $\hat{\sigma}$  and the variance is  $\frac{\hat{\sigma}}{c}$ . By default,  $c=10^{-4}$ .

**SHAPE**=*a***ISCALE**=*b*

when both specified, results in a  $G(a, b)$  prior.

**SHAPE**=*c*

when specified alone, results in a  $G(c, c)$  prior.

**ISCALE**=*c*

when specified alone, results in a  $G(c, c)$  prior.

**SEED**=*number*

specifies an integer seed in the range 1 to  $2^{31} - 1$  for the random number generator in the simulation. Specifying a seed enables you to reproduce identical Markov chains for the same specification. If the SEED= option is not specified, or if you specify a nonpositive seed, a random seed is derived from the time of day.

**STATISTICS** <(global-options)> = **ALL** | **NONE** | *keyword* | (*keyword-list*)

**STATS** <(global-statoptions)> = **ALL** | **NONE** | *keyword* | (*keyword-list*)

controls the number of posterior statistics produced. Specifying STATISTICS=ALL is equivalent to specifying STATISTICS= (SUMMARY INTERVAL COV CORR). If you do not want any posterior statistics, you specify STATISTICS=NONE. The default is STATISTICS=(SUMMARY INTERVAL). See the section “[Summary Statistics](#)” on page 153 for details. The *global-options* include the following:

**ALPHA**=*numeric-list*

controls the probabilities of the credible intervals. The ALPHA= values must be between 0 and 1. Each ALPHA= value produces a pair of 100(1-ALPHA)% equal-tail and HPD intervals for each parameters. The default is ALPHA=0.05, which yields the 95% credible intervals for each parameter.

**PERCENT**=*numeric-list*

requests the percentile points of the posterior samples. The PERCENT= values must be between 0 and 100. The default is PERCENT=25, 50, 75, which yields the 25th, 50th, and 75th percentile points, respectively, for each parameter.

The list of *keywords* includes the following:

**CORR**

produces the posterior correlation matrix.

**COV**

produces the posterior covariance matrix.

**SUMMARY**

produces the means, standard deviations, and percentile points for the posterior samples. The default is to produce the 25th, 50th, and 75th percentile points, but you can use the global PERCENT= option to request specific percentile points.

**INTERVAL**

produces equal-tail credible intervals and HPD intervals. The default is to produce the 95% equal-tail credible intervals and 95% HPD intervals, but you can use the global ALPHA= option to request intervals of any probabilities.

**NONE**

suppresses printing all summary statistics.

**THINNING**=*number*

**THIN**=*number*

controls the thinning of the Markov chain. Only one in every  $k$  samples is used when THINNING= $k$ , and if  $NBI=n_0$  and  $NMC=n$ , the number of samples kept is

$$\left[ \frac{n_0 + n}{k} \right] - \left[ \frac{n_0}{k} \right]$$

where  $[a]$  represents the integer part of the number  $a$ . The default is THINNING=1.

**WEIBULLSCALEPRIOR=GAMMA**< *options* >

**WSCALEPRIOR=GAMMA**< *options* >

**WSCPRIOR=GAMMA**< *options* >

specifies that Gibbs sampling be performed on the Weibull model scale parameter and the prior distribution for the scale parameter. This option applies only when a Weibull distribution and no covariates are specified. When this option is specified, PROC LIFEREG performs Gibbs sampling on the Weibull scale parameter, which is defined as  $\exp(\mu)$ , where  $\mu$  is the intercept term.

A gamma prior  $G(a, b)$  is specified by WEIBULLSCALEPRIOR=GAMMA, which can be followed by one of the following *gamma-options* enclosed in parentheses. The gamma probability density is given by  $g(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$ . The hyperparameters  $a$  and  $b$  are the shape and inverse-scale parameters of the gamma distribution, respectively. See the section “Gamma Prior” on page 3949 for details about the gamma prior. The default is  $G(10^{-4}, 10^{-4})$ .

**RELSHAPE**<=*c*>

specifies independent  $G(c\hat{\alpha}, c)$  distribution, where  $\hat{\alpha}$  is the MLE of the Weibull scale parameter. With this choice of hyperparameters, the mean of the prior distribution is  $\hat{\alpha}$  and the variance is  $\frac{\hat{\alpha}}{c}$ . By default,  $c=10^{-4}$ .

**SHAPE**=*a*

**ISCALE**=*b*

when both specified, results in a  $G(a, b)$  prior.

**SHAPE**=*c*

when specified alone, results in a  $G(c, c)$  prior.

**ISCALE**=*c*

when specified alone, results in a  $G(c, c)$  prior.

**WEIBULLSHAPEPRIOR=GAMMA**< *options* >

**WSHAPEPRIOR=GAMMA**< *options* >

**WSPRIOR=GAMMA**< *options* >

specifies that Gibbs sampling be performed on the Weibull model shape parameter and the prior distribution for the shape parameter. When this option is specified, PROC LIFEREG performs Gibbs sampling on the Weibull shape parameter, which is defined as  $\sigma^{-1}$ , where  $\sigma$  is the location-scale model scale parameter.

A gamma prior  $G(a, b)$  with density  $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$  is specified by WEIBULLSHAPEPRIOR=GAMMA, which can be followed by one of the following *gamma-options* enclosed in parentheses. The hyperparameters  $a$  and  $b$  are the shape and inverse-scale parameters of the gamma distribution, respectively. See the section “Gamma Prior” on page 3949 for details about the gamma prior. The default is  $G(10^{-4}, 10^{-4})$ .

**RELSHAPE**<=*c*>

specifies independent  $G(c\hat{\beta}, c)$  distribution, where  $\hat{\beta}$  is the MLE of the Weibull shape parameter. With this choice of hyperparameters, the mean of the prior distribution is  $\hat{\beta}$  and the variance is  $\frac{\hat{\beta}}{c}$ . By default,  $c=10^{-4}$ .

**SHAPE**< =*a* >

**ISCALE**=*b*

when both specified, results in a  $G(a, b)$  prior.

**SHAPE**=*c*

when specified alone, results in a  $G(c, c)$  prior.

**ISCALE**=*c*

when specified alone, results in a  $G(c, c)$  prior.

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC LIFEREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the LIFEREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## CLASS Statement

**CLASS** *variables* < / **TRUNCATE** > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS*

*Formats and Informats: Reference.* You can adjust the order of CLASS variable levels with the **ORDER=** option in the **PROC LIFEREG** statement. You can specify the following option in the CLASS statement after a slash (/):

### TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

## EFFECTPLOT Statement

**EFFECTPLOT** < *plot-type* < (*plot-definition-options*) >> < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 51.3 describes the available *plot-types* and their *plot-definition-options*.

**Table 51.3** *Plot-Types and Plot-Definition-Options*

| Plot-Type and Description                                                                                                                                                                                                                 | Plot-Definition-Options                                                                                                            |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>BOX</b><br/>Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the <b>INTERACTION</b> <i>plot-type</i>.</p>     | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>X=</b> CLASS variable or effect</p>                                              |
| <p><b>CONTOUR</b><br/>Displays a contour plot of predicted values against two continuous covariates.</p>                                                                                                                                  | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>X=</b> continuous variable<br/><b>Y=</b> continuous variable</p>                 |

| <p><b>INTERACTION</b><br/>Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.</p> | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>SLICEBY=</b> variable or CLASS effect<br/><b>X=</b> CLASS variable or effect</p> |
| <p><b>SLICEFIT</b><br/>Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.</p>                                                                                                     | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>SLICEBY=</b> variable or CLASS effect<br/><b>X=</b> continuous variable</p>      |

For full details about the syntax and options of the EFFECTPLOT statement, see the section “**EFFECTPLOT Statement**” on page 411 in Chapter 19, “**Shared Concepts and Topics**.”

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 <, ... <'label'> estimate-specification <(divisor=n)>>
 </options>;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $\mathbf{L}\boldsymbol{\beta}$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 51.4 summarizes the options available in the ESTIMATE statement.

**Table 51.4** ESTIMATE Statement Options

| Option                                                     | Description                                                               |
|------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                           |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                     |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects |
| SINGULAR=                                                  | Tunes the estimability checking difference                                |
| <b>Degrees of Freedom and <math>p</math>-values</b>        |                                                                           |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates     |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                          |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                |
| STEPDOWN                                                   | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                      |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                |
| <b>Statistical Output</b>                                  |                                                                           |
| CL                                                         | Constructs confidence limits                                              |
| CORR                                                       | Displays the correlation matrix of estimates                              |
| COV                                                        | Displays the covariance matrix of estimates                               |
| E                                                          | Prints the $\mathbf{L}$ matrix                                            |
| JOINT                                                      | Produces a joint $F$ or chi-square test for the estimable functions       |
| PLOTS=                                                     | Requests ODS statistical graphics if the analysis is sampling-based       |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers         |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## INSET Statement

**INSET** < keyword-list > < / options > ;

The box or table of summary information produced on plots made with the **PROBPLOT** statement is called an *inset*. You can use the **INSET** statement to customize the information that is displayed in the inset box as well as to customize the appearance of the inset box. To supply the information that is displayed in the inset box, you specify *keywords* corresponding to the information that you want shown. For example, the following statements produce a probability plot with the number of observations, the number of right-censored observations, the name of the distribution, and the estimated Weibull shape parameter in the inset:

```
proc lifereg data=epidemic;
 model life = dose / dist = Weibull;
 probplot;
 inset nobs right dist shape;
run;
```

By default, inset entries are identified with appropriate labels. However, you can provide a customized label by specifying the *keyword* for that entry followed by the equal sign (=) and the label in quotes. For example, the following **INSET** statement produces an inset containing the number of observations and the name of the distribution, labeled “Sample Size” and “Distribution” in the inset:

```
inset nobs='Sample Size' dist='Distribution';
```

If you specify a keyword that does not apply to the plot you are creating, then the keyword is ignored.

If you specify more than one **INSET** statement, only the first one is used.

Table 51.5 lists keywords available in the **INSET** statement to display summary statistics, distribution parameters, and distribution fitting information.

**Table 51.5** INSET Statement Keywords

| Keyword           | Description                                         |
|-------------------|-----------------------------------------------------|
| <b>CONFIDENCE</b> | Confidence coefficient for all confidence intervals |
| <b>DIST</b>       | Name of the distribution                            |
| <b>INTERVAL</b>   | Number of interval-censored observations            |
| <b>LEFT</b>       | Number of left-censored observations                |
| <b>NOBS</b>       | Number of observations                              |
| <b>NMISS</b>      | Number of observations with missing values          |
| <b>RIGHT</b>      | Number of right-censored observations               |
| <b>SCALE</b>      | Value of the scale parameter                        |
| <b>SHAPE</b>      | Value of the shape parameter                        |
| <b>UNCENSORED</b> | Number of uncensored observations                   |

The following *options* control the appearance of the box when you use traditional graphics. These options are not available if ODS Graphics is enabled. Table 51.6 summarizes the options available in the **INSET** statement.

**Table 51.6** INSET Statement Options

| Option           | Description                                    |
|------------------|------------------------------------------------|
| <b>CFILL=</b>    | Specifies the color for the filling box        |
| <b>CFILLH=</b>   | Specifies the color for the filling box header |
| <b>CFRAME=</b>   | Specifies the color for the frame              |
| <b>CHEADER=</b>  | Specifies the color for text in the header     |
| <b>CTEXT=</b>    | Specifies the color for the text               |
| <b>FONT=</b>     | Specifies the software font for the text       |
| <b>HEIGHT=</b>   | Specifies the height of the text               |
| <b>HEADER=</b>   | Specifies the text for the header or box title |
| <b>NOFRAME</b>   | Omits the frame around the box                 |
| <b>POS=</b>      | Determines the position of the inset           |
| <b>REFPOINT=</b> | Specifies the reference point for an inset     |

All *options* are specified after the slash (/) in the INSET statement.

**CFILL=***color*

specifies the color for the filling box.

**CFILLH=***color*

specifies the color for the filling box header.

**CFRAME=***color*

specifies the color for the frame.

**CHEADER=***color*

specifies the color for text in the header.

**CTEXT=***color*

specifies the color for the text.

**FONT=***font*

specifies the software font for the text.

**HEIGHT=***value*

specifies the height of the text.

**HEADER=**'*quoted string*'

specifies the text for the header or box title.

**NOFRAME**

omits the frame around the box.

**POS=***value* < **DATA** | **PERCENT** >

determines the position of the inset. The *value* can be a compass point (N, NE, E, SE, S, SW, W, NW) or a pair of coordinates (x, y) enclosed in parentheses. The coordinates can be specified in screen percentage units or axis data units. The default is screen percentage units.

**REFPOINT=*name***

specifies the reference point for an inset that is positioned by a pair of coordinates with the POS= option. You use the REFPOINT= option in conjunction with the POS= coordinates. The REFPOINT= option specifies which corner of the inset frame you have specified with coordinates (x, y), and it can take the value of BR (bottom right), BL (bottom left), TR (top right), or TL (top left). The default is REFPOINT=BL. If the inset position is specified as a compass point, then the REFPOINT= option is ignored.

---

## LSMEANS Statement

**LSMEANS** < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 51.7 summarizes the options available in the LSMEANS statement.

**Table 51.7** LSMEANS Statement Options

| Option                                          | Description                                                                                 |
|-------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                                                             |
| AT                                              | Modifies the covariate value in computing LS-means                                          |
| BYLEVEL                                         | Computes separate margins                                                                   |
| DIFF                                            | Requests differences of LS-means                                                            |
| OM=                                             | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| SINGULAR=                                       | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <i>p</i>-values</b>   |                                                                                             |
| ADJUST=                                         | Determines the method for multiple-comparison adjustment of LS-means differences            |
| ALPHA= $\alpha$                                 | Determines the confidence level ( $1 - \alpha$ )                                            |
| STEPDOWN                                        | Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion                 |
| <b>Statistical Output</b>                       |                                                                                             |
| CL                                              | Constructs confidence limits for means and mean differences                                 |
| CORR                                            | Displays the correlation matrix of LS-means                                                 |
| COV                                             | Displays the covariance matrix of LS-means                                                  |
| E                                               | Prints the <b>L</b> matrix                                                                  |
| LINES                                           | Produces a “Lines” display for pairwise LS-means differences                                |
| MEANS                                           | Prints the LS-means                                                                         |
| PLOTS=                                          | Requests graphs of means and mean comparisons                                               |
| SEED=                                           | Specifies the seed for computations that depend on random numbers                           |

---

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 in Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 51.8 summarizes the options available in the LSMESTIMATE statement.

**Table 51.8** LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level $(1 - \alpha)$                                      |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |
| <b>Statistical Output</b>                           |                                                                                     |
| CL                                                  | Constructs confidence limits for means and mean differences                         |
| CORR                                                | Displays the correlation matrix of LS-means                                         |
| COV                                                 | Displays the covariance matrix of LS-means                                          |
| E                                                   | Prints the <b>L</b> matrix                                                          |
| ELSM                                                | Prints the <b>K</b> matrix                                                          |
| JOINT                                               | Produces a joint $F$ or chi-square test for the LS-means and LS-means differences   |
| PLOTS=                                              | Requests graphs of means and mean comparisons                                       |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                   |

---

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” on page 470 in Chapter 19, “Shared Concepts and Topics.”

## MODEL Statement

```
<label:> MODEL response< *censor(list)> = effects </ options> ;
```

```
<label:> MODEL (lower,upper)= effects </ options> ;
```

```
<label:> MODEL events/trials = effects </ options> ;
```

Only a single MODEL statement can be used with one invocation of the LIFEREG procedure. If multiple MODEL statements are present, only the last is used. The optional *label* is used to label the model estimates in the output SAS data set and OUTEST= data set.

The first MODEL syntax is appropriate for right censoring. The variable *response* is possibly right censored. If the *response* variable can be right censored, then a second variable, denoted *censor*, must appear after the *response* variable with a list of parenthesized values, separated by commas or blanks, to indicate censoring. That is, if the *censor* variable takes on a value given in the list, the *response* is a right-censored value; otherwise, it is an observed value.

The second MODEL syntax specifies two variables, *lower* and *upper*, that contain values of the endpoints of the censoring interval. If the two values are the same (and not missing), it is assumed that there is no censoring and the actual response value is observed. If the lower value is missing, then the upper value is used as a left-censored value. If the upper value is missing, then the lower value is taken as a right-censored value. If both values are present and the lower value is less than the upper value, it is assumed that the values specify a censoring interval. If the lower value is greater than the upper value or both values are missing, then the observation is not used in the analysis, although predicted values can still be obtained if none of the covariates are missing.

The following table summarizes the ways of specifying censoring.

| <i>lower</i> | <i>upper</i> | Comparison    | Interpretation                      |
|--------------|--------------|---------------|-------------------------------------|
| Not missing  | Not missing  | Equal         | No censoring                        |
| Not missing  | Not missing  | Lower < upper | Censoring interval                  |
| Missing      | Not missing  |               | Upper used as left-censoring value  |
| Not missing  | Missing      |               | Lower used as right-censoring value |
| Not missing  | Not missing  | Lower > upper | Observation not used                |
| Missing      | Missing      |               | Observation not used                |

The third MODEL syntax specifies two variables that contain count data for a binary response. The value of the first variable, *events*, is the number of successes. The value of the second variable, *trials*, is the number of tries. The values of both *events* and (*trials-events*) must be nonnegative, and *trials* must be positive for the response to be valid. The values of the two variables do not need to be integers and are not modified to be integers.

The *effects* following the equal sign are the covariates in the model. Higher-order effects, such as interactions and nested terms, are allowed in the list, similar to the GLM procedure. Variable names and combinations of variable names representing higher-order terms are allowed to appear in this list. Classification, or CLASS, variables can be used as effects, and indicator variables are generated for the class levels. If you do not specify any covariates following the equal sign, an intercept-only model is fit.

Examples of three valid MODEL statements follow:

```
a: model time*flag(1,3)=temp;
```

```
b: model (start, finish)=;
```

```
c: model r/n=dose;
```

MODEL statement a indicates that the response is contained in a variable named time and that, if the variable flag takes on the values 1 or 3, the observation is right censored. The explanatory variable is temp, which could be a CLASS variable. MODEL statement b indicates that the response is known to be in the interval between the values of the variables start and finish and that there are no covariates except for a default intercept term. MODEL statement c indicates a binary response, with the variable r containing the number of responses and the variable n containing the number of trials.

Table 51.9 summarizes the options available in the MODEL statement.

**Table 51.9** MODEL Statement Options

| Option                     | Description                                                                  |
|----------------------------|------------------------------------------------------------------------------|
| <b>Model specification</b> |                                                                              |
| ALPHA=                     | Sets the significance level                                                  |
| DISTRIBUTION=              | Specifies the distribution type for failure time                             |
| NOLOG                      | Requests no log transformation of response                                   |
| INTERCEPT=                 | Specifies initial estimate for intercept term                                |
| NOINT                      | Holds the intercept term fixed                                               |
| INITIAL=                   | Specifies initial estimates for regression parameters                        |
| OFFSET=                    | Specifies an offset variable                                                 |
| SCALE=                     | Initializes the scale parameter                                              |
| NOSCALE                    | Holds the scale parameter fixed                                              |
| SHAPE1=                    | Initializes the first shape parameter                                        |
| NOSHAPE1                   | Holds the first shape parameter fixed                                        |
| <b>Model fitting</b>       |                                                                              |
| CONVERGE=                  | Sets the convergence criterion                                               |
| MAXITER=                   | Sets the maximum number of iterations                                        |
| SINGULAR=                  | Sets the tolerance for testing singularity                                   |
| <b>Output</b>              |                                                                              |
| CORRB                      | Displays the estimated correlation matrix                                    |
| COVB                       | Displays the estimated covariance matrix                                     |
| ITPRINT                    | Displays the iteration history, final gradient, and second derivative matrix |

The following options can appear in the MODEL statement.

**ALPHA=value**

sets the significance level for the confidence intervals for regression parameters and estimated survival probabilities. The value must be between 0 and 1. By default, ALPHA=0.05.

**CONVERGE=value**

sets the convergence criterion. Convergence is declared when the maximum change in the parameter estimates between Newton-Raphson steps is less than the value specified. The change is a relative change if the parameter is greater than 0.01 in absolute value; otherwise, it is an absolute change. By default, CONVERGE=1E-8.

**CONVG=value**

sets the relative Hessian convergence criterion; *value* must be between 0 and 1. After convergence is determined with the change in parameter criterion specified with the CONVERGE= option, the quantity  $tc = \frac{\mathbf{g}'\mathbf{H}^{-1}\mathbf{g}}{|f|}$  is computed and compared to *value*, where  $\mathbf{g}$  is the gradient vector,  $\mathbf{H}$  is the Hessian matrix for the model parameters, and  $f$  is the log-likelihood function. If  $tc$  is greater than *value*, a warning that the relative Hessian convergence criterion has been exceeded is displayed. This criterion detects the occasional case where the change in parameter convergence criterion is satisfied, but a maximum in the log-likelihood function has not been attained. By default, CONVG=1E-4.

**CORRB**

produces the estimated correlation matrix of the parameter estimates.

**COVB**

produces the estimated covariance matrix of the parameter estimates.

**DISTRIBUTION=distribution-type****DIST=distribution-type****D=distribution-type**

specifies the distribution type assumed for the failure time. By default, PROC LIFEREG fits a type 1 extreme-value distribution to the log of the response. This is equivalent to fitting the Weibull distribution, since the scale parameter for the extreme-value distribution is related to a Weibull shape parameter and the intercept is related to the Weibull scale parameter in this case. When the NOLOG option is specified, PROC LIFEREG models the untransformed response with a type 1 extreme-value distribution as the default. See the section “Supported Distributions” on page 3933 for descriptions of the distributions. The following are valid values for *distribution-type*:

|                    |                                                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------------------------------|
| <b>EXPONENTIAL</b> | the exponential distribution, which is treated as a restricted Weibull distribution                                                      |
| <b>GAMMA</b>       | a generalized gamma distribution (Lawless 2003, p. 240). The standard two-parameter gamma distribution is not available in PROC LIFEREG. |
| <b>LLOGISTIC</b>   | a log-logistic distribution                                                                                                              |
| <b>LNORMAL</b>     | a lognormal distribution                                                                                                                 |
| <b>LOGISTIC</b>    | a logistic distribution (equivalent to LLOGISTIC when the NOLOG option is specified)                                                     |
| <b>NORMAL</b>      | a normal distribution (equivalent to LNORMAL when the NOLOG option is specified)                                                         |

**WEIBULL** a Weibull distribution. If NOLOG is specified, it fits a type 1 extreme-value distribution to the raw, untransformed data.

By default, PROC LIFEREG transforms the response with the natural logarithm before fitting the specified model when you specify the GAMMA, LLOGISTIC, LNORMAL, or WEIBULL option. You can suppress the log transformation with the NOLOG option. The following table summarizes the resulting distributions when the preceding distribution options are used in combination with the NOLOG option.

|                      | <b>NOLOG</b>      |                                                                                                                                               |
|----------------------|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------|
| <b>DISTRIBUTION=</b> | <b>Specified?</b> | <b>Resulting Distribution</b>                                                                                                                 |
| <b>EXPONENTIAL</b>   | No                | Exponential                                                                                                                                   |
| <b>EXPONENTIAL</b>   | Yes               | One-parameter extreme value                                                                                                                   |
| <b>GAMMA</b>         | No                | Generalized log-gamma using the log of the response.<br>(This is the same as fitting the generalized gamma using the untransformed response.) |
| <b>GAMMA</b>         | Yes               | Generalized log-gamma with untransformed responses                                                                                            |
| <b>LOGISTIC</b>      | No                | Logistic                                                                                                                                      |
| <b>LOGISTIC</b>      | Yes               | Logistic (NOLOG has no effect)                                                                                                                |
| <b>LLOGISTIC</b>     | No                | Log-logistic                                                                                                                                  |
| <b>LLOGISTIC</b>     | Yes               | Logistic                                                                                                                                      |
| <b>LNORMAL</b>       | No                | Lognormal                                                                                                                                     |
| <b>LNORMAL</b>       | Yes               | Normal                                                                                                                                        |
| <b>NORMAL</b>        | No                | Normal                                                                                                                                        |
| <b>NORMAL</b>        | Yes               | Normal (NOLOG has no effect)                                                                                                                  |
| <b>WEIBULL</b>       | No                | Weibull                                                                                                                                       |
| <b>WEIBULL</b>       | Yes               | Extreme value                                                                                                                                 |

**INITIAL=values**

sets initial values for the regression parameters. This option can be helpful in the case of convergence difficulty. Specified values are used to initialize the regression coefficients for the covariates specified in the MODEL statement. The intercept parameter is initialized with the INTERCEPT= option and is not included here. The values are assigned to the variables in the MODEL statement in the same order in which they are listed in the MODEL statement. Note that a CLASS variable requires  $k - 1$  values when the CLASS variable takes on  $k$  different levels. The order of the CLASS levels is determined by the ORDER= option. If there is no intercept term, the first CLASS variable requires  $k$  initial values. If a BY statement is used, all CLASS variables must take on the same number of levels in each BY group or no meaningful initial values can be specified. The INITIAL= option can be specified as follows.

| <b>Type of List</b>      | <b>Specification</b>       |
|--------------------------|----------------------------|
| List separated by blanks | <b>initial=3 4 5</b>       |
| List separated by commas | <b>initial=3,4,5</b>       |
| x to y                   | <b>initial=3 to 5</b>      |
| x to y by z              | <b>initial=3 to 5 by 1</b> |
| Combination of methods   | <b>initial=1,3 to 5,9</b>  |

By default, PROC LIFEREG computes initial estimates with ordinary least squares. See the section “Computational Method” on page 3931 for details.

**NOTE:** The INITIAL= option is overwritten by the INEST= option. See the section “INEST= Data Set” on page 3945 for details.

**INTERCEPT=***value*

initializes the intercept term to *value*. By default, the intercept is initialized by an ordinary least squares estimate.

**ITPRINT**

displays the iteration history for computing maximum likelihood estimates, the final evaluation of the gradient, and the final evaluation of the negative of the second derivative matrix—that is, the negative of the Hessian. If you perform a Bayesian analysis by specifying the BAYES statement, the iteration history for computing the mode of the posterior distribution is also displayed.

**MAXITER=***n*

sets the maximum allowable number of iterations during the model estimation. By default, MAXITER=50.

**NOINT**

holds the intercept term fixed. Because of the usual log transformation of the response, the intercept parameter is usually a scale parameter for the untransformed response, or a location parameter for a transformed response.

**NOLOG**

requests that no log transformation of the response variable be performed. By default, PROC LIFEREG models the log of the response variable for the GAMMA, LLOGISTIC, LOGNORMAL, and WEIBULL distribution options. NOLOG is implicitly assumed for the NORMAL and LOGISTIC distribution options.

**NOSCALE**

holds the scale parameter fixed. Note that if the log transformation has been applied to the response, the effect of the scale parameter is a power transformation of the original response. If no SCALE= value is specified, the scale parameter is fixed at the value 1.

**NOSHAPE1**

holds the first shape parameter, SHAPE1, fixed. If no SHAPE1= value is specified, SHAPE1 is fixed at a value that depends on the DISTRIBUTION type.

**OFFSET=***variable*

specifies a variable in the input data set to be used as an offset variable. This variable cannot be a CLASS variable, and it cannot be the response variable or one of the explanatory variables.

**SCALE=***value*

initializes the scale parameter to *value*. If the Weibull distribution is specified, this scale parameter is the scale parameter of the type 1 extreme-value distribution, not the Weibull scale parameter. Note that, with a log transformation, the exponential model is the same as a Weibull model with the scale parameter fixed at the value 1.

**SHAPE1=value**

initializes the first shape parameter to *value*. If the specified distribution does not depend on this parameter, then this option has no effect. The only distribution that depends on this shape parameter is the generalized gamma distribution. See the section “Supported Distributions” on page 3933 for descriptions of the parameterizations of the distributions.

**SINGULAR=value**

sets the tolerance for testing singularity of the information matrix and the crossproducts matrix for the initial least squares estimates. Roughly, the test requires that a pivot be at least this value times the original diagonal value. By default, SINGULAR=1E-12.

---

## OUTPUT Statement

**OUTPUT** < **OUT=SAS-data-set** > < *keyword=name* > ... < *keyword=name* > ;

The OUTPUT statement creates a new SAS data set containing statistics calculated after fitting the model. At least one specification of the form *keyword=name* is required.

All variables in the original data set are included in the new data set, along with the variables created as options for the OUTPUT statement. These new variables contain fitted values and estimated quantiles. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. Each OUTPUT statement applies to the preceding MODEL statement. See [Example 51.1](#) for illustrations of the OUTPUT statement.

The following specifications can appear in the OUTPUT statement:

**OUT=SAS-data-set**

specifies the new data set. By default, the procedure uses the *DATA**n* convention to name the new data set.

*keyword=name*

specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

**CENSORED=variable**

specifies a *variable* to signal whether an observation is censored, and the type of censoring. The variable takes on values according to [Table 51.10](#).

**Table 51.10** Censoring Variable Values

| Type of Response  | CENSORED Variable Value |
|-------------------|-------------------------|
| Uncensored        | 0                       |
| Right-censored    | 1                       |
| Left-censored     | 2                       |
| Interval-censored | 3                       |

**CDF=variable**

specifies a *variable* to contain the estimates of the cumulative distribution function evaluated at the observed response. If the data are interval censored, then the cumulative distribution function is evaluated at the response lower interval endpoint. See the section “[Predicted Values](#)” on page 3937 for more information.

**CONTROL=variable**

specifies a *variable* in the input data set to control the estimation of quantiles. See [Example 51.1](#) for an illustration. If the specified variable has the value 1, estimates for all the values listed in the QUANTILE= list are computed for that observation in the input data set; otherwise, no estimates are computed. If no CONTROL= variable is specified, all quantiles are estimated for all observations. If the response variable in the MODEL statement is binomial, then this option has no effect.

**CRESIDUAL | CRES=variable**

specifies a *variable* to contain the Cox-Snell residuals

$$-\log(S(u_i))$$

where  $S$  is the standard survival function and

$$u_i = \frac{y_i - \mathbf{x}'_i \mathbf{b}}{\sigma}$$

If the data are interval censored, residuals are computed for  $y_i$  values corresponding to lower interval endpoints. If the response variable in the corresponding model statement is binomial, then the residuals are not computed, and this variable contains missing values.

**SRESIDUAL | SRES=variable**

specifies a *variable* to contain the standardized residuals

$$\frac{y_i - \mathbf{x}'_i \mathbf{b}}{\sigma}$$

If the data are interval censored, residuals are computed for  $y_i$  values corresponding to lower interval endpoints. If the response variable in the corresponding model statement is binomial, then the residuals are not computed, and this variable contains missing values.

**PREDICTED | P=variable**

specifies a *variable* to contain the quantile estimates. If the response variable in the corresponding model statement is binomial, then this variable contains the estimated probabilities,  $1 - F(-\mathbf{x}'\mathbf{b})$ .

**QUANTILES | QUANTILE | Q=value-list**

gives a list of *values* for which quantiles are calculated. The values must be between 0 and 1, noninclusive. For each value, a corresponding quantile is estimated. This option is not used if the response variable in the corresponding MODEL statement is binomial.

By default, QUANTILES=0.5. When the response is not binomial, a numeric variable, `_PROB_`, is added to the OUTPUT data set whenever the QUANTILES= option is specified. The variable `_PROB_` gives the probability value for the quantile estimates. These are the values taken from the QUANTILES= list and are given as values between 0 and 1, not as values between 0 and 100. The list of QUANTILES values can be specified as in [Table 51.11](#).

**Table 51.11** Types of Value Lists

| Type of List             | Specification      |
|--------------------------|--------------------|
| List separated by blanks | .2 .4 .6 .8        |
| List separated by commas | .2, .4, .6, .8     |
| x to y                   | .2 to .8           |
| x to y by z              | .2 to .8 by .1     |
| Combination of methods   | .1, .2 to .8 by .2 |

**STD\_ERR | STD=variable**

specifies a *variable* to contain the estimates of the standard errors of the estimated quantiles or  $x'b$ . If the response used in the MODEL statement is a binomial response, then these are the standard errors of  $x'b$ . Otherwise, they are the standard errors of the quantile estimates. These estimates can be used to compute confidence intervals for the quantiles. However, if the model is fit to the log of the event time, better confidence intervals can usually be computed by transforming the confidence intervals for the log response. See [Example 51.1](#) for such a transformation.

**XBETA=variable**

specifies a *variable* to contain the computed value of  $x'b$ , where  $x$  is the covariate vector and  $b$  is the vector of parameter estimates.

---

## PROBPLOT Statement

**PROBPLOT | PLOT** </options> ;

You can use the PROBPLOT statement to create a probability plot from lifetime data. The data can be uncensored, right censored, or arbitrarily censored. You can specify any number of PROBPLOT statements after a MODEL statement. The syntax used for the response in the MODEL statement determines the type of censoring assumed in creating the probability plot. The model fit with the MODEL statement is plotted along with the data. If there are covariates in the model, they are set to constant values specified in the XDATA= data set when creating the probability plot. If no XDATA= data set is specified, continuous variables are set to their overall mean values and categorical variables specified in the CLASS statement are set to their highest levels.

Table 51.12 summarizes the options available in the PROBPLOT statement.

**Table 51.12** PROBPLOT Statement Options

| Option                      | Description                                          |
|-----------------------------|------------------------------------------------------|
| <b>Traditional Graphics</b> |                                                      |
| ANNOTATE=                   | Specifies an Annotate data set                       |
| CAXIS=                      | Specifies the color used for the axes and tick marks |
| CCENSOR=                    | Specifies the color for filling the censor plot area |
| CENBIN                      | Plots censored data as frequency counts              |
| CENCOLOR=                   | Specifies the color for the censor symbol            |
| CENSYMBOL=                  | Specifies symbols for censored values                |

Table 51.12 continued

| Option       | Description                                                                      |
|--------------|----------------------------------------------------------------------------------|
| CFIT=        | Specifies the color for the fitted probability line and confidence curves        |
| CFRAME=      | Specifies the color for the area enclosed by the axes and frame                  |
| CGRID=       | Specifies the color for grid lines                                               |
| CHREF=       | Specifies the color for lines requested by the HREF= option                      |
| CTEXT=       | Specifies the color for tick mark values and axis labels                         |
| CVREF=       | Specifies the color for lines requested by the VREF= option                      |
| DESCRIPTION= | Specifies a description that appears in the PROC GREPLAY master menu             |
| FONT=        | Specifies a software font for reference line and axis labels                     |
| HCL          | Computes and draws confidence limits                                             |
| HEIGHT=      | Specifies the height of text used outside framed areas                           |
| HLOWER=      | Specifies the lower limit on the lifetime axis scale                             |
| HOFFSET=     | Specifies the offset for the horizontal axis                                     |
| HUPPER=      | Specifies <i>value</i> as the upper lifetime axis tick mark                      |
| HREF         | Draws reference lines perpendicular to the horizontal axis                       |
| HREFLABELS=  | Specifies labels for the lines requested by the HREF= option                     |
| HREFLABPOS=  | Specifies the vertical position of labels for HREF= lines                        |
| INBORDER     | Requests a border around probability plots                                       |
| INTERTILE=   | Specifies the distance between tiles                                             |
| ITPRINTEM    | Displays the iteration history for the Turnbull algorithm                        |
| JITTER=      | Specifies the amount to jitter overlaying plot symbols, in units of symbol width |
| LFIT=        | Specifies a line style for fitted curves and confidence limits                   |
| LGRID=       | Specifies a line style for all grid lines                                        |
| LHREF=       | Specifies the line type for lines requested by the HREF= option                  |
| LVREF=       | Specifies the line type for lines requested by the VREF= option                  |
| MAXITEM=     | Specifies the maximum number of iterations for the Turnbull algorithm            |
| NAME=        | Specifies a name for the plot                                                    |
| NOCENPLOT    | Suppresses the plotting of censored data points                                  |
| NOCONF       | Suppresses the default confidence bands                                          |
| NODATA       | Suppresses plotting of the estimated empirical probability plot                  |
| NOFIT        | Suppresses the fitted probability (percentile) line and confidence bands         |
| NOFRAME      | Suppresses the frame around plotting areas                                       |
| NOGRID       | Suppresses grid lines                                                            |
| NOHLABEL     | Suppresses horizontal label                                                      |
| NOHTICK      | Suppresses horizontal tick marks                                                 |
| NOPOLISH     | Suppresses setting small interval probabilities to zero                          |
| NOVLABEL     | Suppresses vertical labels                                                       |
| NOVTICK      | Suppresses vertical tick marks                                                   |
| NPINTERVALS= | Displays one of the two kinds of confidence limit                                |
| PCTLIST=     | Specifies the list of percentages for which to compute percentile estimates      |
| FLOWER=      | Specifies the lower limit on the probability axis scale                          |
| PRINTPROBS   | Displays intervals and associated probabilities for the Turnbull algorithm       |
| PUPPER=      | Specifies the upper limit on the probability axis scale                          |
| PPOS=        | Specifies the plotting position type                                             |
| PPOUT        | Displays a table of the cumulative probabilities                                 |

Table 51.12 continued

| Option              | Description                                                                                    |
|---------------------|------------------------------------------------------------------------------------------------|
| PROBLIST=           | Specifies the list of initial values for the Turnbull algorithm                                |
| ROTATE              | Requests probability plots with probability scale on the horizontal axis                       |
| SQUARE              | Makes the layout of the probability plots square                                               |
| TOLLIKE=            | Specifies the criterion for convergence in the Turnbull algorithm                              |
| TOLPROB=            | Specifies the criterion for setting the interval probability to zero in the Turnbull algorithm |
| VAXISLABEL=         | Specifies a label for the vertical axis                                                        |
| VREF                | Draws reference lines perpendicular to the vertical axis                                       |
| VREFLABELS=         | Specifies labels for the lines requested by the VREF= option                                   |
| VREFLABPOS=         | Specifies the horizontal position of labels for VREF= lines                                    |
| WAXIS=              | Specifies line thickness for axes and frame                                                    |
| WFIT=               | Specifies line thickness for fitted curves                                                     |
| WGRID=              | Specifies line thickness for grids                                                             |
| WREFL=              | Specifies line thickness for reference lines                                                   |
| <b>ODS Graphics</b> |                                                                                                |
| HCL                 | Computes and draws confidence limits for the predicted probabilities                           |
| HLOWER=             | Specifies <i>value</i> as the lower lifetime axis tick mark                                    |
| HUPPER=             | Specifies <i>value</i> as the upper lifetime axis tick mark                                    |
| HREF                | Draws reference lines perpendicular to the horizontal axis                                     |
| HREFLABELS=         | Specifies labels for the lines requested by the HREF= option                                   |
| ITPRINTEM           | Displays the iteration history for the Turnbull algorithm                                      |
| MAXITEM=            | Specifies the maximum number of iterations for the Turnbull algorithm                          |
| NOCENPLOT           | Suppresses the plotting of censored data points                                                |
| NOCONF              | Suppresses the default confidence bands                                                        |
| NODATA              | Suppresses plotting of the estimated empirical probability plot                                |
| NOFIT               | Suppresses the fitted probability (percentile) line and confidence bands                       |
| NOFRAME             | Suppresses the frame around plotting areas                                                     |
| NOGRID              | Suppresses grid lines                                                                          |
| NOPOLISH            | Suppresses setting small interval probabilities to zero in the Turnbull algorithm              |
| NPINTERVALS=        | Displays one of the two kinds of confidence limits                                             |
| PCTLIST=            | Specifies the list of percentages for which to compute percentile estimates                    |
| PLOWER=             | Specifies the lower limit on the probability axis scale                                        |
| PRINTPROBS          | Displays intervals and associated probabilities for the Turnbull algorithm                     |
| PUPPER=             | Specifies the upper limit on the probability axis scale                                        |
| PPOS=               | Specifies the plotting position type                                                           |
| PPOUT               | Displays a table of the cumulative probabilities                                               |
| PROBLIST=           | Specifies the list of initial values for the Turnbull algorithm                                |
| ROTATE              | Requests probability plots with probability scale on the horizontal axis                       |
| SQUARE              | Makes the layout of the probability plots square                                               |
| TOLLIKE=            | Specifies the criterion for convergence in the Turnbull algorithm                              |
| TOLPROB=            | Specifies the criterion for setting the interval probability to zero in the Turnbull algorithm |
| VREF                | Draws reference lines perpendicular to the vertical axis                                       |

You can specify the following options to control the content, layout, and appearance of a probability plot.

## Traditional Graphics

The following options are available if you use traditional graphics—that is, if ODS Graphics is not enabled.

**ANNOTATE=***SAS-data-set*

**ANNO=***SAS-data-set*

specifies an Annotate data set, as described in *SAS/GRAPH: Reference*, that enables you to add features to the probability plot. The data set you specify with the ANNOTATE= option in the PROBLOT statement provides the Annotate data set for all plots created by the statement.

**CAXIS=***color*

**CAXES=***color*

specifies the color used for the axes and tick marks. This option overrides any COLOR= specifications in an AXIS statement. The default is the first color in the device color list.

**CCENSOR=***color*

specifies the color for filling the censor plot area. The default is the first color in the device color list.

**CENBIN**

plots censored data as frequency counts (rounding for noninteger frequency) rather than as individual points.

**CENCOLOR=***color*

specifies the color for the censor symbol. The default is the first color in the device color list.

**CENSYMBOL=***symbol* | (*symbol list*)

specifies symbols for censored values. The *symbol* is one of the symbol names (plus, star, square, diamond, triangle, hash, paw, point, dot, and circle) or a letter (A–Z). If you do not specify the CENSYMBOL= option, the symbol used for censored values is the same as for failures.

**CFIT=***color*

specifies the color for the fitted probability line and confidence curves. The default is the first color in the device color list.

**CFRAME=***color*

**CFR=***color*

specifies the color for the area enclosed by the axes and frame. This area is not shaded by default.

**CGRID=***color*

specifies the color for grid lines. The default is the first color in the device color list.

**CHREF=***color*

**CH=***color*

specifies the color for lines requested by the HREF= option. The default is the first color in the device color list.

**CTEXT=***color*

specifies the color for tick mark values and axis labels. The default is the color specified for the CTEXT= option in the most recent GOPTIONS statement.

**CVREF=***color*

**CV=***color*

specifies the color for lines requested by the VREF= option. The default is the first color in the device color list.

**DESCRIPTION=**'*string*'

**DES=**'*string*'

specifies a description, up to 40 characters, that appears in the PROC GREPLAY master menu. The default is the variable name.

**FONT=***font*

specifies a software font for reference line and axis labels. You can also specify fonts for axis labels in an AXIS statement. The FONT= font takes precedence over the FTEXT= font specified in the most recent GOPTIONS statement. Hardware characters are used by default.

**HCL**

computes and draws confidence limits for the predicted probabilities based on distribution percentiles instead of the default CDF limits. See the section “[Confidence Limits for Percentiles](#)” on page 3945 for details of the computation.

**HEIGHT=***value*

specifies the height of text used outside framed areas. The default value is 3.846 (in percentage).

**HLOWER=***value*

specifies the lower limit on the lifetime axis scale. The HLOWER= option specifies *value* as the lower lifetime axis tick mark. The tick mark interval and the upper axis limit are determined automatically.

**HOFFSET=***value*

specifies the offset for the horizontal axis. The default value is 1.

**HUPPER=***value*

specifies *value* as the upper lifetime axis tick mark. The tick mark interval and the lower axis limit are determined automatically.

**HREF < (INTERSECT) > =***value-list*

requests reference lines perpendicular to the horizontal axis be drawn at horizontal axis values in the *value-list*. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified with the HREFLABELS= option, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

**HREFLABELS=**'*label1*' ... '*labeln*'

**HREFLABEL=**'*label1*' ... '*labeln*'

**HREFLAB=**'*label1*' ... '*labeln*'

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

**HREFLABPOS=*n***

specifies the vertical position of labels for HREF= lines. The following table shows the valid values for *n* and the corresponding label placements.

| <i>n</i> | Label Placement         |
|----------|-------------------------|
| 1        | Top                     |
| 2        | Staggered from top      |
| 3        | Bottom                  |
| 4        | Staggered from bottom   |
| 5        | Alternating from top    |
| 6        | Alternating from bottom |

**INBORDER**

requests a border around probability plots.

**INTERTILE=*value***

specifies the distance between tiles.

**ITPRINTEM**

displays the iteration history for the Turnbull algorithm.

**JITTER=*value***

specifies the amount to jitter overlaying plot symbols, in units of symbol width.

**LFIT=*linetype***

specifies a line style for fitted curves and confidence limits. By default, fitted curves are drawn by connecting solid lines (*linetype* = 1), and confidence limits are drawn by connecting dashed lines (*linetype* = 3).

**LGRID=*linetype***

specifies a line style for all grid lines; *linetype* is between 1 and 46. The default is 35.

**LHREF=*linetype*****LH=*linetype***

specifies the line type for lines requested by the HREF= option. The default is 2, which produces a dashed line.

**LVREF=*linetype*****LV=*linetype***

specifies the line type for lines requested by the VREF= option. The default is 2, which produces a dashed line.

**MAXITEM=*n1* <, *n2*>**

specifies the maximum number of iterations for the Turnbull algorithm. Iteration history will be displayed in increments of *n2* if requested with the ITPRINTEM option. See the section “[Arbitrarily Censored Data](#)” on page 3942 for details.

**NAME=*'string'***

specifies a name for the plot, up to eight characters, that appears in the PROC GREPLAY master menu. The default is 'LIFEREG'.

**NOCENPLOT**

suppresses the plotting of censored data points.

**NOCONF**

suppresses the default confidence bands on the probability plot.

**NODATA**

suppresses plotting of the estimated empirical probability plot.

**NOFIT**

suppresses the fitted probability (percentile) line and confidence bands.

**NOFRAME**

suppresses the frame around plotting areas.

**NOGRID**

suppresses grid lines.

**NOHLABEL**

suppresses horizontal labels.

**NOHTICK**

suppresses horizontal tick marks.

**NOPOLISH**

suppresses setting small interval probabilities to zero in the Turnbull algorithm.

**NOVLABEL**

suppresses vertical labels.

**NOVTICK**

suppresses vertical tick marks.

**NPINTERVALS=*interval type***

specifies one of the two kinds of confidence limits for the estimated cumulative probabilities, pointwise (NPINTERVALS=POINT) or simultaneous (NPINTERVALS=SIMUL), requested by the PPOUT option to be displayed in the tabular output.

**PCTLIST=*value-list***

specifies the list of percentages for which to compute percentile estimates; *value-list* must be a list of values separated by blanks or commas. Each value in the list must be between 0 and 100.

**PLOWER=*value***

specifies the lower limit on the probability axis scale. The PLOWER= option specifies *value* as the lower probability axis tick mark. The tick mark interval and the upper axis limit are determined automatically.

**PRINTPROBS**

displays intervals and associated probabilities for the Turnbull algorithm.

**PUPPER=***value*

specifies the upper limit on the probability axis scale. The PUPPER= option specifies *value* as the upper probability axis tick mark. The tick mark interval and the lower axis limit are determined automatically.

**PPOS=***character-list*

specifies the plotting position type. See the section “Probability Plotting” on page 3940 for details.

| <b>PPOS=</b>    | <b>Method</b>                   |
|-----------------|---------------------------------|
| <b>EXPRANK</b>  | Expected ranks                  |
| <b>MEDRANK</b>  | Median ranks                    |
| <b>MEDRANK1</b> | Median ranks (exact formula)    |
| <b>KM</b>       | Kaplan-Meier                    |
| <b>MKM</b>      | Modified Kaplan-Meier (default) |

**PPOUT**

specifies that a table of the cumulative probabilities plotted on the probability plot be displayed. Kaplan-Meier estimates of the cumulative probabilities are also displayed, along with standard errors and confidence limits. The confidence limits can be pointwise or simultaneous, as specified by the NPINTERVALS= option.

**PROBLIST=***value-list*

specifies the list of initial values for the Turnbull algorithm.

**ROTATE**

requests probability plots with probability scale on the horizontal axis.

**SQUARE**

makes the layout of the probability plots square.

**TOLLIKE=***value*

specifies the criterion for convergence in the Turnbull algorithm.

**TOLPROB=***value*

specifies the criterion for setting the interval probability to zero in the Turnbull algorithm.

**VAXISLABEL=***'string'*

specifies a label for the vertical axis.

**VREF**<(INTERSECT)>=*value-list*

requests reference lines perpendicular to the vertical axis be drawn at vertical axis values in the *value-list*. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified with the VREFLABELS= option, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

**VREFLABELS=**'label1' ... 'labeln'

**VREFLABEL=**'label1' ... 'labeln'

**VREFLAB=**'label1' ... 'labeln'

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

**VREFLABPOS=***n*

specifies the horizontal position of labels for VREF= lines. The valid values for *n* and the corresponding label placements are shown in the following table.

| <i>n</i> | Label Placement |
|----------|-----------------|
| 1        | Left            |
| 2        | Right           |

**WAXIS=***n*

specifies line thickness for axes and frame. The default value is 1.

**WFIT=***n*

specifies line thickness for fitted curves. The default value is 1.

**WGRID=***n*

specifies line thickness for grids. The default value is 1.

**WREFL=***n*

specifies line thickness for reference lines. The default value is 1.

## ODS Graphics

The following options are available if ODS Graphics is enabled.

**HCL**

computes and draws confidence limits for the predicted probabilities in the horizontal direction.

**HLOWER=***value*

specifies the lower limit on the lifetime axis scale. The HLOWER= option specifies *value* as the lower lifetime axis tick mark. The tick mark interval and the upper axis limit are determined automatically.

**HUPPER=***value*

specifies *value* as the upper lifetime axis tick mark. The tick mark interval and the lower axis limit are determined automatically.

**HREF < (INTERSECT) > =***value-list*

requests reference lines perpendicular to the horizontal axis be drawn at horizontal axis values in the *value-list*. If (INTERSECT) is specified, a second reference line perpendicular to the vertical axis is drawn that intersects the fit line at the same point as the horizontal axis reference line. If a horizontal axis reference line label is specified with the HREFLABELS= option, the intersecting vertical axis reference line is labeled with the vertical axis value. See also the CHREF=, HREFLABELS=, and LHREF= options.

**HREFLABELS=***'label1' ... 'labeln'*

**HREFLABEL=***'label1' ... 'labeln'*

**HREFLAB=***'label1' ... 'labeln'*

specifies labels for the lines requested by the HREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

**ITPRINTEM**

displays the iteration history for the Turnbull algorithm.

**MAXITEM=***n1 <,n2>*

specifies the maximum number of iterations for the Turnbull algorithm. Iteration history will be displayed in increments of *n2* if requested with the ITPRINTEM option. See the section “[Arbitrarily Censored Data](#)” on page 3942 for details.

**NOCENPLOT**

suppresses the plotting of censored data points.

**NOCONF**

suppresses the default confidence bands on the probability plot.

**NODATA**

suppresses plotting of the estimated empirical probability plot.

**NOFIT**

suppresses the fitted probability (percentile) line and confidence bands.

**NOFRAME**

suppresses the frame around plotting areas.

**NOGRID**

suppresses grid lines.

**NOPOLISH**

suppresses setting small interval probabilities to zero in the Turnbull algorithm.

**NPINTERVALS=***interval type*

specifies one of the two kinds of confidence limits for the estimated cumulative probabilities, pointwise (NPINTERVALS=POINT) or simultaneous (NPINTERVALS=SIMUL), requested by the PPOUT option to be displayed in the tabular output.

**PCTLIST=***value-list*

specifies the list of percentages for which to compute percentile estimates; *value-list* must be a list of values separated by blanks or commas. Each value in the list must be between 0 and 100.

**PLOWER=***value*

specifies the lower limit on the probability axis scale. The PLOWER= option specifies *value* as the lower probability axis tick mark. The tick mark interval and the upper axis limit are determined automatically.

**PRINTPROBS**

displays intervals and associated probabilities for the Turnbull algorithm.

**PUPPER=*value***

specifies the upper limit on the probability axis scale. The PUPPER= option specifies *value* as the upper probability axis tick mark. The tick mark interval and the lower axis limit are determined automatically.

**PPOS=*plotting-position-type***

specifies the plotting position type. See the section “Probability Plotting” on page 3940 for details.

| <b>PPOS=</b>    | <b>Method</b>                   |
|-----------------|---------------------------------|
| <b>EXPRANK</b>  | Expected ranks                  |
| <b>MEDRANK</b>  | Median ranks                    |
| <b>MEDRANK1</b> | Median ranks (exact formula)    |
| <b>KM</b>       | Kaplan-Meier                    |
| <b>MKM</b>      | Modified Kaplan-Meier (default) |

**PPOUT**

specifies that a table of the cumulative probabilities plotted on the probability plot be displayed. Kaplan-Meier estimates of the cumulative probabilities are also displayed, along with standard errors and confidence limits. The confidence limits can be pointwise or simultaneous, as specified by the NPINTERVALS= option.

**PROBLIST=*value-list***

specifies the list of initial values for the Turnbull algorithm.

**ROTATE**

requests probability plots with probability scale on the horizontal axis.

**SQUARE**

makes the layout of the probability plots square.

**TOLLIKE=*value***

specifies the criterion for convergence in the Turnbull algorithm.

**TOLPROB=*value***

specifies the criterion for setting the interval probability to zero in the Turnbull algorithm.

**VREF<(INTERSECT)>=*value-list***

requests reference lines perpendicular to the vertical axis be drawn at vertical axis values in the *value-list*. If (INTERSECT) is specified, a second reference line perpendicular to the horizontal axis is drawn that intersects the fit line at the same point as the vertical axis reference line. If a vertical axis reference line label is specified with the VREFLABELS= option, the intersecting horizontal axis reference line is labeled with the horizontal axis value. See also the CVREF=, LVREF=, and VREFLABELS= options.

**VREFLABELS=*'label1' ... 'labeln'*****VREFLABEL=*'label1' ... 'labeln'*****VREFLAB=*'label1' ... 'labeln'***

specifies labels for the lines requested by the VREF= option. The number of labels must equal the number of lines. Enclose each label in quotes. Labels can be up to 16 characters.

---

## SLICE Statement

**SLICE** *model-effect* </ options > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

---

## STORE Statement

**STORE** < **OUT=** > *item-store-name* </ **LABEL=** 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

---

## TEST Statement

**TEST** < *model-effects* > </ options > ;

The TEST statement enables you to perform chi-square tests for model effects that test Type I, Type II, or Type III hypotheses. By default, the Type III tests are performed. For more information, see Chapter 19, “Shared Concepts and Topics.”

---

## WEIGHT Statement

**WEIGHT** *variable* ;

If you want to use weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model. The WEIGHT variable multiplies the contribution to the log likelihood for each observation.

---

## Details: LIFEREG Procedure

---

### Missing Values

Any observation with missing values for the dependent variable is not used in the model estimation unless it is one and only one of the values in an interval specification. Also, if one of the explanatory variables or the censoring variable is missing, the observation is not used. For any observation to be used in the estimation of a model, only the variables needed in that model have to be nonmissing. Predicted values are computed for all observations with no missing explanatory variable values. If the censoring variable is missing, the CENSORED= variable in the OUT= SAS data set is also missing.

---

### Model Specification

Main effects as well as interaction terms are allowed in the model specification, similar to the GLM procedure. For numeric variables, a main effect is a linear term equal to the value of the variable unless the variable appears in the CLASS statement. For variables listed in the CLASS statement, PROC LIFEREG creates indicator variables (variables taking the values zero or one) for every level of the variable except the last level. If there is no intercept term, the first CLASS variable has indicator variables created for all levels including the last level. The levels are ordered according to the ORDER= option. Estimates of a main effect depend upon other effects in the model and, therefore, are adjusted for the presence of other effects in the model.

---

### Computational Method

By default, the LIFEREG procedure computes initial values for the parameters by using ordinary least squares (OLS) and ignoring censoring. This might not be the best set of starting values for a given set of data. For example, if there are extreme values in your data, the OLS fit might be excessively influenced by the extreme observations, causing an overflow or convergence problems. See [Example 51.3](#) for one way to deal with convergence problems.

You can specify the INITIAL= option in the MODEL statement to override these starting values. You can also specify the INTERCEPT=, SCALE=, and SHAPE= options to set initial values of the intercept, scale, and shape parameters. For models with multilevel interaction effects, it is a little difficult to use the INITIAL= option to provide starting values for all parameters. In this case, you can use the INEST= data set. See the section “[INEST= Data Set](#)” on page 3945 for details. The INEST= data set overrides all previous specifications for starting values of parameters.

The rank of the design matrix  $\mathbf{X}$  is estimated before the model is fit. Columns of  $\mathbf{X}$  that are judged linearly dependent on other columns have the corresponding parameters set to zero. The test for linear dependence is controlled by the SINGULAR= option in the MODEL statement. Variables are included in the model in the order in which they are listed in the MODEL statement with the continuous variables included in the model before any classification variables.

The log-likelihood function is maximized by means of a ridge-stabilized Newton-Raphson algorithm. The maximized value of the log likelihood can take positive or negative values, depending on the specified model and the values of the maximum likelihood estimates of the model parameters.

If convergence of the maximum likelihood estimates is attained, a Type III chi-square test statistic is computed for each effect, testing whether there is any contribution from any of the levels of the effect. This statistic is computed as a quadratic form in the appropriate parameter estimates by using the corresponding submatrix of the asymptotic covariance matrix estimate. See Chapter 42, “The GLM Procedure,” and Chapter 15, “The Four Types of Estimable Functions,” for more information about Type III estimable functions. The asymptotic covariance matrix is computed as the inverse of the observed information matrix. Note that if the NOINT option is specified and CLASS variables are used, the first CLASS variable contains a contribution from an intercept term. The results are displayed in an ODS table named “Type3Analysis.” Chi-square tests for individual parameters are Wald tests based on the observed information matrix and the parameter estimates. If an effect has a single degree of freedom in the parameter estimates table, the chi-square test for this parameter is equivalent to the Type III test for this effect.

Before SAS 8.2, a multiple-degree-of-freedom statistic was computed for each effect to test for contribution from any level of the effect. In general, the Type III test statistic in a main-effect-only model (no interaction terms) will be equal to the previously computed effect statistic, unless there are collinearities among the effects. If there are collinearities, the Type III statistic will adjust for them, and the value of the Type III statistic and the number of degrees of freedom might not be equal to those of the previous effect statistic.

Suppose there are  $n$  observations from the model  $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \sigma\boldsymbol{\epsilon}$  (or  $\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{O} + \sigma\boldsymbol{\epsilon}$  if there is an offset variable), where  $\mathbf{X}$  is an  $n \times k$  matrix of covariate values (including the intercept),  $\mathbf{y}$  is a vector of responses,  $\mathbf{O}$  is a vector of offset variable values, and  $\boldsymbol{\epsilon}$  is a vector of errors with survival function  $S$ , cumulative distribution function  $F$ , and probability density function  $f$ . That is,  $S(t) = \Pr(\epsilon_i > t)$ ,  $F(t) = \Pr(\epsilon_i \leq t)$ , and  $f(t) = dF(t)/dt$ , where  $\epsilon_i$  is a component of the error vector. Then, if all the responses are observed, the log likelihood,  $L$ , can be written as

$$L = \sum \log \left( \frac{f(u_i)}{\sigma} \right)$$

where  $u_i = \frac{1}{\sigma}(y_i - \mathbf{x}'_i\boldsymbol{\beta})$ .

If some of the responses are left, right, or interval censored, the log likelihood can be written as

$$L = \sum \log \left( \frac{f(u_i)}{\sigma} \right) + \sum \log (S(u_i)) + \sum \log (F(u_i)) + \sum \log (F(u_i) - F(v_i))$$

with the first sum over uncensored observations, the second sum over right-censored observations, the third sum over left-censored observations, the last sum over interval-censored observations, and

$$v_i = \frac{1}{\sigma}(z_i - \mathbf{x}'_i\boldsymbol{\beta})$$

where  $z_i$  is the lower end of a censoring interval.

If the response is specified in the binomial format, *events/trials*, then the log-likelihood function is

$$L = \sum r_i \log(P_i) + (n_i - r_i) \log(1 - P_i)$$

where  $r_i$  is the number of events and  $n_i$  is the number of trials for the  $i$ th observation. In this case,  $P_i = 1 - F(-\mathbf{x}'_i\boldsymbol{\beta})$ . For the symmetric distributions, logistic and normal, this is the same as  $F(\mathbf{x}'_i\boldsymbol{\beta})$ . Additional

information about censored and limited dependent variable models can be found in Kalbfleisch and Prentice (1980) and Maddala (1983).

The estimated covariance matrix of the parameter estimates is computed as the negative inverse of  $\mathbf{I}$ , which is the information matrix of second derivatives of  $L$  with respect to the parameters evaluated at the final parameter estimates. If  $\mathbf{I}$  is not positive definite, a positive-definite submatrix of  $\mathbf{I}$  is inverted, and the remaining rows and columns of the inverse are set to zero. If some of the parameters, such as the scale and intercept, are restricted, the corresponding elements of the estimated covariance matrix are set to zero. The standard error estimates for the parameter estimates are taken as the square roots of the corresponding diagonal elements.

For restrictions placed on the intercept, scale, and shape parameters, one-degree-of-freedom Lagrange multiplier test statistics are computed. These statistics are computed as

$$\chi^2 = \frac{g^2}{V}$$

where  $g$  is the derivative of the log likelihood with respect to the restricted parameter at the restricted maximum and

$$V = \mathbf{I}_{11} - \mathbf{I}_{12}\mathbf{I}_{22}^{-1}\mathbf{I}_{21}$$

where the 1 subscripts refer to the restricted parameter and the 2 subscripts refer to the unrestricted parameters. The information matrix is evaluated at the restricted maximum. These statistics are asymptotically distributed as chi-squares with one degree of freedom under the null hypothesis that the restrictions are valid, provided that some regularity conditions are satisfied. See Rao (1973, p. 418) for a more complete discussion. It is possible for these statistics to be missing if the observed information matrix is not positive definite. Higher-degree-of-freedom tests for multiple restrictions are not currently computed.

A Lagrange multiplier test statistic is computed to test this constraint. Notice that this test statistic is comparable to the Wald test statistic for testing that the scale is one. The Wald statistic is the result of squaring the difference of the estimate of the scale parameter from one and dividing this by the square of its estimated standard error.

---

## Supported Distributions

For most distributions, the baseline survival function ( $S$ ) and the probability density function ( $f$ ) are listed for the additive random disturbance ( $y_0$  or  $\log(T_0)$ ) with location parameter  $\mu$  and scale parameter  $\sigma$ . See the section “[Overview: LIFEREG Procedure](#)” on page 3878 for more information. These distributions apply when the log of the response is modeled (this is the default analysis). The corresponding survival function ( $G$ ) and its density function ( $g$ ) are given for the untransformed baseline distribution ( $T_0$ ).

For the normal and logistic distributions, the response is not log transformed by PROC LIFEREG, and the survival functions and probability density functions listed apply to the untransformed response.

For example, for the WEIBULL distribution,  $S(w)$  and  $f(w)$  are the survival function and the probability density function for the extreme-value distribution (distribution of the log of the response), while  $G(t)$  and  $g(t)$  are the survival function and the probability density function of a Weibull distribution (using the untransformed response).

The chosen baseline functions define the meaning of the intercept, scale, and shape parameters. Only the gamma distribution has a free shape parameter in the following parameterizations. Notice that some of the

distributions do not have mean zero and that  $\sigma$  is not, in general, the standard deviation of the baseline distribution.

For the Weibull distribution, the accelerated failure time model is also a proportional-hazards model. However, the parameterization for the covariates differs by a multiple of the scale parameter from the parameterization commonly used for the proportional hazards model.

The distributions supported in the LIFEREG procedure follow. If there are no covariates in the model,  $\mu =$  Intercept in the output; otherwise,  $\mu = \mathbf{x}'\boldsymbol{\beta}$ .  $\sigma =$  Scale in the output.

## Exponential

$$\begin{aligned} S(w) &= \exp(-\exp(w - \mu)) \\ f(w) &= \exp(w - \mu) \exp(-\exp(w - \mu)) \\ G(t) &= \exp(-\alpha t) \\ g(t) &= \alpha \exp(-\alpha t) \end{aligned}$$

where  $\exp(-\mu) = \alpha$ .

## Generalized Gamma

$S(w) = S'(u)$ ,  $f(w) = \sigma^{-1} f'(u)$ ,  $G(t) = G'(v)$ ,  $g(t) = \frac{v}{t\sigma} g'(v)$ ,  $u = \frac{w-\mu}{\sigma}$ ,  $v = \exp(\frac{\log(t)-\mu}{\sigma})$ , and

$$\begin{aligned} S'(u) &= \begin{cases} 1 - \frac{\Gamma(\delta^{-2}, \delta^{-2} \exp(\delta u))}{\Gamma(\delta^{-2})} & \text{if } \delta > 0 \\ \frac{\Gamma(\delta^{-2}, \delta^{-2} \exp(\delta u))}{\Gamma(\delta^{-2})} & \text{if } \delta < 0 \end{cases} \\ f'(u) &= \frac{|\delta|}{\Gamma(\delta^{-2})} (\delta^{-2} \exp(\delta u))^{\delta^{-2}} \exp(-\exp(\delta u) \delta^{-2}) \\ G'(v) &= \begin{cases} 1 - \frac{\Gamma(\delta^{-2}, \delta^{-2} v^\delta)}{\Gamma(\delta^{-2})} & \text{if } \delta > 0 \\ \frac{\Gamma(\delta^{-2}, \delta^{-2} v^\delta)}{\Gamma(\delta^{-2})} & \text{if } \delta < 0 \end{cases} \\ g'(v) &= \frac{|\delta|}{v\Gamma(\delta^{-2})} (\delta^{-2} v^\delta)^{\delta^{-2}} \exp(-v^\delta \delta^{-2}) \end{aligned}$$

where  $\Gamma(a)$  denotes the complete gamma function,  $\Gamma(a, z)$  denotes the incomplete gamma function, and  $\delta$  is a free shape parameter. The  $\delta$  parameter is called Shape by PROC LIFEREG. See Lawless (2003, p. 240), and Klein and Moeschberger (1997, p. 386) for a description of the generalized gamma distribution.

**Logistic**

$$S(w) = \left(1 + \exp\left(\frac{w - \mu}{\sigma}\right)\right)^{-1}$$

$$f(w) = \frac{\exp\left(\frac{w - \mu}{\sigma}\right)}{\sigma \left(1 + \exp\left(\frac{w - \mu}{\sigma}\right)\right)^2}$$

**Log-Logistic**

$$S(w) = \left(1 + \exp\left(\frac{w - \mu}{\sigma}\right)\right)^{-1}$$

$$f(w) = \frac{\exp\left(\frac{w - \mu}{\sigma}\right)}{\sigma \left(1 + \exp\left(\frac{w - \mu}{\sigma}\right)\right)^2}$$

$$G(t) = \frac{1}{1 + \alpha t^\gamma}$$

$$g(t) = \frac{\alpha \gamma t^{\gamma-1}}{(1 + \alpha t^\gamma)^2}$$

where  $\gamma = 1/\sigma$  and  $\alpha = \exp(-\mu/\sigma)$ .

**Lognormal**

$$S(w) = 1 - \Phi\left(\frac{w - \mu}{\sigma}\right)$$

$$f(w) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{1}{2}\left(\frac{w - \mu}{\sigma}\right)^2\right)$$

$$G(t) = 1 - \Phi\left(\frac{\log(t) - \mu}{\sigma}\right)$$

$$g(t) = \frac{1}{\sqrt{2\pi}\sigma t} \exp\left(-\frac{1}{2}\left(\frac{\log(t) - \mu}{\sigma}\right)^2\right)$$

where  $\Phi$  is the cumulative distribution function for the normal distribution.

**Normal**

$$S(w) = 1 - \Phi\left(\frac{w - \mu}{\sigma}\right)$$

$$f(w) = \frac{1}{\sqrt{2\pi}\sigma} \exp\left(-\frac{1}{2}\left(\frac{w - \mu}{\sigma}\right)^2\right)$$

where  $\Phi$  is the cumulative distribution function for the normal distribution.

**Weibull**

$$S(w) = \exp\left(-\exp\left(\frac{w - \mu}{\sigma}\right)\right)$$

$$f(w) = \frac{1}{\sigma} \exp\left(\frac{w - \mu}{\sigma}\right) \exp\left(-\exp\left(\frac{w - \mu}{\sigma}\right)\right)$$

$$G(t) = \exp(-\alpha t^\gamma)$$

$$g(t) = \gamma \alpha t^{\gamma-1} \exp(-\alpha t^\gamma)$$

where  $\sigma = 1/\gamma$  and  $\alpha = \exp(-\mu/\sigma)$ .

If your parameterization is different from the ones shown here, you can still use the procedure to fit your model. For example, a common parameterization for the Weibull distribution is

$$g(t; \lambda, \beta) = \left(\frac{\beta}{\lambda}\right) \left(\frac{t}{\lambda}\right)^{\beta-1} \exp\left(-\left(\frac{t}{\lambda}\right)^\beta\right)$$

$$G(t; \lambda, \beta) = \exp\left(-\left(\frac{t}{\lambda}\right)^\beta\right)$$

so that  $\lambda = \exp(\mu)$  and  $\beta = 1/\sigma$ .

Again note that the expected value of the baseline log response is, in general, not zero and that the distributions are not symmetric in all cases. Thus, for a given set of covariates,  $\mathbf{x}$ , the expected value of the log response is not always  $\mathbf{x}'\boldsymbol{\beta}$ .

Some relations among the distributions are as follows:

- The gamma with Shape=1 is a Weibull distribution.
- The gamma with Shape=0 is a lognormal distribution.
- The Weibull with Scale=1 is an exponential distribution.

## Predicted Values

For a given set of covariates,  $\mathbf{x}$  (including the intercept term), the  $p$ th quantile of the log response,  $y_p$ , is given by

$$y_p = \mathbf{x}'\boldsymbol{\beta} + \sigma u_p$$

if no offset variable has been specified, or

$$y_p = \mathbf{x}'\boldsymbol{\beta} + o + \sigma u_p$$

for a given value  $o$  of an offset variable, where  $u_p$  is the  $p$ th quantile of the baseline distribution. The estimated quantile is computed by replacing the unknown parameters with their estimates, including any shape parameters on which the baseline distribution might depend. The estimated quantile of the original response is obtained by taking the exponential of the estimated log quantile unless the NOLOG option is specified in the preceding MODEL statement.

The following table shows how  $u_p$  is computed from the baseline distribution  $F(u)$ :

**Table 51.13** Baseline Probability Functions and  $u_p$

| Distribution      | $F(u)$                                                                                                                                                                                                                                     | $u_p$                |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------|
| Exponential       | $1 - \exp(-\exp(u))$                                                                                                                                                                                                                       | $\log(-\log(1 - p))$ |
| Generalized Gamma | $\begin{cases} \frac{\Gamma(\delta^{-2}, \delta^{-2} \exp(\delta u))}{\Gamma(\delta^{-2})} & \text{if } \delta > 0 \\ 1 - \frac{\Gamma(\delta^{-2}, \delta^{-2} \exp(\delta u))}{\Gamma(\delta^{-2})} & \text{if } \delta < 0 \end{cases}$ | $F^{-1}(p)$          |
| Logistic          | $1 - (1 + \exp(u))^{-1}$                                                                                                                                                                                                                   | $\log(p/(1 - p))$    |
| Log-logistic      | $1 - (1 + \exp(u))^{-1}$                                                                                                                                                                                                                   | $\log(p/(1 - p))$    |
| Lognormal         | $\Phi(u)$                                                                                                                                                                                                                                  | $\Phi^{-1}(p)$       |
| Normal            | $\Phi(u)$                                                                                                                                                                                                                                  | $\Phi^{-1}(p)$       |
| Weibull           | $1 - \exp(-\exp(u))$                                                                                                                                                                                                                       | $\log(-\log(1 - p))$ |

For the generalized gamma distribution,  $u_p$  is computed numerically.

The standard errors of the quantile estimates are computed using the estimated covariance matrix of the parameter estimates and a Taylor series expansion of the quantile estimate. The standard error is computed as

$$\text{STD} = \sqrt{\mathbf{z}'\mathbf{V}\mathbf{z}}$$

where  $\mathbf{V}$  is the estimated covariance matrix of the parameter vector  $(\boldsymbol{\beta}', \sigma, \delta)'$ , and  $\mathbf{z}$  is the vector

$$\mathbf{z} = \begin{bmatrix} \mathbf{x} \\ \hat{u}_p \\ \hat{\sigma} \frac{\partial u_p}{\partial \delta} \end{bmatrix}$$

where  $\delta$  is the vector of the shape parameters. Unless the NOLOG option is specified, this standard error estimate is converted into a standard error estimate for  $\exp(y_p)$  as  $\exp(\hat{y}_p)\text{STD}$ . It might be more desirable

to compute confidence limits for the log response and convert them back to the original response variable than to use the standard error estimates for  $\exp(y_p)$  directly. See [Example 51.1](#) for a 90% confidence interval of the response constructed by exponentiating a confidence interval for the log response.

The variable CDF is computed as

$$\text{CDF}_i = F(u_i)$$

where the residual is defined by

$$u_i = \left( \frac{y_i - \mathbf{x}'_i \mathbf{b}}{\hat{\sigma}} \right)$$

and  $F$  is the baseline cumulative distribution function. If the data are interval-censored, then the cumulative distribution function,  $\text{CDF}_i = F(u_i)$ , is evaluated at the lower interval endpoint.

## Confidence Intervals

Confidence intervals are computed for all model parameters and are reported in the “Analysis of Parameter Estimates” table. The confidence coefficient can be specified with the ALPHA= $\alpha$  MODEL statement option, resulting in a  $(1 - \alpha) \times 100\%$  two-sided confidence coefficient. The default confidence coefficient is 95%, corresponding to  $\alpha = 0.05$ .

## Regression Parameters

A two-sided  $(1 - \alpha) \times 100\%$  confidence interval  $[\beta_{iL}, \beta_{iU}]$  for the regression parameter  $\beta_i$  is based on the asymptotic normality of the maximum likelihood estimator  $\hat{\beta}_i$  and is computed by

$$\beta_{iL} = \hat{\beta}_i - z_{1-\alpha/2}(\text{SE}_{\hat{\beta}_i})$$

$$\beta_{iU} = \hat{\beta}_i + z_{1-\alpha/2}(\text{SE}_{\hat{\beta}_i})$$

where  $\text{SE}_{\hat{\beta}_i}$  is the estimated standard error of  $\hat{\beta}_i$ , and  $z_p$  is the  $p \times 100\%$  percentile of the standard normal distribution.

## Scale Parameter

A two-sided  $(1 - \alpha) \times 100\%$  confidence interval  $[\sigma_L, \sigma_U]$  for the scale parameter  $\sigma$  in the location-scale model is based on the asymptotic normality of the logarithm of the maximum likelihood estimator  $\log(\hat{\sigma})$ , and is computed by

$$\sigma_L = \hat{\sigma} / \exp[z_{1-\alpha/2}(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$$

$$\sigma_U = \hat{\sigma} \exp[z_{1-\alpha/2}(\text{SE}_{\hat{\sigma}})/\hat{\sigma}]$$

See Meeker and Escobar (1998) for more information.

## Weibull Scale and Shape Parameters

The Weibull distribution scale parameter  $\eta$  and shape parameter  $\beta$  are obtained by transforming the extreme-value location parameter  $\mu$  and scale parameter  $\sigma$ :

$$\eta = \exp(\mu)$$

$$\beta = 1/\sigma$$

Consequently, two-sided  $(1 - \alpha) \times 100\%$  confidence intervals for the Weibull scale and shape parameters are computed as

$$[\eta_L, \eta_U] = [\exp(\mu_L), \exp(\mu_U)]$$

$$[\beta_L, \beta_U] = [1/\sigma_U, 1/\sigma_L]$$

## Gamma Shape Parameter

A two-sided  $(1 - \alpha) \times 100\%$  confidence interval for the three-parameter gamma shape parameter  $\delta$  is computed by

$$[\delta_L, \delta_U] = [\hat{\delta} - z_{1-\alpha/2}(\text{SE}_{\hat{\delta}}), \hat{\delta} + z_{1-\alpha/2}(\text{SE}_{\hat{\delta}})]$$

---

## Fit Statistics

Suppose that the model contains  $p$  parameters and that  $n$  observations are used in model fitting. The fit criteria displayed by the LIFEREG procedure are calculated as follows:

- $-2 \log$  likelihood:

$$-2\log(L)$$

where  $L$  is the maximized likelihood for the model.

- Akaike's information criterion:

$$\text{AIC} = -2\log(L) + 2p$$

- corrected Akaike's information criterion:

$$\text{AICC} = \text{AIC} + \frac{2p(p+1)}{n-p-1}$$

- Bayesian information criterion:

$$\text{BIC} = -2\log(L) + p \log(n)$$

If you specify the Weibull, exponential, lognormal, log-logistic, or gamma distribution, then maximum likelihood estimates of model parameters are computed by maximizing the log likelihood of the distribution of the logarithm of the response. This is equivalent to computing maximum likelihood parameter estimates based on the response on the original, rather than log, scale. If you specify the Weibull, exponential, lognormal, log-logistic, or gamma distribution, then fit statistics based on the maximized log likelihood  $\log(L)$  of the log of the response are reported in the “Fit Statistics” table. Fit criteria computed in this way cannot be meaningfully compared with fit criteria that are based on the log likelihood of the unlogged response. If you specify the normal or logistic distribution, or if you specify the NOLOG option in the MODEL statement, then the fit criteria reported in the “Fit Statistics” table are based on the response on the original, rather than log, scale.

In addition to the “Fit Statistics” table described previously, if you specify the Weibull, exponential, lognormal, log-logistic, or gamma distribution, fit criteria that are based on the distribution of the response on the original scale, rather than the log of the response, are reported in the “Fit Statistics (Unlogged Response)” table.

When comparing models, you should compare fit criteria based on the log likelihood that is computed by using the response on the same scale, either always based on the log of the response or always based on the response on the original scale.

See Akaike (1981, 1979) for details of AIC and BIC. See Simonoff (2003) for a discussion of using AIC, AICC, and BIC in statistical modeling.

## Probability Plotting

Probability plots are useful tools for the display and analysis of lifetime data. Probability plots use an inverse distribution scale so that a cumulative distribution function (CDF) plots as a straight line. A nonparametric estimate of the CDF of the lifetime data will plot approximately as a straight line, thus providing a visual assessment of goodness of fit.

You can use the PROBLOT statement in PROC LIFEREG to create probability plots of data that are complete, right censored, interval censored, or a combination of censoring types (arbitrarily censored). A line representing the maximum likelihood fit from the MODEL statement and pointwise parametric confidence bands for the cumulative probabilities are also included in the plot.

A random variable  $Y$  belongs to a *location-scale* family of distributions if its CDF  $F$  is of the form

$$\Pr\{Y \leq y\} = F(y) = G\left(\frac{y - \mu}{\sigma}\right)$$

where  $\mu$  is the location parameter and  $\sigma$  is the scale parameter. Here,  $G$  is a CDF that cannot depend on any unknown parameters, and  $G$  is the CDF of  $Y$  if  $\mu = 0$  and  $\sigma = 1$ . For example, if  $Y$  is a normal random variable with mean  $\mu$  and standard deviation  $\sigma$ ,

$$G(u) = \Phi(u) = \int_{-\infty}^u \frac{1}{\sqrt{2\pi}} \exp\left(-\frac{u^2}{2}\right) du$$

and

$$F(y) = \Phi\left(\frac{y - \mu}{\sigma}\right)$$

The normal, extreme-value, and logistic distributions are location-scale models. The three-parameter gamma distribution is a location-scale model if the shape parameter  $\delta$  is fixed. If  $T$  has a lognormal, Weibull, or log-logistic distribution, then  $\log(T)$  has a distribution that is a location-scale model. These distributions are said to be of type log-location-scale. Probability plots are constructed for lognormal, Weibull, and log-logistic distributions by using  $\log(T)$  instead of  $T$  in the plots.

Let  $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(n)}$  be ordered observations of a random sample with distribution function  $F(y)$ . A probability plot is a plot of the points  $y_{(i)}$  against  $m_i = G^{-1}(a_i)$ , where  $a_i = \hat{F}(y_i)$  is an estimate of the CDF  $F(y_{(i)}) = G\left(\frac{y_{(i)} - \mu}{\sigma}\right)$ . The nonparametric CDF estimates  $a_i$  are sometimes called *plotting positions*. The axis on which the points  $m_i$  are plotted is usually labeled with a probability scale (the scale of  $a_i$ ).

If  $F$  is one of the location-scale distributions, then  $y$  is the lifetime; otherwise, the log of the lifetime is used to transform the distribution to a location-scale model.

If the data actually have the stated distribution, then  $\hat{F} \approx F$ ,

$$m_i = G^{-1}(\hat{F}(y_i)) \approx G^{-1}\left(G\left(\frac{y_{(i)} - \mu}{\sigma}\right)\right) = \frac{y_{(i)} - \mu}{\sigma}$$

and points  $(y_{(i)}, m_i)$  should fall approximately in a straight line.

There are several ways to compute the nonparametric CDF estimates used in probability plots from lifetime data. These are discussed in the next two sections.

## Complete and Right-Censored Data

The censoring times must be taken into account when you compute plotting positions for right-censored data. The modified Kaplan-Meier method described in the following section is the default method for computing nonparametric CDF estimates for display on probability plots. See Abernethy (1996), Meeker and Escobar (1998), and Nelson (1982) for discussions of the methods described in the following sections.

### Expected Ranks, Kaplan-Meier, and Modified Kaplan-Meier Methods

Let  $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(n)}$  be ordered observations of a random sample including failure times and censor times. Order the data in increasing order. Label all the data with reverse ranks  $r_i$ , with  $r_1 = n, \dots, r_n = 1$ . For the lifetime (not censoring time) corresponding to reverse rank  $r_i$ , compute the survival function estimate

$$S_i = \left[ \frac{r_i}{r_i + 1} \right] S_{i-1}$$

with  $S_0 = 1$ . The expected rank plotting position is computed as  $a_i = 1 - S_i$ . The option PPOS=EXPRANK specifies the expected rank plotting position.

For the Kaplan-Meier method,

$$S_i = \left[ \frac{r_i - 1}{r_i} \right] S_{i-1}$$

The Kaplan-Meier plotting position is then computed as  $a'_i = 1 - S_i$ . The option PPOS=KM specifies the Kaplan-Meier plotting position.

For the modified Kaplan-Meier method, use

$$S'_i = \frac{S_i + S_{i-1}}{2}$$

where  $S_i$  is computed from the Kaplan-Meier formula with  $S_0 = 1$ . The plotting position is then computed as  $a_i'' = 1 - S_i'$ . The option PPOS=MKM specifies the modified Kaplan-Meier plotting position. If the PPOS option is not specified, the modified Kaplan-Meier plotting position is used as the default method.

For complete samples,  $a_i = i/(n + 1)$  for the expected rank method,  $a_i' = i/n$  for the Kaplan-Meier method, and  $a_i'' = (i - 0.5)/n$  for the modified Kaplan-Meier method. If the largest observation is a failure for the Kaplan-Meier estimator, then  $F_n = 1$  and the point is not plotted.

### Median Ranks

Let  $y_{(1)} \leq y_{(2)} \leq \dots \leq y_{(n)}$  be ordered observations of a random sample including failure times and censor times. A failure order number  $j_i$  is assigned to the  $i$ th failure:  $j_i = j_{i-1} + \Delta$ , where  $j_0 = 0$ . The increment  $\Delta$  is initially 1 and is modified when a censoring time is encountered in the ordered sample. The new increment is computed as

$$\Delta = \frac{(n + 1) - \text{previous failure order number}}{1 + \text{number of items beyond previous censored item}}$$

The plotting position is computed for the  $i$ th failure time as

$$a_i = \frac{j_i - 0.3}{n + 0.4}$$

For complete samples, the failure order number  $j_i$  is equal to  $i$ , the order of the failure in the sample. In this case, the preceding equation for  $a_i$  is an approximation of the median plotting position computed as the median of the  $i$ th-order statistic from the uniform distribution on  $(0, 1)$ . In the censored case,  $j_i$  is not necessarily an integer, but the preceding equation still provides an approximation to the median plotting position. The PPOS=MEDRANK option specifies the median rank plotting position.

### Arbitrarily Censored Data

The LIFEREG procedure can create probability plots for data that consist of combinations of exact, left-censored, right-censored, and interval-censored lifetimes—that is, arbitrarily censored data. The LIFEREG procedure uses an iterative algorithm developed by Turnbull (1976) to compute a nonparametric maximum likelihood estimate of the cumulative distribution function for the data. Since the technique is maximum likelihood, standard errors of the cumulative probability estimates are computed from the inverse of the associated Fisher information matrix. This algorithm is an example of the expectation-maximization (EM) algorithm. The default initial estimate assigns equal probabilities to each interval. You can specify different initial values with the PROBLIST= option. Convergence is determined if the change in the log likelihood between two successive iterations is less than delta, where the default value of delta is  $10^{-8}$ . You can specify a different value for delta with the TOLLIKE= option. Iterations will be terminated if the algorithm does not converge after a fixed number of iterations. The default maximum number of iterations is 1000. Some data might require more iterations for convergence. You can specify the maximum allowed number of iterations with the MAXITEM= option in the PROBLOT statement. The iteration history of the log likelihood is displayed if you specify the ITPRINTEM option. The iteration history of the estimated interval probabilities are also displayed if you specify both options ITPRINTEM and PRINTPROBS.

If an interval probability is smaller than a tolerance ( $10^{-6}$  by default) after convergence, the probability is set to zero, the interval probabilities are renormalized so that they add to one, and iterations are restarted. Usually the algorithm converges in just a few more iterations. You can change the default value of the tolerance with the TOLPROB= option. You can specify the NOPOLISH option to avoid setting small probabilities to zero and restarting the algorithm.

If you specify the ITPRINTEM option, a table summarizing the Turnbull estimate of the interval probabilities is displayed. The columns labeled “Reduced Gradient” and “Lagrange Multiplier” are used in checking final convergence of the maximum likelihood estimate. The Lagrange multipliers must all be greater than or equal to zero, or the solution is not maximum likelihood. See Gentleman and Geyer (1994) for more details of the convergence checking. Also see Meeker and Escobar (1998, Chapter 3) for more information.

See Example 51.6 for an illustration.

## Nonparametric Confidence Intervals

You can use the PPOUT option in the PROB PLOT statement to create a table containing the nonparametric CDF estimates computed by the selected method, Kaplan-Meier CDF estimates, standard errors of the Kaplan-Meier estimator, and nonparametric confidence limits for the CDF. The confidence limits are either pointwise or simultaneous, depending on the value of the NPINTERVALS= option in the PROB PLOT statement. The method used in the LIFEREG procedure for computation of approximate pointwise and simultaneous confidence intervals for cumulative failure probabilities relies on the Kaplan-Meier estimator of the cumulative distribution function of failure time and approximate standard deviation of the Kaplan-Meier estimator. For the case of arbitrarily censored data, the Turnbull algorithm, discussed previously, provides an extension of the Kaplan-Meier estimator. Both the Kaplan-Meier and the Turnbull estimators provide an estimate of the standard error of the CDF estimator,  $se_{\hat{F}}$ , that is used in computing confidence intervals.

### Pointwise Confidence Intervals

Approximate  $(1 - \alpha)100\%$  pointwise confidence intervals are computed as in Meeker and Escobar (1998, Section 3.6) as

$$[F_L, F_U] = \left[ \frac{\hat{F}}{\hat{F} + (1 - \hat{F})w}, \frac{\hat{F}}{\hat{F} + (1 - \hat{F})/w} \right]$$

where

$$w = \exp \left[ \frac{z_{1-\alpha/2} se_{\hat{F}}}{(\hat{F}(1 - \hat{F}))} \right]$$

where  $z_p$  is the  $p$ th quantile of the standard normal distribution.

### Simultaneous Confidence Intervals

Approximate  $(1 - \alpha)100\%$  simultaneous confidence bands valid over the lifetime interval  $(t_a, t_b)$  are computed as the “Equal Precision” case of Nair (1984) and Meeker and Escobar (1998, Section 3.8) as

$$[F_L, F_U] = \left[ \frac{\hat{F}}{\hat{F} + (1 - \hat{F})w}, \frac{\hat{F}}{\hat{F} + (1 - \hat{F})/w} \right]$$

where

$$w = \exp \left[ \frac{e_{a,b,1-\alpha/2} \text{SE}_{\hat{F}}}{(\hat{F}(1 - \hat{F}))} \right]$$

where the factor  $x = e_{a,b,1-\alpha/2}$  is the solution of

$$x \exp(-x^2/2) \log \left[ \frac{(1-a)b}{(1-b)a} \right] / \sqrt{8\pi} = \alpha/2$$

The time interval  $(t_a, t_b)$  over which the bands are valid depends in a complicated way on the constants  $a$  and  $b$  defined in Nair (1984),  $0 < a < b < 1$ . The constants  $a$  and  $b$  are chosen by default so that the confidence bands are valid between the lowest and highest times corresponding to failures in the case of multiply censored data, or to the lowest and highest intervals for which probabilities are computed for arbitrarily censored data. You can optionally specify  $a$  and  $b$  directly with the NPINTERVALS=SIMULTANEOUS( $a$ ,  $b$ ) option in the PROBLOT statement.

## Parametric Confidence Intervals

Pointwise parametric confidence bands are displayed in a probability plot, unless you specify the NOCONF option in the PROBLOT statement. Two kinds of confidence intervals are available for display in a probability plot: confidence limits for the estimated cumulative distribution function (CDF) and confidence limits for estimated distribution percentiles.

### Confidence Limits for the Estimated CDF

If the distribution is of type log-location-scale, let  $y = \log(t)$  where  $t$  is the value of time at which the confidence limits are to be computed. If the distribution is of type location-scale, let  $y$  be the value at which you want to evaluate confidence limits for the estimated CDF  $\hat{F}(y)$ . Let

$$\hat{u} = \frac{y - \mathbf{x}'\hat{\boldsymbol{\beta}}}{\hat{\sigma}}$$

where the column vector  $\mathbf{x}$  of covariate values is determined by the rules summarized in the section “XDATA= Data Set” on page 3947. If an offset variable is specified, the mean of the offset variable values is included in  $\mathbf{x}'\hat{\boldsymbol{\beta}}$ .

The CDF estimate is given by

$$\hat{F}(y) = G(\hat{u})$$

where  $G$  is the baseline distribution. The approximate standard error of  $\hat{F}(y)$  is computed as in Meeker and Escobar (1998, Section 8.4.3) as

$$\text{SE}_{\hat{F}} = \frac{g(\hat{u})}{\hat{\sigma}} \left[ \text{Var}(\mathbf{x}'\hat{\boldsymbol{\beta}}) + 2\hat{u}\text{Cov}(\mathbf{x}'\hat{\boldsymbol{\beta}}, \hat{\sigma}) + \hat{u}^2 \text{Var}(\hat{\sigma}) \right]^{\frac{1}{2}}$$

where  $g$  is the probability density function corresponding to  $G$ . Two-sided  $(1 - \alpha) \times 100\%$  confidence limits are given by

$$[F_L, F_U] = \left[ \frac{\hat{F}}{\hat{F} + (1 - \hat{F}) \times w}, \frac{\hat{F}}{\hat{F} + (1 - \hat{F})/w} \right]$$

where

$$w = \exp \left[ \frac{z_{1-\alpha/2} \text{SE}_{\hat{F}}}{\hat{F}(1 - \hat{F})} \right]$$

and  $z_p$  is the  $p \times 100\%$  percentile of the standard normal distribution. The quantities  $\text{Var}(\mathbf{x}'\hat{\boldsymbol{\beta}})$ ,  $\text{Cov}(\mathbf{x}'\hat{\boldsymbol{\beta}}, \hat{\sigma})$ , and  $\text{Var}(\hat{\sigma})$  are computed based on the covariance matrix of the estimated parameter vector  $(\hat{\boldsymbol{\beta}}, \hat{\sigma})$ .

### Confidence Limits for Percentiles

If the **HCL** option is specified in the **PROBPLOT** statement, confidence limits based on estimated distribution percentiles instead of the default CDF limits are displayed in the probability plot.

For location-scale distributions, the estimated  $p \times 100\%$  percentile of the distribution  $F$  is given by

$$y_p = \mathbf{x}'\hat{\boldsymbol{\beta}} + G^{-1}(p)\hat{\sigma}$$

where  $G$  is the baseline distribution and the column vector  $\mathbf{x}$  of covariate values is determined by the rules summarized in the section “**XDATA= Data Set**” on page 3947. The standard error of  $y_p$  is estimated by  $\text{SE}_y = \mathbf{z}'\Sigma\mathbf{z}$  where  $\mathbf{z} = (\mathbf{x}', G^{-1}(p))'$  and  $\Sigma$  is the covariance matrix of the parameter estimates  $(\hat{\boldsymbol{\beta}}, \hat{\sigma})'$ . Two-sided  $(1 - \alpha) \times 100\%$  confidence limits for  $y_p$  are given by

$$[y_L, y_U] = [y_p - z_{1-\alpha/2}\text{SE}_y, y_p + z_{1-\alpha/2}\text{SE}_y]$$

For distributions of type log-location-scale, the confidence limits are computed as

$$[t_L = \exp(y_L), t_U = \exp(y_U)]$$

For example, if  $T$  has the Weibull distribution,  $G$  is the standardized extreme value distribution,  $[y_L, y_U]$  are confidence limits for the  $p \times 100\%$  percentile of the extreme value distribution for  $\log(T)$ , and  $[t_L = \exp(y_L), t_U = \exp(y_U)]$  are confidence limits for the  $p \times 100\%$  percentile of the Weibull distribution for  $T$ .

---

## INEST= Data Set

If specified, the **INEST=** data set specifies initial estimates for all the parameters in the model. The **INEST=** data set must contain the intercept variable (named **Intercept**) and all independent variables in the **MODEL** statement.

If **BY** processing is used, the **INEST=** data set should also include the **BY** variables, and there must be at least one observation for each **BY** group. If there is more than one observation in one **BY** group, the first observation read is used for that **BY** group.

If the **INEST=** data set also contains the **\_TYPE\_** variable, only observations with **\_TYPE\_** value 'PARMS' are used as starting values. Combining the **INEST=** data set and the **MAXITER=** option in the **MODEL**

statement, partial scoring can be done, such as predicting on a validation data set by using the model built from a training data set.

You can specify starting values for the iterative algorithm in the INEST= data set. This data set overwrites the INITIAL= option in the MODEL statement, which is a little difficult to use for models including multilevel interaction effects. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization. See [Example 51.3](#) for an illustration.

---

## OUTEST= Data Set

The OUTEST= data set contains parameter estimates and the log likelihood for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different models fit with the LIFEREG procedure. If the COVOUT option is specified, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates. Note that, if the LIFEREG procedure does not converge, the parameter estimates are set to missing in the OUTEST data set.

The OUTEST= data set contains all variables specified in the MODEL statement and the BY statement. One observation consists of parameter values for the model with the dependent variable having the value  $-1$ . If the COVOUT option is specified, there are additional observations containing the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

|                        |                                                                                                                                                                        |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_MODEL_</code>   | a character variable containing the label of the MODEL statement, if present. Otherwise, the variable's value is blank.                                                |
| <code>_NAME_</code>    | a character variable containing the name of the dependent variable for the parameter estimates observations or the name of the row for the covariance matrix estimates |
| <code>_TYPE_</code>    | a character variable containing the type of the observation, either PARMS for parameter estimates or COV for covariance estimates                                      |
| <code>_DIST_</code>    | a character variable containing the name of the distribution modeled                                                                                                   |
| <code>_LNLIKE_</code>  | a numeric variable containing the last computed value of the log likelihood                                                                                            |
| <code>INTERCEPT</code> | a numeric variable containing the intercept parameter estimates and covariances                                                                                        |
| <code>_SCALE_</code>   | a numeric variable containing the scale parameter estimates and covariances                                                                                            |
| <code>_SHAPE1_</code>  | a numeric variable containing the first shape parameter estimates and covariances if the specified distribution has additional shape parameters                        |

Any BY variables specified are also added to the OUTEST= data set.

---

## XDATA= Data Set

The XDATA= data set is used for plotting the predicted probability when there are covariates specified in a MODEL statement and a probability plot is specified with a PROBPLOT statement. See [Example 51.4](#) for an illustration.

The XDATA= data set is an input SAS data set that contains values for all the independent variables in the MODEL statement and variables in the CLASS statement. The XDATA= data set has the same structure as the DATA= data set but is not required to have all the variables or observations that appear in the DATA= data set.

The XDATA= data set must contain all the independent variables in the MODEL statement and variables in the CLASS statement. Even though variables in the CLASS statement might not be used, valid values are required for these variables in the XDATA= data set. Missing values are not allowed. Missing values are not allowed in the XDATA= data set for any of the independent variables, either. Missing values are allowed for the dependent variables and other variables if they are included in the XDATA= data set.

If BY processing is used, the XDATA= data set should also include the BY variables, and there must be at least one valid observation for each BY group. If there is more than one valid observation in a BY group, the last one read is used for that BY group.

If there is no XDATA= data set in the PROC LIFEREG statement, by default, the LIFEREG procedure will use the overall mean for effects containing a continuous variable (or variables) and the highest level of a single classification variable as reference level. The rules are summarized as follows:

- If the effect contains a continuous variable (or variables), the overall mean of this effect (not the variables) is used.
- If the effect is a single classification variable, the highest level of the variable is used.

---

## Computational Resources

Let  $p$  be the number of parameters estimated in the model. The minimum working space (in bytes) needed is

$$16p^2 + 100p$$

However, if sufficient space is available, the input data set is also kept in memory; otherwise, the input data set is reread for each evaluation of the likelihood function and its derivatives, with the resulting execution time of the procedure substantially increased.

Let  $n$  be the number of observations used in the model estimation. Each evaluation of the likelihood function and its first and second derivatives requires  $O(np^2)$  multiplications and additions,  $n$  individual function evaluations for the log density or log distribution function, and  $n$  evaluations of the first and second derivatives of the function. The calculation of each updating step from the gradient and Hessian requires  $O(p^3)$  multiplications and additions. The  $O(v)$  notation means that, for large values of the argument,  $v$ ,  $O(v)$  is approximately a constant times  $v$ .

## Bayesian Analysis

### Gibbs Sampling

This section provides details about Bayesian analysis by Gibbs sampling in the location-scale models for survival data available in PROC LIFEREG. See the section “Gibbs Sampler” on page 135 for a general discussion of Gibbs sampling. PROC LIFEREG fits parametric location-scale survival models. That is, the probability density of the response  $Y$  can be expressed in the general form

$$f(y) = g\left(\frac{y - \mu}{\sigma}\right)$$

where  $Y = \log(T)$  for lifetimes  $T$ . The function  $g$  determines the specific distribution. The location parameter  $\mu_i$  is modeled through regression parameters as  $\mu_i = \mathbf{x}_i' \boldsymbol{\beta}$ . The LIFEREG procedure can provide Bayesian estimates of the regression parameters and  $\sigma$ . The OUTPUT and PROBPLOT statements, if specified, are ignored. The PLOTS=PROBPLOT option in the PROC LIFEREG statement and the CORRB and COVB options in the MODEL statement are also ignored.

For the Weibull distribution, you can specify that Gibbs sampling be performed on the Weibull shape parameter  $\beta = \sigma^{-1}$  instead of the scale parameter  $\sigma$  by specifying a prior distribution for the shape parameter with the WEIBULLSHAPEPRIOR= option. In addition, if there are no covariates in the model, you can specify Gibbs sampling on the Weibull scale parameter  $\alpha = \exp(\mu)$ , where  $\mu$  is the intercept term, with the WEIBULLSCALEPRIOR= option.

In the case of the exponential distribution with no covariates, you can specify Gibbs sampling on the exponential scale parameter  $\alpha = \exp(\mu)$ , where  $\mu$  is the intercept term, with the EXPSCALEPRIOR= option.

Let  $\boldsymbol{\theta} = (\theta_1, \dots, \theta_k)'$  be the parameter vector. For location-scale models, the  $\theta_i$ 's are the regression coefficients  $\beta_i$ 's and the scale parameter  $\sigma$ . In the case of the three-parameter gamma distribution, there is an additional gamma shape parameter  $\tau$ . Let  $L(D|\boldsymbol{\theta})$  be the likelihood function, where  $D$  is the observed data. Let  $\pi(\boldsymbol{\theta})$  be the prior distribution. The full conditional distribution of  $[\theta_i|\theta_j, i \neq j]$  is proportional to the joint distribution; that is,

$$\pi(\theta_i|\theta_j, i \neq j, D) \propto L(D|\boldsymbol{\theta})p(\boldsymbol{\theta})$$

For instance, the one-dimensional conditional distribution of  $\theta_1$  given  $\theta_j = \theta_j^*, 2 \leq j \leq k$ , is computed as

$$\pi(\theta_1|\theta_j = \theta_j^*, 2 \leq j \leq k, D) = L(D|(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \dots, \theta_k^*)'))p(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \dots, \theta_k^*)')$$

Suppose you have a set of arbitrary starting values  $\{\theta_1^{(0)}, \dots, \theta_k^{(0)}\}$ . Using the ARMS (adaptive rejection Metropolis sampling) algorithm of Gilks and Wild (1992) and Gilks, Best, and Tan (1995), you can do the following:

draw  $\theta_1^{(1)}$  from  $[\theta_1|\theta_2^{(0)}, \dots, \theta_k^{(0)}]$   
 draw  $\theta_2^{(1)}$  from  $[\theta_2|\theta_1^{(1)}, \theta_3^{(0)}, \dots, \theta_k^{(0)}]$   
 ...  
 draw  $\theta_k^{(1)}$  from  $[\theta_k|\theta_1^{(1)}, \dots, \theta_{k-1}^{(1)}]$

This completes one iteration of the Gibbs sampler. After one iteration, you have  $\{\theta_1^{(1)}, \dots, \theta_k^{(1)}\}$ . After  $n$  iterations, you have  $\{\theta_1^{(n)}, \dots, \theta_k^{(n)}\}$ . PROC LIFEREG implements the ARMS algorithm based on a program provided by Gilks (2003) to draw a sample from a full conditional distribution. See the section “Assessing Markov Chain Convergence” on page 139 for information about assessing the convergence of the chain of posterior samples.

You can output these posterior samples into a SAS data set. The following option in the BAYES statement outputs the posterior samples into the SAS data set Post: `OUTPOST=Post`. The data set also includes the variables LogPost and LogLike, which represent the log of the posterior distribution and the log of the likelihood, respectively.

## Priors for Model Parameters

The model parameters are the regression coefficients and the dispersion parameter (or the precision or scale), if the model has one. The priors for the dispersion parameter and the priors for the regression coefficients are assumed to be independent, while you can have a joint multivariate normal prior for the regression coefficients.

### Scale and Shape Parameters

**Gamma Prior** The gamma distribution  $G(a, b)$  has a PDF

$$f_{a,b}(u) = \frac{b(bu)^{a-1}e^{-bu}}{\Gamma(a)}, \quad u > 0$$

where  $a$  is the shape parameter and  $b$  is the inverse-scale parameter. The mean is  $\frac{a}{b}$  and the variance is  $\frac{a}{b^2}$ .

**Improper Prior** The joint prior density is given by

$$p(u) \propto u^{-1}, \quad u > 0$$

### Regression Coefficients

Let  $\boldsymbol{\beta}$  be the regression coefficients.

**Normal Prior** Assume  $\boldsymbol{\beta}$  has a multivariate normal prior with mean vector  $\boldsymbol{\beta}_0$  and covariance matrix  $\boldsymbol{\Sigma}_0$ . The joint prior density is given by

$$p(\boldsymbol{\beta}) \propto e^{-\frac{1}{2}(\boldsymbol{\beta}-\boldsymbol{\beta}_0)'\boldsymbol{\Sigma}_0^{-1}(\boldsymbol{\beta}-\boldsymbol{\beta}_0)}$$

**Uniform Prior** The joint prior density is given by

$$p(\boldsymbol{\beta}) \propto 1$$

## Posterior Distribution

Denote the observed data by  $D$ .

The posterior distribution is

$$\pi(\boldsymbol{\theta}|D) \propto L_P(D|\boldsymbol{\theta})p(\boldsymbol{\theta})$$

where  $L_P(D|\boldsymbol{\theta})$  is the likelihood function with regression coefficients and any additional parameters, such as scale or shape,  $\boldsymbol{\theta}$  as parameters; and  $p(\boldsymbol{\theta})$  is the joint prior distribution of the parameters.

## Deviance Information Criterion

Let  $\theta_i$  be the model parameters at iteration  $i$  of the Gibbs sampler, and let  $LL(\theta_i)$  be the corresponding model log likelihood. PROC LIFEREG computes the following fit statistics defined by Spiegelhalter et al. (2002):

- effective number of parameters:

$$p_D = \overline{LL(\theta)} - LL(\bar{\theta})$$

- deviance information criterion (DIC):

$$DIC = \overline{LL(\theta)} + p_D$$

where

$$\overline{LL(\theta)} = \frac{1}{n} \sum_{i=1}^n LL(\theta_i)$$

$$\bar{\theta} = \frac{1}{n} \sum_{i=1}^n \theta_i$$

and  $n$  is the number of Gibbs samples.

## Starting Values of the Markov Chains

When the BAYES statement is specified, PROC LIFEREG generates one Markov chain containing the approximate posterior samples of the model parameters. Additional chains are produced when the Gelman-Rubin diagnostics are requested. Starting values (or initial values) can be specified in the INITIAL= data set in the BAYES statement. If INITIAL= option is not specified, PROC LIFEREG picks its own initial values for the chains.

Denote  $[x]$  as the integral value of  $x$ . Denote  $\hat{s}(X)$  as the estimated standard error of the estimator  $X$ .

### Regression Coefficients and Gamma Shape Parameter

For the first chain that the summary statistics and regression diagnostics are based on, the default initial values are estimates of the mode of the posterior distribution. If the INITIALMLE option is specified, the initial values are the maximum likelihood estimates; that is,

$$\beta_i^{(0)} = \hat{\beta}_i$$

Initial values for the  $r$ th chain ( $r \geq 2$ ) are given by

$$\beta_i^{(0)} = \hat{\beta}_i \pm \left( 2 + \left\lceil \frac{r}{2} \right\rceil \right) \hat{s}(\hat{\beta}_i)$$

with the plus sign for odd  $r$  and minus sign for even  $r$ .

**Scale, Exponential Scale, Weibull Scale, or Weibull Shape Parameter  $\lambda$** 

Let  $\lambda$  be the parameter sampled.

For the first chain that the summary statistics and diagnostics are based on, the initial values are estimates of the mode of the posterior distribution; or the maximum likelihood estimates if the INITIALMLE option is specified; that is,

$$\lambda^{(0)} = \hat{\lambda}$$

The initial values of the  $r$ th chain ( $r \geq 2$ ) are given by

$$\lambda^{(0)} = \hat{\lambda} e^{\pm \left( \left[ \frac{r}{2} \right] + 2 \right) \hat{s}(\hat{\lambda})}$$

with the plus sign for odd  $r$  and minus sign for even  $r$ .

**OUTPOST= Output Data Set**

The OUTPOST= data set contains the generated posterior samples. There are  $2+n$  variables, where  $n$  is the number of model parameters. The variable Iteration represents the iteration number and the variable LogPost contains the log posterior likelihood values. The other  $n$  variables represent the draws of the Markov chain for the model parameters.

**Displayed Output for Classical Analysis**

For each model, PROC LIFEREG displays the following.

**Model Information**

The “Model Information” table displays the two-level name of the input data set, the distribution name, and the name and label of the dependent variable; the name and label of the censor indicator variable, for right-censored data; if you specify the WEIGHT statement, the name and label of the weight variable; and the maximum value of the log likelihood.

**Number of Observations**

The “Number of Observations” table displays the number of observations read from the input data set, and the number of observations used in the analysis.

**Class Level Information**

The “Class Level Information” table displays the levels of classification variables if you specify a CLASS statement.

**Fit Statistics**

The “Fit Statistics” table displays the negative of twice the log likelihood, Akaike’s information criterion (AIC), the corrected Akaike’s information criterion (AICC), and the Bayesian information criterion (BIC). If the specified distribution is Weibull, lognormal, log-logistic, or gamma, the fit criteria are based on the log likelihood for the log of the response, rather than for the response on the original scale.

### Fit Statistics (Unlogged Response)

If the specified distribution is Weibull, lognormal, log-logistic, or gamma, the “Fit Statistics (Unlogged Response)” table displays fit criteria that are based on the log likelihood for the response on the original, rather than log, scale. The negative of twice the log likelihood, Akaike’s information criterion (AIC), the corrected Akaike’s information criterion (AICC), and the Bayesian information criterion (BIC) are displayed.

### Type III Analysis of Effects

The “Type III Analysis of Effects” table displays, for each effect in the model, the effect name, the degrees of freedom associated with the type III contrast for the effect, the chi-square statistic for the contrast, and the  $p$ -value for the statistic.

### Analysis of Maximum Likelihood Parameter Estimates

The “Analysis of Maximum Likelihood Parameter Estimates” table displays the parameter name, the degrees of freedom for each parameter, the maximum likelihood estimate of each parameter, the estimated standard error of the parameter estimator, confidence limits for each parameter, a chi-square statistic for testing whether the parameter is zero, and the associated  $p$ -value for the statistic.

### Lagrange Multiplier Statistics

If there are constrained parameters in the model, such as the scale or intercept, then the “Lagrange Multiplier Statistics” table displays a Lagrange multiplier test for the constraint.

---

## Displayed Output for Bayesian Analysis

If a Bayesian analysis is requested with a BAYES statement, the displayed output includes the following.

### Model Information

The “Model Information” table displays the two-level name of the input data set, the number of burn-in iterations, the number of iterations after the burn-in, the number of thinning iterations, the distribution name, and the name and label of the dependent variable; the name and label of the censor indicator variable, for right-censored data; if you specify the WEIGHT statement, the name and label of the weight variable; and the maximum value of the log likelihood.

### Class Level Information

The “Class Level Information” table displays the levels of classification variables if you specify a CLASS statement.

### Maximum Likelihood Estimates

The “Analysis of Maximum Likelihood Parameter Estimates” table displays the maximum likelihood estimate of each parameter, the estimated standard error of the parameter estimator, and confidence limits for each parameter.

## Coefficient Prior

The “Coefficient Prior” table displays the prior distribution of the regression coefficients.

## Independent Prior Distributions for Model Parameters

The “Independent Prior Distributions for Model Parameters” table displays the prior distributions of additional model parameters (scale, exponential scale, Weibull scale, Weibull shape, gamma shape).

## Initial Values and Seeds

The “Initial Values and Seeds” table displays the initial values and random number generator seeds for the Gibbs chains.

## Fit Statistics

The “Fit Statistics” table displays the deviance information criterion (DIC) and the effective number of parameters.

## Posterior Summaries

The “Posterior Summaries” table contains the size of the sample, the mean, the standard deviation, and the quartiles for each model parameter.

## Posterior Intervals

The “Posterior Intervals” table contains the HPD intervals and the credible intervals for each model parameter.

## Correlation Matrix of the Posterior Samples

The “Correlation Matrix of the Posterior Samples” table is produced if you include the CORR suboption in the SUMMARY= option in the BAYES statement. This table displays the sample correlation of the posterior samples.

## Covariance Matrix of the Posterior Samples

The “Covariance Matrix of the Posterior Samples” table is produced if you include the COV suboption in the SUMMARY= option in the BAYES statement. This table displays the sample covariance of the posterior samples.

## Autocorrelations of the Posterior Samples

The “Autocorrelations of the Posterior Samples” table displays the lag1, lag5, lag10, and lag50 autocorrelations for each parameter.

## Gelman and Rubin Diagnostics

The “Gelman and Rubin Diagnostics” table is produced if you include the GELMAN suboption in the DIAGNOSTIC= option in the BAYES statement. This table displays the estimate of the potential scale reduction factor and its 97.5% upper confidence limit for each parameter.

## Geweke Diagnostics

The “Geweke Diagnostics” table displays the Geweke statistic and its  $p$ -value for each parameter.

## Raftery and Lewis Diagnostics

The “Raftery Diagnostics” tables is produced if you include the RAFTERY suboption in the DIAGNOSTIC= option in the BAYES statement. This table displays the Raftery and Lewis diagnostics for each variable.

## Heidelberger and Welch Diagnostics

The “Heidelberger and Welch Diagnostics” table is displayed if you include the HEIDELBERGER suboption in the DIAGNOSTIC= option in the BAYES statement. This table shows the results of a stationary test and a halfwidth test for each parameter.

## Effective Sample Size

The “Effective Sample Size” table displays, for each parameter, the effective sample size, the correlation time, and the efficiency.

## Monte Carlo Standard Errors

The “Monte Carlo Standard Errors” table displays, for each parameter, the Monte Carlo standard error, the posterior sample standard deviation, and the ratio of the two.

---

## ODS Table Names

PROC LIFEREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed separately in Table 51.14 for a maximum likelihood analysis and in Table 51.15 for a Bayesian analysis. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 51.14** ODS Tables Produced in PROC LIFEREG for a Classical Analysis

| ODS Table Name     | Description                              | Statement | Option                                                       |
|--------------------|------------------------------------------|-----------|--------------------------------------------------------------|
| ClassLevels        | Classification variable levels           | CLASS     | Default*                                                     |
| ConvergenceStatus  | Convergence status                       | MODEL     | Default                                                      |
| CorrB              | Parameter estimate correlation matrix    | MODEL     | CORRB                                                        |
| CovB               | Parameter estimate covariance matrix     | MODEL     | COVB                                                         |
| IterEM             | Iteration history for Turnbull algorithm | PROBPLOT  | ITPRINTM                                                     |
| FitStatistics      | Fit statistics                           | MODEL     | Default                                                      |
| FitStatisticsUL    | Fit statistics for unlogged response     | MODEL     | DISTRIBUTION=WEIBULL,<br>LOGNORMAL, LLO-<br>GISTIC, or GAMMA |
| IterHistory        | Iteration history                        | MODEL     | ITPRINT                                                      |
| LagrangeStatistics | Lagrange statistics                      | MODEL     | NOINT   NOSCALE                                              |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Some graphs are produced by default; other graphs are produced by using statements and options.

## ODS Graph Names

PROC LIFEREG assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names of the graphs that PROC LIFEREG generates are listed in [Table 51.16](#), along with the required statements and options.

Table 51.16 Graphs Produced by PROC LIFEREG

| ODS Graph Name | Description                                        | Statement             | Option                                |
|----------------|----------------------------------------------------|-----------------------|---------------------------------------|
| ADPanel        | Autocorrelation function and density panel         | BAYES                 | <code>PLOTS=(AUTOCORR DENSITY)</code> |

---

## Examples: LIFEREG Procedure

---

### Example 51.1: Motorette Failure

This example fits a Weibull model and a lognormal model to the example given in Kalbfleisch and Prentice (1980, p. 5). An output data set called `models` is specified to contain the parameter estimates. By default, the natural log of the variable `time` is used by the procedure as the response. After this log transformation, the Weibull model is fit using the extreme-value baseline distribution, and the lognormal is fit using the normal baseline distribution.

Since the extreme-value and normal distributions do not contain any shape parameters, the variable `SHAPE1` is missing in the `models` data set. An additional output data set, `out`, is created that contains the predicted quantiles and their standard errors for values of the covariate corresponding to `temp=130` and `temp=150`. This is done with the control variable, which is set to 1 for only two observations.

Using the standard error estimates obtained from the output data set, approximate 90% confidence limits for the predicted quantities are then created in a subsequent `DATA` step for the log response. The logs of the predicted values are obtained because the values of the `P=` variable in the `OUT=` data set are in the same units as the original response variable, `time`. The standard errors of the quantiles of  $\log(\text{time})$  are approximated (using a Taylor series approximation) by the standard deviation of `time` divided by the mean value of `time`. These confidence limits are then converted back to the original scale by the exponential function.

The following statements produce [Output 51.1.1](#):

```

**Example 51.2: Computing Predicted Values for a Tobit Model**

The LIFEREG procedure can be used to perform a Tobit analysis. The Tobit model, described by Tobin (1958), is a regression model for left-censored data assuming a normally distributed error term. The model parameters are estimated by maximum likelihood. PROC LIFEREG provides estimates of the parameters of the distribution of the *uncensored* data. See Greene (1993) and Maddala (1983) for a more complete discussion of censored normal data and related distributions. This example shows how you can use PROC LIFEREG and the DATA step to compute two of the three types of predicted values discussed there.

Consider a continuous random variable  $Y$  and a constant  $C$ . If you were to sample from the distribution of  $Y$  but discard values less than (greater than)  $C$ , the distribution of the remaining observations would be *truncated* on the left (right). If you were to sample from the distribution of  $Y$  and report values less than (greater than)  $C$  as  $C$ , the distribution of the sample would be left (right) *censored*.

The probability density function of the truncated random variable  $Y'$  is given by

$$f_{Y'}(y) = \frac{f_Y(y)}{\Pr(Y > C)} \text{ for } y > C$$

where  $f_Y(y)$  is the probability density function of  $Y$ . PROC LIFEREG cannot compute the proper likelihood function to estimate parameters or predicted values for a truncated distribution. Suppose the model being fit is specified as follows:

$$Y_i^* = \mathbf{x}_i' \boldsymbol{\beta} + \epsilon_i$$

where  $\epsilon_i$  is a normal error term with zero mean and standard deviation  $\sigma$ .

Define the censored random variable  $Y_i$  as

$$\begin{aligned} Y_i &= 0 \text{ if } Y_i^* \leq 0 \\ Y_i &= Y_i^* \text{ if } Y_i^* > 0 \end{aligned}$$

This is the Tobit model for left-censored normal data.  $Y_i^*$  is sometimes called the *latent variable*. PROC LIFEREG estimates parameters of the distribution of  $Y_i^*$  by maximum likelihood.

You can use the LIFEREG procedure to compute predicted values based on the mean functions of the latent and observed variables. The mean of the latent variable  $Y_i^*$  is  $\mathbf{x}'_i\boldsymbol{\beta}$ , and you can compute values of the mean for different settings of  $\mathbf{x}_i$  by specifying `XBETA=variable-name` in an OUTPUT statement. Estimates of  $\mathbf{x}'_i\boldsymbol{\beta}$  for each observation will be written to the OUT= data set. Predicted values of the observed variable  $Y_i$  can be computed based on the mean

$$E(Y_i) = \Phi\left(\frac{\mathbf{x}'_i\boldsymbol{\beta}}{\sigma}\right)(\mathbf{x}'_i\boldsymbol{\beta} + \sigma\lambda_i)$$

where

$$\lambda_i = \frac{\phi(\mathbf{x}'_i\boldsymbol{\beta}/\sigma)}{\Phi(\mathbf{x}'_i\boldsymbol{\beta}/\sigma)}$$

$\phi$  and  $\Phi$  represent the normal probability density and cumulative distribution functions.

Although the distribution of  $\epsilon_i$  in the Tobit model is often assumed normal, you can use other distributions for the Tobit model in the LIFEREG procedure by specifying a distribution with the `DISTRIBUTION=` option in the MODEL statement. One distribution that should be mentioned is the logistic distribution. For this distribution, the MLE has bounded influence function with respect to the response variable, but not the design variables. If you believe your data have outliers in the response direction, you might try this distribution for some robust estimation of the Tobit model.

With the logistic distribution, the predicted values of the observed variable  $Y_i$  can be computed based on the mean of  $Y_i^*$ ,

$$E(Y_i) = \sigma \ln(1 + \exp(\mathbf{x}'_i\boldsymbol{\beta}/\sigma))$$

The following table shows a subset of the Mroz (1987) data set. In these data, Hours is the number of hours the wife worked outside the household in a given year, Yrs\_Ed is the years of education, and Yrs\_Exp is the years of work experience. A Tobit model will be fit to the hours worked with years of education and experience as covariates.

| Hours | Yrs_Ed | Yrs_Exp |
|-------|--------|---------|
| 0     | 8      | 9       |
| 0     | 8      | 12      |
| 0     | 9      | 10      |
| 0     | 10     | 15      |
| 0     | 11     | 4       |
| 0     | 11     | 6       |
| 1000  | 12     | 1       |
| 1960  | 12     | 29      |
| 0     | 13     | 3       |
| 2100  | 13     | 36      |
| 3686  | 14     | 11      |
| 1920  | 14     | 38      |
| 0     | 15     | 14      |
| 1728  | 16     | 3       |
| 1568  | 16     | 19      |
| 1316  | 17     | 7       |
| 0     | 17     | 15      |

If the wife was not employed (worked 0 hours), her hours worked will be left censored at zero. In order to accommodate left censoring in PROC LIFEREG, you need two variables to indicate censoring status of observations. You can think of these variables as lower and upper endpoints of interval censoring. If there is no censoring, set both variables to the observed value of Hours. To indicate left censoring, set the lower endpoint to missing and the upper endpoint to the censored value, zero in this case.

The following statements create a SAS data set with the variables Hours, Yrs\_Ed, and Yrs\_Exp from the preceding data. A new variable, Lower, is created such that Lower=. if Hours=0 and Lower=Hours if Hours>0.

```

data subset;
 input Hours Yrs_Ed Yrs_Exp @@;
 if Hours eq 0
 then Lower=.;
 else Lower=Hours;
 datalines;
0 8 9 0 8 12 0 9 10 0 10 15 0 11 4 0 11 6
1000 12 1 1960 12 29 0 13 3 2100 13 36
3686 14 11 1920 14 38 0 15 14 1728 16 3
1568 16 19 1316 17 7 0 17 15
;

```

The following statements fit a normal regression model to the left-censored Hours data with Yrs\_Ed and Yrs\_Exp as covariates. You need the estimated standard deviation of the normal distribution to compute the predicted values of the censored distribution from the preceding formulas. The data set OUTEST contains the standard deviation estimate in a variable named `_SCALE_`. You also need estimates of  $x'_i\beta$ . These are contained in the data set OUT as the variable Xbeta.

```
proc lifereg data=subset outest=OUTEST(keep=_scale_);
 model (lower, hours) = yrs_ed yrs_exp / d=normal;
 output out=OUT xbeta=xbeta;
run;
```

Output 51.2.1 shows the results of the model fit. These tables show parameter estimates for the uncensored, or latent variable, distribution.

**Output 51.2.1** Parameter Estimates from PROC LIFEREG

The following statements combine the two data sets created by PROC LIFEREG to compute predicted values for the censored distribution. The OUTEST= data set contains the estimate of the standard deviation from the uncensored distribution, and the OUT= data set contains estimates of  $x_i'\beta$ .

```
data predict;
 drop lambda _scale_ _prob_;
 set out;
 if _n_ eq 1 then set outest;
 lambda = pdf('NORMAL', Xbeta/_scale_)
 / cdf('NORMAL', Xbeta/_scale_);
 Predict = cdf('NORMAL', Xbeta/_scale_)
 * (Xbeta + _scale_*lambda);
 label Xbeta='MEAN OF UNCENSORED VARIABLE'
 Predict = 'MEAN OF CENSORED VARIABLE';
run;
```

Output 51.2.2 shows the original variables, the predicted means of the uncensored distribution, and the predicted means of the censored distribution.

**Output 51.2.2** Predicted Means from PROC LIFEREG

### Example 51.3: Overcoming Convergence Problems by Specifying Initial Values

This example illustrates the use of parameter initial value specification to help overcome convergence difficulties.

The following statements create a SAS data set.

```
data raw;
 input censor x c1 @@;
 datalines;
0 16 0.00 0 17 0.00 0 18 0.00
0 17 0.04 0 18 0.04 0 18 0.04
0 23 0.40 0 22 0.40 0 22 0.40
0 33 4.00 0 34 4.00 0 35 4.00
1 54 40.00 1 54 40.00 1 54 40.00
1 54 400.00 1 54 400.00 1 54 400.00
;
```

Output 51.3.1 shows the contents of the data set raw.

**Output 51.3.1** Contents of the Data Set

| Obs | sensor | x  | c1     |
|-----|--------|----|--------|
| 1   | 0      | 16 | 0.00   |
| 2   | 0      | 17 | 0.00   |
| 3   | 0      | 18 | 0.00   |
| 4   | 0      | 17 | 0.04   |
| 5   | 0      | 18 | 0.04   |
| 6   | 0      | 18 | 0.04   |
| 7   | 0      | 23 | 0.40   |
| 8   | 0      | 22 | 0.40   |
| 9   | 0      | 22 | 0.40   |
| 10  | 0      | 33 | 4.00   |
| 11  | 0      | 34 | 4.00   |
| 12  | 0      | 35 | 4.00   |
| 13  | 1      | 54 | 40.00  |
| 14  | 1      | 54 | 40.00  |
| 15  | 1      | 54 | 40.00  |
| 16  | 1      | 54 | 400.00 |
| 17  | 1      | 54 | 400.00 |
| 18  | 1      | 54 | 400.00 |

The following SAS statements request that a Weibull regression model be fit to the data:

```

title 'OLS (Default) Initial Values';
proc lifereg data=raw;
 model x*censor(1) = c1 / distribution = Weibull itprint;
run;

```

Convergence was not attained in 50 iterations for this model, as the following messages to the log indicate:

```

WARNING: Convergence was not attained in 50 iterations. You might want to
increase the maximum number of iterations (MAXITER= option) or
change the convergence criteria (CONVERGE = value) in the MODEL
statement.

```

```

WARNING: The procedure is continuing in spite of the above warning. Results
shown are based on the last maximum likelihood iteration. Validity
of the model fit is questionable.

```

The first line (iter=0) of the iteration history table, shown in [Output 51.3.2](#), shows the default initial ordinary least squares (OLS) estimates of the parameters.

## Output 51.3.2 Initial Least Squares

| OLS (Default) Initial Values              |       |               |              |              |              |
|-------------------------------------------|-------|---------------|--------------|--------------|--------------|

The log-logistic distribution is more robust to large values of the response than the Weibull distribution, so one approach to improving the convergence performance is to fit a log-logistic distribution, and if this converges, use the resulting parameter estimates as initial values in a subsequent fit of a model with the Weibull distribution.

The following statements fit a log-logistic distribution to the data:

```
proc lifereg data=raw;
 model x*censor(1) = c1 / distribution = llogistic;
run;
```

The algorithm converges, and the maximum likelihood estimates for the log-logistic distribution are shown in [Output 51.3.3](#)

**Output 51.3.3** Estimates from the Log-Logistic Distribution

| OLS (Default) Initial Values                       |    |          |                |                       |        |            |            |

| Analysis of Maximum Likelihood Parameter Estimates |    |          |                |                       |        |            |            |
| Parameter                                          | DF | Estimate | Standard Error | 95% Confidence Limits |        | Chi-Square | Pr > ChiSq |
| Intercept                                          | 1  | 2.8983   | 0.0318         | 2.8360                | 2.9606 | 8309.43    | <.0001     |
| c1                                                 | 1  | 0.1592   | 0.0133         | 0.1332                | 0.1852 | 143.85     | <.0001     |
| Scale                                              | 1  | 0.0498   | 0.0122         | 0.0308                | 0.0804 |            |            |

The following statements refit the Weibull model by using the maximum likelihood estimates from the log-logistic fit as initial values:

```
proc lifereg data=raw outest=outest;
 model x*censor(1) = c1 / itprint distribution = weibull
 intercept=2.898 initial=0.16 scale=0.05;
 output out=out xbeta=xbeta;
run;
```

Examination of the resulting output in [Output 51.3.4](#) shows that the convergence problem has been solved by specifying different initial values.

**Output 51.3.4** Final Estimates from the Weibull Distribution

```

 OLS (Default) Initial Values

 The LIFEREG Procedure

```

As an example of an alternative way of specifying initial values, the following invocation of PROC LIFEREG, using the INEST= data set to provide starting values for the three parameters, is equivalent to the previous invocation:

```

data in;
 input intercept c1 scale;
 datalines;
2.898 0.16 0.05
;

proc lifereg data=raw inest=in outest=outest;
 model x*censor(1) = c1 / itprint distribution = weibull;
 output out=out xbeta=xbeta;
run;

```

## Example 51.4: Analysis of Arbitrarily Censored Data with Interaction Effects

The artificial data in this example are from a study of the natural recovery time of mice after injection of a certain toxin. Twenty mice were grouped by sex (sex: 1 = Male, 2 = Female) with equal sizes. Their ages (in days) were recorded at the injection. Their recovery times (in minutes) were also recorded. Toxin density in blood was used to decide whether a mouse recovered. Mice were checked at two times for recovery. If a mouse had recovered at the first time, the observation is left censored, and no further measurement is made. The variable `time1` is set to missing and `time2` is set to the measurement time to indicate left censoring. If a mouse had not recovered at the first time, it was checked later at a second time. If it had recovered by the second measurement time, the observation is interval censored, and the variable `time1` is set to the first measurement time and `time2` is set to the second measurement time. If there was no recovery at the second measurement, the observation is right censored, and `time1` is set to the second measurement time and `time2` is set to missing to indicate right censoring.

The following statements create a SAS data set containing the data from the experiment:

```

title 'Natural Recovery Time';
data mice;
 input sex age time1 time2;
 datalines;
1 57 631 631
1 45 . 170
1 54 227 227
1 43 143 143
1 64 916 .
1 67 691 705
1 44 100 100
1 59 730 .
1 47 365 365
1 74 1916 1916
2 79 1326 .
2 75 837 837
2 84 1200 1235
2 54 . 365
2 74 1255 1255
2 71 1823 .
2 65 537 637
2 33 583 683
2 77 955 .
2 46 577 577
;

```

The following SAS statements create the SAS data sets xrow1 and xrow2:

```
data xrow1;
 input sex age time1 time2;
 datalines;
1 50 . .
;

data xrow2;
 input sex age time1 time2;
 datalines;
2 60.6 . .
;
```

The following SAS statements fit a Weibull model with age, sex, and an age-by-sex interaction term as covariates, and create a plot of predicted probabilities against recovery time for the fixed values of age and sex specified in the SAS data set xrow1:

```
ods graphics on;
proc lifereg data=mice xdata=xrow1;
 class sex;
 model (time1, time2) = age sex age*sex / dist=Weibull;

 probplot / nodata
 plower=.5
 vref(intersect) = 75
 vreflab = '75 Percent';
 inset;
run;
```

Standard output is shown in [Output 51.4.1](#). Tables containing general model information, Type III tests for the main effects and interaction terms, and parameter estimates are created.

**Output 51.4.1** Parameter Estimates for the Interaction Model

The following two plots display the predicted probability against the recovery time for two different populations. **Output 51.4.2** is created with the `PROBPLOT` statement with the option `XDATA= xrow1`, which specifies the population with `sex = 1`, `age = 50`. **Output 51.4.3** is created with the `PROBPLOT` statement with the option `XDATA= xrow2`, which specifies the population with `sex = 2`, `age = 60.6`. These are the default values that the `LIFEREG` procedure would use for the probability plot if the `XDATA=` option had not been specified. Reference lines are used to display specified predicted probability points and their relative locations in the plot.

**Output 51.4.2** Probability Plot for Recovery Time with `sex = 1`, `age = 50`

The following SAS statements fit a Weibull model with age, sex, and an age-by-sex interaction term as covariates, and create the plot of predicted probabilities against recovery time shown in [Output 51.4.3](#), for the fixed values of age and sex specified in the SAS data set xrow2:

```
proc lifereg data=mice xdata=xrow2;
 class sex;
 model (time1, time2) = age sex age*sex / dist=Weibull;

 probplot / nodata
 plower=.5
 vref(intersect) = 75
 vreflab = '75 Percent';
 inset;
run;
title;
ods graphics off;
```

**Output 51.4.3** Probability Plot for Recovery Time with sex = 2, age = 60.6

## Example 51.5: Probability Plotting—Right Censoring

The following statements create a SAS data set containing observed and right-censored lifetimes of 70 diesel engine fans (Nelson 1982):

```
data Fan;
 input Lifetime Censor@@;
 Lifetime = Lifetime / 1000;
 datalines;
 450 0 460 1 1150 0 1150 0 1560 1

;
```

Some of the fans had not failed at the time the data were collected, and the unfailed units have right-censored lifetimes. The variable LIFETIME represents either a failure time or a censoring time, in thousands of hours. The variable CENSOR is equal to 0 if the value of LIFETIME is a failure time, and it is equal to 1 if the value is a censoring time. The following statements use the LIFEREG procedure to produce the probability plot with an inset for the engine lifetimes:

```
ods graphics on;
proc lifereg data=Fan;
 model Lifetime*Censor(1) = / d = Weibull;
 probplot
 ppout
 npintervals=simul;
 inset;
run;
ods graphics off;
```

The resulting graphical output is shown in [Output 51.5.1](#). The estimated CDF, a line representing the maximum likelihood fit, and pointwise parametric confidence bands are plotted in the body of [Output 51.5.1](#). The values of right-censored observations are plotted along the bottom of the graph. The “Cumulative Probability Estimates” table is also created in [Output 51.5.2](#).

### Example 51.6: Probability Plotting—Arbitrary Censoring

Table 51.17 contains microprocessor failure data (Nelson 1990). Units were inspected at predetermined time intervals. The data consist of inspection interval endpoints (in hours) and the number of units failing in each interval. A missing (.) lower endpoint indicates left censoring, and a missing upper endpoint indicates right censoring. These can be thought of as semi-infinite intervals with a lower (upper) endpoint of negative (positive) infinity for left (right) censoring.

**Table 51.17** Interval-Censored Data

| Lower Endpoint | Upper Endpoint | Number Failed |
|----------------|----------------|---------------|
| .              | 6              | 6             |
| 6              | 12             | 2             |
| 24             | 48             | 2             |
| 24             | .              | 1             |
| 48             | 168            | 1             |
| 48             | .              | 839           |
| 168            | 500            | 1             |
| 168            | .              | 150           |
| 500            | 1000           | 2             |
| 500            | .              | 149           |
| 1000           | 2000           | 1             |
| 1000           | .              | 147           |
| 2000           | .              | 122           |

The following SAS statements create the SAS data set Micro:

```
data Micro;
 input t1 t2 f;
 datalines;
. 6 6
6 12 2
12 24 0
24 48 2
24 . 1
48 168 1
48 . 839
168 500 1
168 . 150
500 1000 2
500 . 149
1000 2000 1
1000 . 147
2000 . 122
;
```

The following SAS statements compute the nonparametric Turnbull estimate of the cumulative distribution function and create a lognormal probability plot:

```
ods graphics on;
proc lifereg data=Micro;
 model (t1 t2) = / d=lognormal intercept=25 scale=5;
 weight f;
 probplot
 pupper = 10
 itprintem
 printprobs
 maxitem = (1000,25)
 ppout;
 inset;
run;
ods graphics off;
```

The two initial values INTERCEPT=25 and SCALE=5 in the MODEL statement are used to aid convergence in the model-fitting algorithm.

The following tables are created by the PROBLOT statement in addition to the standard tabular output from the MODEL statement. Output 51.6.1 shows the iteration history for the Turnbull estimate of the CDF for the microprocessor data. With both options ITPRINTEM and PRINTPROBS specified in the PROBLOT statement, this table contains the log likelihoods and interval probabilities for every 25th iteration and the last iteration. It would contain only the log likelihoods if the option PRINTPROBS were not specified.

**Output 51.6.1** Iteration History for the Turnbull Estimate

| 2000           | .              | 0.9736      | 0.0003038877     | 0                   |

[Output 51.6.3](#) shows the final estimate of the CDF, along with standard errors and nonparametric confidence limits. Two kinds of nonparametric confidence limits, pointwise or simultaneous, are available. The default is the pointwise nonparametric confidence limits. You can specify the simultaneous nonparametric confidence limits by using the NPINTERVALS=SIMUL option.

**Output 51.6.3** Final CDF Estimates for Turnbull Algorithm

**Output 51.6.4** Lognormal Probability Plot for the Microprocessor Data

## Example 51.7: Bayesian Analysis of Clinical Trial Data

Consider the data on melanoma patients from a clinical trial described in Ibrahim, Chen, and Sinha (2001). A partial listing of the data is shown in [Output 51.7.1](#).

The survival time is modeled by a Weibull regression model with three covariates. An analysis of the right-censored survival data is performed with PROC LIFEREG to obtain Bayesian estimates of the regression coefficients by using the following SAS statements:

```
ods graphics on;
proc lifereg data=e1684;
 class Sex;
 model Survtime*Surv cens(1)=Age Sex Perform / dist=Weibull;
 bayes WeibullShapePrior=gamma seed=9999;
run;
ods graphics off;
```

**Output 51.7.1** Clinical Trial Data

Output 51.7.10 Diagnostic Plots

## Example 51.8: Model Postfitting Analysis

PROC LIFEREG enables you to make model-based inferences. This example uses the larynx cancer data (Klein and Moeschberger 1997) to illustrate usage of the LSMEANS, LSMESTIMATE, and EFFECTPLOT statements for model postfitting analysis.

The survival time is modeled by a proportional odds model with two covariates: patient age and cancer stage (1, 2, 3, 4). The following statements use PROC LIFEREG to fit this model:

```
ods graphics on;

proc sort data=Larynx;
 by DESCENDING Stage;
run;

proc lifereg data=Larynx order=data;
 class Stage;
 model Time*Death(0) = Age Stage / dist = llogistic;
 lsmeans Stage / diff adjust=Sidak;
 effectplot / noobs;
run;
```

The LSMEANS statement compares pairwise differences in survival times among the four different cancer stages, while adjusting for age. The ADJUST=SIDAK option uses the Sidak method to control the overall Type I error rate of these comparisons. Results are displayed in [Output 51.8.1](#).

**Output 51.8.1** LS-Means Differences between Disease Stages

| The LIFEREG Procedure                      |        |          |                |         |         |        |
|--------------------------------------------|--------|----------|----------------|---------|---------|--------|
| Differences of Stage Least Squares Means   |        |          |                |         |         |        |
| Adjustment for Multiple Comparisons: Sidak |        |          |                |         |         |        |
| Stage                                      | _Stage | Estimate | Standard Error | z Value | Pr >  z | Adj P  |
| 4                                          | 3      | -0.9604  | 0.4379         | -2.19   | 0.0283  | 0.1581 |
| 4                                          | 2      | -1.6404  | 0.4931         | -3.33   | 0.0009  | 0.0053 |
| 4                                          | 1      | -1.7661  | 0.4257         | -4.15   | <.0001  | 0.0002 |
| 3                                          | 2      | -0.6800  | 0.4316         | -1.58   | 0.1151  | 0.5199 |
| 3                                          | 1      | -0.8057  | 0.3539         | -2.28   | 0.0228  | 0.1292 |
| 2                                          | 1      | -0.1257  | 0.4152         | -0.30   | 0.7621  | 0.9998 |

All the LS-means differences and their significance are displayed by the mean-mean scatter plot in [Output 51.8.2](#).

**Output 51.8.2** Plot of Pairwise LS-Means Differences

Suppose you want to jointly test whether the effects of stages 2, 3, and 4 are different from stage 1. The following LSMESTIMATE statement contrasts the LS-means of stages 2, 3, and 4 against the LS-means of stage 1:

```
proc lifereg data=Larynx order=data;
 class Stage year;
 model Time*Death(0) = Age Stage / dist = llogistic;
 lsmestimate Stage 'Stage 4 vs 1' 1 0 0 -1,
 'Stage 3 vs 1' 0 1 0 -1,
 'Stage 2 vs 1' 0 0 1 -1 / cl adjust=Sidak;
run;
```

The CL option produces 95% confidence limits, including both unadjusted ones and those adjusted for multiple comparisons according to the ADJUST= option. Results are displayed in [Output 51.8.3](#).

**Output 51.8.3** Custom LS-Means Tests and Relative Odds

As displayed in [Output 51.8.4](#), the EFFECTPLOT statement generates a plot of age effects on survival time on a natural logarithm scale by four disease stages.

Output 51.8.4 Age Effects by Disease Stages

You can also perform the preceding analysis for a Bayesian model. The following statements generate posterior samples from a Bayesian model and request an LS-means analysis to compare the stage effects:

```
proc lifereg data=Larynx order=data;
 class Stage;
 model Time*Death(0) = Age Stage / dist = llogistic;
 bayes seed=100 nmc=500 nbi=500 diagnostic=none outpost=000;
 lsmeans Stage / diff exp;
 lsmestimate Stage 'Stage 4 vs 1' 1 0 0 -1,
 'Stage 3 vs 1' 0 1 0 -1,
 'Stage 2 vs 1' 0 0 1 -1
 / cl plots=boxplot(orient=horizontal);
run;
```

Because no prior distributions for the regression coefficients were specified, the default uniform improper distributions shown in the “Uniform Prior for Regression Coefficients” table in [Output 51.8.5](#) are used. The specified gamma prior for the scale parameter is also shown in [Output 51.8.5](#).

**Output 51.8.5** Model Parameter Priors

Under the Bayesian framework, the LS-means differences are treated as random variables for which posterior samples are readily available according to the linear relationship of LS-means and the regression coefficients. [Output 51.8.6](#) lists the sample mean, standard deviation, and percentiles for each LS-means difference.

**Output 51.8.6** LS-Means Differences between Disease Stages

## Overview: LIFETEST Procedure

A common feature of lifetime or survival data is the presence of right-censored observations due either to withdrawal of experimental units or to termination of the experiment. For such observations, you know only that the lifetime exceeded a given value; the exact lifetime remains unknown. Such data cannot be analyzed by ignoring the censored observations because, among other considerations, the longer-lived units are generally more likely to be censored. The analysis methodology must correctly use the censored observations in addition to the uncensored observations.

Texts that discuss the survival analysis methodology include Collett (1994), Cox and Oakes (1984); Kalbfleisch and Prentice (1980); Klein and Moeschberger (1997); Lawless (1982); Lee (1992). Users interested in the theory should consult Fleming and Harrington (1991); Andersen et al. (1992).

Usually, a first step in the analysis of survival data is the estimation of the distribution of the survival times. Survival times are often called *failure* times, and *event* times are uncensored survival times. The survival distribution function (SDF), also known as the survivor function, is used to describe the lifetimes of the population of interest. The SDF evaluated at  $t$  is the probability that an experimental unit from the population will have a lifetime that exceeds  $t$ —that is,

$$S(t) = \Pr(T > t)$$

where  $S(t)$  denotes the survivor function and  $T$  is the lifetime of a randomly selected experimental unit. The LIFETEST procedure can be used to compute nonparametric estimates of the survivor function either by the product-limit method (also called the Kaplan-Meier method) or by the life-table method (also called the actuarial method). The life-table estimator is a grouped-data analog of the Kaplan-Meier estimator. The procedure can also compute the Breslow estimator or the Fleming-Harrington estimator, which are asymptotic equivalent alternatives to the Kaplan-Meier estimator.

Some functions closely related to the SDF are the cumulative distribution function (CDF), the probability density function (PDF), and the hazard function. The CDF, denoted  $F(t)$ , is defined as  $1 - S(t)$  and is the probability that a lifetime does not exceed  $t$ . The PDF, denoted  $f(t)$ , is defined as the derivative of  $F(t)$ , and the hazard function, denoted  $h(t)$ , is defined as  $f(t)/S(t)$ . If the life-table method is chosen, the estimates of the probability density function can also be computed. Plots of these estimates can be produced by a graphical or line printer device, or based on the output delivery system (ODS).

An important task in the analysis of survival data is the comparison of survival curves. It is of interest to determine whether the underlying populations of  $k$  ( $k \geq 2$ ) samples have identical survivor functions. PROC LIFETEST provides nonparametric  $k$ -sample tests based on weighted comparisons of the estimated hazard rate of the individual population under the null and alternative hypotheses. Corresponding to various weight functions, a variety of tests can be specified, which include the log-rank test, Wilcoxon test, Tarone-Ware test, Peto-Peto test, modified Peto-Peto test, and Fleming-Harrington  $G_\rho$  family of tests. PROC LIFETEST also provides corresponding trend tests to detect ordered alternatives. Stratified tests can be specified to adjust for prognostic factors that affect the events rates in the various populations. A likelihood ratio test, based on an underlying exponential model, is also included to compare the survival curves of the samples.

There are other prognostic variables, called covariates, that are thought to be related to the failure time. These covariates can also be used to construct statistics to test for association between the covariates and the lifetime variable. PROC LIFETEST can compute two such test statistics: censored data linear rank statistics based on the exponential scores and the Wilcoxon scores. The corresponding tests are known as the log-rank test and the Wilcoxon test, respectively. These tests are computed by pooling over any defined strata, thus adjusting for the stratum variables.

One change in SAS 9.2 and later is that the calculation of confidence limits for the quartiles of survival time is based on the transformation specified by the `CONFTYPE=` option. Another change is that the SURVIVAL statement in SAS 9.1 is folded into the PROC LIFETEST statement; that is, options that were in the SURVIVAL statement can now be specified in the PROC LIFETEST statement. The SURVIVAL statement is no longer needed and it is not documented.

---

## Getting Started: LIFETEST Procedure

You can use the LIFETEST procedure to compute nonparametric estimates of the survivor functions, to compare survival curves, and to compute rank tests for association of the failure time variable with covariates.

For simple analyses, only the PROC LIFETEST and TIME statements are required. Consider a sample of survival data. Suppose that the time variable is T and the censoring variable is C with value 1 indicating censored observations. The following statements compute the product-limit estimate for the sample:

```
proc lifetest;
 time t*c(1);
run;
```

You can use the STRATA statement to divide the data into various strata. A separate survivor function is then estimated for each stratum, and tests of the homogeneity of strata are performed. However, if the GROUP= option is also specified in the STRATA statement, the GROUP= variable is used to identify the samples whose survivor functions are to be compared, and the STRATA variables are used to define the strata for the stratified tests. You can specify covariates (prognostic variables) in the TEST statement, and PROC LIFETEST computes linear rank statistics to test the effects of these covariates on survival.

For example, consider the results of a small randomized trial on rats. Suppose you randomize 40 rats that have been exposed to a carcinogen into two treatment groups (Drug X and Placebo). The event of interest is death from cancer induced by the carcinogen. The response is the time from randomization to death. Four rats died of other causes; their survival times are regarded as censored observations. Interest lies in whether the survival distributions differ between the two treatments.

The following DATA step creates the data set Exposed, which contains four variables: Days (survival time in days from treatment to death), Status (censoring indicator variable: 0 if censored and 1 if not censored), Treatment (treatment indicator), and Sex (gender: F if female and M if male).

```

proc format;
 value Rx 1='Drug X' 0='Placebo';
run;
data exposed;
 input Days Status Treatment Sex $ @@;
 format Treatment Rx.;
 datalines;
179 1 1 F 378 0 1 M
256 1 1 F 355 1 1 M
262 1 1 M 319 1 1 M
256 1 1 F 256 1 1 M
255 1 1 M 171 1 1 F
224 0 1 F 325 1 1 M
225 1 1 F 325 1 1 M
287 1 1 M 217 1 1 F
319 1 1 M 255 1 1 F
264 1 1 M 256 1 1 F
237 0 0 F 291 1 0 M
156 1 0 F 323 1 0 M
270 1 0 M 253 1 0 M
257 1 0 M 206 1 0 F
242 1 0 M 206 1 0 F
157 1 0 F 237 1 0 M
249 1 0 M 211 1 0 F
180 1 0 F 229 1 0 F
226 1 0 F 234 1 0 F
268 0 0 M 209 1 0 F
;

```

PROC LIFETEST is invoked as follows to compute the product-limit estimate of the survivor function for each treatment and to compare the survivor functions between the two treatments:

```

ods graphics on;
proc lifetest data=Exposed plots=(survival(atrisk) logsurv);
 time Days*Status(0);
 strata Treatment;
run;
ods graphics off;

```

In the TIME statement, the survival time variable, Days, is crossed with the censoring variable, Status, with the value 0 indicating censoring. That is, the values of Days are considered censored if the corresponding values of Status are 0; otherwise, they are considered as event times. In the STRATA statement, the variable Treatment is specified, which indicates that the data are to be divided into strata based on the values of Treatment. ODS Graphics must be enabled before producing graphs. Two plots are requested through the PLOTS= option—a plot of the survival curves with at risk numbers and a plot of the negative log of the survival curves.

The results of the analysis are displayed in the following figures.

Figure 52.1 displays the product-limit survival estimate for the Drug X group (Treatment=1). The figure lists, for each observed time, the survival estimate, failure rate, standard error of the estimate, cumulative number of failures, and number of subjects remaining in the study.

**Figure 52.1** Survivor Function Estimate for the Drug X-Treated Rats

| 378.000*                         | 0.0531   | .       | .                             | 18               | 0              |

NOTE: The marked survival times are censored observations.

Figure 52.2 displays summary statistics of survival times for the Drug X group. It contains estimates of the 25th, 50th, and 75th percentiles and the corresponding 95% confidence limits. The median survival time for rats in this treatment is 256 days. The mean and standard error are also displayed; however, these values are underestimated because the largest observed time is censored and the estimation is restricted to the largest event time.

**Figure 52.2** Summary Statistics of Survival Times for Drug X-Treated Rats

| Quartile Estimates |                   |                         |         |         |

| Total                                                   |           | 40    | 36     | 4        | 10.00            |

[Figure 52.6](#) displays the graph of the product-limit survivor function estimates versus survival time. The two treatments differ primarily at larger survival times. Note the number of subjects at risk in the plot. You can display the number of subjects at risk at specific time points by using the `ATRISK=` option.

**Figure 52.6** Plot of Estimated Survivor Functions

Figure 52.7 displays the graph of the log survivor function estimates versus survival time. Neither curve approximates a straight line through the origin—the exponential model is not appropriate for the survival data.

Note that these graphical displays are generated through ODS. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

**Figure 52.7** Plot of Estimated Negative Log Survivor Functions

Results of the comparison of survival curves between the two treatments are shown in Figure 52.8. The rank tests for homogeneity indicate a significant difference between the treatments ( $p = 0.0175$  for the log-rank test and  $p = 0.0249$  for the Wilcoxon test). Rats treated with Drug X live significantly longer than those treated with Placebo. Since the survival curves for the two treatments differ primarily at longer survival times, the Wilcoxon test, which places more weight on shorter survival times, becomes less significant than the log-rank test. As noted earlier, the exponential model is not appropriate for the given survival data; consequently, the result of the likelihood ratio test should be ignored.

**Figure 52.8** Results of the Two-Sample Tests

| Test of Equality over Strata |            |    |                 |
|------------------------------|------------|----|-----------------|
| Test                         | Chi-Square | DF | Pr > Chi-Square |
| Log-Rank                     | 5.6485     | 1  | 0.0175          |
| Wilcoxon                     | 5.0312     | 1  | 0.0249          |
| -2Log(LR)                    | 0.1983     | 1  | 0.6561          |

Next, suppose male rats and female rats are thought to have different survival rates, and you want to assess the treatment effect while adjusting for the gender differences. By specifying the variable `Sex` in the `STRATA` statement as a stratifying variable and by specifying the variable `Treatment` in the `GROUP=` option, you can carry out a stratified test to test `Treatment` while adjusting for `Sex`. The test statistics are computed by pooling over the strata defined by the values of `Sex`, thus controlling for the effect of `Sex`. The `NOTABLE` option is added to the `PROC LIFETEST` statement as follows to avoid estimating a survival curve for each gender:

```
proc lifetest data=Exposed notable;
 time Days*Status(0);
 strata Sex / group=Treatment;
run;
```

Results of the stratified tests are shown in [Figure 52.9](#). The treatment effect is statistically significant for both the log-rank test ( $p = 0.0071$ ) and the Wilcoxon test ( $p = 0.0150$ ). As compared to the results of the unstratified tests in [Figure 52.8](#), the significance of the treatment effect has been sharpened by controlling for the effect of the gender of the subjects.

**Figure 52.9** Results of the Stratified Two-Sample Tests

| The LIFETEST Procedure                 |            |    |                    |
|----------------------------------------|------------|----|--------------------|
| Stratified Test of Equality over Group |            |    |                    |
| Test                                   | Chi-Square | DF | Pr ><br>Chi-Square |
| Log-Rank                               | 7.2466     | 1  | 0.0071             |
| Wilcoxon                               | 5.9179     | 1  | 0.0150             |

Since `Treatment` is a binary variable, another way to study the effect of `Treatment` is to carry out a censored linear rank test with `Treatment` as an independent variable. This test is less popular than the two-sample test; nevertheless, in situations where the independent variables are continuous and are difficult to discretize, it might be infeasible to perform a  $k$ -sample test. To compute the censored linear rank statistics to test the `Treatment` effect, `Treatment` is specified in the `TEST` statement as follows:

```
proc lifetest data=Exposed notable;
 time Days*Status(0);
 test Treatment;
run;
```

Results of the linear rank tests are shown [Figure 52.10](#). The  $p$ -values are very similar to those of the two-sample tests in [Figure 52.8](#).

**Figure 52.10** Results of Linear Rank Tests of Treatment

| The LIFETEST Procedure                       |                   |                   |            |                    |
|----------------------------------------------|-------------------|-------------------|------------|--------------------|
| Univariate Chi-Squares for the Wilcoxon Test |                   |                   |            |                    |
| Variable                                     | Test<br>Statistic | Standard<br>Error | Chi-Square | Pr ><br>Chi-Square |
| Treatment                                    | 3.9525            | 1.7524            | 5.0875     | 0.0241             |
| Univariate Chi-Squares for the Log-Rank Test |                   |                   |            |                    |
| Variable                                     | Test<br>Statistic | Standard<br>Error | Chi-Square | Pr ><br>Chi-Square |
| Treatment                                    | 6.2708            | 2.6793            | 5.4779     | 0.0193             |

With Sex as a prognostic factor that you want to control, you can compute a stratified linear rank statistic to test the effect of Treatment by specifying Sex in the STRATA statement and Treatment in the TEST statement as in the following program. The TEST=NONE option is specified in the STRATA statement to suppress the two-sample tests for Sex.

```
proc lifetest data=Exposed notable;
 time Days*Status(0);
 strata Sex / test=none;
 test Treatment;
run;
```

Results of the stratified linear rank tests are shown in Figure 52.11. The  $p$ -values are very similar to those of the stratified tests in Figure 52.9.

---

## Syntax: LIFETEST Procedure

The following statements are available in the LIFETEST procedure:

```

PROC LIFETEST < options > ;
 BY variables ;
 FREQ variable ;
 ID variables ;
 STRATA variable < (list) > < . . . variable < (list) > > < / options > ;
 TEST variables ;
 TIME variable < * censor(list) > ;
 WEIGHT variable ;

```

The simplest use of PROC LIFETEST is to request the nonparametric estimates of the survivor function for a sample of survival times. In such a case, only the PROC LIFETEST statement and the TIME statement are required. You can use the STRATA statement to divide the data into various strata. A separate survivor function is then estimated for each stratum, and tests of the homogeneity of strata are performed. However, if the GROUP= option is also specified in the STRATA statement, stratified tests are carried out to test the  $k$  samples defined by the GROUP= variable while controlling for the effect of the STRATA variables. You can specify covariates in the TEST statement. PROC LIFETEST computes linear rank statistics to test the effects of these covariates on survival.

The PROC LIFETEST statement invokes the procedure. All statements except the TIME statement are optional, and there is no required order for the statements that follow the PROC LIFETEST statement. The TIME statement is used to specify the variables that define the survival time and censoring indicator. The STRATA statement specifies a variable or set of variables that define the strata for the analysis. The TEST statement specifies a list of numeric covariates to be tested for their association with the response survival time. Each variable is tested individually, and a joint test statistic is also computed. The ID statement provides a list of variables whose values are used to identify observations in the product-limit, Breslow, or Fleming-Harrington estimates. When only the TIME statement appears, no strata are defined and no tests of homogeneity are performed.

---

## PROC LIFETEST Statement

```

PROC LIFETEST < options > ;

```

The PROC LIFETEST statement invokes the LIFETEST procedure. Optionally, this statement identifies an input and an OUTSURV= data set, and specifies the computation details of the survivor function estimation. Table 52.1 summarizes the options available in the PROC LIFETEST statement. These options are described in alphabetic order. If no options are requested, PROC LIFETEST computes and displays the product-limit estimate of the survivor function; and if ODS Graphics is enabled, a plot of the estimated survivor function is also displayed.

**Table 52.1** Options Available in the PROC LIFETEST Statement

| Option                                    | Description                                                                                               |
|-------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <b>Input and Output Data Sets</b>         |                                                                                                           |
| DATA=                                     | Specifies the input SAS data set                                                                          |
| OUTSURV=                                  | Names an output data set to contain survival estimates and confidence limits                              |
| OUTTEST=                                  | Names an output data set to contain rank test statistics for association of survival time with covariates |
| <b>Nonparametric Estimation</b>           |                                                                                                           |
| INTERVALS=                                | Specifies interval endpoints for life-table estimates                                                     |
| NELSON                                    | Adds the Nelson-Aalen estimates                                                                           |
| METHOD=                                   | Specifies the method to compute survivor function                                                         |
| NINTERVAL=                                | Specifies the number of intervals for life-table estimates                                                |
| WIDTH=                                    | Specifies the width of intervals for life-table estimates                                                 |
| <b>Confidence Limits for Survivorship</b> |                                                                                                           |
| ALPHA=                                    | Sets the confidence level for interval estimation estimates                                               |
| BANDMAXTIME=                              | Specifies the maximum time for confidence band                                                            |
| BANDMINTIME=                              | Specifies the minimum time for confidence band                                                            |
| CONFBAND=                                 | Specifies the type of confidence band in the OUTSURV= data set                                            |
| CONFTYPE=                                 | Specifies the transformation applied to the survivor function to obtain confidence limits                 |
| <b>Line Printer Plots</b>                 |                                                                                                           |
| FORMCHAR(1,2,7,9)=                        | Defines the characters used for line printer plot axes                                                    |
| LINEPRINTER                               | Specifies that plots be produced by a line printer                                                        |
| MAXTIME=                                  | Specifies the maximum time value for plotting                                                             |
| NOCENSLOT                                 | Suppresses the plot of censored observations                                                              |
| PLOTS=                                    | Specifies the plots to display                                                                            |
| <b>ODS Graphics</b>                       |                                                                                                           |
| MAXTIME=                                  | Specifies the maximum time value for plotting                                                             |
| PLOTS=                                    | Specifies plots to display                                                                                |
| <b>Traditional Graphics</b>               |                                                                                                           |
| ANNOTATE=                                 | Specifies an Annotate data set that adds features to plots                                                |
| CENSORED SYMBOL=                          | Defines the symbol used for censored observations in plots                                                |
| DESCRIPTION=                              | Specifies the string that appears in the description field of the PROC GREPLAY master menu for the plots  |
| EVENTSYMBOL=                              | Specifies the symbol used for event observations in plots                                                 |
| GOUT=                                     | Specifies the graphics catalog name for saving graphics output                                            |
| LANNOTATE=                                | Specifies an input data set that contains variables for local annotation                                  |
| MAXTIME=                                  | Specifies the maximum time value for plotting                                                             |
| PLOTS=                                    | Specifies the plots to display                                                                            |
| <b>Control Output</b>                     |                                                                                                           |
| ATRISK                                    | Adds the number of subjects at risk to the survival estimate table                                        |

Table 52.1 *continued*

| Option               | Description                                                                                |
|----------------------|--------------------------------------------------------------------------------------------|
| NOPRINT              | Suppresses the display of printed output                                                   |
| NOTABLE              | Suppresses the display of survival function estimates                                      |
| INTERVALS=           | Displays only the estimate for the smallest time in each interval                          |
| NOLEFT               | Suppresses the Number Left column in the survival estimate table                           |
| TIMELIST=            | Specifies a list of time points to display the survival estimate                           |
| REDUCEOUT            | Specifies that only INTERVAL= or TIMELIST= observations be listed in the OUTSURV= data set |
| <b>Miscellaneous</b> |                                                                                            |
| ALPHAQT=             | Sets the confidence level for survival time quartiles                                      |
| MISSING              | Allows missing values to be a stratum level                                                |
| SINGULAR=            | Sets the tolerance for testing singularity of covariance matrix of rank statistics         |
| STDERR               | Outputs the standard error for the survival estimators to the OUTSURV= data set            |
| TIMELIM=             | Specifies the time limit used to estimate the mean survival time and its standard error    |

The PLOTS= option in the PROC LIFETEST statement specifies the plots to display. You can select one of the following three types of graphics in PROC LIFETEST: line printer, traditional, and ODS. If you specify the LINEPRINTER option, line printer plots are produced; otherwise traditional graphics are produced if ODS Graphics is not enabled, or ODS Graphics plots are produced if the ODS Graphics is enabled.

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

Table 52.2 shows whether graphics are produced, and the type of graphics, for all possible combinations:

Table 52.2 Ways of Displaying Graphics

| ODS Graphics | PLOTS= Option | LINEPRINTER Option | Graphics Results           |
|--------------|---------------|--------------------|----------------------------|
| Disabled     | No            | No                 | No graphics                |
| Disabled     | No            | Yes                | No graphics                |
| Disabled     | Yes           | No                 | Traditional graphics       |
| Disabled     | Yes           | Yes                | Line printer plot          |
| Enabled      | No            | No                 | ODS Graphics survival plot |
| Enabled      | No            | Yes                | No graphics                |
| Enabled      | Yes           | No                 | ODS Graphics               |
| Enabled      | Yes           | Yes                | Line printer plot          |

ODS Graphics is the preferred method of creating graphs. Many new features have been added to the ODS Graphics plots in PROC LIFETEST. For example, you can display the number of subjects at risk in a survival plot through ODS Graphics, but such a feature is not available in traditional graphics or line printer plots. The PLOTS= option syntax is documented separately for each type of graphics and is preceded by a heading that indicates the graphics type.

**ALPHA= $\alpha$** 

specifies the level of significance  $\alpha$  for the  $100(1 - \alpha)\%$  confidence intervals for the survivor, hazard, and density functions. For example, the option ALPHA=0.05 requests the 95% confidence limits for the survivor function. The default value is 0.05.

**ALPHAQT= $\alpha$** 

specifies the significance level  $\alpha$  for the  $100(1 - \alpha)\%$  confidence intervals for the quartiles of the survival time. For example, the option ALPHAQT=0.05 requests a 95% confidence interval for the quartiles of the survival time. The default value is 0.05.

**ANNOTATE=SAS-data-set****ANNO=SAS-data-set**

specifies an input data set that contains appropriate variables for annotation of the traditional graphics. The ANNOTATE= option enables you to add features (for example, labels that explain extreme observations) to plots produced on graphics devices. The ANNOTATE= option cannot be used if the [LINEPRINTER](#) option is specified or if ODS Graphics is enabled. The data set specified must be an ANNOTATE= type data set, as described in *SAS/GRAPH: Reference*.

The data set specified with the ANNOTATE= option in the PROC LIFETEST statement is “global” in the sense that the information in this data set is displayed in every plot produced by a single invocation of PROC LIFETEST.

**ATRISK**

adds a column that represents the number of subjects at risk to the survival estimate table. Also added is a column that represents the number of events at each observed time. This option has no effect for the life-table method.

**BANDMAXTIME=value****BANDMAX=value**

specifies the maximum time for the confidence bands. The default is the largest observed event time. If the specified BANDMAX= time exceeds the largest observed event time, it is truncated to the largest observed event time.

**BANDMINTIME=value****BANDMIN=value**

specifies the minimum time for the confidence bands. The default is the smallest observed event time. For the equal-precision band, if the BANDMIN= value is less than the smallest observed event time, it is defaulted to the smallest observed event time.

**CENSORED SYMBOL=name | 'string'****CS=name | 'string'**

specifies the symbol value for the censored observations in traditional graphics. The value, *name* or *'string'*, is the symbol value specification allowed in SAS/GRAPH software. The default is CS=CIRCLE. If you want to omit plotting the censored observations, specify CS=NONE. The CENSORED SYMBOL= option cannot be used if the [LINEPRINTER](#) option is specified or if ODS Graphics is enabled.

**CONF BAND=keyword**

specifies the confidence bands to be output to the OUTSURV= data set. Confidence bands are available for METHOD=KM, METHOD=BRESLOW, or METHOD=FH. You can use the following *keywords*:

|     |                                                                         |
|-----|-------------------------------------------------------------------------|
| ALL | outputs both the Hall-Wellner and the equal-precision confidence bands. |
| EP  | outputs the equal-precision confidence bands.                           |
| HW  | outputs the Hall-Wellner confidence bands.                              |

**CONFTYPE=keyword**

specifies the transformation applied to  $S(t)$  to obtain the pointwise confidence intervals and the confidence bands for the survivor function in addition to the confidence intervals for the quartiles of the survival times. The following *keywords* can be used; the default is CONFTYPE=LOGLOG.

ASINSQRT      the arcsine-square root transformation,

$$g(x) = \sin^{-1}(\sqrt{x})$$

LOGLOG      the log-log transformation,

$$g(x) = \log(-\log(x))$$

This is also referred to as the log cumulative hazard transformation since it applies the logarithmic function to the cumulative hazard function. Collett (1994) and Lachin (2000) refer to it as the complementary log-log transformation.

LINEAR      the identity transformation,

$$g(x) = x$$

LOG      the logarithmic transformation,

$$g(x) = \log(x)$$

LOGIT      the logit transformation,

$$g(x) = \log\left(\frac{x}{1-x}\right)$$

**DATA=SAS-data-set**

names the SAS data set used by PROC LIFETEST. By default, the most recently created SAS data set is used.

**DESCRIPTION='string'****DES='string'**

specifies a descriptive string of up to 256 characters that appears in the “Description” field of the traditional graphics catalog. The description does not appear in the plots. By default, PROC LIFETEST assigns a description of the form PLOT OF *vname* versus *hname*, where *vname* and *hname* are the names of the y variable and the x variable, respectively. The DESCRIPTION= option cannot be used if the **LINEPRINTER** option is specified or if ODS Graphics is enabled.

**EVENTSYMBOL**=*name* | '*string*'

**ES**=*name* | '*string*'

specifies the symbol value for the event observations in traditional graphics. The value, *name* or '*string*', is the symbol value specification allowed in SAS/GRAPH software. The default is ES=NONE. The EVENTSYMBOL= option cannot be used if the [LINEPRINTER](#) option is specified or if ODS Graphics is enabled.

**FORMCHAR(1,2,7,9)**= '*string*'

defines the characters used for constructing the vertical and horizontal axes of the line printer plots. The string should be four characters. The first and second characters define the vertical and horizontal bars, respectively, which are also used in drawing the steps of the Kaplan-Meier, Breslow, or Fleming-Harrington survival curve. The third character defines the tick mark for the axes, and the fourth character defines the lower left corner of the plot. The default is FORMCHAR(1,2,7,9)='|+-'. Any character or hexadecimal string can be used to customize the plot appearance. If you use hexadecimal, you must put an x after the closing quote. For example, to send the plot output to a printer with the IBM graphics character set (1 or 2), specify the following:

```
formchar (1, 2, 7, 9) = 'B3C4C5C0' x
```

See the chapter titled “The PLOT Procedure” in the *Base SAS Procedures Guide* for further information.

**GOUT**=*graphics-catalog*

specifies the graphics catalog for saving traditional graphics output from PROC LIFETEST. The default is Work.Gseg. The GOUT= option cannot be used if the [LINEPRINTER](#) option is specified or if ODS Graphics is enabled. For more information, see the chapter titled “The GREPLAY Procedure” in *SAS/GRAPH: Reference*.

**INTERVALS**=*values*

specifies a list of interval endpoints for the life-table method. These endpoints must all be nonnegative numbers. The initial interval is assumed to start at zero whether or not zero is specified in the list. Each interval contains its lower endpoint but does not contain its upper endpoint. When this option is used with METHOD=KM, METHOD=BRESLOW, or METHOD=FH, it reduces the number of survival estimates displayed by showing only the estimates for the smallest time within each specified interval. The INTERVALS= option can be specified in any of the following ways:

- A list separated by blanks      **INTERVALS=1 3 5 7**
- A list separated by commas      **INTERVALS=1, 3, 5, 7**
- *x* to *y*      **INTERVALS=1 to 7**
- *x* to *y* BY *z*      **INTERVALS=1 to 7 by 1**
- A combination of the above      **INTERVALS=1, 3 to 5, 7**

For example, the specification

```
intervals=5,10 to 30 by 10
```

produces the set of intervals

```
{[0, 5), [5, 10), [10, 20), [20, 30), [30, ∞)}
```

**LANNOTATE=SAS-data-set**

**LANN=SAS-data-set**

specifies an input data set that contains variables for local annotation of traditional graphics. You can use the LANNOTATE= option to specify a different annotation for each BY group, in which case the BY variables must be included in the LANNOTATE= data set. The LANNOTATE= option cannot be used if the **LINEPRINTER** option is specified or if ODS Graphics is enabled. The data set specified must be an **ANNOTATE=** type data set, as described in *SAS/GRAPH: Reference*.

If there is no BY-group processing, the **ANNOTATE=** and **LANNOTATE=** options have the same effects.

**LINEPRINTER**

**LS**

specifies that plots are produced by a line printer instead of by a graphical device.

**MAXTIME=value**

specifies the maximum value of the time variable allowed on the plots so that outlying points do not determine the scale of the time axis of the plots. This option affects only the displayed plots and has no effect on any calculations.

**METHOD=type**

specifies the method to be used to compute the survival function estimates. Valid values for *type* are as follows:

**BRESLOW**

specifies that the Breslow estimates be computed. The Breslow estimator is the exponentiation of the negative Nelson-Aalen estimator of the cumulative hazard function.

**FH**

specifies that the Fleming-Harrington (FH) estimates be computed. The FH estimator is a tie-breaking modification of the Breslow estimator. If there are no tied event times, this estimator is the same as the Breslow estimator.

**KM**

**PL**

specifies that Kaplan-Meier estimates (also known as the product-limit estimates) be computed.

**ACT**

**LIFE**

**LT**

specifies that life-table estimates (also known as actuarial estimates) be computed.

By default, **METHOD=KM**.

**MISSING**

allows missing values for numeric variables and blank values for character variables as valid stratum levels. See the section “**Missing Values**” on page 4031 for details.

By default, PROC LIFETEST does not use observations with missing values for any stratum variables.

**NELSON****AALEN**

produces the Nelson-Aalen estimates of the cumulative hazards and the corresponding standard errors. This option is ignored if METHOD=LT is specified.

**NINTERVAL=***value*

specifies the number of intervals used to compute the life-table estimates of the survivor function. This parameter is overridden by the WIDTH= option or the INTERVALS= option. When you specify the NINTERVAL= option, PROC LIFETEST tries to find an interval that results in round numbers for the endpoints. Consequently, the number of intervals can be different from the number requested. Use the INTERVALS= option to control the interval endpoints. The default is NINTERVAL=10.

**NOCENS PLOT****NOCENS**

requests that the plot of censored observations be suppressed when the LINEPRINTER and PLOTS= options are specified. This option is not needed when the life-table method is used to compute the survival estimates, because the plot of censored observations is not produced.

**NOLEFT**

suppresses the Number Left and Number Event columns in the survival estimate table. This option has no effect for the life-table estimate.

**NOPRINT**

suppresses the display of output. This option is useful when only an output data set is needed. It temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System” for more information.

**NOTABLE**

suppresses the display of survival function estimates. Only the number of censored and event times, plots, and test results is displayed.

**OUTSURV=***SAS-data-set***OUTS=***SAS-data-set*

creates an output SAS data set to contain the estimates of the survival function and corresponding confidence limits for all strata. See the section “OUTSURV= Data Set” on page 4049 for more information about the contents of the OUTSURV= data set.

**OUTTEST=***SAS-data-set***OUTT=***SAS-data-set*

creates an output SAS data set to contain the overall chi-square test statistic for association with failure time for the variables in the TEST statement, the values of the univariate rank test statistics for each variable in the TEST statement, and the estimated covariance matrix of the univariate rank test statistics. See the section “OUTTEST= Data Set” on page 4051 for more information about the contents of the OUTTEST= data set.

**Line Printer PLOTS= Option****PLOTS=***plot-request***PLOTS=**(*plot-requests*)

controls the line printer plots produced. You must also specify the **LINEPRINTER** option to obtain line printer plots. When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. Here are some examples:

```
plots=s
plots=(s ls lls)
```

The *plot-requests* include the following:

**CENSORED****C**

specifies a plot of censored observations. This option is available for **METHOD=KM**, **METHOD=BRESLOW**, or **METHOD=FH** only.

**SURVIVAL****S**

specifies a plot of the estimated SDF versus time.

**LOGSURV****LS**

specifies a plot of the negative log of the estimated SDF versus time.

**LOGLOGS****LLS**

specifies a plot of the log of the negative log of the estimated SDF versus the log of time.

**HAZARD****H**

specifies a plot of the estimated hazard function versus time (life-table method only).

**PDF****P**

specifies a plot of the estimated probability density function versus time (life-table method only).

**ODS Graphics PLOTS= Option****PLOTS**< (*global-plot-option*) > = *plot-request* < (*options*) >**PLOTS**< (*global-plot-option*) > = (*plot-request* < (*options*) > < ... *plot-request* < (*options*) > >

controls the plots produced using ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. Here are some examples:

```
plots=none
plots=(survival(atrisk=100 to 350 by 50) logsurv)
plots(only)=hazard
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc lifetest plots=survival(atrisk);
 time T*Status(0);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC LIFETEST produces a plot of the estimated survivor functions by default.

The only *global-plot-option* follows:

#### ONLY

specifies that only the specified plots in the list be produced; otherwise, the default survivor function plot is also displayed.

The *plot-requests* and *plot-request options* include the following.

#### ALL

produces all appropriate plots. For METHOD=KM, METHOD=BRESLOW, or METHOD=FH, specifying PLOTS=ALL is equivalent to specifying PLOTS=(SURVIVAL LOGSURV LOGLOGLS HAZARD); for the life-table method, PLOTS=ALL is equivalent to specifying PLOTS=(SURVIVAL LOGSURV LOGLOGS DENSITY HAZARD).

#### HAZARD <(hazard-options)>

##### H <hazard-options>

plots the estimated hazard functions. Kernel-smoothed estimates are produced for METHOD=KM, METHOD=BRESLOW, or METHOD=FH. You can specify the following *hazard-options*, but only the CL option can be used for the life-table method:

##### BANDWIDTH=*bandwidth-option*

##### BW=*bandwidth-option*

specifies what bandwidth is chosen for the kernel-smoothing and how it is chosen. You can specify one of the following *bandwidth-options*.

##### *value*

sets the bandwidth to the given *value*.

##### *numeric-list*

selects the bandwidth from the given *numeric-list* that minimizes the mean integrated squared error.

##### RANGE(*lower,upper*)

selects the bandwidth from the interval (*lower, upper*) that minimizes the mean integrated squared error. PROC LIFETEST uses the golden section search algorithm to find the minimum. If there is more than one local minimum in the interval, there is no guarantee that the local minimum found is also the global minimum.

See the section “Optimal Bandwidth” on page 4042 for details about the mean integrated squared error. If the BANDWIDTH= option is not specified, the default is BANDWIDTH=RANGE(0.2b,20b), where  $b = \frac{g_u - g_l}{8n^{.2}}$ ,  $g_l$  and  $g_u$  are the values of the GRIDL= and GRIDU= options, respectively, and  $n$  is the total number of noncensored observations.

**GRIDL=number**

specifies the lower grid limit for the kernel-smoothed estimate. The default value is the time origin.

**GRIDU=number**

specifies the upper grid limit for the kernel-smoothed estimate. The default value equals the maximum event time.

**KERNEL=kernel-option**

specifies the kernel used. The choices are as follows:

**BIWEIGHT****BW**

$$K_{BW}(x) = \frac{15}{16}(1 - x^2)^2, \quad -1 \leq x \leq 1$$

**EPANECHNIKOV****E**

$$K_E(x) = \frac{3}{4}(1 - x^2), \quad -1 \leq x \leq 1$$

**UNIFORM****U**

$$K_U(x) = \frac{1}{2}, \quad -1 \leq x \leq 1$$

The default is KERNEL=EPANECHNIKOV.

**NMINGRID=number**

specifies the number of grid points in determining the mean integrated square error (MISE). The default value is 51.

**NGRID=number**

specifies the number of grid points. The default is 101.

**CL**

displays the pointwise confidence limits for the smoothed hazard.

**LOGLOGS****LLS**

plots the log of negative log of estimated survivor functions versus the log of time.

**LOGSURV****LS**

plots the negative log of estimated survivor functions versus time.

**NONE**

suppresses all plots.

**PDF <(CL)>****P <(CL)>**

plots the estimated probability density functions (life-table method only). Pointwise confidence limits are displayed optionally by specifying the CL option.

**SURVIVAL <(survival-options)>****S <(survival-options)>**

plots the estimated survivor functions. Censored times are plotted as a plus sign on the Kaplan-Meier, Breslow, or Fleming-Harrington survival curves unless the NOCENSOR option is specified. You can customize the display by using the following *survival-options*. If these options are not sufficient for your purposes, you can customize the survival plot by modifying its graphical template (see the section “[Modifying the ODS Template for Survival Plots](#)” on page 4061 for more information).

**ATRISK <(options)> <=number-list >**

displays the numbers of subjects at risk at the given times. The following *options* can be specified:

**ATRISKTICK****ATRISKLABEL**

shows the time values at which the numbers of subjects at risk are displayed.

**MAXLEN=*n***

specifies the number of characters *n* that are allowed for displaying the stratum labels. If *n* is greater than or equal to the maximum length of the stratum labels, the stratum labels are used in the at-risk display; otherwise, the stratum numbers are used. The default is MAXLEN=12.

**OUTSIDE<(ρ)>**

specifies that the at-risk table be drawn outside the plot area. PROC LIFETEST uses an ODS graphical template with a two-row lattice layout. The upper cell displays the survival plot, and the bottom cell displays the at-risk table. You can specify an optional number *ρ* that represents the fractional proportion of the at-risk table height relative to the overall grid height. By default, *ρ* is set to 0.035 times the number of strata, with a maximum value of 0.5.

The *number-list* identifies the times at which the numbers at risk are displayed. If the *number-list* is not specified, PROC LIFETEST uses the default list  $\{0, a, 2a, \dots, n \times a\}$ , where *a* and *n* are computed by the following algorithm. Let *m* be the MAXTIME= value or the largest observed time if the MAXTIME= option is not specified; let *b* =

$10^{\text{ceil}(\log_{10}(m)-1)}$ , where  $\text{ceil}()$  is the ceiling function.

$$a = \begin{cases} \frac{b}{2} & \text{if } m < 0.25b \\ 2b & \text{if } m > 0.75b \\ b & \text{otherwise} \end{cases}$$

$$n = \text{integral value of } m/a$$

**CB** <=*keyword*>

displays the confidence bands (that is, simultaneous confidence intervals) for the survivor functions. You can specify one of the following *keywords*. The default is CB=HW.

**ALL**

displays both the equal-precision and the Hall-Wellner bands.

**EP**

displays the equal-precision band.

**HW**

displays the Hall-Wellner confidence band.

**CL**

displays the pointwise confidence limits for the survivor functions.

**FAILURE**

**F**

changes all the displays for survivor functions to those for the failure functions. For example, if both the FAILURE and CL options are specified, the plot displays the failure curves in addition to the pointwise confidence limits for the failure functions.

**NOCENSOR**

suppresses the plotting of the censored times on a Kaplan-Meier, Breslow, or Fleming-Harrington survival curve.

**STRATA**=*strata-option*

specifies how to display the survival/failure curves for multiple strata. This option has no effect if there is only one stratum. You can choose one of the following *strata options*:

**INDIVIDUAL**

**UNPACK**

specifies that a separate plot be displayed for each stratum.

**OVERLAY**

specifies that the survival/failure curves for the strata be overlaid in one plot.

**PANEL**

specifies that separate plots for the strata be organized into panels of two or four plots, depending on the number of strata.

The default is STRATA=OVERLAY.

**TEST**

displays the  $p$ -value of a homogeneity test specified in the STRATA statement. If more than one test is produced, the test is chosen in the following order: LOGRANK, WILCOXON, TARONE, PETO, MODPETO, FLEMING, and LR.

**Traditional Graphics PLOTS= Option**

**PLOTS=***plot-request* <(NAME=*name* | '*string*')>

**PLOTS=**(*plot-request* <(NAME=*name* | '*string*')> <, ..., *plot-request* <(NAME=*name* | '*string*')> >)

controls plots produced in traditional graphics. To obtain traditional graphics, you must neither enable ODS Graphics nor specify the **LINEPRINTER** option. For each *plot-request*, you can use the NAME= option to specify a name to identify the plot. The name can be specified as a SAS name or as a quoted string of up to 256 characters. Only the first eight characters are used as the entry name in the **GOUT=** catalog. The *plot-requests* include the following:

**SURVIVAL****S**

plots the estimated survivor functions versus time.

**LOGSURV****LS**

plots the negative log of estimated survivor functions versus time.

**LOGLOGS****LLS**

plots the log of negative log of estimated survivor functions versus the log of time.

**HAZARD****H**

plots estimated hazard function versus time (life-table method only).

**PDF****P**

plots the estimated probability density function versus time (life-table method only).

When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. Here are some examples:

```
plots=s
plots=(s(name=Surv2), h(name=Haz2))
```

The latter requests a plot of the estimated survivor function versus time and a plot of the estimated hazard function versus time, with Surv2 and Haz2 as their names in the **GOUT=** catalog, respectively.

**REDUCEOUT**

specifies that the **OUTSURV=** data set contain only those observations that are included in the **INTERVALS=** or **TIMELIST=** option. This option has no effect if the **OUTSURV=** option is not specified. It also has no effect if neither the **INTERVALS=** option nor the **TIMELIST=** option is specified.

**SINGULAR=value**

specifies the tolerance for testing singularity of the covariance matrix for the rank test statistics. The test requires that a pivot for sweeping a covariance matrix be at least this number times a norm of the matrix. The default value is 1E-12.

**STDERR**

specifies that the standard error of the survivor function (SDF\_STDERR) be output to the OUT-SURV= data set. If the life-table method is used, the standard error of the density function (PDF\_STDERR) and the standard error of the hazard function (HAZ\_STDERR) are also output.

**TIMELIM=time-limit**

specifies the time limit used in the estimation of the mean survival time and its standard error. The mean survival time can be shown to be the area under the Kaplan-Meier survival curve. However, if the largest observed time in the data is censored, the area under the survival curve is not a closed area. In such a situation, you can choose a time limit  $L$  and estimate the mean survival curve limited to a time  $L$  (Lee 1992, pp. 72–76). This option is ignored if the largest observed time is an event time. Valid *time-limit* values are as follows:

**EVENT****LET**

specifies that the time limit  $L$  be the largest event time in the data. TIMELIM=EVENT is the default.

**OBSERVED****LOT**

specifies that the time limit  $L$  be the largest observed time in the data.

*number*

specifies that the time limit  $L$  be the given *number*. The *number* must be positive and at least as large as the largest event time in the data.

**TIMELIST=number-list**

specifies a list of time points at which the Kaplan-Meier estimates are displayed. The time points are listed in the column labeled Timelist. Since the Kaplan-Meier survival curve is a decreasing step function, each given time point falls in an interval that has a constant survival estimate. The event time that corresponds to the beginning of the time interval is displayed along with its survival estimate.

**WIDTH=value**

sets the width of the intervals used in the life-table calculation of the survival function. This parameter is overridden by the INTERVALS= option.

**BY Statement****BY variables ;**

You can specify a BY statement with PROC LIFETEST to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the LIFETEST procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

The BY statement is more efficient than the STRATA statement for defining strata in large data sets. However, if you use the BY statement to define strata, PROC LIFETEST does not pool over strata for testing the association of survival time with covariates, nor does it test for homogeneity across the BY groups.

When the life-table method is used to estimate survivor functions, each BY group might have a different set of intervals. To make intervals the same across BY groups, use the INTERVALS= or WIDTH= option in the PROC LIFETEST statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## FREQ Statement

**FREQ** *variable* </ *option* > ;

The FREQ statement identifies a *variable* that contains the frequency of occurrence of each observation. PROC LIFETEST treats each observation as if it appeared  $n$  times, where  $n$  is the value of the FREQ variable for the observation. The FREQ statement is useful for producing life tables when the data are already in the form of a summary data set. If it is not an integer, it is truncated to an integer unless the NOTRUNCATE option is specified. If it is missing or less than or equal zero, the observation is not used.

The following *option* can be specified in the FREQ statement after a slash (/):

### NOTRUNCATE

#### NOTRUNC

specifies that the frequency values are not truncated to integers. This option does not apply to the Fleming-Harrington estimator (METHOD=FH).

## ID Statement

**ID** *variables* ;

The ID statement identifies *variables* whose values are used to label the observations of the Kaplan-Meier, Breslow, or Fleming-Harrington survivor function estimates. SAS format statements can be used to format the values of the ID variables.

## STRATA Statement

**STRATA** *variable* <(list)> <... *variable* <(list)>> </ options > ;

The STRATA statement identifies the variables that determine the strata levels. Strata are formed according to the nonmissing values of these variables. The MISSING option can be used to allow missing values as a valid stratum level. Other options enable you to specify various  $k$ -sample tests, stratified tests, or trend tests and to make multiple-comparison adjustments for paired differences.

In the preceding syntax, *variable* is a variable whose values determine the stratum levels, and *list* is a list of endpoints for a numeric variable. The values for *variable* can be formatted or unformatted. If *variable* is a character variable, or if *variable* is numeric and no list appears, then the strata are defined by the unique values of the STRATA *variable*. More than one *variable* can be specified in the STRATA statement, and each numeric variable can be followed by a list. Each interval contains its lower endpoint but not its upper endpoint. The corresponding strata are formed by the combination of levels. If a variable is numeric and is followed by a list, then the levels for that variable correspond to the intervals defined by the list. The initial interval is assumed to start at  $-\infty$ , and the final interval is assumed to end at  $\infty$ .

The specification of a STRATA *variable* can have any of the following forms:

- A list separated by blanks      **Age (5 10 20 30)**
- A list separated by commas      **Age (5, 10, 20, 30)**
- $x$  to  $y$       **Age (5 to 10)**
- $x$  to  $y$  by  $z$       **Age (5 to 30 by 10)**
- A combination of the above      **Age (5, 10 to 50 by 10)**

For example, the specification

```
strata Age(5,20 to 50 by 10) Sex;
```

indicates the following levels for the Age variable:

$\{(-\infty, 5), [5, 20), [20, 30), [30, 40), [40, 50), [50, \infty)\}$

This statement also specifies that the Age strata be further subdivided by values of the variable Sex. In this example, there are six age groups by two sex groups, forming a total of 12 strata.

The specification of several STRATA *variables*, such as

```
strata A B C;
```

is equivalent to the A\*B\*C syntax of the TABLES statement in the FREQ procedure. The number of strata levels usually grows very rapidly with the number of STRATA variables, so you must be cautious when specifying the list of STRATA variables.

When comparing more than two survival curves, a  $k$ -sample test tells you whether the curves are significantly different from each other, but it does not identify which pairs of curves are different. A multiple-comparison adjustment of the  $p$ -values for the paired comparisons retains the same overall false positives as the  $k$ -sample test. Two types of paired comparisons can be made: comparisons between all pairs of curves and comparisons between a control curve and all other curves. You use the DIFF= option to specify the comparison type, and you use the ADJUST= option to select a method of multiple-comparison adjustments.

Table 52.3 summarizes the options available in the STRATA statement.

**Table 52.3** Options Available in the STRATA Statement

| Option                      | Description                                                  |
|-----------------------------|--------------------------------------------------------------|
| <b>Homogeneity Tests</b>    |                                                              |
| GROUP=                      | Specifies the group variable for stratified tests            |
| NODETAIL                    | Suppresses printing the test statistic and covariance matrix |
| NOTEST                      | Suppresses any tests                                         |
| TEST=                       | Specifies tests corresponding to various weight functions    |
| TREND                       | Requests a trend test                                        |
| <b>Multiple Comparisons</b> |                                                              |
| ADJUST=                     | Requests a multiple-comparison adjustment                    |
| DIFF=                       | Specifies the type of differences to consider                |
| <b>Missing Strata Value</b> |                                                              |
| MISSING                     | Allows missing values as valid stratum values                |
| <b>Display Option</b>       |                                                              |
| NOLABEL                     | Uses the names of the STRATA variables in the display        |

You can specify the following *options* in the STRATA statement after a slash (“/”).

**ADJUST=method**

specifies the multiple-comparison method for adjusting the  $p$ -values of the paired tests. See the section “Multiple-Comparison Adjustments” on page 4045 for mathematical details; also see Westfall et al. (1999). The adjustment methods include the following:

**BONFERRONI****BON**

applies the Bonferroni correction to the raw  $p$ -values.

**DUNNETT**

performs Dunnett’s two-tailed comparisons of the control group with all other groups. PROC LIFETEST uses the factor-analytic covariance approximation described in Hsu (1992) and identifies the adjustment in the results as “Dunnett-Hsu.” Note that ADJUST=DUNNETT is incompatible with DIFF=ALL.

**SCHEFFE**

performs Scheffé’s multiple-comparison adjustment.

**SIDAK**

applies the Šidák correction to the raw  $p$ -values.

**SMM****GTE**

performs the paired comparisons based on the studentized maximum modulus test.

**TUKEY**

performs the paired comparisons based on Tukey’s studentized range test. PROC LIFETEST uses the approximation described in Kramer (1956) and identifies the adjustment as “Tukey-Kramer” in the results. Note that ADJUST=TUKEY is incompatible with DIFF=CONTROL.

**SIMULATE** <(simulate-options)>

computes the adjusted  $p$ -values from the simulated distribution of the maximum or maximum absolute value of a multivariate normal random vector. The simulation estimates  $q$ , the true  $(1 - \alpha)$  quantile, where  $\alpha$  is the value of the ALPHA= *simulate-option*.

The number of samples for the SIMULATE adjustment is set so that the tail area for the simulated  $q$  is within a certain accuracy radius  $\gamma$  of  $1 - \alpha$  with an accuracy confidence of  $100(1 - \epsilon)\%$ . In equation form,

$$\Pr(|F(\hat{q}) - (1 - \alpha)| \leq \gamma) = 1 - \epsilon$$

where  $\hat{q}$  is the simulated  $q$  and  $F$  is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default,  $\gamma = 0.005$  and  $\epsilon = 0.01$  so that the tail area of  $\hat{q}$  is within 0.005 of 0.95 with 99% confidence.

The *simulate-options* include the following:

**ACC=***value*

specifies the target accuracy radius  $\gamma$  of a  $100(1 - \epsilon)\%$  confidence interval for the true probability content of the estimated  $(1 - \alpha)$  quantile. The default value is ACC=0.005.

**ALPHA=***value*

specifies the value  $\alpha$  for estimating the  $(1 - \alpha)$  quantile. The default value is the ALPHA= value in the PROC LIFETEST statement, or 0.05 if that option is not specified.

**EPS=***value*

specifies the value  $\epsilon$  for a  $100(1 - \epsilon)\%$  confidence interval for the true probability content of the estimated  $(1 - \alpha)$  quantile. The default value for the accuracy confidence is 99%, corresponding to EPS=0.01.

**NSAMP=***n*

specifies the sample size for the simulation. By default,  $n$  is set based on the values of the target accuracy radius  $\gamma$  and accuracy confidence  $100(1 - \epsilon)\%$  for an interval for the true probability content of the estimated  $(1 - \alpha)$  quantile. With the default values for  $\gamma$ ,  $\epsilon$ , and  $\alpha$  (0.005, 0.01, and 0.05, respectively), NSAMP=12604 by default.

**REPORT**

specifies that a report on the simulation should be displayed, including a listing of the parameters, such as  $\gamma$ ,  $\epsilon$ , and  $\alpha$ , in addition to an analysis of various methods for estimating or approximating the quantile.

**SEED=***number*

specifies an integer used to start the pseudorandom number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated by default from reading the time of day from the computer's clock.

**DIFF=ALL | CONTROL**<('string' <... , 'string')>

specifies which pairs of survival curves are considered for the multiple comparisons.

**DIFF=ALL**

requests all paired comparisons

**DIFF=CONTROL** <('string' <... 'string'>)>

requests comparisons of the control curve with all other curves. To specify the control curve, you specify the quotes strings of formatted values that represent the curve in parentheses. For example, if Cell='large' identifies the control group, you specify

```
DIFF=CONTROL (' large ')
```

If more than one variable is used to identify the curves (for example, if Cell='large' and Sex='F' represent the control), you specify

```
DIFF=CONTROL (' large ' ' F ')
```

The order of the quoted strings should correspond to the order of the stratum variables. If no specific curve is specified as the control, the first stratum or group value is used.

By default, DIFF=ALL unless you specify **ADJUST= DUNNETT**, in which case DIFF=CONTROL.

**GROUP=variable**

specifies the variable whose formatted values identify the various samples whose underlying survival curves are to be compared. The tests are stratified on the levels of the STRATA variables. For example, in a multicenter trial in which two forms of therapy are to be compared, you specify the variable that identifies therapies as the **GROUP= variable** and the variable that identifies centers as the STRATA variable, in order to perform a stratified test to compare the therapies while controlling the effect of the centers.

**MISSING**

allows missing values to be a stratum level or a valid value of the **GROUP= variable**.

**NODETAIL**

suppresses the display of the rank statistics and the corresponding covariance matrices for various strata. If you specified the **TREND** option, the display of the scores for computing the trend tests is suppressed.

**NOLABEL**

specifies that the names instead of the labels of the STRATA variables be used in the display of the survival estimate table and in the legend of the survival plot.

**NOTEST**

suppresses the *k*-sample tests, stratified tests, and trend tests.

**ORDER=FORMATTED | INTERNAL**

specifies the sorting order of the values of the STRATA variables. The strata are presented in the specified order in the analysis results. You can use this option, for example, to display the curve labels in your preferred order in the survival plot legend (see [Example 52.2](#) for an illustration). The default is **ORDER=FORMATTED**, which sorts the strata according to their external formatted values, except for numeric variable with no explicit format, which are sorted by the unformatted (internal) values. **ORDER=INTERNAL** sorts the strata by their internal values. The **ORDER=** option has no effect on a stratum variable with cutpoints specified.

**TREND**

computes the trend tests for testing the null hypothesis that the  $k$  population hazards rate are the same versus an ordered alternatives. If there is only one STRATA variable and the variable is numeric, the unformatted values of the variable are used as the scores; otherwise, the scores are 1, 2, . . . , in the given order of the strata.

**TEST**=*test-request*

**TEST**=(*test-request* < . . . *test-request* > )

controls the tests produced. Each test corresponds to a different weight function (see the section “Nonparametric Tests” on page 4043 for the weight functions). The *test-requests* include the following:

|                             |                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|-----------------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| ALL                         | specifies all the nonparametric tests with $\rho_1=1$ and $\rho_2=0$ for the Fleming and Harrington test—FLEMING(1,0).                                                                                                                                                                                                                                                                                                                      |
| FLEMING( $\rho_1, \rho_2$ ) | specifies the family of tests in Harrington and Fleming (1982), where $\rho_1$ and $\rho_2$ are nonnegative numbers. FLEMING( $\rho_1, \rho_2$ ) reduces to the Fleming-Harrington $G^{\rho}$ family (Fleming and Harrington 1981) when $\rho_2=0$ , which you can specify as FLEMING( $\rho$ ) with one argument. When $\rho=0$ , the test becomes the log-rank test. When $\rho=1$ , the test should be very close to the Peto-Peto test. |
| LOGRANK                     | specifies the log-rank test.                                                                                                                                                                                                                                                                                                                                                                                                                |
| NONE                        | suppresses all comparison tests. Specifying TEST=NONE is equivalent to specify NOTEST.                                                                                                                                                                                                                                                                                                                                                      |
| LR                          | specifies the likelihood ratio test based on the exponential model.                                                                                                                                                                                                                                                                                                                                                                         |
| MODPETO                     | specifies the modified Peto-Peto test.                                                                                                                                                                                                                                                                                                                                                                                                      |
| PETO                        | specifies the Peto-Peto test. The test is also referred to as the Peto-Peto-Prentice test.                                                                                                                                                                                                                                                                                                                                                  |
| WILCOXON                    | specifies the Wilcoxon test. The test is also referred to as the Gehan test or the Breslow test.                                                                                                                                                                                                                                                                                                                                            |
| TARONE                      | specifies the Tarone-Ware test.                                                                                                                                                                                                                                                                                                                                                                                                             |

By default, TEST=(LOGRANK WILCOXON LR) for the  $k$ -sample tests, and TEST=(LOGRANK WILCOXON) for stratified and trend tests.

---

## TEST Statement

**TEST** *variables* ;

The TEST statement specifies a list of numeric covariates (prognostic variables) that you want tested for association with the failure time.

Two sets of rank statistics are computed. These rank statistics and their variances are pooled over all strata. Univariate (marginal) test statistics are displayed for each of the covariates.

Additionally, a sequence of test statistics for joint effects of covariates is displayed. The first element of the sequence is the largest univariate test statistic. Other variables are then added on the basis of the largest

increase in the joint test statistic. The process continues until all the variables have been added or until the remaining variables are linearly dependent on the previously added variables.

See the section “Rank Tests for the Association of Survival Time with Covariates” on page 4047 for more information.

## TIME Statement

**TIME** *variable* < \*  *censor(list)* > ;

The TIME statement is required. It is used to indicate the failure time variable, where *variable* is the name of the failure time variable that can be optionally followed by an asterisk, the name of the censoring variable, and a parenthetical list of values that correspond to right censoring. The censoring values should be numeric, nonmissing values. For example, the statement

```
time T*Flag(1,2);
```

identifies the variable T as containing the observed failure times (event or censored). If the variable Flag has the value 1 or 2, the corresponding value of T is a right-censored value.

## WEIGHT Statement

**WEIGHT** *variable* ;

The *variable* in the WEIGHT statement identifies the variable in the input data set that contains the weights of the subjects. Values of the WEIGHT *variable* can be nonintegral and are not truncated. Observations with negative, zero, or missing values for the WEIGHT *variable* are not used in the computation.

The implementation of weights in PROC LIFETEST is based on Xie and Liu (2005, 2011), who use inverse probability of treatment weights to reduce confounding effects. A weight is assigned to each subject as the inverse probability of being in a certain group. If a subject has a higher probability of being in a group, it is considered as overrepresented and is therefore assigned a lower weight; on the other hand, if the subject has a smaller probability of being in a group, it is considered as underrepresented and is assigned a higher weight.

## Details: LIFETEST Procedure

### Missing Values

Observations with a missing value for either the failure time or the censoring variable are not used in the analysis. If a stratum variable value is missing, the observation is not used; however, the MISSING option can be used to request that missing values be treated as valid stratum values. If any variable specified in the TEST statement has a missing value, that observation is not used in the calculation of the rank statistics.

## Computational Formulas

### Breslow, Fleming-Harrington, and Kaplan-Meier Methods

Let  $t_1 < t_2 < \dots < t_D$  represent the distinct event times. For each  $i = 1, \dots, D$ , let  $Y_i$  be the number of surviving units (the size of the risk set) just prior to  $t_i$  and let  $d_i$  be the number of units that fail at  $t_i$ . If the NOTRUNCATE option is specified in the FREQ statement,  $Y_i$  and  $d_i$  can be nonintegers.

The Breslow estimate of the survivor function is

$$\hat{S}(t_i) = \exp\left(-\sum_{j=1}^i \frac{d_j}{Y_j}\right)$$

Note that the Breslow estimate is the exponentiation of the negative Nelson-Aalen estimate of the cumulative hazard function.

The Fleming-Harrington estimate (Fleming and Harrington 1984) of the survivor function is

$$\hat{S}(t_i) = \exp\left(-\sum_{k=1}^i \sum_{j=0}^{d_k-1} \frac{1}{Y_k - j}\right)$$

If the frequency values are not integers, the Fleming-Harrington estimate cannot be computed.

The Kaplan-Meier (product-limit) estimate of the survivor function at  $t_i$  is the cumulative product

$$\hat{S}(t_i) = \prod_{j=1}^i \left(1 - \frac{d_j}{Y_j}\right)$$

Notice that all the estimators are defined to be right continuous; that is, the events at  $t_i$  are included in the estimate of  $S(t_i)$ . The corresponding estimate of the standard error is computed using Greenwood's formula (Kalbfleisch and Prentice 1980) as

$$\hat{\sigma}\left(\hat{S}(t_i)\right) = \hat{S}(t_i) \sqrt{\sum_{j=1}^i \frac{d_j}{Y_j(Y_j - d_j)}}$$

The first quartile (or the 25th percentile) of the survival time is the time beyond which 75% of the subjects in the population under study are expected to survive. It is estimated by

$$q_{.25} = \min\{t_j | \hat{S}(t_j) < 0.75\}$$

If  $\hat{S}(t)$  is exactly equal to 0.75 from  $t_j$  to  $t_{j+1}$ , the first quartile is taken to be  $(t_j + t_{j+1})/2$ . If it happens that  $\hat{S}(t)$  is greater than 0.75 for all values of  $t$ , the first quartile cannot be estimated and is represented by a missing value in the printed output.

The general formula for estimating the 100 $p$  percentile point is

$$q_p = \min\{t_j | \hat{S}(t_j) < 1 - p\}$$

The second quartile (the median) and the third quartile of survival times correspond to  $p = 0.5$  and  $p = 0.75$ , respectively.

Brookmeyer and Crowley (1982) have constructed the confidence interval for the median survival time based on the confidence interval for the  $S(t)$ . The methodology is generalized to construct the confidence interval for the  $100p$  percentile based on a  $g$ -transformed confidence interval for  $S(t)$  (Klein and Moeschberger 1997). You can use the CONFTYPE= option to specify the  $g$ -transformation. The  $100(1 - \alpha)\%$  confidence interval for the first quantile survival time is the set of all points  $t$  that satisfy

$$\left| \frac{g(\hat{S}(t)) - g(1 - 0.25)}{g'(\hat{S}(t))\hat{\sigma}(\hat{S}(t))} \right| \leq z_{1-\frac{\alpha}{2}}$$

where  $g'(x)$  is the first derivative of  $g(x)$  and  $z_{1-\frac{\alpha}{2}}$  is the  $100(1 - \frac{\alpha}{2})$  percentile of the standard normal distribution.

Consider the bone marrow transplant data described in Example 52.2. The following table illustrates the construction of the confidence limits for the first quartile in the ALL group. Values of  $\frac{g(\hat{S}(t)) - g(1 - 0.25)}{g'(\hat{S}(t))\hat{\sigma}(\hat{S}(t))}$  that lie between  $\pm z_{1-\frac{0.05}{2}} = \pm 1.965$  are highlighted.

| 662                                                        | 0.35306      | 0.079296                   | -5.0059                                                                      | -5.96222        | -3.3546        | -4.95358        | -4.90900        |

Consider the LINEAR transformation where  $g(x) = x$ . The event times that satisfy  $\left| \frac{g(\hat{S}(t)) - g(1 - p)}{g'(\hat{S}(t))\sqrt{\hat{V}(\hat{S}(t))}} \right| \leq 1.9599$  include 107, 109, 110, 122, 129, 172, 192, 194, and 230. The confidence of the interval [107, 230] is less than 95%. Brookmeyer and Crowley (1982) suggest extending the confidence interval to but not

including the next event time. As such the 95% confidence interval for the first quartile based on the linear transform is [107, 276). The following table lists the confidence intervals for the various transforms.

| 95% CI's for the 25th Percentile |        |        |
|----------------------------------|--------|--------|
| CONFTYPE                         | [Lower | Upper) |
| LINEAR                           | 107    | 276    |
| LOGLOG                           | 86     | 230    |
| LOG                              | 107    | 332    |
| ASINSQRT                         | 104    | 276    |
| LOGIT                            | 104    | 230    |

Sometimes, the confidence limits for the quartiles cannot be estimated. For convenience of explanation, consider the linear transform  $g(x) = x$ . If the curve that represents the upper confidence limits for the survivor function lies above 0.75, the upper confidence limit for first quartile cannot be estimated. On the other hand, if the curve that represents the lower confidence limits for the survivor function lies above 0.75, the lower confidence limit for the quartile cannot be estimated.

The estimated mean survival time is

$$\hat{\mu} = \sum_{i=1}^D \hat{S}(t_{i-1})(t_i - t_{i-1})$$

where  $t_0$  is defined to be zero. When the largest observed time is censored, this sum underestimates the mean. The standard error of  $\hat{\mu}$  is estimated as

$$\hat{\sigma}(\hat{\mu}) = \sqrt{\frac{m}{m-1} \sum_{i=1}^{D-1} \frac{A_i^2}{Y_i(Y_i - d_i)}}$$

where

$$A_i = \sum_{j=i}^{D-1} \hat{S}(t_j)(t_{j+1} - t_j)$$

$$m = \sum_{j=1}^D d_j$$

If the largest observed time is not an event, you can use the TIMELIM= option to specify a time limit  $L$  and estimate the mean survival time limited to the time  $L$  and its standard error by replacing  $k$  by  $k + 1$  with  $t_{k+1} = L$ .

### **Nelson-Aalen Estimate of the Cumulative Hazard Function**

The Nelson-Aalen cumulative hazard estimator, defined up to the largest observed time on study, is

$$\tilde{H}(t) = \sum_{t_i \leq t} \frac{d_i}{Y_i}$$

and its estimated variance is

$$\hat{\sigma}^2(\tilde{H}(t)) = \sum_{t_i \leq t} \frac{d_i}{Y_i^2}$$

### Adjusted Kaplan-Meier Estimate

PROC LIFETEST computes the adjusted Kaplan-Meier estimate (AKME) of the survivor function if you specify both METHOD=KM and the WEIGHT statement. Let  $(T_i, \delta_i, w_i), i = 1, \dots, n$ , denote an independent sample of right-censored survival data, where  $T_i$  is the possibly right-censored time,  $\delta_i$  is the censoring indicator ( $\delta_i = 0$  if  $T_i$  is censored and  $\delta_i = 1$  if  $T_i$  is an event time), and  $w_i$  is the weight (from the WEIGHT statement). Let  $t_1 < t_2, \dots < t_D$  be the  $D$  distinct event times in the sample. At time  $t_j, j = 1, \dots, D$ , there are  $d_j = \sum_i \delta_i I(T_i = t_j)$  events out of  $Y_j = \sum_i I(T_i \geq t_j)$  subjects. The weighted number of events and the weighted number at risk are  $d_j^w = \sum_i w_i \delta_i I(T_i = t_j)$  and  $Y_j^w = \sum_i w_i I(T_i \geq t_j)$ , respectively. The AKME (Xie and Liu 2005) is

$$\hat{S}(t) = \begin{cases} 1 & \text{if } t < t_1 \\ \prod_{t_j \leq t} \left[ 1 - \frac{d_j^w}{Y_j^w} \right] & \text{if } t \geq t_1 \end{cases}$$

The estimated variance of  $\hat{S}(t)$  is

$$\hat{\sigma}^2(\hat{S}(t)) = (\hat{S}(t))^2 \sum_{j:t_j \leq t} \frac{d_j^w / Y_j^w}{M_j (1 - d_j^w / Y_j^w)}$$

where

$$M_j = \frac{\left( \sum_{i:T_i \geq t_j} w_i \right)^2}{\sum_{i:T_i \geq t_j} w_i^2}$$

### Life-Table Method

The life-table estimates are computed by counting the numbers of censored and uncensored observations that fall into each of the time intervals  $[t_{i-1}, t_i), i = 1, 2, \dots, k + 1$ , where  $t_0 = 0$  and  $t_{k+1} = \infty$ . Let  $n_i$  be the number of units that enter the interval  $[t_{i-1}, t_i)$ , and let  $d_i$  be the number of events that occur in the interval. Let  $b_i = t_i - t_{i-1}$ , and let  $n'_i = n_i - w_i/2$ , where  $w_i$  is the number of units censored in the interval. The effective sample size of the interval  $[t_{i-1}, t_i)$  is denoted by  $n'_i$ . Let  $t_{mi}$  denote the midpoint of  $[t_{i-1}, t_i)$ .

The conditional probability of an event in  $[t_{i-1}, t_i)$  is estimated by

$$\hat{q}_i = \frac{d_i}{n'_i}$$

and its estimated standard error is

$$\hat{\sigma}(\hat{q}_i) = \sqrt{\frac{\hat{q}_i \hat{p}_i}{n'_i}}$$

where  $\hat{p}_i = 1 - \hat{q}_i$ .

The estimate of the survival function at  $t_i$  is

$$\hat{S}(t_i) = \begin{cases} 1 & i = 0 \\ \hat{S}(t_{i-1})p_{i-1} & i > 0 \end{cases}$$

and its estimated standard error is

$$\hat{\sigma}(\hat{S}(t_i)) = \hat{S}(t_i) \sqrt{\sum_{j=1}^{i-1} \frac{\hat{q}_j}{n'_j \hat{p}_j}}$$

The density function at  $t_{mi}$  is estimated by

$$\hat{f}(t_{mi}) = \frac{\hat{S}(t_i)\hat{q}_i}{b_i}$$

and its estimated standard error is

$$\hat{\sigma}(\hat{f}(t_{mi})) = \hat{f}(t_{mi}) \sqrt{\sum_{j=1}^{i-1} \frac{\hat{q}_j}{n'_j \hat{p}_j} + \frac{\hat{p}_i}{n'_i \hat{q}_i}}$$

The estimated hazard function at  $t_{mi}$  is

$$\hat{h}(t_{mi}) = \frac{2\hat{q}_i}{b_i(1 + \hat{p}_i)}$$

and its estimated standard error is

$$\hat{\sigma}(\hat{h}(t_{mi})) = \hat{h}(t_{mi}) \sqrt{\frac{1 - (b_i \hat{h}(t_{mi})/2)^2}{n'_i \hat{q}_i}}$$

Let  $[t_{j-1}, t_j]$  be the interval in which  $\hat{S}(t_{j-1}) \geq \hat{S}(t_i)/2 > \hat{S}(t_j)$ . The median residual lifetime at  $t_i$  is estimated by

$$\hat{M}_i = t_{j-1} - t_i + b_j \frac{\hat{S}(t_{j-1}) - \hat{S}(t_i)/2}{\hat{S}(t_{j-1}) - \hat{S}(t_j)}$$

and the corresponding standard error is estimated by

$$\hat{\sigma}(\hat{M}_i) = \frac{\hat{S}(t_i)}{2\hat{f}(t_{mj})\sqrt{n'_i}}$$

### Interval Determination

If you want to determine the intervals exactly, use the INTERVALS= option in the PROC LIFETEST statement to specify the interval endpoints. Use the WIDTH= option to specify the width of the intervals, thus indirectly determining the number of intervals. If neither the INTERVALS= option nor the WIDTH= option is specified in the life-table estimation, the number of intervals is determined by the NINTERVAL= option. The width of the time intervals is 2, 5, or 10 times an integer (possibly a negative integer) power of 10. Let

$c = \log_{10}(\text{maximum observed time/number of intervals})$ , and let  $b$  be the largest integer not exceeding  $c$ . Let  $d = 10^{c-b}$  and let

$$a = 2 \times I(d \leq 2) + 5 \times I(2 < d \leq 5) + 10 \times I(d > 5)$$

with  $I$  being the indicator function. The width is then given by

$$\text{width} = a \times 10^b$$

By default, NINTERVAL=10.

### Pointwise Confidence Limits in the OUTSURV= Data Set

Pointwise confidence limits are computed for the survivor function, and for the density function and hazard function when the life-table method is used. Let  $\alpha$  be specified by the ALPHA= option. Let  $z_{\alpha/2}$  be the critical value for the standard normal distribution. That is,  $\Phi(-z_{\alpha/2}) = \alpha/2$ , where  $\Phi$  is the cumulative distribution function of the standard normal random variable.

#### Survivor Function

When the computation of confidence limits for the survivor function  $S(t)$  is based on the asymptotic normality of the survival estimator  $\hat{S}(t)$ , the approximate confidence interval might include impossible values outside the range  $[0,1]$  at extreme values of  $t$ . This problem can be avoided by applying the asymptotic normality to a transformation of  $S(t)$  for which the range is unrestricted. In addition, certain transformed confidence intervals for  $S(t)$  perform better than the usual linear confidence intervals (Borgan and Liestøl 1990). The CONFTYPE= option enables you to pick one of the following transformations: the log-log function (Kalbfleisch and Prentice 1980), the arcsine-square root function (Nair 1984), the logit function (Meeker and Escobar 1998), the log function, and the linear function.

Let  $g$  be the transformation that is being applied to the survivor function  $S(t)$ . By the delta method, the standard error of  $g(\hat{S}(t))$  is estimated by

$$\tau(t) = \hat{\sigma} \left[ g(\hat{S}(t)) \right] = g'(\hat{S}(t)) \hat{\sigma}[\hat{S}(t)]$$

where  $g'$  is the first derivative of the function  $g$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$g^{-1} \left\{ g[\hat{S}(t)] \pm z_{\alpha/2} g'[\hat{S}(t)] \hat{\sigma}[\hat{S}(t)] \right\}$$

where  $g^{-1}$  is the inverse function of  $g$ . That choices of the transformation  $g$  are as follows:

- arcsine-square root transformation: The estimated variance of  $\sin^{-1}(\sqrt{\hat{S}(t)})$  is  $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2[\hat{S}(t)]}{4\hat{S}(t)[1-\hat{S}(t)]}$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\sin^2 \left\{ \max \left[ 0, \sin^{-1}(\sqrt{\hat{S}(t)}) - z_{\alpha/2} \hat{\tau}(t) \right] \right\} \leq S(t) \leq \sin^2 \left\{ \min \left[ \frac{\pi}{2}, \sin^{-1}(\sqrt{\hat{S}(t)}) + z_{\alpha/2} \hat{\tau}(t) \right] \right\}$$

- linear transformation: This is the same as having no transformation in which  $g$  is the identity. The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\hat{S}(t) - z_{\alpha/2} \hat{\sigma}[\hat{S}(t)] \leq S(t) \leq \hat{S}(t) + z_{\alpha/2} \hat{\sigma}[\hat{S}(t)]$$

- log transformation: The estimated variance of  $\log(\hat{S}(t))$  is  $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2(\hat{S}(t))}{\hat{S}^2(t)}$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\hat{S}(t) \exp\left(-z_{\frac{\alpha}{2}} \hat{\tau}(t)\right) \leq S(t) \leq \hat{S}(t) \exp\left(z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)$$

- log-log transformation: The estimated variance of  $\log(-\log(\hat{S}(t)))$  is  $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2[\hat{S}(t)]}{[\hat{S}(t) \log(\hat{S}(t))]^2}$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\left[\hat{S}(t)\right]^{\exp\left(z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)} \leq S(t) \leq \left[\hat{S}(t)\right]^{\exp\left(-z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)}$$

- logit transformation: The estimated variance of  $\log\left(\frac{\hat{S}(t)}{1-\hat{S}(t)}\right)$  is

$$\hat{\tau}^2(t) = \frac{\hat{\sigma}^2(\hat{S}(t))}{\hat{S}^2(t)[1-\hat{S}(t)]^2}$$

The  $100(1-\alpha)\%$  confidence limits for  $S(t)$  are given by

$$\frac{\hat{S}(t)}{\hat{S}(t) + \left[1 - \hat{S}(t)\right] \exp\left(z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)} \leq S(t) \leq \frac{\hat{S}(t)}{\hat{S}(t) + \left[1 - \hat{S}(t)\right] \exp\left(-z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)}$$

### Density and Hazard Functions

For the life-table method, a  $100(1-\alpha)\%$  confidence interval for hazard function or density function at time  $t$  is computed as

$$\hat{g}(t) \pm z_{\alpha/2} \hat{\sigma}[\hat{g}(t)]$$

where  $\hat{g}(t)$  is the estimate of either the hazard function or the density function at time  $t$ , and  $\hat{\sigma}[\hat{g}(t)]$  is the corresponding standard error estimate.

### Simultaneous Confidence Intervals for Kaplan-Meier Curves

The pointwise confidence interval for the survivor function  $S(t)$  is valid for a single fixed time at which the inference is to be made. In some applications, it is of interest to find the upper and lower confidence bands that guarantee, with a given confidence level, that the survivor function falls within the band for all  $t$  in some interval. Hall and Wellner (1980) and Nair (1984) provide two different approaches for deriving the confidence bands. An excellent review can be found in Klein and Moeschberger (1997). You can use the CONF BAND= option in the SURVIVAL statement to select the confidence bands. The EP confidence band provides confidence bounds that are proportional to the pointwise confidence interval, while those of the HW band are not proportional to the pointwise confidence bounds. The maximum time,  $t_U$ , for the bands can be specified by the BANDMAX= option; the minimum time,  $t_L$ , can be specified by the BANDMIN= option. Transformations that are used to improve the pointwise confidence intervals can be applied to improve the confidence bands. It might turn out that the upper and lower bounds of the confidence bands are not decreasing in  $t_L < t < t_U$ , which is contrary to the nonincreasing characteristic of survivor function. Meeker and Escobar (1998) suggest making an adjustment so that the bounds do not increase: if the upper bound is increasing on the right, it is made flat from the minimum to  $t_U$ ; if the lower bound is

increasing from the right, it is made flat from  $t_L$  to the maximum. PROC LIFETEST does not make any adjustment for the nondecreasing behavior of the confidence bands in the OUTSURV= data set. However, the adjustment was made in the display of the confidence bands by using ODS Graphics.

For Kaplan-Meier estimation, let  $t_1 < t_2 < \dots < t_D$  be the  $D$  distinct events times, and at time  $t_i$ , there are  $d_i$  events. Let  $Y_i$  be the number of individuals who are at risk at time  $t_i$ . The variance of  $\hat{S}(t)$ , given by the Greenwood formula, is  $\hat{\sigma}^2[\hat{S}(t)] = \sigma_S^2(t)\hat{S}^2(t)$ , where

$$\sigma_S^2(t) = \sum_{t_i \leq t} \frac{d_i}{Y_i(Y_i - d_i)}$$

Let  $t_L < t_U$  be the time range for the confidence band so that  $t_U$  is less than or equal to the largest event time. For the Hall-Wellner band,  $t_L$  can be zero, but for the equal-precision band,  $t_L$  is greater than or equal to the smallest event time. Let

$$a_L = \frac{n\sigma_S^2(t_L)}{1 + n\sigma_S^2(t_L)} \quad \text{and} \quad a_U = \frac{n\sigma_S^2(t_U)}{1 + n\sigma_S^2(t_U)}$$

Let  $\{W^0(u), 0 \leq u \leq 1\}$  be a Brownian bridge.

### Hall-Wellner Band

The 100(1- $\alpha$ )% HW band of Hall and Wellner (1980) is

$$\hat{S}(t) - h_\alpha(a_L, a_U)n^{-\frac{1}{2}}[1 + n\sigma_S^2(t)]\hat{S}(t) \leq S(t) \leq \hat{S}(t) + h_\alpha(a_L, a_U)n^{-\frac{1}{2}}[1 + n\sigma_S^2(t)]\hat{S}(t)$$

for all  $t_L \leq t \leq t_U$ , where the critical value  $h_\alpha(a_L, a_U)$  is given by

$$\alpha = \Pr\left\{ \sup_{a_L \leq u \leq a_U} |W^0(u)| > h_\alpha(a_L, a_U) \right\}$$

The critical values are computed from the results in Chung (1986).

Note that the given confidence band has a formula similar to that of the (linear) pointwise confidence interval, where  $h_\alpha(a_L, a_U)$  and  $n^{-\frac{1}{2}}[1 + n\sigma_S^2(t)]\hat{S}(t)$  in the former correspond to  $z_{\frac{\alpha}{2}}$  and  $\hat{\sigma}(\hat{S}(t))$  in the latter, respectively. You can obtain the other transformations (arcsine-square root, log-log, log, and logit) for the confidence bands by replacing  $z_{\frac{\alpha}{2}}$  and  $\hat{\tau}(t)$  in the corresponding pointwise confidence interval formula by  $h_\alpha(a_L, a_U)$  and the following  $\hat{\tau}(t)$ , respectively:

- arcsine-square root transformation:

$$\hat{\tau}(t) = \frac{1 + n\sigma_S^2(t)}{2} \sqrt{\frac{S(t)}{n[1 - S(t)]}}$$

- log transformation:

$$\hat{\tau}(t) = \frac{1 + n\sigma_S^2(t)}{\sqrt{n}}$$

- log-log transformation:

$$\hat{t}(t) = \frac{1 + n\sigma_S^2(t)}{\sqrt{n}|\log[\hat{S}(t)]|}$$

- logit transformation:

$$\hat{t}(t) = \frac{1 + n\sigma_S^2(t)}{\sqrt{n}[1 - \hat{S}(t)]}$$

### Equal-Precision Band

The  $100(1-\alpha)\%$  EP band of Nair (1984) is

$$\hat{S}(t) - e_\alpha(a_L, a_U)\hat{S}(t)\sigma_S(t) \leq S(t) \leq \hat{S}(t) + e_\alpha(a_L, a_U)\hat{S}(t)\sigma_S(t)$$

for all  $t_L \leq t \leq t_U$ , where  $e_\alpha(a_L, a_U)$  is given by

$$\alpha = \Pr\left\{ \sup_{a_L \leq u \leq a_U} \frac{|W^0(u)|}{[u(1-u)]^{\frac{1}{2}}} > e_\alpha(a_L, a_U) \right\}$$

PROC LIFETEST uses the approximation of Miller and Siegmund (1982, Equation 8) to approximate the tail probability in which  $e_\alpha(a_L, a_U)$  is obtained by solving  $x$  in

$$\frac{4x\phi(x)}{x} + \phi(x) \left( x - \frac{1}{x} \right) \log \left[ \frac{a_U(1-a_L)}{a_L(1-a_U)} \right] = \alpha$$

where  $\phi(x)$  is the standard normal density function evaluated at  $x$ . Note that the confidence bounds given are proportional to the pointwise confidence intervals. As a matter of fact, this confidence band and the (linear) pointwise confidence interval have the same formula except for the critical values ( $z_{\frac{\alpha}{2}}$  for the pointwise confidence interval and  $e_\alpha(a_L, a_U)$  for the band). You can obtain the other transformations (arcsine-square root, log-log, log, and logit) for the confidence bands by replacing  $z_{\frac{\alpha}{2}}$  by  $e_\alpha(a_L, a_U)$  in the formula of the pointwise confidence intervals.

### Kernel-Smoothed Hazard Estimate

Kernel-smoothed estimators of the hazard function  $h(t)$  are based on the Nelson-Aalen estimator  $\tilde{H}(t)$  and its variance  $\hat{V}(\tilde{H}(t))$ . Consider the jumps of  $\tilde{H}(t)$  and  $\hat{V}(\tilde{H}(t))$  at the event times  $t_1 < t_2 < \dots < t_D$  as follows:

$$\begin{aligned} \Delta\tilde{H}(t_i) &= \tilde{H}(t_i) - \tilde{H}(t_{i-1}) \\ \hat{V}(\tilde{H}(t_i)) &= \hat{V}(\tilde{H}(t_i)) - \hat{V}(\tilde{H}(t_{i-1})) \end{aligned}$$

where  $t_0=0$ .

The kernel-smoothed estimator of  $h(t)$  is a weighted average of  $\Delta\tilde{H}(t)$  over event times that are within a bandwidth distance  $b$  of  $t$ . The weights are controlled by the choice of kernel function,  $K()$ , defined on the interval  $[-1,1]$ . The choices are as follows:

- uniform kernel:

$$K_U(x) = \frac{1}{2}, \quad -1 \leq x \leq 1$$

- Epanechnikov kernel:

$$K_E(x) = \frac{3}{4}(1 - x^2), \quad -1 \leq x \leq 1$$

- biweight kernel:

$$K_{BW}(x) = \frac{15}{16}(1 - x^2)^2, \quad -1 \leq x \leq 1$$

The kernel-smoothed hazard rate estimator is defined for all time points on  $(0, t_D)$ . For time points  $t$  for which  $b \leq t \leq t_D - b$ , the kernel-smoothed estimated of  $h(t)$  based on the kernel  $K()$  is given by

$$\hat{h}(t) = \frac{1}{b} \sum_{i=1}^D K\left(\frac{t - t_i}{b}\right) \Delta \tilde{H}(t_i)$$

The variance of  $\hat{h}(t)$  is estimated by

$$\hat{\sigma}^2(\hat{h}(t)) = \frac{1}{b^2} \sum_{i=1}^D K\left(\frac{t - t_i}{b}\right)^2 \Delta \hat{V}(\tilde{H}(t_i))$$

For  $t < b$ , the symmetric kernels  $K()$  are replaced by the corresponding asymmetric kernels of Gasser and Müller (1979). Let  $q = \frac{t}{b}$ . The modified kernels are as follows:

- uniform kernel:

$$K_{U,q}(x) = \frac{4(1 + q^3)}{(1 + q)^4} + \frac{6(1 - q)}{(1 + q)^3}x, \quad -1 \leq x \leq q$$

- Epanechnikov kernel:

$$K_{E,q}(x) = K_E(x) \frac{64(2 - 4q + 6q^2 - 3q^3) + 240(1 - q)^2x}{(1 + q)^4(19 - 18q + 3q^2)}, \quad -1 \leq x \leq q$$

- biweight kernel:

$$K_{BW,q}(x) = K_{BW}(x) \frac{64(8 - 24q + 48q^2 - 45q^3 + 15q^4) + 1120(1 - q)^3x}{(1 + q)^5(81 - 168q + 126q^2 - 40q^3 + 5q^4)}, \quad -1 \leq x \leq q$$

For  $t_D - b \leq t \leq t_D$ , let  $q = \frac{t_D - t}{b}$ . The asymmetric kernels for  $t < b$  are used with  $x$  replaced by  $-x$ .

Using the log transform on the smoothed hazard rate, the  $100(1 - \alpha)\%$  pointwise confidence interval for the smoothed hazard rate  $h(t)$  is given by

$$\hat{h}(t) = \hat{h}(t) \exp\left[\pm \frac{z_{1-\alpha/2} \hat{\sigma}(\hat{h}(t))}{\hat{h}(t)}\right]$$

where  $z_{1-\frac{\alpha}{2}}$  is the  $100(1 - \frac{\alpha}{2})$ th percentile of the standard normal distribution.

### Optimal Bandwidth

The following mean integrated squared error (MISE) over the range  $\tau_L$  and  $\tau_U$  is used as a measure of the global performance of the kernel function estimator:

$$\begin{aligned} \text{MISE}(b) &= E \int_{\tau_L}^{\tau_U} (\hat{h}(i) - h(u))^2 du \\ &= E \int_{\tau_L}^{\tau_U} \hat{h}^2(u) du - 2E \int_{\tau_L}^{\tau_U} \hat{h}(u)h(u) du + E \int_{\tau_L}^{\tau_U} h^2(u) du \end{aligned}$$

The last term is independent of the choice of the kernel and bandwidth and can be ignored when you are looking for the best value of  $b$ . The first integral can be approximated by using the trapezoid rule by evaluating  $\hat{h}(t)$  at a grid of points  $\tau_L = u_1 < \dots < u_M = \tau_U$ . You can specify  $\tau_L$ ,  $\tau_R$ , and  $M$  by using the options GRIDL=, GRIDU=, and NMINGRID=, respectively, of the HAZARD plot. The second integral can be estimated by the Ramlau-Hansen (1983a, b) cross-validation estimate:

$$\frac{1}{b} \sum_{i \neq j} K\left(\frac{t_i - t_j}{b}\right) \Delta \hat{H}(t_i) \Delta \hat{H}(t_j)$$

Therefore, for a fixed kernel, the optimal bandwidth is the quantity  $b$  that minimizes

$$g(b) = \sum_{i=1}^{M-1} \left[ \frac{u_{i+1} - u_i}{2} \left( \hat{h}^2(u_i) + \hat{h}^2(u_{i+1}) \right) \right] - \frac{2}{b} \sum_{i \neq j} K\left(\frac{t_i - t_j}{b}\right) \Delta \hat{H}(t_i) \Delta \hat{H}(t_j)$$

The minimization is carried out by the golden section search algorithm.

### Comparison of Two or More Groups of Survival Data

Let  $K$  be the number of groups. Let  $S_k(t)$  be the underlying survivor function of the  $k$ th group,  $k = 1, \dots, K$ . The null and alternative hypotheses to be tested are

$$H_0 : S_1(t) = S_2(t) = \dots = S_K(t) \text{ for all } t \leq \tau$$

versus

$$H_1 : \text{at least one of the } S_k(t)\text{'s is different for some } t \leq \tau$$

respectively, where  $\tau$  is the largest observed time.

### Likelihood Ratio Test

The likelihood ratio test statistic (Lawless 1982) for test  $H_0$  versus  $H_1$  assumes that the data in the various samples are exponentially distributed and tests that the scale parameters are equal. The test statistic is computed as

$$\chi^2 = 2N \log\left(\frac{T}{N}\right) - 2 \sum_{k=1}^K N_k \log\left(\frac{T_k}{N_k}\right)$$

where  $N_k$  is the total number of events in the  $k$ th group,  $N = \sum_{k=1}^K N_k$ ,  $T_k$  is the total time on test in the  $k$ th stratum, and  $T = \sum_{k=1}^K T_k$ . The approximate probability value is computed by treating  $\chi^2$  as having a chi-square distribution with  $K - 1$  degrees of freedom.

**Nonparametric Tests**

Let  $(T_i, \delta_i, X_i), i = 1, \dots, n$ , denote an independent sample of right-censored survival data, where  $T_i$  is the possibly right-censored time,  $\delta_i$  is the censoring indicator ( $\delta_i=0$  if  $T_i$  is censored and  $\delta_i=1$  if  $T_i$  is an event time), and  $X_i = 1, \dots, K$  for  $K$  different groups. Let  $t_1 < t_2 < \dots < t_D$  be the distinct event times in the sample. At time  $t_j, j = 1, \dots, D$ , let  $W(t_j)$  be a positive weight function, and let  $Y_{jk} = \sum_{i:T_i \geq t_j} I(X_i = k)$  and  $d_{jk} = \sum_{i:T_i = t_j} \delta_i I(X_i = k)$  be the size of the risk set and the number of events in the  $k$ th group, respectively. Let  $Y_j = \sum_{k=1}^K Y_{jk}, d_j = \sum_{k=1}^K d_{jk}$ .

The choices of the weight function  $W(t_j)$  are given in Table 52.4.

**Table 52.4** Weight Functions for Various Tests

| Test                       | $W(t_i)$                                                    |
|----------------------------|-------------------------------------------------------------|
| Log-rank                   | 1.0                                                         |
| Wilcoxon                   | $Y_j$                                                       |
| Tarone-Ware                | $\sqrt{Y_j}$                                                |
| Peto-Peto                  | $\hat{S}(t_j)$                                              |
| Modified Peto-Peto         | $\tilde{S}(t_j) \frac{Y_j}{Y_j+1}$                          |
| Harrington-Fleming $(p,q)$ | $[\hat{S}(t_j)]^p [1 - \hat{S}(t_j)]^q, p \geq 0, q \geq 0$ |

In Table 52.4,  $\hat{S}(t)$  is the product-limit estimate at  $t$  for the pooled sample, and  $\tilde{S}(t)$  is a survivor function estimate close to  $\hat{S}(t)$  given by

$$\tilde{S}(t) = \prod_{t_j \leq t} \left( 1 - \frac{d_j}{Y_j + 1} \right)$$

**Unstratified Tests** The rank statistics (Klein and Moeschberger 1997, Section 7.3) for testing  $H_0$  versus  $H_1$  have the form of a  $K$ -vector  $\mathbf{v} = (v_1, v_2, \dots, v_K)'$  with

$$v_k = \sum_{j=1}^D \left[ W(t_j) \left( d_{jk} - Y_{jk} \frac{d_j}{Y_j} \right) \right]$$

and the variance of  $v_k$  and the covariance of  $v_k$  and  $v_h$  are, respectively,

$$V_{kk} = \sum_{j=1}^D \left[ W^2(t_j) \frac{d_j(Y_j - d_j)Y_{jk}(Y_j - Y_{jk})}{Y_j^2(Y_j - 1)} \right], \quad 1 \leq k \leq K$$

$$V_{kh} = - \sum_{j=1}^D \left[ W^2(t_j) \frac{d_j(Y_j - d_j)Y_{jk}Y_{jh}}{Y_j^2(Y_j - 1)} \right], \quad 1 \leq k \neq h \leq K$$

The statistic  $v_k$  can be interpreted as a weighted sum of observed minus expected numbers of failure for the  $k$ th group under the null hypothesis of identical survival curves. Let  $\mathbf{V} = (V_{kh})$ . The overall test statistic for homogeneity is  $\mathbf{v}'\mathbf{V}^-\mathbf{v}$ , where  $\mathbf{V}^-$  denotes a generalized inverse of  $\mathbf{V}$ . This statistic is treated as having a chi-square distribution with degrees of freedom equal to the rank of  $\mathbf{V}$  for the purposes of computing an approximate probability level.

**Adjusted Log-Rank Test** PROC LIFETEST computes the weighted log-rank test (Xie and Liu 2005, 2011) if you specify the WEIGHT statement. Let  $(T_i, \delta_i, X_i, w_i), i = 1, \dots, n$ , denote an independent sample of right-censored survival data, where  $T_i$  is the possibly right-censored time,  $\delta_i$  is the censoring indicator ( $\delta_i=0$  if  $T_i$  is censored and  $\delta_i=1$  if  $T_i$  is an event time),  $X_i = 1, \dots, K$  for  $K$  different groups, and  $w_i$  is the weight from the WEIGHT statement. Let  $t_1 < t_2 < \dots < t_D$  be the distinct event times in the sample. At each  $t_j, j = 1, \dots, D$ , and for each  $1 \leq k \leq K$ , let

$$d_{jk} = \sum_{i:T_i=t_j} I(X_i = k) \quad d_{jk}^w = \sum_{i:T_i=t_j} w_i I(X_i = k)$$

$$Y_{jk} = \sum_{i:T_i \geq t_j} I(X_i = k) \quad Y_{jk}^w = \sum_{i:T_i \geq t_j} w_i I(X_i = k)$$

Let  $d_j = \sum_{k=1}^K d_{jk}$  and  $Y_j = \sum_{k=1}^K Y_{jk}$  denote the number of events and the number at risk, respectively, in the combined sample at time  $t_j$ . Similarly, let  $d_j^w = \sum_{k=1}^K d_{jk}^w$  and  $Y_j^w = \sum_{k=1}^K Y_{jk}^w$  denote the weighted number of events and the weighted number at risk, respectively, in the combined sample at time  $t_j$ . The test statistic is

$$v_k = \sum_{j=1}^D \left( d_{jk}^w - Y_{jk}^w \frac{d_j^w}{Y_j^w} \right) \quad k = 1, \dots, K$$

and the variance of  $v_k$  and the covariance of  $v_k$  and  $v_h$  are, respectively,

$$V_{kk} = \sum_{j=1}^D \left\{ \frac{d_j(Y_j - d_j)}{Y_j(Y_j - 1)} \sum_{i=1}^{Y_j} \left[ \left( \frac{Y_{jk}^w}{Y_j^w} \right)^2 w_i^2 I\{X_i \neq k\} + \left( \frac{Y_j^w - Y_{jk}^w}{Y_j^w} \right)^2 w_i^2 I\{X_i = k\} \right] \right\}, \quad 1 \leq k \leq K$$

$$V_{kh} = \sum_{j=1}^D \left\{ \frac{d_j(Y_j - d_j)}{Y_j(Y_j - 1)} \sum_{i=1}^{Y_j} \left[ \frac{Y_{jk}^w Y_{jh}^w}{(Y_j^w)^2} w_i^2 I\{X_i \neq k, h\} - \frac{(Y_j^w - Y_{jk}^w) Y_{jh}^w}{(Y_j^w)^2} w_i^2 I\{X_i = k\} \right. \right. \\ \left. \left. - \frac{(Y_j^w - Y_{jh}^w) Y_{jk}^w}{(Y_j^w)^2} w_i^2 I\{X_i = h\} \right] \right\}, \quad 1 \leq k \neq h \leq K$$

Let  $V = (V_{kh})$ . Under  $H_0$ , the weighted  $K$ -sample test has a  $\chi^2$  statistic given by

$$\chi^2 = (v_1, \dots, v_K) \mathbf{V}^{-1} (v_1, \dots, v_K)'$$

with  $K - 1$  degrees of freedom.

**Stratified Tests** Suppose the test is to be stratified on  $M$  levels of a set of STRATA variables. Based only on the data of the  $s$ th stratum ( $s = 1 \dots M$ ), let  $\mathbf{v}_s$  be the test statistic (Klein and Moeschberger 1997, Section 7.5) for the  $s$ th stratum, and let  $\mathbf{V}_s$  be its covariance matrix. Let

$$\mathbf{v} = \sum_{s=1}^M \mathbf{v}_s$$

$$\mathbf{V} = \sum_{s=1}^M \mathbf{V}_s$$

A global test statistic is constructed as

$$\chi^2 = \mathbf{v}'\mathbf{V}^{-1}\mathbf{v}$$

Under the null hypothesis, the test statistic has a  $\chi^2$  distribution with the same degrees of freedom as the individual test for each stratum.

**Multiple-Comparison Adjustments** Let  $\chi_r^2$  denote a chi-square random variable with  $r$  degrees of freedom. Denote  $\phi$  and  $\Phi$  as the density function and the cumulative distribution function of a standard normal distribution, respectively. Let  $m$  be the number of comparisons; that is,

$$m = \begin{cases} \frac{k(k-1)}{2} & \text{DIFF} = \text{ALL} \\ k-1 & \text{DIFF} = \text{CONTROL} \end{cases}$$

For a two-sided test that compares the survival of the  $j$ th group with that of  $l$ th group,  $1 \leq j \neq l \leq r$ , the test statistic is

$$z_{jl}^2 = \frac{(v_j - v_l)^2}{V_{jj} + V_{ll} - 2V_{jl}}$$

and the raw  $p$ -value is

$$p = \Pr(\chi_1^2 > z_{jl}^2)$$

Adjusted  $p$ -values for various multiple-comparison adjustments are computed as follows:

- Bonferroni adjustment:

$$p = \min\{1, m\Pr(\chi_1^2 > z_{jl}^2)\}$$

- Dunnett-Hsu adjustment: With the first group being the control, let  $\mathbf{C} = (c_{ij})$  be the  $(r-1) \times r$  matrix of contrasts; that is,

$$c_{ij} = \begin{cases} 1 & i = 1, \dots, r-1, j = 2, \dots, r \\ -1 & j = i+1, i = 2, \dots, r \\ 0 & \text{otherwise} \end{cases}$$

Let  $\mathbf{\Sigma} \equiv (\sigma_{ij})$  and  $\mathbf{R} \equiv (r_{ij})$  be covariance and correlation matrices of  $\mathbf{C}\mathbf{v}$ , respectively; that is,

$$\mathbf{\Sigma} = \mathbf{C}\mathbf{V}\mathbf{C}'$$

and

$$r_{ij} = \frac{\sigma_{ij}}{\sqrt{\sigma_{ii}\sigma_{jj}}}$$

The factor-analytic covariance approximation of Hsu (1992) is to find  $\lambda_1, \dots, \lambda_{r-1}$  such that

$$\mathbf{R} = \mathbf{D} + \boldsymbol{\lambda}\boldsymbol{\lambda}'$$

where  $\mathbf{D}$  is a diagonal matrix with the  $j$ th diagonal element being  $1 - \lambda_j$  and  $\boldsymbol{\lambda} = (\lambda_1, \dots, \lambda_{r-1})'$ . The adjusted  $p$ -value is

$$p = 1 - \int_{-\infty}^{\infty} \phi(y) \prod_{i=1}^{r-1} \left[ \Phi\left(\frac{\lambda_i y + z_{jl}}{\sqrt{1 - \lambda_i^2}}\right) - \Phi\left(\frac{\lambda_i y - z_{jl}}{\sqrt{1 - \lambda_i^2}}\right) \right] dy$$

which can be obtained in a DATA step as

$$p = \text{PROBMC}(\text{"DUNNETT2"}, z_{ij}, \dots, r - 1, \lambda_1, \dots, \lambda_{r-1}).$$

- Scheffé adjustment:

$$p = \Pr(\chi_{r-1}^2 > z_{jl}^2)$$

- Šidák adjustment:

$$p = 1 - \{1 - \Pr(\chi_1^2 > z_{jl}^2)\}^m$$

- SMM adjustment:

$$p = 1 - [2\Phi(z_{jl}) - 1]^m$$

which can also be evaluated in a DATA step as

$$p = 1 - \text{PROBMC}(\text{"MAXMOD"}, z_{jl}, \dots, m).$$

- Tukey adjustment:

$$p = 1 - \int_{-\infty}^{\infty} r\phi(y)[\Phi(y) - \Phi(y - \sqrt{2}z_{jl})]^{r-1} dy$$

which can also be evaluated in a DATA step as

$$p = 1 - \text{PROBMC}(\text{"RANGE"}, \sqrt{2}z_{jl}, \dots, r).$$

**Trend Tests** Trend tests (Klein and Moeschberger 1997, Section 7.4) have more power to detect ordered alternatives as

$$H_2 : S_1(t) \geq S_2(t) \geq \dots \geq S_k(t), t \leq \tau, \text{ with at least one inequality}$$

or

$$H_2 : S_1(t) \leq S_2(t) \leq \dots \leq S_k(t), t \leq \tau, \text{ with at least one inequality}$$

Let  $a_1 < a_2 < \dots < a_k$  be a sequence of scores associated with the  $k$  samples. The test statistic and its standard error are given by  $\sum_{j=1}^k a_j v_j$  and  $\sum_{j=1}^k \sum_{l=1}^k a_j a_l V_{jl}$ , respectively. Under  $H_0$ , the  $z$ -score

$$Z = \frac{\sum_{j=1}^k a_j v_j}{\sqrt{\sum_{j=1}^k \sum_{l=1}^k a_j a_l V_{jl}}}$$

has, asymptotically, a standard normal distribution. PROC LIFETEST provides both one-tail and two-tail  $p$ -values for the test.

## Rank Tests for the Association of Survival Time with Covariates

The rank tests for the association of covariates (Kalbfleisch and Prentice 1980, Chapter 6) are more general cases of the rank tests for homogeneity. In this section, the index  $\alpha$  is used to label all observations,  $\alpha = 1, 2, \dots, n$ , and the indices  $i, j$  range only over the observations that correspond to events,  $i, j = 1, 2, \dots, k$ . The ordered event times are denoted as  $t_{(i)}$ , the corresponding vectors of covariates are denoted as  $\mathbf{z}_{(i)}$ , and the ordered times, both censored and event times, are denoted as  $t_\alpha$ .

The rank test statistics have the form

$$\mathbf{v} = \sum_{\alpha=1}^n c_{\alpha, \delta_\alpha} \mathbf{z}_\alpha$$

where  $n$  is the total number of observations,  $c_{\alpha, \delta_\alpha}$  are rank scores, which can be either log-rank or Wilcoxon rank scores,  $\delta_\alpha$  is 1 if the observation is an event and 0 if the observation is censored, and  $\mathbf{z}_\alpha$  is the vector of covariates in the TEST statement for the  $\alpha$ th observation. Notice that the scores,  $c_{\alpha, \delta_\alpha}$ , depend on the censoring pattern and that the terms are summed up over all observations.

The log-rank scores are

$$c_{\alpha, \delta_\alpha} = \sum_{(j:t_{(j)} \leq t_\alpha)} \left( \frac{1}{n_j} - \delta_\alpha \right)$$

and the Wilcoxon scores are

$$c_{\alpha, \delta_\alpha} = 1 - (1 + \delta_\alpha) \prod_{(j:t_{(j)} \leq t_\alpha)} \frac{n_j}{n_j + 1}$$

where  $n_j$  is the number at risk just prior to  $t_{(j)}$ .

The estimates used for the covariance matrix of the log-rank statistics are

$$\mathbf{V} = \sum_{i=1}^k \frac{\mathbf{V}_i}{n_i}$$

where  $\mathbf{V}_i$  is the corrected sum of squares and crossproducts matrix for the risk set at time  $t_{(i)}$ ; that is,

$$\mathbf{V}_i = \sum_{(\alpha:t_\alpha \geq t_{(i)})} (\mathbf{z}_\alpha - \bar{\mathbf{z}}_i)' (\mathbf{z}_\alpha - \bar{\mathbf{z}}_i)$$

where

$$\bar{\mathbf{z}}_i = \sum_{(\alpha:t_\alpha \geq t_{(i)})} \frac{\mathbf{z}_\alpha}{n_i}$$

The estimate used for the covariance matrix of the Wilcoxon statistics is

$$\mathbf{V} = \sum_{i=1}^k \left[ a_i (1 - a_i^*) (2\mathbf{z}_{(i)} \mathbf{z}'_{(i)} + \mathbf{S}_i) - (a_i^* - a_i) \left( a_i \mathbf{x}_i \mathbf{x}'_i + \sum_{j=i+1}^k a_j (\mathbf{x}_i \mathbf{x}'_j + \mathbf{x}_j \mathbf{x}'_i) \right) \right]$$

where

$$a_i = \prod_{j=1}^i \frac{n_j}{n_j + 1}$$

$$a_i^* = \prod_{j=1}^i \frac{n_j + 1}{n_j + 2}$$

$$S_i = \sum_{(\alpha: t_{(i+1)} > t_\alpha > t_{(i)})} \mathbf{z}_\alpha \mathbf{z}'_\alpha$$

$$\mathbf{x}_i = 2\mathbf{z}_{(i)} + \sum_{(\alpha: t_{(i+1)} > t_\alpha > t_{(i)})} \mathbf{z}_\alpha$$

In the case of tied failure times, the statistics  $\mathbf{v}$  are averaged over the possible orderings of the tied failure times. The covariance matrices are also averaged over the tied failure times. Averaging the covariance matrices over the tied orderings produces functions with appropriate symmetries for the tied observations; however, the actual variances of the  $\mathbf{v}$  statistics would be smaller than the preceding estimates. Unless the proportion of ties is large, it is unlikely that this will be a problem.

The univariate tests for each covariate are formed from each component of  $\mathbf{v}$  and the corresponding diagonal element of  $\mathbf{V}$  as  $v_i^2 / V_{ii}$ . These statistics are treated as coming from a chi-square distribution for calculation of probability values.

The statistic  $\mathbf{v}'\mathbf{V}^{-1}\mathbf{v}$  is computed by sweeping each pivot of the  $\mathbf{V}$  matrix in the order of greatest increase to the statistic. The corresponding sequence of partial statistics is tabulated. Sequential increments for including a given covariate and the corresponding probabilities are also included in the same table. These probabilities are calculated as the tail probabilities of a chi-square distribution with one degree of freedom. Because of the selection process, these probabilities should not be interpreted as  $p$ -values.

If desired for data screening purposes, the output data set requested by the OUTTEST= option can be treated as a sum of squares and crossproducts matrix and processed by the REG procedure by using the option METHOD=RSQUARE. Then the sets of variables of a given size can be found that give the largest test statistics. [Output 52.1](#) illustrates this process.

---

## Computer Resources

The data are first read and sorted into strata. If the data are originally sorted by failure time and censoring state, with smaller failure times coming first and event values preceding censored values in cases of ties, the data can be processed by strata without additional sorting. Otherwise, the data are read into memory by strata and sorted.

## Memory Requirements

For a given BY group, define the following:

|      |                                                       |
|------|-------------------------------------------------------|
| $N$  | the total number of observations                      |
| $V$  | the number of STRATA variables                        |
| $C$  | the number of covariates listed in the TEST statement |
| $L$  | total length of the ID variables in bytes             |
| $S$  | number of strata                                      |
| $n$  | maximum number of observations within strata          |
| $b$  | $12 + 8C + L$                                         |
| $m1$ | $(112 + 16V) \times S$                                |
| $m2$ | $50 \times b \times S$                                |
| $m3$ | $(50 + n) \times (b + 4)$                             |
| $m4$ | $8(C + 4)^2$                                          |
| $m5$ | $20N + 8S \times (S + 4)$                             |

The memory, in bytes, required to process the BY group is at least

$$m1 + \max(m2, m3) + m4$$

The test of equality of survival functions across strata requires additional memory ( $m5$  bytes). However, if this additional memory is not available, PROC LIFETEST skips the test for equality of survival functions and finishes the other computations. Additional memory is required for the PLOTS= option. Temporary storage of  $16n$  bytes is required to store the product-limit estimates for plotting.

---

## Output Data Sets

### OUTSURV= Data Set

You can specify the OUTSURV= option in the PROC LIFETEST statement to create an output data set that contains the following columns:

- any specified BY variables
- any specified STRATA variables, their values coming from either their original values or the midpoints of the stratum intervals if endpoints are used to define strata (semi-infinite intervals are labeled by their finite endpoint)
- STRATUM, a numeric variable that numbers the strata

- the time variable as given in the TIME statement. For METHOD=KM, METHOD=BRESLOW, or METHOD=FM, it contains the observed failure or censored times. For the life-table estimates, it contains the lower endpoints of the time intervals.
- SURVIVAL, a variable that contains the survivor function estimates
- CONFTYPE, a variable that contains the name of the transformation applied to the survival time in the computation of confidence intervals (if the OUT= option is specified in the SURVIVAL statement)
- SDF\_LCL, a variable that contains the lower limits of the pointwise confidence intervals for the survivor function
- SDF\_UCL, a variable that contains the upper limits of the pointwise confidence intervals for the survivor function

If the estimation uses the product-limit, Breslow, or Fleming-Harrington method, then the data set also contains the following:

- \_CENSOR\_, an indicator variable that has a value 1 for a censored observation and a value 0 for an event observation
- SDF\_STDERR, a variable that contains the standard error of the survivor function estimator (if the STDERR option is specified in the PROC LIFETEST statement)
- HW\_LCL, a variable that contains the lower limits of the Hall-Wellner confidence bands (if the CONFBAND=HW option or the CONFBAND=ALL option is specified in the PROC LIFETEST statement)
- HW\_UCL, a variable that contains the upper limits of the Hall-Wellner confidence bands (if the CONFBAND=HW option or the CONFBAND=ALL option is specified in the PROC LIFETEST statement)
- EP\_LCL, a variable that contains the lower limits of the equal-precision confidence bands (if the CONFBAND=EP option or the CONFBAND=ALL option is specified in the PROC LIFETEST statement)
- EP\_UCL, a variable that contains the upper limits of the equal-precision confidence bands (if the CONFBAND=EP option or the CONFBAND=ALL option is specified in the PROC LIFETEST statement)

If the estimation uses the life-table method, then the data set also contains the following:

- MIDPOINT, a variable that contains the value of the midpoint of the time interval
- PDF, a variable that contains the density function estimates
- PDF\_LCL, a variable that contains the lower endpoints of the PDF confidence intervals
- PDF\_UCL, a variable that contains the upper endpoints of the PDF confidence intervals
- HAZARD, a variable that contains the hazard estimates
- HAZ\_LCL, a variable that contains the lower endpoints of the hazard confidence intervals

- HAZ\_UCL, a variable that contains the upper endpoints of the hazard confidence intervals

Each survival function contains an initial observation with the value 1 for the SDF and the value 0 for the time. The output data set contains an observation for each distinct failure time if the product-limit, Breslow, or Fleming-Harrington method is used, or it contains an observation for each time interval if the life-table method is used. The product-limit, Breslow, or Fleming-Harrington survival estimates are defined to be right continuous; that is, the estimates at a given time include the factor for the failure events that occur at that time.

Labels are assigned to all the variables in the output data set except the BY variable and the STRATA variable.

### OUTTEST= Data Set

The OUTTEST= option in the LIFETEST statement creates an output data set that contains the rank statistics for testing the association of failure time with covariates. It contains the following:

- any specified BY variables
- \_TYPE\_, a character variable of length 8 that labels the type of rank test, either “LOG-RANK” or “WILCOXON”
- \_NAME\_, a character variable of length 8 that labels the rows of the covariance matrix and the test statistics
- the TIME variable, containing the overall test statistic in the observation that has \_NAME\_ equal to the name of the time variable and the univariate test statistics under their respective covariates.
- all variables listed in the TEST statement

The output is in the form of a symmetric matrix formed by the covariance matrix of the rank statistics bordered by the rank statistics and the overall chi-square statistic. If the value of \_NAME\_ is the name of a variable in the TEST statement, the observation contains a row of the covariance matrix and the value of the rank statistic in the time variable. If the value of \_NAME\_ is the name of the TIME variable, the observation contains the values of the rank statistics in the variables from the TEST list and the value of the overall chi-square test statistic in the TIME variable.

Two complete sets of statistics labeled by the \_TYPE\_ variable are produced, one for the log-rank test and one for the Wilcoxon test.

---

## Displayed Output

If you use the NOPRINT option in the PROC LIFETEST statement, the procedure does not display any output.

## Product-Limit Survival Estimates

The “Product-Limit Survival Estimates” table is displayed if you request the product-limit method of estimation. The table displays the following:

- the observed (event or censored) time
- the number of units at risk (if you specify the ATRISK option in the PROC LIFETEST statement)
- the number of events (if you specify the ATRISK option in the PROC LIFETEST statement)
- the product-limit estimate of the survivor function
- the corresponding estimate of the cumulative distribution function of the failure time
- the standard error estimate of the survivor function estimator
- the Nelson-Aalen cumulative hazard function estimate (if the NELSON option is specified in the PROC LIFETEST statement)
- the standard error of the Nelson-Aalen estimator (if the NELSON option is specified in the PROC LIFETEST statement)
- the number of event times that have been observed
- the number of event or censored times that remain to be observed
- the frequency of the observed times (if you specify the FREQ statement)
- values of the ID variables (if you specify the ID statement)

The ODS name of this table is ProductLimitEstimates.

## Breslow Survival Estimates

The “Breslow Survival Estimates” table is displayed if you request the Breslow method of estimation. The table displays the following:

- the observed (event or censored) time
- the number of units at risk (if you specify the ATRISK option in the PROC LIFETEST statement)
- the number of events (if you specify the ATRISK option in the PROC LIFETEST statement)
- the Breslow estimate of the survivor function
- the corresponding estimate of the cumulative distribution function of the failure time
- the standard error estimate of the survivor function estimator
- the Nelson-Aalen cumulative hazard function estimate (if the NELSON option is specified in the PROC LIFETEST statement)
- the standard error of the Nelson-Aalen estimator (if the NELSON option is specified in the PROC LIFETEST statement)

- the number of event times that have been observed
- the number of event or censored times that remain to be observed
- the frequency of the observed times (if you specify the `FREQ` statement)
- values of the ID variables (if you specify the `ID` statement)

The ODS name of this table is `BreslowEstimates`.

### Fleming-Harrington Survival Estimates

The “Fleming-Harrington Survival Estimates” table is displayed if you request the Fleming-Harrington method of estimation. The table displays the following:

- the observed (event or censored) time
- the number of units at risk (if you specify the `ATRISK` option in the `PROC LIFETEST` statement)
- the number of events (if you specify the `ATRISK` option in the `PROC LIFETEST` statement)
- the Fleming-Harrington estimate of the survivor function
- the corresponding estimate of the cumulative distribution function of the failure time
- the standard error estimate of the survivor function estimator
- the Nelson-Aalen cumulative hazard function estimate (if the `NELSON` option is specified in the `PROC LIFETEST` statement)
- the standard error of the Nelson-Aalen estimator (if the `NELSON` option is specified in the `PROC LIFETEST` statement)
- the number of event times that have been observed
- the number of event or censored times that remain to be observed
- the frequency of the observed times (if you specify the `FREQ` statement)
- values of the ID variables (if you specify the `ID` statement)

The ODS name of this table is `FlemingEstimates`.

### Quartile Estimates

The “Quartiles Estimates” table is displayed if you request the product-limit, Breslow, or Fleming-Harrington method of estimation. The table displays the following:

- point estimates of the quartiles of the survival times
- the lower and upper confidence limits for the quartiles

For ODS purposes, the name of this table is “Quartiles.”

## Mean Estimate

The “Mean Estimate” table is displayed if you request the product-limit, Breslow, or Fleming-Harrington method of estimation. The table displays the following:

- the estimated mean survival time
- the estimated standard error of the mean estimator

The ODS name of this table is Means.

## Life-Table Survival Estimates

The “Life-Table Survival Estimates” table is displayed if you request the life-table method of estimation. The table displays the following:

- the time intervals into which the failure and censored times are distributed. Each interval is from the lower limit, up to but not including the upper limit; if the upper limit is infinity, the missing value is printed.
- the number of events that occur in the interval
- the number of censored observations that fall into the interval
- the effective sample size for the interval
- the estimate of conditional probability of events (failures) in the interval
- the standard error of the conditional probability estimator
- the estimate of the survival function at the beginning of the interval
- the estimate of the cumulative distribution function of the failure time at the beginning of the interval
- the standard error estimate of the survivor function estimator
- the estimate of the median residual lifetime, which is the amount of time elapsed before reducing the number of at-risk units to one-half. This is also known as the *median future lifetime* in Elandt-Johnson and Johnson (1980).
- the estimated standard error of the median residual lifetime estimator
- the density function estimated at the midpoint of the interval
- the standard error estimate of the density estimator
- the hazard rate estimated at the midpoint of the interval
- the standard error estimate of the hazard estimator

The ODS name of this table is LifetableEstimates.

## Summary of the Number of Censored and Uncensored Values

The “Summary of the Number of Censored and Uncensored Values” table displays following:

- the stratum identification (if the STRATA statement is specified)
- the total number of observations
- the number of event observations
- the number of censored observations
- the percentage of censored observations

The ODS name of this table is CensoredSummary.

## Rank Statistics

The “Rank Statistics” table contains the test statistics of the nonparametric  $k$ -sample tests. The ODS name of this table is HomStats.

## Covariance Matrix for the Log-Rank Statistics

The “Covariance Matrix for the Log-Rank Statistics” table is displayed if the log-rank  $k$ -sample test is requested. The ODS name of this table is LogrankHomCov.

## Covariance Matrix for the Wilcoxon Statistics

The “Covariance Matrix for the Wilcoxon Statistics” table is displayed if the Wilcoxon  $k$ -sample test is requested. The ODS name of this table is WilHomCov.

## Covariance Matrix for the Tarone Statistics

The “Covariance Matrix for the Tarone Statistics” table is displayed if the Tarone-Ware  $k$ -sample test is requested. The ODS name of this table is TaroneHomCov.

## Covariance Matrix for the Peto Statistics

The “Covariance Matrix for the Peto Statistics” table is displayed if the Peto-Peto  $k$ -sample test is requested. The ODS name of this table is PetoHomCov.

## Covariance Matrix for the ModPeto Statistics

The “Covariance Matrix for the ModPeto Statistics” table is displayed if the modified Peto-Peto  $k$ -sample test is requested. The ODS name of this table is ModPetoHomCov.

## Covariance Matrix for the Fleming Statistics

The “Covariance Matrix for the Fleming Statistics” table is displayed if the Fleming-Harrington  $k$ -sample test is requested. The ODS name of this table is FlemingHomCov.

### Test of Equality over Strata

The “Test of Equality over Strata” table is displayed if an unstratified  $k$ -sample test is carried out. The table contains the chi-square statistics, degrees of freedom, and  $p$ -values of the nonparametric tests and the likelihood ratio test (which is based on the exponential distribution). The ODS name of this table is HomTests.

### Stratified Test of Equality over Group

The “Stratified Test of Equality over Group” table is displayed if a stratified test is carried out. The table contains the chi-square statistics, degrees of freedom, and  $p$ -values of the stratified tests. The ODS name of this table is HomTests.

### Scores for Trend Test

The “Scores for Trend Test” table is displayed if the TREND option is specified in the STRATA statement. The table contains the set of scores used to construct the trend tests. For ODS purposes, the name of this table is “TrendScores.”

### Trend Tests

The “Trend Tests” table is displayed if the TREND option is specified in the STRATA statement. The table contains the results of the trend tests. The ODS name of this table is TrendTests.

### Adjustment for Multiple Comparisons for the Log-Rank Test

The “Adjustment for Multiple Comparisons for the Log-Rank Test” table is displayed if the log-rank test and a multiple-comparison adjustment method are specified. The table contains the chi-square statistics and the raw and adjusted  $p$ -values of the paired comparisons. The ODS name of this table is SurvDiff.

### Adjustment for Multiple Comparisons for the Wilcoxon Test

The “Adjustment for Multiple Comparisons for the Wilcoxon Test” table is displayed if the Wilcoxon test and a multiple-comparison method are specified. The table contains the chi-square statistics and the raw and adjusted  $p$ -values of the paired comparisons. The ODS name of this table is SurvDiff.

### Adjustment for Multiple Comparisons for the Tarone Test

The “Adjustment for Multiple Comparisons for the Tarone Test” table is displayed if the Tarone-Ware test and a multiple-comparison method are specified. The table contains the chi-square statistics and the raw and adjusted  $p$ -values of the paired comparisons. The ODS name of this table is SurvDiff.

### Adjustment for Multiple Comparisons for the Peto Test

The “Adjustment for Multiple Comparisons for the Peto Test” table is displayed if the Peto-Peto test and a multiple-comparison method are specified. The table contains the chi-square statistics and the raw and adjusted  $p$ -values of the paired comparisons. The ODS name of this table is SurvDiff.

### Adjustment for Multiple Comparisons for the ModPeto Test

The “Adjustment for Multiple Comparisons for the ModPeto Test” table is displayed if the modified Peto-Peto test and a multiple-comparison method are specified. The table contains the chi-square statistics and the raw and adjusted  $p$ -values of the paired comparisons. The ODS name of this table is SurvDiff.

### Adjustment for Multiple Comparisons for the Fleming Test

The “Adjustment for Multiple Comparisons for the Fleming Test” table is displayed if the Fleming-Harrington test and a multiple-comparison method are specified. The table contains the chi-square statistics and the raw and adjusted  $p$ -values of the paired comparisons. The ODS name of this table is SurvDiff.

### Univariate Chi-Squares for the Log-Rank Test

The “Univariate Chi-Squares for the Log-Rank Test” table is displayed if the TEST statement is specified. The table displays the log-rank test results for individual variables in the TEST statement. The ODS name of this table is LogUniChiSq.

### Covariance Matrix of the Log-Rank Statistics

The “Covariance Matrix of the Log-Rank Statistics” table is displayed if the TEST statement is specified. The table displays the estimated covariance matrix of the log-rank statistics for association. The ODS name of this table is LogTestCov.

### Forward Stepwise Sequence of Chi-Squares for the Log-Rank Test

The “Forward Stepwise Sequence of Chi-Squares for the Log-Rank Test” table is displayed if the TEST statement is specified. The table contains the sequence of partial chi-square statistics for the log-rank test in the order of the greatest increase to the overall test statistic, the degrees of freedom of the partial chi-square statistics, the approximate probability values of the partial chi-square statistics, the chi-square increments for including the given variables, and the probability values of the chi-square increments. The ODS name of this table is LogForStepSeq.

### Univariate Chi-Squares for the Wilcoxon Test

The “Univariate Chi-Squares for the Wilcoxon Test” table displays the Wilcoxon test results for individual variables in the TEST statement. The ODS name of this table is WilUniChiSq.

### Covariance Matrix of the Wilcoxon Statistics

The “Covariance Matrix of the Wilcoxon Statistics” table is displayed if the TEST statement is specified. The table displays the estimated covariance matrix of the Wilcoxon statistics for association. The ODS name of this table is WilTestCov.

### Forward Stepwise Sequence of Chi-Squares for the Wilcoxon Test

The “Forward Stepwise Sequence of Chi-Squares for the Wilcoxon Test” table is displayed if the TEST statement is specified. The table contains the sequence of partial chi-square statistics for the Wilcoxon test in the order of the greatest increase to the overall test statistic, the degrees of freedom of the partial chi-square statistics, the approximate probability values of the partial chi-square statistics, the chi-square

increments for including the given variables, and the probability values of the chi-square increments. The ODS name of this table is WilForStepSeq.

## ODS Table Names

PROC LIFETEST assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 52.5. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 52.5** ODS Tables Produced by PROC LIFETEST

| ODS Table Name        | Description                                                           | Statement / Option                  |
|-----------------------|-----------------------------------------------------------------------|-------------------------------------|
| BreslowEstimates      | Breslow estimates                                                     | PROC LIFETEST METHOD=B              |
| CensoredSummary       | Number of event and censored observations                             | PROC LIFETEST<br>METHOD=PL   B   FH |
| FlemingEstimates      | Fleming-Harrington estimates                                          | PROC LIFETEST<br>METHOD=FH          |
| FlemingHomCov         | Covariance matrix for $k$ -sample FLEMING statistics                  | STRATA / TEST=FLEMING               |
| HomStats              | Test statistics for $k$ -sample tests                                 | STRATA / TEST=                      |
| HomTests              | Results of $k$ -sample tests                                          | STRATA / TEST=                      |
| LifetableEstimates    | Life-table survival estimates                                         | PROC LIFETEST<br>METHOD=LT          |
| LogForStepSeq         | Forward stepwise sequence for the log-rank statistics for association | TEST                                |
| LogrankHomCov         | Covariance matrix for $k$ -sample LOGRANK statistics                  | STRATA / TEST=LOGRANK               |
| LogTestCov            | Covariance matrix for log-rank statistics for association             | TEST                                |
| LogUniChisq           | Univariate chi-squares for log-rank statistics for association        | TEST                                |
| Means                 | Mean and standard error of survival times                             | PROC LIFETEST<br>METHOD=PL          |
| ModPetoHomCov         | Covariance matrix for $k$ -sample MODPETO statistics                  | STRATA / TEST=MODPETO               |
| PetoHomCov            | Covariance matrix for $k$ -sample PETO statistics                     | STRATA / TEST=PETO                  |
| ProductLimitEstimates | Product-limit survival estimates                                      | PROC LIFETEST<br>METHOD=PL          |
| Quartiles             | Quartiles of the survival times                                       | PROC LIFETEST<br>METHOD=PL   B   FH |
| SurvDiff              | Adjustments for multiple comparisons                                  | STRATA / ADJUST= and DIFF=          |
| TaroneHomCov          | Covariance matrix for $k$ -sample TARONE statistics                   | STRATA / TEST=TARONE                |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The survival plot is produced by default; other graphs are produced by using the PLOTS= option in the PROC LIFETEST statement. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC LIFETEST generates are listed in [Table 52.6](#), along with the required keywords for the PLOTS= option.

**Table 52.6** Graphs Produced by PROC LIFETEST

| ODS Graph Name        | Plot Description                                                                                                            | PLOTS=Option      |
|-----------------------|-----------------------------------------------------------------------------------------------------------------------------|-------------------|
| DensityPlot           | Estimated density for life-table method                                                                                     | PDF               |
| FailurePlot           | Estimated failure function                                                                                                  | SURVIVAL(FAILURE) |
| HazardPlot            | Estimated hazard function for life-table method or smoothed hazard for product-limit, Breslow, or Fleming-Harrington method | HAZARD            |
| LogNegLogSurvivalPlot | Log of negative log of the estimated survivor function                                                                      | LOGLOGS           |

Table 52.6 *continued*

| ODS Graph Name     | Plot Description                                              | PLOTS=Option      |
|--------------------|---------------------------------------------------------------|-------------------|
| NegLogSurvivalPlot | Negative log of the estimated survivor function               | LOGSURV           |
| SurvivalPlot       | Estimated survivor function                                   | SURVIVAL          |
| SurvivalPlot       | Estimated survivor function with number of subjects at risk   | SURVIVAL(ATRISK=) |
| SurvivalPlot       | Estimated survivor function with point-wise confidence limits | SURVIVAL(CL)      |
| SurvivalPlot       | Estimated survivor function with equal-precision band         | SURVIVAL(CB=EP)   |
| SurvivalPlot       | Estimated survivor function with Hall-Wellner band            | SURVIVAL(CB=HW)   |
| SurvivalPlot       | Estimated survivor function with homogeneity test $p$ -value  | SURVIVAL(TEST)    |

### Additional Dynamic Variables for Survival Plots Using ODS Graphics

PROC LIFETEST passes a number of summary statistics as dynamic variables to the ODS Graphics for survival plots. Table 52.7 and Table 52.8 list these additional dynamic variables for the Kaplan-Meier curves and the life-table curves, respectively. These dynamic variables are not declared in the templates for the survival curves, but you can declare them and use them to enhance the default plots. The names of the dynamic variables depend on the STRATA= suboption of the PLOTS=SURVIVAL option: STRATA=INDIVIDUAL produces a separate plot for each stratum, and STRATA=OVERALL produces one plot with overlaid curves.

Table 52.7 Additional Dynamic Variables for `Stat.Graphics.ProductLimitSurvival`

| STRATA=    | Dynamic         | Description                                      |
|------------|-----------------|--------------------------------------------------|
| OVERLAY    | StrVal $j$      | Label for the $j$ th stratum                     |
|            | NObs $j$        | Number of observations in the $j$ th stratum     |
|            | NEvent $j$      | Number of events in the $j$ th stratum           |
|            | Median $j$      | Median survival time of the $j$ th stratum       |
|            | LowerMedian $j$ | Lower median survival time of the $j$ th stratum |
|            | UpperMedian $j$ | Upper median survival time of the $j$ th stratum |
| INDIVIDUAL | PctMedianConfid | Confidence of the median intervals in percent    |
|            | NObs            | Number of observations                           |
|            | NEvent          | Number of events                                 |
|            | Median          | Median survival time                             |
|            | LowerMedian     | Lower median survival time                       |
|            | UpperMedian     | Upper median survival time                       |
|            | PctMedianConfid | Confidence of the median interval in percent     |

**Table 52.8** Additional Dynamic Variables for `Stat.Graphics.LifetableSurvival`

| STRATA=    | Dynamic | Description                                       |
|------------|---------|---------------------------------------------------|
| OVERLAY    | StrValj | Label for the <i>j</i> th stratum                 |
|            | NObsj   | Number of observations in the <i>j</i> th stratum |
|            | NEventj | Number of events in the <i>j</i> th stratum       |
| INDIVIDUAL | NObs    | Number of observations                            |
|            | NEvent  | Number of events                                  |

See the section “The Graph Template Language” on page 707 in Chapter 22, “ODS Graphics Template Modification,” for the general use of dynamic variables. For the use of the particular dynamic variables shown in this section, see the sections “Modifying the Layout and Adding a New Inset Table” on page 766 and “Displaying Survival Summary Statistics” on page 784 in Chapter 22, “ODS Graphics Template Modification.”

## Modifying the ODS Template for Survival Plots

PROC LIFETEST, like other statistical procedures, provides a PLOTS= option and other options for modifying its output without requiring template changes. Those options are sufficient for most purposes. When those options are not sufficient, you can change a graph by changing the graph template. “Example 22.3: Customizing Survival Plots” on page 748 in Chapter 22, “ODS Graphics Template Modification,” shows how to find the name of the template, display the template by using PROC TEMPLATE and the SOURCE statement, and make a series of template changes.

The example consists of the following parts:

- **Modifying the plot title:** This part identifies the template, displays it, explains its overall structure, and modifies the titles. See the section “Modifying the Plot Title” on page 749 in Chapter 22, “ODS Graphics Template Modification.”
- **Modifying the axes:** This part explains the options that control the X and Y axes, and shows how to modify the ticks and axis labels. See the section “Modifying the Axes” on page 753 in Chapter 22, “ODS Graphics Template Modification.”
- **Creating a template that is easy to modify:** This part shows how you can reorganize and modularize the entire template to make it easy to customize in various ways. See the section “Creating a Template That Is Easy to Modify” on page 756 in Chapter 22, “ODS Graphics Template Modification.”
- **Modifying the plot title in the revised template:** This part shows how to change the title by using the revised template. See the section “Modifying the Plot Title in the Revised Template” on page 762 in Chapter 22, “ODS Graphics Template Modification.”
- **Modifying the legend and inset table:** This part removes the small inset table and moves the legend inside the graph. The censoring information above the X axis is moved outside the graph. See the section “Modifying the Legend and Inset Table” on page 763 in Chapter 22, “ODS Graphics Template Modification.”

- **Modifying the layout and adding a new inset table:** This part moves the event and total information out of the graph and the legend in. It also moves the small inset table. See the section “[Modifying the Layout and Adding a New Inset Table](#)” on page 766 in Chapter 22, “[ODS Graphics Template Modification](#).”
- **Changing line styles:** This part shows how to modify a style template to change line colors and styles. See the section “[Changing Line Styles](#)” on page 773 in Chapter 22, “[ODS Graphics Template Modification](#).”
- **Changing fonts:** This part shows how to change the graph template and the style template to change some of the fonts that are used in the graph. See the section “[Changing Fonts](#)” on page 776 in Chapter 22, “[ODS Graphics Template Modification](#).”
- **Changing how censored data are displayed:** This part shows how to change or remove the plus marks that are used to display censored observations. See the section “[Changing How Censored Data Are Displayed](#)” on page 781 in Chapter 22, “[ODS Graphics Template Modification](#).”
- **Displaying survival summary statistics:** This part adds to the graph a table with event, censoring, and survival information. See the section “[Displaying Survival Summary Statistics](#)” on page 784 in Chapter 22, “[ODS Graphics Template Modification](#).”

## Examples: LIFETEST Procedure

---

### Example 52.1: Product-Limit Estimates and Tests of Association

The data presented in Appendix I of Kalbfleisch and Prentice (1980) are coded in the following DATA step. The response variable, `SurvTime`, is the survival time in days of a lung cancer patient. Negative values of `SurvTime` are censored values. The covariates are `Cell` (type of cancer cell), `Therapy` (type of therapy: standard or test), `Prior` (prior therapy: 0=no, 1=yes), `Age` (age in years), `DiagTime` (time in months from diagnosis to entry into the trial), and `Kps` (performance status). A censoring indicator variable `Censor` is created from the data, with the value 1 indicating a censored time and the value 0 indicating an event time. Since there are only two types of therapy, an indicator variable, `Treatment`, is constructed for therapy type, with value 0 for standard therapy and value 1 for test therapy.

```

In the following statements, PROC LIFETEST is invoked to compute the product-limit estimate of the survivor function for each type of cancer cell and to analyze the effects of the variables Age, Prior, DiagTime, Kps, and Treatment on the survival of the patients. These prognostic factors are specified in the TEST statement, and the variable Cell is specified in the STRATA statement. ODS Graphics must be enabled before producing graphs. Graphical displays of the product-limit estimates (S), the negative log estimates (LS), and the log of negative log estimates (LLS) are requested through the PLOTS= option in the PROC LIFETEST statement. Because of a few large survival times, a MAXTIME of 600 is used to set the scale of the time axis; that is, the time scale extends from 0 to a maximum of 600 days in the plots. The variable Therapy is specified in the ID statement to identify the type of therapy for each observation in the product-limit estimates. The OUTTEST option specifies the creation of an output data set named Test to contain the rank test matrices for the covariates.

```

ods graphics on;
proc lifetest data=VALung plots=(s,ls,lls) outtest=Test maxtime=600;
 time SurvTime*Censor(1);
 id Therapy;
 strata Cell;
 test Age Prior DiagTime Kps Treatment;
run;
ods graphics off;

```

Output 52.1.1 through Output 52.1.4 display the product-limit estimates of the survivor functions for the four cell types. Summary statistics of the survival times are also shown. The median survival times are 51 days, 156 days, 51 days, and 118 days for patients with adeno cells, large cells, small cells, and squamous cells, respectively.

**Output 52.1.1** Estimation Results for Adeno Cells

NOTE: The marked survival times are censored observations.

The distribution of event and censored observations among the four cell types is summarized in [Output 52.1.5](#).

**Output 52.1.5** Summary of Censored and Uncensored Values

| Summary of the Number of Censored and Uncensored Values |          |       |        |          |                  |
|---------------------------------------------------------|----------|-------|--------|----------|------------------|
| Stratum                                                 | Cell     | Total | Failed | Censored | Percent Censored |
| 1                                                       | adeno    | 27    | 26     | 1        | 3.70             |
| 2                                                       | large    | 27    | 26     | 1        | 3.70             |
| 3                                                       | small    | 48    | 45     | 3        | 6.25             |
| 4                                                       | squamous | 35    | 31     | 4        | 11.43            |
| -----                                                   |          |       |        |          |                  |
| Total                                                   |          | 137   | 128    | 9        | 6.57             |

The graph of the estimated survivor functions is shown in [Output 52.1.6](#). The adeno cell curve and the small cell curve are much closer to each other than they are to the large cell curve or the squamous cell curve. The survival rates of the adeno cell patients and the small cell patients decrease rapidly to approximately 29% in 90 days. Shapes of the large cell curve and the squamous cell curve are quite different, although both decrease less rapidly than those of the adeno and small cells. The squamous cell curve decreases more rapidly initially than the large cell curve, but the role is reversed in the later period.

**Output 52.1.6** Graph of the Estimated Survivor Functions

The graph of the negative log of the estimated survivor functions is displayed in [Output 52.1.7](#). [Output 52.1.8](#) displays the log of the negative log of the estimated survivor functions against the log of time.

Output 52.1.7 Graph of Negative Log of the Estimated Survivor Functions

**Output 52.1.8** Graph of Log of the Negative Log of the Estimated Survivor Functions

Results of the homogeneity tests across cell types are given in [Output 52.1.9](#). The log-rank and Wilcoxon statistics and their corresponding covariance matrices are displayed. Also given is a table that consists of the approximate chi-square statistics, degrees of freedom, and  $p$ -values for the log-rank, Wilcoxon, and likelihood ratio tests. All three tests indicate strong evidence of a significant difference among the survival curves for the four types of cancer cells ( $p < 0.0001$ ).

**Output 52.1.9** Homogeneity Tests across Cell Types

| Rank Statistics |          |          |
|-----------------|----------|----------|
| Cell            | Log-Rank | Wilcoxon |
| adeno           | 10.306   | 697.0    |
| large           | -8.549   | -1085.0  |
| small           | 14.898   | 1278.0   |
| squamous        | -16.655  | -890.0   |

Results of the log-rank test of the prognostic variables are shown in [Output 52.1.10](#). The univariate test results correspond to testing each prognostic factor marginally. The joint covariance matrix of these univariate test statistics is also displayed. In computing the overall chi-square statistic, the partial chi-square statistics following a forward stepwise entry approach are tabulated.

Consider the log-rank test in [Output 52.1.10](#). Since the univariate test for Kps has the largest chi-square (43.4747) among all the covariates, Kps is entered first. At this stage, the partial chi-square and the chi-square increment for Kps are the same as the univariate chi-square. Among all the covariates not in the model (Age, Prior, DiagTime, Treatment), Treatment has the largest approximate chi-square increment (1.7261) and is entered next. The approximate chi-square for the model that contains Kps and Treatment is  $43.4747 + 1.7261 = 45.2008$  with 2 degrees of freedom. The third covariate entered is Age. The fourth is Prior, and the fifth is DiagTime. The overall chi-square statistic in the last line of the output is the partial chi-square for including all the covariates. It has a value of 46.4200 with 5 degrees of freedom, which is highly significant ( $p < 0.0001$ ).

**Output 52.1.10** Log-Rank Test of the Prognostic Factors

You can establish this forward stepwise entry of prognostic factors by passing the matrix corresponding to the log-rank test to the RSQUARE method in the REG procedure, as follows. PROC REG finds the sets of variables that yield the largest chi-square statistics.

```

data RSq;
 set Test;
 if _type_='LOG RANK';
 type='cov';
run;
proc print data=RSq;
run;
proc reg data=RSq(type=COV);
 model SurvTime=Age Prior DiagTime Kps Treatment
 / selection=rsquare;
 title 'All Possible Subsets of Covariates for the log-rank Test';
run;

```

Output 52.1.11 displays the univariate statistics and their covariance matrix for the log-rank test.

**Output 52.1.11** Log-Rank Statistics and Covariance Matrix

| Obs | _TYPE_ | _NAME_    | SurvTime | Age      | Prior   | DiagTime | Kps      | Treatment |
|-----|--------|-----------|----------|----------|---------|----------|----------|-----------|

Results of the best subset regression are shown in [Output 52.1.12](#). The variable Kps generates the largest univariate test statistic among all the covariates, the pair Kps and Age generate the largest test statistic among any other pairs of covariates, and so on. The entry order of covariates is identical to that of PROC LIFETEST.

## Example 52.2: Enhanced Survival Plot and Multiple-Comparison Adjustments

This example highlights a number of features in the survival plot that uses ODS Graphics. Also shown in this example are comparisons of survival curves based on multiple comparison adjustments. Data of 137 bone marrow transplant patients extracted from Klein and Moeschberger (1997) have been saved in the data set BMT in the Sashelp library. At the time of transplant, each patient is classified into one of three risk categories: ALL (acute lymphoblastic leukemia), AML (acute myelocytic leukemia)-Low Risk, and AML-High Risk. The endpoint of interest is the disease-free survival time, which is the time to death or relapse or to the end of the study in days. In this data set, the variable Group represents the patient's risk category, the variable T represents the disease-free survival time, and the variable Status is the censoring indicator, with the value 1 indicating an event time and the value 0 a censored time.

The following step displays the first 10 observations of the BMT data set in [Output 52.2.1](#). The data set is available in the Sashelp library.

```
proc print data=Sashelp.BMT(obs=10);
run;
```

**Output 52.2.1** A Subset of the Bone Marrow Transplant Data

| Obs | Group | T    | Status |
|-----|-------|------|--------|
| 1   | ALL   | 2081 | 0      |
| 2   | ALL   | 1602 | 0      |
| 3   | ALL   | 1496 | 0      |
| 4   | ALL   | 1462 | 0      |
| 5   | ALL   | 1433 | 0      |
| 6   | ALL   | 1377 | 0      |
| 7   | ALL   | 1330 | 0      |
| 8   | ALL   | 996  | 0      |
| 9   | ALL   | 226  | 0      |
| 10  | ALL   | 1199 | 0      |

In the following statements, PROC LIFETEST is invoked to compute the product-limit estimate of the survivor function for each risk category. Using ODS Graphics, you can display the number of subjects at risk in the survival plot. The **PLOTS=** option requests that the survival curves be plotted, and the **ATRISK=** suboption specifies the time points at which the at-risk numbers are displayed. In the STRATA statement, the **ADJUST=SIDAK** option requests the Šidák multiple-comparison adjustment, and by default, all paired comparisons are carried out.

```
ods graphics on;

proc lifetest data=sashelp.BMT plots=survival(atrisk=0 to 2500 by 500);
 time T * Status(0);
 strata Group / test=logrank adjust=sidak;
run;
```

[Output 52.2.2](#) displays the estimated disease-free survival for the three leukemia groups with the number of subjects at risk at 0, 500, 1,000, 1,500, 2,000, and 2,500 days. Patients in the AML-Low Risk group experience a longer disease-free survival than those in the ALL group, who in turn fare better than those in the AML-High Risk group.

**Output 52.2.2** Estimated Disease-Free Survival for 137 Bone Marrow Transplant Patients

The log-rank test (Output 52.2.3) shows that the disease-free survival times for these three risk groups are significantly different ( $p = 0.001$ ).

**Output 52.2.3** Log-Rank Test of Disease Group Homogeneity

| Test of Equality over Strata |            |    |                 |
|------------------------------|------------|----|-----------------|
| Test                         | Chi-Square | DF | Pr > Chi-Square |
| Log-Rank                     | 13.8037    | 2  | 0.0010          |

The Šidák multiple-comparison results are shown in [Output 52.2.4](#). There is no significant difference in disease-free survivor functions between the ALL and AML-High Risk groups ( $p = 0.2779$ ). The difference between the ALL and AML-Low Risk groups is marginal ( $p = 0.0685$ ), but the AML-Low Risk and AML-High Risk groups have significantly different disease-free survivor functions ( $p = 0.0006$ ).

**Output 52.2.4** All Paired Comparisons

| Adjustment for Multiple Comparisons for the Logrank Test |               |            |          |        |
|----------------------------------------------------------|---------------|------------|----------|--------|
| Strata Comparison                                        |               |            | p-Values |        |
| Group                                                    | Group         | Chi-Square | Raw      | Sidak  |
| ALL                                                      | AML-High Risk | 2.6610     | 0.1028   | 0.2779 |
| ALL                                                      | AML-Low Risk  | 5.1400     | 0.0234   | 0.0685 |
| AML-High Risk                                            | AML-Low Risk  | 13.8011    | 0.0002   | 0.0006 |

Suppose you consider the AML-Low Risk group as the reference group. You can use the `DIFF=` option in the `STRATA` statement to designate this risk group as the control and apply a multiple-comparison adjustment to the  $p$ -values for the paired comparison between the AML-Low Risk group with each of the other groups. Consider the Šidák correction again. You specify the `ADJUST=` and `DIFF=` options as in the following statements:

```
proc lifetest data=sashelp.BMT notable plots=none;
 time T * Status(0);
 strata Group / test=logrank adjust=sidak diff=control('AML-Low Risk');
run;
```

[Output 52.2.5](#) shows that although both the ALL and AML-High Risk groups differ from the AML-Low Risk group at the 0.05 level, the difference between the AML-High Risk and the AML-Low Risk group is highly significant ( $p = 0.0004$ ).

**Output 52.2.5** Comparisons with the Reference Group

| The LIFETEST Procedure                                   |              |            |          |        |
|----------------------------------------------------------|--------------|------------|----------|--------|
| Adjustment for Multiple Comparisons for the Logrank Test |              |            | p-Values |        |
| Strata Comparison                                        |              |            | p-Values |        |
| Group                                                    | Group        | Chi-Square | Raw      | Sidak  |
| ALL                                                      | AML-Low Risk | 5.1400     | 0.0234   | 0.0462 |
| AML-High Risk                                            | AML-Low Risk | 13.8011    | 0.0002   | 0.0004 |

The survival plot that is displayed in [Output 52.2.2](#) might be sufficient for many purposes, but you might have other preferences. Typical alternatives include displaying the number of subjects at risk outside the plot area, reordering the stratum labels in the survival plot legend, and displaying the strata in the at-risk table by using their full labels. PROC LIFETEST provides options that you can use to make these changes without requiring template changes. In the `sashelp.BMT` data set, the variable `Group` that represents the strata is a character variable with three values, namely (in alphabetical order), ALL, AML-High Risk, and AML-Low Risk. It might be desirable to present the strata in the order ALL, AML-Low Risk, and AML-High Risk. The `ORDER=INTERNAL` option in the `STRATA` statement enables you to order the strata by their internal values. In the following statements, the new dataset `Bmt2` is a copy of `sashelp.BMT` with the variable `Group` changed to a numeric variable with values 1, 2, and 3 representing ALL, AML-Low Risk, and AML-High Risk, respectively. The original character values of `Group` are kept as the formatted values, which are used to label the strata in the printed output.

```
proc format;
 invalue $bmtifmt 'ALL' = 1 'AML-Low Risk' = 2 'AML-High Risk' = 3;
 value bmtfmt 1 = 'ALL' 2 = 'AML-Low Risk' 3 = 'AML-High Risk';
run;

data Bmt2;
 set sashelp.BMT(rename=(Group=G));
 Group = input(input(G, $bmtifmt.), 1.);
 label Group = 'Disease Group';
 format Group bmtfmt.;
run;
```

The following statements produce a survival plot that has all the aforementioned modifications. The new data set `Bmt2` is used as the input data. The `OUTSIDE` and `MAXLEN=` options are specified in the `PLOTS=` option. The `OUTSIDE` option draws the at-risk table outside the plot area. Because the longest label of the strata has 13 characters, specifying `MAXLEN=13` is sufficient to display all the stratum labels in the at-risk table. The `ORDER=INTERNAL` option in the `STRATA` statement orders the strata by their numerical values 1, 2, and 3, which represent the order ALL, AML-Low Risk, and AML-High Risk, respectively.

```
proc LIFETEST data=Bmt2 plots=s(atrisk(outside maxlen=13)=0 to 2500 by 500);
 time T*Status(0);
 strata Group / order=internal;
run;
```

The modified survival plot is displayed in [Output 52.2.6](#). The most noticeable change from [Output 52.2.2](#) is that the number of subjects at risk is displayed below the time axis. Other changes include displaying the full labels of the strata in the at-risk table and presenting the strata in the order ALL, AML-Low Risk, and AML-High Risk.

**Output 52.2.6** Modified Disease-Free Survival for Bone Marrow Transplant Patients

Klein and Moeschberger (1997, Section 4.4) describe in detail how to compute the Hall-Wellner (HW) and equal-precision (EP) confidence bands for the survivor function. You can output these simultaneous confidence intervals to a SAS data set by using the `CONFBAND=` and `OUTSURV=` options in the `PROC LIFETEST` statement. You can display survival curves with pointwise and simultaneous confidence limits through ODS Graphics. When the survival data are stratified, displaying all the survival curves and their confidence limits in the same plot can make the plot appear cluttered. In the following statements, the `PLOTS=` specification requests that the survivor functions be displayed along with their pointwise confidence limits (CL) and Hall-Wellner confidence bands (`CB=HW`). The `STRATA=``PANEL` specification requests that the survival curves be displayed in a panel of three plots, one for each risk group.

```
proc lifetest data=Bmt2 plots=survival(cl cb=hw strata=panel);
 time T * Status(0);
 strata Group/order=internal;
run;
```

```
ods graphics off;
```

The panel plot is shown in [Output 52.2.7](#).

**Output 52.2.7** Estimated Disease-Free Survivor Functions with Confidence Limits

## Example 52.3: Life-Table Estimates for Males with Angina Pectoris

The data in this example come from Lee (1992, p. 91) and represent the survival rates of males with angina pectoris. Survival time is measured as years from the time of diagnosis. In the following DATA step, the data are read as number of events and number of withdrawals in each one-year time interval for 16 intervals. Three variables are constructed from the data: Years (an artificial time variable with values that are the midpoints of the time intervals), Censored (a censoring indicator variable with the value 1 indicating censored observations and the value 0 indicating event observations), and Freq (the frequency variable). Two observations are created for each interval, one representing the event observations and the other representing the censored observations.

```

title 'Survival of Males with Angina Pectoris';
data Males;
 keep Freq Years Censored;
 retain Years -.5;
 input fail withdraw @@;
 Years + 1;
 Censored=0;
 Freq=fail;
 output;
 Censored=1;
 Freq=withdraw;
 output;
 datalines;
456 0 226 39 152 22 171 23 135 24 125 107
 83 133 74 102 51 68 42 64 43 45 34 53
 18 33 9 27 6 23 0 30
;

```

In the following statements, the ODS GRAPHICS ON specification enables ODS Graphics. PROC LIFETEST is invoked to compute the various life-table survival estimates, the median residual time, and their standard errors. The life-table method of computing estimates is requested by specifying METHOD=LT. The intervals are specified by the INTERVAL= option. Graphical displays of the life-table survivor function estimate, negative log of the estimate, log of negative log of the estimate, estimated density function, and estimated hazard function are requested by the PLOTS= option. No tests for homogeneity are carried out because the data are not stratified.

```

ods graphics on;
proc lifetest data=Males method=lt intervals=(0 to 15 by 1)
 plots=(s,ls,lls,h,p);
 time Years*Censored(1);
 freq Freq;
run;
ods graphics off;

```

Results of the life-table estimation are shown in [Output 52.3.1](#). The five-year survival rate is 0.5193 with a standard error of 0.0103. The estimated median residual lifetime, which is 5.33 years initially, reaches a maximum of 6.34 years at the beginning of the second year and decreases gradually to a value lower than the initial 5.33 years at the beginning of the seventh year.

**Output 52.3.1** Life-Table Survivor Function Estimate

The breakdown of event and censored observations in the data is shown in [Output 52.3.2](#). Note that 32.8% of the patients have withdrawn from the study.

**Output 52.3.2** Summary of Censored and Event Observations

| Summary of the Number of Censored and Uncensored Values                              |        |          |                  |  |
|--------------------------------------------------------------------------------------|--------|----------|------------------|--|
| Total                                                                                | Failed | Censored | Percent Censored |  |
| 2418                                                                                 | 1625   | 793      | 32.80            |  |
| NOTE: 2 observations with invalid time, censoring, or frequency values were deleted. |        |          |                  |  |

Output 52.3.3 displays the graph of the life-table survivor function estimate. The median survival time, read from the survivor function curve, is 5.33 years, and the 25th and 75th percentiles are 1.04 and 11.13 years, respectively.

**Output 52.3.3** Life-Table Survivor Function Estimate

An exponential model might be appropriate for the survival of these male patients with angina pectoris since the curve of the negative log of the survivor function estimate versus the survival time (Output 52.3.4) approximates a straight line through the origin. Note that the graph of the log of the negative log of the survivor function estimate versus the log of time (Output 52.3.5) is practically a straight line.

**Output 52.3.4** Negative Log of Survivor Function Estimate

As discussed in Lee (1992), the graph of the estimated hazard function ([Output 52.3.6](#)) shows that the death rate is highest in the first year of diagnosis. From the end of the first year to the end of the tenth year, the death rate remains relatively constant, fluctuating between 0.09 and 0.12. The death rate is generally higher after the tenth year. This could indicate that a patient who has survived the first year has a better chance than a patient who has just been diagnosed. The profile of the median residual lifetimes also supports this interpretation.

**Output 52.3.5** Log of Negative Log of Survivor Function Estimate

Output 52.3.6 Hazard Function Estimate

The density estimate is shown in (Output 52.3.7). Visually, it resembles the density function of an exponential distribution.

**Output 52.3.7** Density Function Estimate

## Overview: LOESS Procedure

The LOESS procedure implements a nonparametric method for estimating regression surfaces pioneered by Cleveland, Devlin, and Grosse (1988); Cleveland and Grosse (1991); Cleveland, Grosse, and Shyu (1992). The LOESS procedure allows great flexibility because no assumptions about the parametric form of the regression surface are needed.

The SAS System provides many regression procedures such as the GLM, REG, and NLIN procedures for situations in which you can specify a reasonable parametric model for the regression surface. You can use the LOESS procedure for situations in which you do not know a suitable parametric form of the regression surface. Furthermore, the LOESS procedure is suitable when there are outliers in the data and a robust fitting method is necessary.

The main features of the LOESS procedure are as follows:

- fits nonparametric models
- supports the use of multidimensional data
- supports multiple dependent variables
- supports both direct and interpolated fitting that uses  $k$ -d trees
- performs statistical inference
- performs automatic smoothing parameter selection
- performs iterative reweighting to provide robust fitting when there are outliers in the data
- produces graphs with ODS Graphics

---

## Local Regression and the Loess Method

Assume that for  $i = 1$  to  $n$ , the  $i$ th measurement  $y_i$  of the response  $y$  and the corresponding measurement  $x_i$  of the vector  $\mathbf{x}$  of  $p$  predictors are related by

$$y_i = g(x_i) + \epsilon_i$$

where  $g$  is the regression function and  $\epsilon_i$  is a random error. The idea of local regression is that at a predictor  $\mathbf{x}$ , the regression function  $g(\mathbf{x})$  can be locally approximated by the value of a function in some specified parametric class. Such a local approximation is obtained by fitting a regression surface to the data points within a chosen neighborhood of the point  $x_i$ .

In the loess method, weighted least squares is used to fit linear or quadratic functions of the predictors at the centers of neighborhoods. The radius of each neighborhood is chosen so that the neighborhood contains a specified percentage of the data points. The fraction of the data, called the *smoothing parameter*, in each local neighborhood controls the smoothness of the estimated surface. Data points in a given local neighborhood are weighted by a smooth decreasing function of their distance from the center of the neighborhood.

In a direct implementation, such fitting is done at each point at which the regression surface is to be estimated. A much faster computational procedure is to perform such local fitting at a selected sample of points in predictor space and then to blend these local polynomials to obtain a regression surface.

You can use the LOESS procedure to perform statistical inference provided that the error distribution satisfies some basic assumptions. In particular, such analysis is appropriate when the  $\epsilon_i$  are iid normal random variables with mean 0. By using the iterative reweighting, the LOESS procedure can also provide statistical inference when the error distribution is symmetric but not necessarily normal. Furthermore, by doing iterative reweighting, you can use the LOESS procedure to perform robust fitting in the presence of outliers in the data.

While all output of the LOESS procedure can be optionally displayed, most often the LOESS procedure is used to produce output data sets that will be viewed and manipulated by other SAS procedures. PROC LOESS uses the Output Delivery System (ODS) to place results in output data sets. Alternatively, PROC LOESS also provides an OUTPUT statement to create SAS data sets from analysis results.

## Getting Started: LOESS Procedure

---

### Scatter Plot Smoothing

The following data from the Connecticut Tumor Registry presents age-adjusted numbers of melanoma incidences per 100,000 people for the 37 years from 1936 to 1972 (Houghton, Flannery, and Viola 1980).

```
data Melanoma;
 input Year Incidences @@;
 format Year d4.0;
 datalines;
1936 0.9 1937 0.8 1938 0.8 1939 1.3
1940 1.4 1941 1.2 1942 1.7 1943 1.8
1944 1.6 1945 1.5 1946 1.5 1947 2.0
1948 2.5 1949 2.7 1950 2.9 1951 2.5
1952 3.1 1953 2.4 1954 2.2 1955 2.9
1956 2.5 1957 2.6 1958 3.2 1959 3.8
1960 4.2 1961 3.9 1962 3.7 1963 3.3
1964 3.7 1965 3.9 1966 4.1 1967 3.8
1968 4.7 1969 4.4 1970 4.8 1971 4.8
1972 4.8
;
```

The following PROC SGPLOT statements produce the simple scatter plot of these data displayed in [Figure 53.1](#).

```
proc sgplot data=Melanoma;
 scatter y=Incidence x=Year;
run;
```

**Figure 53.1** Scatter Plot of the Melanoma Data

Suppose that you want to smooth the response variable `Incidence` as a function of the variable `Year`. The following PROC LOESS statements request this analysis with the default settings:

```
ods graphics on;

proc loess data=Melanoma;
 model Incidence=Year;
run;
```

You use the PROC LOESS statement to invoke the procedure and specify the data set. The MODEL statement names the dependent and independent variables.

**Figure 53.2** Default Loess Fit for the Melanoma Data

When ODS Graphics is enabled, PROC LOESS produces several default plots. [Figure 53.2](#) shows the “Fit Plot” that overlays the loess fit on a scatter plot of the data. You can see that the loess fit captures the increasing trend in the data as well as the periodic pattern in the data, which is related to an 11-year sunspot activity cycle.

**Figure 53.3** Fit Summary

| The LOESS Procedure                 |          |
|-------------------------------------|----------|
| Selected Smoothing Parameter: 0.257 |          |
| Dependent Variable: Incidences      |          |
| Fit Summary                         |          |
| Fit Method                          | kd Tree  |
| Blending                            | Linear   |
| Number of Observations              | 37       |
| Number of Fitting Points            | 37       |
| kd Tree Bucket Size                 | 1        |
| Degree of Local Polynomials         | 1        |
| Smoothing Parameter                 | 0.25676  |
| Points in Local Neighborhood        | 9        |
| Residual Sum of Squares             | 2.03105  |
| Trace[L]                            | 8.62243  |
| GCV                                 | 0.00252  |
| AICC                                | -1.17277 |

Figure 53.3 shows the “Fit Summary” table. This table details the settings used and provides statistics about the fit that is produced. You can see that smoothing parameter value for this loess fit is 0.257. This smoothing parameter determines the fraction of the data in each local neighborhood. In this example, there are 37 data points and so the smoothing parameter value of 0.257 yields local neighborhoods containing 9 observations.

**Figure 53.4** Smoothing Parameter Selection

| Optimal Smoothing<br>Criterion |                        |
|--------------------------------|------------------------|
| AICC                           | Smoothing<br>Parameter |
| -1.17277                       | 0.25676                |

The “Smoothing Criterion” table provides information about how this smoothing parameter value is selected. The default method implemented in PROC LOESS chooses the smoothing parameter that minimizes the AICC criterion (Hurvich, Simonoff, and Tsai 1998) that strikes a balance between the residual sum of squares and the complexity of the fit.

You use options in the MODEL statement to change the default settings and request optionally displayed tables. For example, the following statements request that the “Model Summary” and “Output Statistics” tables be included in the displayed output. By default, these tables are not displayed.

```
proc loess data=Melanoma;
 model Incidences=Year / details(ModelSummary OutputStatistics);
run;
```

**Figure 53.5** Model Summary Table

| The LOESS Procedure            |                 |             |         |          |
|--------------------------------|-----------------|-------------|---------|----------|
| Dependent Variable: Incidences |                 |             |         |          |
| Model Summary                  |                 |             |         |          |
| Smoothing<br>Parameter         | Local<br>Points | Residual SS | GCV     | AICC     |
| 0.41892                        | 15              | 3.42229     | 0.00339 | -0.96252 |
| 0.68919                        | 25              | 4.05838     | 0.00359 | -0.93459 |
| 0.31081                        | 11              | 2.51054     | 0.00279 | -1.12034 |
| 0.20270                        | 7               | 1.58513     | 0.00239 | -1.12221 |
| 0.17568                        | 6               | 1.56896     | 0.00241 | -1.09706 |
| 0.28378                        | 10              | 2.50487     | 0.00282 | -1.10402 |
| 0.20270                        | 7               | 1.58513     | 0.00239 | -1.12221 |
| 0.25676                        | 9               | 2.03105     | 0.00252 | -1.17277 |
| 0.22973                        | 8               | 2.02965     | 0.00256 | -1.15145 |
| 0.25676                        | 9               | 2.03105     | 0.00252 | -1.17277 |

The “Model Summary” table shown in [Figure 53.5](#) provides information about all the models that PROC LOESS evaluated in choosing the smoothing parameter value.

**Figure 53.6** AICC Criterion by Smoothing Parameter

Figure 53.6 shows the “Criterion Plot” that provides a graphical display of the smoothing parameter selection process.

| 30                                  | 1965 | 3.90000    | 3.82382              | 0.07618  |
| 31                                  | 1966 | 4.10000    | 4.00515              | 0.09485  |
| 32                                  | 1967 | 3.80000    | 4.18573              | -0.38573 |
| 33                                  | 1968 | 4.70000    | 4.35152              | 0.34848  |
| 34                                  | 1969 | 4.40000    | 4.50284              | -0.10284 |
| 35                                  | 1970 | 4.80000    | 4.64413              | 0.15587  |
| 36                                  | 1971 | 4.80000    | 4.78291              | 0.01709  |
| 37                                  | 1972 | 4.80000    | 4.91602              | -0.11602 |

Figure 53.7 show the “Output Statistics” table that contains the predicted loess fit value at each observation in the input data set.

Although the default method for selecting the smoothing parameter value is often satisfactory, it is often a good practice to examine how the loess fit varies with the smoothing parameter. In some cases, fits with different smoothing parameters might reveal important features of the data that cannot be discerned by looking at a fit with just a single “best” smoothing parameter. Example 53.4 provides such an example.

You can produce the loess fits for a range of smoothing parameters by using the `SMOOTH=` option in the `MODEL` statement as follows:

```
proc loess data=Melanoma;
 model Incidences=Year/smooth=0.1 0.25 0.4 0.6 residual;
 ods output OutputStatistics=Results;
run;
```

The `RESIDUAL` option causes the residuals to be added to the “Output Statistics” table. Note that, even if you do not specify the `DETAILS` option in the `MODEL` statement to request the display of the “Output Statistics” table, you can use an `ODS OUTPUT` statement to output this and other optionally displayed tables as data sets.

`PROC PRINT` displays the first five observations of the Results data set:

```
proc print data=Results(obs=5);
 id obs;
run;
```

**Figure 53.8** PROC PRINT Output of the Results Data Set

| Obs | Smoothing<br>Parameter | Year | Dep<br>Var | Pred    | Residual |
|-----|------------------------|------|------------|---------|----------|
| 1   | 0.1                    | 1936 | 0.9        | 0.90000 | 0        |
| 2   | 0.1                    | 1937 | 0.8        | 0.80000 | 0        |
| 3   | 0.1                    | 1938 | 0.8        | 0.80000 | 0        |
| 4   | 0.1                    | 1939 | 1.3        | 1.30000 | 0        |
| 5   | 0.1                    | 1940 | 1.4        | 1.40000 | 0        |

Note that the fits for all the smoothing parameters are placed in single data set. A variable named `SmoothingParameter` that you use to distinguish each fit is included in this data set.

When you specify a list of smoothing parameters for a model and `ODS Graphics` is enabled, `PROC LOESS` produces a panel containing up to six plots that show the fit obtained for each value of the smoothing parameter that you specify. If you specify more than six smoothing values, then multiple panels are produced. For each regressor, `PROC LOESS` also produces panels of the residuals versus each regressor by the smoothing parameters that you specify.

**Figure 53.9** Loess Fits for a Range of Smoothing Parameters

If you examine the plots in [Figure 53.9](#), you see that a visually reasonable fit is obtained with smoothing parameter values of 0.25. With smoothing parameter value 0.1, there is gross overfitting in the sense that the original data are exactly interpolated. When the smoothing parameter value is 0.4, you obtain an overly smooth fit where the contribution of the sunspot cycle has been mostly averaged away. At smoothing parameter value 0.6 the fit shows just the increasing trend in the data.

It is also instructive to look at scatter plots of the residuals for each of the fits. These are also produced by default by PROC LOESS when ODS Graphics is enabled.

**Figure 53.10** Residuals of Loess Fits for a Range of Smoothing Parameters

Figure 53.10 shows a scatter plot of the residuals by year for each smoothing parameter value. One way to discern patterns in these residuals is to superimpose a loess fit on each plot in the panel. You request loess fits on the residual plots in this panel by specifying the `SMOOTH=` suboption of the `PLOTS=RESIDUALSBYSMOOTH` option in the `PROC LOESS` statement. Note that the loess fits that are displayed on each of the residual plots are obtained independently of the loess fit that produces these residuals. The following statements show how you do this for the Melanoma data.

```
proc loess data=Melanoma plots=ResidualsBySmooth(smooth);
 model Incidences=Year/smooth=0.1 0.25 0.4 0.6;
run;
```

**Figure 53.11** Residuals with Superimposed Loess Fits

The loess fits shown on the plots in [Figure 53.11](#) help confirm the conclusions obtained when you look at [Figure 53.9](#). Note that residuals for smoothing parameter value 0.25 do not exhibit any pattern, confirming that at this value the loess fit of the melanoma data has successfully modeled the variation in this data. By contrast, the residuals for the fit with smoothing parameter 0.6 retain the variation caused by the sunspot cycle.

The examination of the fits and residuals obtained with a range of smoothing parameter values confirms that the value of 0.257 that PROC LOESS selects automatically is appropriate for these data. The next step in this analysis is to examine fit diagnostics and produce confidence limit for the fit. If ODS Graphics is enabled, then a panel of fit diagnostics is produced. Furthermore, you can request prediction confidence limits by adding the CLM option in the MODEL statement. By default 95% limits are produced, but you can use the ALPHA= option in the MODEL statement to change the significance level. The following statements request 90% confidence limits.

```
proc loess data=Melanoma;
 model Incidences=Year/clm alpha=0.1;
run;

ods graphics off;
```

Figure 53.12 Fit Diagnostics

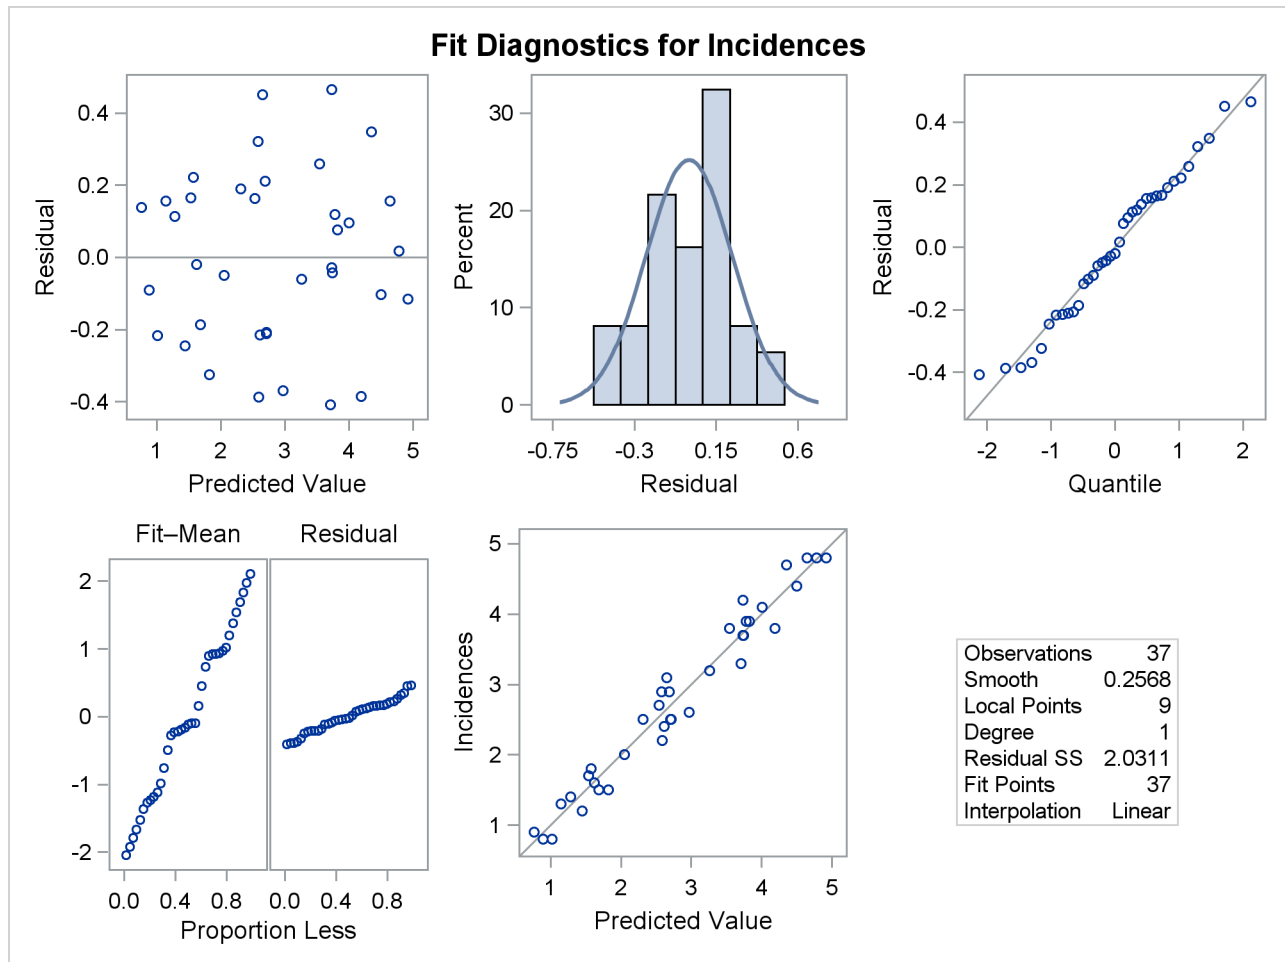

Figure 53.12 shows the fit diagnostics panel. The histogram of the residuals with overlaid normal density estimator and the normal quantile plot show that the residuals do exhibit some small departure from normality. The “Residual-Fit” spread plot shows that the spread in the centered fit is much wider than the spread in the residuals. This indicates that the fit has accounted for most of the variation in the incidences of melanoma in this data. This conclusion is supported by the absence of any clear pattern in the scatter plot of residuals by predicted values and the closeness of the points to the 45-degree reference line in the plot of observed by predicted values.

**Figure 53.13** Loess Fit of Melanoma Data with 90% Confidence Limits

Finally, Figure 53.13 shows the selected loess fit with 90% confidence limits.

## Syntax: LOESS Procedure

The following statements are available in the LOESS procedure:

```

PROC LOESS < DATA=SAS-data-set > ;
 MODEL dependents = regressors < / options > ;
 OUTPUT < OUT=SAS-data-set > < keyword < =name > > < ... keyword < =name > > < / options > ;
 ID variables ;
 BY variables ;
 WEIGHT variable ;
 SCORE DATA=SAS-data-set < ID=(variable-list) > < / options > ;

```

The PROC LOESS and MODEL statements are required. The OUTPUT, BY, WEIGHT, and ID statements are optional. The SCORE statement is optional, and more than one SCORE statement can be used.

The statements used with the LOESS procedure, in addition to the PROC LOESS statement, are as follows.

|               |                                                                                                                                                        |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BY</b>     | specifies variables to define subgroups for the analysis.                                                                                              |
| <b>ID</b>     | names variables to identify observations in the displayed output.                                                                                      |
| <b>MODEL</b>  | specifies the dependent and independent variables in the loess model, details and parameters for the computational algorithm, and the required output. |
| <b>OUTPUT</b> | creates an output data set containing predicted values, residuals, and results of statistical inference.                                               |
| <b>SCORE</b>  | specifies a data set containing observations to be scored.                                                                                             |
| <b>WEIGHT</b> | declares a variable to weight observations.                                                                                                            |

---

## PROC LOESS Statement

**PROC LOESS** < options > ;

The PROC LOESS statement invokes the LOESS procedure. The PROC LOESS statement is required. You can specify the following options in the PROC LOESS statement:

**DATA=SAS-data-set**

names the SAS data set to be used by PROC LOESS. If the DATA= option is not specified, PROC LOESS uses the most recently created SAS data set.

**PLOTS** < (global-plot-options) > < = plot-request < (options) > >

**PLOTS** < (global-plot-options) > < = (plot-request < (options) > < ... plot-request < (options) > > >

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=residuals(smooth)
plots(unpack)=diagnostics
plots(only)=(fit residualHistogram)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc loess;
 model y = x;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC LOESS produces a default set of plots. The following table lists the default set of plots produced.

**Table 53.1** Default Graphs Produced

| Plot              | Conditional On                                                     |
|-------------------|--------------------------------------------------------------------|
| ContourFitPanel   | SMOOTH= option specified in the <b>MODEL</b> statement             |
| ContourFit        | Model with two regressors                                          |
| CriterionPlot     | Smoothing parameter selection performed                            |
| DiagnosticsPanel  | Unconditional                                                      |
| ResidualsBySmooth | SMOOTH= option specified in the <b>MODEL</b> statement             |
| ResidualPanel     | Unconditional                                                      |
| FitPanel          | SMOOTH= option specified in the <b>MODEL</b> statement             |
| FitPlot           | Model with one regressor                                           |
| ScorePlot         | One or more <b>SCORE</b> statements and a model with one regressor |

For models with multiple dependent variables, separate plots are produced for each dependent variable. For models where multiple smoothing parameters are requested with the SMOOTH= option in the **MODEL** statement and smoothing parameter value selection is not requested, separate plots are produced for each smoothing parameter. If smoothing parameter value selection is requested with the SELECT= option in the **MODEL** statement, then the plots are produced for the selected model only. However, if you specify the STEPS suboption of the SELECT= option, then plots are produced for all smoothing parameters examined in the selection process.

The *global-plot-options* apply to all relevant plots generated by the LOESS procedure, unless they are overridden with a *specific-plot-option*. The *global-plot-options* supported by the LOESS procedure follow.

## Global Plot Options

### **MAXPOINTS=NONE** | *number*

specifies that plots with elements that require processing more than *number* points are suppressed. The default is MAXPOINTS=5000. This cutoff is ignored if you specify MAXPOINTS=NONE.

### **ONLY**

suppresses the default plots. Only the plots specifically requested are produced.

### **UNPACK**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACK to get each plot individually. You can specify PLOTS(UNPACK) to unpack the default plots. You can also specify UNPACK as a suboption with CONTOURFITPANEL, DIAGNOSTICS, FITPANEL, RESIDUALS and RESIDUALSBYSMOOTH.

## Specific Plot Options

The following listing describes the specific plots and their options.

### **ALL**

requests that all plots appropriate for the particular analysis be produced. You can specify other options with ALL; for example, to request all plots and unpack only the residuals, specify PLOTS=(ALL RESIDUALS(UNPACK)).

**CONTOURFIT** <(contour-options)>

produces a contour plot of the fitted surface overlaid with a scatter plot of the data for models with two regressors. Contour plots are not produced if you specify the **DIRECT** option in the **MODEL** statement. You can use the following *contour-options* to control how the observations are displayed:

**OBS=GRADIENT**

specifies that observations be displayed as circles colored by the observed response. The same color gradient is used to display the fitted surface and the observations. Observations where the predicted response is close to the observed response have similar colors—the greater the contrast between the color of an observation and the surface, the larger the residual is at that point. **OBS=GRADIENT** is the default if you do not specify any *contour-options*.

**OBS=NONE**

suppresses the observations.

**OBS=OUTLINE**

specifies that observations be displayed as circles with a border but with a completely transparent fill.

**OBS=OUTLINEGRADIENT**

is the same as **OBS=GRADIENT** except that a border is shown around each observation. This option is useful to identify the location of observations where the residuals are small, because at these points the color of the observations and the color of the surface are indistinguishable.

**CONTOURFITPANEL** <(UNPACK < contour-options > )>

produces panels of contour plots overlaid with a scatter plot of the data for each smoothing parameter specified in the **SMOOTH=** option in the **MODEL** statement, for models with two regressors. This plot is not produced if you specify the **DIRECT** option in the **MODEL** statement. If you do not specify the **SMOOTH=** option or if the model does not have two regressors, then this plot is not produced. If you specify the **SELECT=** option in addition to the **SMOOTH=** option in the **MODEL** statement, then you need to additionally specify the **STEPS** suboption of the **SELECT=** option to obtain this plot. Note that each panel contains at most six plots, and multiple panels are used in the case that there are more than six smoothing parameters in the **SMOOTH=** option in the **MODEL** statement. See the **CONTOURFIT** option for a description of the individual plots in this panel. The **UNPACK** option suppresses paneling, and the *contour-options* are the same as for the **CONTOURFIT** option.

**CRITERIONPLOT** | **CRITERION**

displays a scatter plot of the value of the **SELECTION=** criterion versus the smoothing parameter value for all smoothing parameter values examined in the selection process. This plot is not produced if smoothing parameter selection is not done.

**DIAGNOSTICSPANEL** | **DIAGNOSTICS** <(UNPACK)>

produces a summary panel of fit diagnostics consisting of the following:

- residuals versus the predicted values
- histogram of the residuals
- normal quantile plot of the residuals
- a “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals.

- dependent variable values versus the predicted values

You can request the five plots in this panel as individual plots by specifying the UNPACK option. You can also request individual plots in the panel by name without having to unpack the panel. Note that the fit diagnostics panel is produced by default whenever ODS Graphics is enabled.

#### **FITPANEL <(UNPACK)>**

produces panels of plots showing the fitted LOESS curve overlaid on a scatter plot of the input data for each smoothing parameter specified in the SMOOTH= option in the **MODEL** statement. If you do not specify the SMOOTH= option or the model has more than one regressor, then this plot is not produced. If you specify the SELECT= option in addition to the SMOOTH= option in the **MODEL** statement, then you need to additionally specify the STEPS suboption of the SELECT= option to obtain this plot. Note that each panel contains at most six plots, and multiple panels are used in the case that there are more than six smoothing parameters in the SMOOTH= option in the **MODEL** statement. If the CLM option is specified in the **MODEL** statement, then a confidence band at the significance level specified in the ALPHA= option is included in each plot in the panels. If you specify the UNPACK option, then all fit panels are unpacked.

#### **FITPLOT | FIT**

produces a scatter plot of the input data with the fitted LOESS curve overlaid for models with a single regressor. If the CLM option is specified in the **MODEL** statement, then a confidence band at the significance level specified in the ALPHA= option is included in the plot.

#### **NONE**

suppresses all plots.

#### **OBSERVEDBYPREDICTED**

produces a scatter plot of the dependent variable values by the predicted values.

#### **QQPLOT | QQ**

produces a normal quantile plot of the residuals.

#### **RESIDUALSBYSMOOTH <(< UNPACK > < SMOOTH > )>**

produces for each regressor panels of plots showing the residuals of the LOESS fit versus the regressor for each smoothing parameter specified in the SMOOTH= option in the **MODEL** statement. If you do not specify the SMOOTH= option, then this plot is not produced. If you specify the SELECT= option in addition to the SMOOTH= option in the **MODEL** statement, then you need to additionally specify the STEPS suboption of the SELECT= option to obtain this plot. Note that each panel contains at most six plots, and multiple panels are used in the case that there are more than six smoothing parameters in the SMOOTH= option in the **MODEL** statement. If you specify the UNPACK option, then all RESIDUALSBYSMOOTH panels are unpacked.

The SMOOTH option requests that a nonparametric fit line be shown in each plot in the panel. The type of nonparametric fit and the options used are controlled by the template that underlies this plot. In the standard template that is provided, the nonparametric smooth is specified to be a loess fit corresponding to the default options of PROC LOESS, except that the PRESEARCH suboption is always used. It is important to note that the loess fit that is shown in each of the residual plots is computed independently of the loess fit that is used to obtain the residuals.

**RESIDUALBYPREDICTED**

produces a scatter plot of the residuals by the predicted values.

**RESIDUALHISTOGRAM**

produces a histogram of the residuals.

**RESIDUALPANEL | RESIDUALS** <(residual-options)>

produces panels of the residuals versus the regressors in the model. Note that each panel contains at most six plots, and multiple panels are used when there are more than six regressors in the model.

The following *residual-options* are available:

**SMOOTH**

requests that a nonparametric fit line be shown in each plot in the panel. The type of nonparametric fit and the options used are controlled by the template that underlies this plot. In the standard template that is provided, the nonparametric smooth is specified to be a loess fit corresponding to the default options of PROC LOESS, except that the PRESEARCH suboption is always used. It is important to note that the loess fit that is shown in each of the residual plots is computed independently of the loess fit that is used to obtain the residuals.

**UNPACK**

suppresses paneling.

**RFPLOT | RF**

produces a “Residual-Fit” (or RF) plot consisting of side-by-side quantile plots of the centered fit and the residuals. This plot “shows how much variation in the data is explained by the fit and how much remains in the residuals” (Cleveland 1993).

**SCOREPLOT | SCORE**

produces a scatter plot of the scored values at the score points for each **SCORE** statement. **SCORE** plots are not produced for models with more than one regressor. If the **CLM** option is specified in the **MODEL** statement, then confidence bars at the significance level specified in the **ALPHA=** option are shown at score data points.

**BY Statement**

**BY** *variables* ;

You can specify a **BY** statement with PROC LOESS to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar **BY** statement.
- Specify the **NOTSORTED** or **DESCENDING** option in the **BY** statement for the LOESS procedure. The **NOTSORTED** option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the **BY** variables) and that these groups are not necessarily in alphabetical or increasing numeric order.

- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## ID Statement

**ID** *variables* ;

The ID statement is optional, and more than one ID statement can be used. The variables listed in any of the ID statements are displayed in the “Output Statistics” table beside each observation. Any variables specified as a regressor or dependent variable in the **MODEL** statement already appear in the “Output Statistics” table and are not treated as ID variables, even if they appear in the variable list of an ID statement.

---

## MODEL Statement

**MODEL** *dependents = regressors </ options >* ;

The MODEL statement names the dependent variables and the independent variables. Variables specified in the MODEL statement must be numeric variables in the data set being analyzed.

Table 53.2 summarizes the options available in the MODEL statement.

**Table 53.2** Summary of MODEL Statement Options

| Option                                 | Description                                                                                    |
|----------------------------------------|------------------------------------------------------------------------------------------------|
| <b>Fit Options</b>                     |                                                                                                |
| BUCKET=                                | specifies the number of points in <i>k</i> -d tree buckets                                     |
| DEGREE=                                | specifies the degree of local polynomials (1 or 2)                                             |
| DFMETHOD=                              | specifies the method of computing lookup degrees of freedom                                    |
| DIRECT                                 | specifies direct fitting at every data point                                                   |
| DROPSQUARE=                            | specifies the variables whose squares are to be dropped from local quadratic polynomials       |
| INTERP=                                | specifies the interpolating polynomials (linear or cubic)                                      |
| ITERATIONS=                            | specifies the number of reweighting iterations                                                 |
| SCALE=                                 | specifies the method used to scale the regressor variables                                     |
| SELECT=                                | specifies that automatic smoothing parameter selection be done                                 |
| SMOOTH=                                | specifies the list of smoothing values                                                         |
| <b>Output Statistics Table Options</b> |                                                                                                |
| ALL                                    | requests <b>CLM</b> , <b>RESIDUAL</b> , <b>SCALEDINDEP</b> , <b>STD</b> , and <b>T</b> options |
| CLM                                    | displays confidence limits for mean predictions                                                |
| RESIDUAL                               | displays residuals                                                                             |
| SCALEDINDEP                            | displays scaled independent variable coordinates                                               |
| STD                                    | displays standard errors of the mean predicted values                                          |

Table 53.2 continued

| Option               | Description                                      |
|----------------------|--------------------------------------------------|
| T                    | displays $t$ statistics                          |
| <b>Other options</b> |                                                  |
| ALPHA=               | sets significance level for confidence intervals |
| DETAILS=             | specifies which tables are to be displayed       |
| TRACEL               | displays the trace of the smoothing matrix       |

The following options are available in the MODEL statement after a slash (/).

**ALL**

requests all these options: CLM, RESIDUAL, SCALEDINDEP, STD, and T.

**ALPHA=number**

sets the significance level used for the construction of confidence intervals for the current MODEL statement. The value must be between 0 and 1; the default value of 0.05 results in 95% intervals.

**BUCKET=number**

specifies the maximum number of points in the leaf nodes of the  $k$ -d tree. The default value used is  $s * n/5$ , where  $s$  is a smoothing parameter value specified using the SMOOTH= option and  $n$  is the number of observations being used in the current BY group. The BUCKET= option is ignored if the DIRECT option is specified.

**CLM**

requests that  $100(1 - \alpha)\%$  confidence limits on the mean predicted value be added to the “Output Statistics” table. By default, 95% limits are computed; the ALPHA= option in the MODEL statement can be used to change the significance level. The use of this option implicitly selects the model option DFMETHOD=EXACT if the DFMETHOD= option has not been explicitly used.

**DEGREE=1 | 2**

sets the degree of the local polynomials to use for each local regression. The valid values are 1 for local linear fitting and 2 for local quadratic fitting, with 1 being the default.

**DETAILS < ( tables ) >**

selects which tables to display, where *tables* is one or more of the specifications KDTREE, MODEL-SUMMARY, OUTPUTSTATISTICS, and PREDATVERTICES:

- KDTREE displays the  $k$ -d tree structure.
- MODELSUMMARY displays the fit criteria for all smoothing parameter values that are specified in the SMOOTH= option in the MODEL statement, or that are fit with automatic smoothing parameter selection.
- OUTPUTSTATISTICS displays the predicted values and other requested statistics at the points in the input data set.
- PREDATVERTICES displays fitted values and coordinates of the  $k$ -d tree vertices where the local least squares fitting is done.

The KDTREE and PREDATVERTICES specifications are ignored if the DIRECT option is specified in the MODEL statement. Specifying the option DETAILS with no qualifying list outputs all tables.

**DFMETHOD=NONE | EXACT | APPROX <(approx-options)>**

specifies the method used to calculate the lookup degrees of freedom used in performing statistical inference. The default is DFMETHOD=NONE, unless you specify any of the MODEL statement options ALL, CLM, STD, and T, or any SCORE statement CLM option, in which case the default is DFMETHOD=EXACT.

You can specify the following *approx-options* in parentheses after the DFMETHOD=APPROX option:

**QUANTILE=number**

specifies that the smallest 100(*number*)% of the nonzero coefficients in the smoothing matrix be set to zero in computing the approximate lookup degrees of freedom. The default value is QUANTILE=0.9.

**CUTOFF=number**

specifies that coefficients in the smoothing matrix whose magnitude is less than the specified value be set to zero in computing the approximate lookup degrees of freedom. Using the CUTOFF= option overrides the QUANTILE= option.

See the section “Sparse and Approximate Degrees of Freedom Computation” on page 4130 for a description of the method used when the DFMETHOD=APPROX option is specified.

**DIRECT**

specifies that local least squares fits are to be done at every point in the input data set. When the direct option is not specified, a computationally faster method is used. This faster method performs local fitting at vertices of a *k*-d tree decomposition of the predictor space followed by blending of the local polynomials to obtain a regression surface.

**DROPSQUARE=(variables)**

specifies the quadratic monomials to exclude from the local quadratic fits. This option is ignored unless the DEGREE=2 option has been specified.

For example,

```
model z=x y / degree=2 dropsquare=(y)
```

uses the monomials 1, *x*, *y*,  $x^2$ , and *xy* in performing the local fitting.

**INTERP=LINEAR | CUBIC**

specifies the degree of the interpolating polynomials used for blending local polynomial fits at the *k*-d tree vertices. This option is ignored if the DIRECT option is specified in the model statement. INTERP=CUBIC is not supported for models with more than two regressors. The default is INTERP=LINEAR.

**ITERATIONS=number**

specifies the total number of iterations to be done. The first iteration performs an initial LOESS fit. Subsequent iterations perform iterative reweighting. Such iterations are appropriate when there are outliers in the data or when the error distribution is a symmetric long-tailed distribution. The default number of iterations is 1.

**RESIDUAL | R**

specifies that residuals be included in the “Output Statistics” table.

**SCALE=NONE | SD < (number) >**

specifies the scaling method to be applied to scale the regressors. The default is NONE, in which case no scaling is applied. A specification of SD(*number*) indicates that a trimmed standard deviation is to be used as a measure of scale, where *number* is the trimming fraction. A specification of SD with no qualification defaults to 10% trimmed standard deviation.

**SCALEDINDEP**

specifies that scaled regressor coordinates be included in the output tables. This option is ignored if the SCALE= model option is not used or if SCALE=NONE is specified.

**SELECT=criterion** < ( < GLOBAL > < PRESEARCH > < STEPS > < RANGE(*lower,upper*) > ) >

**SELECT=DFCriterion** < ( *target* < GLOBAL > < PRESEARCH > < STEPS > < RANGE(*lower,upper*) > ) >

specifies that automatic smoothing parameter selection be done using the named *criterion* or *DFCriterion*. Valid values for the *criterion* are as follows:

- AICC specifies the  $AIC_C$  criterion (Hurvich, Simonoff, and Tsai 1998).
- AICC1 specifies the  $AIC_{C_1}$  criterion (Hurvich, Simonoff, and Tsai 1998).
- GCV specifies the generalized cross validation criterion (Craven and Wahba 1979).

The *DFCriterion* specifies the measure used to estimate the model degrees of freedom. The measures implemented in PROC LOESS all depend on prediction matrix **L** relating the observed and predicted values of the dependent variable. Valid values for the *DFCriterion* are as follows:

- DF1 specifies Trace(**L**).
- DF2 specifies Trace(**L'L**).
- DF3 specifies  $2\text{Trace}(\mathbf{L}) - \text{Trace}(\mathbf{L}'\mathbf{L})$ .

For both types of selection, the smoothing parameter value is selected to yield a minimum of an optimization criterion. If you specify *criterion* as one of AICC, AICC1, or GCV, the optimization criterion is the specified *criterion*. If you specify *DFCriterion* as one of DF1, DF2, or DF3, the optimization criterion is  $|DFCriterion - target|$ , where *target* is a specified target degree of freedom value. Note that if you specify a *DFCriterion*, then you must also specify a target value. See the section “[Automatic Smoothing Parameter Selection](#)” on page 4127 for definitions and properties of the selection criteria.

The selection is done as follows:

- If you specify the SMOOTH=*value-list* option, then PROC LOESS selects the largest value in this list that yields the global minimum of the specified optimization criterion.
- If you do not specify the SMOOTH= option, then PROC LOESS finds a local minimum of the specified optimization criterion by using a golden section search of values less than or equal to one.

You can specify the following suboptions in parentheses after the specified criterion to alter the behavior of the SELECT= option:

**GLOBAL**

specifies that a global minimum be found within the range of smoothing parameter values examined. This suboption has no effect if you also specify the SMOOTH= option in the MODEL statement.

**PRESEARCH**

requests an initial grid search to find a smoothing parameter range within which the subsequent golden section search is done. The initial point in this grid is the smoothing parameter value corresponding to the smallest number of points,  $n$ , in the local neighborhoods that yields a fit that does not interpolate all the data points. Subsequent fits with number of local points  $n + 1$ ,  $n + 2$ ,  $n + 4$ ,  $n + 8$ , ... are evaluated until either the number of local points exceeds the number of fitting points or the SELECT=criterion starts increasing. This suboption is ignored if you additionally specify the GLOBAL suboption of the SELECT= option or if you specify the SMOOTH= option in the MODEL statement. If you additionally specify the RANGE= suboption, then the golden section search is done on the intersection of the range found by this grid search and the range that you specify in the RANGE= suboption. This option is useful for data exhibiting features at multiple scales, because in such cases the SELECT= criterion often has multiple local minima. Using the PRESEARCH option increases the likelihood that the golden section search will find the global minimum of the SELECT= criterion. See [Example 53.4](#) for such an example.

**RANGE(lower,upper)**

specifies that only smoothing parameter values greater than or equal to *lower* and less than or equal to *upper* be examined.

**STEPS**

specifies that all models evaluated in the selection process be displayed.

For models with one dependent variable, if you specify neither the SELECT= nor the SMOOTH= options in the MODEL statement, then PROC LOESS uses SELECT=AICC.

The following table summarizes how the smoothing parameter values are chosen for various combinations of the SMOOTH= option, the SELECT= option, and the SELECT= option modifiers.

**Table 53.3** Smoothing Parameter Value(s) Used for Combinations of SMOOTH= and SELECT= OPTIONS for Models with One Dependent Variable

| Syntax                                                                        | Search Method             | Search Domain                                        |
|-------------------------------------------------------------------------------|---------------------------|------------------------------------------------------|
| <i>default</i>                                                                | golden section using AICC | (0, 1]                                               |
| SMOOTH= <i>list</i>                                                           | no selection              | values in <i>list</i>                                |
| SMOOTH= <i>list</i> SELECT= <i>criterion</i>                                  | global                    | values in <i>list</i>                                |
| SMOOTH= <i>list</i> SELECT= <i>criterion</i> ( RANGE( <i>l</i> , <i>u</i> ) ) | global                    | values in <i>list</i> within [ <i>l</i> , <i>u</i> ] |
| SELECT= <i>criterion</i>                                                      | golden section            | (0, 1]                                               |
| SELECT= <i>criterion</i> ( RANGE( <i>l</i> , <i>u</i> ) )                     | golden section            | [ <i>l</i> , <i>u</i> ]                              |
| SELECT= <i>criterion</i> ( GLOBAL )                                           | global                    | (0, 1]                                               |
| SELECT= <i>criterion</i> ( GLOBAL RANGE( <i>l</i> , <i>u</i> ) )              | global                    | [ <i>l</i> , <i>u</i> ]                              |

Some examples of using the SELECT= option follow:

|                      |                                                                                                                                                               |
|----------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------|
| SELECT=GCV           | specifies selection that uses the GCV <i>criterion</i> .                                                                                                      |
| SELECT=DF1(6.3)      | specifies selection that uses the DF1 <i>DFCriterion</i> with target value 6.3.                                                                               |
| SELECT=AICC(STEPS)   | specifies selection that uses the AICC <i>criterion</i> , showing all step details.                                                                           |
| SELECT=DF2(7 GLOBAL) | specifies selection that uses a global search algorithm to find the smoothing parameter that yields the DF2 <i>DFCriterion</i> closest to the target value 7. |

**NOTE:** The SELECT= option cannot be used for models with more than one dependent variable.

**SMOOTH=***value-list*

specifies a list of positive smoothing parameter values. If you do not specify the SELECT= option in the MODEL statement, then a separate fit is obtained for each SMOOTH= value specified. If you do specify the SELECT= option, then models with all values specified in the SMOOTH= list are examined, and PROC LOESS selects the value that minimizes the criterion specified in the SELECT= option.

For models with two or more dependent variables, if the SMOOTH= option is not specified in the MODEL statement, then SMOOTH=0.5 is used as a default.

**STD**

specifies that standard errors of the mean predicted values be included in the “Output Statistics” table. The use of this option implicitly selects the model option DFMETHOD=EXACT if the DFMETHOD= option has not been explicitly used.

**T**

specifies that *t* statistics are to be included in the “Output Statistics” table. The use of this option implicitly selects the model option DFMETHOD=EXACT if the DFMETHOD= option has not been explicitly used.

**TRACEL**

specifies that the trace of the prediction matrix as well as the GCV and AICC statistics be included in the “Fit Summary” table. The use of any of the MODEL statement options ALL, CLM, DFMETHOD=EXACT, DIRECT, SELECT=, STD, and T implicitly selects the TRACEL option.

## OUTPUT Statement

**OUTPUT** <OUT= SAS-data-set> <keyword <= name>> <... keyword <=name>> </options>;

The OUTPUT statement creates a new SAS data set that saves the predicted values and other requested statistics that are calculated after models for all smoothing parameter values that are specified in the SMOOTH= option in the MODEL statement have been fit. If you do not specify a *keyword*, then only the predicted response is included.

All the variables in the original data set are included in the new data set, along with variables created by the OUTPUT statement. These new variables contain the predicted values and a variety of other statistics that are calculated for each observation in the data set.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

You can specify the following *options* in the OUTPUT statement:

**OUT=SAS data set**

specifies the name of the new data set. By default, the procedure uses the *DATA*n** convention to name the new data set.

*keyword* <=*name*>

specifies the statistics to include in the output data set as new variables and optionally names the new variables. Specify a keyword for each desired statistic (see the following list of keywords), followed optionally by an equal sign and a variable to contain the statistic.

The new variables are named as follows: If you specify *keyword=**name*, the new variable has the specified *name*. If you omit the optional *=name* after a *keyword*, then the new variable name is formed by using a default character string that identifies the statistic. In either case, if you also specify the ROWWISE option after a slash and you specify more than one dependent variable or smoothing value in the MODEL statement, the variable name is appended with an order number. For details, see the ROWWISE option.

The keywords allowed and the statistics they represent are as follows:

- |                      |                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|----------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>PREDICTED   P</b> | creates a new variable that contains predicted values. The default <i>name</i> is Predicted.                                                                                                                                                                                                                                                                                                                                              |
| <b>RESIDUAL   R</b>  | creates a new variable that contains residual values, which are calculated as ACTUAL – PREDICTED. The default <i>name</i> is Residual.                                                                                                                                                                                                                                                                                                    |
| <b>STD</b>           | creates a new variable that contains standard errors of the mean predicted values. The use of this option implicitly selects the model option DFMETHOD=EXACT even if the DFMETHOD= option has not been explicitly used. The default <i>name</i> is StdErr.                                                                                                                                                                                |
| <b>T</b>             | creates a new variable that contains <i>t</i> statistics. The use of this option implicitly selects the model option DFMETHOD=EXACT even if the DFMETHOD= option has not been explicitly used. The default <i>name</i> is tValue.                                                                                                                                                                                                         |
| <b>LCLM</b>          | creates a new variable that contains the lower part of 100(1 – $\alpha$ )% confidence limits on the mean predicted value. By default, the 95% limits are computed; the ALPHA= option in the <b>MODEL</b> statement can be used to change the significance level. The use of this option implicitly selects the model option DFMETHOD=EXACT even if the DFMETHOD= option has not been explicitly used. The default <i>name</i> is LowerCL. |
| <b>UCLM</b>          | creates a new variable that contains the upper part of 100(1 – $\alpha$ )% confidence limits on the mean predicted value. By default, the 95% limits are computed; the ALPHA= option in the <b>MODEL</b> statement can be used to change the significance level. The use of this option implicitly selects the model option DFMETHOD=EXACT even if the DFMETHOD= option has not been explicitly used. The default <i>name</i> is UpperCL. |

You can specify the following *options* in the OUTPUT statement after a slash (/).

**ALL**

requests all these keywords: PREDICTED, RESIDUAL, STD, T, LCLM, and UCLM.

**ROWWISE | ROW**

arranges the created OUTPUT data set in rowwise format. For each dependent variable and each smoothing value specified in the SMOOTH= option in the MODEL statement, one variable is generated for each specified keyword and the variable name is appended with an order number if there are multiple occurrences of the requested statistic. Those variables appear in an order that corresponds to the specified order of the dependent variables and the smoothing values in the MODEL statement. For each variable generated, a label is also created automatically; the label contains the default name of the represented statistic, the name of the dependent variable selected to be modeled, and the smoothing value used for calculating the represented statistic.

By default, the OUTPUT data set is created in columnwise format, where the input data is repeated for each dependent variable and for each smoothing value. Three extra columns, named SmoothingParameter for smoothing parameter values, DepVar for dependent variable names, and Obs for observation numbers, are also added to the OUTPUT data set to distinguish each model.

---

## SCORE Statement

**SCORE DATA=SAS-data-set < ID=(variable-list) > < / options > ;**

The fitted loess model is used to score the data in the specified SAS data set. This data set must contain all the regressor variables specified in the MODEL statement. Furthermore, when a BY statement is used, the score data set must also contain all the BY variables sorted in the order of the BY variables. A SCORE statement is optional, and more than one SCORE statement can be used. SCORE statements cannot be used if the DIRECT option is specified in the MODEL statement. The optional ID= (variable-list) specifies ID variables to be included in the “Score Results” table.

You find the results of the SCORE statement in the “Score Results” table. This table contains all the data in the data set named in the SCORE statement, including observations with missing values. However, only those observations with nonmissing regressor variables are scored. If no data set is named in the SCORE statement, the data set named in the PROC LOESS statement is scored. You use the PRINT option in the SCORE statement to request that the “Score Results” table be displayed. You can place the “Score Results” table in an output data set by using an ODS OUTPUT statement even if this table is not displayed.

You can specify the following options in the SCORE statement after a slash (/).

**CLM**

requests that  $100(1 - \alpha)\%$  confidence limits on the mean predicted value be added to the “Score Results” table. By default the 95% limits are computed; the ALPHA= option in the MODEL statement can be used to change the significance level. The use of this option implicitly selects the model option DFMETHOD=EXACT if the DFMETHOD= option has not been explicitly used.

**PRINT < (VAR=variables) >**

specifies that the “Score Results” table be displayed. By default only the variables named in the MODEL statement, the variables listed in the ID list in the SCORE statement, and the scored dependent variables are displayed. You can use the VAR= option to specify additional variables in the score data set that are to be included in the displayed output. Note, however, that all columns in the SCORE

data set are placed in the SCORE results table, even if you do not request that they be included in the displayed output.

#### **RESIDUAL | R**

requests that residuals be added to the “Score Results” table. If the data set you specify in DATA= option in the SCORE statement does not contain one or more of the model dependent variables, then the corresponding residual values in the “Score Results” table are set to missing.

#### **SCALEDINDEP**

specifies that scaled regressor coordinates be included in the “Score Results” table. This option is ignored if the SCALE= option is not specified in the MODEL statement.

#### **STEPS**

requests that all models evaluated during smoothing parameter value selection be scored, provided that the SELECT= option together with the STEPS modifier is specified in the MODEL statement. By default only the selected model is scored.

## **WEIGHT Statement**

**WEIGHT** *variable* ;

The WEIGHT statement specifies a variable in the input data set that contains values to be used as a priori weights for a loess fit.

The values of the weight variable must be nonnegative. If an observation’s weight is zero, negative, or missing, the observation is deleted from the analysis.

## **Details: LOESS Procedure**

### **Missing Values**

PROC LOESS deletes any observation with missing values for any variable specified in the MODEL statement. This enables the procedure to reuse the  $k$ -d tree for all the dependent variables that appear in the MODEL statement. If you have multiple dependent variables with different missing value structures for the same set of independent variables, you might want to use separate PROC LOESS steps for each dependent variable.

### **Output Data Sets**

PROC LOESS assigns a name to each table it creates. You can use the ODS OUTPUT statement to place one or more of these tables in output data sets. See the section “ODS Table Names” on page 4131 for a list of the table names created by PROC LOESS. For detailed information about ODS, see Chapter 20, “Using the Output Delivery System.”

For example, the following statements create an output data set named MyOutStats containing the “Output Statistics” table and an output data set named MySummary containing the “Fit Summary” table.

```
proc loess data=Melanoma;
 model Incidences=Year;
 ods output OutputStatistics = MyOutStats
 FitSummary = MySummary;
run;
```

Often, a single MODEL statement describes more than one model. For example, the following statements fit eight different models (four smoothing parameter values for each dependent variable).

```
proc loess;
 model y1 y2 = x1 x2 x3/smooth =0.1 to 0.7 by 0.2;
 ods output OutputStatistics = MyOutStats;
run;
```

The eight “Output Statistics” tables for these models are stacked in a single data set called MyOutStats. The data set contains a column named DepVarName and a column named SmoothingParameter that distinguish each model (see [Figure 53.8](#) for an example). If you want the “Output Statistics” table for each model to be in its own data set, you can use the MATCH\_ALL option in the ODS OUTPUT statement. The following statements create eight data sets named MyOutStats, MyOutStats1, . . . , MyOutStats7.

```
proc loess;
 model y1 y2 = x1 x2 x3/smooth =0.1 to 0.7 by 0.2;
 ods output OutputStatistics(match_all) = MyOutStats;
run;
```

For further options available in the ODS OUTPUT statement, see Chapter 20, “Using the Output Delivery System.”

Only the “Scale Details” and “Fit Summary” tables are displayed by default. The other tables are optionally displayed by using the DETAILS option in the MODEL statement and the PRINT option in the SCORE statement. Note that it is not necessary to display a table in order for that table to be used in an ODS OUTPUT statement. For example, the following statements display the “Output Statistics” and “*k*-d Tree” tables but place the “Output Statistics” and “Prediction at Vertices” tables in output data sets.

```
proc loess data=Melanoma;
 model Incidences=Year/details(OutputStatistics kdTree);
 ods output OutputStatistics = MyOutStats
 PredAtVertices = MyVerticesOut;
run;
```

Using the DETAILS option alone causes all tables to be displayed.

The MODEL statement options CLM, RESIDUAL, STD, SCALEDINDEP, and T control which optional columns are added to the OutputStatistics table. For example, to obtain an OutputStatistics output data set containing residuals and confidence limits in addition to the model variables and predicted value, you need to specify the RESIDUAL and CLM options in the MODEL statement as in the following example:

```
proc loess data=Melanoma;
 model Incidences=Year/residual clm;
 ods output OutputStatistics = MyOutStats;
run;
```

Finally, note that using the ALL option in the MODEL statement causes all optional columns to be included in the output. Also, ID columns can be added to the OutputStatistics table by using the ID statement.

---

## Data Scaling

The loess algorithm to obtain a predicted value at a given point in the predictor space proceeds by doing a least squares fit that uses all data points close to the given point. Thus the algorithm depends critically on the metric used to define closeness. This has the consequence that if you have more than one predictor variable and these predictor variables have significantly different scales, then closeness depends almost entirely on the variable with the largest scaling. It also means that merely changing the units of one of your predictors can significantly change the loess model fit.

To circumvent this problem, it is necessary to standardize the scale of the independent variables in the loess model. The SCALE= option in the MODEL statement is provided for this purpose. PROC LOESS uses a symmetrically trimmed standard deviation as the scale estimate for each independent variable of the loess model. This is a robust scale estimator in that extreme values of a variable are discarded before estimating the data scaling. For example, to compute a 10% trimmed standard deviation of a sample, you discard the smallest and largest 5% of the data and compute the standard deviation of the remaining 90% of the data points. In this case, the trimming fraction is 0.1.

For example, the following statement specifies that the variables Temperature and Catalyst are scaled before performing the loess fitting. In this case, because the trimming fraction is 0.1, the scale estimate used for each of these variables is a 10% trimmed standard deviation.

```
model Yield=Temperature Catalyst / scale = SD(0.1);
```

The default trimming fraction used by PROC LOESS is 0.1 and need not be specified by the SCALE= option. Thus the following MODEL statement is equivalent to the previous MODEL statement.

```
model Yield=Temperature Catalyst / scale = SD;
```

If the SCALE= option is not specified, no scaling of the independent variables is done. This is appropriate when there is only a single independent variable or when all the independent variables are a priori scaled similarly.

When the SCALE= option is specified, the scaling details for each independent variable are added to the ScaleDetails table (see [Output 53.3.2](#) for an example). By default, this table contains only the minimum and maximum values of each independent variable in the model. Finally, note that when the SCALE= option is used, specifying the SCALEDINDEP option in the MODEL statement adds the scaled values of the independent variables to the OutputStatistics and PredAtVertices tables. If the SCALEDINDEP option is specified in the SCORE statement, then scaled values of the independent variables are included in the ScoreResults table. By default, only the unscaled values are placed in these tables.

---

## Direct versus Interpolated Fitting

Local regression to obtain a predicted value at a given point in the predictor space is done by doing a least squares fit that uses all data points in a local neighborhood of the given point. This method is computationally expensive because a local neighborhood must be determined and a least squares problem must be solved for each point at which a fitted value is required. A faster method is to obtain such fits at a representative sample of points in the predictor space and to obtain fitted values at all other points by interpolation.

PROC LOESS can fit models by using either of these two methods. By default, PROC LOESS uses fitting at a sample of points and interpolation. The method fitting a local model at every data point is selected by specifying the `DIRECT` option in the `MODEL` statement.

---

## *k*-d Trees and Blending

PROC LOESS uses a *k*-d tree to divide the box (also called the *initial cell* or *bucket*) enclosing all the predictor data points into rectangular cells. The vertices of these cells are the points at which local least squares fitting is done.

Starting from the initial cell, the direction of the longest cell edge is selected as the split direction. The median of this coordinate of the data in the cell is the split value. The data in the starting cell are partitioned into two child cells. The left child consists of all data from the parent cell whose coordinate in the split direction is less than the split value. This procedure is repeated for each child cell that has more than a prespecified number of points, called the *bucket size* of the *k*-d tree.

You can specify the bucket size with the `BUCKET=` option in the `MODEL` statement. If you do not specify the `BUCKET=` option, the default value used is the largest integer less than or equal to  $ns/5$ , where  $n$  is the number of observations and  $s$  is the value of the smoothing parameter. Note that if fitting is being done for a range of smoothing parameter values, the bucket size can change for each value.

The set of vertices of all the cells of the *k*-d tree are the points at which PROC LOESS performs its local fitting. The fitted value at an original data point (or at any other point within the original data cell) is obtained by blending the fitted values at the vertices of the *k*-d tree cell that contains that data point.

The univariate blending methods available in PROC LOESS are linear and cubic polynomial interpolation, with linear interpolation being the default. You can request cubic interpolation by specifying the `INTERP=CUBIC` option in the `MODEL` statement. In this case, PROC LOESS uses the unique cubic polynomial whose values and first derivatives match those of the fitted local polynomials evaluated at the two endpoints of the *k*-d tree cell edge.

In the multivariate case, such univariate interpolating polynomials are computed on each edge of the *k*-d tree cells and are combined using blending functions (Gordon 1971). In the case of two regressors, if you specify `INTERP=CUBIC` in the `MODEL` statement, PROC LOESS uses Hermite cubic polynomials as blending functions. If you do not specify `INTERP=CUBIC`, or if you specify a model with more than two regressors, then PROC LOESS uses linear polynomials as blending functions. In these cases, the blending method reduces to tensor product interpolation from the  $2^p$  vertices of each *k*-d tree cell, where  $p$  is the number of regressors.

While the details of the *k*-d tree and the fitted values at the vertices of the *k*-d tree are implementation details that seldom need to be examined, PROC LOESS does provide options for their display. Each *k*-d tree subdivision of the data used by PROC LOESS is placed in the “kdTree” table. The predicted values at

the vertices of each  $k$ -d tree are placed in the “PredAtVertices” table. You can request these tables by using the DETAILS option in the MODEL statement.

---

## Local Weighting

The size of the local neighborhoods that PROC LOESS uses in performing local fitting is determined by the smoothing parameter value  $s$ . When  $s < 1$ , the local neighborhood used at a point  $x_i$  contains the  $s$  fraction of the data points closest to the point  $x_i$ . When  $s \geq 1$ , all data points are used.

Suppose  $q$  denotes the number of points in the local neighborhoods and  $d_1, d_2, \dots, d_q$  denote the distances in increasing order of the  $q$  points closest to  $x_i$ . The point at distance  $d_i$  from  $x_i$  is given a weight  $w_i$  in the local regression that decreases as the distance from  $x_i$  increases. PROC LOESS uses a tricube weight function to define

$$w_i = \frac{32}{5} \left( 1 - \left( \frac{d_i}{d_q} \right)^3 \right)^3$$

If  $s > 1$ , then  $d_q$  is replaced by  $d_q s^{1/p}$  in the previous formula, where  $p$  is the number of predictors in the model.

Finally, note that if a weight variable has been specified using a WEIGHT statement, then  $w_i$  is multiplied by the corresponding value of the specified weight variable.

---

## Iterative Reweighting

PROC LOESS can do iterative reweighting to improve the robustness of the fit in the presence of outliers in the data. Iterative reweighting is also appropriate when statistical inference is requested and the error distribution is symmetric but not Gaussian.

The number of iterations is specified by the ITERATIONS= option in the MODEL statement. The default is ITERATIONS=1, which corresponds to no reweighting.

At iterations beyond the first iteration, the local weights  $w_i$  of the previous section are replaced by  $r_i w_i$ , where  $r_i$  is a weight that decreases as the residual of the fitted value at the previous iteration at the point corresponding to  $d_i$  increases. See Cleveland and Grosse (1991) and Cleveland, Grosse, and Shyu (1992) for details.

---

## Specifying the Local Polynomials

PROC LOESS uses linear or quadratic polynomials in doing the local least squares fitting. The option DEGREE = in the MODEL statement is used to specify the degree of the local polynomials used by PROC LOESS, with DEGREE = 1 being the default. In addition, when DEGREE = 2 is specified, the MODEL statement DROPSQUARE= option can be used to exclude specific monomials during the least squares fitting.

For example, the following statements use the monomials 1, x1, x2, x1\*x2, and x2\*x2 for the local least squares fitting.

```
proc loess;
 model y= x1 x2/ degree=2 dropsquare=(x1);
run;
```

---

## Smoothing Matrix

When no iterative reweighting is done, the “Smoothing Matrix” denoted by  $\mathbf{L}$  defines the linear relationship between the fitted and observed dependent variable values of a loess model. You can obtain the predicted values of a loess fit from the observed values via

$$\hat{\mathbf{y}} = \mathbf{L}\mathbf{y}$$

where  $\mathbf{y}$  is the vector of observed values and  $\hat{\mathbf{y}}$  is the corresponding vector of predicted values of the dependent variable. Note that  $\mathbf{L}$  is an  $n$  by  $n$  matrix, where  $n$  is the number of observations in the analysis. PROC LOESS does not explicitly form  $\mathbf{L}$  if the DFMETHOD=EXACT option is not explicitly or implicitly selected.

---

## Model Degrees of Freedom

The approximate model degrees of freedom in a nonparametric fit is a number that is analogous to the number of free parameters in a parametric model. There are three commonly used measures of model degrees of freedom in nonparametric models. These criteria are as follows:

$$\begin{aligned} \text{DF1} &\equiv \text{Trace}(\mathbf{L}) \\ \text{DF2} &\equiv \text{Trace}(\mathbf{L}'\mathbf{L}) \\ \text{DF3} &\equiv 2\text{Trace}\mathbf{L} - \text{Trace}(\mathbf{L}'\mathbf{L}) \end{aligned}$$

A discussion of their properties can be found in Hastie and Tibshirani (1990). DF2 is also referred to as the “Equivalent Number of Parameters,” and this is the name that PROC LOESS uses for DF2 when it appears in the “Fit Summary” table.

---

## Statistical Inference and Lookup Degrees of Freedom

If you denote the  $i$ th measurement of the response by  $y_i$  and the corresponding measurement of predictors by  $x_i$ , then

$$y_i = g(x_i) + \epsilon_i$$

where  $g$  is the regression function and  $\epsilon_i$  are independent random errors with mean zero. If the errors are normally distributed with constant variance, then you can obtain confidence intervals for the predictions

from PROC LOESS. You can also obtain confidence limits in the case where  $\epsilon_i$  is heteroscedastic but  $a_i\epsilon_i$  has constant variance and  $a_i$  are a priori weights that are specified using the **WEIGHT** statement of PROC LOESS. You can do inference in the case in which the error distribution is symmetric by using iterative reweighting. Formulas for doing statistical inference under the preceding conditions can be found in Cleveland and Grosse (1991) and Cleveland, Grosse, and Shyu (1992). Cleveland and Grosse (1991) show that standardized residuals for a loess model follow a  $t$  distribution with  $\rho$  degrees of freedom where

$$\begin{aligned}\delta_1 &\equiv \text{Trace}(\mathbf{I} - \mathbf{L})'(\mathbf{I} - \mathbf{L}) \\ \delta_2 &\equiv \text{Trace}((\mathbf{I} - \mathbf{L})'(\mathbf{I} - \mathbf{L}))^2 \\ \rho &\equiv \text{Lookup Degrees of Freedom} \\ &\equiv \delta_1^2/\delta_2\end{aligned}$$

The residual standard error that you find in the “Fit Summary” table is defined by

$$\text{Residual Standard Error} \equiv \sqrt{\text{Residual SS}/\delta_1}$$

The determination of  $\rho$  is computationally expensive and is not done by default. It is computed if you specify the **DFMETHOD=EXACT** or **DFMETHOD=APPROX** option in the **MODEL** statement. It is also computed if you specify any of the options **CLM**, **STD**, and **T** in the **MODEL** statement. Note that the values of  $\delta_1$ ,  $\delta_2$ , and  $\rho$  are reported in the “Fit Summary” table.

If you specify the **CLM** option in the **MODEL** statement, confidence limits are added to the **OutputStatistics** table. By default, 95% limits are computed, but you can change this by using the **ALPHA=** option in the **MODEL** statement.

---

## Automatic Smoothing Parameter Selection

There are several methodologies for automatic smoothing parameter selection. One class of methods chooses the smoothing parameter value to minimize a criterion that incorporates both the tightness of the fit and model complexity. Such a criterion can usually be written as a function of the error mean square,  $\hat{\sigma}^2$ , and a penalty function designed to decrease with increasing smoothness of the fit. This penalty function is usually defined in terms of the smoothing matrix **L** (see the section “Smoothing Matrix” on page 4126).

Examples of specific criteria are generalized cross validation (Craven and Wahba 1979) and the Akaike information criterion (Akaike 1973). These classical selectors have two undesirable properties when used with local polynomial and kernel estimators: they tend to undersmooth small data sets and tend to be nonrobust in the sense that small variations of the input data can change the choice of smoothing parameter value significantly. Hurvich, Simonoff, and Tsai (1998) obtained several corrected AIC criteria that address the small-sample bias and perform comparably with the *plug-in selectors* (Ruppert, Sheather, and Wand 1995). PROC LOESS provides automatic smoothing parameter selection that uses two of these corrected AIC criteria, named  $\text{AIC}_{C_1}$  and  $\text{AIC}_C$  in Hurvich, Simonoff, and Tsai (1998), and generalized cross validation, denoted by GCV.

The relevant formulas are

$$\begin{aligned} \text{AIC}_{C_1} &= n \log(\hat{\sigma}^2) + n \frac{\delta_1/\delta_2(n + \nu_1)}{\delta_1^2/\delta_2 - 2} \\ \text{AIC}_C &= \log(\hat{\sigma}^2) + 1 + \frac{2(\text{Trace}(\mathbf{L}) + 1)}{n - \text{Trace}(\mathbf{L}) - 2} \\ \text{GCV} &= \frac{n\hat{\sigma}^2}{(n - \text{Trace}(\mathbf{L}))^2} \end{aligned}$$

where  $n$  is the number of observations and

$$\begin{aligned} \delta_1 &\equiv \text{Trace}(\mathbf{I} - \mathbf{L})'(\mathbf{I} - \mathbf{L}) \\ \delta_2 &\equiv \text{Trace}((\mathbf{I} - \mathbf{L})'(\mathbf{I} - \mathbf{L}))^2 \\ \nu_1 &\equiv \text{Equivalent Number of Parameters} \\ &\equiv \text{Trace}(\mathbf{L}'\mathbf{L}) \end{aligned}$$

You invoke these methods for automatic smoothing parameter selection by specifying the `SELECT=criterion` option in the `MODEL` statement, where *criterion* is AICC1, AICC, or GCV. The LOESS procedure evaluates the specified criterion for a sequence of smoothing parameter values and selects the value in this sequence that minimizes the specified criterion. If multiple values yield the optimum, then the largest of these values is selected.

A second class of methods seeks to set an approximate measure of model degrees of freedom to a specified target value. These methods are useful for making meaningful comparisons between loess fits and other nonparametric and parametric fits. Three approximate model degrees of freedom for a loess model are defined in the section “[Model Degrees of Freedom](#)” on page 4126. You invoke these methods by specifying the `SELECT=DFcriterion(target)` option in the `MODEL` statement, where *DFcriterion* is DF1, DF2, or DF3. The criterion that is minimized is given in the following table.

**Table 53.4** Minimization Criteria

| Syntax                          | Minimization Criterion                                                              |
|---------------------------------|-------------------------------------------------------------------------------------|
| <code>SELECT=DF1(target)</code> | $ \text{Trace}(\mathbf{L}) - \text{target} $                                        |
| <code>SELECT=DF2(target)</code> | $ \text{Trace}(\mathbf{L}'\mathbf{L}) - \text{target} $                             |
| <code>SELECT=DF3(target)</code> | $ 2\text{Trace}(\mathbf{L}) - \text{Trace}(\mathbf{L}'\mathbf{L}) - \text{target} $ |

The results are summarized in the “Smoothing Criterion” table. This table is displayed whenever automatic smoothing parameter selection is performed. You can obtain details of the sequence of models examined by specifying the `DETAILS(MODELSUMMARY)` option in the `MODEL` statement to display the “Model Summary” table.

There are several ways in which you can control the sequence of models examined by PROC LOESS. If you specify the `SMOOTH=value-list` option in the `MODEL` statement, then only the values in this list are examined in performing the selection. For example, the following statements select the model that

minimizes the AICC1 criterion among the three models with smoothing parameter values 0.1, 0.3, and 0.4:

```
proc loess;
 model y= x1/ smooth=0.1 0.3 0.4 select=AICC1;
run;
```

If you do not specify the SMOOTH= option in the MODEL statement, then by default PROC LOESS uses a golden section search method to find a local minimum of the specified criterion in the range (0, 1]. You can use the RANGE(*lower,upper*) modifier in the SELECT= option to change the interval in which the golden section search is performed. For example, the following statements request a golden section search to find a local minimizer of the GCV criterion for smoothing parameter values in the interval [0.1,0.5]:

```
proc loess;
 model y= x1/select=GCV(range(0.1,0.5));
run;
```

If you want to be sure of obtaining a global minimum in the range of smoothing parameter values examined, you can specify the GLOBAL modifier in the SELECT= option. For example, the following statements request that a global minimizer of the AICC criterion be obtained for smoothing parameter values in the interval [0.2, 0.8]:

```
proc loess;
 model y= x1/select=AICC(global range(0.2,0.8));
run;
```

Note that even though the smoothing parameter is a continuous variable, a given range of smoothing parameter values corresponds to a finite set of local models. For example, for a data set with 100 observations, the range [0.2, 0.4] corresponds to models with 20, 21, 22, . . . , 40 points in the local neighborhoods. If the GLOBAL modifier is specified, all possible models in the range are evaluated sequentially.

Note that by default PROC LOESS displays a “Fit Summary” and other optionally requested tables only for the selected model. You can request that these tables be displayed for all models in the selection process by adding the STEPS modifier in the SELECT= option. Also note that by default scoring requested with SCORE statements is done only for the selected model. However, if you specify the STEPS in both the MODEL and SCORE statements, then all models evaluated in the selection process are scored.

In terms of computation,  $AIC_C$ , GCV, and DF1 depend on the smoothing matrix  $\mathbf{L}$  only through its trace. In the direct method, this trace can be computed efficiently. In the interpolated method that uses  $k$ -d trees, there is some additional computational cost but the overall work is not significant compared to the rest of the computation. In contrast, the quantities  $\delta_1$ ,  $\delta_2$ , and  $\nu_1$  that appear in the  $AIC_{C_1}$  criterion, and the DF2 and DF3 criteria, depend on the entire  $\mathbf{L}$  matrix and for this reason, the time needed to compute these quantities dominates the time required for the model fitting. Hence SELECT=AICC1, SELECT=DF2, and SELECT=DF3 are much more computationally expensive than SELECT=AICC, SELECT=GCV, and SELECT=DF1, especially when combined with the GLOBAL modifier. Hurvich, Simonoff, and Tsai (1998) note that  $AIC_C$  can be regarded as an approximation of  $AIC_{C_1}$  and that “the  $AIC_C$  selector generally performs well in all circumstances.”

For models with one dependent variable, PROC LOESS uses SELECT=AICC as its default, if you specify neither the SMOOTH= nor the SELECT= option in the MODEL statement. With two or more dependent variables, automatic smoothing parameter selection needs to be done separately for each dependent variable. For this reason automatic smoothing parameter selection is not available for models with multiple dependent

variables. In such cases you should use a separate PROC LOESS step for each dependent variable, if you want to use automatic smoothing parameter selection.

---

## Sparse and Approximate Degrees of Freedom Computation

As noted in the section “Statistical Inference and Lookup Degrees of Freedom” on page 4126, obtaining confidence limits in loess models requires the computation of the lookup degrees of freedom. This in turn requires the computation of

$$\delta_2 \equiv \text{Trace}((\mathbf{I} - \mathbf{L})'(\mathbf{I} - \mathbf{L}))^2$$

where  $\mathbf{L}$  is the loess smoothing matrix (see the section “Smoothing Matrix” on page 4126).

The work in a direct implementation of this formula grows as  $n^3$ , where  $n$  is the number of observations in analysis. For large  $n$ , this work dominates the time needed to fit the loess model itself. To alleviate this computational bottleneck, Cleveland and Grosse (1991) and Cleveland, Grosse, and Shyu (1992) developed approximate methods for estimating this quantity in terms of more readily computable statistics. A different approach to obtaining a computationally cheap estimate of  $\delta_2$  has been implemented in PROC LOESS.

For large data sets with significant local structure, the loess model is often used with small values of the smoothing parameter. Recalling that the smoothing parameter defines the fraction of the data used in each local regression, this means that the loess fit at any point in regressor space depends on only a small fraction of the data. This is reflected in the smoothing matrix  $\mathbf{L}$  whose  $(i, j)$  entry is nonzero only if the  $i$ th and  $j$ th observations lie in at least one common local neighborhood. Hence the smoothing matrix is a sparse matrix (has mostly zero entries) in such cases. By exploiting this sparsity, PROC LOESS now computes  $\delta_2$  orders of magnitude faster than in previous implementations.

When each local neighborhood contains a large subset of the data—i.e., when the smoothing parameter is large—then it is no longer true that the smoothing matrix is sparse. However, since a point in a local neighborhood is given a local weight that decreases with its distance from the center of the neighborhood, many of the coefficients in the smoothing matrix turn out to be nonzero but with orders of magnitude smaller than that of the larger coefficients in the matrix. The approximate method for computing  $\delta_2$  that has been implemented in PROC LOESS exploits these disparities in magnitudes of the elements in the smoothing matrix by setting the small elements to zero. This creates a sparse approximation of the smoothing matrix to which the fast sparse methods can be applied.

In order to decide the threshold at which elements in the smoothing matrix are set to zero, PROC LOESS samples the elements in the smoothing matrix to obtain the value of the element in a specified lower quantile in this sample. The magnitude of the element at this quantile is used as a cutoff value, and all elements in the smoothing matrix whose magnitude is less than this cutoff are set to zero for the approximate computation. By default all elements in the lower ninetieth percentile are set to zero. You can use the `DFMETHOD=APPROX(QUANTILE= )` option in the `MODEL` statement to change this value. As you increase the value for the quantile to be zeroed, you speed up the degrees of freedom computation at the expense of increasing approximation errors. You can also use the `DFMETHOD=APPROX(CUTOFF= )` option in the `MODEL` statement to specify the cutoff value directly.

For small data sets, the approximate computation is not needed and would be rougher than for larger data sets. Hence PROC LOESS performs the exact computation for analyses with fewer than 500 points, even if `DFMETHOD=APPROX` is specified in the model statement. Also, for small values of the smoothing

parameter, elements in the lower specified quantile might already all be zero. In such cases the approximate method is the same as the exact method. PROC LOESS labels as approximate any statistics that depend on the approximate computation of  $\delta_2$  only in the cases where the approximate computation was used and is different from the exact computation.

---

## Scoring Data Sets

One or more **SCORE** statements can be used with PROC LOESS. A data set that includes all the variables specified in the **MODEL** and **BY** statements must be specified in each **SCORE** statement. Score results are placed in the ScoreResults table. This table is not displayed by default, but specifying the **PRINT** option in the **SCORE** statement produces the table. If you specify the **CLM** option in the **SCORE** statement, confidence intervals are included in the ScoreResults table.

Note that scoring is not supported when the **DIRECT** option is specified in the **MODEL** statement. Scoring at a point specified in a score data set is done by first finding the cell in the  $k$ -d tree containing this point and then interpolating the scored value from the predicted values at the vertices of this cell. This methodology precludes scoring any points that are not contained in the box that surrounds the data used in fitting the loess model.

---

## ODS Table Names

PROC LOESS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 53.5** ODS Tables Produced by PROC LOESS

| ODS Table Name     | Description                                           | Statement | Option                    |
|--------------------|-------------------------------------------------------|-----------|---------------------------|
| FitSummary         | Specified fit parameters and fit summary              |           | default                   |
| kdTree             | Structure of $k$ -d tree used                         | MODEL     | DETAILS(kdTree)           |
| ModelSummary       | Summary of all models evaluated                       | MODEL     | DETAILS(ModelSummary)     |
| OutputStatistics   | Coordinates and fit results at input data points      | MODEL     | DETAILS(OutputStatistics) |
| PredAtVertices     | Coordinates and fitted values at $k$ -d tree vertices | MODEL     | DETAILS(PredAtVertices)   |
| ScaleDetails       | Extent and scaling of the independent variables       |           | default                   |
| ScoreResults       | Coordinates and fit results at scoring points         | SCORE     | PRINT                     |
| SmoothingCriterion | Criterion value and selected smoothing parameter      | MODEL     | SELECT                    |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC LOESS generates are listed in Table 53.6, along with the relevant PLOTS= options.

**Table 53.6** Graphs Produced by PROC LOESS

| ODS Graph Name      | Plot Description                                                         | PLOTS Option        |
|---------------------|--------------------------------------------------------------------------|---------------------|
| ContourFitPanel     | Panel of loess contour surfaces overlaid on scatter plots of data        | CONTOURFITPANEL     |
| ContourFit          | Loess contour surface overlaid on scatter plot of data                   | CONTOURFITPANEL     |
| DiagnosticsPanel    | Panel of fit diagnostics                                                 | DIAGNOSTICS         |
| FitPanel            | Panel of loess curves overlaid on scatter plots of data                  | FITPANEL            |
| FitPlot             | Loess curve overlaid on scatter plot of data                             | FIT                 |
| ObservedByPredicted | Dependent variable versus loess fit                                      | OBSERVEDBYPREDICTED |
| QQPlot              | Normal quantile plot of residuals                                        | QQPLOT              |
| ResidualsBySmooth   | Panel of residuals versus regressor by smoothing parameter values        | RESIDUALSBYSMOOTH   |
| ResidualByPredicted | Residuals versus loess fit                                               | RESIDUALBYPREDICTED |
| ResidualHistogram   | Histogram of fit residuals                                               | RESIDUALHISTOGRAM   |
| ResidualPanel       | Panel of residuals versus regressors for fixed smoothing parameter value | RESIDUALS           |
| ResidualPlot        | Plot of residuals versus regressor                                       | RESIDUALS           |
| RFPlot              | Side-by-side plots of quantiles of centered fit and residuals            | RFPLOT              |
| ScorePlot           | Loess fit evaluated at scoring points                                    | SCOREPLOT           |
| CriterionPlot       | Selection criterion versus smoothing parameter                           | CRITERION           |

## Examples: LOESS Procedure

---

### Example 53.1: Engine Exhaust Emissions

Investigators studied the exhaust emissions of a one-cylinder engine (Brinkman 1981). The SAS data set Gas contains the results data. The dependent variable, NO<sub>x</sub>, measures the concentration, in micrograms per joule, of nitric oxide and nitrogen dioxide normalized by the amount of work of the engine. The independent variable, E, is a measure of the richness of the air and fuel mixture.

```
data Gas;
 input NOx E @@;
 format NOx f3.1;
 format E f3.1;
 datalines;
4.818 0.831 2.849 1.045
3.275 1.021 4.691 0.97
4.255 0.825 5.064 0.891
2.118 0.71 4.602 0.801
2.286 1.074 0.97 1.148
3.965 1 5.344 0.928
3.834 0.767 1.99 0.701
5.199 0.807 5.283 0.902
3.752 0.997 0.537 1.224
1.64 1.089 5.055 0.973
4.937 0.98 1.561 0.665
;
```

The following PROC SGPLOT statements produce the simple scatter plot of these data displayed in [Output 53.1.1](#).

```
proc sgplot data=Gas;
 scatter x=E y=NOx;
run;
```

**Output 53.1.1** Scatter Plot of the Gas Data

The following statements fit two loess models for these data. Because this is a small data set, it is reasonable to do direct fitting at every data point. As there is substantial curvature in the data, quadratic local polynomials are used. An ODS OUTPUT statement creates two output data sets containing the “Output Statistics” and “Fit Summary” tables.

```
ods graphics on;

proc loess data=Gas;
 ods output OutputStatistics = GasFit
 FitSummary=Summary;
 model NOx = E / degree=2 select=AICC(steps) smooth = 0.6 1.0
 direct alpha=.01 all details;
run;

ods graphics off;
```

**Output 53.1.2** Fit Summary Table

| Residual Standard Error           | 0.33707  |

The “Fit Summary” table for smoothing parameter value 0.6, shown in [Output 53.1.2](#), records the fitting parameters specified and some overall fit statistics. See the section “[Smoothing Matrix](#)” on page 4126 for a definition of the smoothing matrix  $L$ , and the sections “[Model Degrees of Freedom](#)” on page 4126 and “[Statistical Inference and Lookup Degrees of Freedom](#)” on page 4126 for definitions of the statistics that appear in this table.

The “Output Statistics” table for smoothing parameter value 0.6 is shown in [Output 53.1.3](#). Note that, because the ALL option is specified in the `MODEL` statement, this table includes all the relevant optional columns. Furthermore, because the ALPHA=0.01 option is specified in the `MODEL` statement, the confidence limits in this table are 99% limits.

## Output 53.1.3 Output Statistics Table

| 21                                | 4.12632               | 4.92139 |                  |                                          |          |         |  |
| 22                                | 0.41375               | 1.98401 |                  |                                          |          |         |  |

**Output 53.1.4** Output Statistics Table

| Optimal Smoothing Criterion |                     |
|-----------------------------|---------------------|
| AICC                        | Smoothing Parameter |
| -0.45637                    | 0.60000             |

The combination of the options `SELECT=AICC` and `SMOOTH=0.6 1` in the `MODEL` statement specifies that PROC LOESS fit models with smoothing parameters of 0.6 and 1 and select the model that yields the smaller value of the AICC statistic. The “Smoothing Criterion” shown in [Output 53.1.4](#) shows that PROC LOESS selects the model with smoothing parameter value 0.6 as it yields the smaller value of the AICC statistic.

With ODS Graphics enabled, PROC LOESS produces a panel of fit plots whenever you specify the `SMOOTH=` option in the `MODEL` statement. These fit plots include confidence limits if you additionally specify the `CLM` option in the `MODEL` statement.

**Output 53.1.5** Loess Fits with 99% Confidence Limits for the Gas Data

[Output 53.1.5](#) shows the “Fit Panel” that displays the fitted models with 99% confidence limits overlaid on scatter plots of the data.

Based on the AICC criterion, the model with smoothing parameter 0.6 is preferred. You can address the question of whether the differences between these models are significant using analysis of variance. You do this by using the model with smoothing parameter value 1 as the null model.

The statistic

$$F = \frac{(\text{rss}^{(n)} - \text{rss}) / (\delta_1^{(n)} - \delta_1)}{\text{rss} / \delta_1}$$

has a distribution that is well approximated by an  $F$  distribution with

$$\nu = \frac{(\delta_1^{(n)} - \delta_1)^2}{\delta_2^{(n)} - \delta_2}$$

numerator degrees of freedom and  $\rho$  denominator degrees of freedom (Cleveland and Grosse 1991). Here quantities with superscript  $n$  refer to the null model,  $\text{rss}$  is the residual sum of squares, and  $\delta_1$ ,  $\delta_2$ , and  $\rho$  are defined in the section “[Statistical Inference and Lookup Degrees of Freedom](#)” on page 4126.

The “Fit Summary” tables contain the information needed to carry out such an analysis. These tables have been captured in the output data set named `Summary` by using an `ODS OUTPUT` statement. The following statements extract the relevant information from this data set and carry out the analysis of variance:

```

data h0 h1;
 set Summary(keep=SmoothingParameter Label1 nValue1
 where=(Label1 in ('Residual Sum of Squares', 'Delta1',
 'Delta2', 'Lookup Degrees of Freedom')));
 if SmoothingParameter = 1 then output h0;
 else output h1;
run;

proc transpose data=h0(drop=SmoothingParameter Label1) out=h0;
run;

data h0(drop=_NAME_);
 set h0;
 rename Col1 = RSSNull
 Col2 = delta1Null
 Col3 = delta2Null;
run;

proc transpose data=h1(drop=SmoothingParameter Label1) out=h1;
run;

data h1(drop=_NAME_);
 set h1;
 rename Col1 = RSS Col2 = delta1
 Col3 = delta2 Col4 = rho;
run;

data ftest;
 merge h0 h1;
 nu = (delta1Null - delta1)**2 / (delta2Null - delta2);
 Numerator = (RSSNull - RSS)/(delta1Null - delta1);
 Denominator = RSS/delta1;
 FValue = Numerator / Denominator;
 PValue = 1 - ProbF(FValue, nu, rho);
 label nu = 'Num DF' rho = 'Den DF'
 FValue = 'F Value' PValue = 'Pr > F';

```

```
run;

proc print data=ftest label;
 var nu rho Numerator Denominator FValue PValue;
 format nu rho FValue 7.2 PValue 6.4;
run;
```

The results are shown in [Output 53.1.6](#).

**Output 53.1.6** Test ANOVA for Loess Models of Gas Data

| Obs | Num DF | Den DF | Numerator | Denominator | F Value | Pr > F |
|-----|--------|--------|-----------|-------------|---------|--------|
| 1   | 2.67   | 15.53  | 1.05946   | 0.11362     | 9.32    | 0.0012 |

The small  $p$ -value confirms that the fit with smoothing parameter value 0.6 is significantly different from the loess model with smoothing parameter value 1.

Alternatively, you can use the OUTPUT statement to generate the statistics you want to include in the output data set. The following statements produce essentially the same results as the ODS OUTPUT statement does, except all the statistics for each of the two smoothing parameter values are included because the SELECT= option is not specified in the MODEL statement. In addition, with the ROW option specified, the output data set is arranged in rowwise format which enables you to compare statistics side-by-side for a sequence of smoothing values. The ALL option after the slash produces all the statistics (predicted values, residual values, standard errors of the mean predicted values,  $t$  statistics, and the lower and upper parts of  $100(1 - \alpha)\%$  confidence limits on the mean predicted value). All these requested statistics are given their respective default names in the output data set except the predicted value. The P=PREDVAL option causes the name for the predicted value to start with predval.

```
proc loess data=Gas;
 model NOx = E / degree=2 smooth = 0.6 1.0
 direct alpha=.01;
 output out=GasFit p=predval /all row;
run;
```

---

## Example 53.2: Sulfate Deposits in the U.S. for 1990

The following data set contains measurements in grams per square meter of sulfate ( $\text{SO}_4$ ) deposits during 1990 at 179 sites throughout the 48 contiguous states.

```
data SO4;
 input Latitude Longitude SO4 @@;
 format Latitude f4.0;
 format Longitude f4.0;
 format SO4 f4.1;
 datalines;
32.45833 87.24222 1.403 34.28778 85.96889 2.103
33.07139 109.86472 0.299 36.07167 112.15500 0.304
31.95056 112.80000 0.263 33.60500 92.09722 1.950
```

```

34.17944 93.09861 2.168 36.08389 92.58694 1.578

... more lines ...

43.87333 104.19222 0.306 44.91722 110.42028 0.210
45.07611 72.67556 2.646
;

```

As longitudes decrease from west to east in the western hemisphere, the roles of east and west get interchanged if you use these longitudes on the horizontal axis of a plot. You can address this by using negative values to represent longitudes in the western hemisphere. The following statements change the sign of longitude in the SO4 data set and define a format to display these negative values with a suffix of “W”.

```

proc format;
 picture latitude -90 - 0 = '000S'
 0 - 90 = '000N';
 picture longitude -180 - 0 = '000W'
 0 - 180 = '000E';
run;
data SO4;
 set SO4;
 format longitude longitude. latitude latitude.;
 longitude = -longitude;
run;

```

The following statements use ODS Graphics to plot the locations of the sulfate measurements. The circles indicating the locations are colored using a gradient that denotes the value of SO4.

```

proc template;
 define statgraph gradientScatter;
 beginGraph;
 layout overlay;
 scatterPlot x=longitude y=latitude /
 markercolorgradient = SO4
 markerattrs = (symbol=circleFilled)
 colormodel = ThreeColorRamp
 name = "Scatter";
 scatterPlot x=longitude y=latitude /
 markerattrs = (symbol=circle);
 continuousLegend "Scatter"/title= "SO4";
 endlayout;
 endgraph;
 end;
run;

proc sgrender data=SO4 template=gradientScatter;
run;

```

Output 53.2.1 Sulfate Measurements

Figure 53.2.1 shows that the largest concentrations of sulfate deposits occur in the northeastern United States.

The following statements fit a loess model.

```
ods graphics on;

proc loess data=SO4;
 model SO4=Longitude Latitude / degree=2 interp=cubic;
run;

ods graphics off;
```

**Output 53.2.2** Fit Plot for the SO4 Data

Figure 53.2.2 shows a contour plot of the fitted loess surface overlaid with a scatter plot of the data. The data are colored by the observed sulfate concentrations, using the same color gradient as the gradient-filled contour plot of the fitted surface. Note that for observations where the residual is small, the observations blend in with the contour plot. The greater the size of the residual, the greater the contrast between the observation color and the surface color.

The sulfate measurements are irregularly spaced. To facilitate producing a plot of the fitted loess surface, you can create a data set containing a regular grid of longitudes and latitudes and then use the **SCORE** statement to evaluate the loess surface at these points. The following statements show how you do this:

```
data PredPoints;
 format longitude longitude.
 latitude latitude.;
 do Latitude = 26 to 46 by 1;
 do Longitude = -79 to -123 by -1;
 output;
 end;
 end;
run;

proc loess data=S04;
 model S04=Longitude Latitude;
 score data=PredPoints / print;
 ods Output ScoreResults=ScoreOut;
run;
```

The **PRINT** option in the **SCORE** statement requests that the “Score Results” table be displayed as part of the PROC LOESS output. The ODS OUTPUT statement outputs this table to a data set named ScoreOut. If you do not want to display the score results but you do want the score results in an output data set, then you can omit the **PRINT** option from the **SCORE** statement. To plot the surface shown in Figure 53.2.3 by using ODS Graphics, use the following statements:

```
proc template;
 define statgraph surface;
 begingraph;
 layout overlay3d / rotate=340 tilt=30 cube=false;
 surfaceplotparm x=Longitude y=Latitude z=p_S04;
 endlayout;
 endgraph;
end;
run;

proc sgrender data=ScoreOut template=surface;
run;
```

**Output 53.2.3** Loess Fit of SO4 Surface

---

### Example 53.3: Catalyst Experiment

The following data set records the results of an experiment to determine how the yield of a chemical reaction varies with temperature and amount of a catalyst used.

```

data Experiment;
 input Temperature Catalyst MeasuredYield;
 if ranuni(1) < 0.1
 then CorruptedYield = MeasuredYield + 10 * ranuni(1);
 else CorruptedYield = MeasuredYield;
 datalines;
80 0.000 6.85601
80 0.002 7.26355
80 0.004 7.41448
80 0.006 7.82640

... more lines ...

140 0.078 5.20562
140 0.080 5.49371
;

```

The aim of this example is to show how you can use PROC LOESS for robust fitting in the presence of outliers. To simulate an intermittent equipment malfunction, the variable `CorruptedYield` is the same as the variable `MeasuredYield` except for about 10% of the observations where an offset has been added. This example shows how you can use PROC LOESS obtain a fit for `CorruptedYield` that is close to the fit you obtain for `MeasuredYield`.

The following statements produce a scatter plot of Temperature by Catalyst where the observations are colored by `CorruptedYield`:

```
proc template;
 define statgraph gradientScatter;
 beginGraph;
 layout overlay;
 scatterPlot x=Catalyst y=Temperature /
 markercolorgradient = CorruptedYield
 markerattrs = (symbol=circleFilled)
 colormodel = ThreeColorRamp
 name = "Yield";

 scatterPlot x=Catalyst y=Temperature /
 markerattrs = (symbol=circle);

 continuousLegend "Yield" / title= "CorruptedYield";
 endlayout;
 endgraph;
 end;
run;

proc sgrender data=Experiment template=gradientScatter;
run;
```

**Output 53.3.1** Scatter Plot of Experiment Data Colored by CorruptedYield

Output 53.3.1 shows a scatter plot of the data where the observations are shaded by the value of `CorruptedYield`. The darkly shaded points that are surrounded by lightly shaded points are points where the simulated incorrect measurements occur.

The following code fits a loess model to the measured data:

```
ods graphics on;

proc loess data=Experiment;
 model MeasuredYield = Temperature Catalyst / scale=sd(0.1);
run;
```

**Output 53.3.2** Scale Details for the Experiment Data

| The LOESS Procedure                             |             |          |
|-------------------------------------------------|-------------|----------|
| Independent Variable Scaling                    |             |          |
| Scaling applied: 10% trimmed standard deviation |             |          |
| Statistic                                       | Temperature | Catalyst |
| Minimum Value                                   | 80.00000    | 0        |
| Maximum Value                                   | 140.00000   | 0.08000  |
| Trimmed Mean                                    | 110.00000   | 0.04000  |
| Trimmed Standard Deviation                      | 14.32149    | 0.01894  |

The `SCALE=SD(0.1)` option in the `MODEL` statement specifies that the independent variables in the model are to be divided by their respective 10% trimmed standard deviations before the fitted model is computed. This is appropriate because the independent variables `Temperature` and `Catalyst` are not similarly scaled. The “Scale Details” table in [Output 53.3.2](#) displays the details of ranges of the regressors and the scale factors applied to each regressor.

[Output 53.3.3](#) displays the loess fit. Because the fitted surface is a good fit of the observed data, the observations on this plot are not clearly distinguishable from the fitted surface. The results are dramatically different when the outliers are included. The following statements fit a loess model to the corrupted response, using the same smoothing parameter that was selected for the measured response.

**Output 53.3.3** Fit for MeasuredYield

```
proc loess data=Experiment;
 model CorruptedYield = Temperature Catalyst /
 scale=sd(0.1) smooth=0.018;
run;
```

Output 53.3.4 Fit for CorruptedYield

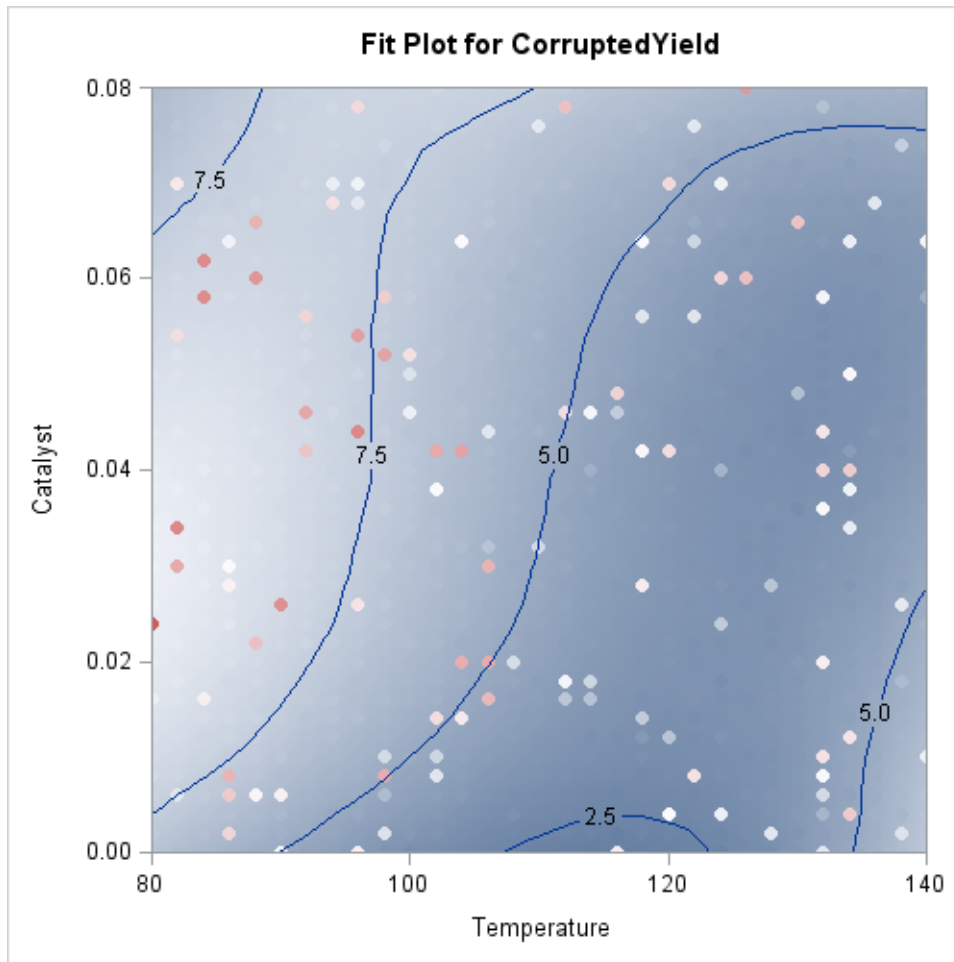

Output 53.3.4 displays the loess fit. The fit is pulled upward in the neighborhoods of these outliers. If you use a larger smoothing parameter value, then these local perturbations in the fit get smoothed out, but at the expense of smoothing away the information in the underlying measured response. In such cases a robust fitting method is indicated. The following statements show how you do this:

```
proc loess data=Experiment;
 model CorruptedYield = Temperature Catalyst /
 scale = sd(0.1)
 smooth = 0.018
 iterations=4;
run;
```

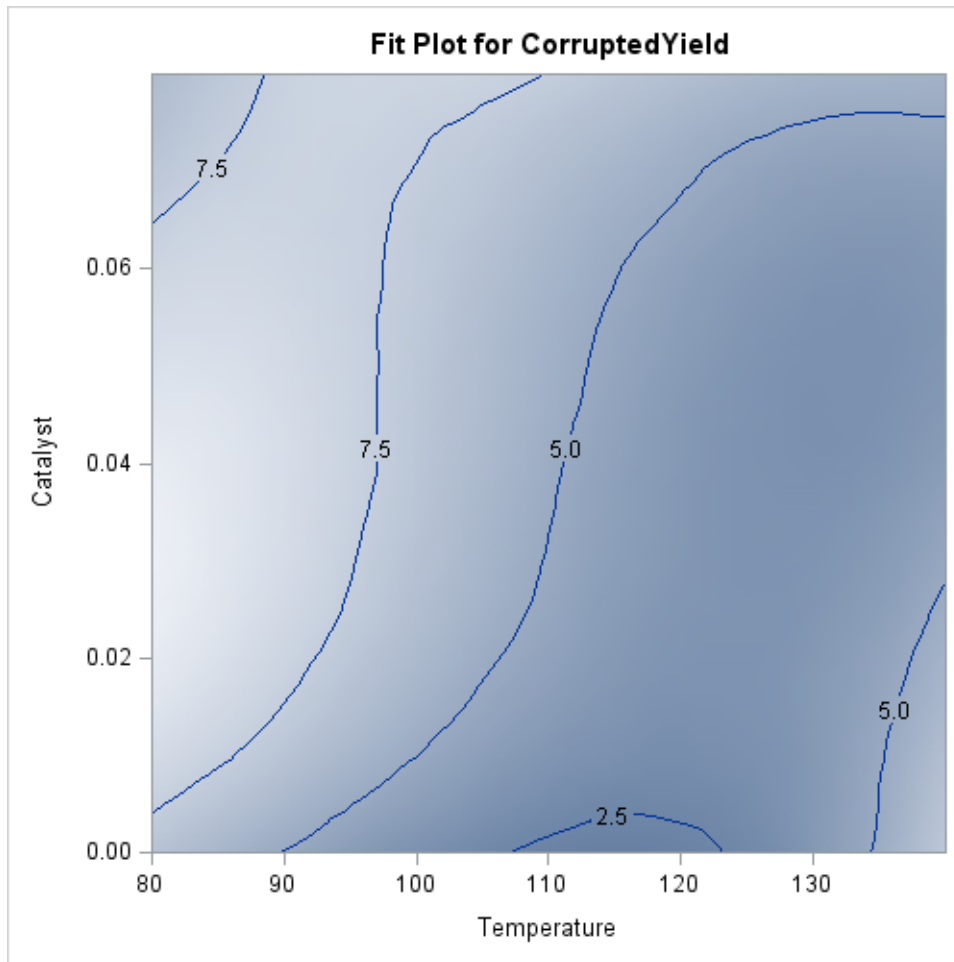

The ITERATIONS=4 option in the MODEL statement requests the initial loess fit followed by three iteratively reweighted iterations.

**Output 53.3.5** Robust Fit for CorruptedYield

You can see the impact of the robust fitting by comparing the robust fit shown in [Output 53.3.5](#) with the nonrobust fit in [Output 53.3.4](#). In the robust fit you see that the local perturbations caused by the outliers have been eliminated as these the outlying observations get down-weighted during the robustness iterations. By comparing the labeled contours on the fit plot for the uncorrupted response shown in [Output 53.3.3](#) with the labeled contours for the corrupted response shown in [Output 53.3.4](#), you can see that the robust fit has produced a reasonable fit for the underlying measured data. The color gradient in [Output 53.3.5](#) is chosen to accommodate the outliers that are present in the observed data, and so you cannot easily compare the color gradient in this plot with that in [Output 53.3.3](#). The following statements repeat the robust analysis with an option added to suppress the display of the observations on the fit plot:

```
proc loess data=Experiment plots=contourFit(obs=None);
 model CorruptedYield = Temperature Catalyst /
 scale = sd(0.1)
 smooth = 0.018
 iterations=4;
run;
ods graphics off;
```

**Output 53.3.6** Robust Fit for CorruptedYield with Observations Suppressed

Output 53.3.6 shows the robust fit with the observations suppressed. The range of the fitted surface values in this plot is similar to the range in Output 53.3.3. By comparing this contour plot with the contour plot in Output 53.3.3, you clearly see that the robust loess fit has successfully modeled the underlying surface despite the presence of the outliers.

### Example 53.4: El Niño Southern Oscillation

The data set `sashelp. ENSO`, which is available in the `Sashelp` library, contains measurements of monthly averaged atmospheric pressure differences between Easter Island and Darwin, Australia, for a period of 168 months (National Institute of Standards and Technology 1998).

The following PROC SGPLOT statements produce the simple scatter plot of the ENSO data, displayed in Output 53.4.1.

```
proc sgplot data=sashelp. ENSO;
 scatter y=Pressure x=Month;
run;
```

Output 53.4.1 Scatter Plot of ENSO Data

You can compute a loess fit and obtain graphical results for these data by using the following statements:

```
ods graphics on;

proc loess data=sashelp.ENS0 plots=residuals(smooth);
 model Pressure=Month;
run;
```

The “Smoothing Criterion” and “Fit Summary” tables are shown in [Output 53.4.2](#), and the fit plot is shown in [Output 53.4.3](#).

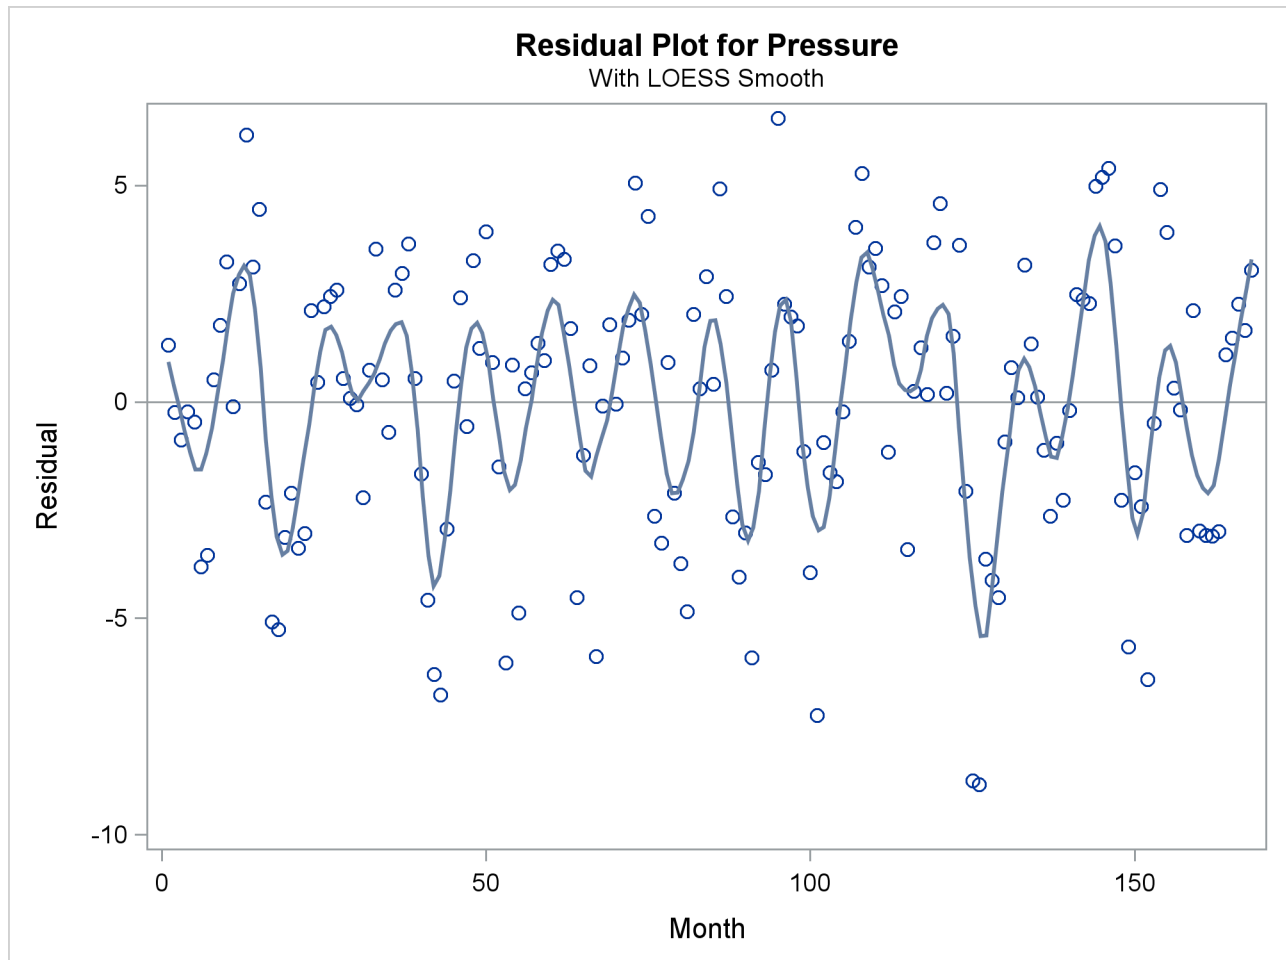

### Output 53.4.2 Output from PROC LOESS

**Output 53.4.3** Oversmoothed Loess Fit for the ENSO Data

This weather-related data should exhibit an annual cycle. However, the loess fit in [Output 53.4.3](#) indicates a longer cycle but no annual cycle. This suggests that the loess fit is oversmoothed. One way to detect oversmoothing is to look for patterns in the fit residuals. With ODS Graphics enabled, PROC LOESS produces a scatter plot of the residuals versus each regressor in the model. To aid in visually detecting patterns in these scatter plots, it is useful to superimpose a nonparametric fit on these scatter plots. You can request this by specifying the SMOOTH suboption of the PLOTS=RESIDUALS option in the PROC LOESS statement. The nonparametric fit that is produced is again a loess fit that is produced independently of the loess fit used to obtain these residuals.

With the superimposed loess fit shown in [Output 53.4.4](#), you can clearly identify an annual cycle in the residuals, which confirms that the loess fit for the ENSO is oversmoothed. What accounts for this poor fit?

**Output 53.4.4** Residuals for the Loess Fit for the ENSO Data

The smoothing parameter value used for the loess fit shown in [Output 53.4.3](#) was chosen using the default method of PROC LOESS, namely a golden section minimization of the AICC criterion over the interval (0, 1]. One possibility is that the golden section search has found a local rather than a global minimum of the AICC criterion. You can test this by redoing the fit requesting a global minimum. You do this with the following statements:

```
proc loess data=sashelp.ENS0;
 model Pressure=Month/select=AICC(global);
run;
```

**Output 53.4.5** AICC versus Smoothing Parameter Showing Local Minima

The explanation for the oversmoothed fit in [Output 53.4.3](#) is now apparent. [Output 53.4.5](#) shows that the golden section search algorithm found the local minimum that occurs near the value 0.22 of the smoothing parameter rather than the global minimum that occurs near 0.06. Note that if you restrict the range of smoothing parameter values examined to lie below 0.2, then the golden section search finds the global minimum, as the following statements demonstrate:

```
proc loess data=sashelp.ENS0;
 model Pressure=Month/select=AICC(range(0.03,0.2));
run;
```

**Output 53.4.6** Selected Smoothing Parameter Value

| The LOESS Procedure          |                     |
|------------------------------|---------------------|
| Dependent Variable: Pressure |                     |
| Optimal Smoothing Criterion  |                     |
| AICC                         | Smoothing Parameter |
| 2.86660                      | 0.05655             |

Output 53.4.6 shows that with the restricted range of smoothing parameter values examined, PROC LOESS finds the global minimum of the AICC criterion. Often you might not know an appropriate range of smoothing parameter values to examine. In such cases, you can use the PRESEARCH suboption of the SELECT= option in the MODEL statement. When you specify this option, PROC LOESS does a preliminary search to try to locate a smoothing parameter value range that contains just the first local minimum of the criterion being used for the selection. The following statements provide an example.

```
proc loess data=sashelp. ENSO plots=residuals(smooth);
 model Pressure=Month/select=AICC(presearch);
run;

ods graphics off;
```

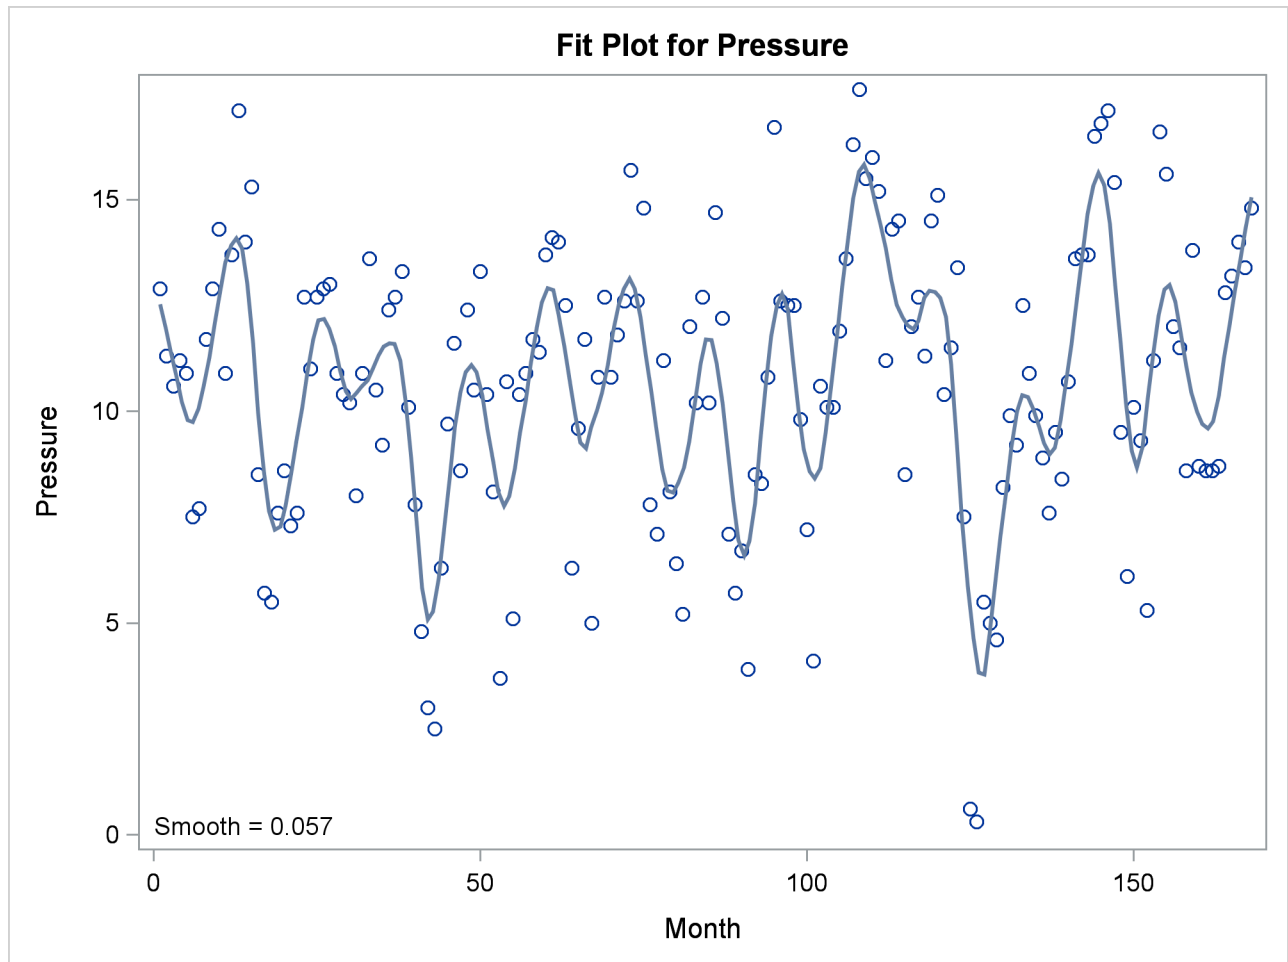

**Output 53.4.7** Selected Smoothing Parameter Value When Presearch Is Specified

| The LOESS Procedure          |                     |
|------------------------------|---------------------|
| Dependent Variable: Pressure |                     |
| Optimal Smoothing Criterion  |                     |
| AICC                         | Smoothing Parameter |
| 2.86660                      | 0.05655             |

Output 53.4.7 shows that with the PRESEARCH suboption specified, PROC LOESS selects the smoothing parameter value that yields the global minimum of the AICC criterion. The fit obtained is shown in Output 53.4.8, and a plot of the residuals with a superimposed loess fit is shown in Output 53.4.9.

**Output 53.4.8** Loess Fit Showing an Annual Cycle

**Output 53.4.9** Residuals of the Selected Model

In contrast to the residual plot shown in [Output 53.4.4](#), the residuals plotted in [Output 53.4.9](#) do not exhibit any pattern, indicating that the corresponding loess fit has captured all the systematic variation in the data.

An interesting question is whether there is some phenomenon captured in the data that would explain the presence of the local minimum near 0.22 in the AICC curve. Note that there is some evidence of a cycle of about 42 months in the oversmoothed fit in [Output 53.4.3](#). You can see this cycle because the strong annual cycle in [Output 53.4.8](#) has been smoothed out. The physical phenomenon that accounts for the existence of this cycle has been identified as the periodic warming of the Pacific Ocean known as “El Niño.”

## Overview: LOGISTIC Procedure

Binary responses (for example, success and failure), ordinal responses (for example, normal, mild, and severe), and nominal responses (for example, major TV networks viewed at a certain hour) arise in many fields of study. Logistic regression analysis is often used to investigate the relationship between these discrete responses and a set of explanatory variables. Texts that discuss logistic regression include Agresti (2002); Allison (1999); Collett (2003); Cox and Snell (1989); Hosmer and Lemeshow (2000); Stokes, Davis, and Koch (2012).

For binary response models, the response,  $Y$ , of an individual or an experimental unit can take on one of two possible values, denoted for convenience by 1 and 2 (for example,  $Y = 1$  if a disease is present, otherwise  $Y = 2$ ). Suppose  $\mathbf{x}$  is a vector of explanatory variables and  $\pi = \Pr(Y = 1 \mid \mathbf{x})$  is the response probability to be modeled. The linear logistic model has the form

$$\text{logit}(\pi) \equiv \log\left(\frac{\pi}{1 - \pi}\right) = \alpha + \boldsymbol{\beta}'\mathbf{x}$$

where  $\alpha$  is the intercept parameter and  $\boldsymbol{\beta} = (\beta_1, \dots, \beta_s)'$  is the vector of  $s$  slope parameters. Notice that the LOGISTIC procedure, by default, models the probability of the *lower* response levels.

The logistic model shares a common feature with a more general class of linear models: a function  $g = g(\mu)$  of the mean of the response variable is assumed to be linearly related to the explanatory variables. Since the mean  $\mu$  implicitly depends on the stochastic behavior of the response, and the explanatory variables are assumed to be fixed, the function  $g$  provides the link between the random (stochastic) component and the systematic (deterministic) component of the response variable  $Y$ . For this reason, Nelder and Wedderburn (1972) refer to  $g(\mu)$  as a link function. One advantage of the logit function over other link functions is that differences on the logistic scale are interpretable regardless of whether the data are sampled prospectively or retrospectively (McCullagh and Nelder 1989, Chapter 4). Other link functions that are widely used in practice are the probit function and the complementary log-log function. The LOGISTIC procedure enables you to choose one of these link functions, resulting in fitting a broader class of binary response models of the form

$$g(\pi) = \alpha + \boldsymbol{\beta}'\mathbf{x}$$

For ordinal response models, the response,  $Y$ , of an individual or an experimental unit might be restricted to one of a (usually small) number of ordinal values, denoted for convenience by  $1, \dots, k, k + 1$ . For example, the severity of coronary disease can be classified into three response categories as 1=no disease, 2=angina pectoris, and 3=myocardial infarction. The LOGISTIC procedure fits a common slopes cumulative model, which is a parallel lines regression model based on the cumulative probabilities of the response categories rather than on their individual probabilities. The cumulative model has the form

$$g(\Pr(Y \leq i \mid \mathbf{x})) = \alpha_i + \boldsymbol{\beta}'\mathbf{x}, \quad i = 1, \dots, k$$

where  $\alpha_1, \dots, \alpha_k$  are  $k$  intercept parameters, and  $\boldsymbol{\beta}$  is the vector of slope parameters. This model has been considered by many researchers. Aitchison and Silvey (1957) and Ashford (1959) employ a probit scale and provide a maximum likelihood analysis; Walker and Duncan (1967) and Cox and Snell (1989) discuss the use of the log odds scale. For the log odds scale, the cumulative logit model is often referred to as the *proportional odds* model.

For nominal response logistic models, where the  $k + 1$  possible responses have no natural ordering, the logit model can also be extended to a *multinomial* model known as a *generalized* or *baseline-category* logit model, which has the form

$$\log \left( \frac{\Pr(Y = i | \mathbf{x})}{\Pr(Y = k + 1 | \mathbf{x})} \right) = \alpha_i + \boldsymbol{\beta}'_i \mathbf{x}, \quad i = 1, \dots, k$$

where the  $\alpha_1, \dots, \alpha_k$  are  $k$  intercept parameters, and the  $\boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_k$  are  $k$  vectors of slope parameters. These models are a special case of the *discrete choice* or *conditional logit* models introduced by McFadden (1974).

The LOGISTIC procedure fits linear logistic regression models for discrete response data by the method of maximum likelihood. It can also perform conditional logistic regression for binary response data and exact logistic regression for binary and nominal response data. The maximum likelihood estimation is carried out with either the Fisher scoring algorithm or the Newton-Raphson algorithm, and you can perform the bias-reducing penalized likelihood optimization as discussed by Firth (1993) and Heinze and Schemper (2002). You can specify starting values for the parameter estimates. The logit link function in the logistic regression models can be replaced by the probit function, the complementary log-log function, or the generalized logit function.

Any term specified in the model is referred to as an *effect*. The LOGISTIC procedure enables you to specify categorical variables (also known as *classification* or *CLASS variables*) and continuous variables as explanatory effects. You can also specify more complex model terms such as interactions and nested terms in the same way as in the GLM procedure. You can create complex *constructed effects* with the EFFECT statement. An effect in the model that is not an interaction or a nested term or a constructed effect is referred to as a *main effect*.

The LOGISTIC procedure allows either a full-rank parameterization or a less-than-full-rank parameterization of the CLASS variables. The full-rank parameterization offers eight coding methods: effect, reference, ordinal, polynomial, and orthogonalizations of these. The effect coding is the same method that is used in the CATMOD procedure. The less-than-full-rank parameterization, often called *dummy coding*, is the same coding as that used in the GLM procedure.

The LOGISTIC procedure provides four effect selection methods: forward selection, backward elimination, stepwise selection, and best subset selection. The best subset selection is based on the likelihood score statistic. This method identifies a specified number of best models containing one, two, three effects, and so on, up to a single model containing effects for all the explanatory variables.

The LOGISTIC procedure has some additional options to control how to move effects in and out of a model with the forward selection, backward elimination, or stepwise selection model-building strategies. When there are no interaction terms, a main effect can enter or leave a model in a single step based on the  $p$ -value of the score or Wald statistic. When there are interaction terms, the selection process also depends on whether you want to preserve model hierarchy. These additional options enable you to specify whether model hierarchy is to be preserved, how model hierarchy is applied, and whether a single effect or multiple effects can be moved in a single step.

Odds ratio estimates are displayed along with parameter estimates. You can also specify the change in the continuous explanatory main effects for which odds ratio estimates are desired. Confidence intervals for the regression parameters and odds ratios can be computed based either on the profile-likelihood function or on the asymptotic normality of the parameter estimators. You can also produce odds ratios for effects that are involved in interactions or nestings, and for any type of parameterization of the CLASS variables.

Various methods to correct for overdispersion are provided, including Williams' method for grouped binary response data. The adequacy of the fitted model can be evaluated by various goodness-of-fit tests, including the Hosmer-Lemeshow test for binary response data.

Like many procedures in SAS/STAT software that enable the specification of CLASS variables, the LOGISTIC procedure provides a **CONTRAST** statement for specifying customized hypothesis tests concerning the model parameters. The **CONTRAST** statement also provides estimation of individual rows of contrasts, which is particularly useful for obtaining odds ratio estimates for various levels of the CLASS variables. The LOGISTIC procedure also provides testing capability through the **ESTIMATE** and **TEST** statements. Analyses of LS-means are enabled with the **LSMEANS**, **LSMESTIMATE**, and **SLICE** statements.

You can perform a conditional logistic regression on binary response data by specifying the **STRATA** statement. This enables you to perform matched-set and case-control analyses. The number of events and nonevents can vary across the strata. Many of the features available with the unconditional analysis are also available with a conditional analysis.

The LOGISTIC procedure enables you to perform exact logistic regression, also known as exact conditional logistic regression, by specifying one or more **EXACT** statements. You can test individual parameters or conduct a joint test for several parameters. The procedure computes two exact tests: the exact conditional score test and the exact conditional probability test. You can request exact estimation of specific parameters and corresponding odds ratios where appropriate. Point estimates, standard errors, and confidence intervals are provided. You can perform stratified exact logistic regression by specifying the **STRATA** statement.

Further features of the LOGISTIC procedure enable you to do the following:

- control the ordering of the response categories
- compute a generalized R Square measure for the fitted model
- reclassify binary response observations according to their predicted response probabilities
- test linear hypotheses about the regression parameters
- create a data set for producing a receiver operating characteristic curve for each fitted model
- specify contrasts to compare several receiver operating characteristic curves
- create a data set containing the estimated response probabilities, residuals, and influence diagnostics
- score a data set by using a previously fitted model

The LOGISTIC procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For more information about the plots implemented in PROC LOGISTIC, see the section “[ODS Graphics](#)” on page 4294.

The remaining sections of this chapter describe how to use PROC LOGISTIC and discuss the underlying statistical methodology. The section “[Getting Started: LOGISTIC Procedure](#)” on page 4166 introduces PROC LOGISTIC with an example for binary response data. The section “[Syntax: LOGISTIC Procedure](#)” on page 4174 describes the syntax of the procedure. The section “[Details: LOGISTIC Procedure](#)” on page 4237 summarizes the statistical technique employed by PROC LOGISTIC. The section “[Examples: LOGISTIC Procedure](#)” on page 4295 illustrates the use of the LOGISTIC procedure.

For more examples and discussion on the use of PROC LOGISTIC, see Stokes, Davis, and Koch (2012); Allison (1999); SAS Institute Inc. (1995).

## Getting Started: LOGISTIC Procedure

The LOGISTIC procedure is similar in use to the other regression procedures in the SAS System. To demonstrate the similarity, suppose the response variable  $y$  is binary or ordinal, and  $x_1$  and  $x_2$  are two explanatory variables of interest. To fit a logistic regression model, you can specify a MODEL statement similar to that used in the REG procedure. For example:

```
proc logistic;
 model y=x1 x2;
run;
```

The response variable  $y$  can be either character or numeric. PROC LOGISTIC enumerates the total number of response categories and orders the response levels according to the response variable option ORDER= in the MODEL statement.

You can also input binary response data that are grouped. In the following statements,  $n$  represents the number of trials and  $r$  represents the number of events:

```
proc logistic;
 model r/n=x1 x2;
run;
```

The following example illustrates the use of PROC LOGISTIC. The data, taken from Cox and Snell (1989, pp. 10–11), consist of the number,  $r$ , of ingots not ready for rolling, out of  $n$  tested, for a number of combinations of heating time and soaking time.

```
data ingots;
 input Heat Soak r n @@;
 datalines;
7 1.0 0 10 14 1.0 0 31 27 1.0 1 56 51 1.0 3 13
7 1.7 0 17 14 1.7 0 43 27 1.7 4 44 51 1.7 0 1
7 2.2 0 7 14 2.2 2 33 27 2.2 0 21 51 2.2 0 1
7 2.8 0 12 14 2.8 0 31 27 2.8 1 22 51 4.0 0 1
7 4.0 0 9 14 4.0 0 19 27 4.0 1 16
;
```

The following invocation of PROC LOGISTIC fits the binary logit model to the grouped data. The continuous covariates Heat and Soak are specified as predictors, and the bar notation (“|”) includes their interaction, Heat\*Soak. The ODDSRATIO statement produces odds ratios in the presence of interactions, and a graphical display of the requested odds ratios is produced when ODS Graphics is enabled.

```
ods graphics on;
proc logistic data=ingots;
 model r/n = Heat | Soak;
 oddsratio Heat / at (Soak=1 2 3 4);
run;
ods graphics off;
```

The results of this analysis are shown in the following figures. PROC LOGISTIC first lists background information in Figure 54.1 about the fitting of the model. Included are the name of the input data set, the response variable(s) used, the number of observations used, and the link function used.

**Figure 54.1** Binary Logit Model

| The LOGISTIC Procedure      |                  |
|-----------------------------|------------------|
| Model Information           |                  |
| Data Set                    | WORK.INGOTS      |
| Response Variable (Events)  | r                |
| Response Variable (Trials)  | n                |
| Model                       | binary logit     |
| Optimization Technique      | Fisher's scoring |
|                             |                  |
| Number of Observations Read | 19               |
| Number of Observations Used | 19               |
| Sum of Frequencies Read     | 387              |
| Sum of Frequencies Used     | 387              |

The “Response Profile” table (Figure 54.2) lists the response categories (which are Event and Nonevent when grouped data are input), their ordered values, and their total frequencies for the given data.

**Figure 54.2** Response Profile with Events/Trials Syntax

| Response Profile                              |                |                 |
|-----------------------------------------------|----------------|-----------------|
| Ordered Value                                 | Binary Outcome | Total Frequency |
| 1                                             | Event          | 12              |
| 2                                             | Nonevent       | 375             |
|                                               |                |                 |
| Model Convergence Status                      |                |                 |
| Convergence criterion (GCONV=1E-8) satisfied. |                |                 |

The “Model Fit Statistics” table (Figure 54.3) contains Akaike’s information criterion (AIC), the Schwarz criterion (SC), and the negative of twice the log likelihood ( $-2 \text{ Log L}$ ) for the intercept-only model and the fitted model. AIC and SC can be used to compare different models, and the ones with smaller values are preferred. Results of the likelihood ratio test and the efficient score test for testing the joint significance of the explanatory variables (Soak, Heat, and their interaction) are included in the “Testing Global Null Hypothesis: BETA=0” table (Figure 54.3); the small  $p$ -values reject the hypothesis that all slope parameters are equal to zero.

**Figure 54.3** Fit Statistics and Hypothesis Tests

| Model Fit Statistics |           |                          |                     |
|----------------------|-----------|--------------------------|---------------------|
| Criterion            | Intercept | Intercept and Covariates |                     |
|                      | Only      | Log Likelihood           | Full Log Likelihood |
| AIC                  | 108.988   | 103.222                  | 35.957              |
| SC                   | 112.947   | 119.056                  | 51.791              |

The “Analysis of Maximum Likelihood Estimates” table in [Figure 54.4](#) lists the parameter estimates, their standard errors, and the results of the Wald test for individual parameters. Note that the Heat\*Soak parameter is not significantly different from zero ( $p=0.727$ ), nor is the Soak variable ( $p=0.6916$ ).

**Figure 54.4** Parameter Estimates

| Analysis of Maximum Likelihood Estimates |    |          |                |                 |            |
|------------------------------------------|----|----------|----------------|-----------------|------------|
| Parameter                                | DF | Estimate | Standard Error | Wald Chi-Square | Pr > ChiSq |

| Soak                                     | 1  | 0.2996   | 0.7551         | 0.1574          | 0.6916     |
| Heat*Soak                                | 1  | -0.00884 | 0.0253         | 0.1219          | 0.7270     |

The “Association of Predicted Probabilities and Observed Responses” table ([Figure 54.5](#)) contains four measures of association for assessing the predictive ability of a model. They are based on the number of pairs of observations with different response values, the number of concordant pairs, and the number of discordant pairs, which are also displayed. Formulas for these statistics are given in the section “Rank Correlation of Observed Responses and Predicted Probabilities” on page 4253.

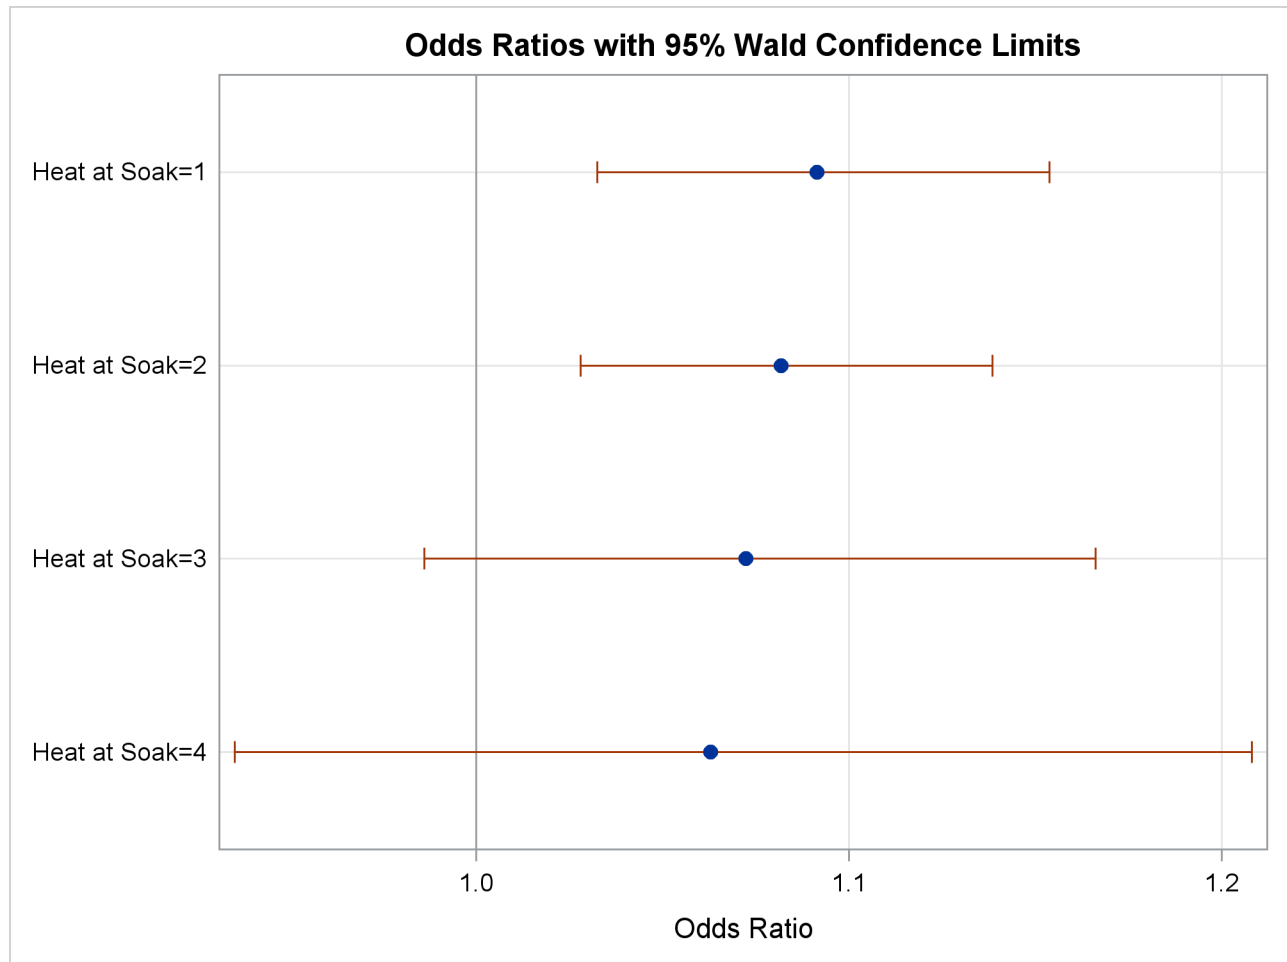

**Figure 54.5** Association Table

| Association of Predicted Probabilities and Observed Responses |      |           |       |
|---------------------------------------------------------------|------|-----------|-------|
| Percent Concordant                                            | 70.9 | Somers' D | 0.537 |
| Percent Discordant                                            | 17.3 | Gamma     | 0.608 |
| Percent Tied                                                  | 11.8 | Tau-a     | 0.032 |
| Pairs                                                         | 4500 | c         | 0.768 |

The **ODDSRATIO** statement produces the “Odds Ratio Estimates and Wald Confidence Intervals” table (Figure 54.6), and a graphical display of these estimates is shown in Figure 54.7. The differences between the odds ratios are small compared to the variability shown by their confidence intervals, which confirms the previous conclusion that the Heat\*Soak parameter is not significantly different from zero.

**Figure 54.6** Odds Ratios of Heat at Several Values of Soak

| Odds Ratio Estimates and Wald Confidence Intervals |          |                       |       |
|----------------------------------------------------|----------|-----------------------|-------|
| Label                                              | Estimate | 95% Confidence Limits |       |
| Heat at Soak=1                                     | 1.091    | 1.032                 | 1.154 |
| Heat at Soak=2                                     | 1.082    | 1.028                 | 1.139 |
| Heat at Soak=3                                     | 1.072    | 0.986                 | 1.166 |
| Heat at Soak=4                                     | 1.063    | 0.935                 | 1.208 |

**Figure 54.7** Plot of Odds Ratios of Heat at Several Values of Soak

Since the Heat\*Soak interaction is nonsignificant, the following statements fit a main-effects model:

```
proc logistic data=ingots;
 model r/n = Heat Soak;
run;
```

The results of this analysis are shown in the following figures. The model information and response profiles are the same as those in Figure 54.1 and Figure 54.2 for the saturated model. The “Model Fit Statistics” table in Figure 54.8 shows that the AIC and SC for the main-effects model are smaller than for the saturated model, indicating that the main-effects model might be the preferred model. As in the preceding model, the “Testing Global Null Hypothesis: BETA=0” table indicates that the parameters are significantly different from zero.

**Figure 54.8** Fit Statistics and Hypothesis Tests

| The LOGISTIC Procedure |           |                          |                     |

| Wald                                   | 13.0315    | 2  | 0.0015     |

The “Analysis of Maximum Likelihood Estimates” table in [Figure 54.9](#) again shows that the Soak parameter is not significantly different from zero ( $p=0.8639$ ). The odds ratio for each effect parameter, estimated by exponentiating the corresponding parameter estimate, is shown in the “Odds Ratios Estimates” table ([Figure 54.9](#)), along with 95% Wald confidence intervals. The confidence interval for the Soak parameter contains the value 1, which also indicates that this effect is not significant.

**Figure 54.9** Parameter Estimates and Odds Ratios

Figure 54.9 continued

| Association of Predicted Probabilities and Observed Responses |      |           |       |
|---------------------------------------------------------------|------|-----------|-------|
| Percent Concordant                                            | 64.4 | Somers' D | 0.460 |
| Percent Discordant                                            | 18.4 | Gamma     | 0.555 |
| Percent Tied                                                  | 17.2 | Tau-a     | 0.028 |
| Pairs                                                         | 4500 | c         | 0.730 |

Using these parameter estimates, you can calculate the estimated logit of  $\pi$  as

$$-5.5592 + 0.082 \times \text{Heat} + 0.0568 \times \text{Soak}$$

For example, if Heat=7 and Soak=1, then  $\text{logit}(\hat{\pi}) = -4.9284$ . Using this logit estimate, you can calculate  $\hat{\pi}$  as follows:

$$\hat{\pi} = 1/(1 + e^{4.9284}) = 0.0072$$

This gives the predicted probability of the event (ingot not ready for rolling) for Heat=7 and Soak=1. Note that PROC LOGISTIC can calculate these statistics for you; use the **OUTPUT** statement with the **PREDICTED=** option, or use the **SCORE** statement.

To illustrate the use of an alternative form of input data, the following program creates the ingots data set with the new variables NotReady and Freq instead of n and r. The variable NotReady represents the response of individual units; it has a value of 1 for units not ready for rolling (event) and a value of 0 for units ready for rolling (nonevent). The variable Freq represents the frequency of occurrence of each combination of Heat, Soak, and NotReady. Note that, compared to the previous data set, NotReady=1 implies Freq=r, and NotReady=0 implies Freq=n-r.

```
data ingots;
 input Heat Soak NotReady Freq @@;
 datalines;
7 1.0 0 10 14 1.0 0 31 14 4.0 0 19 27 2.2 0 21 51 1.0 1 3
7 1.7 0 17 14 1.7 0 43 27 1.0 1 1 27 2.8 1 1 51 1.0 0 10
7 2.2 0 7 14 2.2 1 2 27 1.0 0 55 27 2.8 0 21 51 1.7 0 1
7 2.8 0 12 14 2.2 0 31 27 1.7 1 4 27 4.0 1 1 51 2.2 0 1
7 4.0 0 9 14 2.8 0 31 27 1.7 0 40 27 4.0 0 15 51 4.0 0 1
;
```

The following statements invoke PROC LOGISTIC to fit the main-effects model by using the alternative form of the input data set:

```
proc logistic data=ingots;
 model NotReady(event='1') = Heat Soak;
 freq Freq;
run;
```

Results of this analysis are the same as the preceding single-trial main-effects analysis. The displayed output for the two runs are identical except for the background information of the model fit and the “Response Profile” table shown in Figure 54.10.

**Figure 54.10** Response Profile with Single-Trial Syntax

| The LOGISTIC Procedure |          |                 |
|------------------------|----------|-----------------|
| Response Profile       |          |                 |
| Ordered Value          | NotReady | Total Frequency |
| 1                      | 0        | 375             |
| 2                      | 1        | 12              |

Probability modeled is NotReady=1.

By default, Ordered Values are assigned to the sorted response values in ascending order, and PROC LOGISTIC models the probability of the response level that corresponds to the Ordered Value 1. There are several methods to change these defaults; the preceding statements specify the response variable option `EVENT=` to model the probability of `NotReady=1` as displayed in Figure 54.10. See the section “Response Level Ordering” on page 4237 for more details.

## Syntax: LOGISTIC Procedure

The following statements are available in the LOGISTIC procedure:

```

PROC LOGISTIC < options > ;
 BY variables ;
 CLASS variable < (options) > < variable < (options) > ... > < / options > ;
 CODE < options > ;
 CONTRAST 'label' effect values< , effect values, ... > < / options > ;
 EFFECT name=effect-type(variables < / options >) ;
 EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
 ESTIMATE < 'label' > estimate-specification < / options > ;
 EXACT < 'label' > < INTERCEPT > < effects > < / options > ;
 EXACTOPTIONS options ;
 FREQ variable ;
 ID variables ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 < label: > MODEL variable < (variable_options) > = < effects > < / options > ;
 < label: > MODEL events/trials = < effects > < / options > ;
 NLOPTIONS options ;
 ODDSRATIO < 'label' > variable < / options > ;
 OUTPUT < OUT=SAS-data-set > < keyword=name < keyword=name ... > > < / option > ;
 ROC < 'label' > < specification > < / options > ;
 ROCCONTRAST < 'label' > < contrast > < / options > ;
 SCORE < options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 STRATA effects < / options > ;
 < label: > TEST equation1 < ,equation2, ... > < / option > ;
 UNITS < independent1=list1 < independent2=list2 ... > > < / option > ;
 WEIGHT variable < / option > ;

```

The PROC LOGISTIC and MODEL statements are required. The CLASS and EFFECT statements (if specified) must precede the MODEL statement, and the CONTRAST, EXACT, and ROC statements (if specified) must follow the MODEL statement.

The PROC LOGISTIC, MODEL, and ROCCONTRAST statements can be specified at most once. If a FREQ or WEIGHT statement is specified more than once, the variable specified in the first instance is used. If a BY, OUTPUT, or UNITS statement is specified more than once, the last instance is used.

The rest of this section provides detailed syntax information for each of the preceding statements, beginning with the PROC LOGISTIC statement. The remaining statements are covered in alphabetical order. The CODE, EFFECT, EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, SLICE, and STORE statements are also available in many other procedures. Summary descriptions of functionality and syntax for these statements are provided, but you can find full documentation on them in the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

## PROC LOGISTIC Statement

**PROC LOGISTIC** < options > ;

The PROC LOGISTIC statement invokes the LOGISTIC procedure. Optionally, it identifies input and output data sets, suppresses the display of results, and controls the ordering of the response levels. Table 54.1 summarizes the options available in the PROC LOGISTIC statement.

**Table 54.1** PROC LOGISTIC Statement Options

| Option                                     | Description                                                      |
|--------------------------------------------|------------------------------------------------------------------|
| <b>Input/Output Data Set Options</b>       |                                                                  |
| COVOUT                                     | Displays the estimated covariance matrix in the OUTEST= data set |
| DATA=                                      | Names the input SAS data set                                     |
| INEST=                                     | Specifies the initial estimates SAS data set                     |
| INMODEL=                                   | Specifies the model information SAS data set                     |
| NOCOVAR                                    | Does not save covariance matrix in the OUTMODEL= data set        |
| OUTDESIGN=                                 | Specifies the design matrix output SAS data set                  |
| OUTDESIGNONLY                              | Outputs the design matrix only                                   |
| OUTEST=                                    | Specifies the parameter estimates output SAS data set            |
| OUTMODEL=                                  | Specifies the model output data set for scoring                  |
| <b>Response and CLASS Variable Options</b> |                                                                  |
| DESCENDING                                 | Reverses the sort order of the response variable                 |
| NAMELEN=                                   | Specifies the maximum length of effect names                     |
| ORDER=                                     | Specifies the sort order of the response variable                |
| TRUNCATE                                   | Truncates class level names                                      |
| <b>Displayed Output Options</b>            |                                                                  |
| ALPHA=                                     | Specifies the significance level for confidence intervals        |
| NOPRINT                                    | Suppresses all displayed output                                  |
| PLOTS                                      | Specifies options for plots                                      |
| SIMPLE                                     | Displays descriptive statistics                                  |
| <b>Large Data Set Option</b>               |                                                                  |
| MULTIPASS                                  | Does not copy the input SAS data set for internal computations   |
| <b>Control of Other Statement Options</b>  |                                                                  |
| EXACTONLY                                  | Performs exact analysis only                                     |
| EXACTOPTIONS                               | Specifies global options for EXACT statements                    |
| ROCOPTIONS                                 | Specifies global options for ROC statements                      |

### **ALPHA=number**

specifies the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals. The value *number* must be between 0 and 1; the default value is 0.05, which results in 95% intervals. This value is used as the default confidence level for limits computed by the following options:

| Statement     | Options                    |
|---------------|----------------------------|
| CONTRAST      | ESTIMATE=                  |
| EXACT         | ESTIMATE=                  |
| MODEL         | CLODDS= CLPARM=            |
| ODDSRATIO     | CL=                        |
| OUTPUT        | LOWER= UPPER=              |
| PROC LOGISTIC | PLOTS=EFFECT(CLBAR CLBAND) |
| ROCONTRAST    | ESTIMATE=                  |
| SCORE         | CLM                        |

You can override the default in most of these cases by specifying the ALPHA= option in the separate statements.

### COVOUT

adds the estimated covariance matrix to the OUTEST= data set. For the COVOUT option to have an effect, the OUTEST= option must be specified. See the section “OUTEST= Output Data Set” on page 4279 for more information.

### DATA=SAS-data-set

names the SAS data set containing the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set. The INMODEL= option cannot be specified with this option.

### DESCENDING

#### DESC

reverses the sort order for the levels of the response variable. If both the DESCENDING and ORDER= options are specified, PROC LOGISTIC orders the levels according to the ORDER= option and then reverses that order. This option has the same effect as the response variable option DESCENDING in the MODEL statement. See the section “Response Level Ordering” on page 4237 for more detail.

### EXACTONLY

requests only the exact analyses. The asymptotic analysis that PROC LOGISTIC usually performs is suppressed.

### EXACTOPTIONS (options)

specifies options that apply to every EXACT statement in the program. The available options are summarized here, and full descriptions are available in the EXACTOPTIONS statement.

| Option       | Description                                                              |
|--------------|--------------------------------------------------------------------------|
| ADDTOBS      | Adds the observed sufficient statistic to the sampled exact distribution |
| BUILDSUBSETS | Builds every distribution for sampling                                   |
| EPSILON=     | Specifies the comparison fuzz for partial sums of sufficient statistics  |
| MAXTIME=     | Specifies the maximum time allowed in seconds                            |
| METHOD=      | Specifies the DIRECT, NETWORK, or NETWORKMC algorithm                    |
| N=           | Specifies the number of Monte Carlo samples                              |
| ONDISK       | Uses disk space                                                          |
| SEED=        | Specifies the initial seed for sampling                                  |
| STATUSN=     | Specifies the sampling interval for printing a status line               |
| STATUSTIME=  | Specifies the time interval for printing a status line                   |

**INEST=SAS-data-set**

names the SAS data set that contains initial estimates for all the parameters in the model. If BY-group processing is used, it must be accommodated in setting up the INEST= data set. See the section “INEST= Input Data Set” on page 4280 for more information.

**INMODEL=SAS-data-set**

specifies the name of the SAS data set that contains the model information needed for scoring new data. This INMODEL= data set is the OUTMODEL= data set saved in a previous PROC LOGISTIC call. The OUTMODEL= data set should not be modified before its use as an INMODEL= data set.

The DATA= option cannot be specified with this option; instead, specify the data sets to be scored in the SCORE statements. FORMAT statements are not allowed when the INMODEL= data set is specified; variables in the DATA= and PRIOR= data sets in the SCORE statement should be formatted within the data sets.

You can specify the BY statement provided that the INMODEL= data set is created under the same BY-group processing.

The CLASS, EFFECT, EFFECTPLOT, ESTIMATE, EXACT, LSMEANS, LSMESTIMATE, MODEL, OUTPUT, ROC, ROCONTRAST, SLICE, STORE, TEST, and UNIT statements are not available with the INMODEL= option.

**MULTIPASS**

forces the procedure to reread the DATA= data set as needed rather than require its storage in memory or in a temporary file on disk. By default, the data set is cleaned up and stored in memory or in a temporary file. This option can be useful for large data sets. All exact analyses are ignored in the presence of the MULTIPASS option. If a STRATA statement is specified, then the data set must first be grouped or sorted by the strata variables.

**NAMELEN=n**

specifies the maximum length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

**NOCOV**

specifies that the covariance matrix not be saved in the OUTMODEL= data set. The covariance matrix is needed for computing the confidence intervals for the posterior probabilities in the OUT= data set in the SCORE statement. Specifying this option will reduce the size of the OUTMODEL= data set.

**NOPRINT**

suppresses all displayed output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL****RORDER=DATA | FORMATTED | INTERNAL**

specifies the sort order for the levels of the response variable. See the response variable option ORDER= in the MODEL statement for more information. For ordering of CLASS variable levels, see the ORDER= option in the CLASS statement.

**OUTDESIGN=SAS-data-set**

specifies the name of the data set that contains the design matrix for the model. The data set contains the same number of observations as the corresponding DATA= data set and includes the response

variable (with the same format as in the DATA= data set), the **FREQ** variable, the **WEIGHT** variable, the **OFFSET=** variable, and the design variables for the covariates, including the Intercept variable of constant value 1 unless the **NOINT** option in the **MODEL** statement is specified.

#### **OUTDESIGNONLY**

suppresses the model fitting and creates only the **OUTDESIGN=** data set. This option is ignored if the **OUTDESIGN=** option is not specified.

#### **OUTEST=SAS-data-set**

creates an output SAS data set that contains the final parameter estimates and, optionally, their estimated covariances (see the preceding **COVOUT** option). The output data set also includes a variable named **\_LNLIKE\_**, which contains the log likelihood. See the section “**OUTEST= Output Data Set**” on page 4279 for more information.

#### **OUTMODEL=SAS-data-set**

specifies the name of the SAS data set that contains the information about the fitted model. This data set contains sufficient information to score new data without having to refit the model. It is solely used as the input to the **INMODEL=** option in a subsequent PROC LOGISTIC call. The **OUTMODEL=** option is not available with the **STRATA** statement. Information in this data set is stored in a very compact form, so you should not modify it manually.

**NOTE:** The **STORE** statement can also be used to save your model. See the section “**STORE Statement**” on page 4233 for more information.

**PLOTS** < (*global-plot-options*) > < =*plot-request*< (*options*) > >

**PLOTS** < (*global-plot-options*) > =(*plot-request*< (*options*)>< ... *plot-request*< (*options*)>>

controls the plots produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses from around the *plot-request*. For example:

```
PLOTS = ALL
PLOTS = (ROC EFFECT INFLUENCE (UNPACK))
PLOTS (ONLY) = EFFECT (CLBAR SHOWOBS)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc logistic plots=all;
 model y=x;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “**Enabling and Disabling ODS Graphics**” on page 600 in Chapter 21, “**Statistical Graphics Using ODS**.”

If the **PLOTS** option is not specified or is specified with no *plot-requests*, then graphics are produced by default in the following situations:

- If the **INFLUENCE** or **IPLOTS** option is specified in the **MODEL** statement, then the line-printer plots are suppressed, and the **INFLUENCE** plots are produced unless the **MAXPOINTS=** cutoff is exceeded.

- If you specify the **OUTROC=** option in the **MODEL** statement, then ROC curves are produced. If you also specify a **SELECTION=** method, then an overlaid plot of all the ROC curves for each step of the selection process is displayed.
- If the **OUTROC=** option is specified in a **SCORE** statement, then the ROC curve for the scored data set is displayed.
- If you specify **ROC** statements, then an overlaid plot of the ROC curves for the model (or the selected model if a **SELECTION=** method is specified) and for all the ROC statement models is displayed.
- If an odds ratio table is produced, then a plot of the odds ratios and their confidence limits is displayed. These plots correspond to the default odds ratio table and the tables produced by the **CLODDS=** option in the **MODEL** statement and the tables produced by the **ODDSRATIO** statement.

For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

The following *global-plot-options* are available:

#### **LABEL**

displays a label on diagnostic plots to aid in identifying the outlying observations. This option enhances the plots produced by the **DFBETAS**, **DPC**, **INFLUENCE**, **LEVERAGE**, and **PHAT** options. If an **ID** statement is specified, then the plots are labeled with the ID variables. Otherwise, the observation number is displayed.

#### **MAXPOINTS=NONE** | *number*

suppresses the plots produced by the **DFBETAS**, **DPC**, **INFLUENCE**, **LEVERAGE**, and **PHAT** options if there are more than *number* observations. Also, observations are not displayed on the **EFFECT** plots when the cutoff is exceeded. The default is **MAXPOINTS=5000**. The cutoff is ignored if you specify **MAXPOINTS=NONE**.

#### **ONLY**

specifically requested *plot-requests* are displayed.

#### **UNPACKPANELS** | **UNPACK**

suppresses paneling. By default, multiple plots can appear in some output *panels*. Specify **UNPACKPANEL** to display each plot separately.

The following *plot-requests* are available:

#### **ALL**

produces all appropriate plots. You can specify other options with **ALL**. For example, to display all plots and unpack the **DFBETAS** plots you can specify **plots=(all dfbetas(unpack))**.

#### **DFBETAS <(UNPACK)>**

displays plots of **DFBETAS** versus the case (observation) number. This displays the statistics generated by the **DFBETAS=\_ALL\_** option in the **OUTPUT** statement. The **UNPACK** option displays the plots separately. See [Output 54.6.5](#) for an example of this plot.

**DPC<(UNPACK)>**

displays plots of **DIFCHISQ** and **DIFDEV** versus the predicted event probability, and colors the markers according to the value of the confidence interval displacement **C**. The **UNPACK** option displays the plots separately. See [Output 54.6.8](#) for an example of this plot.

**EFFECT<(effect-options)>**

displays and enhances the effect plots for the model. For more information about effect plots and the available *effect-options*, see the section “**PLOTS=EFFECT Plots**” on page 4182.

**NOTE:** The **EFFECTPLOT** statement provides you with much of the same functionality and more options for creating effect plots. See [Outputs 54.2.11, 54.3.5, 54.4.8, 54.7.4, and 54.15.4](#) for examples of effect plots.

**INFLUENCE<(UNPACK | STDRES)>**

displays index plots of **RESCHI**, **RESDEV**, leverage, confidence interval displacements **C** and **CBar**, **DIFCHISQ**, and **DIFDEV**. These plots are produced by default when any *plot-request* is specified and the **MAXPOINTS=** cutoff is not exceeded. The **UNPACK** option displays the plots separately. The **STDRES** option also displays index plots of **STDRESCHI**, **STDRESDEV**, and **RESLIK**. See [Outputs 54.6.3 and 54.6.4](#) for examples of these plots.

**LEVERAGE<(UNPACK)>**

displays plots of **DIFCHISQ**, **DIFDEV**, confidence interval displacement **C**, and the predicted probability versus the leverage. The **UNPACK** option displays the plots separately. See [Output 54.6.7](#) for an example of this plot.

**NONE**

suppresses all plots.

**ODDSRATIO <(oddsratio-options)>**

displays and enhances the odds ratio plots for the model. For more information about odds ratio plots and the available *oddsratio-options*, see the section “**Odds Ratio Plots**” on page 4185. See [Outputs 54.7, 54.2.9, 54.3.3, and 54.4.5](#) for examples of this plot.

**PHAT<(UNPACK)>**

displays plots of **DIFCHISQ**, **DIFDEV**, confidence interval displacement **C**, and leverage versus the predicted event probability. The **UNPACK** option displays the plots separately. See [Output 54.6.6](#) for an example of this plot.

**ROC<(ID<=keyword>)>**

displays the ROC curve. If you also specify a **SELECTION=** method, then an overlaid plot of all the ROC curves for each step of the selection process is displayed. If you specify **ROC** statements, then an overlaid plot of the model (or the selected model if a **SELECTION=** method is specified) and the ROC statement models is displayed. If the **OUTROC=** option is specified in a **SCORE** statement, then the ROC curve for the scored data set is displayed.

The **ID=** option labels certain points on the ROC curve. Typically, the labeled points are closest to the upper-left corner of the plot, and points directly below or to the right of a labeled point are suppressed. This option is identical to, and has the same *keywords* as, the **ID=** suboption of the **ROCOPTIONS** option.

See [Output 54.7.3](#) and [Example 54.8](#) for examples of these ROC plots.

**ROCOPTIONS** (*options*)

specifies options that apply to every model specified in a **ROC** statement. Some of these options also apply to the **SCORE** statement. The following *options* are available:

**ALPHA=number**

sets the significance level for creating confidence limits of the areas and the pairwise differences. The **ALPHA=** value specified in the PROC LOGISTIC statement is the default. If neither **ALPHA=** value is specified, then **ALPHA=0.05** by default.

**EPS=value**

is an alias for the **ROCEPS=** option in the MODEL statement. This value is used to determine which predicted probabilities are equal. The default value is the square root of the machine epsilon, which is about  $1E-8$ .

**ID<=keyword>**

displays labels on certain points on the individual ROC curves and also on the **SCORE** statement's ROC curve. This option overrides the **ID=** suboption of the **PLOTS=ROC** option. If several observations lie at the same place on the ROC curve, the value for the last observation is displayed. If you specify the **ID** option with no *keyword*, any variables that are listed in the **ID** statement are used. If no **ID** statement is specified, the observation number is displayed. The following *keywords* are available:

|                 |                                                                  |
|-----------------|------------------------------------------------------------------|
| <b>PROB</b>     | displays the model predicted probability.                        |
| <b>OBS</b>      | displays the (last) observation number.                          |
| <b>SENSIT</b>   | displays the true positive fraction (sensitivity).               |
| <b>1MSPEC</b>   | displays the false positive fraction (1–specificity).            |
| <b>FALPOS</b>   | displays the fraction of nonevents that are predicted as events. |
| <b>FALNEG</b>   | displays the fraction of events that are predicted as nonevents. |
| <b>POSPRED</b>  | displays the positive predictive value (1–FALPOS).               |
| <b>NEGPRED</b>  | displays the negative predictive value (1–FALNEG).               |
| <b>MISCLASS</b> | displays the misclassification rate.                             |
| <b>ID</b>       | displays the ID variables.                                       |

The **SENSIT**, **1MSPEC**, **FALPOS**, and **FALNEG** statistics are defined in the section “**Receiver Operating Characteristic Curves**” on page 4260. The misclassification rate is the number of events that are predicted as nonevents and the number of nonevents that are predicted as events as calculated by using the given cutpoint (predicted probability) divided by the number of observations. If the **PEVENT=** option is also specified, then **FALPOS** and **FALNEG** are computed using the first **PEVENT=** value and Bayes' theorem, as discussed in the section “**Predicted Probability of an Event for Classification**” on page 4255.

**NODETAILS**

suppresses the display of the model fitting information for the models specified in the **ROC** statements.

**OUT=SAS-data-set-name**

is an alias for the **OUTROC=** option in the **MODEL** statement.

**WEIGHTED**

uses frequency×weight in the ROC computations (Izrael et al. 2002) instead of just frequency. Typically, weights are considered in the fit of the model only, and hence are accounted for in the parameter estimates. The “Association of Predicted Probabilities and Observed Responses” table uses frequency (unless the **BINWIDTH=0** option is also specified on the **MODEL** statement), and is suppressed when ROC comparisons are performed. This option also affects **SCORE** statement ROC and AUC computations.

**SIMPLE**

displays simple descriptive statistics (mean, standard deviation, minimum and maximum) for each continuous explanatory variable. For each **CLASS** variable involved in the modeling, the frequency counts of the classification levels are displayed. The **SIMPLE** option generates a breakdown of the simple descriptive statistics or frequency counts for the entire data set and also for individual response categories.

**TRUNCATE**

determines class levels by using no more than the first 16 characters of the formatted values of **CLASS**, response, and strata variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases previous to SAS 9.0. This option invokes the same option in the **CLASS** statement.

**PLOTS=EFFECT Plots**

Only one **PLOTS=EFFECT** plot is produced by default; you must specify other *effect-options* to produce multiple plots. For binary response models, the following plots are produced when an **EFFECT** option is specified with no *effect-options*:

- If you only have continuous covariates in the model, then a plot of the predicted probability versus the first continuous covariate fixing all other continuous covariates at their means is displayed. See [Output 54.7.4](#) for an example with one continuous covariate.
- If you only have classification covariates in the model, then a plot of the predicted probability versus the first **CLASS** covariate at each level of the second **CLASS** covariate, if any, holding all other **CLASS** covariates at their reference levels is displayed.
- If you have **CLASS** and continuous covariates, then a plot of the predicted probability versus the first continuous covariate at up to 10 cross-classifications of the **CLASS** covariate levels, while fixing all other continuous covariates at their means and all other **CLASS** covariates at their reference levels, is displayed. For example, if your model has four binary covariates, there are 16 cross-classifications of the **CLASS** covariate levels. The plot displays the 8 cross-classifications of the levels of the first three covariates while the fourth covariate is fixed at its reference level.

For polytomous response models, similar plots are produced by default, except that the response levels are used in place of the **CLASS** covariate levels. Plots for polytomous response models involving **OFFSET=** variables with multiple values are not available.

The following *effect-options* specify the type of graphic to produce:

**AT**(*variable=value-list* | **ALL**<...*variable=value-list* | **ALL**>)

specifies fixed values for a covariate. For continuous covariates, you can specify one or more numbers in the *value-list*. For classification covariates, you can specify one or more formatted levels of the covariate enclosed in single quotes (for example, **A='cat' 'dog'**), or you can specify the keyword **ALL** to select all levels of the classification variable. You can specify a variable at most once in the **AT** option. By default, continuous covariates are set to their means when they are not used on an axis, while classification covariates are set to their reference level when they are not used as an **X=**, **SLICEBY=**, or **PLOTBY=** effect. For example, for a model that includes a classification variable **A={cat,dog}** and a continuous covariate **X**, specifying **AT (A='cat' X=7 9)** will set **A** to 'cat' when **A** does not appear in the plot. When **X** does not define an axis it first produces plots setting **X = 7** and then produces plots setting **X = 9**. Note in this example that specifying **AT ( A=ALL )** is the same as specifying the **PLOTBY=A** option.

**FITOBSONLY**

computes the predicted values only at the observed data. If the **FITOBSONLY** option is omitted and the **X**-axis variable is continuous, the predicted values are computed at a grid of points extending slightly beyond the range of the data (see the **EXTEND=** option for more information). If the **FITOBSONLY** option is omitted and the **X**-axis effect is categorical, the predicted values are computed at all possible categories.

**INDIVIDUAL**

displays the individual probabilities instead of the cumulative probabilities. This option is available only with cumulative models, and it is not available with the **LINK** option.

**LINK**

displays the linear predictors instead of the probabilities on the **Y** axis. For example, for a binary logistic regression, the **Y** axis will be displayed on the logit scale. The **INDIVIDUAL** and **POLYBAR** options are not available with the **LINK** option.

**PLOTBY=effect**

displays an effect plot at each unique level of the **PLOTBY=** effect. You can specify *effect* as one **CLASS** variable or as an interaction of classification covariates. For polytomous-response models, you can also specify the response variable as the lone **PLOTBY=** effect. For nonsingular parameterizations, the complete cross-classification of the **CLASS** variables specified in the effect define the different **PLOTBY=** levels. When the **GLM** parameterization is used, the **PLOTBY=** levels can depend on the model and the data.

**SLICEBY=effect**

displays predicted probabilities at each unique level of the **SLICEBY=** effect. You can specify *effect* as one **CLASS** variable or as an interaction of classification covariates. For polytomous-response models, you can also specify the response variable as the lone **SLICEBY=** effect. For nonsingular parameterizations, the complete cross-classification of the **CLASS** variables specified in the effect define the different **SLICEBY=** levels. When the **GLM** parameterization is used, the **SLICEBY=** levels can depend on the model and the data.

**X=effect****X=(effect...effect)**

specifies effects to be used on the **X** axis of the effect plots. You can specify several different **X** axes: continuous variables must be specified as main effects, while **CLASS** variables can be crossed. For nonsingular parameterizations, the complete cross-classification of the **CLASS** variables specified in

the effect define the axes. When the **GLM** parameterization is used, the **X=** levels can depend on the model and the data. The response variable is not allowed as an *effect*.

**NOTE:** Any variable not specified in a **SLICEBY=** or **PLOTBY=** option is available to be displayed on the X axis. A variable can be specified in at most one of the **SLICEBY=**, **PLOTBY=**, and **X=** options.

The following *effect-options* enhance the graphical output:

**ALPHA=number**

specifies the size of the confidence limits. The **ALPHA=** value specified in the PROC LOGISTIC statement is the default. If neither **ALPHA=** value is specified, then **ALPHA=0.05** by default.

**CLBAND<=YES | NO>**

displays confidence limits on the plots. This option is not available with the **INDIVIDUAL** option. If you have **CLASS** covariates on the X axis, then error bars are displayed (see the **CLBAR** option) unless you also specify the **CONNECT** option.

**CLBAR**

displays the error bars on the plots when you have **CLASS** covariates on the X axis; if the X axis is continuous, then this invokes the **CLBAND** option. For polytomous-response models with **CLASS** covariates only and with the **POLYBAR** option specified, the stacked bar charts are replaced by side-by-side bar charts with error bars.

**CLUSTER<=percent>**

displays the levels of the **SLICEBY=** effect in a side-by-side fashion instead of stacking them. This option is available when you have **CLASS** covariates on the X axis. You can specify *percent* as a percentage of half the distance between X levels. The *percent* value must be between 0.1 and 1; the default *percent* depends on the number of X levels and the number of **SLICEBY=** levels. Default clustering can be removed by specifying the **NOCLUSTER** option.

**CONNECT<=YES | NO>**

**JOIN<=YES | NO>**

connects the predicted values with a line. This option is available when you have **CLASS** covariates on the X axis. Default connecting lines can be suppressed by specifying the **NOCONNECT** option.

**EXTEND=value**

extends continuous X axes by a factor of *value/2* in each direction. By default, **EXTEND=0.2**.

**MAXATLEN=length**

specifies the maximum number of characters used to display the levels of all the fixed variables. If the text is too long, it is truncated and ellipses (“...”) are appended. By default, *length* is equal to its maximum allowed value, 256.

**NOCLUSTER**

prevents clustering of the levels of the **SLICEBY=** effect. This option is available when you have **CLASS** covariates on the X axis.

**NOCONNECT**

removes the line that connects the predicted values. This option is available when you have **CLASS** covariates on the X axis.

**POLYBAR**

replaces scatter plots of polytomous response models with bar charts. This option has no effect on binary-response models, and it is overridden by the **CONNECT** option. By default, the X axis is chosen to be a crossing of available classification variables so that there are no more than 16 levels; if no such crossing is possible then the first available classification variable is used. You can override this default by specifying the **X=** option.

**SHOWOBS<=YES | NO>**

displays observations on the plot when the **MAXPOINTS=** cutoff is not exceeded. For events/trials notation, the observed proportions are displayed; for single-trial binary-response models, the observed events are displayed at  $\hat{p} = 1$  and the observed nonevents are displayed at  $\hat{p} = 0$ . For polytomous response models the predicted probabilities at the observed values of the covariate are computed and displayed.

**YRANGE=(*< min >*,*< max >*)**

displays the Y axis as [*min*,*max*]. Note that the axis might extend beyond your specified values. By default, the entire Y axis, [0,1], is displayed for the predicted probabilities. This option is useful if your predicted probabilities are all contained in some subset of this range.

**Odds Ratio Plots**

The odds ratios and confidence limits from the default Odds Ratio Estimates table and from the tables produced by the **CLODDS=** option or the **ODDSRATIO** statement can be displayed in a graphic. If you have many odds ratios, you can produce multiple graphics, or *panels*, by displaying subsets of the odds ratios. Odds ratios with duplicate labels are not displayed. See Outputs 54.2.9 and 54.3.3 for examples of odds ratio plots.

The following *oddsratio-options* modify the default odds ratio plot:

**CLDISPLAY=**SERIF** | **LINE** | **BAR**< *width* >**

controls the look of the confidence limit error bars. The default **CLDISPLAY=SERIF** displays the confidence limits as lines with serifs, **CLDISPLAY=LINE** removes the serifs from the error bars, and **CLDISPLAY=BAR** < *width* > displays the limits with a bar of width equal to the size of the marker. You can control the width of the bars and the size of the marker by specifying the *width* value as a percentage of the distance between the bars,  $0 < \textit{width} \leq 1$ .

**NOTE:** Your bar might disappear with small values of *width*.

**DOTPLOT**

displays dotted gridlines on the plot.

**GROUP**

displays the odds ratios in panels defined by the **ODDSRATIO** statements. The **NPANELPOS=** option is ignored when this option is specified.

**LOGBASE=2 | E | 10**

displays the odds ratio axis on the specified log scale.

**NPANELPOS=*n***

breaks the plot into multiple graphics having at most  $|n|$  odds ratios per graphic. If  $n$  is positive, then the number of odds ratios per graphic is balanced; but if  $n$  is negative, then no balancing of the number of odds ratios takes place. By default,  $n = 0$  and all odds ratios are displayed in a single plot. For example, suppose you want to display 21 odds ratios. Then specifying **NPANELPOS=20** displays two plots, the first with 11 odds ratios and the second with 10; but specifying **NPANELPOS=-20** displays 20 odds ratios in the first plot and only 1 odds ratio in the second.

**ORDER=ASCENDING | DESCENDING**

displays the odds ratios in sorted order. By default the odds ratios are displayed in the order in which they appear in the corresponding table.

**RANGE=(*< min >* , *< max >*) | CLIP**

specifies the range of the displayed odds ratio axis. The RANGE=CLIP option has the same effect as specifying the minimum odds ratio as *min* and the maximum odds ratio as *max*. By default, all odds ratio confidence intervals are displayed.

**TYPE=HORIZONTAL | HORIZONTALSTAT | VERTICAL | VERTICALBLOCK**

controls the look of the graphic. The default TYPE=HORIZONTAL option places the odds ratio values on the X axis, while the TYPE=HORIZONTALSTAT option also displays the values of the odds ratios and their confidence limits on the right side of the graphic. The TYPE=VERTICAL option places the odds ratio values on the Y axis, while the TYPE=VERTICALBLOCK option (available only with the CLODDS= option) places the odds ratio values on the Y axis and puts boxes around the labels.

**BY Statement**

**BY variables ;**

You can specify a BY statement with PROC LOGISTIC to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the LOGISTIC procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

If a SCORE statement is specified, then define the *training data set* to be the DATA= data set or the IN-MODEL= data set in the PROC LOGISTIC statement, and define the *scoring data set* to be the DATA= data set and PRIOR= data set in the SCORE statement. The training data set contains all of the BY variables, and

the scoring data set must contain either all of them or none of them. If the scoring data set contains all the BY variables, matching is carried out between the training and scoring data sets. If the scoring data set does not contain any of the BY variables, the entire scoring data set is used for every BY group in the training data set and the BY variables are added to the output data sets that are specified in the **SCORE** statement.

**CAUTION:** The order of the levels in the response and classification variables is determined from all the data regardless of BY groups. However, different sets of levels might appear in different BY groups. This might affect the value of the reference level for these variables, and hence your interpretation of the model and the parameters.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

```
CLASS variable <(options)> ... <variable <(options)>> </global-options>;
```

The CLASS statement names the classification variables to be used as explanatory variables in the analysis. Response variables do not need to be specified in the CLASS statement.

The CLASS statement must precede the **MODEL** statement. Most options can be specified either as individual variable *options* or as *global-options*. You can specify *options* for each variable by enclosing the options in parentheses after the variable name. You can also specify *global-options* for the CLASS statement by placing them after a slash (/). *Global-options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the *global-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*. You can specify the following values for either an *option* or a *global-option*:

### **CPREFIX=*n***

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding design variables. The default is  $32 - \min(32, \max(2, f))$ , where *f* is the formatted length of the CLASS variable.

### **DESCENDING**

#### **DESC**

reverses the sort order of the classification variable. If both the DESCENDING and **ORDER=** options are specified, PROC LOGISTIC orders the categories according to the ORDER= option and then reverses that order.

### **LPREFIX=*n***

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding design variables. The default is  $256 - \min(256, \max(2, f))$ , where *f* is the formatted length of the CLASS variable.

### **MISSING**

treats missing values ('.', '.\_', '.A', ..., '.Z' for numeric variables and blanks for character variables) as valid values for the CLASS variable.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option can be useful when you use the CONTRAST statement. By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC LOGISTIC interprets values of the ORDER= option.

| Value of ORDER= | Levels Sorted By                                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DATA            | Order of appearance in the input data set                                                                                                |
| FORMATTED       | External formatted values, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) values |
| FREQ            | Descending frequency count; levels with more observations come earlier in the order                                                      |
| INTERNAL        | Unformatted value                                                                                                                        |

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PARAM=keyword**

specifies the parameterization method for the classification variable or variables. You can specify any of the *keywords* shown in the following table; the default is PARAM=EFFEFFECT. Design matrix columns are created from CLASS variables according to the corresponding coding schemes:

| Value of PARAM=           | Coding                                                                                              |
|---------------------------|-----------------------------------------------------------------------------------------------------|
| EFFEFFECT                 | Effect coding                                                                                       |
| GLM                       | Less-than-full-rank reference cell coding (this <i>keyword</i> can be used only in a global option) |
| ORDINAL<br>THERMOMETER    | Cumulative parameterization for an ordinal CLASS variable                                           |
| POLYNOMIAL<br>POLY        | Polynomial coding                                                                                   |
| REFERENCE<br>REF          | Reference cell coding                                                                               |
| ORTHEFFECT                | Orthogonalizes PARAM=EFFEFFECT coding                                                               |
| ORTHORDINAL<br>ORTHOTHERM | Orthogonalizes PARAM=ORDINAL coding                                                                 |
| ORTHPOLY                  | Orthogonalizes PARAM=POLYNOMIAL coding                                                              |
| ORTHREF                   | Orthogonalizes PARAM=REFERENCE coding                                                               |

All parameterizations are full rank, except for the GLM parameterization. The REF= option in the

CLASS statement determines the reference level for EFFECT and REFERENCE coding and for their orthogonal parameterizations. It also indirectly determines the reference level for a singular GLM parameterization through the order of levels.

If PARAM=ORTHPOLY or PARAM=POLY and the classification variable is numeric, then the ORDER= option in the CLASS statement is ignored, and the internal unformatted values are used. See the section “Other Parameterizations” on page 387 of Chapter 19, “Shared Concepts and Topics,” for further details.

**REF=** *'level' | keyword*

specifies the reference level for PARAM=EFFECT, PARAM=REFERENCE, and their orthogonalizations. For PARAM=GLM, the REF= option specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the linear estimates with a singular parameterization.

For an individual variable REF= option (but not for a global REF= option), you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a global or individual variable REF= option, you can use one of the following *keywords*. The default is REF=LAST.

**FIRST**     designates the first ordered level as reference.

**LAST**       designates the last ordered level as reference.

**TRUNCATE**< =*n*>

specifies the length *n* of CLASS variable values to use in determining CLASS variable levels. The default is to use the full formatted length of the CLASS variable. If you specify TRUNCATE without the length *n*, the first 16 characters of the formatted values are used. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases before SAS 9. The TRUNCATE option is available only as a global option.

## Class Variable Naming Convention

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization. See the section “Other Parameterizations” on page 387 in Chapter 19, “Shared Concepts and Topics,” for examples and further details.

## Class Variable Parameterization with Unbalanced Designs

PROC LOGISTIC initially parameterizes the CLASS variables by looking at the levels of the variables across the complete data set. If you have an *unbalanced* replication of levels across variables or BY groups, then the design matrix and the parameter interpretation might be different from what you expect. For instance, suppose you have a model with one CLASS variable A with three levels (1, 2, and 3), and another CLASS variable B with two levels (1 and 2). If the third level of A occurs only with the first level of B, if you use the EFFECT parameterization, and if your model contains the effect A(B) and an intercept, then the design for A within the second level of B is not a differential effect. In particular, the design looks like the following:

|   |   | Design Matrix |    |        |    |
|---|---|---------------|----|--------|----|
|   |   | A(B=1)        |    | A(B=2) |    |
| B | A | A1            | A2 | A1     | A2 |
| 1 | 1 | 1             | 0  | 0      | 0  |
| 1 | 2 | 0             | 1  | 0      | 0  |
| 1 | 3 | -1            | -1 | 0      | 0  |
| 2 | 1 | 0             | 0  | 1      | 0  |
| 2 | 2 | 0             | 0  | 0      | 1  |

PROC LOGISTIC detects linear dependency among the last two design variables and sets the parameter for A2(B=2) to zero, resulting in an interpretation of these parameters as if they were reference- or dummy-coded. The REFERENCE or GLM parameterization might be more appropriate for such problems.

## CODE Statement

**CODE** < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 54.2 summarizes the *options* available in the CODE statement.

**Table 54.2** CODE Statement Options

| Option    | Description                                                                  |
|-----------|------------------------------------------------------------------------------|
| CATALOG=  | Names the catalog entry where the generated code is saved                    |
| DUMMIES   | Retains the dummy variables in the data set                                  |
| ERROR     | Computes the error function                                                  |
| FILE=     | Names the file where the generated code is saved                             |
| FORMAT=   | Specifies the numeric format for the regression coefficients                 |
| GROUP=    | Specifies the group identifier for array names and statement labels          |
| IMPUTE    | Imputes predicted values for observations with missing or invalid covariates |
| LINESIZE= | Specifies the line size of the generated code                                |
| LOOKUP=   | Specifies the algorithm for looking up CLASS levels                          |
| RESIDUAL  | Computes residuals                                                           |

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

## CONTRAST Statement

**CONTRAST** 'label' row-description<, . . . , row-description > < / options > ;

where a *row-description* is defined as follows:

*effect values*<, . . . , *effect values*>

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST and ESTIMATE statements in other modeling procedures.

The CONTRAST statement enables you to specify a matrix,  $\mathbf{L}$ , for testing the hypothesis  $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ , where  $\boldsymbol{\beta}$  is the vector of intercept and slope parameters. You must be familiar with the details of the model parameterization that PROC LOGISTIC uses (for more information, see the [PARAM=](#) option in the section “[CLASS Statement](#)” on page 4187). Optionally, the CONTRAST statement enables you to estimate each row,  $\mathbf{l}'_i\boldsymbol{\beta}$ , of  $\mathbf{L}\boldsymbol{\beta}$  and test the hypothesis  $\mathbf{l}'_i\boldsymbol{\beta} = 0$ . Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the [MODEL](#) statement.

The following parameters are specified in the CONTRAST statement:

- label* identifies the contrast in the displayed output. A label is required for every contrast specified, and it must be enclosed in quotes.
- effect* identifies an effect that appears in the [MODEL](#) statement. The name INTERCEPT can be used as an effect when one or more intercepts are included in the model. You do not need to include all effects that are included in the [MODEL](#) statement.
- values* are constants that are elements of the  $\mathbf{L}$  matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The [E](#) option, described later in this section, enables you to verify the proper correspondence of *values* to parameters. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*; the rows of  $\mathbf{L}$  are specified in order and are separated by commas. The degrees of freedom is the number of linearly independent constraints implied by the CONTRAST statement—that is, the rank of  $\mathbf{L}$ .

More details for specifying contrasts involving effects with full-rank parameterizations are given in the section “[Full-Rank Parameterized Effects](#)” on page 4192, while details for less-than-full-rank parameterized effects are given in the section “[Less-Than-Full-Rank Parameterized Effects](#)” on page 4193.

You can specify the following options after a slash (/):

**ALPHA=***number*

specifies the level of significance  $\alpha$  for the  $100(1-\alpha)\%$  confidence interval for each contrast when the ESTIMATE option is specified. The value of *number* must be between 0 and 1. By default, *number* is equal to the value of the [ALPHA=](#) option in the PROC LOGISTIC statement, or 0.05 if that option is not specified.

**E**

displays the  $\mathbf{L}$  matrix.

**ESTIMATE=keyword**

estimates and tests each individual contrast (that is, each row,  $l'_i\beta$ , of  $L\beta$ ), exponentiated contrast ( $e^{l'_i\beta}$ ), or predicted probability for the contrast ( $g^{-1}(l'_i\beta)$ ). PROC LOGISTIC displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test. The significance level of the confidence interval is controlled by the **ALPHA=** option. You can estimate the individual contrast, the exponentiated contrast, or the predicted probability for the contrast by specifying one of the following *keywords*:

**PARM**

estimates the individual contrast.

**EXP**

estimates the exponentiated contrast.

**BOTH**

estimates both the individual contrast and the exponentiated contrast.

**PROB**

estimates the predicted probability of the contrast.

**ALL**

estimates the individual contrast, the exponentiated contrast, and the predicted probability of the contrast.

For details about the computations of the standard errors and confidence limits, see the section “[Linear Predictor, Predicted Probability, and Confidence Limits](#)” on page 4253.

**SINGULAR=number**

tunes the estimability check. This option is ignored when a full-rank parameterization is specified. If  $\mathbf{v}$  is a vector, define  $\text{ABS}(\mathbf{v})$  to be the largest absolute value of the elements of  $\mathbf{v}$ . For a row vector  $l'$  of the contrast matrix  $L$ , define  $c = \text{ABS}(l')$  if  $\text{ABS}(l')$  is greater than 0; otherwise,  $c = 1$ . If  $\text{ABS}(l' - l'\mathbf{T})$  is greater than  $c * \text{number}$ , then  $l$  is declared nonestimable. The  $\mathbf{T}$  matrix is the Hermite form matrix  $\mathbf{I}_0^{-1}\mathbf{I}_0$ , where  $\mathbf{I}_0^{-1}$  represents a generalized inverse of the (observed or expected) information matrix  $\mathbf{I}_0$  of the null model. The value for *number* must be between 0 and 1; the default value is 1E-4.

**Full-Rank Parameterized Effects**

If an effect involving a CLASS variable with a full-rank parameterization does not appear in the CONTRAST statement, then all of its coefficients in the  $L$  matrix are set to 0.

If you use effect coding by default or by specifying **PARAM=EFFECT** in the **CLASS** statement, then all parameters are directly estimable and involve no other parameters. For example, suppose an effect-coded CLASS variable  $A$  has four levels. Then there are three parameters ( $\beta_1, \beta_2, \beta_3$ ) representing the first three levels, and the fourth parameter is represented by

$$-\beta_1 - \beta_2 - \beta_3$$

To test the first versus the fourth level of  $A$ , you would test

$$\beta_1 = -\beta_1 - \beta_2 - \beta_3$$

or, equivalently,

$$2\beta_1 + \beta_2 + \beta_3 = 0$$

which, in the form  $\mathbf{L}\boldsymbol{\beta} = 0$ , is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \beta_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\beta_1 + \beta_2}{2} = \beta_3$$

or, equivalently,

$$\beta_1 + \beta_2 - 2\beta_3 = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements are constructed similarly. For example:

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
A 0 1 0,
A 0 0 1;
```

## Less-Than-Full-Rank Parameterized Effects

When you use the less-than-full-rank parameterization (by specifying `PARAM=GLM` in the `CLASS` statement), each row is checked for estimability; see the section “[Estimable Functions](#)” on page 59 in Chapter 3, “[Introduction to Statistical Modeling with SAS/STAT Software](#),” for more information. If PROC LOGISTIC finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. PROC LOGISTIC handles missing level combinations of classification variables in the same manner as PROC GLM: parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the  $\mathbf{L}$  matrix in your CONTRAST statement. If the elements of  $\mathbf{L}$  are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the GLM procedure does for its CONTRAST and ESTIMATE statements. For example, suppose that the model contains effects A and B and their interaction A\*B. If you specify a CONTRAST statement involving A alone, the  $\mathbf{L}$  matrix contains nonzero terms for both A and A\*B, since A\*B contains A. See rule 4 in the section “[Construction of Least Squares Means](#)” on page 3363 in Chapter 42, “[The GLM Procedure](#),” for more details.

## EFFECT Statement

**EFFECT** *name=effect-type (variables < / options>)* ;

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>COLLECTION</b>        | is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.       |
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                           |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                             |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 54.3 summarizes the *options* available in the EFFECT statement.

**Table 54.3** EFFECT Statement Options

| Option                             | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Collection Effects Options</b>  |                                                                                                                                                      |
| DETAILS                            | Displays the constituents of the collection effect                                                                                                   |
| <b>Lag Effects Options</b>         |                                                                                                                                                      |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                        |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                            |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                           |
| PERIOD=                            | Names the variable that defines the period                                                                                                           |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                            |
| <b>Multimember Effects Options</b> |                                                                                                                                                      |
| NOEFFECT                           | Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                            |

Table 54.3 *continued*

| Option                            | Description                                                                                             |
|-----------------------------------|---------------------------------------------------------------------------------------------------------|
| <b>Polynomial Effects Options</b> |                                                                                                         |
| DEGREE=                           | Specifies the degree of the polynomial                                                                  |
| MDEGREE=                          | Specifies the maximum degree of any variable in a term of the polynomial                                |
| STANDARDIZE=                      | Specifies centering and scaling suboptions for the variables that define the polynomial                 |
| <b>Spline Effects Options</b>     |                                                                                                         |
| BASIS=                            | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion |
| DEGREE=                           | Specifies the degree of the spline transformation                                                       |
| KNOTMETHOD=                       | Specifies how to construct the knots for spline effects                                                 |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

## EFFECTPLOT Statement

**EFFECTPLOT** < *plot-type* < (*plot-definition-options*) > > < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 54.4 describes the available *plot-types* and their *plot-definition-options*.

Table 54.4 *Plot-Types and Plot-Definition-Options*

| Plot-Type and Description                                                                                                                                                                                                      | Plot-Definition-Options                                                                                   |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------|
| <b>BOX</b><br>Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the <b>INTERACTION</b> <i>plot-type</i> . | <b>PLOTBY=</b> variable or CLASS effect<br><b>X=</b> CLASS variable or effect                             |
| <b>CONTOUR</b><br>Displays a contour plot of predicted values against two continuous covariates.                                                                                                                               | <b>PLOTBY=</b> variable or CLASS effect<br><b>X=</b> continuous variable<br><b>Y=</b> continuous variable |
| <b>FIT</b><br>Displays a curve of predicted values versus a continuous variable.                                                                                                                                               | <b>PLOTBY=</b> variable or CLASS effect<br><b>X=</b> continuous variable                                  |

Table 54.4 continued

| Plot-Type and Description                                                                                                                                                                                                                    | Plot-Definition-Options                                                                                             |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------------------------------------------------|
| <p><b>INTERACTION</b></p> <p>Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.</p> | <p>PLOTBY= variable or CLASS effect</p> <p>SLICEBY= variable or CLASS effect</p> <p>X= CLASS variable or effect</p> |
| <p><b>SLICEFIT</b></p> <p>Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.</p>                                                                                                     | <p>PLOTBY= variable or CLASS effect</p> <p>SLICEBY= variable or CLASS effect</p> <p>X= continuous variable</p>      |

For full details about the syntax and options of the EFFECTPLOT statement, see the section “EFFECTPLOT Statement” on page 411 in Chapter 19, “Shared Concepts and Topics.”

See Outputs 54.2.11, 54.2.12, 54.3.5, 54.4.8, 54.7.4, and 54.15.4 for examples of plots produced by this statement.

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 < , ... <'label'> estimate-specification <(divisor=n)> >
 </ options > ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $L\beta$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 54.5 summarizes the options available in the ESTIMATE statement.

Table 54.5 ESTIMATE Statement Options

| Option                                                     | Description                                                               |
|------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                           |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                     |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects |
| SINGULAR=                                                  | Tunes the estimability checking difference                                |

Table 54.5 *continued*

| Option                                              | Description                                                                     |
|-----------------------------------------------------|---------------------------------------------------------------------------------|
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                 |
| ADJUST=                                             | Determines the method for multiple comparison adjustment of estimates           |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                |
| LOWER                                               | Performs one-sided, lower-tailed inference                                      |
| STEPDOWN                                            | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion       |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                            |
| UPPER                                               | Performs one-sided, upper-tailed inference                                      |
| <b>Statistical Output</b>                           |                                                                                 |
| CL                                                  | Constructs confidence limits                                                    |
| CORR                                                | Displays the correlation matrix of estimates                                    |
| COV                                                 | Displays the covariance matrix of estimates                                     |
| E                                                   | Prints the $L$ matrix                                                           |
| JOINT                                               | Produces a joint $F$ or chi-square test for the estimable functions             |
| SEED=                                               | Specifies the seed for computations that depend on random numbers               |
| <b>Generalized Linear Modeling</b>                  |                                                                                 |
| CATEGORY=                                           | Specifies how to construct estimable functions with multinomial data            |
| EXP                                                 | Exponentiates and displays estimates                                            |
| ILINK                                               | Computes and displays estimates and standard errors on the inverse linked scale |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## EXACT Statement

**EXACT** < *label* > < INTERCEPT > < *effects* > < / *options* > ;

The EXACT statement performs exact tests of the parameters for the specified *effects* and optionally estimates the parameters and outputs the exact conditional distributions. You can specify the keyword INTERCEPT and any effects in the MODEL statement. Inference on the parameters of the specified effects is performed by conditioning on the sufficient statistics of all the other model parameters (possibly including the intercept).

You can specify several EXACT statements, but they must follow the MODEL statement. Each statement can optionally include an identifying *label*. If several EXACT statements are specified, any statement without a label is assigned a label of the form “Exact $n$ ,” where  $n$  indicates the  $n$ th EXACT statement. The label is included in the headers of the displayed exact analysis tables.

If a **STRATA** statement is also specified, then a stratified exact logistic regression is performed. The model contains a different intercept for each stratum, and these intercepts are conditioned out of the model along with any other nuisance parameters (parameters for effects specified in the **MODEL** statement that are not in the **EXACT** statement).

If the **LINK=GLOGIT** option is specified in the **MODEL** statement, then the **METHOD=DIRECT** option is invoked in the **EXACTOPTIONS** statement by default and a generalized logit model is fit. Since each effect specified in the **MODEL** statement adds  $k$  parameters to the model (where  $k + 1$  is the number of response levels), exact analysis of the generalized logit model by using this method is limited to rather small problems.

The **CONTRAST**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **ODDSRATIO**, **OUTPUT**, **ROC**, **ROCCONTRAST**, **SCORE**, **SLICE**, **STORE**, **TEST**, and **UNITS** statements are not available with an exact analysis; results from these statements are based on the asymptotic results. Exact analyses are not performed when you specify a **WEIGHT** statement, a link other than **LINK=LOGIT** or **LINK=GLOGIT**, an offset variable, the **NOFIT** option, or a model selection method. Exact estimation is not available for ordinal response models.

For classification variables, use of the reference parameterization is recommended.

The following options can be specified in each **EXACT** statement after a slash (/):

**ALPHA=number**

specifies the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence limits for the parameters or odds ratios. The value of *number* must be between 0 and 1. By default, *number* is equal to the value of the **ALPHA=** option in the **PROC LOGISTIC** statement, or 0.05 if that option is not specified.

**CLTYPE=EXACT | MIDP**

requests either the exact or mid- $p$  confidence intervals for the parameter estimates. By default, the exact intervals are produced. The confidence coefficient can be specified with the **ALPHA=** option. The mid- $p$  interval can be modified with the **MIDPFACTOR=** option. See the section “Exact Conditional Logistic Regression” on page 4274 for details.

**ESTIMATE <=keyword>**

estimates the individual parameters (conditioned on all other parameters) for the effects specified in the **EXACT** statement. For each parameter, a point estimate, a standard error, a confidence interval, and a  $p$ -value for a two-sided test that the parameter is zero are displayed. Note that the two-sided  $p$ -value is twice the one-sided  $p$ -value. You can optionally specify one of the following keywords:

**PARAM** specifies that the parameters be estimated. This is the default.

**ODDS** specifies that the odds ratios be estimated. If you have classification variables, then you must also specify the **PARAM=REF** option in the **CLASS** statement.

**BOTH** specifies that both the parameters and odds ratios be estimated.

**JOINT**

performs the joint test that all of the parameters are simultaneously equal to zero, performs individual hypothesis tests for the parameter of each continuous variable, and performs joint tests for the parameters of each classification variable. The joint test is indicated in the “Conditional Exact Tests” table by the label “Joint.”

**JOINTONLY**

performs only the joint test of the parameters. The test is indicated in the “Conditional Exact Tests” table by the label “Joint.” When this option is specified, individual tests for the parameters of each continuous variable and joint tests for the parameters of the classification variables are not performed.

**MIDPFACTOR= $\delta_1$  | ( $\delta_1, \delta_2$ )**

sets the tie factors used to produce the mid- $p$  hypothesis statistics and the mid- $p$  confidence intervals.  $\delta_1$  modifies both the hypothesis tests and confidence intervals, while  $\delta_2$  affects only the hypothesis tests. By default,  $\delta_1 = 0.5$  and  $\delta_2 = 1.0$ . See the section “[Exact Conditional Logistic Regression](#)” on page 4274 for details.

**ONESIDED**

requests one-sided confidence intervals and  $p$ -values for the individual parameter estimates and odds ratios. The one-sided  $p$ -value is the smaller of the left- and right-tail probabilities for the observed sufficient statistic of the parameter under the null hypothesis that the parameter is zero. The two-sided  $p$ -values (default) are twice the one-sided  $p$ -values. See the section “[Exact Conditional Logistic Regression](#)” on page 4274 for more details.

**OUTDIST=*SAS-data-set***

names the SAS data set that contains the exact conditional distributions. This data set contains all of the exact conditional distributions that are required to process the corresponding EXACT statement. This data set contains the possible sufficient statistics for the parameters of the effects specified in the EXACT statement, the counts, and, when hypothesis tests are performed on the parameters, the probability of occurrence and the score value for each sufficient statistic. When you request an OUTDIST= data set, the observed sufficient statistics are displayed in the “Sufficient Statistics” table. See the section “[OUTDIST= Output Data Set](#)” on page 4281 for more information.

**EXACT Statement Examples**

In the following example, two exact tests are computed: one for  $x_1$  and the other for  $x_2$ . The test for  $x_1$  is based on the exact conditional distribution of the sufficient statistic for the  $x_1$  parameter given the observed values of the sufficient statistics for the intercept,  $x_2$ , and  $x_3$  parameters; likewise, the test for  $x_2$  is conditional on the observed sufficient statistics for the intercept,  $x_1$ , and  $x_3$ .

```
proc logistic;
 model y= x1 x2 x3;
 exact x1 x2;
run;
```

PROC LOGISTIC determines, from all the specified EXACT statements, the distinct conditional distributions that need to be evaluated. For example, there is only one exact conditional distribution for the following two EXACT statements:

```
exact 'One' x1 / estimate=parm;
exact 'Two' x1 / estimate=parm onesided;
```

For each EXACT statement, individual tests for the parameters of the specified effects are computed unless the **JOINTONLY** option is specified. Consider the following EXACT statements:

```

exact 'E12' x1 x2 / estimate;
exact 'E1' x1 / estimate;
exact 'E2' x2 / estimate;
exact 'J12' x1 x2 / joint;

```

In the E12 statement, the parameters for x1 and x2 are estimated and tested separately. Specifying the E12 statement is equivalent to specifying both the E1 and E2 statements. In the J12 statement, the joint test for the parameters of x1 and x2 is computed in addition to the individual tests for x1 and x2.

---

## EXACTOPTIONS Statement

**EXACTOPTIONS** *options* ;

The EXACTOPTIONS statement specifies options that apply to every **EXACT** statement in the program. The following *options* are available:

### ABSFCNV=*value*

specifies the absolute function convergence criterion. Convergence requires a small change in the log-likelihood function in subsequent iterations,

$$|l_i - l_{i-1}| < \textit{value}$$

where  $l_i$  is the value of the log-likelihood function at iteration  $i$ .

By default, ABSFCNV=1E-12. You can also specify the **FCNV=** and **XCONV=** criteria; optimizations are terminated as soon as one criterion is satisfied.

### ADDTOBS

adds the observed sufficient statistic to the sampled exact distribution if the statistic was not sampled. This option has no effect unless the **METHOD=NETWORKMC** option is specified and the **ESTIMATE** option is specified in the **EXACT** statement. If the observed statistic has not been sampled, then the parameter estimate does not exist; by specifying this option, you can produce (biased) estimates.

### BUILDSUBSETS

builds every distribution for sampling. By default, some exact distributions are created by taking a subset of a previously generated exact distribution. When the **METHOD=NETWORKMC** option is invoked, this subsetting behavior has the effect of using fewer than the desired  $n$  samples; see the **N=** option for more details. Use the **BUILDSUBSETS** option to suppress this subsetting.

### EPSILON=*value*

controls how the partial sums  $\sum_{i=1}^j y_i x_i$  are compared. *value* must be between 0 and 1; by default, *value*=1E-8.

### FCNV=*value*

specifies the relative function convergence criterion. Convergence requires a small relative change in the log-likelihood function in subsequent iterations,

$$\frac{|l_i - l_{i-1}|}{|l_{i-1}| + 1\text{E-}6} < \textit{value}$$

where  $l_i$  is the value of the log likelihood at iteration  $i$ .

By default, FCONV=1E-8. You can also specify the ABSFCONV= and XCONV= criteria; if more than one criterion is specified, then optimizations are terminated as soon as one criterion is satisfied.

**MAXTIME=seconds**

specifies the maximum clock time (in seconds) that PROC LOGISTIC can use to calculate the exact distributions. If the limit is exceeded, the procedure halts all computations and prints a note to the LOG. The default maximum clock time is seven days.

**METHOD=keyword**

specifies which exact conditional algorithm to use for every EXACT statement specified. You can specify one of the following keywords:

**DIRECT** invokes the multivariate shift algorithm of Hirji, Mehta, and Patel (1987). This method directly builds the exact distribution, but it can require an excessive amount of memory in its intermediate stages. METHOD=DIRECT is invoked by default when you are conditioning out at most the intercept, or when the LINK=GLOGIT option is specified in the MODEL statement.

**NETWORK** invokes an algorithm described in Mehta, Patel, and Senchaudhuri (1992). This method builds a network for each parameter that you are conditioning out, combines the networks, then uses the multivariate shift algorithm to create the exact distribution. The NETWORK method can be faster and require less memory than the DIRECT method. The NETWORK method is invoked by default for most analyses.

**NETWORKMC** invokes the hybrid network and Monte Carlo algorithm of Mehta, Patel, and Senchaudhuri (1992). This method creates a network, then samples from that network; this method does not reject any of the samples at the cost of using a large amount of memory to create the network. METHOD=NETWORKMC is most useful for producing parameter estimates for problems that are too large for the DIRECT and NETWORK methods to handle and for which asymptotic methods are invalid—for example, for sparse data on a large grid.

**N=n**

specifies the number of Monte Carlo samples to take when the METHOD=NETWORKMC option is specified. By default,  $n = 10,000$ . If the procedure cannot obtain  $n$  samples due to a lack of memory, then a note is printed in the SAS log (the number of valid samples is also reported in the listing) and the analysis continues.

The number of samples used to produce any particular statistic might be smaller than  $n$ . For example, let  $X1$  and  $X2$  be continuous variables, denote their joint distribution by  $f(X1, X2)$ , and let  $f(X1 | X2 = x2)$  denote the marginal distribution of  $X1$  conditioned on the observed value of  $X2$ . If you request the JOINT test of  $X1$  and  $X2$ , then  $n$  samples are used to generate the estimate  $\hat{f}(X1, X2)$  of  $f(X1, X2)$ , from which the test is computed. However, the parameter estimate for  $X1$  is computed from the subset of  $\hat{f}(X1, X2)$  that has  $X2 = x2$ , and this subset need not contain  $n$  samples. Similarly, the distribution for each level of a classification variable is created by extracting the appropriate subset from the joint distribution for the CLASS variable.

In some cases, the marginal sample size can be too small to admit accurate estimation of a particular statistic; a note is printed in the SAS log when a marginal sample size is less than 100. Increasing  $n$

increases the number of samples used in a marginal distribution; however, if you want to control the sample size exactly, you can either specify the **BUILDSUBSETS** option or do both of the following:

- Remove the **JOINT** option from the **EXACT** statement.
- Create dummy variables in a **DATA** step to represent the levels of a **CLASS** variable, and specify them as independent variables in the **MODEL** statement.

### **NOLOGSCALE**

specifies that computations for the exact conditional models be computed by using normal scaling. Log scaling can handle numerically larger problems than normal scaling; however, computations in the log scale are slower than computations in normal scale.

### **ONDISK**

uses disk space instead of random access memory to build the exact conditional distribution. Use this option to handle larger problems at the cost of slower processing.

### **SEED=seed**

specifies the initial seed for the random number generator used to take the Monte Carlo samples when the **METHOD=NETWORKMC** option is specified. The value of the **SEED=** option must be an integer. If you do not specify a seed, or if you specify a value less than or equal to zero, then PROC LOGISTIC uses the time of day from the computer's clock to generate an initial seed.

### **STATUSN=number**

prints a status line in the SAS log after every *number* of Monte Carlo samples when the **METHOD=NETWORKMC** option is specified. The number of samples taken and the current exact *p*-value for testing the significance of the model are displayed. You can use this status line to track the progress of the computation of the exact conditional distributions.

### **STATUSTIME=seconds**

specifies the time interval (in seconds) for printing a status line in the LOG. You can use this status line to track the progress of the computation of the exact conditional distributions. The time interval you specify is approximate; the actual time interval varies. By default, no status reports are produced.

### **XCONV=value**

specifies the relative parameter convergence criterion. Convergence requires a small relative parameter change in subsequent iterations,

$$\max_j |\delta_j^{(i)}| < value$$

where

$$\delta_j^{(i)} = \begin{cases} \beta_j^{(i)} - \beta_j^{(i-1)} & |\beta_j^{(i-1)}| < 0.01 \\ \frac{\beta_j^{(i)} - \beta_j^{(i-1)}}{\beta_j^{(i-1)}} & \text{otherwise} \end{cases}$$

and  $\beta_j^{(i)}$  is the estimate of the *j*th parameter at iteration *i*.

By default, **XCONV=1E-4**. You can also specify the **ABSFCNV=** and **FCONV=** criteria; if more than one criterion is specified, then optimizations are terminated as soon as one criterion is satisfied.

---

## FREQ Statement

**FREQ** *variable* ;

The FREQ statement identifies a *variable* that contains the frequency of occurrence of each observation. PROC LOGISTIC treats each observation as if it appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. If it is not an integer, the frequency value is truncated to an integer. If the frequency value is less than 1 or missing, the observation is not used in the model fitting. When the FREQ statement is not specified, each observation is assigned a frequency of 1. If you specify more than one FREQ statement, then the first statement is used.

If a SCORE statement is specified, then the FREQ variable is used for computing fit statistics and the ROC curve, but they are not required for scoring. If the DATA= data set in the SCORE statement does not contain the FREQ variable, the frequency values are assumed to be 1 and a warning message is issued in the LOG. If you fit a model and perform the scoring in the same run, the same FREQ variable is used for fitting and scoring. If you fit a model in a previous run and input it with the INMODEL= option in the current run, then the FREQ variable can be different from the one used in the previous run. However, if a FREQ variable was not specified in the previous run, you can still specify a FREQ variable in the current run.

---

## ID Statement

**ID** *variable*< *variable*,... > ;

The ID statement specifies variables in the DATA= data set that are used for labeling ROC curves and influence diagnostic plots. If more than one ID variable is specified, then the plots are labeled by concatenating the ID variable values together. See the PLOTS(LABEL) and ROCOPTIONS(ID) options in the PROC LOGISTIC statement for more details.

---

## LSMEANS Statement

**LSMEANS** < *model-effects* > < / *options* > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 54.6 summarizes the options available in the LSMEANS statement.

**Table 54.6** LSMEANS Statement Options

| Option                                              | Description                                                                                                       |
|-----------------------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                                                   |
| AT                                                  | Modifies the covariate value in computing LS-means                                                                |
| BYLEVEL                                             | Computes separate margins                                                                                         |
| DIFF                                                | Requests differences of LS-means                                                                                  |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by the input data set                       |
| SINGULAR=                                           | Tunes estimability checking                                                                                       |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                                                   |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences                                  |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                                                  |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion                                            |
| <b>Statistical Output</b>                           |                                                                                                                   |
| CL                                                  | Constructs confidence limits for means and mean differences                                                       |
| CORR                                                | Displays the correlation matrix of LS-means                                                                       |
| COV                                                 | Displays the covariance matrix of LS-means                                                                        |
| E                                                   | Prints the L matrix                                                                                               |
| LINES                                               | Produces a “Lines” display for pairwise LS-means differences                                                      |
| MEANS                                               | Prints the LS-means                                                                                               |
| PLOTS=                                              | Requests graphs of means and mean comparisons                                                                     |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                                                 |
| <b>Generalized Linear Modeling</b>                  |                                                                                                                   |
| EXP                                                 | Exponentiates and displays estimates of LS-means or LS-means differences                                          |
| ILINK                                               | Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale |
| ODDSRATIO                                           | Reports (simple) differences of least squares means in terms of odds ratios if permitted by the link function     |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 in Chapter 19, “Shared Concepts and Topics.”

**NOTE:** If you have classification variables in your model, then the LSMEANS statement is allowed only if you also specify the `PARAM=GLM` option.

---

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </ options > ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 54.7 summarizes the options available in the LSMESTIMATE statement.

**Table 54.7** LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                    |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |
| <b>Statistical Output</b>                           |                                                                                     |
| CL                                                  | Constructs confidence limits for means and mean differences                         |
| CORR                                                | Displays the correlation matrix of LS-means                                         |
| COV                                                 | Displays the covariance matrix of LS-means                                          |
| E                                                   | Prints the <b>L</b> matrix                                                          |
| ELSM                                                | Prints the <b>K</b> matrix                                                          |
| JOINT                                               | Produces a joint $F$ or chi-square test for the LS-means and LS-means differences   |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                   |

---

| Option                             | Description                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Generalized Linear Modeling</b> |                                                                                                                   |
| CATEGORY=                          | Specifies how to construct estimable functions with multinomial data                                              |
| EXP                                | Exponentiates and displays LS-means estimates                                                                     |
| ILINK                              | Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale |

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

**NOTE:** If you have classification variables in your model, then the LSMESTIMATE statement is allowed only if you also specify the [PARAM=GLM](#) option.

## MODEL Statement

```
< label: > MODEL variable< (variable_options) > = < effects > < / options > ;
```

```
< label: > MODEL events/trials = < effects > < / options > ;
```

The MODEL statement names the response variable and the explanatory effects, including covariates, main effects, interactions, and nested effects; see the section “[Specification of Effects](#)” on page 3324 of Chapter 42, “[The GLM Procedure](#),” for more information. If you omit the explanatory effects, the procedure fits an intercept-only model. You must specify exactly one MODEL statement.

Two forms of the MODEL statement can be specified. The first form, referred to as *single-trial* syntax, is applicable to binary, ordinal, and nominal response data. The second form, referred to as *events/trials* syntax, is restricted to the case of binary response data. The single-trial syntax is used when each observation in the DATA= data set contains information about only a single trial, such as a single subject in an experiment. When each observation contains information about multiple binary-response trials, such as the counts of the number of subjects observed and the number responding, then events/trials syntax can be used.

In the events/trials syntax, you specify two variables that contain count data for a binomial experiment. These two variables are separated by a slash. The value of the first variable, *events*, is the number of positive responses (or events). The value of the second variable, *trials*, is the number of trials. The values of both *events* and (*trials*–*events*) must be nonnegative and the value of *trials* must be positive for the response to be valid.

In the single-trial syntax, you specify one variable (on the left side of the equal sign) as the response variable. This variable can be character or numeric. [Variable\\_options](#) specific to the response variable can be specified immediately after the response variable with parentheses around them.

For both forms of the MODEL statement, explanatory *effects* follow the equal sign. Variables can be either continuous or classification variables. Classification variables can be character or numeric, and they must be declared in the [CLASS](#) statement. When an effect is a classification variable, the procedure inserts a set of coded columns into the design matrix instead of directly entering a single column containing the values of the variable.

## Response Variable Options

### DESCENDING | DESC

reverses the order of the response categories. If both the DESCENDING and ORDER= options are specified, PROC LOGISTIC orders the response categories according to the ORDER= option and then reverses that order. See the section “Response Level Ordering” on page 4237 for more detail.

### EVENT='category' | keyword

specifies the event category for the binary response model. PROC LOGISTIC models the probability of the event category. The EVENT= option has no effect when there are more than two response categories. You can specify the value (formatted if a format is applied) of the event category in quotes, or you can specify one of the following keywords. The default is EVENT=FIRST.

#### FIRST

designates the first ordered category as the event.

#### LAST

designates the last ordered category as the event.

One of the most common sets of response levels is {0,1}, with 1 representing the event for which the probability is to be modeled. Consider the example where Y takes the values 1 and 0 for event and nonevent, respectively, and Exposure is the explanatory variable. To specify the value 1 as the event category, use the following MODEL statement:

```
model Y(event='1') = Exposure;
```

### ORDER= DATA | FORMATTED | FREQ | INTERNAL

specifies the sort order for the levels of the response variable. The following table displays the available ORDER= options:

| ORDER=    | Levels Sorted By                                                                                                                       |
|-----------|----------------------------------------------------------------------------------------------------------------------------------------|
| DATA      | order of appearance in the input data set                                                                                              |
| FORMATTED | external formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| FREQ      | descending frequency count; levels with the most observations come first in the order                                                  |
| INTERNAL  | unformatted value                                                                                                                      |

By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**REFERENCE=**'category' | keyword

**REF=**'category' | keyword

specifies the reference category for the generalized logit model and the binary response model. For the generalized logit model, each logit contrasts a nonreference category with the reference category. For the binary response model, specifying one response category as the reference is the same as specifying the other response category as the event category. You can specify the value (formatted if a format is applied) of the reference category in quotes, or you can specify one of the following keywords:

**FIRST** designates the first ordered category as the reference.

**LAST** designates the last ordered category as the reference. This is the default.

## Model Options

Table 54.8 summarizes the options available in the MODEL statement. These options can be specified after a slash (/).

**Table 54.8** Model Statement Options

| Option                                     | Description                                                                                                                                        |
|--------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model Specification Options</b>         |                                                                                                                                                    |
| <b>LINK=</b>                               | Specifies the link function                                                                                                                        |
| <b>NOFIT</b>                               | Suppresses model fitting                                                                                                                           |
| <b>NOINT</b>                               | Suppresses the intercept                                                                                                                           |
| <b>OFFSET=</b>                             | Specifies the offset variable                                                                                                                      |
| <b>SELECTION=</b>                          | Specifies the effect selection method                                                                                                              |
| <b>UNEQUALSLOPES</b>                       | Specifies cumulative partial proportional odds models                                                                                              |
| <b>Effect Selection Options</b>            |                                                                                                                                                    |
| <b>BEST=</b>                               | Controls the number of models displayed for <b>SCORE</b> selection                                                                                 |
| <b>DETAILS</b>                             | Requests detailed results at each step                                                                                                             |
| <b>FAST</b>                                | Uses the fast elimination method                                                                                                                   |
| <b>HIERARCHY=</b>                          | Specifies whether and how hierarchy is maintained and whether a single effect or multiple effects are allowed to enter or leave the model per step |
| <b>INCLUDE=</b>                            | Specifies the number of effects included in every model                                                                                            |
| <b>MAXSTEP=</b>                            | Specifies the maximum number of steps for <b>STEPWISE</b> selection                                                                                |
| <b>SEQUENTIAL</b>                          | Adds or deletes effects in sequential order                                                                                                        |
| <b>SLENTRY=</b>                            | Specifies the significance level for entering effects                                                                                              |
| <b>SLSTAY=</b>                             | Specifies the significance level for removing effects                                                                                              |
| <b>START=</b>                              | Specifies the number of variables in the first model                                                                                               |
| <b>STOP=</b>                               | Specifies the number of variables in the final model                                                                                               |
| <b>STOPRES</b>                             | Adds or deletes variables by the residual chi-square criterion                                                                                     |
| <b>Model-Fitting Specification Options</b> |                                                                                                                                                    |
| <b>ABSFCNV=</b>                            | Specifies the absolute function convergence criterion                                                                                              |
| <b>FCONV=</b>                              | Specifies the relative function convergence criterion                                                                                              |

Table 54.8 *continued*

| Option                                                 | Description                                                                                                                |
|--------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| FIRTH                                                  | Specifies Firth's penalized likelihood method                                                                              |
| GCONV=                                                 | Specifies the relative gradient convergence criterion                                                                      |
| MAXFUNCTION=                                           | Specifies the maximum number of function calls for the conditional analysis                                                |
| MAXITER=                                               | Specifies the maximum number of iterations                                                                                 |
| NOCHECK                                                | Suppresses checking for infinite parameters                                                                                |
| RIDGING=                                               | Specifies the technique used to improve the log-likelihood function when its value is worse than that of the previous step |
| SINGULAR=                                              | Specifies the tolerance for testing singularity                                                                            |
| TECHNIQUE=                                             | Specifies the iterative algorithm for maximization                                                                         |
| XCONV=                                                 | Specifies the relative parameter convergence criterion                                                                     |
| <b>Confidence Interval Options</b>                     |                                                                                                                            |
| ALPHA=                                                 | Specifies $\alpha$ for the $100(1 - \alpha)\%$ confidence intervals                                                        |
| CLODDS=                                                | Computes confidence intervals for odds ratios                                                                              |
| CLPARAM=                                               | Computes confidence intervals for parameters                                                                               |
| PLCONV=                                                | Specifies the profile-likelihood convergence criterion                                                                     |
| <b>Classification Options</b>                          |                                                                                                                            |
| CTABLE                                                 | Displays the classification table                                                                                          |
| PEVENT=                                                | Specifies prior event probabilities                                                                                        |
| PPROB=                                                 | Specifies probability cutpoints for classification                                                                         |
| <b>Overdispersion and Goodness-of-Fit Test Options</b> |                                                                                                                            |
| AGGREGATE=                                             | Determines subpopulations for Pearson chi-square and deviance                                                              |
| LACKFIT                                                | Requests the Hosmer and Lemeshow goodness-of-fit test                                                                      |
| SCALE=                                                 | Specifies the method to correct overdispersion                                                                             |
| <b>ROC Curve Options</b>                               |                                                                                                                            |
| OUTROC=                                                | Names the output ROC data set                                                                                              |
| ROCEPS=                                                | Specifies the probability grouping criterion                                                                               |
| <b>Regression Diagnostics Options</b>                  |                                                                                                                            |
| INFLUENCE                                              | Displays influence statistics                                                                                              |
| ILOTS                                                  | Requests index plots                                                                                                       |
| <b>Display Options</b>                                 |                                                                                                                            |
| CORRB                                                  | Displays the correlation matrix                                                                                            |
| COVB                                                   | Displays the covariance matrix                                                                                             |
| EXPB                                                   | Displays exponentiated values of the estimates                                                                             |
| ITPRINT                                                | Displays the iteration history                                                                                             |
| NODUMMYPRINT                                           | Suppresses the "Class Level Information" table                                                                             |
| PARMLABEL                                              | Displays parameter labels                                                                                                  |
| PCORR                                                  | Displays the partial correlation statistic                                                                                 |
| RSQUARE                                                | Displays the generalized R Square                                                                                          |
| STB                                                    | Displays standardized estimates                                                                                            |

Table 54.8 continued

| Option                       | Description                                                  |
|------------------------------|--------------------------------------------------------------|
| <b>Computational Options</b> |                                                              |
| <b>BINWIDTH=</b>             | Specifies the bin size for estimating association statistics |
| <b>NOLOGSCALE</b>            | Performs calculations by using normal scaling                |

The following list describes these options.

**ABSFCNV=*value***

specifies the absolute function convergence criterion. Convergence requires a small change in the log-likelihood function in subsequent iterations,

$$|l_i - l_{i-1}| < \textit{value}$$

where  $l_i$  is the value of the log-likelihood function at iteration  $i$ . See the section “[Convergence Criteria](#)” on page 4242 for more information.

**AGGREGATE<=(*variable-list*)>**

specifies the subpopulations on which the Pearson chi-square test statistic and the likelihood ratio chi-square test statistic (deviance) are calculated. Observations with common values in the given list of variables are regarded as coming from the same subpopulation. Variables in the list can be any variables in the input data set. Specifying the AGGREGATE option is equivalent to specifying the AGGREGATE= option with a variable list that includes all explanatory variables in the MODEL statement. The deviance and Pearson goodness-of-fit statistics are calculated only when the SCALE= option is specified. Thus, the AGGREGATE (or AGGREGATE=) option has no effect if the SCALE= option is not specified.

See the section “[Rescaling the Covariance Matrix](#)” on page 4257 for more information.

**ALPHA=*number***

sets the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals for regression parameters or odds ratios. The value of *number* must be between 0 and 1. By default, *number* is equal to the value of the ALPHA= option in the PROC LOGISTIC statement, or 0.05 if the option is not specified. This option has no effect unless confidence limits for the parameters (CLPARM= option) or odds ratios (CLODDS= option or ODDSRATIO statement) are requested.

**BEST=*n***

specifies that  $n$  models with the highest score chi-square statistics are to be displayed for each model size. It is used exclusively with the SCORE model selection method. If the BEST= option is omitted and there are no more than 10 explanatory variables, then all possible models are listed for each model size. If the option is omitted and there are more than 10 explanatory variables, then the number of models selected for each model size is, at most, equal to the number of explanatory variables listed in the MODEL statement.

**BINWIDTH=*width***

specifies the size of the bins used for estimating the association statistics. See the section “[Rank Correlation of Observed Responses and Predicted Probabilities](#)” on page 4253 for details. Valid values are  $0 \leq \textit{width} < 1$  (for polytomous response models,  $0 < \textit{width} < 1$ ). The default *width* is 0.002. If the *width* does not evenly divide the unit interval, it is reduced to a valid value and a message

is displayed in the SAS log. The width is also constrained by the amount of memory available on your machine; if you specify a *width* that is too small, it is adjusted to a value for which memory can be allocated and a note is displayed in the SAS log.

If you have a binary response and specify **BINWIDTH=0**, then no binning is performed and the exact values of the statistics are computed; this method is a bit slower and might require more memory than the binning approach.

The **BINWIDTH=** option is ignored and no binning is performed when a **ROC** statement is specified, when ROC graphics are produced, or when the **SCORE** statement computes an ROC area.

#### **CLODDS=PL | WALD | BOTH**

produces confidence intervals for odds ratios of main effects not involved in interactions or nestings. Computation of these confidence intervals is based on the profile likelihood (**CLODDS=PL**) or based on individual Wald tests (**CLODDS=WALD**). By specifying **CLODDS=BOTH**, the procedure computes two sets of confidence intervals for the odds ratios, one based on the profile likelihood and the other based on the Wald tests. The confidence coefficient can be specified with the **ALPHA=** option. The **CLODDS=PL** option is not available with the **STRATA** statement. Classification main effects that use parameterizations other than **REF**, **EFFECT**, or **GLM** are ignored. If you need to compute odds ratios for an effect involved in interactions or nestings, or using some other parameterization, then you should specify an **ODDSRATIO** statement for that effect.

#### **CLPARM=PL | WALD | BOTH**

requests confidence intervals for the parameters. Computation of these confidence intervals is based on the profile likelihood (**CLPARM=PL**) or individual Wald tests (**CLPARM=WALD**). If you specify **CLPARM=BOTH**, the procedure computes two sets of confidence intervals for the parameters, one based on the profile likelihood and the other based on individual Wald tests. The confidence coefficient can be specified with the **ALPHA=** option. The **CLPARM=PL** option is not available with the **STRATA** statement.

See the section “[Confidence Intervals for Parameters](#)” on page 4248 for more information.

#### **CORRB**

displays the correlation matrix of the parameter estimates.

#### **COVB**

displays the covariance matrix of the parameter estimates.

#### **CTABLE**

classifies the input binary response observations according to whether the predicted event probabilities are above or below some cutpoint value  $z$  in the range (0, 1). An observation is predicted as an event if the predicted event probability exceeds or equals  $z$ . You can supply a list of cutpoints other than the default list by specifying the **PPROB=** option (page 4217). Also, false positive and negative rates can be computed as posterior probabilities by using Bayes’ theorem. You can use the **PEVENT=** option to specify prior probabilities for computing these rates. The **CTABLE** option is ignored if the data have more than two response levels. The **CTABLE** option is not available with the **STRATA** statement.

For more information, see the section “[Classification Table](#)” on page 4255.

**DETAILS**

produces a summary of computational details for each step of the effect selection process. It produces the “Analysis of Effects Eligible for Entry” table before displaying the effect selected for entry for forward or stepwise selection. For each model fitted, it produces the “Type 3 Analysis of Effects” table if the fitted model involves CLASS variables, the “Analysis of Maximum Likelihood Estimates” table, and measures of association between predicted probabilities and observed responses. For the statistics included in these tables, see the section “[Displayed Output](#)” on page 4286. The DETAILS option has no effect when SELECTION=NONE.

**EXPB****EXPEST**

displays the exponentiated values ( $e^{\hat{\beta}_i}$ ) of the parameter estimates  $\hat{\beta}_i$  in the “Analysis of Maximum Likelihood Estimates” table for the logit model. These exponentiated values are the estimated odds ratios for parameters corresponding to the continuous explanatory variables, and for CLASS effects that use reference or GLM parameterizations.

**FAST**

uses a computational algorithm of Lawless and Singhal (1978) to compute a first-order approximation to the remaining slope estimates for each subsequent elimination of a variable from the model. Variables are removed from the model based on these approximate estimates. The FAST option is extremely efficient because the model is not refitted for every variable removed. The FAST option is used when SELECTION=BACKWARD and in the backward elimination steps when SELECTION=STEPWISE. The FAST option is ignored when SELECTION=FORWARD or SELECTION=NONE.

**FCONV=value**

specifies the relative function convergence criterion. Convergence requires a small relative change in the log-likelihood function in subsequent iterations,

$$\frac{|l_i - l_{i-1}|}{|l_{i-1}| + 1\text{E-}6} < \text{value}$$

where  $l_i$  is the value of the log likelihood at iteration  $i$ . See the section “[Convergence Criteria](#)” on page 4242 for more information.

**FIRTH**

performs Firth’s penalized maximum likelihood estimation to reduce bias in the parameter estimates (Heinze and Schemper 2002; Firth 1993). This method is useful in cases of separability, as often occurs when the event is rare, and is an alternative to performing an exact logistic regression. See the section “[Firth’s Bias-Reducing Penalized Likelihood](#)” on page 4242 for more information.

**NOTE:** The intercept-only log likelihood is modified by using the full-model Hessian, computed with the slope parameters equal to zero. Therefore, in order to use the likelihood ratio test to compare models, you should use the log likelihoods from the “Model Fit Statistics” tables instead of the Likelihood Ratio statistic that is reported in the “Testing Global Null Hypothesis: BETA=0” table. When fitting a model and scoring a data set in the same PROC LOGISTIC step, the model is fit using Firth’s penalty for parameter estimation purposes, but the penalty is not applied to the scored log likelihood.

**GCONV=value**

specifies the relative gradient convergence criterion. Convergence requires that the normalized prediction function reduction is small,

$$\frac{\mathbf{g}'_i \mathbf{I}_i^{-1} \mathbf{g}_i}{|l_i| + 1\text{E-}6} < \text{value}$$

where  $l_i$  is the value of the log-likelihood function,  $\mathbf{g}_i$  is the gradient vector, and  $\mathbf{I}_i$  is the negative (expected) Hessian matrix, all at iteration  $i$ . This is the default convergence criterion, and the default value is 1E-8. See the section “[Convergence Criteria](#)” on page 4242 for more information.

**HIERARCHY=keyword****HIER=keyword**

specifies whether and how the model hierarchy requirement is applied and whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only CLASS effects, or both CLASS and interval effects, be subject to the hierarchy requirement. The HIERARCHY= option is ignored unless you also specify one of the following options: [SELECTION=FORWARD](#), [SELECTION=BACKWARD](#), or [SELECTION=STEPWISE](#).

Model hierarchy refers to the requirement that, for any term to be in the model, all effects contained in the term must be present in the model. For example, in order for the interaction A\*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor B can leave the model while the interaction A\*B is in the model.

The keywords you can specify in the HIERARCHY= option are as follows:

**NONE** indicates that the model hierarchy is not maintained. Any single effect can enter or leave the model at any given step of the selection process.

**SINGLE** indicates that only one effect can enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that you specify the main effects A and B and the interaction A\*B in the model. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already been entered. Also, before A or B can be removed from the model, the A\*B interaction must first be removed. All effects (CLASS and interval) are subject to the hierarchy requirement.

**SINGLECLASS** is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

**MULTIPLE** indicates that more than one effect can enter or leave the model at one time, subject to the model hierarchy requirement. In a forward selection step, a single main effect can enter the model, or an interaction can enter the model together with all the effects that are contained in the interaction. In a backward elimination step, an interaction itself, or the interaction together with all the effects that the interaction contains, can be removed. All effects (CLASS and continuous) are subject to the hierarchy requirement.

**MULTIPLECLASS** is the same as HIERARCHY=MULTIPLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=SINGLE, which means that model hierarchy is to be maintained for all effects (that is, both CLASS and continuous effects) and that only a single effect can enter or leave the model at each step.

**INCLUDE=*n***

includes the first *n* effects in the MODEL statement in every model. By default, INCLUDE=0. The INCLUDE= option has no effect when SELECTION=NONE.

Note that the INCLUDE= and START= options perform different tasks: the INCLUDE= option includes the first *n* effects variables in every model, whereas the START= option requires only that the first *n* effects appear in the first model.

**INFLUENCE<(STDRES)>**

displays diagnostic measures for identifying influential observations in the case of a binary response model. For each observation, the INFLUENCE option displays the case number (which is the sequence number of the observation), the values of the explanatory variables included in the final model, and the regression diagnostic measures developed by Pregibon (1981). The STDRES option includes standardized and likelihood residuals in the display.

For a discussion of these diagnostic measures, see the section “Regression Diagnostics” on page 4263. When a STRATA statement is specified, the diagnostics are computed following Storer and Crowley (1985); see the section “Regression Diagnostic Details” on page 4272 for details.

**IPLOTS**

produces an index plot for the regression diagnostic statistics developed by Pregibon (1981). An index plot is a scatter plot with the regression diagnostic statistic represented on the Y axis and the case number on the X axis. See Example 54.6 for an illustration.

**ITPRINT**

displays the iteration history of the maximum-likelihood model fitting. The ITPRINT option also displays the last evaluation of the gradient vector and the final change in the  $-2$  Log Likelihood.

**LACKFIT<(n)>**

performs the Hosmer and Lemeshow goodness-of-fit test (Hosmer and Lemeshow 2000) for the case of a binary response model. The subjects are divided into approximately 10 groups of roughly the same size based on the percentiles of the estimated probabilities. The discrepancies between the observed and expected number of observations in these groups are summarized by the Pearson chi-square statistic, which is then compared to a chi-square distribution with *t* degrees of freedom, where *t* is the number of groups minus *n*. By default, *n* = 2. A small *p*-value suggests that the fitted model is not an adequate model. The LACKFIT option is not available with the STRATA statement. See the section “The Hosmer-Lemeshow Goodness-of-Fit Test” on page 4259 for more information.

**LINK=keyword****L=keyword**

specifies the link function linking the response probabilities to the linear predictors. You can specify one of the following keywords. The default is LINK=LOGIT.

**CLOGLOG** is the complementary log-log function. PROC LOGISTIC fits the binary complementary log-log model when there are two response categories and fits the cumulative complementary log-log model when there are more than two response categories. The aliases are CCLOGLOG, CCLL, and CUMCLOGLOG.

- GLOGIT** is the generalized logit function. PROC LOGISTIC fits the generalized logit model where each nonreference category is contrasted with the reference category. You can use the response variable option **REF=** to specify the reference category.
- LOGIT** is the log odds function. PROC LOGISTIC fits the binary logit model when there are two response categories and fits the cumulative logit model when there are more than two response categories. The aliases are CLOGIT and CUMLOGIT.
- PROBIT** is the inverse standard normal distribution function. PROC LOGISTIC fits the binary probit model when there are two response categories and fits the cumulative probit model when there are more than two response categories. The aliases are NORMIT, CPROBIT, and CUMPROBIT.

The **LINK=** option is not available with the **STRATA** statement.

See the section “[Link Functions and the Corresponding Distributions](#)” on page 4238 for more details.

**MAXFUNCTION=number**

specifies the maximum number of function calls to perform when maximizing the conditional likelihood. This option is valid only when a **STRATA** statement or the **UNEQUALSLOPES** option is specified. The default values are as follows:

- 125 when the number of parameters  $p < 40$
- 500 when  $40 \leq p < 400$
- 1000 when  $p \geq 400$

Since the optimization is terminated only after completing a full iteration, the number of function calls that are actually performed can exceed *number*. If convergence is not attained, the displayed output and all output data sets created by the procedure contain results based on the last maximum likelihood iteration.

**MAXITER=number**

specifies the maximum number of iterations to perform. By default, **MAXITER=25**. If convergence is not attained in *number* iterations, the displayed output and all output data sets created by the procedure contain results that are based on the last maximum likelihood iteration.

**MAXSTEP=n**

specifies the maximum number of times any explanatory variable is added to or removed from the model when **SELECTION=STEPWISE**. The default number is twice the number of explanatory variables in the MODEL statement. When the **MAXSTEP=** limit is reached, the stepwise selection process is terminated. All statistics displayed by the procedure (and included in output data sets) are based on the last model fitted. The **MAXSTEP=** option has no effect when **SELECTION=NONE**, **FORWARD**, or **BACKWARD**.

**NOCHECK**

disables the checking process to determine whether maximum likelihood estimates of the regression parameters exist. If you are sure that the estimates are finite, this option can reduce the execution time if the estimation takes more than eight iterations. For more information, see the section “[Existence of Maximum Likelihood Estimates](#)” on page 4242.

**NODUMMYPRINT****NODESIGNPRINT****NODP**

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.

**NOINT**

suppresses the intercept for the binary response model, the first intercept for the ordinal response model (which forces all intercepts to be nonnegative), or all intercepts for the generalized logit model. This can be particularly useful in conditional logistic analysis; see [Example 54.11](#).

**NOFIT**

performs the global score test without fitting the model. The global score test evaluates the joint significance of the effects in the MODEL statement. No further analyses are performed. If the NOFIT option is specified along with other MODEL statement options, NOFIT takes effect and all other options except FIRTH, LINK=, NOINT, OFFSET=, ROC, and TECHNIQUE= are ignored. The NOFIT option is not available with the STRATA statement.

**NOLOGSCALE**

specifies that computations for the conditional and exact logistic regression models should be computed by using normal scaling. Log scaling can handle numerically larger problems than normal scaling; however, computations in the log scale are slower than computations in normal scale.

**OFFSET=*name***

names the offset variable. The regression coefficient for this variable will be fixed at 1. For an example that uses this option, see [Example 54.13](#). You can also use the OFFSET= option to restrict parameters to a fixed value. For example, if you want to restrict the parameter for variable X1 to 1 and the parameter for X2 to 2, compute Restrict=  $X1 + 2 * X2$  in a DATA step, specify the option `offset=Restrict`, and leave X1 and X2 out of the model.

**OUTROC=*SAS-data-set*****OUTR=*SAS-data-set***

creates, for binary response models, an output SAS data set that contains the data necessary to produce the receiver operating characteristic (ROC) curve. The OUTROC= option is not available with the STRATA statement. See the section “[OUTROC= Output Data Set](#)” on page 4283 for the list of variables in this data set.

**PARMLABEL**

displays the labels of the parameters in the “Analysis of Maximum Likelihood Estimates” table.

**PCORR**

computes the partial correlation statistic  $sign(\beta_i) \sqrt{\frac{\chi_i^2 - 2}{-2 \log L_0}}$  for each parameter  $i$ , where  $\chi_i^2$  is the Wald chi-square statistic for the parameter and  $\log L_0$  is the log-likelihood of the intercept-only model (Hilbe 2009, p. 101). If  $\chi_i^2 < 2$  then the partial correlation is set to 0. The partial correlation for the intercept terms is set to missing.

**PEVENT=*value***

**PEVENT=(*list*)**

specifies one prior probability or a list of prior probabilities for the event of interest. The false positive and false negative rates are then computed as posterior probabilities by Bayes' theorem. The prior probability is also used in computing the rate of correct prediction. For each prior probability in the given list, a classification table of all observations is computed. By default, the prior probability is the total sample proportion of events. The PEVENT= option is useful for stratified samples. It has no effect if the CTABLE option is not specified. For more information, see the section “False Positive, False Negative, and Correct Classification Rates Using Bayes' Theorem” on page 4256. Also see the PPROB= option for information about how the *list* is specified.

**PLCL**

is the same as specifying **CLPARAM=PL**.

**PLCONV=*value***

controls the convergence criterion for confidence intervals based on the profile-likelihood function. The quantity *value* must be a positive number, with a default value of 1E-4. The PLCONV= option has no effect if profile-likelihood confidence intervals (**CLPARAM=PL**) are not requested.

**PLRL**

is the same as specifying **CLODDS=PL**.

**PPROB=*value***

**PPROB=(*list*)**

specifies one critical probability value (or cutpoint) or a list of critical probability values for classifying observations with the **CTABLE** option. Each *value* must be between 0 and 1. A response that has a cross validated predicted probability greater than or equal to the current PPROB= value is classified as an event response. The PPROB= option is ignored if the **CTABLE** option is not specified.

A classification table for each of several cutpoints can be requested by specifying a list. For example, the following statement requests a classification of the observations for each of the cutpoints 0.3, 0.5, 0.6, 0.7, and 0.8:

```
pprob= (0.3, 0.5 to 0.8 by 0.1)
```

If the PPROB= option is not specified, the default is to display the classification for a range of probabilities from the smallest estimated probability (rounded down to the nearest 0.02) to the highest estimated probability (rounded up to the nearest 0.02) with 0.02 increments.

**RIDGING=ABSOLUTE | RELATIVE | NONE**

specifies the technique used to improve the log-likelihood function when its value in the current iteration is less than that in the previous iteration. If you specify the **RIDGING=ABSOLUTE** option, the diagonal elements of the negative (expected) Hessian are inflated by adding the ridge value. If you specify the **RIDGING=RELATIVE** option, the diagonal elements are inflated by a factor of 1 plus the ridge value. If you specify the **RIDGING=NONE** option, the crude line search method of taking half a step is used instead of ridging. By default, **RIDGING=RELATIVE**.

**RISKLIMITS****RL****WALDRL**

is the same as specifying `CLODDS=WALD`.

**ROCEPS=*number***

specifies a criterion for the ROC curve used for grouping estimated event probabilities that are close to each other. In each group, the difference between the largest and the smallest estimated event probabilities does not exceed the given value. The value for *number* must be between 0 and 1; the default value is the square root of the machine epsilon, which is about 1E-8 (in releases prior to 9.2, the default was 1E-4). The smallest estimated probability in each group serves as a cutpoint for predicting an event response. The `ROCEPS=` option has no effect unless the `OUTROC=` option, the `BINWIDTH=0` option, or a `ROC` statement is specified.

**RSQUARE****RSQ**

requests a generalized R Square measure for the fitted model. For more information, see the section “Generalized Coefficient of Determination” on page 4246.

**SCALE=*scale***

enables you to supply the value of the dispersion parameter or to specify the method for estimating the dispersion parameter. It also enables you to display the “Deviance and Pearson Goodness-of-Fit Statistics” table. To correct for overdispersion or underdispersion, the covariance matrix is multiplied by the estimate of the dispersion parameter. Valid values for *scale* are as follows:

**D | DEVIANCE** specifies that the dispersion parameter be estimated by the deviance divided by its degrees of freedom.

**P | PEARSON** specifies that the dispersion parameter be estimated by the Pearson chi-square statistic divided by its degrees of freedom.

**WILLIAMS** *<(constant)>* specifies that Williams’ method be used to model overdispersion. This option can be used only with the events/trials syntax. An optional *constant* can be specified as the scale parameter; otherwise, a scale parameter is estimated under the full model. A set of weights is created based on this scale parameter estimate. These weights can then be used in fitting subsequent models of fewer terms than the full model. When fitting these submodels, specify the computed scale parameter as *constant*. See [Example 54.10](#) for an illustration.

**N | NONE** specifies that no correction is needed for the dispersion parameter; that is, the dispersion parameter remains as 1. This specification is used for requesting the deviance and the Pearson chi-square statistic without adjusting for overdispersion.

*constant* sets the estimate of the dispersion parameter to be the square of the given *constant*. For example, `SCALE=2` sets the dispersion parameter to 4. The value *constant* must be a positive number.

You can use the `AGGREGATE` (or `AGGREGATE=`) option to define the subpopulations for calculating the Pearson chi-square statistic and the deviance. In the absence of the `AGGREGATE` (or `AGGREGATE=`) option, each observation is regarded as coming from a different subpopulation. For the events/trials syntax, each observation consists of *n* Bernoulli trials, where *n* is the value of the

*trials* variable. For single-trial syntax, each observation consists of a single response, and for this setting it is not appropriate to carry out the Pearson or deviance goodness-of-fit analysis. Thus, PROC LOGISTIC ignores specifications SCALE=P, SCALE=D, and SCALE=N when single-trial syntax is specified without the **AGGREGATE** (or **AGGREGATE=**) option.

The “Deviance and Pearson Goodness-of-Fit Statistics” table includes the Pearson chi-square statistic, the deviance, the degrees of freedom, the ratio of each statistic divided by its degrees of freedom, and the corresponding *p*-value. The SCALE= option is not available with the **STRATA** statement. For more information, see the section “**Overdispersion**” on page 4257.

**SELECTION=BACKWARD | B**

| **FORWARD | F**

| **NONE | N**

| **STEPWISE | S**

| **SCORE**

specifies the method used to select the variables in the model. **BACKWARD** requests backward elimination, **FORWARD** requests forward selection, **NONE** fits the complete model specified in the MODEL statement, and **STEPWISE** requests stepwise selection. **SCORE** requests best subset selection. By default, SELECTION=NONE.

For more information, see the section “**Effect-Selection Methods**” on page 4244.

**SEQUENTIAL**

**SEQ**

forces effects to be added to the model in the order specified in the MODEL statement or eliminated from the model in the reverse order of that specified in the MODEL statement. The model-building process continues until the next effect to be added has an insignificant adjusted chi-square statistic or until the next effect to be deleted has a significant Wald chi-square statistic. The SEQUENTIAL option has no effect when **SELECTION=NONE**.

**SINGULAR=value**

specifies the tolerance for testing the singularity of the Hessian matrix (Newton-Raphson algorithm) or the expected value of the Hessian matrix (Fisher scoring algorithm). The Hessian matrix is the matrix of second partial derivatives of the log-likelihood function. The test requires that a pivot for sweeping this matrix be at least this number times a norm of the matrix. Values of the SINGULAR= option must be numeric. By default, *value* is the machine epsilon times 1E7, which is approximately 1E-9.

**SLENTY=value**

**SLE=value**

specifies the significance level of the score chi-square for entering an effect into the model in the FORWARD or STEPWISE method. Values of the SLENTY= option should be between 0 and 1, inclusive. By default, SLENTY=0.05. The SLENTY= option has no effect when **SELECTION=NONE**, **SELECTION=BACKWARD**, or **SELECTION=SCORE**.

**SLSTAY=value****SLS=value**

specifies the significance level of the Wald chi-square for an effect to stay in the model in a backward elimination step. Values of the SLSTAY= option should be between 0 and 1, inclusive. By default, SLSTAY=0.05. The SLSTAY= option has no effect when **SELECTION=NONE**, **SELECTION=FORWARD**, or **SELECTION=SCORE**.

**START=n**

begins the FORWARD, BACKWARD, or STEPWISE effect selection process with the first  $n$  effects listed in the MODEL statement. The value of  $n$  ranges from 0 to  $s$ , where  $s$  is the total number of effects in the MODEL statement. The default value of  $n$  is  $s$  for the BACKWARD method and 0 for the FORWARD and STEPWISE methods. Note that START= $n$  specifies only that the first  $n$  effects appear in the first model, while **INCLUDE= $n$**  requires that the first  $n$  effects be included in every model. For the SCORE method, START= $n$  specifies that the smallest models contain  $n$  effects, where  $n$  ranges from 1 to  $s$ ; the default value is 1. The START= option has no effect when **SELECTION=NONE**.

**STB**

displays the standardized estimates for the parameters in the “Analysis of Maximum Likelihood Estimates” table. The standardized estimate of  $\beta_i$  is given by  $\hat{\beta}_i / (s/s_i)$ , where  $s_i$  is the total sample standard deviation for the  $i$ th explanatory variable and

$$s = \begin{cases} \pi/\sqrt{3} & \text{Logistic} \\ 1 & \text{Normal} \\ \pi/\sqrt{6} & \text{Extreme-value} \end{cases}$$

The sample standard deviations for parameters associated with **CLASS** and **EFFECT** variables are computed using their codings. For the intercept parameters, the standardized estimates are set to missing.

**STOP=n**

specifies the maximum (**SELECTION=FORWARD**) or minimum (**SELECTION=BACKWARD**) number of effects to be included in the final model. The effect selection process is stopped when  $n$  effects are found. The value of  $n$  ranges from 0 to  $s$ , where  $s$  is the total number of effects in the MODEL statement. The default value of  $n$  is  $s$  for the FORWARD method and 0 for the BACKWARD method. For the SCORE method, STOP= $n$  specifies that the largest models contain  $n$  effects, where  $n$  ranges from 1 to  $s$ ; the default value of  $n$  is  $s$ . The STOP= option has no effect when **SELECTION=NONE** or **STEPWISE**.

**STOPRES****SR**

specifies that the removal or entry of effects be based on the value of the residual chi-square. If **SELECTION=FORWARD**, then the STOPRES option adds the effects into the model one at a time until the residual chi-square becomes insignificant (until the  $p$ -value of the residual chi-square exceeds the **SLENTY= value**). If **SELECTION=BACKWARD**, then the STOPRES option removes effects from the model one at a time until the residual chi-square becomes significant (until the  $p$ -value of the residual chi-square becomes less than the **SLSTAY= value**). The STOPRES option has no effect when **SELECTION=NONE** or **SELECTION=STEPWISE**.

**TECHNIQUE=FISHER | NEWTON****TECH=FISHER | NEWTON**

specifies the optimization technique for estimating the regression parameters. NEWTON (or NR) is the Newton-Raphson algorithm and FISHER (or FS) is the Fisher scoring algorithm. Both techniques yield the same estimates, but the estimated covariance matrices are slightly different except for the case when the LOGIT link is specified for binary response data. The default is TECHNIQUE=FISHER. If the LINK=GLOGIT option is specified, then Newton-Raphson is the default and only available method. The TECHNIQUE= option is not applied to conditional and exact conditional analyses. This option is not available when the UNEQUALSLOPES option is specified. See the section “Iterative Algorithms for Model Fitting” on page 4240 for more details.

**UNEQUALSLOPES< =effect | (effect-list)>**

specifies one or more effects in a cumulative response model that have a different set of parameters for each response function. If you specify more than one effect, enclose the effects in parentheses. The effects must be explanatory effects that are specified in the MODEL statement.

If you do not specify this option, the cumulative response models make the parallel lines assumption,  $F(\Pr(Y < i)) = \alpha_i + \mathbf{x}'\boldsymbol{\beta}$ , where each response function has the same slope parameters  $\boldsymbol{\beta}$ . If you specify this option without an *effect* or *effect-list*, all slope parameters vary across the response functions, resulting in the model  $F(\Pr(Y < i)) = \alpha_i + \mathbf{x}'\boldsymbol{\beta}_i$ . Specifying an *effect* or *effect-list* enables you to choose which effects have different parameters across the response functions. If you select the first  $\mathbf{x}_1$  parameters to have equal slopes and the remaining  $\mathbf{x}_2$  parameters to have unequal slopes, the model can be written as  $F(\Pr(Y < i)) = \alpha_i + \mathbf{x}'_1\boldsymbol{\beta}_1 + \mathbf{x}'_2\boldsymbol{\beta}_{2i}$ . A model that uses the CLOGIT link is called a *partial proportional odds model* (Peterson and Harrell 1990).

For more information, see Example 54.17. The following statements are not available with this option: EFFECTPLOT, ESTIMATE, EXACT, LSMEANS, LSMESTIMATE, ROC, ROCCONTRAST, SLICE, STORE, and STRATA. The following options are not available with this option: FIRTH, RIDGING=, TECHNIQUE=, CTABLE, PEVENT=, PPROB=, OUTROC=, and ROCEPS=.

**WALDCL****CL**

is the same as specifying CLPARM=WALD.

**XCONV=value**

specifies the relative parameter convergence criterion. Convergence requires a small relative parameter change in subsequent iterations,

$$\max_j |\delta_j^{(i)}| < value$$

where

$$\delta_j^{(i)} = \begin{cases} \frac{\beta_j^{(i)} - \beta_j^{(i-1)}}{\beta_j^{(i-1)}} & |\beta_j^{(i-1)}| < 0.01 \\ \beta_j^{(i)} - \beta_j^{(i-1)} & \text{otherwise} \end{cases}$$

and  $\beta_j^{(i)}$  is the estimate of the  $j$ th parameter at iteration  $i$ . See the section “Convergence Criteria” on page 4242 for more information.

---

## NLOPTIONS Statement

**NLOPTIONS** < options > ;

The NLOPTIONS statement controls the optimization process for conditional analyses (which result from specifying a **STRATA** statement) and for partial parallel slope models (which result from specifying the **UNEQUALSLOPES** option in the **MODEL** statement). An *option* specified in the NLOPTIONS statement takes precedence over the same option specified in the **MODEL** statement.

The default optimization techniques are chosen according to the number of parameters,  $p$ , as follows:

- Newton-Raphson with ridging when  $p < 40$
- quasi-Newton when  $40 \leq p < 400$
- conjugate gradient when  $p \geq 400$

The available *options* are described in the section “NLOPTIONS Statement” on page 482 of Chapter 19, “Shared Concepts and Topics.”

---

## ODDSRATIO Statement

**ODDSRATIO** < 'label' > variable < / options > ;

The ODDSRATIO statement produces odds ratios for *variable* even when the variable is involved in interactions with other covariates, and for classification variables that use any parameterization. You can also specify variables on which **constructed effects** are based, in addition to the names of **COLLECTION** or **MULTIMEMBER** effects. You can specify several ODDSRATIO statements.

If *variable* is continuous, then the odds ratios honor any values specified in the **UNITS** statement. If *variable* is a classification variable, then odds ratios comparing each pairwise difference between the levels of *variable* are produced. If *variable* interacts with a continuous variable, then the odds ratios are produced at the mean of the interacting covariate by default. If *variable* interacts with a classification variable, then the odds ratios are produced at each level of the interacting covariate by default. The computed odds ratios are independent of the parameterization of any classification variable.

The odds ratios are uniquely labeled by concatenating the following terms to *variable*:

1. If this is a polytomous response model, then prefix the response variable and the level describing the logit followed by a colon; for example, “Y 0:”.
2. If *variable* is continuous and the **UNITS** statement provides a value that is not equal to 1, then append “Units=value”; otherwise, if *variable* is a classification variable, then append the levels being contrasted; for example, “cat vs dog”.
3. Append all interacting covariates preceded by “At”; for example, “At X=1.2 A=cat”.

If you are also creating odds ratio plots, then this label is displayed on the plots (see the **PLOTS** option for more information). If you specify a ‘label’ in the ODDSRATIO statement, then the odds ratios produced by this statement are also labeled: ‘label’, ‘label 2’, ‘label 3’, . . . , and these are the labels used in the plots. If

there are any duplicated labels across all ODDSRATIO statements, then the corresponding odds ratios are not displayed on the plots.

The following *options* are available:

**AT**(*covariate=value-list* | **REF** | **ALL**< ...*covariate=value-list* | **REF** | **ALL**>)

specifies fixed levels of the interacting covariates. If a specified *covariate* does not interact with the *variable*, then its AT list is ignored.

For continuous interacting covariates, you can specify one or more numbers in the *value-list*. For classification covariates, you can specify one or more formatted levels of the covariate enclosed in single quotes (for example, **A=' cat' ' dog'**), you can specify the keyword **REF** to select the reference-level, or you can specify the keyword **ALL** to select all levels of the classification variable. By default, continuous covariates are set to their means, while **CLASS** covariates are set to **ALL**. For a model that includes a classification variable  $A=\{\text{cat,dog}\}$  and a continuous covariate  $X$ , specifying **AT (A=' cat' x=7 9)** will set  $A$  to 'cat', and  $X$  to 7 and then 9.

**CL=WALD** | **PL** | **BOTH**

specifies whether to create Wald or profile-likelihood confidence limits, or both. By default, Wald confidence limits are produced.

**DIFF=REF** | **ALL**

specifies whether the odds ratios for a classification variable are computed against the reference level, or all pairs of variable are compared. By default, **DIFF=ALL**. The **DIFF=** option is ignored when variable is continuous.

**PLCONV=value**

controls the convergence criterion for confidence intervals based on the profile-likelihood function. The quantity *value* must be a positive number, with a default value of  $1E-4$ . The **PLCONV=** option has no effect if profile-likelihood confidence intervals (**CL=PL**) are not requested.

**PLMAXITER=n**

specifies the maximum number of iterations to perform. By default, **PLMAXITER=25**. If convergence is not attained in  $n$  iterations, the odds ratio or the confidence limits are set to missing. The **PLMAXITER=** option has no effect if profile-likelihood confidence intervals (**CL=PL**) are not requested.

**PLSINGULAR=value**

specifies the tolerance for testing the singularity of the Hessian matrix (Newton-Raphson algorithm) or the expected value of the Hessian matrix (Fisher scoring algorithm). The test requires that a pivot for sweeping this matrix be at least this number times a norm of the matrix. Values of the **PLSINGULAR=** option must be numeric. By default, *value* is the machine epsilon times  $1E7$ , which is approximately  $1E-9$ . The **PLSINGULAR=** option has no effect if profile-likelihood confidence intervals (**CL=PL**) are not requested.

---

## OUTPUT Statement

**OUTPUT** < **OUT=SAS-data-set** > < *options* > ;

The OUTPUT statement creates a new SAS data set that contains all the variables in the input data set and, optionally, the estimated linear predictors and their standard error estimates, the estimates of the cumulative or individual response probabilities, and the confidence limits for the cumulative probabilities. Regression diagnostic statistics and estimates of cross validated response probabilities are also available for binary response models. If you specify more than one OUTPUT statement, only the last one is used. Formulas for the statistics are given in the sections “[Linear Predictor, Predicted Probability, and Confidence Limits](#)” on page 4253 and “[Regression Diagnostics](#)” on page 4263, and, for conditional logistic regression, in the section “[Conditional Logistic Regression](#)” on page 4271.

If you use the single-trial syntax, the data set also contains a variable named `_LEVEL_`, which indicates the level of the response that the given row of output is referring to. For instance, the value of the cumulative probability variable is the probability that the response variable is as large as the corresponding value of `_LEVEL_`. For details, see the section “[OUT= Output Data Set in the OUTPUT Statement](#)” on page 4280.

The estimated linear predictor, its standard error estimate, all predicted probabilities, and the confidence limits for the cumulative probabilities are computed for all observations in which the explanatory variables have no missing values, even if the response is missing. By adding observations with missing response values to the input data set, you can compute these statistics for new observations or for settings of the explanatory variables not present in the data without affecting the model fit. Alternatively, the SCORE statement can be used to compute predicted probabilities and confidence intervals for new observations.

Table 54.9 summarizes the options available in the OUTPUT statement. These options can be specified after a slash (/). The statistic and diagnostic options specify the statistics to be included in the output data set and name the new variables that contain the statistics. If a STRATA statement is specified, only the PREDICTED=, DFBETAS=, and H= options are available; see the section “[Regression Diagnostic Details](#)” on page 4272 for details.

**Table 54.9** OUTPUT Statement Options

| Option                                        | Description                                                                     |
|-----------------------------------------------|---------------------------------------------------------------------------------|
| ALPHA=                                        | Specifies $\alpha$ for the $100(1 - \alpha)\%$ confidence intervals             |
| OUT=                                          | Names the output data set                                                       |
| <b>Statistic Options</b>                      |                                                                                 |
| LOWER=                                        | Names the lower confidence limit                                                |
| PREDICTED=                                    | Names the predicted probabilities                                               |
| PREDPROBS=                                    | Requests the individual, cumulative, or cross validated predicted probabilities |
| STDXBETA=                                     | Names the standard error estimate of the linear predictor                       |
| UPPER=                                        | Names the upper confidence limit                                                |
| XBETA=                                        | Names the linear predictor                                                      |
| <b>Diagnostic Options for Binary Response</b> |                                                                                 |
| C=                                            | Names the confidence interval displacement                                      |
| CBAR=                                         | Names the confidence interval displacement                                      |
| DFBETAS=                                      | Names the standardized deletion parameter differences                           |
| DIFCHISQ=                                     | Names the deletion chi-square goodness-of-fit change                            |
| DIFDEV=                                       | Names the deletion deviance change                                              |
| H=                                            | Names the leverage                                                              |
| RESCHI=                                       | Names the Pearson chi-square residual                                           |
| RESDEV=                                       | Names the deviance residual                                                     |

Table 54.9 *continued*

| Option     | Description                                        |
|------------|----------------------------------------------------|
| RESLIK=    | Names the likelihood residual                      |
| STDRESCHI= | Names the standardized Pearson chi-square residual |
| STDRESDEV= | Names the standardized deviance residual           |

The following list describes these options.

**ALPHA=number**

sets the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence limits for the appropriate response probabilities. The value of *number* must be between 0 and 1. By default, *number* is equal to the value of the ALPHA= option in the PROC LOGISTIC statement, or 0.05 if that option is not specified.

**C=name**

specifies the confidence interval displacement diagnostic that measures the influence of individual observations on the regression estimates.

**CBAR=name**

specifies the confidence interval displacement diagnostic that measures the overall change in the global regression estimates due to deleting an individual observation.

**DFBETAS= \_ALL\_****DFBETAS=var-list**

specifies the standardized differences in the regression estimates for assessing the effects of individual observations on the estimated regression parameters in the fitted model. You can specify a list of up to  $s + 1$  variable names, where  $s$  is the number of explanatory variables in the MODEL statement, or you can specify just the keyword `_ALL_`. In the former specification, the first variable contains the standardized differences in the intercept estimate, the second variable contains the standardized differences in the parameter estimate for the first explanatory variable in the MODEL statement, and so on. In the latter specification, the DFBETAS statistics are named DFBETA\_XXX, where XXX is the name of the regression parameter. For example, if the model contains two variables X1 and X2, the specification DFBETAS=\_ALL\_ produces three DFBETAS statistics: DFBETA\_Intercept, DFBETA\_X1, and DFBETA\_X2. If an explanatory variable is not included in the final model, the corresponding output variable named in DFBETAS=var-list contains missing values.

**DIFCHISQ=name**

specifies the change in the chi-square goodness-of-fit statistic attributable to deleting the individual observation.

**DIFDEV=name**

specifies the change in the deviance attributable to deleting the individual observation.

**H=name**

specifies the diagonal element of the hat matrix for detecting extreme points in the design space.

**LOWER=name****L=name**

names the variable containing the lower confidence limits for  $\pi$ , where  $\pi$  is the probability of the event response if events/trials syntax or single-trial syntax with binary response is specified; for a cumulative model,  $\pi$  is cumulative probability (that is, the probability that the response is less than

or equal to the value of `_LEVEL_`); for the generalized logit model, it is the individual probability (that is, the probability that the response category is represented by the value of `_LEVEL_`). See the [ALPHA=](#) option to set the confidence level.

**OUT=SAS-data-set**

names the output data set. If you omit the `OUT=` option, the output data set is created and given a default name by using the `DATAn` convention.

**PREDICTED=name****PRED=name****PROB=name****P=name**

names the variable containing the predicted probabilities. For the events/trials syntax or single-trial syntax with binary response, it is the predicted event probability. For a cumulative model, it is the predicted cumulative probability (that is, the probability that the response variable is less than or equal to the value of `_LEVEL_`); and for the generalized logit model, it is the predicted individual probability (that is, the probability of the response category represented by the value of `_LEVEL_`).

**PREDPROBS=(keywords)**

requests individual, cumulative, or cross validated predicted probabilities. Descriptions of the *keywords* are as follows.

**INDIVIDUAL | I** requests the predicted probability of each response level. For a response variable `Y` with three levels, 1, 2, and 3, the individual probabilities are  $\Pr(Y=1)$ ,  $\Pr(Y=2)$ , and  $\Pr(Y=3)$ .

**CUMULATIVE | C** requests the cumulative predicted probability of each response level. For a response variable `Y` with three levels, 1, 2, and 3, the cumulative probabilities are  $\Pr(Y \leq 1)$ ,  $\Pr(Y \leq 2)$ , and  $\Pr(Y \leq 3)$ . The cumulative probability for the last response level always has the constant value of 1. For generalized logit models, the cumulative predicted probabilities are not computed and are set to missing.

**CROSSVALIDATE | XVALIDATE | X** requests the cross validated individual predicted probability of each response level. These probabilities are derived from the leave-one-out principle—that is, dropping the data of one subject and reestimating the parameter estimates. PROC LOGISTIC uses a less expensive one-step approximation to compute the parameter estimates. This option is valid only for binary response models; for nominal and ordinal models, the cross validated probabilities are not computed and are set to missing.

See the section “[Details of the PREDPROBS= Option](#)” on page 4227 at the end of this section for further details.

**RESCHI=name**

specifies the Pearson (chi-square) residual for identifying observations that are poorly accounted for by the model.

**RESDEV=name**

specifies the deviance residual for identifying poorly fitted observations.

**RESLIK=*name***

specifies the likelihood residual for identifying poorly fitted observations.

**STDRESCHI=*name***

specifies the standardized Pearson (chi-square) residual for identifying observations that are poorly accounted for by the model.

**STDRESDEV=*name***

specifies the standardized deviance residual for identifying poorly fitted observations.

**STDXBETA=*name***

names the variable containing the standard error estimates of **XBETA**. See the section “[Linear Predictor, Predicted Probability, and Confidence Limits](#)” on page 4253 for details.

**UPPER=*name*****U=*name***

names the variable containing the upper confidence limits for  $\pi$ , where  $\pi$  is the probability of the event response if events/trials syntax or single-trial syntax with binary response is specified; for a cumulative model,  $\pi$  is cumulative probability (that is, the probability that the response is less than or equal to the value of `_LEVEL_`); for the generalized logit model, it is the individual probability (that is, the probability that the response category is represented by the value of `_LEVEL_`). See the [ALPHA=](#) option to set the confidence level.

**XBETA=*name***

names the variable containing the estimates of the linear predictor  $\alpha_i + \beta'x$ , where  $i$  is the corresponding ordered value of `_LEVEL_`.

## Details of the PREDPROBS= Option

You can request any of the three types of predicted probabilities. For example, you can request both the individual predicted probabilities and the cross validated probabilities by specifying `PREDPROBS=(I X)`.

When you specify the `PREDPROBS=` option, two automatic variables, `_FROM_` and `_INTO_`, are included for the single-trial syntax and only one variable, `_INTO_`, is included for the events/trials syntax. The variable `_FROM_` contains the formatted value of the observed response. The variable `_INTO_` contains the formatted value of the response level with the largest individual predicted probability.

If you specify `PREDPROBS=INDIVIDUAL`, the `OUT=` data set contains  $k$  additional variables representing the individual probabilities, one for each response level, where  $k$  is the maximum number of response levels across all `BY` groups. The names of these variables have the form `IP_xxx`, where `xxx` represents the particular level. The representation depends on the following situations:

- If you specify events/trials syntax, `xxx` is either ‘Event’ or ‘Nonevent’. Thus, the variable containing the event probabilities is named `IP_Event` and the variable containing the nonevent probabilities is named `IP_Nonevent`.
- If you specify the single-trial syntax with more than one `BY` group, `xxx` is 1 for the first ordered level of the response, 2 for the second ordered level of the response, and so forth, as given in the “Response Profile” table. The variable containing the predicted probabilities  $\Pr(Y=1)$  is named `IP_1`, where `Y` is the response variable. Similarly, `IP_2` is the name of the variable containing the predicted probabilities  $\Pr(Y=2)$ , and so on.

- If you specify the single-trial syntax with no BY-group processing, *xxx* is the left-justified formatted value of the response level (the value might be truncated so that *IP\_**xxx* does not exceed 32 characters). For example, if *Y* is the response variable with response levels ‘None’, ‘Mild’, and ‘Severe’, the variables representing individual probabilities  $\Pr(Y='None')$ ,  $\Pr(Y='Mild')$ , and  $\Pr(Y='Severe')$  are named *IP\_None*, *IP\_Mild*, and *IP\_Severe*, respectively.

If you specify `PREDPROBS=CUMULATIVE`, the `OUT=` data set contains *k* additional variables representing the cumulative probabilities, one for each response level, where *k* is the maximum number of response levels across all BY groups. The names of these variables have the form *CP\_**xxx*, where *xxx* represents the particular response level. The naming convention is similar to that given by `PREDPROBS=INDIVIDUAL`. The `PREDPROBS=CUMULATIVE` values are the same as those output by the `PREDICT=` option, but are arranged in variables on each output observation rather than in multiple output observations.

If you specify `PREDPROBS=CROSSVALIDATE`, the `OUT=` data set contains *k* additional variables representing the cross validated predicted probabilities of the *k* response levels, where *k* is the maximum number of response levels across all BY groups. The names of these variables have the form *XP\_**xxx*, where *xxx* represents the particular level. The representation is the same as that given by `PREDPROBS=INDIVIDUAL` except that for the events/trials syntax there are four variables for the cross validated predicted probabilities instead of two:

*XP\_EVENT\_R1E* is the cross validated predicted probability of an event when a single event is removed from the current observation.

*XP\_NONEVENT\_R1E* is the cross validated predicted probability of a nonevent when a single event is removed from the current observation.

*XP\_EVENT\_R1N* is the cross validated predicted probability of an event when a single nonevent is removed from the current observation.

*XP\_NONEVENT\_R1N* is the cross validated predicted probability of a nonevent when a single nonevent is removed from the current observation.

The cross validated predicted probabilities are precisely those used in the `CTABLE` option. See the section “[Predicted Probability of an Event for Classification](#)” on page 4255 for details of the computation.

---

## ROC Statement

```
ROC < 'label' > < specification > < / options > ;
```

The ROC statements specify models to be used in the ROC comparisons. You can specify more than one ROC statement. ROC statements are identified by their *label*—if you do not specify a *label*, the *i*th ROC statement is labeled “ROC*i*”. Additionally, the specified or selected model is labeled with the `MODEL` statement label or “Model” if the `MODEL` label is not present. The *specification* can be either a list of effects that have previously been specified in the `MODEL` statement, or `PRED=variable`, where the *variable* does not have to be specified in the `MODEL` statement. The `PRED=` option enables you to input a criterion produced outside PROC LOGISTIC; for example, you can fit a random-intercept model by using PROC GLIMMIX or use survey weights in PROC SURVEYLOGISTIC, then use the predicted values from those models to produce an ROC curve for the comparisons. If you do not make a *specification*, then an intercept-only model is fit to the data, resulting in a noninformative ROC curve that can be used for comparing the area under another ROC curve to 0.5.

You can specify a **ROCCONTRAST** statement and a **ROCOPTIONS** option in the PROC LOGISTIC statement to control how the models are compared, while the **PLOTS=ROC** option controls the ODS Graphics displays. See [Example 54.8](#) for an example that uses the ROC statement.

If you specify any *options*, then a “ROC Model Information” table summarizing the new ROC model is displayed. The *options* are ignored for the PRED= specification. The following *options* are available:

#### **NOOFFSET**

does not include an offset variable if the OFFSET= option is specified in the **MODEL** statement. A constant offset has no effect on the ROC curve, although the cutpoints might be different, but a nonconstant offset can affect the parameter estimates and hence the ROC curve.

#### **LINK=keyword**

specifies the link function to be used in the model. The available keywords are LOGIT, NORMIT, and CLOGLOG. The logit link is the default. Note that the **LINK=** option in the MODEL statement is ignored.

---

## **ROCCONTRAST Statement**

**ROCCONTRAST** < 'label' > < contrast > < / options > ;

The ROCCONTRAST statement compares the different ROC models. You can specify only one ROCCONTRAST statement. The **ROCOPTIONS** options in the PROC LOGISTIC statement control how the models are compared. You can specify one of the following *contrast* specifications:

#### **REFERENCE**< (MODEL | 'roc-label') >

produces a contrast matrix of differences between each ROC curve and a reference curve. The MODEL keyword specifies that the reference curve is that produced from the MODEL statement; the *roc-label* specifies the *label* of the ROC curve that is to be used as the reference curve. If neither the MODEL keyword nor the *roc-label* label is specified, then the reference ROC curve is either the curve produced from the MODEL statement, the selected model if a selection method is specified, or the model from the first ROC statement if the **NOFIT** option is specified.

#### **ADJACENTPAIRS**

produces a contrast matrix of each ROC curve minus the succeeding curve.

#### *matrix*

specifies the contrast in the form **row1, row2, . . .**, where each *row* contains the coefficients used to compare the ROC curves. Each *row* must contain the same number of entries as there are ROC curves being compared. The elements of each *row* refer to the ROC statements in the order in which they are specified. However, the first element of each *row* refers either to the fitted model, the selected model if a **SELECTION=** method is specified, or the first specified ROC statement if the **NOFIT** option is specified.

If no *contrast* is specified, then the REFERENCE contrast with the default reference curve is used. See the section “[Comparing ROC Curves](#)” on page 4261 for more information about comparing ROC curves, and see [Example 54.8](#) for an example.

The following *options* are available:

**E**

displays the contrast.

**ESTIMATE <= ROWS | ALLPAIRS >**

produces estimates of each row of the contrast when ESTIMATE or ESTIMATE=ROWS is specified. If the ESTIMATE=ALLPAIRS option is specified, then estimates of every pairwise difference of ROC curves are produced.

The row contrasts are labeled “ModelLabel1 – ModelLabel2”, where the model labels are as described in the ROC statement; in particular, for the REFERENCE contrast, ModelLabel2 is the reference model label. If you specify your own contrast matrix, then the *i*th contrast row estimate is labeled “Row*i*”.

**COV**

displays covariance matrices used in the computations.

---

## SCORE Statement

**SCORE** < options > ;

The SCORE statement creates a data set that contains all the data in the DATA= data set together with posterior probabilities and, optionally, prediction confidence intervals. Fit statistics are displayed on request. If you have binary response data, the SCORE statement can be used to create a data set containing data for the ROC curve. You can specify several SCORE statements. **FREQ**, **WEIGHT**, and **BY** statements can be used with the SCORE statements. The SCORE statement is not available with the STRATA statement.

If a SCORE statement is specified in the same run as fitting the model, FORMAT statements should be specified after the SCORE statement in order for the formats to apply to all the DATA= and PRIOR= data sets in the SCORE statement.

See the section “Scoring Data Sets” on page 4266 for more information, and see Example 54.15 for an illustration of how to use this statement.

Table 54.10 summarizes the options available in the SCORE statement.

**Table 54.10** SCORE Statement Options

| Option      | Description                                                                |
|-------------|----------------------------------------------------------------------------|
| ALPHA=      | Specifies the significance level                                           |
| CLM         | Outputs the Wald-test-based confidence limits                              |
| CUMULATIVE  | Outputs the cumulative predicted probabilities                             |
| DATA=       | Names the SAS data that you want to score                                  |
| FITSTAT     | Displays fit statistics                                                    |
| OUT=        | Names the SAS data set that contains the predicted information             |
| OUTROC=     | Names the SAS data set that contains the ROC curve                         |
| PRIOR=      | Names the SAS data set that contains the priors of the response categories |
| PRIOREVENT= | Specifies the prior event probability                                      |
| ROCEPS=     | Specifies the criterion for grouping estimated event probabilities         |

You can specify the following options:

**ALPHA=number**

specifies the significance level  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals. By default, the value of *number* is equal to the **ALPHA=** option in the PROC LOGISTIC statement, or 0.05 if that option is not specified. This option has no effect unless the **CLM** option in the SCORE statement is requested.

**CLM**

outputs the Wald-test-based confidence limits for the predicted probabilities. This option is not available when the **INMODEL=** data set is created with the **NOCOV** option.

**CUMULATIVE**

outputs the cumulative predicted probabilities  $\Pr(Y \leq i), i = 1, \dots, k + 1$ , to the **OUT=** data set. This option is valid only when you have more than two response levels; otherwise, the option is ignored and a note is printed in the SAS log. These probabilities are named *CP\_level\_i*, where *level\_i* is the *i*th response level.

If the **CLM** option is also specified in the SCORE statement, then the Wald-based confidence limits for the cumulative predicted probabilities are also output. The confidence limits are named *CLCL\_level\_i* and *CUCL\_level\_i*. In particular, for the lowest response level, the cumulative values (CP, CLCL, CUCL) should be identical to the individual values (P, LCL, UCL), and for the highest response level  $CP=CLCL=CUCL=1$ .

**DATA=SAS-data-set**

names the SAS data set that you want to score. If you omit the **DATA=** option in the SCORE statement, then scoring is performed on the **DATA=** input data set in the PROC LOGISTIC statement, if specified; otherwise, the **DATA=\_LAST\_** data set is used.

It is not necessary for the **DATA=** data set in the SCORE statement to contain the response variable unless you are specifying the **FITSTAT** or **OUTROC=** option.

Only those variables involved in the fitted model effects are required in the **DATA=** data set in the SCORE statement. For example, the following statements use forward selection to select effects:

```
proc logistic data=Neuralgia outmodel=sasuser.Model;
 class Treatment Sex;
 model Pain(event='Yes') = Treatment|Sex Age
 / selection=forward sle=.01;
run;
```

Suppose Treatment and Age are the effects selected for the final model. You can score a data set that does not contain the variable Sex since the effect Sex is not in the model that the scoring is based on. For example, the following statements score the Neuralgia data set after dropping the Sex variable:

```
proc logistic inmodel=sasuser.Model;
 score data=Neuralgia(drop=Sex);
run;
```

**FITSTAT**

displays fit statistics for the data set you are scoring. The data set must contain the response variable. See the section “[Fit Statistics for Scored Data Sets](#)” on page 4266 for details.

**OUT=SAS-data-set**

names the SAS data set that contains the predicted information. If you omit the OUT= option, the output data set is created and given a default name by using the DATA*n* convention.

**OUTROC=SAS-data-set**

names the SAS data set that contains the ROC curve for the DATA= data set. The ROC curve is computed only for binary response data. See the section “[OUTROC= Output Data Set](#)” on page 4283 for the list of variables in this data set.

**PRIOR=SAS-data-set**

names the SAS data set that contains the priors of the response categories. The priors can be values proportional to the prior probabilities; thus, they do not necessarily sum to one. This data set should include a variable named `_PRIOR_` that contains the prior probabilities. For events/trials MODEL statement syntax, this data set should also include an `_OUTCOME_` variable that contains the values EVENT and NONEVENT; for single-trial syntax, this data set should include the response variable that contains the unformatted response categories. See [Example 54.15](#) for an example.

**PRIOREVENT=value**

specifies the prior event probability for a binary response model. If both PRIOR= and PRIOREVENT= options are specified, the PRIOR= option takes precedence.

**ROCEPS=value**

specifies the criterion for grouping estimated event probabilities that are close to each other for the ROC curve. In each group, the difference between the largest and the smallest estimated event probability does not exceed the given value. The *value* must be between 0 and 1; the default value is the square root of the machine epsilon, which is about 1E–8 (in releases prior to 9.2, the default was 1E–4). The smallest estimated probability in each group serves as a cutpoint for predicting an event response. The ROCEPS= option has no effect if the OUTROC= option is not specified in the SCORE statement.

**SLICE Statement**

```
SLICE model-effect </ options > ;
```

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

**NOTE:** If you have classification variables in your model, then the SLICE statement is allowed only if you also specify the PARAM=GLM option.

---

## STORE Statement

**STORE** <OUT=>*item-store-name* </ LABEL='label'> ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

---

## STRATA Statement

**STRATA** *variable* <(option)> ... <*variable* <(option)>> </ options> ;

The STRATA statement names the *variables* that define *strata* or *matched sets* to use in *stratified logistic regression* of binary response data.

Observations that have the same *variable* values are in the same matched set. For a stratified logistic model, you can analyze 1: 1, 1:  $n$ ,  $m$ :  $n$ , and general  $m_i$ :  $n_i$  matched sets where the number of cases and controls varies across strata. At least one variable must be specified to invoke the stratified analysis, and the usual unconditional asymptotic analysis is not performed. The stratified logistic model has the form

$$\text{logit}(\pi_{hi}) = \alpha_h + \mathbf{x}'_{hi} \boldsymbol{\beta}$$

where  $\pi_{hi}$  is the event probability for the  $i$ th observation in stratum  $h$  with covariates  $\mathbf{x}_{hi}$  and where the stratum-specific intercepts  $\alpha_h$  are the nuisance parameters that are to be conditioned out.

STRATA variables can also be specified in the MODEL statement as classification or continuous covariates; however, the effects are nondegenerate only when crossed with a nonstratification variable. Specifying several STRATA statements is the same as specifying one STRATA statement that contains all the strata variables. The STRATA variables can be either character or numeric, and the formatted values of the STRATA variables determine the levels. Thus, you can also use formats to group values into levels; see the discussion of the FORMAT procedure in the *Base SAS Procedures Guide*.

The “Strata Summary” table is displayed by default. For an exact logistic regression, it displays the number of strata that have a specific number of events and non-events. For example, if you are analyzing a 1: 5 matched study, this table enables you to verify that every stratum in the analysis has exactly one event and five non-events. Strata that contain only events or only non-events are reported in this table, but such strata are uninformative and are not used in the analysis.

If an EXACT statement is also specified, then a stratified *exact* logistic regression is performed.

The EFFECTPLOT, SCORE, and WEIGHT statements are not available with a STRATA statement. The following MODEL options are also not supported with a STRATA statement: CLPARM=PL, CLODDS=PL, CTABLE, FIRTH, LACKFIT, LINK=, NOFIT, OUTMODEL=, OUTROC=, ROC, and SCALE=.

The following *option* can be specified for a stratification variable by enclosing the option in parentheses after the variable name, or it can be specified globally for all STRATA variables after a slash (/).

**MISSING**

treats missing values ('.', '\_', 'A', ..., 'Z' for numeric variables and blanks for character variables) as valid STRATA variable values.

The following strata *options* are also available after the slash:

**CHECKDEPENDENCY | CHECK=keyword**

specifies which variables are to be tested for dependency before the analysis is performed. The available *keywords* are as follows:

**NONE** performs no dependence checking. Typically, a message about a singular information matrix is displayed if you have dependent variables. Dependent variables can be identified after the analysis by noting any missing parameter estimates.

**COVARIATES** checks dependence between covariates and an added intercept. Dependent covariates are removed from the analysis. However, covariates that are linear functions of the strata variable might not be removed, which results in a singular information matrix message being displayed in the SAS log. This is the default.

**ALL** checks dependence between all the strata and covariates. This option can adversely affect performance if you have a large number of strata.

**NOSUMMARY**

suppresses the display of the “Strata Summary” table.

**INFO**

displays the “Strata Information” table, which includes the stratum number, levels of the STRATA variables that define the stratum, the number of events, the number of non-events, and the total frequency for each stratum. Since the number of strata can be very large, this table is displayed only by request.

**TEST Statement**

```
<label> TEST equation1 <, equation2, ... > </option>;
```

The TEST statement tests linear hypotheses about the regression coefficients. The Wald test is used to perform a joint test of the null hypotheses  $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$  specified in a single TEST statement, where  $\boldsymbol{\beta}$  is the vector of intercept and slope parameters. When  $\mathbf{c} = \mathbf{0}$  you should specify a CONTRAST statement instead.

Each *equation* specifies a linear hypothesis (a row of the **L** matrix and the corresponding element of the **c** vector). Multiple *equations* are separated by commas. The *label*, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an *equation* is as follows:

```
term< ± term ... > <= ± term < ± term ... >>
```

where *term* is a parameter of the model, or a constant, or a constant times a parameter. Intercept and CLASS variable parameter names should be specified as described in the section “Parameter Names in the OUTEST= Data Set” on page 4279. Note for generalized logit models that this enables you to construct tests of parameters from specific logits. When no equal sign appears, the expression is set to 0. The following statements illustrate possible uses of the TEST statement:

```

proc logistic;
 model y= a1 a2 a3 a4;
 test1: test intercept + .5 * a2 = 0;
 test2: test intercept + .5 * a2;
 test3: test a1=a2=a3;
 test4: test a1=a2, a2=a3;
run;

```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

You can specify the following option in the TEST statement after a slash(/):

### PRINT

displays intermediate calculations in the testing of the null hypothesis  $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$ . This includes  $\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}'$  bordered by  $(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})$  and  $[\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}']^{-1}$  bordered by  $[\mathbf{L}\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\widehat{\boldsymbol{\beta}} - \mathbf{c})$ , where  $\widehat{\boldsymbol{\beta}}$  is the maximum likelihood estimator of  $\boldsymbol{\beta}$  and  $\widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}})$  is the estimated covariance matrix of  $\widehat{\boldsymbol{\beta}}$ .

For more information, see the section “Testing Linear Hypotheses about the Regression Coefficients” on page 4262.

## UNITS Statement

**UNITS** < *independent1=list1* < *independent2=list2* . . . > < / *option* > ;

The UNITS statement enables you to specify units of change for the continuous explanatory variables so that customized odds ratios can be estimated. If you specify more than one UNITS statement, only the last one is used. An estimate of the corresponding odds ratio is produced for each unit of change specified for an explanatory variable. The UNITS statement is ignored for CLASS variables. Odds ratios are computed only for main effects that are not involved in interactions or nestings, unless an **ODDSRATIO** statement is also specified. If the **CLODDS=** option is specified in the MODEL statement, the corresponding confidence limits for the odds ratios are also displayed, as are odds ratios and confidence limits for any CLASS main effects that are not involved in interactions or nestings. The CLASS effects must use the GLM, reference, or effect coding.

The UNITS statement also enables you to customize the odds ratios for effects specified in **ODDSRATIO** statements, in which case interactions and nestings are allowed, and CLASS variables can be specified with any parameterization.

The term *independent* is the name of an explanatory variable and *list* represents a list of units of change, separated by spaces, that are of interest for that variable. Each unit of change in a list has one of the following forms:

- *number*
- SD or –SD
- *number* \* SD

where *number* is any nonzero number, and SD is the sample standard deviation of the corresponding independent variable. For example,  $X = -2$  requests an odds ratio that represents the change in the odds when

the variable  $X$  is decreased by two units.  $X = 2*SD$  requests an estimate of the change in the odds when  $X$  is increased by two sample standard deviations.

You can specify the following option in the UNITS statement after a slash(/):

**DEFAULT=*list***

gives a list of units of change for all explanatory variables that are not specified in the UNITS statement. Each unit of change can be in any of the forms described previously. If the DEFAULT= option is not specified, PROC LOGISTIC does not produce customized odds ratio estimates for any continuous explanatory variable that is not listed in the UNITS statement.

For more information, see the section “Odds Ratio Estimation” on page 4250.

## WEIGHT Statement

**WEIGHT** *variable* </ option > ;

When a WEIGHT statement appears, each observation in the input data set is weighted by the value of the WEIGHT variable. Unlike a FREQ variable, the values of the WEIGHT variable can be nonintegral and are not truncated. Observations with negative, zero, or missing values for the WEIGHT variable are not used in the model fitting. When the WEIGHT statement is not specified, each observation is assigned a weight of 1. The WEIGHT statement is not available with the STRATA statement. If you specify more than one WEIGHT statement, then the first WEIGHT variable is used.

If a SCORE statement is specified, then the WEIGHT variable is used for computing fit statistics and the ROC curve, but it is not required for scoring. If the DATA= data set in the SCORE statement does not contain the WEIGHT variable, the weights are assumed to be 1 and a warning message is issued in the SAS log. If you fit a model and perform the scoring in the same run, the same WEIGHT variable is used for fitting and scoring. If you fit a model in a previous run and input it with the INMODEL= option in the current run, then the WEIGHT variable can be different from the one used in the previous run; however, if a WEIGHT variable was not specified in the previous run, you can still specify a WEIGHT variable in the current run.

**CAUTION:** PROC LOGISTIC does not compute the proper variance estimators if you are analyzing survey data and specifying the sampling weights through the WEIGHT statement. The SURVEYLOGISTIC procedure is designed to perform the necessary, and correct, computations.

The following option can be added to the WEIGHT statement after a slash (/):

**NORMALIZE**

**NORM**

causes the weights specified by the WEIGHT variable to be normalized so that they add up to the actual sample size. Weights  $w_i$  are normalized by multiplying them by  $\frac{n}{\sum_{i=1}^n w_i}$ , where  $n$  is the sample size. With this option, the estimated covariance matrix of the parameter estimators is invariant to the scale of the WEIGHT variable.

---

## Details: LOGISTIC Procedure

---

### Missing Values

Any observation with missing values for the response, offset, strata, or explanatory variables is excluded from the analysis; however, missing values are valid for variables specified with the `MISSING` option in the `CLASS` or `STRATA` statement. Observations with a nonpositive or missing weight or with a frequency less than 1 are also excluded. The estimated linear predictor and its standard error estimate, the fitted probabilities and confidence limits, and the regression diagnostic statistics are not computed for any observation with missing offset or explanatory variable values. However, if only the response value is missing, the linear predictor, its standard error, the fitted individual and cumulative probabilities, and confidence limits for the cumulative probabilities can be computed and output to a data set by using the `OUTPUT` statement.

---

### Response Level Ordering

Response level ordering is important because, by default, PROC LOGISTIC models the probability of response levels with *lower Ordered Value*. Ordered Values are assigned to response levels in ascending sorted order (that is, the lowest response level is assigned Ordered Value 1, the next lowest is assigned Ordered Value 2, and so on) and are displayed in the “Response Profiles” table. If your response variable  $Y$  takes values in  $\{1, \dots, k + 1\}$ , then, by default, the functions modeled with the binary or cumulative model are

$$\text{logit}(\Pr(Y \leq i | \mathbf{x})), \quad i = 1, \dots, k$$

and for the generalized logit model the functions modeled are

$$\log \left( \frac{\Pr(Y = i | \mathbf{x})}{\Pr(Y = k + 1 | \mathbf{x})} \right), \quad i = 1, \dots, k$$

where the highest Ordered Value  $Y = k + 1$  is the reference level. You can change which probabilities are modeled by specifying the `EVENT=`, `REF=`, `DESCENDING`, or `ORDER=` response variable options in the `MODEL` statement.

For binary response data with event and nonevent categories, if your event category has a higher Ordered Value, then by default the nonevent is modeled. Since the default response function modeled is

$$\text{logit}(\pi) = \log \left( \frac{\pi}{1 - \pi} \right)$$

where  $\pi$  is the probability of the response level assigned Ordered Value 1, and since

$$\text{logit}(\pi) = -\text{logit}(1 - \pi)$$

the effect of modeling the nonevent is to change the signs of  $\alpha$  and  $\beta$  in the model for the event,  $\text{logit}(\pi) = \alpha + \beta' \mathbf{x}$ .

For example, suppose the binary response variable  $Y$  takes the values 1 and 0 for event and nonevent, respectively, and `Exposure` is the explanatory variable. By default, PROC LOGISTIC assigns Ordered

Value 1 to response level  $Y=0$ , and Ordered Value 2 to response level  $Y=1$ . As a result, PROC LOGISTIC models the probability of the nonevent (Ordered Value=1) category, and your parameter estimates have the opposite sign from those in the model for the event. To model the event without using a DATA step to change the values of the variable  $Y$ , you can control the ordering of the response levels or select the event or reference level, as shown in the following list:

- Explicitly state which response level is to be modeled by using the response variable option `EVENT=` in the `MODEL` statement:

```
model Y(event='1') = Exposure;
```

- Specify the nonevent category for the response variable in the response variable option `REF=` in the `MODEL` statement. This option is most useful for generalized logit models where the `EVENT=` option cannot be used.

```
model Y(ref='0') = Exposure;
```

- Specify the response variable option `DESCENDING` in the `MODEL` statement to assign the lowest Ordered Value to  $Y=1$ :

```
model Y(descending)=Exposure;
```

- Assign a format to  $Y$  such that the first formatted value (when the formatted values are put in sorted order) corresponds to the event. In the following example,  $Y=1$  is assigned the formatted value 'event' and  $Y=0$  is assigned the formatted value 'nonevent'. Since `ORDER=FORMATTED` by default, Ordered Value 1 is assigned to response level  $Y=1$ , so the procedure models the event.

```
proc format;
 value Disease 1='event' 0='nonevent';
run;
proc logistic;
 format Y Disease.;
 model Y=Exposure;
run;
```

---

## Link Functions and the Corresponding Distributions

Four link functions are available in the LOGISTIC procedure. The logit function is the default. To specify a different link function, use the `LINK=` option in the `MODEL` statement. The link functions and the corresponding distributions are as follows:

- The logit function

$$g(p) = \log(p/(1 - p))$$

is the inverse of the cumulative logistic distribution function, which is

$$F(x) = 1/(1 + \exp(-x)) = \exp(x)/(1 + \exp(x))$$

- The probit (or normit) function

$$g(p) = \Phi^{-1}(p)$$

is the inverse of the cumulative standard normal distribution function, which is

$$F(x) = \Phi(x) = (2\pi)^{-1/2} \int_{-\infty}^x \exp(-z^2/2) dz$$

Traditionally, the probit function contains the additive constant 5, but throughout PROC LOGISTIC, the terms probit and normit are used interchangeably.

- The complementary log-log function

$$g(p) = \log(-\log(1 - p))$$

is the inverse of the cumulative extreme-value function (also called the Gompertz distribution), which is

$$F(x) = 1 - \exp(-\exp(x))$$

- The generalized logit function extends the binary logit link to a vector of levels  $(p_1, \dots, p_{k+1})$  by contrasting each level with a fixed level

$$g(p_i) = \log(p_i/p_{k+1}) \quad i = 1, \dots, k$$

The variances of the normal, logistic, and extreme-value distributions are not the same. Their respective means and variances are shown in the following table:

| Distribution  | Mean      | Variance  |
|---------------|-----------|-----------|
| Normal        | 0         | 1         |
| Logistic      | 0         | $\pi^2/3$ |
| Extreme-value | $-\gamma$ | $\pi^2/6$ |

Here  $\gamma$  is the Euler constant. In comparing parameter estimates from different link functions, you need to take into account the different scalings of the corresponding distributions and, for the complementary log-log function, a possible shift in location. For example, if the fitted probabilities are in the neighborhood of 0.1 to 0.9, then the parameter estimates from the logit link function should be about  $\pi/\sqrt{3}$  larger than the estimates from the probit link function.

---

## Determining Observations for Likelihood Contributions

If you use events/trials MODEL statement syntax, split each observation into two observations. One has response value 1 with a frequency equal to the frequency of the original observation (which is 1 if the FREQ statement is not used) times the value of the *events* variable. The other observation has response value 2 and a frequency equal to the frequency of the original observation times the value of (*trials-events*). These two observations will have the same explanatory variable values and the same FREQ and WEIGHT values as the original observation.

For either single-trial or events/trials syntax, let  $j$  index all observations. In other words, for single-trial syntax,  $j$  indexes the actual observations. And, for events/trials syntax,  $j$  indexes the observations after splitting (as described in the preceding paragraph). If your data set has 30 observations and you use single-trial syntax,  $j$  has values from 1 to 30; if you use events/trials syntax,  $j$  has values from 1 to 60.

Suppose the response variable in a cumulative response model can take on the ordered values  $1, \dots, k, k+1$ , where  $k$  is an integer  $\geq 1$ . The likelihood for the  $j$ th observation with ordered response value  $y_j$  and explanatory variables vector  $\mathbf{x}_j$  is given by

$$L_j = \begin{cases} F(\alpha_1 + \boldsymbol{\beta}'\mathbf{x}_j) & y_j = 1 \\ F(\alpha_i + \boldsymbol{\beta}'\mathbf{x}_j) - F(\alpha_{i-1} + \boldsymbol{\beta}'\mathbf{x}_j) & 1 < y_j = i \leq k \\ 1 - F(\alpha_k + \boldsymbol{\beta}'\mathbf{x}_j) & y_j = k + 1 \end{cases}$$

where  $F(\cdot)$  is the logistic, normal, or extreme-value distribution function,  $\alpha_1, \dots, \alpha_k$  are ordered intercept parameters, and  $\boldsymbol{\beta}$  is the common slope parameter vector.

For the generalized logit model, letting the  $k+1$ st level be the reference level, the intercepts  $\alpha_1, \dots, \alpha_k$  are unordered and the slope vector  $\boldsymbol{\beta}_i$  varies with each logit. The likelihood for the  $j$ th observation with response value  $y_j$  and explanatory variables vector  $\mathbf{x}_j$  is given by

$$L_j = \Pr(Y = y_j | \mathbf{x}_j) = \begin{cases} \frac{e^{\alpha_i + \mathbf{x}'_j \boldsymbol{\beta}_i}}{1 + \sum_{m=1}^k e^{\alpha_m + \mathbf{x}'_j \boldsymbol{\beta}_m}} & 1 \leq y_j = i \leq k \\ \frac{1}{1 + \sum_{m=1}^k e^{\alpha_m + \mathbf{x}'_j \boldsymbol{\beta}_m}} & y_j = k + 1 \end{cases}$$

---

## Iterative Algorithms for Model Fitting

Two iterative maximum likelihood algorithms are available in PROC LOGISTIC for fitting an unconditional logistic regression, and these two methods are discussed in this section. For conditional logistic regression and models with the `UNEQUALSLOPES` specification, see the section “`NLOPTIONS` Statement” on page 4222 for details about available optimization techniques. Exact logistic regression uses a special algorithm described in the section “`Exact Conditional Logistic Regression`” on page 4274.

The default maximum likelihood algorithm is the Fisher scoring method, which is equivalent to fitting by iteratively reweighted least squares. The alternative algorithm is the Newton-Raphson method. Both algorithms give the same parameter estimates; however, the estimated covariance matrix of the parameter estimators can differ slightly. This is due to the fact that Fisher scoring is based on the expected information matrix while the Newton-Raphson method is based on the observed information matrix. In the case of a binary logit model, the observed and expected information matrices are identical, resulting in identical estimated covariance matrices for both algorithms. You can specify the `TECHNIQUE=` option to select a fitting algorithm, and specify the `FIRTH` option to perform a bias-reducing penalized maximum likelihood fit. Note for generalized logit models that only the Newton-Raphson technique is available.

### Iteratively Reweighted Least Squares Algorithm (Fisher Scoring)

Consider the multinomial variable  $\mathbf{Z}_j = (Z_{1j}, \dots, Z_{k+1,j})'$  such that

$$Z_{ij} = \begin{cases} 1 & \text{if } Y_j = i \\ 0 & \text{otherwise} \end{cases}$$

With  $\pi_{ij}$  denoting the probability that the  $j$ th observation has response value  $i$ , the expected value of  $\mathbf{Z}_j$  is  $\boldsymbol{\pi}_j = (\pi_{1j}, \dots, \pi_{k+1,j})'$  where  $\pi_{k+1,j} = 1 - \sum_{i=1}^k \pi_{ij}$ . The covariance matrix of  $\mathbf{Z}_j$  is  $\mathbf{V}_j$ , which is the covariance matrix of a multinomial random variable for one trial with parameter vector  $\boldsymbol{\pi}_j$ . Let  $\boldsymbol{\beta}$  be the vector of regression parameters; in other words,  $\boldsymbol{\beta} = (\alpha_1, \dots, \alpha_k, \beta_1, \dots, \beta_s)'$ . Let  $\mathbf{D}_j$  be the matrix of partial derivatives of  $\boldsymbol{\pi}_j$  with respect to  $\boldsymbol{\beta}$ . The estimating equation for the regression parameters is

$$\sum_j \mathbf{D}'_j \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j) = \mathbf{0}$$

where  $\mathbf{W}_j = w_j f_j \mathbf{V}_j^-$ ,  $w_j$  and  $f_j$  are the weight and frequency of the  $j$ th observation, and  $\mathbf{V}_j^-$  is a generalized inverse of  $\mathbf{V}_j$ . PROC LOGISTIC chooses  $\mathbf{V}_j^-$  as the inverse of the diagonal matrix with  $\boldsymbol{\pi}_j$  as the diagonal.

With a starting value of  $\boldsymbol{\beta}^{(0)}$ , the maximum likelihood estimate of  $\boldsymbol{\beta}$  is obtained iteratively as

$$\boldsymbol{\beta}^{(m+1)} = \boldsymbol{\beta}^{(m)} + \left( \sum_j \mathbf{D}'_j \mathbf{W}_j \mathbf{D}_j \right)^{-1} \sum_j \mathbf{D}'_j \mathbf{W}_j (\mathbf{Z}_j - \boldsymbol{\pi}_j)$$

where  $\mathbf{D}_j$ ,  $\mathbf{W}_j$ , and  $\boldsymbol{\pi}_j$  are evaluated at  $\boldsymbol{\beta}^{(m)}$ . The expression after the plus sign is the step size. If the likelihood evaluated at  $\boldsymbol{\beta}^{(m+1)}$  is less than that evaluated at  $\boldsymbol{\beta}^{(m)}$ , then  $\boldsymbol{\beta}^{(m+1)}$  is recomputed by step-halving or ridging as determined by the value of the RIDGING= option. The iterative scheme continues until convergence is obtained—that is, until  $\boldsymbol{\beta}^{(m+1)}$  is sufficiently close to  $\boldsymbol{\beta}^{(m)}$ . Then the maximum likelihood estimate of  $\boldsymbol{\beta}$  is  $\hat{\boldsymbol{\beta}} = \boldsymbol{\beta}^{(m+1)}$ .

The covariance matrix of  $\hat{\boldsymbol{\beta}}$  is estimated by

$$\widehat{\text{Cov}}(\hat{\boldsymbol{\beta}}) = \left( \sum_j \widehat{\mathbf{D}}'_j \widehat{\mathbf{W}}_j \widehat{\mathbf{D}}_j \right)^{-1} = \widehat{\mathbf{I}}^{-1}$$

where  $\widehat{\mathbf{D}}_j$  and  $\widehat{\mathbf{W}}_j$  are, respectively,  $\mathbf{D}_j$  and  $\mathbf{W}_j$  evaluated at  $\hat{\boldsymbol{\beta}}$ .  $\widehat{\mathbf{I}}$  is the information matrix, or the negative expected Hessian matrix, evaluated at  $\hat{\boldsymbol{\beta}}$ .

By default, starting values are zero for the slope parameters, and for the intercept parameters, starting values are the observed cumulative logits (that is, logits of the observed cumulative proportions of response). Alternatively, the starting values can be specified with the INEST= option.

## Newton-Raphson Algorithm

For cumulative models, let the parameter vector be  $\boldsymbol{\beta} = (\alpha_1, \dots, \alpha_k, \beta_1, \dots, \beta_s)'$ , and for the generalized logit model let  $\boldsymbol{\beta} = (\alpha_1, \dots, \alpha_k, \beta'_1, \dots, \beta'_k)'$ . The gradient vector and the Hessian matrix are given, respectively, by

$$\mathbf{g} = \sum_j w_j f_j \frac{\partial l_j}{\partial \boldsymbol{\beta}}$$

$$\mathbf{H} = \sum_j w_j f_j \frac{\partial^2 l_j}{\partial \boldsymbol{\beta}^2}$$

where  $l_j = \log L_j$  is the log likelihood for the  $j$ th observation. With a starting value of  $\boldsymbol{\beta}^{(0)}$ , the maximum likelihood estimate  $\hat{\boldsymbol{\beta}}$  of  $\boldsymbol{\beta}$  is obtained iteratively until convergence is obtained:

$$\boldsymbol{\beta}^{(m+1)} = \boldsymbol{\beta}^{(m)} - \mathbf{H}^{-1} \mathbf{g}$$

where  $\mathbf{H}$  and  $\mathbf{g}$  are evaluated at  $\boldsymbol{\beta}^{(m)}$ . If the likelihood evaluated at  $\boldsymbol{\beta}^{(m+1)}$  is less than that evaluated at  $\boldsymbol{\beta}^{(m)}$ , then  $\boldsymbol{\beta}^{(m+1)}$  is recomputed by step-halving or ridging.

The covariance matrix of  $\hat{\boldsymbol{\beta}}$  is estimated by

$$\widehat{\text{Cov}}(\hat{\boldsymbol{\beta}}) = \hat{\mathbf{I}}^{-1}$$

where the observed information matrix  $\hat{\mathbf{I}} = -\hat{\mathbf{H}}$  is computed by evaluating  $\mathbf{H}$  at  $\hat{\boldsymbol{\beta}}$ .

### Firth's Bias-Reducing Penalized Likelihood

Firth's method is currently available only for binary logistic models. It replaces the usual score (gradient) equation

$$g(\beta_j) = \sum_{i=1}^n (y_i - \pi_i) x_{ij} = 0 \quad (j = 1, \dots, p)$$

where  $p$  is the number of parameters in the model, with the modified score equation

$$g(\beta_j)^* = \sum_{i=1}^n \{y_i - \pi_i + h_i(0.5 - \pi_i)\} x_{ij} = 0 \quad (j = 1, \dots, p)$$

where the  $h_i$ s are the  $i$ th diagonal elements of the hat matrix  $\mathbf{W}^{1/2} \mathbf{X}(\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{X}'\mathbf{W}^{1/2}$  and  $\mathbf{W} = \text{diag}\{\pi_i(1 - \pi_i)\}$ . The Hessian matrix is not modified by this penalty, and the optimization method is performed in the usual manner.

## Convergence Criteria

Four convergence criteria are available: `ABSFCONV=`, `FCONV=`, `GCONV=`, and `XCONV=`. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is `GCONV=1E-8`.

If you specify a `STRATA` statement or the `UNEQUALSLOPES` option in the `MODEL` statement, all unspecified (or nondefault) criteria are also compared to zero. For example, specifying only the criterion `XCONV=1E-8` but attaining `FCONV=0` terminates the optimization even if the `XCONV=` criterion is not satisfied, because the log likelihood has reached its maximum. More convergence criteria are also available; see the section “`NLOPTIONS` Statement” on page 4222 for details.

## Existence of Maximum Likelihood Estimates

The likelihood equation for a logistic regression model does not always have a finite solution. Sometimes there is a nonunique maximum on the boundary of the parameter space, at infinity. The existence, finiteness, and uniqueness of maximum likelihood estimates for the logistic regression model depend on the patterns of data points in the observation space (Albert and Anderson 1984; Santner and Duffy 1986). Existence checks are not performed for conditional logistic regression.

Consider a binary response model. Let  $Y_j$  be the response of the  $j$ th subject, and let  $\mathbf{x}_j$  be the vector of explanatory variables (including the constant 1 associated with the intercept). There are three mutually exclusive and exhaustive types of data configurations: complete separation, quasi-complete separation, and overlap.

**Complete Separation** There is a complete separation of data points if there exists a vector  $\mathbf{b}$  that correctly allocates all observations to their response groups; that is,

$$\begin{cases} \mathbf{b}'\mathbf{x}_j > 0 & Y_j = 1 \\ \mathbf{b}'\mathbf{x}_j < 0 & Y_j = 2 \end{cases}$$

This configuration gives nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the log likelihood diminishes to zero, and the dispersion matrix becomes unbounded.

**Quasi-complete Separation** The data are not completely separable, but there is a vector  $\mathbf{b}$  such that

$$\begin{cases} \mathbf{b}'\mathbf{x}_j \geq 0 & Y_j = 1 \\ \mathbf{b}'\mathbf{x}_j \leq 0 & Y_j = 2 \end{cases}$$

and equality holds for at least one subject in each response group. This configuration also yields nonunique infinite estimates. If the iterative process of maximizing the likelihood function is allowed to continue, the dispersion matrix becomes unbounded and the log likelihood diminishes to a nonzero constant.

**Overlap** If neither complete nor quasi-complete separation exists in the sample points, there is an overlap of sample points. In this configuration, the maximum likelihood estimates exist and are unique.

Complete separation and quasi-complete separation are problems typically encountered with small data sets. Although complete separation can occur with any type of data, quasi-complete separation is not likely with truly continuous explanatory variables.

The LOGISTIC procedure uses a simple empirical approach to recognize the data configurations that lead to infinite parameter estimates. The basis of this approach is that any convergence method of maximizing the log likelihood must yield a solution giving complete separation, if such a solution exists. In maximizing the log likelihood, there is no checking for complete or quasi-complete separation if convergence is attained in eight or fewer iterations. Subsequent to the eighth iteration, the probability of the observed response is computed for each observation. If the predicted response equals the observed response for every observation, there is a complete separation of data points and the iteration process is stopped. If the complete separation of data has not been determined and an observation is identified to have an extremely large probability ( $\geq 0.95$ ) of predicting the observed response, there are two possible situations. First, there is overlap in the data set, and the observation is an atypical observation of its own group. The iterative process, if allowed to continue, will stop when a maximum is reached. Second, there is quasi-complete separation in the data set, and the asymptotic dispersion matrix is unbounded. If any of the diagonal elements of the dispersion matrix for the standardized observations vectors (all explanatory variables standardized to zero mean and unit variance) exceeds 5000, quasi-complete separation is declared and the iterative process is stopped. If either complete separation or quasi-complete separation is detected, a warning message is displayed in the procedure output.

Checking for quasi-complete separation is less foolproof than checking for complete separation. The **NOCHECK** option in the **MODEL** statement turns off the process of checking for infinite parameter estimates. In cases of complete or quasi-complete separation, turning off the checking process typically results

in the procedure failing to converge. The presence of a **WEIGHT** statement also turns off the checking process.

To address the separation issue, you can change your model, specify the **FIRTH** option to use Firth's penalized likelihood method, or for small data sets specify an **EXACT** statement to perform an exact logistic regression.

---

## Effect-Selection Methods

Five effect-selection methods are available by specifying the **SELECTION=** option in the **MODEL** statement. The simplest method (and the default) is **SELECTION=NONE**, for which PROC LOGISTIC fits the complete model as specified in the **MODEL** statement. The other four methods are **FORWARD** for forward selection, **BACKWARD** for backward elimination, **STEPWISE** for stepwise selection, and **SCORE** for best subsets selection. Intercept parameters are forced to stay in the model unless the **NOINT** option is specified.

When **SELECTION=FORWARD**, PROC LOGISTIC first estimates parameters for effects forced into the model. These effects are the intercepts and the first  $n$  explanatory effects in the **MODEL** statement, where  $n$  is the number specified by the **START=** or **INCLUDE=** option in the **MODEL** statement ( $n$  is zero by default). Next, the procedure computes the score chi-square statistic for each effect not in the model and examines the largest of these statistics. If it is significant at the **SLENTRY=** level, the corresponding effect is added to the model. Once an effect is entered in the model, it is never removed from the model. The process is repeated until none of the remaining effects meet the specified level for entry or until the **STOP=** value is reached.

When **SELECTION=BACKWARD**, parameters for the complete model as specified in the **MODEL** statement are estimated unless the **START=** option is specified. In that case, only the parameters for the intercepts and the first  $n$  explanatory effects in the **MODEL** statement are estimated, where  $n$  is the number specified by the **START=** option. Results of the Wald test for individual parameters are examined. The least significant effect that does not meet the **SLSTAY=** level for staying in the model is removed. Once an effect is removed from the model, it remains excluded. The process is repeated until no other effect in the model meets the specified level for removal or until the **STOP=** value is reached. Backward selection is often less successful than forward or stepwise selection because the full model fit in the first step is the model most likely to result in a complete or quasi-complete separation of response values as described in the section “Existence of Maximum Likelihood Estimates” on page 4242.

The **SELECTION=STEPWISE** option is similar to the **SELECTION=FORWARD** option except that effects already in the model do not necessarily remain. Effects are entered into and removed from the model in such a way that each forward selection step can be followed by one or more backward elimination steps. The stepwise selection process terminates if no further effect can be added to the model or if the current model is identical to a previously visited model.

For **SELECTION=SCORE**, PROC LOGISTIC uses the branch-and-bound algorithm of Furnival and Wilson (1974) to find a specified number of models with the highest likelihood score (chi-square) statistic for all possible model sizes, from 1, 2, 3 effect models, and so on, up to the single model containing all of the explanatory effects. The number of models displayed for each model size is controlled by the **BEST=** option. You can use the **START=** option to impose a minimum model size, and you can use the **STOP=** option to impose a maximum model size. For instance, with **BEST=3**, **START=2**, and **STOP=5**, the **SCORE** selection method displays the best three models (that is, the three models with the highest score chi-squares)

containing 2, 3, 4, and 5 effects. The **SELECTION=SCORE** option is not available for models with CLASS variables.

The options **FAST**, **SEQUENTIAL**, and **STOPRES** can alter the default criteria for entering or removing effects from the model when they are used with the **FORWARD**, **BACKWARD**, or **STEPWISE** selection method.

---

## Model Fitting Information

For the  $j$ th observation, let  $\hat{\pi}_j$  be the estimated probability of the observed response. The three criteria displayed by the LOGISTIC procedure are calculated as follows:

- $-2 \log$  likelihood:

$$-2 \text{ Log L} = -2 \sum_j \frac{w_j}{\sigma^2} f_j \log(\hat{\pi}_j)$$

where  $w_j$  and  $f_j$  are the weight and frequency values of the  $j$ th observation, and  $\sigma^2$  is the dispersion parameter, which equals 1 unless the **SCALE=** option is specified. For binary response models that use events/trials MODEL statement syntax, this is

$$-2 \text{ Log L} = -2 \sum_j \frac{w_j}{\sigma^2} f_j \left[ \log \binom{n_j}{r_j} + r_j \log(\hat{\pi}_j) + (n_j - r_j) \log(1 - \hat{\pi}_j) \right]$$

where  $r_j$  is the number of events,  $n_j$  is the number of trials,  $\hat{\pi}_j$  is the estimated event probability, and the statistic is reported both with and without the constant term.

- Akaike's information criterion:

$$\text{AIC} = -2 \text{ Log L} + 2p$$

where  $p$  is the number of parameters in the model. For cumulative response models,  $p = k + s$ , where  $k$  is the total number of response levels minus one and  $s$  is the number of explanatory effects. For the generalized logit model,  $p = k(s + 1)$ .

- Schwarz (Bayesian information) criterion:

$$\text{SC} = -2 \text{ Log L} + p \log \left( \sum_j f_j n_j \right)$$

where  $p$  is the number of parameters in the model,  $n_j$  is the number of trials when events/trials syntax is specified, and  $n_j = 1$  with single-trial syntax.

The AIC and SC statistics give two different ways of adjusting the  $-2 \text{ Log L}$  statistic for the number of terms in the model and the number of observations used. These statistics can be used when comparing different models for the same data (for example, when you use the **SELECTION=STEPWISE** option in the MODEL statement). The models being compared do not have to be nested; lower values of the statistics indicate a more desirable model.

The difference in the  $-2 \text{ Log L}$  statistics between the intercepts-only model and the specified model has a  $p - k$  degree-of-freedom chi-square distribution under the null hypothesis that all the explanatory effects in the model are zero, where  $p$  is the number of parameters in the specified model and  $k$  is the number of intercepts. The likelihood ratio test in the “Testing Global Null Hypothesis: BETA=0” table displays this difference and the associated  $p$ -value for this statistic. The score and Wald tests in that table test the same hypothesis and are asymptotically equivalent; see the sections “Residual Chi-Square” on page 4247 and “Testing Linear Hypotheses about the Regression Coefficients” on page 4262 for details.

---

## Generalized Coefficient of Determination

Cox and Snell (1989, pp. 208–209) propose the following generalization of the coefficient of determination to a more general linear model:

$$R^2 = 1 - \left\{ \frac{L(\mathbf{0})}{L(\hat{\boldsymbol{\beta}})} \right\}^{\frac{2}{n}}$$

where  $L(\mathbf{0})$  is the likelihood of the intercept-only model,  $L(\hat{\boldsymbol{\beta}})$  is the likelihood of the specified model,  $n = \sum_j f_j n_j$  is the sample size,  $f_j$  is the frequency of the  $j$ th observation, and  $n_j$  is the number of trials when events/trials syntax is specified or  $n_j = 1$  with single-trial syntax.

The quantity  $R^2$  achieves a maximum of less than one for discrete models, where the maximum is given by

$$R_{\max}^2 = 1 - \{L(\mathbf{0})\}^{\frac{2}{n}}$$

Nagelkerke (1991) proposes the following adjusted coefficient, which can achieve a maximum value of one:

$$\tilde{R}^2 = \frac{R^2}{R_{\max}^2}$$

Specifying the **NORMALIZE** option in the **WEIGHT** statement makes these coefficients invariant to the scale of the weights.

Like the AIC and SC statistics described in the section “Model Fitting Information” on page 4245,  $R^2$  and  $\tilde{R}^2$  are most useful for comparing competing models that are not necessarily nested—larger values indicate better models. More properties and interpretation of  $R^2$  and  $\tilde{R}^2$  are provided in Nagelkerke (1991). In the “Testing Global Null Hypothesis: BETA=0” table,  $R^2$  is labeled as “RSquare” and  $\tilde{R}^2$  is labeled as “Max-rescaled RSquare.” Use the **RSQUARE** option to request  $R^2$  and  $\tilde{R}^2$ .

---

## Score Statistics and Tests

To understand the general form of the score statistics, let  $\mathbf{g}(\boldsymbol{\beta})$  be the vector of first partial derivatives of the log likelihood with respect to the parameter vector  $\boldsymbol{\beta}$ , and let  $\mathbf{H}(\boldsymbol{\beta})$  be the matrix of second partial derivatives of the log likelihood with respect to  $\boldsymbol{\beta}$ . That is,  $\mathbf{g}(\boldsymbol{\beta})$  is the gradient vector, and  $\mathbf{H}(\boldsymbol{\beta})$  is the Hessian matrix. Let  $\mathbf{I}(\boldsymbol{\beta})$  be either  $-\mathbf{H}(\boldsymbol{\beta})$  or the expected value of  $-\mathbf{H}(\boldsymbol{\beta})$ . Consider a null hypothesis  $H_0$ . Let  $\hat{\boldsymbol{\beta}}_{H_0}$  be the MLE of  $\boldsymbol{\beta}$  under  $H_0$ . The chi-square score statistic for testing  $H_0$  is defined by

$$\mathbf{g}'(\hat{\boldsymbol{\beta}}_{H_0}) \mathbf{I}^{-1}(\hat{\boldsymbol{\beta}}_{H_0}) \mathbf{g}(\hat{\boldsymbol{\beta}}_{H_0})$$

and it has an asymptotic  $\chi^2$  distribution with  $r$  degrees of freedom under  $H_0$ , where  $r$  is the number of restrictions imposed on  $\boldsymbol{\beta}$  by  $H_0$ .

## Residual Chi-Square

When you use **SELECTION=FORWARD**, **BACKWARD**, or **STEPWISE**, the procedure calculates a residual chi-square score statistic and reports the statistic, its degrees of freedom, and the  $p$ -value. This section describes how the statistic is calculated.

Suppose there are  $s$  explanatory effects of interest. The full cumulative response model has a parameter vector

$$\boldsymbol{\beta} = (\alpha_1, \dots, \alpha_k, \beta_1, \dots, \beta_s)'$$

where  $\alpha_1, \dots, \alpha_k$  are intercept parameters, and  $\beta_1, \dots, \beta_s$  are the common slope parameters for the  $s$  explanatory effects. The full generalized logit model has a parameter vector

$$\begin{aligned} \boldsymbol{\beta} &= (\alpha_1, \dots, \alpha_k, \boldsymbol{\beta}'_1, \dots, \boldsymbol{\beta}'_k)' \quad \text{with} \\ \boldsymbol{\beta}'_i &= (\beta_{i1}, \dots, \beta_{is}), \quad i = 1, \dots, k \end{aligned}$$

where  $\beta_{ij}$  is the slope parameter for the  $j$ th effect in the  $i$ th logit.

Consider the null hypothesis  $H_0: \beta_{t+1} = \dots = \beta_s = 0$ , where  $t < s$  for the cumulative response model, and  $H_0: \beta_{i,t+1} = \dots = \beta_{is} = 0, t < s, i = 1, \dots, k$ , for the generalized logit model. For the reduced model with  $t$  explanatory effects, let  $\hat{\alpha}_1, \dots, \hat{\alpha}_k$  be the MLEs of the unknown intercept parameters, let  $\hat{\beta}_1, \dots, \hat{\beta}_t$  be the MLEs of the unknown slope parameters, and let  $\hat{\boldsymbol{\beta}}'_{i(t)} = (\hat{\beta}_{i1}, \dots, \hat{\beta}_{it}), i = 1, \dots, k$ , be those for the generalized logit model. The residual chi-square is the chi-square score statistic testing the null hypothesis  $H_0$ ; that is, the residual chi-square is

$$\mathbf{g}'(\hat{\boldsymbol{\beta}}_{H_0}) \mathbf{I}^{-1}(\hat{\boldsymbol{\beta}}_{H_0}) \mathbf{g}(\hat{\boldsymbol{\beta}}_{H_0})$$

where for the cumulative response model  $\hat{\boldsymbol{\beta}}_{H_0} = (\hat{\alpha}_1, \dots, \hat{\alpha}_k, \hat{\beta}_1, \dots, \hat{\beta}_t, 0, \dots, 0)'$ , and for the generalized logit model  $\hat{\boldsymbol{\beta}}_{H_0} = (\hat{\alpha}_1, \dots, \hat{\alpha}_k, \hat{\boldsymbol{\beta}}'_{1(t)}, \mathbf{0}'_{(s-t)}, \dots, \hat{\boldsymbol{\beta}}'_{k(t)}, \mathbf{0}'_{(s-t)})'$ , where  $\mathbf{0}_{(s-t)}$  denotes a vector of  $s - t$  zeros.

The residual chi-square has an asymptotic chi-square distribution with  $s - t$  degrees of freedom ( $k(s - t)$  for the generalized logit model). A special case is the global score chi-square, where the reduced model consists of the  $k$  intercepts and no explanatory effects. The global score statistic is displayed in the “Testing Global Null Hypothesis: BETA=0” table. The table is not produced when the **NOFIT** option is used, but the global score statistic is displayed.

## Testing Individual Effects Not in the Model

These tests are performed when you specify **SELECTION=FORWARD** or **STEPWISE**, and are displayed when the **DETAILS** option is specified. In the displayed output, the tests are labeled “Score Chi-Square” in the “Analysis of Effects Not in the Model” table and in the “Summary of Stepwise (Forward) Selection” table. This section describes how the tests are calculated.

Suppose that  $k$  intercepts and  $t$  explanatory variables (say  $v_1, \dots, v_t$ ) have been fit to a model and that  $v_{t+1}$  is another explanatory variable of interest. Consider a full model with the  $k$  intercepts and  $t + 1$  explanatory variables ( $v_1, \dots, v_t, v_{t+1}$ ) and a reduced model with  $v_{t+1}$  excluded. The significance of  $v_{t+1}$  adjusted for  $v_1, \dots, v_t$  can be determined by comparing the corresponding residual chi-square with a chi-square distribution with one degree of freedom ( $k$  degrees of freedom for the generalized logit model).

## Testing the Parallel Lines Assumption

For an ordinal response, PROC LOGISTIC performs a test of the parallel lines assumption. In the displayed output, this test is labeled “Score Test for the Equal Slopes Assumption” when the LINK= option is NORMIT or CLOGLOG. When LINK=LOGIT, the test is labeled as “Score Test for the Proportional Odds Assumption” in the output. For small sample sizes, this test might be too liberal (Stokes, Davis, and Koch 2000, p. 249). This section describes the methods used to calculate the test.

For this test the number of response levels,  $k + 1$ , is assumed to be strictly greater than 2. Let  $Y$  be the response variable taking values  $1, \dots, k, k + 1$ . Suppose there are  $s$  explanatory variables. Consider the general cumulative model without making the parallel lines assumption

$$g(\Pr(Y \leq i | \mathbf{x})) = (1, \mathbf{x}')\boldsymbol{\beta}_i, \quad 1 \leq i \leq k$$

where  $g(\cdot)$  is the link function, and  $\boldsymbol{\beta}_i = (\alpha_i, \beta_{i1}, \dots, \beta_{is})'$  is a vector of unknown parameters consisting of an intercept  $\alpha_i$  and  $s$  slope parameters  $\beta_{i1}, \dots, \beta_{is}$ . The parameter vector for this general cumulative model is

$$\boldsymbol{\beta} = (\boldsymbol{\beta}'_1, \dots, \boldsymbol{\beta}'_k)'$$

Under the null hypothesis of parallelism  $H_0: \beta_{1m} = \beta_{2m} = \dots = \beta_{km}, 1 \leq m \leq s$ , there is a single common slope parameter for each of the  $s$  explanatory variables. Let  $\beta_1, \dots, \beta_s$  be the common slope parameters. Let  $\hat{\alpha}_1, \dots, \hat{\alpha}_k$  and  $\hat{\beta}_1, \dots, \hat{\beta}_s$  be the MLEs of the intercept parameters and the common slope parameters. Then, under  $H_0$ , the MLE of  $\boldsymbol{\beta}$  is

$$\hat{\boldsymbol{\beta}}_{H_0} = (\hat{\boldsymbol{\beta}}'_1, \dots, \hat{\boldsymbol{\beta}}'_k)' \quad \text{with} \quad \hat{\boldsymbol{\beta}}_i = (\hat{\alpha}_i, \hat{\beta}_1, \dots, \hat{\beta}_s)' \quad 1 \leq i \leq k$$

and the chi-square score statistic  $\mathbf{g}'(\hat{\boldsymbol{\beta}}_{H_0})\mathbf{I}^{-1}(\hat{\boldsymbol{\beta}}_{H_0})\mathbf{g}(\hat{\boldsymbol{\beta}}_{H_0})$  has an asymptotic chi-square distribution with  $s(k - 1)$  degrees of freedom. This tests the parallel lines assumption by testing the equality of separate slope parameters simultaneously for all explanatory variables.

---

## Confidence Intervals for Parameters

There are two methods of computing confidence intervals for the regression parameters. One is based on the profile-likelihood function, and the other is based on the asymptotic normality of the parameter estimators. The latter is not as time-consuming as the former, since it does not involve an iterative scheme; however, it is not thought to be as accurate as the former, especially with small sample size. You use the CLPARM= option to request confidence intervals for the parameters.

## Likelihood Ratio-Based Confidence Intervals

The likelihood ratio-based confidence interval is also known as the profile-likelihood confidence interval. The construction of this interval is derived from the asymptotic  $\chi^2$  distribution of the generalized likelihood ratio test (Venzon and Moolgavkar 1988). Suppose that the parameter vector is  $\boldsymbol{\beta} = (\beta_0, \beta_1, \dots, \beta_s)'$  and you want to compute a confidence interval for  $\beta_j$ . The profile-likelihood function for  $\beta_j = \gamma$  is defined as

$$l_j^*(\gamma) = \max_{\boldsymbol{\beta} \in \mathcal{B}_j(\gamma)} l(\boldsymbol{\beta})$$

where  $\mathcal{B}_j(\gamma)$  is the set of all  $\boldsymbol{\beta}$  with the  $j$ th element fixed at  $\gamma$ , and  $l(\boldsymbol{\beta})$  is the log-likelihood function for  $\boldsymbol{\beta}$ . If  $l_{\max} = l(\hat{\boldsymbol{\beta}})$  is the log likelihood evaluated at the maximum likelihood estimate  $\hat{\boldsymbol{\beta}}$ , then  $2(l_{\max} - l_j^*(\beta_j))$  has a limiting chi-square distribution with one degree of freedom if  $\beta_j$  is the true parameter value. Let  $l_0 = l_{\max} - 0.5\chi_1^2(1 - \alpha)$ , where  $\chi_1^2(1 - \alpha)$  is the  $100(1 - \alpha)$  percentile of the chi-square distribution with one degree of freedom. A  $100(1 - \alpha)\%$  confidence interval for  $\beta_j$  is

$$\{\gamma : l_j^*(\gamma) \geq l_0\}$$

The endpoints of the confidence interval are found by solving numerically for values of  $\beta_j$  that satisfy equality in the preceding relation. To obtain an iterative algorithm for computing the confidence limits, the log-likelihood function in a neighborhood of  $\boldsymbol{\beta}$  is approximated by the quadratic function

$$\tilde{l}(\boldsymbol{\beta} + \boldsymbol{\delta}) = l(\boldsymbol{\beta}) + \boldsymbol{\delta}'\mathbf{g} + \frac{1}{2}\boldsymbol{\delta}'\mathbf{V}\boldsymbol{\delta}$$

where  $\mathbf{g} = \mathbf{g}(\boldsymbol{\beta})$  is the gradient vector and  $\mathbf{V} = \mathbf{V}(\boldsymbol{\beta})$  is the Hessian matrix. The increment  $\boldsymbol{\delta}$  for the next iteration is obtained by solving the likelihood equations

$$\frac{d}{d\boldsymbol{\delta}} \{\tilde{l}(\boldsymbol{\beta} + \boldsymbol{\delta}) + \lambda(\mathbf{e}_j'\boldsymbol{\delta} - \gamma)\} = \mathbf{0}$$

where  $\lambda$  is the Lagrange multiplier,  $\mathbf{e}_j$  is the  $j$ th unit vector, and  $\gamma$  is an unknown constant. The solution is

$$\boldsymbol{\delta} = -\mathbf{V}^{-1}(\mathbf{g} + \lambda\mathbf{e}_j)$$

By substituting this  $\boldsymbol{\delta}$  into the equation  $\tilde{l}(\boldsymbol{\beta} + \boldsymbol{\delta}) = l_0$ , you can estimate  $\lambda$  as

$$\lambda = \pm \left( \frac{2(l_0 - l(\boldsymbol{\beta}) + \frac{1}{2}\mathbf{g}'\mathbf{V}^{-1}\mathbf{g})}{\mathbf{e}_j'\mathbf{V}^{-1}\mathbf{e}_j} \right)^{\frac{1}{2}}$$

The upper confidence limit for  $\beta_j$  is computed by starting at the maximum likelihood estimate of  $\boldsymbol{\beta}$  and iterating with positive values of  $\lambda$  until convergence is attained. The process is repeated for the lower confidence limit by using negative values of  $\lambda$ .

Convergence is controlled by the value  $\epsilon$  specified with the `PLCONV=` option in the `MODEL` statement (the default value of  $\epsilon$  is  $1\text{E-}4$ ). Convergence is declared on the current iteration if the following two conditions are satisfied:

$$|l(\boldsymbol{\beta}) - l_0| \leq \epsilon$$

and

$$(\mathbf{g} + \lambda\mathbf{e}_j)'\mathbf{V}^{-1}(\mathbf{g} + \lambda\mathbf{e}_j) \leq \epsilon$$

## Wald Confidence Intervals

Wald confidence intervals are sometimes called the normal confidence intervals. They are based on the asymptotic normality of the parameter estimators. The  $100(1 - \alpha)\%$  Wald confidence interval for  $\beta_j$  is given by

$$\widehat{\beta}_j \pm z_{1-\alpha/2} \widehat{\sigma}_j$$

where  $z_p$  is the  $100p$  percentile of the standard normal distribution,  $\widehat{\beta}_j$  is the maximum likelihood estimate of  $\beta_j$ , and  $\widehat{\sigma}_j$  is the standard error estimate of  $\widehat{\beta}_j$ .

---

## Odds Ratio Estimation

Consider a dichotomous response variable with outcomes *event* and *nonevent*. Consider a dichotomous risk factor variable  $X$  that takes the value 1 if the risk factor is present and 0 if the risk factor is absent. According to the logistic model, the log odds function,  $\text{logit}(X)$ , is given by

$$\text{logit}(X) \equiv \log\left(\frac{\Pr(\text{event} | X)}{\Pr(\text{nonevent} | X)}\right) = \alpha + X\beta$$

The odds ratio  $\psi$  is defined as the ratio of the odds for those with the risk factor ( $X = 1$ ) to the odds for those without the risk factor ( $X = 0$ ). The log of the odds ratio is given by

$$\log(\psi) \equiv \log(\psi(X = 1, X = 0)) = \text{logit}(X = 1) - \text{logit}(X = 0) = (\alpha + 1 \times \beta) - (\alpha + 0 \times \beta) = \beta$$

In general, the odds ratio can be computed by exponentiating the difference of the logits between any two population profiles. This is the approach taken by the **ODDSRATIO** statement, so the computations are available regardless of parameterization, interactions, and nestings. However, as shown in the preceding equation for  $\log(\psi)$ , odds ratios of main effects can be computed as functions of the parameter estimates, and the remainder of this section is concerned with this methodology.

The parameter,  $\beta$ , associated with  $X$  represents the change in the log odds from  $X = 0$  to  $X = 1$ . So the odds ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The odds ratio indicates how the odds of the event change as you change  $X$  from 0 to 1. For instance,  $\psi = 2$  means that the odds of an event when  $X = 1$  are twice the odds of an event when  $X = 0$ . You can also express this as follows: the percent change in the odds of an event from  $X = 0$  to  $X = 1$  is  $(\psi - 1)100\% = 100\%$ .

Suppose the values of the dichotomous risk factor are coded as constants  $a$  and  $b$  instead of 0 and 1. The odds when  $X = a$  become  $\exp(\alpha + a\beta)$ , and the odds when  $X = b$  become  $\exp(\alpha + b\beta)$ . The odds ratio corresponding to an increase in  $X$  from  $a$  to  $b$  is

$$\psi = \exp[(b - a)\beta] = [\exp(\beta)]^{b-a} \equiv [\exp(\beta)]^c$$

Note that for any  $a$  and  $b$  such that  $c = b - a = 1$ ,  $\psi = \exp(\beta)$ . So the odds ratio can be interpreted as the change in the odds for any increase of one unit in the corresponding risk factor. However, the change in odds for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight might be too small to be considered important, while a change of 10 pounds might be more meaningful. The odds ratio for a change in  $X$  from  $a$  to  $b$  is estimated by raising the odds ratio estimate for a unit change in  $X$  to the power of  $c = b - a$  as shown previously.

For a polytomous risk factor, the computation of odds ratios depends on how the risk factor is parameterized. For illustration, suppose that Race is a risk factor with four categories: White, Black, Hispanic, and Other.

For the effect parameterization scheme (**PARAM=EFFECT**) with White as the reference group (**REF='White'**), the design variables for Race are as follows:

| Race     | Design Variables |       |       |
|----------|------------------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ |
| Black    | 1                | 0     | 0     |
| Hispanic | 0                | 1     | 0     |
| Other    | 0                | 0     | 1     |
| White    | -1               | -1    | -1    |

The log odds for Black is

$$\begin{aligned}\text{logit(Black)} &= \alpha + (X_1 = 1)\beta_1 + (X_2 = 0)\beta_2 + (X_3 = 0)\beta_3 \\ &= \alpha + \beta_1\end{aligned}$$

The log odds for White is

$$\begin{aligned}\text{logit(White)} &= \alpha + (X_1 = -1)\beta_1 + (X_2 = -1)\beta_2 + (X_3 = -1)\beta_3 \\ &= \alpha - \beta_1 - \beta_2 - \beta_3\end{aligned}$$

Therefore, the log odds ratio of Black versus White becomes

$$\begin{aligned}\log(\psi(\text{Black, White})) &= \text{logit(Black)} - \text{logit(White)} \\ &= 2\beta_1 + \beta_2 + \beta_3\end{aligned}$$

For the reference cell parameterization scheme (**PARAM=REF**) with White as the reference cell, the design variables for race are as follows:

| Race     | Design Variables |       |       |
|----------|------------------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ |
| Black    | 1                | 0     | 0     |
| Hispanic | 0                | 1     | 0     |
| Other    | 0                | 0     | 1     |
| White    | 0                | 0     | 0     |

The log odds ratio of Black versus White is given by

$$\begin{aligned}\log(\psi(\text{Black, White})) &= \text{logit(Black)} - \text{logit(White)} \\ &= (\alpha + (X_1 = 1)\beta_1 + (X_2 = 0)\beta_2 + (X_3 = 0)\beta_3) - \\ &\quad (\alpha + (X_1 = 0)\beta_1 + (X_2 = 0)\beta_2 + (X_3 = 0)\beta_3) \\ &= \beta_1\end{aligned}$$

For the GLM parameterization scheme (**PARAM=GLM**), the design variables are as follows:

| Race     | Design Variables |       |       |       |
|----------|------------------|-------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ | $X_4$ |
| Black    | 1                | 0     | 0     | 0     |
| Hispanic | 0                | 1     | 0     | 0     |
| Other    | 0                | 0     | 1     | 0     |
| White    | 0                | 0     | 0     | 1     |

The log odds ratio of Black versus White is

$$\begin{aligned}
 \log(\psi(\text{Black}, \text{White})) &= \text{logit}(\text{Black}) - \text{logit}(\text{White}) \\
 &= (\alpha + (X_1 = 1)\beta_1 + (X_2 = 0)\beta_2 + (X_3 = 0)\beta_3 + (X_4 = 0)\beta_4) - \\
 &\quad (\alpha + (X_1 = 0)\beta_1 + (X_2 = 0)\beta_2 + (X_3 = 0)\beta_3 + (X_4 = 1)\beta_4) \\
 &= \beta_1 - \beta_4
 \end{aligned}$$

Consider the hypothetical example of heart disease among race in Hosmer and Lemeshow (2000, p. 56). The entries in the following contingency table represent counts:

| Disease Status | Race  |       |          |       |
|----------------|-------|-------|----------|-------|
|                | White | Black | Hispanic | Other |
| Present        | 5     | 20    | 15       | 10    |
| Absent         | 20    | 10    | 10       | 10    |

The computation of odds ratio of Black versus White for various parameterization schemes is tabulated in Table 54.11.

**Table 54.11** Odds Ratio of Heart Disease Comparing Black to White

| PARAM= | Parameter Estimates |                 |                 |                 | Odds Ratio Estimates                          |
|--------|---------------------|-----------------|-----------------|-----------------|-----------------------------------------------|
|        | $\hat{\beta}_1$     | $\hat{\beta}_2$ | $\hat{\beta}_3$ | $\hat{\beta}_4$ |                                               |
| EFFECT | 0.7651              | 0.4774          | 0.0719          |                 | $\exp(2 \times 0.7651 + 0.4774 + 0.0719) = 8$ |
| REF    | 2.0794              | 1.7917          | 1.3863          |                 | $\exp(2.0794) = 8$                            |
| GLM    | 2.0794              | 1.7917          | 1.3863          | 0.0000          | $\exp(2.0794) = 8$                            |

Since the log odds ratio ( $\log(\psi)$ ) is a linear function of the parameters, the Wald confidence interval for  $\log(\psi)$  can be derived from the parameter estimates and the estimated covariance matrix. Confidence intervals for the odds ratios are obtained by exponentiating the corresponding confidence limits for the log odds ratios. In the displayed output of PROC LOGISTIC, the “Odds Ratio Estimates” table contains the odds ratio estimates and the corresponding 95% Wald confidence intervals. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors.

To customize odds ratios for specific units of change for a continuous risk factor, you can use the **UNITS** statement to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized odds ratios are given in a separate table. Let  $(L_j, U_j)$  be a confidence interval for  $\log(\psi)$ . The corresponding lower and upper confidence limits for the customized odds ratio  $\exp(c\beta_j)$  are  $\exp(cL_j)$  and  $\exp(cU_j)$ , respectively (for  $c > 0$ ), or  $\exp(cU_j)$  and  $\exp(cL_j)$ , respectively (for  $c < 0$ ). You use the **CLODDS=** option or **ODDSRATIO** statement to request the confidence intervals for the odds ratios.

For a generalized logit model, odds ratios are computed similarly, except  $k$  odds ratios are computed for each effect, corresponding to the  $k$  logits in the model.

---

## Rank Correlation of Observed Responses and Predicted Probabilities

The predicted mean score of an observation is the sum of the Ordered Values (shown in the “Response Profile” table) minus one, weighted by the corresponding predicted probabilities for that observation; that is, the predicted means score =  $\sum_{i=1}^{k+1} (i-1)\hat{\pi}_i$ , where  $k+1$  is the number of response levels and  $\hat{\pi}_i$  is the predicted probability of the  $i$ th (ordered) response.

A pair of observations with different observed responses is said to be *concordant* if the observation with the lower ordered response value has a lower predicted mean score than the observation with the higher ordered response value. If the observation with the lower ordered response value has a higher predicted mean score than the observation with the higher ordered response value, then the pair is *discordant*. If the pair is neither concordant nor discordant, it is a *tie*. Enumeration of the total numbers of concordant and discordant pairs is carried out by categorizing the predicted mean score into intervals of length  $k/500$  and accumulating the corresponding frequencies of observations. Note that the length of these intervals can be modified by specification of the `BINWIDTH=` option in the `MODEL` statement.

Let  $N$  be the sum of observation frequencies in the data. Suppose there are a total of  $t$  pairs with different responses:  $n_c$  of them are concordant,  $n_d$  of them are discordant, and  $t - n_c - n_d$  of them are tied. PROC LOGISTIC computes the following four indices of rank correlation for assessing the predictive ability of a model:

$$\begin{aligned} c &= (n_c + 0.5(t - n_c - n_d))/t \\ \text{Somers' } D \text{ (Gini coefficient)} &= (n_c - n_d)/t \\ \text{Goodman-Kruskal Gamma} &= (n_c - n_d)/(n_c + n_d) \\ \text{Kendall's Tau-}a &= (n_c - n_d)/(0.5N(N - 1)) \end{aligned}$$

If there are no ties, then Somers'  $D$  (Gini's coefficient) =  $2c - 1$ . Note that the concordance index,  $c$ , also gives an estimate of the area under the receiver operating characteristic (ROC) curve when the response is binary (Hanley and McNeil 1982). See the section “ROC Computations” on page 4261 for more information about this area.

For binary responses, the predicted mean score is equal to the predicted probability for Ordered Value 2. As such, the preceding definition of concordance is consistent with the definition used in previous releases for the binary response model.

These statistics are not available when the `STRATA` statement is specified.

---

## Linear Predictor, Predicted Probability, and Confidence Limits

This section describes how predicted probabilities and confidence limits are calculated by using the maximum likelihood estimates (MLEs) obtained from PROC LOGISTIC. For a specific example, see the section “Getting Started: LOGISTIC Procedure” on page 4166. Predicted probabilities and confidence limits can be output to a data set with the `OUTPUT` statement.

## Binary and Cumulative Response Models

For a vector of explanatory variables  $\mathbf{x}$ , the linear predictor

$$\eta_i = g(\Pr(Y \leq i | \mathbf{x})) = \alpha_i + \mathbf{x}'\boldsymbol{\beta} \quad 1 \leq i \leq k$$

is estimated by

$$\hat{\eta}_i = \hat{\alpha}_i + \mathbf{x}'\hat{\boldsymbol{\beta}}$$

where  $\hat{\alpha}_i$  and  $\hat{\boldsymbol{\beta}}$  are the MLEs of  $\alpha_i$  and  $\boldsymbol{\beta}$ . The estimated standard error of  $\eta_i$  is  $\hat{\sigma}(\hat{\eta}_i)$ , which can be computed as the square root of the quadratic form  $(1, \mathbf{x}')\hat{\mathbf{V}}_{\mathbf{b}}(1, \mathbf{x})'$ , where  $\hat{\mathbf{V}}_{\mathbf{b}}$  is the estimated covariance matrix of the parameter estimates. The asymptotic  $100(1 - \alpha)\%$  confidence interval for  $\eta_i$  is given by

$$\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile point of a standard normal distribution.

The predicted probability and the  $100(1 - \alpha)\%$  confidence limits for  $\pi_i = \Pr(Y \leq i | \mathbf{x})$  are obtained by back-transforming the corresponding measures for the linear predictor, as shown in the following table:

| Link    | Predicted Probability           | 100(1- $\alpha$ )% Confidence Limits                                       |
|---------|---------------------------------|----------------------------------------------------------------------------|
| LOGIT   | $1/(1 + \exp(-\hat{\eta}_i))$   | $1/(1 + \exp(-\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)))$   |
| PROBIT  | $\Phi(\hat{\eta}_i)$            | $\Phi(\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i))$            |
| CLOGLOG | $1 - \exp(-\exp(\hat{\eta}_i))$ | $1 - \exp(-\exp(\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)))$ |

The **CONTRAST** statement also enables you to estimate the exponentiated contrast,  $e^{\hat{\eta}_i}$ . The corresponding standard error is  $e^{\hat{\eta}_i}\hat{\sigma}(\hat{\eta}_i)$ , and the confidence limits are computed by exponentiating those for the linear predictor:  $\exp\{\hat{\eta}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\eta}_i)\}$ .

## Generalized Logit Model

For a vector of explanatory variables  $\mathbf{x}$ , define the linear predictors  $\eta_i = \alpha_i + \mathbf{x}'\boldsymbol{\beta}_i$ , and let  $\pi_i$  denote the probability of obtaining the response value  $i$ :

$$\pi_i = \begin{cases} \pi_{k+1}e^{\eta_i} & 1 \leq i \leq k \\ \frac{1}{1 + \sum_{j=1}^k e^{\eta_j}} & i = k + 1 \end{cases}$$

By the *delta method*,

$$\sigma^2(\pi_i) = \left(\frac{\partial \pi_i}{\partial \boldsymbol{\beta}}\right)' \mathbf{V}(\boldsymbol{\beta}) \frac{\partial \pi_i}{\partial \boldsymbol{\beta}}$$

A  $100(1 - \alpha)\%$  confidence level for  $\pi_i$  is given by

$$\hat{\pi}_i \pm z_{\alpha/2}\hat{\sigma}(\hat{\pi}_i)$$

where  $\hat{\pi}_i$  is the estimated expected probability of response  $i$ , and  $\hat{\sigma}(\hat{\pi}_i)$  is obtained by evaluating  $\sigma(\pi_i)$  at  $\boldsymbol{\beta} = \hat{\boldsymbol{\beta}}$ .

Note that the contrast  $\hat{\eta}_i$  and exponentiated contrast  $e^{\hat{\eta}_i}$ , their standard errors, and their confidence intervals are computed in the same fashion as for the cumulative response models, replacing  $\boldsymbol{\beta}$  with  $\boldsymbol{\beta}_i$ .

## Classification Table

For binary response data, the response is either an *event* or a *nonevent*. In PROC LOGISTIC, the response with Ordered Value 1 is regarded as the event, and the response with Ordered Value 2 is the nonevent. PROC LOGISTIC models the probability of the event. From the fitted model, a predicted event probability can be computed for each observation. A method to compute a reduced-bias estimate of the predicted probability is given in the section “[Predicted Probability of an Event for Classification](#)” on page 4255. If the predicted event probability exceeds or equals some cutpoint value  $z \in [0, 1]$ , the observation is predicted to be an event observation; otherwise, it is predicted as a nonevent. A  $2 \times 2$  frequency table can be obtained by cross-classifying the observed and predicted responses. The `CTABLE` option produces this table, and the `PPROB=` option selects one or more cutpoints. Each cutpoint generates a classification table. If the `PEVENT=` option is also specified, a classification table is produced for each combination of `PEVENT=` and `PPROB=` values.

The accuracy of the classification is measured by its *sensitivity* (the ability to predict an event correctly) and *specificity* (the ability to predict a nonevent correctly). *Sensitivity* is the proportion of event responses that were predicted to be events. *Specificity* is the proportion of nonevent responses that were predicted to be nonevents. PROC LOGISTIC also computes three other conditional probabilities: *false positive rate*, *false negative rate*, and *rate of correct classification*. The *false positive rate* is the proportion of predicted event responses that were observed as nonevents. The *false negative rate* is the proportion of predicted nonevent responses that were observed as events. Given prior probabilities specified with the `PEVENT=` option, these conditional probabilities can be computed as posterior probabilities by using Bayes’ theorem.

### Predicted Probability of an Event for Classification

When you classify a set of binary data, if the same observations used to fit the model are also used to estimate the classification error, the resulting error-count estimate is biased. One way of reducing the bias is to remove the binary observation to be classified from the data, reestimate the parameters of the model, and then classify the observation based on the new parameter estimates. However, it would be costly to fit the model by leaving out each observation one at a time. The LOGISTIC procedure provides a less expensive one-step approximation to the preceding parameter estimates. Let  $\hat{\boldsymbol{\beta}}$  be the MLE of the parameter vector  $(\alpha, \beta_1, \dots, \beta_s)'$  based on all observations. Let  $\hat{\boldsymbol{\beta}}_{(j)}$  denote the MLE computed without the  $j$ th observation. The one-step estimate of  $\hat{\boldsymbol{\beta}}_{(j)}$  is given by

$$\hat{\boldsymbol{\beta}}_{(j)}^1 = \hat{\boldsymbol{\beta}} - \frac{w_j(y_j - \hat{\pi}_j)}{1 - h_j} \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \begin{pmatrix} 1 \\ \mathbf{x}_j \end{pmatrix}$$

where

- $y_j$  is 1 for an observed event response and 0 otherwise
- $w_j$  is the weight of the observation
- $\hat{\pi}_j$  is the predicted event probability based on  $\hat{\boldsymbol{\beta}}$
- $h_j$  is the **hat diagonal element** (defined on page 4263) with  $n_j = 1$  and  $r_j = y_j$
- $\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$  is the estimated covariance matrix of  $\hat{\boldsymbol{\beta}}$

### False Positive, False Negative, and Correct Classification Rates Using Bayes' Theorem

Suppose  $n_1$  of  $n$  individuals experience an event, such as a disease. Let this group be denoted by  $\mathcal{C}_1$ , and let the group of the remaining  $n_2 = n - n_1$  individuals who do not have the disease be denoted by  $\mathcal{C}_2$ . The  $j$ th individual is classified as giving a positive response if the predicted probability of disease ( $\hat{\pi}_{(j)}^*$ ) is large. The probability  $\hat{\pi}_{(j)}^*$  is the reduced-bias estimate based on the one-step approximation given in the preceding section. For a given cutpoint  $z$ , the  $j$ th individual is predicted to give a positive response if  $\hat{\pi}_{(j)}^* \geq z$ .

Let  $B$  denote the event that a subject has the disease, and let  $\bar{B}$  denote the event of not having the disease. Let  $A$  denote the event that the subject responds positively, and let  $\bar{A}$  denote the event of responding negatively. Results of the classification are represented by two conditional probabilities,  $\Pr(A|B)$  and  $\Pr(A|\bar{B})$ , where  $\Pr(A|B)$  is the sensitivity and  $\Pr(A|\bar{B})$  is one minus the specificity.

These probabilities are given by

$$\Pr(A|B) = \frac{\sum_{j \in \mathcal{C}_1} I(\hat{\pi}_{(j)}^* \geq z)}{n_1}$$

$$\Pr(A|\bar{B}) = \frac{\sum_{j \in \mathcal{C}_2} I(\hat{\pi}_{(j)}^* \geq z)}{n_2}$$

where  $I(\cdot)$  is the indicator function.

Bayes' theorem is used to compute several rates of the classification. For a given prior probability  $\Pr(B)$  of the disease, the false positive rate  $P_{F+}$ , the false negative rate  $P_{F-}$ , and the correct classification rate  $P_C$  are given by Fleiss (1981, pp. 4–5) as follows:

$$P_{F+} = \Pr(\bar{B}|A) = \frac{\Pr(A|\bar{B})[1 - \Pr(B)]}{\Pr(A|\bar{B}) + \Pr(B)[\Pr(A|B) - \Pr(A|\bar{B})]}$$

$$P_{F-} = \Pr(B|\bar{A}) = \frac{[1 - \Pr(A|B)]\Pr(B)}{1 - \Pr(A|\bar{B}) - \Pr(B)[\Pr(A|B) - \Pr(A|\bar{B})]}$$

$$P_C = \Pr(B|A) + \Pr(\bar{B}|\bar{A}) = \Pr(A|B)\Pr(B) + \Pr(\bar{A}|\bar{B})[1 - \Pr(B)]$$

The prior probability  $\Pr(B)$  can be specified by the `PEVENT=` option. If the `PEVENT=` option is not specified, the sample proportion of diseased individuals is used; that is,  $\Pr(B) = n_1/n$ . In such a case, the false positive rate and the false negative rate reduce to

$$P_{F+} = \frac{\sum_{j \in \mathcal{C}_2} I(\hat{\pi}_{(j)}^* \geq z)}{\sum_{j \in \mathcal{C}_1} I(\hat{\pi}_{(j)}^* \geq z) + \sum_{j \in \mathcal{C}_2} I(\hat{\pi}_{(j)}^* \geq z)}$$

$$P_{F-} = \frac{\sum_{j \in \mathcal{C}_1} I(\hat{\pi}_{(j)}^* < z)}{\sum_{j \in \mathcal{C}_1} I(\hat{\pi}_{(j)}^* < z) + \sum_{j \in \mathcal{C}_2} I(\hat{\pi}_{(j)}^* < z)}$$

$$P_C = \frac{\sum_{j \in \mathcal{C}_1} I(\hat{\pi}_{(j)}^* \geq z) + \sum_{j \in \mathcal{C}_2} I(\hat{\pi}_{(j)}^* < z)}{n}$$

Note that for a stratified sampling situation in which  $n_1$  and  $n_2$  are chosen a priori,  $n_1/n$  is not a desirable estimate of  $\Pr(B)$ . For such situations, the `PEVENT=` option should be specified.

## Overdispersion

For a correctly specified model, the Pearson chi-square statistic and the deviance, divided by their degrees of freedom, should be approximately equal to one. When their values are much larger than one, the assumption of binomial variability might not be valid and the data are said to exhibit overdispersion. Underdispersion, which results in the ratios being less than one, occurs less often in practice.

When fitting a model, there are several problems that can cause the goodness-of-fit statistics to exceed their degrees of freedom. Among these are such problems as outliers in the data, using the wrong link function, omitting important terms from the model, and needing to transform some predictors. These problems should be eliminated before proceeding to use the following methods to correct for overdispersion.

### Rescaling the Covariance Matrix

One way of correcting overdispersion is to multiply the covariance matrix by a dispersion parameter. This method assumes that the sample sizes in each subpopulation are approximately equal. You can supply the value of the dispersion parameter directly, or you can estimate the dispersion parameter based on either the Pearson chi-square statistic or the deviance for the fitted model.

The Pearson chi-square statistic  $\chi_P^2$  and the deviance  $\chi_D^2$  are given by

$$\chi_P^2 = \sum_{i=1}^m \sum_{j=1}^{k+1} \frac{(r_{ij} - n_i \hat{\pi}_{ij})^2}{n_i \hat{\pi}_{ij}}$$

$$\chi_D^2 = 2 \sum_{i=1}^m \sum_{j=1}^{k+1} r_{ij} \log \left( \frac{r_{ij}}{n_i \hat{\pi}_{ij}} \right)$$

where  $m$  is the number of subpopulation profiles,  $k + 1$  is the number of response levels,  $r_{ij}$  is the total weight (sum of the product of the frequencies and the weights) associated with  $j$ th level responses in the  $i$ th profile,  $n_i = \sum_{j=1}^{k+1} r_{ij}$ , and  $\hat{\pi}_{ij}$  is the fitted probability for the  $j$ th level at the  $i$ th profile. Each of these chi-square statistics has  $mk - p$  degrees of freedom, where  $p$  is the number of parameters estimated. The dispersion parameter is estimated by

$$\widehat{\sigma}^2 = \begin{cases} \chi_P^2 / (mk - p) & \text{SCALE=PEARSON} \\ \chi_D^2 / (mk - p) & \text{SCALE=DEVIANC} \\ (\text{constant})^2 & \text{SCALE=constant} \end{cases}$$

In order for the Pearson statistic and the deviance to be distributed as chi-square, there must be sufficient replication within the subpopulations. When this is not true, the data are sparse, and the  $p$ -values for these statistics are not valid and should be ignored. Similarly, these statistics, divided by their degrees of freedom, cannot serve as indicators of overdispersion. A large difference between the Pearson statistic and the deviance provides some evidence that the data are too sparse to use either statistic.

You can use the **AGGREGATE** (or **AGGREGATE=**) option to define the subpopulation profiles. If you do not specify this option, each observation is regarded as coming from a separate subpopulation. For events/trials syntax, each observation represents  $n$  Bernoulli trials, where  $n$  is the value of the *trials* variable; for single-trial syntax, each observation represents a single trial. Without the **AGGREGATE**

(or AGGREGATE=) option, the Pearson chi-square statistic and the deviance are calculated only for events/trials syntax.

Note that the parameter estimates are not changed by this method. However, their standard errors are adjusted for overdispersion, affecting their significance tests.

### Williams' Method

Suppose that the data consist of  $n$  binomial observations. For the  $i$ th observation, let  $r_i/n_i$  be the observed proportion and let  $\mathbf{x}_i$  be the associated vector of explanatory variables. Suppose that the response probability for the  $i$ th observation is a random variable  $P_i$  with mean and variance

$$E(P_i) = \pi_i \quad \text{and} \quad V(P_i) = \phi\pi_i(1 - \pi_i)$$

where  $\pi_i$  is the probability of the event, and  $\phi$  is a nonnegative but otherwise unknown scale parameter. Then the mean and variance of  $r_i$  are

$$E(r_i) = n_i\pi_i \quad \text{and} \quad V(r_i) = n_i\pi_i(1 - \pi_i)[1 + (n_i - 1)\phi]$$

Williams (1982) estimates the unknown parameter  $\phi$  by equating the value of Pearson's chi-square statistic for the full model to its approximate expected value. Suppose  $w_i^*$  is the weight associated with the  $i$ th observation. The Pearson chi-square statistic is given by

$$\chi^2 = \sum_{i=1}^n \frac{w_i^*(r_i - n_i\hat{\pi}_i)^2}{n_i\hat{\pi}_i(1 - \hat{\pi}_i)}$$

Let  $g'(\cdot)$  be the first derivative of the link function  $g(\cdot)$ . The approximate expected value of  $\chi^2$  is

$$E_{\chi^2} = \sum_{i=1}^n w_i^*(1 - w_i^*v_i d_i)[1 + \phi(n_i - 1)]$$

where  $v_i = n_i/(\pi_i(1 - \pi_i)[g'(\pi_i)]^2)$  and  $d_i$  is the variance of the linear predictor  $\hat{\alpha}_i + \mathbf{x}_i'\hat{\boldsymbol{\beta}}$ . The scale parameter  $\phi$  is estimated by the following iterative procedure.

At the start, let  $w_i^* = 1$  and let  $\pi_i$  be approximated by  $r_i/n_i$ ,  $i = 1, 2, \dots, n$ . If you apply these weights and approximated probabilities to  $\chi^2$  and  $E_{\chi^2}$  and then equate them, an initial estimate of  $\phi$  is

$$\hat{\phi}_0 = \frac{\chi^2 - (n - p)}{\sum_i (n_i - 1)(1 - v_i d_i)}$$

where  $p$  is the total number of parameters. The initial estimates of the weights become  $\hat{w}_{i0}^* = [1 + (n_i - 1)\hat{\phi}_0]^{-1}$ . After a weighted fit of the model, the  $\hat{\alpha}_i$  and  $\hat{\boldsymbol{\beta}}$  are recalculated, and so is  $\chi^2$ . Then a revised estimate of  $\phi$  is given by

$$\hat{\phi}_1 = \frac{\chi^2 - \sum_i w_i^*(1 - w_i^*v_i d_i)}{w_i^*(n_i - 1)(1 - w_i^*v_i d_i)}$$

The iterative procedure is repeated until  $\chi^2$  is very close to its degrees of freedom.

Once  $\phi$  has been estimated by  $\hat{\phi}$  under the full model, weights of  $(1 + (n_i - 1)\hat{\phi})^{-1}$  can be used to fit models that have fewer terms than the full model. See [Example 54.10](#) for an illustration.

**NOTE:** If the **WEIGHT** statement is specified with the **NORMALIZE** option, then the initial  $w_i^*$  values are set to the normalized weights, and the weights resulting from Williams' method will not add up to the actual sample size. However, the estimated covariance matrix of the parameter estimates remains invariant to the scale of the **WEIGHT** variable.

## The Hosmer-Lemeshow Goodness-of-Fit Test

Sufficient replication within subpopulations is required to make the Pearson and deviance goodness-of-fit tests valid. When there are one or more continuous predictors in the model, the data are often too sparse to use these statistics. Hosmer and Lemeshow (2000) proposed a statistic that they show, through simulation, is distributed as chi-square when there is no replication in any of the subpopulations. This test is available only for binary response models.

First, the observations are sorted in increasing order of their estimated event probability. The event is the response level specified in the response variable option `EVENT=`, or the response level that is not specified in the `REF=` option, or, if neither of these options was specified, then the event is the response level identified in the “Response Profiles” table as “Ordered Value 1”. The observations are then divided into approximately 10 groups according to the following scheme. Let  $N$  be the total number of subjects. Let  $M$  be the target number of subjects for each group given by

$$M = [0.1 \times N + 0.5]$$

where  $[x]$  represents the integral value of  $x$ . If the single-trial syntax is used, blocks of subjects are formed of observations with identical values of the explanatory variables. Blocks of subjects are not divided when being placed into groups.

Suppose there are  $n_1$  subjects in the first block and  $n_2$  subjects in the second block. The first block of subjects is placed in the first group. Subjects in the second block are added to the first group if

$$n_1 < M \quad \text{and} \quad n_1 + [0.5 \times n_2] \leq M$$

Otherwise, they are placed in the second group. In general, suppose subjects of the  $(j - 1)$  block have been placed in the  $k$ th group. Let  $c$  be the total number of subjects currently in the  $k$ th group. Subjects for the  $j$ th block (containing  $n_j$  subjects) are also placed in the  $k$ th group if

$$c < M \quad \text{and} \quad c + [0.5 \times n_j] \leq M$$

Otherwise, the  $n_j$  subjects are put into the next group. In addition, if the number of subjects in the last group does not exceed  $[0.05 \times N]$  (half the target group size), the last two groups are collapsed to form only one group.

Note that the number of groups,  $g$ , can be smaller than 10 if there are fewer than 10 patterns of explanatory variables. There must be at least three groups in order for the Hosmer-Lemeshow statistic to be computed.

The Hosmer-Lemeshow goodness-of-fit statistic is obtained by calculating the Pearson chi-square statistic from the  $2 \times g$  table of observed and expected frequencies, where  $g$  is the number of groups. The statistic is written

$$\chi_{HL}^2 = \sum_{i=1}^g \frac{(O_i - N_i \bar{\pi}_i)^2}{N_i \bar{\pi}_i (1 - \bar{\pi}_i)}$$

where  $N_i$  is the total frequency of subjects in the  $i$ th group,  $O_i$  is the total frequency of event outcomes in the  $i$ th group, and  $\bar{\pi}_i$  is the average estimated predicted probability of an event outcome for the  $i$ th group. (Note that the predicted probabilities are computed as shown in the section “[Linear Predictor, Predicted Probability, and Confidence Limits](#)” on page 4253 and are not the cross validated estimates discussed in the section “[Classification Table](#)” on page 4255.) The Hosmer-Lemeshow statistic is then compared to a chi-square distribution with  $(g - n)$  degrees of freedom, where the value of  $n$  can be specified in the `LACKFIT` option in the `MODEL` statement. The default is  $n = 2$ . Large values of  $\chi_{HL}^2$  (and small  $p$ -values) indicate a lack of fit of the model.

## Receiver Operating Characteristic Curves

ROC curves are used to evaluate and compare the performance of diagnostic tests; they can also be used to evaluate model fit. An ROC curve is just a plot of the proportion of true positives (events predicted to be events) versus the proportion of false positives (nonevents predicted to be events).

In a sample of  $n$  individuals, suppose  $n_1$  individuals are observed to have a certain condition or event. Let this group be denoted by  $C_1$ , and let the group of the remaining  $n_2 = n - n_1$  individuals who do not have the condition be denoted by  $C_2$ . Risk factors are identified for the sample, and a logistic regression model is fitted to the data. For the  $j$ th individual, an estimated probability  $\hat{\pi}_j$  of the event of interest is calculated. Note that the  $\hat{\pi}_j$  are computed as shown in the section “[Linear Predictor, Predicted Probability, and Confidence Limits](#)” on page 4253 and are not the cross validated estimates discussed in the section “[Classification Table](#)” on page 4255.

Suppose the  $n$  individuals undergo a test for predicting the event and the test is based on the estimated probability of the event. Higher values of this estimated probability are assumed to be associated with the event. A receiver operating characteristic (ROC) curve can be constructed by varying the cutpoint that determines which estimated event probabilities are considered to predict the event. For each cutpoint  $z$ , the following measures can be output to a data set by specifying the `OUTROC=` option in the `MODEL` statement or the `OUTROC=` option in the `SCORE` statement:

$$\begin{aligned} \_POS\_ (z) &= \sum_{i \in C_1} I(\hat{\pi}_i \geq z) \\ \_NEG\_ (z) &= \sum_{i \in C_2} I(\hat{\pi}_i < z) \\ \_FALPOS\_ (z) &= \sum_{i \in C_2} I(\hat{\pi}_i \geq z) \\ \_FALNEG\_ (z) &= \sum_{i \in C_1} I(\hat{\pi}_i < z) \\ \_SENSIT\_ (z) &= \frac{\_POS\_ (z)}{n_1} \\ \_1MSPEC\_ (z) &= \frac{\_FALPOS\_ (z)}{n_2} \end{aligned}$$

where  $I(\cdot)$  is the indicator function.

Note that  $\_POS\_ (z)$  is the number of correctly predicted event responses,  $\_NEG\_ (z)$  is the number of correctly predicted nonevent responses,  $\_FALPOS\_ (z)$  is the number of falsely predicted event responses,  $\_FALNEG\_ (z)$  is the number of falsely predicted nonevent responses,  $\_SENSIT\_ (z)$  is the sensitivity of the test, and  $\_1MSPEC\_ (z)$  is one minus the specificity of the test.

The ROC curve is a plot of sensitivity ( $\_SENSIT\_$ ) against 1–specificity ( $\_1MSPEC\_$ ). The plot can be produced by using the `PLOTS` option or by using the `GPLOT` or `SGPLOT` procedure with the `OUTROC=` data set. See [Example 54.7](#) for an illustration. The area under the ROC curve, as determined by the trapezoidal rule, is estimated by the concordance index,  $c$ , in the “Association of Predicted Probabilities and Observed Responses” table.

## Comparing ROC Curves

ROC curves can be created from each model fit in a selection routine, from the specified model in the **MODEL** statement, from specified models in ROC statements, or from input variables which act as  $\hat{\pi}$  in the preceding discussion. Association statistics are computed for these models, and the models are compared when the **ROCCONTRAST** statement is specified. The ROC comparisons are performed by using a contrast matrix to take differences of the areas under the empirical ROC curves (DeLong, DeLong, and Clarke-Pearson 1988). For example, if you have three curves and the second curve is the reference, the contrast used for the overall test is

$$\mathbf{L}_1 = \begin{pmatrix} I'_1 \\ I'_2 \end{pmatrix} = \begin{bmatrix} 1 & -1 & 0 \\ 0 & -1 & 1 \end{bmatrix}$$

and you can optionally estimate and test each row of this contrast, in order to test the difference between the reference curve and each of the other curves. If you do not want to use a reference curve, the global test optionally uses the following contrast:

$$\mathbf{L}_2 = \begin{pmatrix} I'_1 \\ I'_2 \end{pmatrix} = \begin{bmatrix} 1 & -1 & 0 \\ 0 & 1 & -1 \end{bmatrix}$$

You can also specify your own contrast matrix. Instead of estimating the rows of these contrasts, you can request that the difference between every pair of ROC curves be estimated and tested.

By default for the reference contrast, the specified or selected model is used as the reference unless the **NOFIT** option is specified in the **MODEL** statement, in which case the first ROC model is the reference.

In order to label the contrasts, a name is attached to every model. The name for the specified or selected model is the **MODEL** statement label, or “Model” if the **MODEL** label is not present. The ROC statement models are named with their labels, or as “ROC*i*” for the *i*th ROC statement if a label is not specified. The contrast  $\mathbf{L}_1$  is labeled as “Reference = ModelName”, where ModelName is the reference model name, while  $\mathbf{L}_2$  is labeled “Adjacent Pairwise Differences”. The estimated rows of the contrast matrix are labeled “ModelName1 – ModelName2”. In particular, for the rows of  $\mathbf{L}_1$ , ModelName2 is the reference model name. If you specify your own contrast matrix, then the contrast is labeled “Specified” and the *i*th contrast row estimates are labeled “Row*i*”.

If ODS Graphics is enabled, then all ROC curves are displayed individually and are also overlaid in a final display. If a selection method is specified, then the curves produced in each step of the model selection process are overlaid onto a single plot and are labeled “Step*i*”, and the selected model is displayed on a separate plot and on a plot with curves from specified ROC statements. See [Example 54.8](#) for an example.

## ROC Computations

The trapezoidal area under an empirical ROC curve is equal to the Mann-Whitney two-sample rank measure of association statistic (a generalized *U*-statistic) applied to two samples,  $\{X_i\}, i = 1, \dots, n_1$ , in  $\mathcal{C}_1$  and  $\{Y_i\}, i = 1, \dots, n_2$ , in  $\mathcal{C}_2$ . PROC LOGISTIC uses the predicted probabilities in place of **X** and **Y**; however, in general any criterion could be used. Denote the frequency of observation *i* in  $\mathcal{C}_k$  as  $f_{ki}$ , and denote the total frequency in  $\mathcal{C}_k$  as  $F_k$ . The **WEIGHTED** option replaces  $f_{ki}$  with  $f_{ki}w_{ki}$ , where  $w_{ki}$  is the weight of

observation  $i$  in group  $C_k$ . The trapezoidal area under the curve is computed as

$$\hat{c} = \frac{1}{F_1 F_2} \sum_{i=1}^{n_1} \sum_{j=1}^{n_2} \psi(X_i, Y_j) f_{1i} f_{2j}$$

$$\psi(X, Y) = \begin{cases} 1 & Y < X \\ \frac{1}{2} & Y = X \\ 0 & Y > X \end{cases}$$

so that  $E(\hat{c}) = \Pr(Y < X) + \frac{1}{2} \Pr(Y = X)$ . Note that the concordance index,  $c$ , in the “Association of Predicted Probabilities and Observed Responses” table does not use weights unless both the **WEIGHTED** and **BINWIDTH=0** options are specified. Also, in this table,  $c$  is computed by creating 500 bins and binning the  $X_i$  and  $Y_j$ ; this results in more ties than the preceding method (unless the **BINWIDTH=0** or **ROCEPS=0** option is specified), so  $c$  is not necessarily equal to  $E(\hat{c})$ .

To compare  $K$  empirical ROC curves, first compute the trapezoidal areas. Asymptotic normality of the estimated area follows from  $U$ -statistic theory, and a covariance matrix  $\mathbf{S}$  can be computed; see DeLong, DeLong, and Clarke-Pearson (1988) for details. A Wald confidence interval for the  $r$ th area,  $1 \leq r \leq K$ , can be constructed as

$$\hat{c}_r \pm z_{1-\frac{\alpha}{2}} s_{r,r}$$

where  $s_{r,r}$  is the  $r$ th diagonal of  $\mathbf{S}$ .

For a contrast of ROC curve areas,  $\mathbf{Lc}$ , the statistic

$$(\hat{\mathbf{c}} - \mathbf{c})' \mathbf{L}' [\mathbf{LSL}']^{-1} \mathbf{L}(\hat{\mathbf{c}} - \mathbf{c})$$

has a chi-square distribution with  $\text{df} = \text{rank}(\mathbf{LSL}')$ . For a row of the contrast,  $\mathbf{l}'\mathbf{c}$ ,

$$\frac{\mathbf{l}'\hat{\mathbf{c}} - \mathbf{l}'\mathbf{c}}{[\mathbf{l}'\mathbf{S}\mathbf{l}]^{1/2}}$$

has a standard normal distribution. The corresponding confidence interval is

$$\mathbf{l}'\hat{\mathbf{c}} \pm z_{1-\frac{\alpha}{2}} [\mathbf{l}'\mathbf{S}\mathbf{l}]^{1/2}$$

## Testing Linear Hypotheses about the Regression Coefficients

Linear hypotheses for  $\boldsymbol{\beta}$  are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

where  $\mathbf{L}$  is a matrix of coefficients for the linear hypotheses, and  $\mathbf{c}$  is a vector of constants. The vector of regression coefficients  $\boldsymbol{\beta}$  includes slope parameters as well as intercept parameters. The Wald chi-square statistic for testing  $H_0$  is computed as

$$\chi_W^2 = (\mathbf{L}\hat{\boldsymbol{\beta}} - \mathbf{c})' [\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1} (\mathbf{L}\hat{\boldsymbol{\beta}} - \mathbf{c})$$

where  $\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$  is the estimated covariance matrix. Under  $H_0$ ,  $\chi_W^2$  has an asymptotic chi-square distribution with  $r$  degrees of freedom, where  $r$  is the rank of  $\mathbf{L}$ .

## Regression Diagnostics

For binary response data, regression diagnostics developed by Pregibon (1981) can be requested by specifying the **INFLUENCE** option. For diagnostics available with conditional logistic regression, see the section “Regression Diagnostic Details” on page 4272. These diagnostics can also be obtained from the **OUTPUT** statement.

This section uses the following notation:

- $r_j, n_j$      $r_j$  is the number of event responses out of  $n_j$  trials for the  $j$ th observation. If events/trials syntax is used,  $r_j$  is the value of *events* and  $n_j$  is the value of *trials*. For single-trial syntax,  $n_j = 1$ , and  $r_j = 1$  if the ordered response is 1, and  $r_j = 0$  if the ordered response is 2.
- $w_j$         is the weight of the  $j$ th observation.
- $\pi_j$         is the probability of an event response for the  $j$ th observation given by  $\pi_j = F(\alpha + \beta'x_j)$ , where  $F(\cdot)$  is the **inverse link function** defined on page 4238.
- $\hat{\beta}$         is the maximum likelihood estimate (MLE) of  $(\alpha, \beta_1, \dots, \beta_s)'$ .
- $\hat{V}(\hat{\beta})$     is the estimated covariance matrix of  $\hat{\beta}$ .
- $\hat{p}_j, \hat{q}_j$      $\hat{p}_j$  is the estimate of  $\pi_j$  evaluated at  $\hat{\beta}$ , and  $\hat{q}_j = 1 - \hat{p}_j$ .

Pregibon (1981) suggests using the index plots of several diagnostic statistics to identify influential observations and to quantify the effects on various aspects of the maximum likelihood fit. In an index plot, the diagnostic statistic is plotted against the observation number. In general, the distributions of these diagnostic statistics are not known, so cutoff values cannot be given for determining when the values are large. However, the **IPLOTS** and **INFLUENCE** options in the **MODEL** statement and the **PLOTS** option in the **PROC LOGISTIC** statement provide displays of the diagnostic values, allowing visual inspection and comparison of the values across observations. In these plots, if the model is correctly specified and fits all observations well, then no extreme points should appear.

The next five sections give formulas for these diagnostic statistics.

### Hat Matrix Diagonal (Leverage)

The diagonal elements of the hat matrix are useful in detecting extreme points in the design space where they tend to have larger values. The  $j$ th diagonal element is

$$h_j = \begin{cases} \tilde{w}_j(1, \mathbf{x}'_j)\hat{V}(\hat{\beta})(1, \mathbf{x}'_j)' & \text{Fisher scoring} \\ \hat{w}_j(1, \mathbf{x}'_j)\hat{V}(\hat{\beta})(1, \mathbf{x}'_j)' & \text{Newton-Raphson} \end{cases}$$

where

$$\tilde{w}_j = \frac{w_j n_j}{\hat{p}_j \hat{q}_j [g'(\hat{p}_j)]^2}$$

$$\hat{w}_j = \tilde{w}_j + \frac{w_j (r_j - n_j \hat{p}_j) [\hat{p}_j \hat{q}_j g''(\hat{p}_j) + (\hat{q}_j - \hat{p}_j) g'(\hat{p}_j)]}{(\hat{p}_j \hat{q}_j)^2 [g'(\hat{p}_j)]^3}$$

and  $g'(\cdot)$  and  $g''(\cdot)$  are the first and second derivatives of the link function  $g(\cdot)$ , respectively.

For a binary response logit model, the hat matrix diagonal elements are

$$h_j = w_j n_j \hat{p}_j \hat{q}_j (1, \mathbf{x}'_j) \widehat{\mathbf{V}}(\widehat{\boldsymbol{\beta}}) \begin{pmatrix} 1 \\ \mathbf{x}_j \end{pmatrix}$$

If the estimated probability is extreme (less than 0.1 and greater than 0.9, approximately), then the hat diagonal might be greatly reduced in value. Consequently, when an observation has a very large or very small estimated probability, its hat diagonal value is not a good indicator of the observation's distance from the design space (Hosmer and Lemeshow 2000, p. 171).

## Residuals

Residuals are useful in identifying observations that are not explained well by the model. Pearson residuals are components of the Pearson chi-square statistic and deviance residuals are components of the deviance. The Pearson residual for the  $j$ th observation is

$$\chi_j = \frac{\sqrt{w_j}(r_j - n_j \hat{p}_j)}{\sqrt{n_j \hat{p}_j \hat{q}_j}}$$

The Pearson chi-square statistic is the sum of squares of the Pearson residuals.

The deviance residual for the  $j$ th observation is

$$d_j = \begin{cases} -\sqrt{-2w_j n_j \log(\hat{q}_j)} & \text{if } r_j = 0 \\ \pm \sqrt{2w_j [r_j \log(\frac{r_j}{n_j \hat{p}_j}) + (n_j - r_j) \log(\frac{n_j - r_j}{n_j \hat{q}_j})]} & \text{if } 0 < r_j < n_j \\ \sqrt{-2w_j n_j \log(\hat{p}_j)} & \text{if } r_j = n_j \end{cases}$$

where the plus (minus) in  $\pm$  is used if  $r_j/n_j$  is greater (less) than  $\hat{p}_j$ . The deviance is the sum of squares of the deviance residuals.

The STDRES option in the **INFLUENCE** and **PLOTS=INFLUENCE** options computes three more residuals (Collett 2003). The Pearson and deviance residuals are standardized to have approximately unit variance:

$$e_{pj} = \frac{\chi_j}{\sqrt{1 - h_j}}$$

$$e_{dj} = \frac{d_j}{\sqrt{1 - h_j}}$$

The likelihood residuals, which estimate components of a likelihood ratio test of deleting an individual observation, are a weighted combination of the standardized Pearson and deviance residuals

$$e_{lj} = \text{sign}(r_j - n_j \hat{p}_j) \sqrt{h_j e_{pj}^2 + (1 - h_j) e_{dj}^2}$$

## DFBETAS

For each parameter estimate, the procedure calculates a DFBETAS diagnostic for each observation. The DFBETAS diagnostic for an observation is the standardized difference in the parameter estimate due to deleting the observation, and it can be used to assess the effect of an individual observation on each estimated parameter of the fitted model. Instead of reestimating the parameter every time an observation is deleted, PROC LOGISTIC uses the one-step estimate. See the section “[Predicted Probability of an Event for Classification](#)” on page 4255. For the  $j$ th observation, the DFBETAS are given by

$$\text{DFBETAS}_{ij} = \Delta_i \hat{\beta}_j^1 / \hat{\sigma}_i$$

where  $i = 0, 1, \dots, s$ ,  $\hat{\sigma}_i$  is the standard error of the  $i$ th component of  $\hat{\beta}$ , and  $\Delta_i \hat{\beta}_j^1$  is the  $i$ th component of the one-step difference

$$\Delta \hat{\beta}_j^1 = \frac{w_j(r_j - n_j \hat{p}_j)}{1 - h_j} \hat{\mathbf{V}}(\hat{\beta}) \begin{pmatrix} 1 \\ \mathbf{x}_j \end{pmatrix}$$

$\Delta \hat{\beta}_j^1$  is the approximate change ( $\hat{\beta} - \hat{\beta}_j^1$ ) in the vector of parameter estimates due to the omission of the  $j$ th observation. The DFBETAS are useful in detecting observations that are causing instability in the selected coefficients.

## C and CBAR

C and CBAR are confidence interval displacement diagnostics that provide scalar measures of the influence of individual observations on  $\hat{\beta}$ . These diagnostics are based on the same idea as the Cook distance in linear regression theory (Cook and Weisberg 1982), but use the one-step estimate. C and CBAR for the  $j$ th observation are computed as

$$C_j = \chi_j^2 h_j / (1 - h_j)^2$$

and

$$\bar{C}_j = \chi_j^2 h_j / (1 - h_j)$$

respectively.

Typically, to use these statistics, you plot them against an index and look for outliers.

## DIFDEV and DIFCHISQ

DIFDEV and DIFCHISQ are diagnostics for detecting ill-fitted observations; in other words, observations that contribute heavily to the disagreement between the data and the predicted values of the fitted model. DIFDEV is the change in the deviance due to deleting an individual observation while DIFCHISQ is the change in the Pearson chi-square statistic for the same deletion. By using the one-step estimate, DIFDEV and DIFCHISQ for the  $j$ th observation are computed as

$$\text{DIFDEV} = d_j^2 + \bar{C}_j$$

and

$$\text{DIFCHISQ} = \bar{C}_j / h_j$$

---

## Scoring Data Sets

*Scoring a data set*, which is especially important for predictive modeling, means applying a previously fitted model to a new data set in order to compute the conditional, or *posterior*, probabilities of each response category given the values of the explanatory variables in each observation.

The **SCORE** statement enables you to score new data sets and output the scored values and, optionally, the corresponding confidence limits into a SAS data set. If the response variable is included in the new data set, then you can request **fit statistics** for the data, which is especially useful for test or validation data. If the response is binary, you can also create a SAS data set containing the *receiver operating characteristic* (ROC) curve. You can specify multiple **SCORE** statements in the same invocation of PROC LOGISTIC.

By default, the posterior probabilities are based on implicit prior probabilities that are proportional to the frequencies of the response categories in the *training data* (the data used to fit the model). Explicit prior probabilities should be specified with the **PRIOR=** or **PRIOREVENT=** option when the sample proportions of the response categories in the training data differ substantially from the operational data to be scored. For example, to detect a rare category, it is common practice to use a training set in which the rare categories are overrepresented; without prior probabilities that reflect the true incidence rate, the predicted posterior probabilities for the rare category will be too high. By specifying the correct priors, the posterior probabilities are adjusted appropriately.

The model fit to the **DATA=** data set in the PROC LOGISTIC statement is the default model used for the scoring. Alternatively, you can save a model fit in one run of PROC LOGISTIC and use it to score new data in a subsequent run. The **OUTMODEL=** option in the PROC LOGISTIC statement saves the model information in a SAS data set. Specifying this data set in the **INMODEL=** option of a new PROC LOGISTIC run will score the **DATA=** data set in the **SCORE** statement without refitting the model.

The **STORE** statement can also be used to save your model. The PLM procedure can use this model to score new data sets; see Chapter 69, “The PLM Procedure,” for more information. You cannot specify priors in PROC PLM.

### Fit Statistics for Scored Data Sets

Specifying the **FITSTAT** option displays the following fit statistics when the data set being scored includes the response variable:

| Statistic                                | Description                                                                        |
|------------------------------------------|------------------------------------------------------------------------------------|
| Total frequency                          | $F = \sum_i f_i n_i$                                                               |
| Total weight                             | $W = \sum_i f_i w_i n_i$                                                           |
| Log likelihood                           | $\log L = \sum_i f_i w_i \log(\hat{\pi}_i)$                                        |
| Full log likelihood                      | $\log L_f = \text{constant} + \log L$                                              |
| Misclassification (error) rate           | $\frac{\sum_i 1\{F\_Y_i \neq L\_Y_i\} f_i n_i}{F}$                                 |
| AIC                                      | $-2 \log L_f + 2p$                                                                 |
| AICC                                     | $-2 \log L_f + \frac{2pn}{n-p-1}$                                                  |
| BIC                                      | $-2 \log L_f + p \log(n)$                                                          |
| SC                                       | $-2 \log L_f + p \log(F)$                                                          |
| R-square                                 | $R^2 = 1 - \left(\frac{L_0}{L}\right)^{2/F}$                                       |
| Maximum-rescaled R-square                | $\frac{R^2}{1 - L_0^{2/F}}$                                                        |
| AUC                                      | Area under the ROC curve                                                           |
| Brier score (polytomous response)        | $\frac{1}{W} \sum_i f_i w_i \sum_j (y_{ij} - \hat{\pi}_{ij})^2$                    |
| Brier score (binary response)            | $\frac{1}{W} \sum_i f_i w_i (r_i (1 - \hat{\pi}_i)^2 + (n_i - r_i) \hat{\pi}_i^2)$ |
| Brier reliability (events/trials syntax) | $\frac{1}{W} \sum_i f_i w_i (r_i / n_i - \hat{\pi}_i)^2$                           |

In the preceding table,  $f_i$  is the frequency of the  $i$ th observation in the data set being scored,  $w_i$  is the weight of the observation, and  $n = \sum_i f_i$ . The number of trials when events/trials syntax is specified is  $n_i$ , and with single-trial syntax  $n_i = 1$ . The values  $F\_Y_i$  and  $L\_Y_i$  are described in the section “[OUT= Output Data Set in a SCORE Statement](#)” on page 4281. The indicator function  $1\{A\}$  is 1 if  $A$  is true and 0 otherwise. The likelihood of the model is  $L$ , and  $L_0$  denotes the likelihood of the intercept-only model. For polytomous response models,  $y_i$  is the observed polytomous response level,  $\hat{\pi}_{ij}$  is the predicted probability of the  $j$ th response level for observation  $i$ , and  $y_{ij} = 1\{y_i = j\}$ . For binary response models,  $\hat{\pi}_i$  is the predicted probability of the observation,  $r_i$  is the number of events when you specify events/trials syntax, and  $r_i = y_i$  when you specify single-trial syntax.

The log likelihood, Akaike’s information criterion (AIC), and Schwarz criterion (SC) are described in the section “[Model Fitting Information](#)” on page 4245. The full log likelihood is displayed for models specified with events/trials syntax, and the constant term is described in the section “[Model Fitting Information](#)” on page 4245. The AICC is a small-sample bias-corrected version of the AIC (Hurvich and Tsai 1993; Burnham and Anderson 1998). The Bayesian information criterion (BIC) is the same as the SC except when events/trials syntax is specified. The area under the ROC curve for binary response models is defined in the section “[ROC Computations](#)” on page 4261. The R-square and maximum-rescaled R-square statistics, defined in “[Generalized Coefficient of Determination](#)” on page 4246, are not computed when you specify both an `OFFSET=` variable and the `INMODEL=` data set. The Brier score (Brier 1950) is the weighted squared difference between the predicted probabilities and their observed response levels. For events/trials syntax, the Brier reliability is the weighted squared difference between the predicted probabilities and the observed proportions (Murphy 1973).

## Posterior Probabilities and Confidence Limits

Let  $F$  be the inverse link function. That is,

$$F(t) = \begin{cases} \frac{1}{1+\exp(-t)} & \text{logistic} \\ \Phi(t) & \text{normal} \\ 1 - \exp(-\exp(t)) & \text{complementary log-log} \end{cases}$$

The first derivative of  $F$  is given by

$$F'(t) = \begin{cases} \frac{\exp(-t)}{(1+\exp(-t))^2} & \text{logistic} \\ \phi(t) & \text{normal} \\ \exp(t) \exp(-\exp(t)) & \text{complementary log-log} \end{cases}$$

Suppose there are  $k + 1$  response categories. Let  $Y$  be the response variable with levels  $1, \dots, k + 1$ . Let  $\mathbf{x} = (x_0, x_1, \dots, x_s)'$  be a  $(s + 1)$ -vector of covariates, with  $x_0 \equiv 1$ . Let  $\boldsymbol{\beta}$  be the vector of intercept and slope regression parameters.

Posterior probabilities are given by

$$p(Y = i | \mathbf{x}) = \frac{p_o(Y = i | \mathbf{x}) \frac{\tilde{p}(Y=i)}{p_o(Y=i)}}{\sum_j p_o(Y = j | \mathbf{x}) \frac{\tilde{p}(Y=j)}{p_o(Y=j)}} \quad i = 1, \dots, k + 1$$

where the old posterior probabilities ( $p_o(Y = i | \mathbf{x}), i = 1, \dots, k + 1$ ) are the conditional probabilities of the response categories given  $\mathbf{x}$ , the old priors ( $p_o(Y = i), i = 1, \dots, k + 1$ ) are the sample proportions of response categories of the training data, and the new priors ( $\tilde{p}(Y = i), i = 1, \dots, k + 1$ ) are specified in the **PRIOR=** or **PRIOREVENT=** option. To simplify notation, absorb the old priors into the new priors; that is

$$p(Y = i) = \frac{\tilde{p}(Y = i)}{p_o(Y = i)} \quad i = 1, \dots, k + 1$$

Note if the **PRIOR=** and **PRIOREVENT=** options are not specified, then  $p(Y = i) = 1$ .

The posterior probabilities are functions of  $\boldsymbol{\beta}$  and their estimates are obtained by substituting  $\boldsymbol{\beta}$  by its MLE  $\hat{\boldsymbol{\beta}}$ . The variances of the estimated posterior probabilities are given by the *delta method* as follows:

$$\text{Var}(\hat{p}(Y = i | \mathbf{x})) = \left[ \frac{\partial p(Y = i | \mathbf{x})}{\partial \boldsymbol{\beta}} \right]' \text{Var}(\hat{\boldsymbol{\beta}}) \left[ \frac{\partial p(Y = i | \mathbf{x})}{\partial \boldsymbol{\beta}} \right]$$

where

$$\frac{\partial p(Y = i | \mathbf{x})}{\partial \boldsymbol{\beta}} = \frac{\frac{\partial p_o(Y=i|\mathbf{x})}{\partial \boldsymbol{\beta}} p(Y = i)}{\sum_j p_o(Y = j | \mathbf{x}) p(Y = j)} - \frac{p_o(Y = i | \mathbf{x}) p(Y = i) \sum_j \frac{\partial p_o(Y=j|\mathbf{x})}{\partial \boldsymbol{\beta}} p(Y = j)}{[\sum_j p_o(Y = j | \mathbf{x}) p(Y = j)]^2}$$

and the old posterior probabilities  $p_o(Y = i | \mathbf{x})$  are described in the following sections.

A  $100(1 - \alpha)\%$  confidence interval for  $p(Y = i | \mathbf{x})$  is

$$\hat{p}(Y = i | \mathbf{x}) \pm z_{1-\alpha/2} \sqrt{\widehat{\text{Var}}(\hat{p}(Y = i | \mathbf{x}))}$$

where  $z_\tau$  is the upper  $100\tau$  percentile of the standard normal distribution.

**Binary and Cumulative Response Models**

Let  $\alpha_1, \dots, \alpha_k$  be the intercept parameters and let  $\boldsymbol{\beta}_s$  be the vector of slope parameters. Denote  $\boldsymbol{\beta} = (\alpha_1, \dots, \alpha_k, \boldsymbol{\beta}_s)'$ . Let

$$\eta_i = \eta_i(\boldsymbol{\beta}) = \alpha_i + \mathbf{x}'\boldsymbol{\beta}_s, i = 1, \dots, k$$

Estimates of  $\eta_1, \dots, \eta_k$  are obtained by substituting the maximum likelihood estimate  $\widehat{\boldsymbol{\beta}}$  for  $\boldsymbol{\beta}$ .

The predicted probabilities of the responses are

$$\widehat{p}_o(Y = i|\mathbf{x}) = \widehat{\Pr}(Y = i) = \begin{cases} F(\widehat{\eta}_1) & i = 1 \\ F(\widehat{\eta}_i) - F(\widehat{\eta}_{i-1}) & i = 2, \dots, k \\ 1 - F(\widehat{\eta}_k) & i = k + 1 \end{cases}$$

For  $i = 1, \dots, k$ , let  $\boldsymbol{\delta}_i(\mathbf{x})$  be a  $(k + 1)$  column vector with  $i$ th entry equal to 1,  $k + 1$  entry equal to  $\mathbf{x}$ , and all other entries 0. The derivative of  $p_o(Y = i|\mathbf{x})$  with respect to  $\boldsymbol{\beta}$  are

$$\frac{\partial p_o(Y = i|\mathbf{x})}{\partial \boldsymbol{\beta}} = \begin{cases} F'(\alpha_1 + \mathbf{x}'\boldsymbol{\beta}_s)\boldsymbol{\delta}_1(\mathbf{x}) & i = 1 \\ F'(\alpha_i + \mathbf{x}'\boldsymbol{\beta}_s)\boldsymbol{\delta}_i(\mathbf{x}) - F'(\alpha_{i-1} + \mathbf{x}'\boldsymbol{\beta}_s)\boldsymbol{\delta}_{i-1}(\mathbf{x}) & i = 2, \dots, k \\ -F'(\alpha_k + \mathbf{x}'\boldsymbol{\beta}_s)\boldsymbol{\delta}_k(\mathbf{x}) & i = k + 1 \end{cases}$$

The cumulative posterior probabilities are

$$p(Y \leq i|\mathbf{x}) = \frac{\sum_{j=1}^i p_o(Y = j|\mathbf{x})p(Y = j)}{\sum_{j=1}^{k+1} p_o(Y = j|\mathbf{x})p(Y = j)} = \sum_{j=1}^i p(Y = j|\mathbf{x}) \quad i = 1, \dots, k + 1$$

Their derivatives are

$$\frac{\partial p(Y \leq i|\mathbf{x})}{\partial \boldsymbol{\beta}} = \sum_{j=1}^i \frac{\partial p(Y = j|\mathbf{x})}{\partial \boldsymbol{\beta}} \quad i = 1, \dots, k + 1$$

In the delta-method equation for the variance, replace  $p(Y = \cdot|\mathbf{x})$  with  $p(Y \leq \cdot|\mathbf{x})$ .

Finally, for the cumulative response model, use

$$\begin{aligned} \widehat{p}_o(Y \leq i|\mathbf{x}) &= F(\widehat{\eta}_i) \quad i = 1, \dots, k \\ \widehat{p}_o(Y \leq k + 1|\mathbf{x}) &= 1 \\ \frac{\partial p_o(Y \leq i|\mathbf{x})}{\partial \boldsymbol{\beta}} &= F'(\alpha_i + \mathbf{x}'\boldsymbol{\beta}_s)\boldsymbol{\delta}_i(\mathbf{x}) \quad i = 1, \dots, k \\ \frac{\partial p_o(Y \leq k + 1|\mathbf{x})}{\partial \boldsymbol{\beta}} &= 0 \end{aligned}$$

**Generalized Logit Model**

Consider the last response level ( $Y=k+1$ ) as the reference. Let  $\beta_1, \dots, \beta_k$  be the (intercept and slope) parameter vectors for the first  $k$  logits, respectively. Denote  $\beta = (\beta'_1, \dots, \beta'_k)'$ . Let  $\eta = (\eta_1, \dots, \eta_k)'$  with

$$\eta_i = \eta_i(\beta) = \mathbf{x}'\beta_i \quad i = 1, \dots, k$$

Estimates of  $\eta_1, \dots, \eta_k$  are obtained by substituting the maximum likelihood estimate  $\hat{\beta}$  for  $\beta$ .

The predicted probabilities are

$$\begin{aligned} \widehat{p}_o(Y = k + 1|\mathbf{x}) &\equiv \Pr(Y = k + 1|\mathbf{x}) = \frac{1}{1 + \sum_{l=1}^k \exp(\hat{\eta}_l)} \\ \widehat{p}_o(Y = i|\mathbf{x}) &\equiv \Pr(Y = i|\mathbf{x}) = \widehat{p}_o(Y = k + 1|\mathbf{x}) \exp(\eta_i), i = 1, \dots, k \end{aligned}$$

The derivative of  $p_o(Y = i|\mathbf{x})$  with respect to  $\beta$  are

$$\begin{aligned} \frac{\partial p_o(Y = i|\mathbf{x})}{\partial \beta} &= \frac{\partial \eta}{\partial \beta} \frac{\partial p_o(Y = i|\mathbf{x})}{\partial \eta} \\ &= (I_k \otimes \mathbf{x}) \left( \frac{\partial p_o(Y = i|\mathbf{x})}{\partial \eta_1}, \dots, \frac{\partial p_o(Y = i|\mathbf{x})}{\partial \eta_k} \right)' \end{aligned}$$

where

$$\frac{\partial p_o(Y = i|\mathbf{x})}{\partial \eta_j} = \begin{cases} p_o(Y = i|\mathbf{x})(1 - p_o(Y = i|\mathbf{x})) & j = i \\ -p_o(Y = i|\mathbf{x})p_o(Y = j|\mathbf{x}) & \text{otherwise} \end{cases}$$

**Special Case of Binary Response Model with No Priors**

Let  $\beta$  be the vector of regression parameters. Let

$$\eta = \eta(\beta) = \mathbf{x}'\beta$$

The variance of  $\hat{\eta}$  is given by

$$\text{Var}(\hat{\eta}) = \mathbf{x}'\text{Var}(\hat{\beta})\mathbf{x}$$

A  $100(1 - \alpha)$  percent confidence interval for  $\eta$  is

$$\hat{\eta} \pm z_{1-\alpha/2} \sqrt{\widehat{\text{Var}}(\hat{\eta})}$$

Estimates of  $p_o(Y = 1|\mathbf{x})$  and confidence intervals for the  $p_o(Y = 1|\mathbf{x})$  are obtained by back-transforming  $\hat{\eta}$  and the confidence intervals for  $\eta$ , respectively. That is,

$$\widehat{p}_o(Y = 1|\mathbf{x}) = F(\hat{\eta})$$

and the confidence intervals are

$$F \left( \hat{\eta} \pm z_{1-\alpha/2} \sqrt{\widehat{\text{Var}}(\hat{\eta})} \right)$$

## Conditional Logistic Regression

The method of maximum likelihood described in the preceding sections relies on large-sample asymptotic normality for the validity of estimates and especially of their standard errors. When you do not have a large sample size compared to the number of parameters, this approach might be inappropriate and might result in biased inferences. This situation typically arises when your data are stratified and you fit intercepts to each stratum so that the number of parameters is of the same order as the sample size. For example, in a 1:1 matched pairs study with  $n$  pairs and  $p$  covariates, you would estimate  $n - 1$  intercept parameters and  $p$  slope parameters. Taking the stratification into account by “conditioning out” (and not estimating) the stratum-specific intercepts gives consistent and asymptotically normal MLEs for the slope coefficients. See Breslow and Day (1980) and Stokes, Davis, and Koch (2012) for more information. If your nuisance parameters are not just stratum-specific intercepts, you can perform an [exact conditional logistic regression](#).

### Computational Details

For each stratum  $h$ ,  $h = 1, \dots, H$ , number the observations as  $i = 1, \dots, n_h$  so that  $hi$  indexes the  $i$ th observation in stratum  $h$ . Denote the  $p$  covariates for the  $hi$ th observation as  $\mathbf{x}_{hi}$  and its binary response as  $y_{hi}$ , and let  $\mathbf{y} = (y_{11}, \dots, y_{1n_1}, \dots, y_{H1}, \dots, y_{Hn_H})'$ ,  $\mathbf{X}_h = (\mathbf{x}_{h1} \dots \mathbf{x}_{hn_h})'$ , and  $\mathbf{X} = (\mathbf{X}'_1 \dots \mathbf{X}'_H)'$ . Let the dummy variables  $z_h$ ,  $h = 1, \dots, H$ , be indicator functions for the strata ( $z_h = 1$  if the observation is in stratum  $h$ ), and denote  $\mathbf{z}_{hi} = (z_1, \dots, z_H)$  for the  $hi$ th observation,  $\mathbf{Z}_h = (\mathbf{z}_{h1} \dots \mathbf{z}_{hn_h})'$ , and  $\mathbf{Z} = (\mathbf{Z}'_1 \dots \mathbf{Z}'_H)'$ . Denote  $\mathbf{X}^* = (\mathbf{Z}|\mathbf{X})$  and  $\mathbf{x}^*_{hi} = (\mathbf{z}'_{hi}|\mathbf{x}'_{hi})'$ . Arrange the observations in each stratum  $h$  so that  $y_{hi} = 1$  for  $i = 1, \dots, m_h$ , and  $y_{hi} = 0$  for  $i = m_h + 1, \dots, n_h$ . Suppose all observations have unit frequency.

Consider the binary logistic regression model on page 4163 written as

$$\text{logit}(\boldsymbol{\pi}) = \mathbf{X}^* \boldsymbol{\theta}$$

where the parameter vector  $\boldsymbol{\theta} = (\boldsymbol{\alpha}', \boldsymbol{\beta}')'$  consists of  $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_H)'$ ,  $\alpha_h$  is the intercept for stratum  $h$ ,  $h = 1, \dots, H$ , and  $\boldsymbol{\beta}$  is the parameter vector for the  $p$  covariates.

From the section “Determining Observations for Likelihood Contributions” on page 4239, you can write the likelihood contribution of observation  $hi$ ,  $i = 1, \dots, n_h$ ,  $h = 1, \dots, H$ , as

$$L_{hi}(\boldsymbol{\theta}) = \frac{e^{y_{hi}\mathbf{x}^*_{hi}'\boldsymbol{\theta}}}{1 + e^{\mathbf{x}^*_{hi}'\boldsymbol{\theta}}}$$

where  $y_{hi} = 1$  when the response takes Ordered Value 1, and  $y_{hi} = 0$  otherwise.

The full likelihood is

$$L(\boldsymbol{\theta}) = \prod_{h=1}^H \prod_{i=1}^{n_h} L_{hi}(\boldsymbol{\theta}) = \frac{e^{\mathbf{y}'\mathbf{X}^*\boldsymbol{\theta}}}{\prod_{h=1}^H \prod_{i=1}^{n_h} (1 + e^{\mathbf{x}^*_{hi}'\boldsymbol{\theta}})}$$

Unconditional likelihood inference is based on maximizing this likelihood function.

When your nuisance parameters are the stratum-specific intercepts  $(\alpha_1, \dots, \alpha_H)'$ , and the slopes  $\boldsymbol{\beta}$  are your parameters of interest, “conditioning out” the nuisance parameters produces the conditional likelihood (Lachin 2000)

$$L(\boldsymbol{\beta}) = \prod_{h=1}^H L_h(\boldsymbol{\beta}) = \prod_{h=1}^H \frac{\prod_{i=1}^{m_h} \exp(\mathbf{x}'_{hi}\boldsymbol{\beta})}{\sum \prod_{j=j_1}^{j_{m_h}} \exp(\mathbf{x}'_{hj}\boldsymbol{\beta})}$$

where the summation is over all  $\binom{n_h}{m_h}$  subsets  $\{j_1, \dots, j_{m_h}\}$  of  $m_h$  observations chosen from the  $n_h$  observations in stratum  $h$ . Note that the nuisance parameters have been factored out of this equation.

For conditional asymptotic inference, maximum likelihood estimates  $\hat{\beta}$  of the regression parameters are obtained by maximizing the conditional likelihood, and asymptotic results are applied to the conditional likelihood function and the maximum likelihood estimators. A relatively fast method of computing this conditional likelihood and its derivatives is given by Gail, Lubin, and Rubinstein (1981) and Howard (1972). The optimization techniques can be controlled by specifying the **NLOPTIONS** statement.

Sometimes the log likelihood converges but the estimates diverge. This condition is flagged by having inordinately large standard errors for some of your parameter estimates, and can be monitored by specifying the **ITPRINT** option. Unfortunately, broad existence criteria such as those discussed in the section “**Existence of Maximum Likelihood Estimates**” on page 4242 do not exist for this model. It might be possible to circumvent such a problem by standardizing your independent variables before fitting the model.

### Regression Diagnostic Details

Diagnostics are used to indicate observations that might have undue influence on the model fit or that might be outliers. Further investigation should be performed before removing such an observation from the data set.

The derivations in this section use an augmentation method described by Storer and Crowley (1985), which provides an estimate of the “one-step” **DFBETAS** estimates advocated by Pregibon (1984). The method also provides estimates of conditional stratum-specific predicted values, residuals, and leverage for each observation. The augmentation method can take a lot of time and memory.

Following Storer and Crowley (1985), the log-likelihood contribution can be written as

$$l_h = \log(L_h) = \mathbf{y}'_h \boldsymbol{\gamma}_h - a(\boldsymbol{\gamma}_h) \quad \text{where}$$

$$a(\boldsymbol{\gamma}_h) = \log \left[ \sum_{j=j_1}^{j_{m_h}} \prod_{j=j_1}^{j_{m_h}} \exp(\boldsymbol{\gamma}_{hj}) \right]$$

and the  $h$  subscript on matrices indicates the submatrix for the stratum,  $\boldsymbol{\gamma}_h = (\gamma_{h1}, \dots, \gamma_{hn_h})'$ , and  $\gamma_{hi} = \mathbf{x}'_{hi} \boldsymbol{\beta}$ . Then the gradient and information matrix are

$$\mathbf{g}(\boldsymbol{\beta}) = \left\{ \frac{\partial l_h}{\partial \boldsymbol{\beta}} \right\}_{h=1}^H = \mathbf{X}'(\mathbf{y} - \boldsymbol{\pi})$$

$$\boldsymbol{\Lambda}(\boldsymbol{\beta}) = \left\{ \frac{\partial^2 l_h}{\partial \boldsymbol{\beta}^2} \right\}_{h=1}^H = \mathbf{X}' \text{diag}(\mathbf{U}_1, \dots, \mathbf{U}_H) \mathbf{X}$$

where

$$\begin{aligned}\pi_{hi} &= \frac{\partial a(\boldsymbol{\gamma}_h)}{\partial \gamma_{hi}} = \frac{\sum_{j(i)} \prod_{j=j_1}^{j_{m_h}} \exp(\gamma_{hj})}{\sum \prod_{j=j_1}^{j_{m_h}} \exp(\gamma_{hj})} \\ \boldsymbol{\pi}_h &= (\pi_{h1}, \dots, \pi_{hn_h}) \\ \mathbf{U}_h &= \frac{\partial^2 a(\boldsymbol{\gamma}_h)}{\partial \boldsymbol{\gamma}_h^2} = \left\{ \frac{\partial^2 a(\boldsymbol{\gamma}_h)}{\partial \gamma_{hi} \partial \gamma_{hj}} \right\} = \{a_{ij}\} \\ a_{ij} &= \frac{\sum_{k(i,j)} \prod_{k=k_1}^{k_{m_h}} \exp(\gamma_{hk})}{\sum \prod_{k=k_1}^{k_{m_h}} \exp(\gamma_{hk})} - \frac{\partial a(\boldsymbol{\gamma}_h)}{\partial \gamma_{hi}} \frac{\partial a(\boldsymbol{\gamma}_h)}{\partial \gamma_{hj}} = \pi_{hij} - \pi_{hi} \pi_{hj}\end{aligned}$$

and where  $\pi_{hi}$  is the conditional stratum-specific probability that subject  $i$  in stratum  $h$  is a case, the summation on  $j(i)$  is over all subsets from  $\{1, \dots, n_h\}$  of size  $m_h$  that contain the index  $i$ , and the summation on  $k(i, j)$  is over all subsets from  $\{1, \dots, n_h\}$  of size  $m_h$  that contain the indices  $i$  and  $j$ .

To produce the true one-step estimate  $\boldsymbol{\beta}_{hi}^1$ , start at the MLE  $\widehat{\boldsymbol{\beta}}$ , delete the  $h$ th observation, and use this reduced data set to compute the next Newton-Raphson step. Note that if there is only one event or one nonevent in a stratum, deletion of that single observation is equivalent to deletion of the entire stratum. The augmentation method does not take this into account.

The augmented model is

$$\text{logit}(\Pr(y_{hi} = 1 | \mathbf{x}_{hi})) = \mathbf{x}'_{hi} \boldsymbol{\beta} + \mathbf{z}'_{hi} \gamma$$

where  $\mathbf{z}_{hi} = (0, \dots, 0, 1, 0, \dots, 0)'$  has a 1 in the  $h$ th coordinate, and use  $\boldsymbol{\beta}^0 = (\widehat{\boldsymbol{\beta}}', 0)'$  as the initial estimate for  $(\boldsymbol{\beta}', \gamma)'$ . The gradient and information matrix before the step are

$$\begin{aligned}\mathbf{g}(\boldsymbol{\beta}^0) &= \begin{bmatrix} \mathbf{X}' \\ \mathbf{z}'_{hi} \end{bmatrix} (\mathbf{y} - \boldsymbol{\pi}) = \begin{bmatrix} \mathbf{0} \\ y_{hi} - \pi_{hi} \end{bmatrix} \\ \boldsymbol{\Lambda}(\boldsymbol{\beta}^0) &= \begin{bmatrix} \mathbf{X}' \\ \mathbf{z}'_{hi} \end{bmatrix} \mathbf{U} [\mathbf{X} \quad \mathbf{z}_{hi}] = \begin{bmatrix} \boldsymbol{\Lambda}(\boldsymbol{\beta}) & \mathbf{X}' \mathbf{U} \mathbf{z}_{hi} \\ \mathbf{z}'_{hi} \mathbf{U} \mathbf{X} & \mathbf{z}'_{hi} \mathbf{U} \mathbf{z}_{hi} \end{bmatrix}\end{aligned}$$

Inserting the  $\boldsymbol{\beta}^0$  and  $(\mathbf{X}', \mathbf{z}'_{hi})'$  into the Gail, Lubin, and Rubinstein (1981) algorithm provides the appropriate estimates of  $\mathbf{g}(\boldsymbol{\beta}^0)$  and  $\boldsymbol{\Lambda}(\boldsymbol{\beta}^0)$ . Indicate these estimates with  $\widehat{\boldsymbol{\pi}} = \boldsymbol{\pi}(\widehat{\boldsymbol{\beta}})$ ,  $\widehat{\mathbf{U}} = \mathbf{U}(\widehat{\boldsymbol{\beta}})$ ,  $\widehat{\mathbf{g}}$ , and  $\widehat{\boldsymbol{\Lambda}}$ .

DFBETA is computed from the information matrix as

$$\begin{aligned}\Delta_{hi} \boldsymbol{\beta} &= \boldsymbol{\beta}^0 - \boldsymbol{\beta}_{hi}^1 \\ &= -\widehat{\boldsymbol{\Lambda}}^{-1}(\boldsymbol{\beta}^0) \widehat{\mathbf{g}}(\boldsymbol{\beta}^0) \\ &= -\widehat{\boldsymbol{\Lambda}}^{-1}(\widehat{\boldsymbol{\beta}}) (\mathbf{X}' \widehat{\mathbf{U}} \mathbf{z}_{hi}) \mathbf{M}^{-1} \mathbf{z}'_{hi} (\mathbf{y} - \widehat{\boldsymbol{\pi}})\end{aligned}$$

where

$$\mathbf{M} = (\mathbf{z}'_{hi} \widehat{\mathbf{U}} \mathbf{z}_{hi}) - (\mathbf{z}'_{hi} \widehat{\mathbf{U}} \mathbf{X}) \widehat{\boldsymbol{\Lambda}}^{-1}(\widehat{\boldsymbol{\beta}}) (\mathbf{X}' \widehat{\mathbf{U}} \mathbf{z}_{hi})$$

For each observation in the data set, a DFBETA statistic is computed for each parameter  $\beta_j$ ,  $1 \leq j \leq p$ , and standardized by the standard error of  $\beta_j$  from the full data set to produce the estimate of DFBETAS.

The estimated leverage is defined as

$$h_{hi} = \frac{\text{trace}\{(\mathbf{z}'_{hi} \widehat{\mathbf{U}} \mathbf{X}) \widehat{\mathbf{\Lambda}}^{-1}(\widehat{\boldsymbol{\beta}}) (\mathbf{X}' \widehat{\mathbf{U}} \mathbf{z}_{hi})\}}{\text{trace}\{\mathbf{z}'_{hi} \widehat{\mathbf{U}} \mathbf{z}_{hi}\}}$$

This definition of leverage produces different values from those defined by Pregibon (1984); Moolgavkar, Lustbader, and Venzon (1985); Hosmer and Lemeshow (2000); however, it has the advantage that no extra computations beyond those for the DFBETAS are required.

The estimated residuals  $e_{hi} = y_{hi} - \widehat{\pi}_{hi}$  are obtained from  $\widehat{\mathbf{g}}(\boldsymbol{\beta}^0)$ , and the weights, or predicted probabilities, are then  $\widehat{\pi}_{hi} = y_{hi} - e_{hi}$ . The residuals are standardized and reported as (estimated) Pearson residuals:

$$\frac{r_{hi} - n_{hi} \widehat{\pi}_{hi}}{\sqrt{n_{hi} \widehat{\pi}_{hi} (1 - \widehat{\pi}_{hi})}}$$

where  $r_{hi}$  is the number of events in the observation and  $n_{hi}$  is the number of trials.

The STDRES option in the INFLUENCE and PLOTS=INFLUENCE options computes the standardized Pearson residual:

$$e_{s,hi} = \frac{e_{hi}}{\sqrt{1 - h_{hi}}}$$

For events/trials MODEL statement syntax, treat each observation as two observations (the first for the nonevents and the second for the events) with frequencies  $f_{h,2i-1} = n_{hi} - r_{hi}$  and  $f_{h,2i} = r_{hi}$ , and augment the model with a matrix  $\mathbf{Z}_{hi} = [\mathbf{z}_{h,2i-1} \mathbf{z}_{h,2i}]$  instead of a single  $\mathbf{z}_{hi}$  vector. Writing  $\gamma_{hi} = \mathbf{x}'_{hi} \boldsymbol{\beta}$  in the preceding section results in the following gradient and information matrix:

$$\mathbf{g}(\boldsymbol{\beta}^0) = \begin{bmatrix} \mathbf{0} \\ f_{h,2i-1}(y_{h,2i-1} - \pi_{h,2i-1}) \\ f_{h,2i}(y_{h,2i} - \pi_{h,2i}) \end{bmatrix}$$

$$\mathbf{\Lambda}(\boldsymbol{\beta}^0) = \begin{bmatrix} \mathbf{\Lambda}(\boldsymbol{\beta}) & \mathbf{X}' \text{diag}(\mathbf{f}) \text{Udiag}(\mathbf{f}) \mathbf{Z}_{hi} \\ \mathbf{Z}'_{hi} \text{diag}(\mathbf{f}) \text{Udiag}(\mathbf{f}) \mathbf{X} & \mathbf{Z}'_{hi} \text{diag}(\mathbf{f}) \text{Udiag}(\mathbf{f}) \mathbf{Z}_{hi} \end{bmatrix}$$

The predicted probabilities are then  $\widehat{\pi}_{hi} = y_{h,2i} - e_{h,2i} / r_{h,2i}$ , while the leverage and the DFBETAS are produced from  $\mathbf{\Lambda}(\boldsymbol{\beta}^0)$  in a fashion similar to that for the preceding single-trial equations.

---

## Exact Conditional Logistic Regression

The theory of exact logistic regression, also known as exact conditional logistic regression, was originally laid out by Cox (1970), and the computational methods employed in PROC LOGISTIC are described in Hirji, Mehta, and Patel (1987); Hirji (1992); Mehta, Patel, and Senchaudhuri (1992). Other useful references for the derivations include Cox and Snell (1989); Agresti (1990); Mehta and Patel (1995).

Exact conditional inference is based on generating the conditional distribution for the sufficient statistics of the parameters of interest. This distribution is called the *permutation* or *exact conditional* distribution. Using the notation in the section “Computational Details” on page 4271, follow Mehta and Patel (1995) and

first note that the sufficient statistics  $\mathbf{T} = (T_1, \dots, T_p)$  for the parameter vector of intercepts and slopes,  $\boldsymbol{\beta}$ , are

$$T_j = \sum_{i=1}^n y_i x_{ij}, \quad j = 1, \dots, p$$

Denote a vector of observable sufficient statistics as  $\mathbf{t} = (t_1, \dots, t_p)'$ .

The probability density function (PDF) for  $\mathbf{T}$  can be created by summing over all binary sequences  $\mathbf{y}$  that generate an observable  $\mathbf{t}$  and letting  $C(\mathbf{t}) = |\{\mathbf{y} : \mathbf{y}'\mathbf{X} = \mathbf{t}\}|$  denote the number of sequences  $\mathbf{y}$  that generate  $\mathbf{t}$

$$\Pr(\mathbf{T} = \mathbf{t}) = \frac{C(\mathbf{t}) \exp(\mathbf{t}'\boldsymbol{\beta})}{\prod_{i=1}^n [1 + \exp(\mathbf{x}_i'\boldsymbol{\beta})]}$$

In order to condition out the nuisance parameters, partition the parameter vector  $\boldsymbol{\beta} = (\boldsymbol{\beta}'_N, \boldsymbol{\beta}'_I)'$ , where  $\boldsymbol{\beta}_N$  is a  $p_N \times 1$  vector of the nuisance parameters, and  $\boldsymbol{\beta}_I$  is the parameter vector for the remaining  $p_I = p - p_N$  parameters of interest. Likewise, partition  $\mathbf{X}$  into  $\mathbf{X}_N$  and  $\mathbf{X}_I$ ,  $\mathbf{T}$  into  $\mathbf{T}_N$  and  $\mathbf{T}_I$ , and  $\mathbf{t}$  into  $\mathbf{t}_N$  and  $\mathbf{t}_I$ . The nuisance parameters can be removed from the analysis by conditioning on their sufficient statistics to create the conditional likelihood of  $\mathbf{T}_I$  given  $\mathbf{T}_N = \mathbf{t}_N$ ,

$$\begin{aligned} \Pr(\mathbf{T}_I = \mathbf{t}_I | \mathbf{T}_N = \mathbf{t}_N) &= \frac{\Pr(\mathbf{T} = \mathbf{t})}{\Pr(\mathbf{T}_N = \mathbf{t}_N)} \\ &= f_{\boldsymbol{\beta}_I}(\mathbf{t}_I | \mathbf{t}_N) = \frac{C(\mathbf{t}_N, \mathbf{t}_I) \exp(\mathbf{t}'_I \boldsymbol{\beta}_I)}{\sum_{\mathbf{u}} C(\mathbf{t}_N, \mathbf{u}) \exp(\mathbf{u}' \boldsymbol{\beta}_I)} \end{aligned}$$

where  $C(\mathbf{t}_N, \mathbf{u})$  is the number of vectors  $\mathbf{y}$  such that  $\mathbf{y}'\mathbf{X}_N = \mathbf{t}_N$  and  $\mathbf{y}'\mathbf{X}_I = \mathbf{u}$ . Note that the nuisance parameters have factored out of this equation, and that  $C(\mathbf{t}_N, \mathbf{t}_I)$  is a constant.

The goal of the exact conditional analysis is to determine how likely the observed response  $\mathbf{y}_0$  is with respect to all  $2^n$  possible responses  $\mathbf{y} = (y_1, \dots, y_n)'$ . One way to proceed is to generate every  $\mathbf{y}$  vector for which  $\mathbf{y}'\mathbf{X}_N = \mathbf{t}_N$ , and count the number of vectors  $\mathbf{y}$  for which  $\mathbf{y}'\mathbf{X}_I$  is equal to each unique  $\mathbf{t}_I$ . Generating the conditional distribution from complete enumeration of the joint distribution is conceptually simple; however, this method becomes computationally infeasible very quickly. For example, if you had only 30 observations, you would have to scan through  $2^{30}$  different  $\mathbf{y}$  vectors.

Several algorithms are available in PROC LOGISTIC to generate the exact distribution. All of the algorithms are based on the following observation. Given any  $\mathbf{y} = (y_1, \dots, y_n)'$  and a design  $\mathbf{X} = (\mathbf{x}_1, \dots, \mathbf{x}_n)'$ , let  $\mathbf{y}_{(i)} = (y_1, \dots, y_i)'$  and  $\mathbf{X}_{(i)} = (\mathbf{x}_1, \dots, \mathbf{x}_i)'$  be the first  $i$  rows of each matrix. Write the sufficient statistic based on these  $i$  rows as  $\mathbf{t}_{(i)} = \mathbf{y}_{(i)}'\mathbf{X}_{(i)}$ . A recursion relation results:  $\mathbf{t}_{(i+1)} = \mathbf{t}_{(i)} + y_{i+1}\mathbf{x}_{i+1}$ .

The following methods are available:

- The *multivariate shift algorithm* developed by Hirji, Mehta, and Patel (1987), which steps through the recursion relation by adding one observation at a time and building an intermediate distribution at each step. If it determines that  $\mathbf{t}_{(i)}$  for the nuisance parameters could eventually equal  $\mathbf{t}$ , then  $\mathbf{t}_{(i)}$  is added to the intermediate distribution.
- An extension of the multivariate shift algorithm to generalized logit models by Hirji (1992). Since the generalized logit model fits a new set of parameters to each logit, the number of parameters in the

model can easily get too large for this algorithm to handle. Note for these models that the hypothesis tests for each effect are computed across the logit functions, while individual parameters are estimated for each logit function.

- A network algorithm described in Mehta, Patel, and Senchaudhuri (1992), which builds a network for each parameter that you are conditioning out in order to identify feasible  $y_i$  for the  $\mathbf{y}$  vector. These networks are combined and the set of feasible  $y_i$  is further reduced, and then the multivariate shift algorithm uses this knowledge to build the exact distribution without adding as many intermediate  $t_{(i+1)}$  as the multivariate shift algorithm does.
- A hybrid Monte Carlo and network algorithm described by Mehta, Patel, and Senchaudhuri (2000), which extends their 1992 algorithm by sampling from the combined network to build the exact distribution.

The bulk of the computation time and memory for these algorithms is consumed by the creation of the networks and the exact joint distribution. After the joint distribution for a set of effects is created, the computational effort required to produce hypothesis tests and parameter estimates for any subset of the effects is (relatively) trivial. See the section “Computational Resources for Exact Logistic Regression” on page 4284 for more computational notes about exact analyses.

**NOTE:** An alternative to using these exact conditional methods is to perform Firth’s bias-reducing penalized likelihood method (see the **FIRTH** option in the **MODEL** statement); this method has the advantage of being much faster and less memory intensive than exact algorithms, but it might not converge to a solution.

## Hypothesis Tests

Consider testing the null hypothesis  $H_0: \boldsymbol{\beta}_I = \mathbf{0}$  against the alternative  $H_A: \boldsymbol{\beta}_I \neq \mathbf{0}$ , conditional on  $\mathbf{T}_N = \mathbf{t}_N$ . Under the null hypothesis, the test statistic for the *exact probability test* is just  $f_{\boldsymbol{\beta}_I=\mathbf{0}}(\mathbf{t}_I|\mathbf{t}_N)$ , while the corresponding  $p$ -value is the probability of getting a less likely (more extreme) statistic,

$$p(\mathbf{t}_I|\mathbf{t}_N) = \sum_{\mathbf{u} \in \Omega_p} f_0(\mathbf{u}|\mathbf{t}_N)$$

where  $\Omega_p = \{\mathbf{u}: \text{there exist } \mathbf{y} \text{ with } \mathbf{y}'\mathbf{X}_I = \mathbf{u}, \mathbf{y}'\mathbf{X}_N = \mathbf{t}_N, \text{ and } f_0(\mathbf{u}|\mathbf{t}_N) \leq f_0(\mathbf{t}_I|\mathbf{t}_N)\}$ .

For the *exact conditional scores test*, the conditional mean  $\boldsymbol{\mu}_I$  and variance matrix  $\boldsymbol{\Sigma}_I$  of the  $\mathbf{T}_I$  (conditional on  $\mathbf{T}_N = \mathbf{t}_N$ ) are calculated, and the score statistic for the observed value,

$$s = (\mathbf{t}_I - \boldsymbol{\mu}_I)' \boldsymbol{\Sigma}_I^{-1} (\mathbf{t}_I - \boldsymbol{\mu}_I)$$

is compared to the score for each member of the distribution

$$S(\mathbf{T}_I) = (\mathbf{T}_I - \boldsymbol{\mu}_I)' \boldsymbol{\Sigma}_I^{-1} (\mathbf{T}_I - \boldsymbol{\mu}_I)$$

The resulting  $p$ -value is

$$p(\mathbf{t}_I|\mathbf{t}_N) = \Pr(S \geq s) = \sum_{\mathbf{u} \in \Omega_s} f_0(\mathbf{u}|\mathbf{t}_N)$$

where  $\Omega_s = \{\mathbf{u}: \text{there exist } \mathbf{y} \text{ with } \mathbf{y}'\mathbf{X}_I = \mathbf{u}, \mathbf{y}'\mathbf{X}_N = \mathbf{t}_N, \text{ and } S(\mathbf{u}) \geq s\}$ .

The mid- $p$  statistic, defined as

$$p(\mathbf{t}_I|\mathbf{t}_N) - \frac{1}{2}f_0(\mathbf{t}_I|\mathbf{t}_N)$$

was proposed by Lancaster (1961) to compensate for the discreteness of a distribution. See Agresti (1992) for more information. However, to allow for more flexibility in handling ties, you can write the mid- $p$  statistic as (based on a suggestion by Lamotte (2002) and generalizing Vollset, Hirji, and Afifi (1991))

$$\sum_{u \in \Omega_{<}} f_0(\mathbf{u}|\mathbf{t}_N) + \delta_1 f_0(\mathbf{t}_I|\mathbf{t}_N) + \delta_2 \sum_{u \in \Omega_{=}} f_0(\mathbf{u}|\mathbf{t}_N)$$

where, for  $i \in \{p, s\}$ ,  $\Omega_{<}$  is  $\Omega_i$  using strict inequalities, and  $\Omega_{=}$  is  $\Omega_i$  using equalities with the added restriction that  $\mathbf{u} \neq \mathbf{t}_I$ . Letting  $(\delta_1, \delta_2) = (0.5, 1.0)$  yields Lancaster's mid- $p$ .

**CAUTION:** When the exact distribution has ties and `METHOD=NETWORKMCMC` is specified, the Monte Carlo algorithm estimates  $p(\mathbf{t}|\mathbf{t}_N)$  with error, and hence it cannot determine precisely which values contribute to the reported  $p$ -values. For example, if the exact distribution has densities  $\{0.2, 0.2, 0.2, 0.4\}$  and if the observed statistic has probability 0.2, then the exact probability  $p$ -value is exactly 0.6. Under Monte Carlo sampling, if the densities after  $N$  samples are  $\{0.18, 0.21, 0.23, 0.38\}$  and the observed probability is 0.21, then the resulting  $p$ -value is 0.39. Therefore, the exact probability test  $p$ -value for this example fluctuates between 0.2, 0.4, and 0.6, and the reported  $p$ -values are actually lower bounds for the true  $p$ -values. If you need more precise values, you can specify the `OUTDIST=` option, determine appropriate cutoff values for the observed probability and score, and then construct the true  $p$ -value estimates from the `OUTDIST=` data set and display them in the SAS log by using the following statements:

```
data _null_;
 set outdist end=end;
 retain pvalueProb 0 pvalueScore 0;
 if prob < ProbCutOff then pvalueProb+prob;
 if score > ScoreCutOff then pvalueScore+prob;
 if end then put pvalueProb= pvalueScore=;
run;
```

## Inference for a Single Parameter

Exact parameter estimates are derived for a single parameter  $\beta_i$  by regarding all the other parameters  $\boldsymbol{\beta}_N = (\beta_1, \dots, \beta_{i-1}, \beta_{i+1}, \dots, \beta_{p_N+p_I})'$  as nuisance parameters. The appropriate sufficient statistics are  $\mathbf{T}_I = T_i$  and  $\mathbf{T}_N = (T_1, \dots, T_{i-1}, T_{i+1}, \dots, T_{p_N+p_I})'$ , with their observed values denoted by the lowercase  $t$ . Hence, the conditional PDF used to create the parameter estimate for  $\beta_i$  is

$$f_{\beta_i}(t_i|\mathbf{t}_N) = \frac{C(\mathbf{t}_N, t_i) \exp(t_i \beta_i)}{\sum_{u \in \Omega} C(\mathbf{t}_N, u) \exp(u \beta_i)}$$

for  $\Omega = \{u: \text{there exist } y \text{ with } T_i = u \text{ and } \mathbf{T}_N = \mathbf{t}_N\}$ .

The maximum exact conditional likelihood estimate is the quantity  $\hat{\beta}_i$ , which maximizes the conditional PDF. A Newton-Raphson algorithm is used to perform this search. However, if the observed  $t_i$  attains either its maximum or minimum value in the exact distribution (that is, either  $t_i = \min\{u : u \in \Omega\}$  or  $t_i = \max\{u : u \in \Omega\}$ ), then the conditional PDF is monotonically increasing in  $\beta_i$  and cannot be maximized. In this case, a median unbiased estimate (Hirji, Tsiatis, and Mehta 1989)  $\hat{\beta}_i$  is produced that satisfies  $f_{\hat{\beta}_i}(t_i|\mathbf{t}_N) = 0.5$ , and a Newton-Raphson algorithm is used to perform the search.

The standard error of the exact conditional likelihood estimate is just the negative of the inverse of the second derivative of the exact conditional log likelihood (Agresti 2002).

Likelihood ratio tests based on the conditional PDF are used to test the null  $H_0: \beta_i = 0$  against the alternative  $H_A: \beta_i > 0$ . The critical region for this UMP test consists of the upper tail of values for  $T_i$  in the exact distribution. Thus, the one-sided significance level  $p_+(t_i; 0)$  is

$$p_+(t_i; 0) = \sum_{u \geq t_i} f_0(u | \mathbf{t}_N)$$

Similarly, the one-sided significance level  $p_-(t_i; 0)$  against  $H_A: \beta_i < 0$  is

$$p_-(t_i; 0) = \sum_{u \leq t_i} f_0(u | \mathbf{t}_N)$$

The two-sided significance level  $p(t_i; 0)$  against  $H_A: \beta_i \neq 0$  is calculated as

$$p(t_i; 0) = 2 \min[p_-(t_i; 0), p_+(t_i; 0)]$$

An upper  $100(1 - 2\epsilon)\%$  exact confidence limit for  $\hat{\beta}_i$  corresponding to the observed  $t_i$  is the solution  $\beta_U(t_i)$  of  $\epsilon = p_-(t_i, \beta_U(t_i))$ , while the lower exact confidence limit is the solution  $\beta_L(t_i)$  of  $\epsilon = p_+(t_i, \beta_L(t_i))$ . Again, a Newton-Raphson procedure is used to search for the solutions. Note that one of the confidence limits for a median unbiased estimate is set to infinity, but the other is still computed at  $\epsilon$ . This results in the display of a one-sided  $100(1 - \epsilon)\%$  confidence interval; if you want the  $2\epsilon$  limit instead, you can specify the **ONESIDED** option.

Specifying the **ONESIDED** option displays only one  $p$ -value and one confidence interval, because small values of  $p_+(t_i; 0)$  and  $p_-(t_i; 0)$  support different alternative hypotheses and only one of these  $p$ -values can be less than 0.50.

The mid- $p$  confidence limits are the solutions to  $\min\{p_-(t_i, \beta(t_i)), p_+(t_i, \beta(t_i))\} - (1 - \delta_1) f_{\beta(t_i)}(t_i | \mathbf{t}_N) = \epsilon$  for  $\epsilon = \alpha/2, 1 - \alpha/2$  (Vollset, Hirji, and Afifi 1991).  $\delta_1 = 1$  produces the usual exact (or *max-p*) confidence interval,  $\delta_1 = 0.5$  yields the mid- $p$  interval, and  $\delta_1 = 0$  gives the *min-p* interval. The mean of the endpoints of the *max-p* and *min-p* intervals provides the *mean-p* interval as defined by Hirji, Mehta, and Patel (1988).

Estimates and confidence intervals for the odds ratios are produced by exponentiating the estimates and interval endpoints for the parameters.

### Notes about Exact $p$ -Values

In the “Conditional Exact Tests” table, the exact probability test is not necessarily a sum of tail areas and can be inflated if the distribution is skewed. The more robust exact conditional scores test is a sum of tail areas and is generally preferred over the exact probability test.

The  $p$ -value reported for a single parameter in the “Exact Parameter Estimates” table is twice the one-sided tail area of a likelihood ratio test against the null hypothesis of the parameter equaling zero.

## Input and Output Data Sets

### OUTEST= Output Data Set

The OUTEST= data set contains one observation for each BY group containing the maximum likelihood estimates of the regression coefficients. If you also use the COVOUT option in the PROC LOGISTIC statement, there are additional observations containing the rows of the estimated covariance matrix. If you specify SELECTION=FORWARD, BACKWARD, or STEPWISE, only the estimates of the parameters and covariance matrix for the final model are output to the OUTEST= data set.

#### *Variables in the OUTEST= Data Set*

The OUTEST= data set contains the following variables:

- any BY variables specified
- `_LINK_`, a character variable of length 8 with four possible values: CLOGLOG for the complementary log-log function, LOGIT for the logit function, NORMIT for the probit (alias normit) function, and GLOGIT for the generalized logit function
- `_TYPE_`, a character variable of length 8 with two possible values: PARMS for parameter estimates or COV for covariance estimates. If an EXACT statement is also specified, then two other values are possible: EPARMMLE for the exact maximum likelihood estimates and EPARMMUE for the exact median unbiased estimates.
- `_NAME_`, a character variable containing the name of the response variable when `_TYPE_=PARMS`, EPARMMLE, and EPARMMUE, or the name of a model parameter when `_TYPE_=COV`
- `_STATUS_`, a character variable that indicates whether the estimates have converged
- one variable for each intercept parameter
- one variable for each slope parameter and one variable for the offset variable if the OFFSET= option is specified. If an effect is not included in the final model in a model building process, the corresponding parameter estimates and covariances are set to missing values.
- `_LNLIKE_`, the log likelihood

#### *Parameter Names in the OUTEST= Data Set*

If there are only two response categories in the entire data set, the intercept parameter is named Intercept. If there are more than two response categories in the entire data set, the intercept parameters are named Intercept\_xxx, where xxx is the value (formatted if a format is applied) of the corresponding response category.

For continuous explanatory variables, the names of the parameters are the same as the corresponding variables. For CLASS variables, the parameter names are obtained by concatenating the corresponding CLASS variable name with the CLASS category; see the section “[Class Variable Naming Convention](#)” on page 4189 for more details. For interaction and nested effects, the parameter names are created by concatenating the names of each effect.

For the generalized logit model, names of parameters corresponding to each nonreference category contain `_xxx` as the suffix, where xxx is the value (formatted if a format is applied) of the corresponding nonreference

category. For example, suppose the variable Net3 represents the television network (ABC, CBS, and NBC) viewed at a certain time. The following statements fit a generalized logit model with Age and Gender (a CLASS variable with values Female and Male) as explanatory variables:

```
proc logistic;
 class Gender;
 model Net3 = Age Gender / link=glogit;
run;
```

There are two logit functions, one contrasting ABC with NBC and the other contrasting CBS with NBC. For each logit, there are three parameters: an intercept parameter, a slope parameter for Age, and a slope parameter for Gender (since there are only two gender levels and the EFFECT parameterization is used by default). The names of the parameters and their descriptions are as follows:

|                  |                                                                      |
|------------------|----------------------------------------------------------------------|
| Intercept_ABC    | intercept parameter for the logit contrasting ABC with NBC           |
| Intercept_CBS    | intercept parameter for the logit contrasting CBS with NBC           |
| Age_ABC          | Age slope parameter for the logit contrasting ABC with NBC           |
| Age_CBS          | Age slope parameter for the logit contrasting CBS with NBC           |
| GenderFemale_ABC | Gender=Female slope parameter for the logit contrasting ABC with NBC |
| GenderFemale_CBS | Gender=Female slope parameter for the logit contrasting CBS with NBC |

### INEST= Input Data Set

You can specify starting values for the iterative algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. A previous OUTEST= data set can be used as, or modified for use as, an INEST= data set.

The INEST= data set must contain the intercept variables (named Intercept for binary response models and Intercept, Intercept\_2, Intercept\_3, and so forth, for ordinal and nominal response models) and all explanatory variables in the MODEL statement. If BY processing is used, the INEST= data set should also include the BY variables, and there must be one observation for each BY group. If the INEST= data set also contains the \_TYPE\_ variable, only observations with \_TYPE\_ value 'PARMS' are used as starting values.

### OUT= Output Data Set in the OUTPUT Statement

The OUT= data set in the OUTPUT statement contains all the variables in the input data set along with statistics you request by specifying *keyword=name* options or the PREDPROBS= option in the OUTPUT statement. In addition, if you use the single-trial syntax and you request any of the XBETA=, STDXBETA=, PREDICTED=, LCL=, and UCL= options, the OUT= data set contains the automatic variable \_LEVEL\_. The value of \_LEVEL\_ identifies the response category upon which the computed values of XBETA=, STDXBETA=, PREDICTED=, LCL=, and UCL= are based.

When there are more than two response levels, only variables named by the XBETA=, STDXBETA=, PREDICTED=, LOWER=, and UPPER= options and the variables given by PREDPROBS=(INDIVIDUAL CUMULATIVE) have their values computed; the other variables have missing values. If you fit a generalized logit model, the cumulative predicted probabilities are not computed.

When there are only two response categories, each input observation produces one observation in the OUT= data set.

If there are more than two response categories and you specify only the PREDPROBS= option, then each input observation produces one observation in the OUT= data set. However, if you fit an ordinal (cumulative) model and specify options other than the PREDPROBS= options, each input observation generates as many output observations as one fewer than the number of response levels, and the predicted probabilities and their confidence limits correspond to the cumulative predicted probabilities. If you fit a generalized logit model and specify options other than the PREDPROBS= options, each input observation generates as many output observations as the number of response categories; the predicted probabilities and their confidence limits correspond to the probabilities of individual response categories.

For observations in which only the response variable is missing, values of the XBETA=, STDXBETA=, PREDICTED=, UPPER=, LOWER=, and the PREDPROBS= options are computed even though these observations do not affect the model fit. This enables, for instance, predicted probabilities to be computed for new observations.

### OUT= Output Data Set in a SCORE Statement

The OUT= data set in a SCORE statement contains all the variables in the data set being scored. The data set being scored can be either the input DATA= data set in the PROC LOGISTIC statement or the DATA= data set in the SCORE statement. The DATA= data set in the SCORE statement does not need to contain the response variable.

If the data set being scored contains the response variable, then denote the *normalized* levels (left-justified, formatted values of 16 characters or less) of your response variable Y by  $Y_1, \dots, Y_{k+1}$ . For each response level, the OUT= data set also contains the following:

- F\_Y, the normalized levels of the response variable Y in the data set being scored. If the events/trials syntax is used, the F\_Y variable is not created.
- I\_Y, the normalized levels that the observations are classified into. Note that an observation is classified into the level with the largest probability. If the events/trials syntax is used, the \_INTO\_ variable is created instead, and it contains the values EVENT and NONEVENT.
- P\_Y<sub>i</sub>, the posterior probabilities of the normalized response level Y<sub>i</sub>
- If the CLM option is specified in the SCORE statement, the OUT= data set also includes the following:
  - LCL\_Y<sub>i</sub>, the lower 100(1 – α)% confidence limits for P\_Y<sub>i</sub>
  - UCL\_Y<sub>i</sub>, the upper 100(1 – α)% confidence limits for P\_Y<sub>i</sub>

### OUTDIST= Output Data Set

The OUTDIST= data set contains every exact conditional distribution necessary to process the corresponding EXACT statement. For example, the following statements create one distribution for the x1 parameter and another for the x2 parameters, and produce the data set dist shown in Table 54.12:

```

data test;
 input y x1 x2 count;
 datalines;
0 0 0 1
1 0 0 1
0 1 1 2
1 1 1 1
1 0 2 3
1 1 2 1
1 2 0 3
1 2 1 2
1 2 2 1
;

proc logistic data=test exactonly;
 class x2 / param=ref;
 model y=x1 x2;
 exact x1 x2/ outdist=dist;
run;
proc print data=dist;
run;

```

Table 54.12 OUTDIST= Data Set

| Obs | x1 | x20 | x21 | Count | Score   | Prob    |
|-----|----|-----|-----|-------|---------|---------|
| 1   | .  | 0   | 0   | 3     | 5.81151 | 0.03333 |
| 2   | .  | 0   | 1   | 15    | 1.66031 | 0.16667 |
| 3   | .  | 0   | 2   | 9     | 3.12728 | 0.10000 |
| 4   | .  | 1   | 0   | 15    | 1.46523 | 0.16667 |
| 5   | .  | 1   | 1   | 18    | 0.21675 | 0.20000 |
| 6   | .  | 1   | 2   | 6     | 4.58644 | 0.06667 |
| 7   | .  | 2   | 0   | 19    | 1.61869 | 0.21111 |
| 8   | .  | 2   | 1   | 2     | 3.27293 | 0.02222 |
| 9   | .  | 3   | 0   | 3     | 6.27189 | 0.03333 |
| 10  | 2  | .   | .   | 6     | 3.03030 | 0.12000 |
| 11  | 3  | .   | .   | 12    | 0.75758 | 0.24000 |
| 12  | 4  | .   | .   | 11    | 0.00000 | 0.22000 |
| 13  | 5  | .   | .   | 18    | 0.75758 | 0.36000 |
| 14  | 6  | .   | .   | 3     | 3.03030 | 0.06000 |

The first nine observations in the `dist` data set contain an exact distribution for the parameters of the `x2` effect (hence the values for the `x1` parameter are missing), and the remaining five observations are for the `x1` parameter. If a joint distribution was created, there would be observations with values for both the `x1` and `x2` parameters. For **CLASS** variables, the corresponding parameters in the `dist` data set are identified by concatenating the variable name with the appropriate classification level.

The data set contains the possible sufficient statistics of the parameters for the effects specified in the **EXACT** statement, and the `Count` variable contains the number of different responses that yield these statistics. In particular, there are six possible response vectors  $y$  for which the dot product  $y'x1$  was equal to 2, and

for which  $y/x20$ ,  $y/x21$ , and  $y/1$  were equal to their actual observed values (displayed in the “Sufficient Statistics” table).

When hypothesis tests are performed on the parameters, the **Prob** variable contains the probability of obtaining that statistic (which is just the count divided by the total count), and the **Score** variable contains the score for that statistic.

The **OUTDIST=** data set can contain a different exact conditional distribution for each specified **EXACT** statement. For example, consider the following **EXACT** statements:

```
exact 'O1' x1 / outdist=o1;
exact 'OJ12' x1 x2 / jointonly outdist=oj12;
exact 'OA12' x1 x2 / joint outdist=oa12;
exact 'OE12' x1 x2 / estimate outdist=oe12;
```

The **O1** statement outputs a single exact conditional distribution. The **OJ12** statement outputs only the joint distribution for  $x1$  and  $x2$ . The **OA12** statement outputs three conditional distributions: one for  $x1$ , one for  $x2$ , and one jointly for  $x1$  and  $x2$ . The **OE12** statement outputs two conditional distributions: one for  $x1$  and the other for  $x2$ . Data set **oe12** contains both the  $x1$  and  $x2$  variables; the distribution for  $x1$  has missing values in the  $x2$  column while the distribution for  $x2$  has missing values in the  $x1$  column.

## OUTROC= Output Data Set

The **OUTROC=** data set contains data necessary for producing the ROC curve, and can be created by specifying the **OUTROC=** option in the **MODEL** statement or the **OUTROC=** option in the **SCORE** statement: It has the following variables:

- any **BY** variables specified
- **\_STEP\_**, the model step number. This variable is not included if model selection is not requested.
- **\_PROB\_**, the estimated probability of an event. These estimated probabilities serve as cutpoints for predicting the response. Any observation with an estimated event probability that exceeds or equals **\_PROB\_** is predicted to be an event; otherwise, it is predicted to be a nonevent. Predicted probabilities that are close to each other are grouped together, with the maximum allowable difference between the largest and smallest values less than a constant that is specified by the **ROCEPS=** option. The smallest estimated probability is used to represent the group.
- **\_POS\_**, the number of correctly predicted event responses
- **\_NEG\_**, the number of correctly predicted nonevent responses
- **\_FALPOS\_**, the number of falsely predicted event responses
- **\_FALNEG\_**, the number of falsely predicted nonevent responses
- **\_SENSIT\_**, the sensitivity, which is the proportion of event observations that were predicted to have an event response
- **\_1MSPEC\_**, one minus specificity, which is the proportion of nonevent observations that were predicted to have an event response

Note that none of these statistics are affected by the bias-correction method discussed in the section “Classification Table” on page 4255. An ROC curve is obtained by plotting `_SENSIT_` against `_1MSPEC_`.

For more information, see the section “Receiver Operating Characteristic Curves” on page 4260.

---

## Computational Resources

The memory needed to fit an unconditional model is approximately  $8n(p + 2) + 24(p + 2)^2$  bytes, where  $p$  is the number of parameters estimated and  $n$  is the number of observations in the data set. For cumulative response models with more than two response levels, a test of the parallel lines assumption requires an additional memory of approximately  $4k^2(m + 1)^2 + 24(m + 2)^2$  bytes, where  $k$  is the number of response levels and  $m$  is the number of slope parameters. However, if this additional memory is not available, the procedure skips the test and finishes the other computations. You might need more memory if you use the `SELECTION=` option for model building.

The data that consist of relevant variables (including the design variables for model effects) and observations for fitting the model are stored in a temporary utility file. If sufficient memory is available, such data will also be kept in memory; otherwise, the data are reread from the utility file for each evaluation of the likelihood function and its derivatives, with the resulting execution time of the procedure substantially increased. Specifying the `MULTIPASS` option in the `MODEL` statement avoids creating this utility file and also does not store the data in memory; instead, the `DATA=` data set is reread when needed. This saves approximately  $8n(p + 2)$  bytes of memory but increases the execution time.

If a conditional logistic regression is performed, then approximately  $4(m^2 + m + 4) \max_h(m_h) + (8s_H + 36)H + 12s_H$  additional bytes of memory are needed, where  $m_h$  is the number of events in stratum  $h$ ,  $H$  is the total number of strata, and  $s_H$  is the number of variables used to define the strata. If the `CHECK-DEPENDENCY=ALL` option is specified in the `STRATA` statement, then an extra  $4(m + H)(m + H + 1)$  bytes are required, and the resulting execution time of the procedure might be substantially increased.

## Computational Resources for Exact Logistic Regression

Many problems require a prohibitive amount of time and memory for exact computations, depending on the speed and memory available on your computer. For such problems, consider whether exact methods are really necessary. Stokes, Davis, and Koch (2012) suggest looking at exact  $p$ -values when the sample size is small and the approximate  $p$ -values from the unconditional analysis are less than 0.10, and they provide *rules of thumb* for determining when various models are valid.

A formula does not exist that can predict the amount of time and memory necessary to generate the exact conditional distributions for a particular problem. The time and memory required depends on several factors, including the total sample size, the number of parameters of interest, the number of nuisance parameters, and the order in which the parameters are processed. To provide a feel for how these factors affect performance, 19 data sets containing  $\text{Nobs} \in \{10, \dots, 500\}$  observations consisting of up to 10 independent uniform binary covariates ( $X_1, \dots, X_N$ ) and a binary response variable ( $Y$ ), are generated, and the following statements create exact conditional distributions for  $X_1$  conditional on the other covariates by using the default `METHOD=NETWORK`. Figure 54.11 displays results obtained on a 400Mhz PC with 768MB RAM running Microsoft Windows NT.

```
data one;
 do obs=1 to HalfNobs;
```

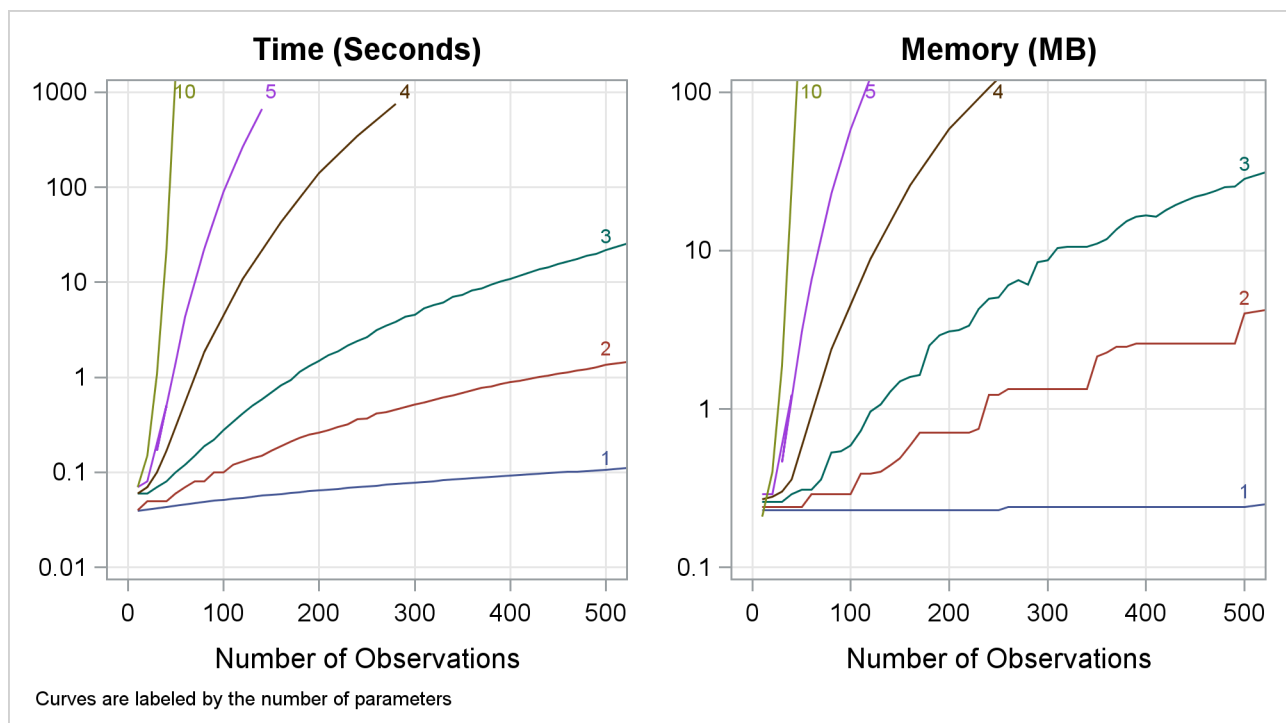

```

do Y=0 to 1;
 X1=round(ranuni(0));
 ...
 XN=round(ranuni(0));
 output;
end;
end;
options fullstimer;
proc logistic exactonly;
 exactoptions method=network maxtime=1200;
 class X1...XN / param=ref;
 model Y=X1...XN;
 exact X1 / outdist=dist;
run;

```

Figure 54.11 Mean Time and Memory Required

At any time while PROC LOGISTIC is deriving the distributions, you can terminate the computations by pressing the system interrupt key sequence (see the SAS Companion for your system) and choosing to stop computations. If you run out of memory, see the SAS Companion for your system to see how to allocate more.

You can use the **EXACTOPTIONS** option **MAXTIME=** to limit the total amount of time PROC LOGISTIC uses to derive all of the exact distributions. If PROC LOGISTIC does not finish within that time, the procedure terminates.

Calculation of frequencies are performed in the log scale by default. This reduces the need to check for excessively large frequencies but can be slower than not scaling. You can turn off the log scaling by specifying the **NOLOGSCALE** option in the **EXACTOPTIONS** statement. If a frequency in the exact distribution is larger than the largest integer that can be held in double precision, a warning is printed to the SAS log. But

since inaccuracies due to adding small numbers to these large frequencies might have little or no effect on the statistics, the exact computations continue.

You can monitor the progress of the procedure by submitting your program with the `EXACTOPTIONS` option `STATUSTIME=`. If the procedure is too slow, you can try another method by specifying the `EXACTOPTIONS` option `METHOD=`, you can try reordering the variables in the `MODEL` statement (note that `CLASS` variables are always processed before continuous covariates), or you can try reparameterizing your classification variables as in the following statement:

```
class class-variables / param=ref ref=first order=freq;
```

---

## Displayed Output

If you use the `NOPRINT` option in the `PROC LOGISTIC` statement, the procedure does not display any output. Otherwise, the tables displayed by the LOGISTIC procedure are discussed in the following section in the order in which they appear in the output. Some of the tables appear only in conjunction with certain options or statements; see the section “[ODS Table Names](#)” on page 4291 for details.

**NOTE:** The `EFFECT`, `ESTIMATE`, `LSMEANS`, `LSMESTIMATE`, and `SLICE` statements also create tables, which are not listed in this section. For information about these tables, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

## Table Summary

### ***Model Information and the Number of Observations***

See the section “[Missing Values](#)” on page 4237 for information about missing-value handling, and the sections “[FREQ Statement](#)” on page 4203 and “[WEIGHT Statement](#)” on page 4236 for information about valid frequencies and weights.

### ***Response Profile***

Displays the Ordered Value assigned to each response level. See the section “[Response Level Ordering](#)” on page 4237 for details.

### ***Class Level Information***

Displays the design values for each `CLASS` explanatory variable. See the section “[Other Parameterizations](#)” on page 387 in Chapter 19, “[Shared Concepts and Topics](#),” for details.

### ***Simple Statistics Tables***

The following tables are displayed if you specify the `SIMPLE` option in the `PROC LOGISTIC` statement:

- **Descriptive Statistics for Continuous Explanatory Variables**
- **Frequency Distribution of Class Variables**
- **Weight Distribution of Class Variables**  
Displays if you also specify a `WEIGHT` statement.

### **Strata Tables for (Exact) Conditional Logistic Regression**

The following tables are displayed if you specify a `STRATA` statement:

- **Strata Summary**  
Shows the pattern of the number of events and the number of nonevents in a stratum. See the section “[STRATA Statement](#)” on page 4233 for more information.
- **Strata Information**  
Displays if you specify the `INFO` option in a `STRATA` statement.

### **Maximum Likelihood Iteration History**

Displays if you specify the `ITPRINT` option in the `MODEL` statement. See the sections “[Iterative Algorithms for Model Fitting](#)” on page 4240, “[Convergence Criteria](#)” on page 4242, and “[Existence of Maximum Likelihood Estimates](#)” on page 4242 for details.

### **Deviance and Pearson Goodness-of-Fit Statistics**

Displays if you specify the `SCALE=` option in the `MODEL` statement. Small  $p$ -values reject the null hypothesis that the fitted model is adequate. See the section “[Overdispersion](#)” on page 4257 for details.

### **Score Test for the Equal Slopes (Proportional Odds) Assumption**

Tests the parallel lines assumption if you fit an ordinal response model with the `LINK=CLOGLOG` or `LINK=PROBIT` options. If you specify `LINK=LOGIT`, this is called the “Proportional Odds” assumption. The table is not displayed if you specify the `UNEQUALSLOPES` option in the `MODEL` statement. Small  $p$ -values reject the null hypothesis that the slope parameters for each explanatory variable are constant across all the response functions. See the section “[Testing the Parallel Lines Assumption](#)” on page 4248 for details.

### **Model Fit Statistics**

Computes various fit criteria based on a model with intercepts only and a model with intercepts and explanatory variables. If you specify the `NOINT` option in the `MODEL` statement, these statistics are calculated without considering the intercept parameters. See the section “[Model Fitting Information](#)” on page 4245 for details.

### **Testing Global Null Hypothesis: BETA=0**

Tests the joint effect of the explanatory variables included in the model. Small  $p$ -values reject the null hypothesis that all slope parameters are equal to zero,  $H_0: \beta = \mathbf{0}$ . See the sections “[Model Fitting Information](#)” on page 4245, “[Residual Chi-Square](#)” on page 4247, and “[Testing Linear Hypotheses about the Regression Coefficients](#)” on page 4262 for details. If you also specify the `RSQUARE` option in the `MODEL` statement, two generalized R Square measures are included; see the section “[Generalized Coefficient of Determination](#)” on page 4246 for details.

### **Score Test for Global Null Hypothesis**

Displays instead of the “Testing Global Null Hypothesis: BETA=0” table if the `NOFIT` option is specified in the `MODEL` statement. The global score test evaluates the joint significance of the effects in the `MODEL` statement. Small  $p$ -values reject the null hypothesis that all slope parameters are equal to zero,  $H_0: \beta = \mathbf{0}$ . See the section “[Residual Chi-Square](#)” on page 4247 for details.

### Model Selection Tables

The tables in this section are produced when the `SELECTION=` option is specified in the `MODEL` statement. See the section “Effect-Selection Methods” on page 4244 for more information.

- **Residual Chi-Square Test**

Displays if you specify `SELECTION=FORWARD`, `BACKWARD`, or `STEPWISE` in the `MODEL` statement. Small  $p$ -values reject the null hypothesis that the reduced model is adequate. See the section “Residual Chi-Square” on page 4247 for details.

- **Analysis of Effects Eligible for Entry**

Displays if you specify the `DETAILS` option and the `SELECTION=FORWARD` or `STEPWISE` option in the `MODEL` statement. Small  $p$ -values reject  $H_0: \beta_i \neq 0$ . The score chi-square is used to determine entry; see the section “Testing Individual Effects Not in the Model” on page 4247 for details.

- **Analysis of Effects Eligible for Removal**

Displays if you specify the `SELECTION=BACKWARD` or `STEPWISE` option in the `MODEL` statement. Small  $p$ -values reject  $H_0: \beta_i = 0$ . The Wald chi-square is used to determine removal; see the section “Testing Linear Hypotheses about the Regression Coefficients” on page 4262 for details.

- **Analysis of Effects Removed by Fast Backward Elimination**

Displays if you specify the `FAST` option and the `SELECTION=BACKWARD` or `STEPWISE` option in the `MODEL` statement. This table gives the approximate chi-square statistic for the variable removed, the corresponding  $p$ -value with respect to a chi-square distribution with one degree of freedom, the residual chi-square statistic for testing the joint significance of the variable and the preceding ones, the degrees of freedom, and the  $p$ -value of the residual chi-square with respect to a chi-square distribution with the corresponding degrees of freedom.

- **Summary of Forward, Backward, and Stepwise Selection**

Displays if you specify `SELECTION=FORWARD`, `BACKWARD`, or `STEPWISE` in the `MODEL` statement. The score chi-square is used to determine entry; see the section “Testing Individual Effects Not in the Model” on page 4247 for details. The Wald chi-square is used to determine removal; see the section “Testing Linear Hypotheses about the Regression Coefficients” on page 4262 for details.

- **Regression Models Selected by Score Criterion**

Displays the score chi-square for all models if you specify the `SELECTION=SCORE` option in the `MODEL` statement. Small  $p$ -values reject the null hypothesis that the fitted model is adequate. See the section “Effect-Selection Methods” on page 4244 for details.

### Type 3 Analysis of Effect

Displays if the model contains a `CLASS` variable. Performs Wald chi-square tests of the joint effect of the parameters for each `CLASS` variable in the model. Small  $p$ -values reject  $H_0: \beta_i = 0$ . See the section “Testing Linear Hypotheses about the Regression Coefficients” on page 4262 for details.

### Analysis of Maximum Likelihood Estimates

`CLASS` effects are identified by their (nonreference) level. For generalized logit models, a response variable column displays the nonreference level of the logit. The table includes the following:

- the estimated standard error of the parameter estimate, computed as the square root of the corresponding diagonal element of the estimated covariance matrix
- the Wald chi-square statistic, computed by squaring the ratio of the parameter estimate divided by its standard error estimate. See the section “Testing Linear Hypotheses about the Regression Coefficients” on page 4262 for details.
- the  $p$ -value tests the null hypothesis  $H_0: \beta_i = 0$ ; small values reject the null.
- the standardized estimate for the slope parameter, if you specify the **STB** option in the **MODEL** statement. See the **STB** option on page 4220 for details.
- exponentiated values of the estimates of the slope parameters, if you specify the **EXPB** option in the **MODEL** statement. See the **EXPB** option on page 4212 for details.
- the label of the variable, if you specify the **PARMLABEL** option in the **MODEL** statement and if space permits. Due to constraints on the line size, the variable label might be suppressed in order to display the table in one panel. Use the SAS system option **LINESIZE=** to specify a larger line size to accommodate variable labels. A shorter line size can break the table into two panels allowing labels to be displayed.

### ***Odds Ratio Estimates***

Displays the odds ratio estimates and the corresponding 95% Wald confidence intervals for variables that are not involved in nestings or interactions. For continuous explanatory variables, these odds ratios correspond to a unit increase in the risk factors. See the section “Odds Ratio Estimation” on page 4250 for details.

### ***Association of Predicted Probabilities and Observed Responses***

See the section “Rank Correlation of Observed Responses and Predicted Probabilities” on page 4253 for details.

### ***Parameter Estimates and Profile-Likelihood or Wald Confidence Intervals***

Displays if you specify the **CLPARAM=** option in the **MODEL** statement. See the section “Confidence Intervals for Parameters” on page 4248 for details.

### ***Odds Ratio Estimates and Profile-Likelihood or Wald Confidence Intervals***

Displays if you specify the **ODDSRATIO** statement for any effects with any class parameterizations. Also displays if you specify the **CLODDS=** option in the **MODEL** statement, except odds ratios are computed only for main effects not involved in interactions or nestings, and if the main effect is a **CLASS** variable, the parameterization must be **EFFECT**, **REFERENCE**, or **GLM**. See the section “Odds Ratio Estimation” on page 4250 for details.

### ***Estimated Covariance or Correlation Matrix***

Displays if you specify the **COVB** or **CORRB** option in the **MODEL** statement. See the section “Iterative Algorithms for Model Fitting” on page 4240 for details.

**Contrast Test Results**

Displays the Wald test for each specified **CONTRAST** statement. Small  $p$ -values reject  $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ . The “Coefficients of Contrast” table displays the contrast matrix if you specify the **E** option, and the “Contrast Estimation and Testing Results by Row” table displays estimates and Wald tests for each row of the contrast matrix if you specify the **ESTIMATE=** option. See the sections “**CONTRAST Statement**” on page 4190, “**Testing Linear Hypotheses about the Regression Coefficients**” on page 4262, and “**Linear Predictor, Predicted Probability, and Confidence Limits**” on page 4253 for details.

**Linear Hypotheses Testing Results**

Displays the Wald test for each specified **TEST** statement. See the sections “**Testing Linear Hypotheses about the Regression Coefficients**” on page 4262 and “**TEST Statement**” on page 4234 for details.

**Hosmer and Lemeshow Goodness-of-Fit Test**

Displays if you specify the **LACKFIT** option in the **MODEL** statement. Small  $p$ -values reject the null hypothesis that the fitted model is adequate. The “Partition for the Hosmer and Lemeshow Test” table displays the grouping used in the test. See the section “**The Hosmer-Lemeshow Goodness-of-Fit Test**” on page 4259 for details.

**Classification Table**

Displays if you use the **CTABLE** option in the **MODEL** statement. If you specify a list of cutpoints with the **PPROB=** option, then the cutpoints are displayed in the Prob Level column. If you specify the prior event probabilities with the **PEVENT=** option, then the probabilities are displayed in the Prob Event column. The Correct column displays the number of correctly classified events and nonevents, the Incorrect Event column displays the number of nonevents incorrectly classified as events, and the Incorrect Nonevent column gives the number of nonevents incorrectly classified as events. See the section “**Classification Table**” on page 4255 for more details.

**Regression Diagnostics**

Displays if you specify the **INFLUENCE** option in the **MODEL** statement. See the section “**Regression Diagnostics**” on page 4263 for more information about diagnostics from an unconditional analysis, and the section “**Regression Diagnostic Details**” on page 4272 for information about diagnostics from a conditional analysis.

**Fit Statistics for SCORE Data**

Displays if you specify the **FITSTAT** option in the **SCORE** statement. See the section “**Scoring Data Sets**” on page 4266 for details.

**ROC Association Statistic and Contrast Tables**

Displayed if a **ROC** statement or a **ROCCONTRAST** statement is specified. See the section “**ROC Computations**” on page 4261 for details about the Mann-Whitney statistics and the test and estimation computations, and see the section “**Rank Correlation of Observed Responses and Predicted Probabilities**” on page 4253 for details about the other statistics.

**Exact Conditional Logistic Regression Tables**

The tables in this section are produced when the **EXACT** statement is specified. If the **METHOD=NETWORKMC** option is specified, the test and estimate tables are renamed “Monte Carlo” tables and a Monte Carlo standard error column ( $\sqrt{p(1-p)/n}$ ) is displayed.

- **Sufficient Statistics**

Displays if you request an `OUTDIST=` data set in an `EXACT` statement. The table lists the parameters and their observed sufficient statistics.

- **(Monte Carlo) Conditional Exact Tests**

See the section “[Hypothesis Tests](#)” on page 4276 for details.

- **(Monte Carlo) Exact Parameter Estimates**

Displays if you specify the `ESTIMATE` option in the `EXACT` statement. This table gives individual parameter estimates for each variable (conditional on the values of all the other parameters in the model), confidence limits, and a two-sided  $p$ -value (twice the one-sided  $p$ -value) for testing that the parameter is zero. See the section “[Inference for a Single Parameter](#)” on page 4277 for details.

- **(Monte Carlo) Exact Odds Ratios**

Displays if you specify the `ESTIMATE=ODDS` or `ESTIMATE=BOTH` option in the `EXACT` statement. See the section “[Inference for a Single Parameter](#)” on page 4277 for details.

---

## ODS Table Names

PROC LOGISTIC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 54.13](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System](#).”

The `EFFECT`, `ESTIMATE`, `LSMEANS`, `LSMESTIMATE`, and `SLICE` statements also create tables, which are not listed in [Table 54.13](#). For information about these tables, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

**Table 54.13** ODS Tables Produced by PROC LOGISTIC

| ODS Table Name | Description                                                      | Statement                 | Option                       |
|----------------|------------------------------------------------------------------|---------------------------|------------------------------|
| Association    | Association of predicted probabilities and observed responses    | MODEL<br>(without STRATA) | Default                      |
| BestSubsets    | Best subset selection                                            | MODEL                     | SELECTION=SCORE              |
| ClassFreq      | Frequency breakdown of CLASS variables                           | PROC                      | Simple<br>(with CLASS vars)  |
| ClassLevelInfo | CLASS variable levels and design variables                       | MODEL                     | Default<br>(with CLASS vars) |
| Classification | Classification table                                             | MODEL                     | CTABLE                       |
| ClassWgt       | Weight breakdown of CLASS variables                              | PROC, WEIGHT              | Simple<br>(with CLASS vars)  |
| CLOddsPL       | Odds ratio estimates and profile-likelihood confidence intervals | MODEL                     | CLODDS=PL                    |
| CLOddsWald     | Odds ratio estimates and Wald confidence intervals               | MODEL                     | CLODDS=WALD                  |

Table 54.13 continued

| ODS Table Name       | Description                                                     | Statement | Option                                        |
|----------------------|-----------------------------------------------------------------|-----------|-----------------------------------------------|
| CLParmPL             | Parameter estimates and profile-likelihood confidence intervals | MODEL     | CLPARM=PL                                     |
| CLParmWald           | Parameter estimates and Wald confidence intervals               | MODEL     | CLPARM=WALD                                   |
| ContrastCoeff        | L matrix from CONTRAST                                          | CONTRAST  | E                                             |
| ContrastEstimate     | Estimates from CONTRAST                                         | CONTRAST  | ESTIMATE=                                     |
| ContrastTest         | Wald test for CONTRAST                                          | CONTRAST  | Default                                       |
| ConvergenceStatus    | Convergence status                                              | MODEL     | Default                                       |
| CorrB                | Estimated correlation matrix of parameter estimators            | MODEL     | CORRB                                         |
| CovB                 | Estimated covariance matrix of parameter estimators             | MODEL     | COVB                                          |
| CumulativeModelTest  | Test of the cumulative model assumption                         | MODEL     | (Ordinal response)                            |
| EffectNotInModel     | Test for effects not in model                                   | MODEL     | SELECTION=SIF                                 |
| ExactOddsRatio       | Exact odds ratios                                               | EXACT     | ESTIMATE=ODDS,<br>ESTIMATE=BOTH               |
| ExactParmEst         | Parameter estimates                                             | EXACT     | ESTIMATE,<br>ESTIMATE=PARAM,<br>ESTIMATE=BOTH |
| ExactTests           | Conditional exact tests                                         | EXACT     | Default                                       |
| FastElimination      | Fast backward elimination                                       | MODEL     | SELECTION=B,FAST                              |
| FitStatistics        | Model fit statistics                                            | MODEL     | Default                                       |
| GlobalScore          | Global score test                                               | MODEL     | NOFIT                                         |
| GlobalTests          | Test for global null hypothesis                                 | MODEL     | Default                                       |
| GoodnessOfFit        | Pearson and deviance goodness-of-fit tests                      | MODEL     | SCALE                                         |
| IndexPlots           | Batch capture of the index plots                                | MODEL     | IPLOTS                                        |
| Influence            | Regression diagnostics                                          | MODEL     | INFLUENCE                                     |
| IterHistory          | Iteration history                                               | MODEL     | ITPRINT                                       |
| LackFitChiSq         | Hosmer-Lemeshow chi-square test results                         | MODEL     | LACKFIT                                       |
| LackFitPartition     | Partition for the Hosmer-Lemeshow test                          | MODEL     | LACKFIT                                       |
| LastGradient         | Last evaluation of gradient                                     | MODEL     | ITPRINT                                       |
| Linear               | Linear combination                                              | PROC      | Default                                       |
| LogLikeChange        | Final change in the log likelihood                              | MODEL     | ITPRINT                                       |
| ModelBuildingSummary | Summary of model building                                       | MODEL     | SELECTION=BIFIS                               |
| ModelInfo            | Model information                                               | PROC      | Default                                       |
| NObs                 | Number of observations                                          | PROC      | Default                                       |

Table 54.13 *continued*

| ODS Table Name      | Description                                                                                                                                      | Statement   | Option                            |
|---------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|-------------|-----------------------------------|
| OddsEst             | Adjusted odds ratios                                                                                                                             | UNITS       | Default                           |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS](#).”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS](#).”

You must also specify the options in the PROC LOGISTIC statement that are indicated in [Table 54.14](#).

When ODS Graphics is enabled, then the EFFECT, EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots that are associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics](#).”

PROC LOGISTIC assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 54.14](#).

**Table 54.14** Graphs Produced by PROC LOGISTIC

| ODS Graph Name          | Plot Description                                                                                      | Statement or Option                               |
|-------------------------|-------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| DfBetasPlot             | Panel of dfbetas by case number                                                                       | PLOTS=DFBETAS<br>or MODEL / INFLUENCE or IPLOTS   |
| DPCPlot                 | Effect dfbetas by case number<br>Difchisq and/or difdev by predicted probability by CI displacement C | PLOTS=DFBETAS(UNPACK)<br>PLOTS=DPC                |
| EffectPlot              | Predicted probability                                                                                 | PLOTS=EFFECT                                      |
| InfluencePlots          | Panel of influence statistics by case number                                                          | PLOTS=INFLUENCE<br>or MODEL / INFLUENCE or IPLOTS |
| CBarPlot                | CI displacement Cbar by case number                                                                   | PLOTS=INFLUENCE(UNPACK)                           |
| CPlot                   | CI displacement C by case number                                                                      | PLOTS=INFLUENCE(UNPACK)                           |
| DevianceResidualPlot    | Deviance residual by case number                                                                      | PLOTS=INFLUENCE(UNPACK)                           |
| DifChisqPlot            | Difchisq by case number                                                                               | PLOTS=INFLUENCE(UNPACK)                           |
| DifDeviancePlot         | Difdev by case number                                                                                 | PLOTS=INFLUENCE(UNPACK)                           |
| LeveragePlot            | Hat diagonal by case number                                                                           | PLOTS=INFLUENCE(UNPACK)                           |
| LikelihoodResidualPlot  | Likelihood residual by case number                                                                    | PLOTS=INFLUENCE(UNPACK<br>STDRES)                 |
| PearsonResidualPlot     | Pearson chi-square residual by case number                                                            | PLOTS=INFLUENCE(UNPACK)                           |
| StdDevianceResidualPlot | Standardized deviance residual by case number                                                         | PLOTS=INFLUENCE(UNPACK<br>STDRES)                 |
| StdPearsonResidualPlot  | Standardized Pearson chi-square residual by case number                                               | PLOTS=INFLUENCE(UNPACK<br>STDRES)                 |

## Examples: LOGISTIC Procedure

### Example 54.1: Stepwise Logistic Regression and Predicted Values

Consider a study on cancer remission (Lee 1974). The data consist of patient characteristics and whether or not cancer remission occurred. The following DATA step creates the data set Remission containing seven variables. The variable remiss is the cancer remission indicator variable with a value of 1 for remission and a value of 0 for nonremission. The other six variables are the risk factors thought to be related to cancer remission.

```
data Remission;
 input remiss cell smear infil li blast temp;
 label remiss='Complete Remission';
 datalines;
1 .8 .83 .66 1.9 1.1 .996
1 .9 .36 .32 1.4 .74 .992
```

```

0 .8 .88 .7 .8 .176 .982
0 1 .87 .87 .7 1.053 .986
1 .9 .75 .68 1.3 .519 .98
0 1 .65 .65 .6 .519 .982
1 .95 .97 .92 1 1.23 .992

1 1 .69 .69 .9 .398 .986
0 1 .73 .73 .7 .398 .986
;

```

The following invocation of PROC LOGISTIC illustrates the use of [stepwise selection](#) to identify the prognostic factors for cancer remission. A significance level of 0.3 is required to allow a variable into the model (`SLENTRY=0.3`), and a significance level of 0.35 is required for a variable to stay in the model (`SLSTAY=0.35`). A detailed account of the variable selection process is requested by specifying the `DETAILS` option. The Hosmer and Lemeshow goodness-of-fit test for the final selected model is requested by specifying the `LACKFIT` option. The `OUTEST=` and `COVOUT` options in the PROC LOGISTIC statement create a data set that contains parameter estimates and their covariances for the final selected model. The response variable option `EVENT=` chooses `remiss=1` (remission) as the event so that the probability of remission is modeled. The `OUTPUT` statement creates a data set that contains the cumulative predicted probabilities and the corresponding confidence limits, and the individual and cross validated predicted probabilities for each observation.

```

In stepwise selection, an attempt is made to remove any insignificant variables from the model before adding a significant variable to the model. Each addition or deletion of a variable to or from a model is listed as a separate step in the displayed output, and at each step a new model is fitted. Details of the model selection steps are shown in Outputs 54.1.1 through 54.1.5.

Prior to the first step, the intercept-only model is fit and individual score statistics for the potential variables are evaluated (Output 54.1.1).

**Output 54.1.1** Startup Model

| Stepwise Regression on Cancer Remission Data  |            |          |                |                 |            |

| Analysis of Effects Eligible for Entry |    |            |            |
|----------------------------------------|----|------------|------------|
| Effect                                 | DF | Score      |            |
|                                        |    | Chi-Square | Pr > ChiSq |
| cell                                   | 1  | 1.8893     | 0.1693     |
| smear                                  | 1  | 1.0745     | 0.2999     |
| infil                                  | 1  | 1.8817     | 0.1701     |
| li                                     | 1  | 7.9311     | 0.0049     |
| blast                                  | 1  | 3.5258     | 0.0604     |
| temp                                   | 1  | 0.6591     | 0.4169     |

In Step 1 (Output 54.1.2), the variable li is selected into the model since it is the most significant variable among those to be chosen ( $p = 0.0049 < 0.3$ ). The intermediate model that contains an intercept and li is then fitted. li remains significant ( $p = 0.0146 < 0.35$ ) and is not removed.

In Step 3 (Output 54.1.4), the variable cell is added to the model. The model then contains an intercept and the variables li, temp, and cell. None of these variables are removed from the model since all are significant at the 0.35 level.

**Output 54.1.4** Step 3 of the Stepwise Analysis

Step 3. Effect cell entered:

| Model Convergence Status                      |  |  |

The data set `pred` created by the `OUTPUT` statement is displayed in [Output 54.1.8](#). It contains all the variables in the input data set, the variable `phat` for the (cumulative) predicted probability, the variables `lcl` and `ucl` for the lower and upper confidence limits for the probability, and four other variables (`IP_1`, `IP_0`, `XP_1`, and `XP_0`) for the `PREDPROBS=` option. The data set also contains the variable `_LEVEL_`, indicating the response value to which `phat`, `lcl`, and `ucl` refer. For instance, for the first row of the `OUTPUT` data set, the values of `_LEVEL_` and `phat`, `lcl`, and `ucl` are 1, 0.72265, 0.16892, and 0.97093, respectively; this means that the estimated probability that `remiss=1` is 0.723 for the given explanatory variable values, and the corresponding 95% confidence interval is (0.16892, 0.97093). The variables `IP_1` and `IP_0` contain the predicted probabilities that `remiss=1` and `remiss=0`, respectively. Note that values of `phat` and `IP_1` are identical since they both contain the probabilities that `remiss=1`. The variables `XP_1` and `XP_0` contain the cross validated predicted probabilities that `remiss=1` and `remiss=0`, respectively.

Next, a different variable selection method is used to select prognostic factors for cancer remission, and an efficient algorithm is employed to eliminate insignificant variables from a model. The following statements invoke PROC LOGISTIC to perform the backward elimination analysis:

```

title 'Backward Elimination on Cancer Remission Data';
proc logistic data=Remission;
 model remiss(event='1')=temp cell li smear blast
 / selection=backward fast slstay=0.2 ctable;
run;

```

The backward elimination analysis (**SELECTION=BACKWARD**) starts with a model that contains all explanatory variables given in the **MODEL** statement. By specifying the **FAST** option, PROC LOGISTIC eliminates insignificant variables without refitting the model repeatedly. This analysis uses a significance level of 0.2 to retain variables in the model (**SLSTAY=0.2**), which is different from the previous stepwise analysis where **SLSTAY=.35**. The **CTABLE** option is specified to produce classifications of input observations based on the final selected model.

Results of the fast elimination analysis are shown in [Output 54.1.9](#) and [Output 54.1.10](#). Initially, a full model containing all six risk factors is fit to the data ([Output 54.1.9](#)). In the next step ([Output 54.1.10](#)), PROC LOGISTIC removes blast, smear, cell, and temp from the model all at once. This leaves li and the intercept as the only variables in the final model. Note that in this analysis, only parameter estimates for the final model are displayed because the **DETAILS** option has not been specified.

**Output 54.1.9** Initial Step in Backward Elimination

Note that you can also use the FAST option when `SELECTION=STEPWISE`. However, the FAST option operates only on backward elimination steps. In this example, the stepwise process only adds variables, so the FAST option would not be useful.

Results of the `CTABLE` option are shown in [Output 54.1.11](#).

| 0.960                | 0       | 18        | 0         | 9         | 66.7        | 0.0         | 100.0       | .         | 33.3      |

Each row of the “Classification Table” corresponds to a cutpoint applied to the predicted probabilities, which is given in the Prob Level column. The  $2 \times 2$  frequency tables of observed and predicted responses are given by the next four columns. For example, with a cutpoint of 0.5, 4 events and 16 nonevents were classified correctly. On the other hand, 2 nonevents were incorrectly classified as events and 5 events were incorrectly classified as nonevents. For this cutpoint, the correct classification rate is  $20/27$  ( $=74.1\%$ ), which is given in the sixth column. Accuracy of the classification is summarized by the sensitivity, specificity, and false positive and negative rates, which are displayed in the last four columns. You can control the number of cutpoints used, and their values, by using the `PPROB=` option.

## Example 54.2: Logistic Modeling with Categorical Predictors

Consider a study of the analgesic effects of treatments on elderly patients with neuralgia. Two test treatments and a placebo are compared. The response variable is whether the patient reported pain or not. Researchers recorded the age and gender of 60 patients and the duration of complaint before the treatment began. The following DATA step creates the data set Neuralgia:

```
data Neuralgia;
 input Treatment $ Sex $ Age Duration Pain $ @@;
 datalines;
P F 68 1 No B M 74 16 No P F 67 30 No
P M 66 26 Yes B F 67 28 No B F 77 16 No
A F 71 12 No B F 72 50 No B F 76 9 Yes
A M 71 17 Yes A F 63 27 No A F 69 18 Yes
B F 66 12 No A M 62 42 No P F 64 1 Yes
A F 64 17 No P M 74 4 No A F 72 25 No
P M 70 1 Yes B M 66 19 No B M 59 29 No
A F 64 30 No A M 70 28 No A M 69 1 No
B F 78 1 No P M 83 1 Yes B F 69 42 No
B M 75 30 Yes P M 77 29 Yes P F 79 20 Yes
A M 70 12 No A F 69 12 No B F 65 14 No
B M 70 1 No B M 67 23 No A M 76 25 Yes
P M 78 12 Yes B M 77 1 Yes B F 69 24 No
P M 66 4 Yes P F 65 29 No P M 60 26 Yes
A M 78 15 Yes B M 75 21 Yes A F 67 11 No
P F 72 27 No P F 70 13 Yes A M 75 6 Yes
B F 65 7 No P F 68 27 Yes P M 68 11 Yes
P M 67 17 Yes B M 70 22 No A M 65 15 No
P F 67 1 Yes A M 67 10 No P F 72 11 Yes
A F 74 1 No B M 80 21 Yes A F 69 3 No
;
```

The data set Neuralgia contains five variables: Treatment, Sex, Age, Duration, and Pain. The last variable, Pain, is the response variable. A specification of Pain=Yes indicates there was pain, and Pain=No indicates no pain. The variable Treatment is a categorical variable with three levels: A and B represent the two test treatments, and P represents the placebo treatment. The gender of the patients is given by the categorical variable Sex. The variable Age is the age of the patients, in years, when treatment began. The duration of complaint, in months, before the treatment began is given by the variable Duration.

The following statements use the LOGISTIC procedure to fit a two-way logit with interaction model for the effect of Treatment and Sex, with Age and Duration as covariates. The categorical variables Treatment and

Sex are declared in the `CLASS` statement.

```
proc logistic data=Neuralgia;
 class Treatment Sex;
 model Pain= Treatment Sex Treatment*Sex Age Duration / expb;
run;
```

In this analysis, PROC LOGISTIC models the probability of no pain (Pain=No). By default, effect coding is used to represent the CLASS variables. Two design variables are created for Treatment and one for Sex, as shown in [Output 54.2.1](#).

**Output 54.2.1** Effect Coding of CLASS Variables

| The LOGISTIC Procedure  |       |                  |    |
|-------------------------|-------|------------------|----|
| Class Level Information |       |                  |    |
| Class                   | Value | Design Variables |    |
| Treatment               | A     | 1                | 0  |
|                         | B     | 0                | 1  |
|                         | P     | -1               | -1 |
| Sex                     | F     | 1                |    |
|                         | M     | -1               |    |

PROC LOGISTIC displays a table of the Type 3 analysis of effects based on the Wald test ([Output 54.2.2](#)). Note that the Treatment\*Sex interaction and the duration of complaint are not statistically significant ( $p = 0.9318$  and  $p = 0.8752$ , respectively). This indicates that there is no evidence that the treatments affect pain differently in men and women, and no evidence that the pain outcome is related to the duration of pain.

**Output 54.2.2** Wald Tests of Individual Effects

| Type 3 Analysis of Effects |    |                 |            |
|----------------------------|----|-----------------|------------|
| Effect                     | DF | Wald Chi-Square | Pr > ChiSq |
| Treatment                  | 2  | 11.9886         | 0.0025     |
| Sex                        | 1  | 5.3104          | 0.0212     |
| Treatment*Sex              | 2  | 0.1412          | 0.9318     |
| Age                        | 1  | 7.2744          | 0.0070     |
| Duration                   | 1  | 0.0247          | 0.8752     |

Parameter estimates are displayed in [Output 54.2.3](#). The Exp(Est) column contains the exponentiated parameter estimates requested with the `EXPB` option. These values can, but do not necessarily, represent odds ratios for the corresponding variables. For continuous explanatory variables, the Exp(Est) value corresponds to the odds ratio for a unit increase of the corresponding variable. For CLASS variables that use effect coding, the Exp(Est) values have no direct interpretation as a comparison of levels. However, when

the reference coding is used, the Exp(Est) values represent the odds ratio between the corresponding level and the reference level. Following the parameter estimates table, PROC LOGISTIC displays the odds ratio estimates for those variables that are not involved in any interaction terms. If the variable is a CLASS variable, the odds ratio estimate comparing each level with the reference level is computed regardless of the coding scheme. In this analysis, since the model contains the Treatment\*Sex interaction term, the odds ratios for Treatment and Sex were not computed. The odds ratio estimates for Age and Duration are precisely the values given in the Exp(Est) column in the parameter estimates table.

### Output 54.2.3 Parameter Estimates with Effect Coding

| Analysis of Maximum Likelihood Estimates |    |          |                |                 |            |          |

| Duration             | 1.005          | 0.942                      | 1.073 |

The following PROC LOGISTIC statements illustrate the use of forward selection on the data set Neuralgia to identify the effects that differentiate the two Pain responses. The option **SELECTION=FORWARD** is specified to carry out the forward selection. The term Treatment|Sex@2 illustrates another way to specify main effects and two-way interactions. (Note that, in this case, the “@2” is unnecessary because no interactions besides the two-way interaction are possible).

```
proc logistic data=Neuralgia;
 class Treatment Sex;
 model Pain=Treatment|Sex@2 Age Duration
 /selection=forward expb;
run;
```

Results of the forward selection process are summarized in [Output 54.2.4](#). The variable Treatment is selected first, followed by Age and then Sex. The results are consistent with the previous analysis ([Output 54.2.2](#)) in which the Treatment\*Sex interaction and Duration are not statistically significant.

**Output 54.2.4** Effects Selected into the Model

| The LOGISTIC Procedure       |                |    |           |                  |            |
|------------------------------|----------------|----|-----------|------------------|------------|
| Summary of Forward Selection |                |    |           |                  |            |
| Step                         | Effect Entered | DF | Number In | Score Chi-Square | Pr > ChiSq |
| 1                            | Treatment      | 2  | 1         | 13.7143          | 0.0011     |
| 2                            | Age            | 1  | 2         | 10.6038          | 0.0011     |
| 3                            | Sex            | 1  | 3         | 5.9959           | 0.0143     |

Output 54.2.5 shows the Type 3 analysis of effects, the parameter estimates, and the odds ratio estimates for the selected model. All three variables, Treatment, Age, and Sex, are statistically significant at the 0.05 level ( $p=0.0018$ ,  $p=0.0213$ , and  $p=0.0057$ , respectively). Since the selected model does not contain the Treatment\*Sex interaction, odds ratios for Treatment and Sex are computed. The estimated odds ratio is 24.022 for treatment A versus placebo, 41.528 for Treatment B versus placebo, and 6.194 for female patients versus male patients. Note that these odds ratio estimates are not the same as the corresponding values in the Exp(Est) column in the parameter estimates table because effect coding was used. From Output 54.2.5, it is evident that both Treatment A and Treatment B are better than the placebo in reducing pain; females tend to have better improvement than males; and younger patients are faring better than older patients.

**Output 54.2.5** Type 3 Effects and Parameter Estimates with Effect Coding

| Type 3 Analysis of Effects |    |                 |            |  |  |  |
|----------------------------|----|-----------------|------------|--|--|--|

Output 54.2.5 continued

| Odds Ratio Estimates |                |                            |         |
|----------------------|----------------|----------------------------|---------|
| Effect               | Point Estimate | 95% Wald Confidence Limits |         |
| Treatment A vs P     | 24.022         | 3.295                      | 175.121 |
| Treatment B vs P     | 41.528         | 4.500                      | 383.262 |
| Sex F vs M           | 6.194          | 1.312                      | 29.248  |
| Age                  | 0.767          | 0.636                      | 0.926   |

Finally, the following statements refit the previously selected model, except that reference coding is used for the CLASS variables instead of effect coding:

```
ods graphics on;
proc logistic data=Neuralgia plots (only)=(oddsratio(range=clip));
 class Treatment Sex /param=ref;
 model Pain= Treatment Sex Age;
 oddsratio Treatment;
 oddsratio Sex;
 oddsratio Age;
 contrast 'Pairwise A vs P' Treatment 1 0 / estimate=exp;
 contrast 'Pairwise B vs P' Treatment 0 1 / estimate=exp;
 contrast 'Pairwise A vs B' Treatment 1 -1 / estimate=exp;
 contrast 'Female vs Male' Sex 1 / estimate=exp;
 effectplot / at(Sex=all) noobs;
 effectplot slicefit(sliceby=Sex plotby=Treatment) / noobs;
run;
ods graphics off;
```

The **ODDSRATIO** statements compute the odds ratios for the covariates. Four **CONTRAST** statements are specified; they provide another method of producing the odds ratios. The three contrasts labeled ‘Pairwise’ specify a contrast vector,  $L$ , for each of the pairwise comparisons between the three levels of Treatment. The contrast labeled ‘Female vs Male’ compares female to male patients. The option **ESTIMATE=EXP** is specified in all **CONTRAST** statements to exponentiate the estimates of  $L'\beta$ . With the given specification of contrast coefficients, the first of the ‘Pairwise’ **CONTRAST** statements corresponds to the odds ratio of A versus P, the second corresponds to B versus P, and the third corresponds to A versus B. You can also specify the ‘Pairwise’ contrasts in a single contrast statement with three rows. The ‘Female vs Male’ **CONTRAST** statement corresponds to the odds ratio that compares female to male patients.

The **PLOTS(ONLY)=** option displays only the requested odds ratio plot when ODS Graphics is enabled. The **EFFECTPLOT** statements do not honor the **ONLY** option, and display the fitted model. The first **EFFECTPLOT** statement by default produces a plot of the predicted values against the continuous Age variable, grouped by the Treatment levels. The **AT** option produces one plot for males and another for females; the **NOOBS** option suppresses the display of the observations. In the second **EFFECTPLOT** statement, a **SLICEFIT** plot is specified to display the Age variable on the X axis, the fits are grouped by the Sex levels, and the **PLOTBY=** option produces a panel of plots that displays each level of the Treatment variable.

The reference coding is shown in [Output 54.2.6](#). The Type 3 analysis of effects, the parameter estimates for the reference coding, and the odds ratio estimates are displayed in [Output 54.2.7](#). Although the parameter

estimates are different because of the different parameterizations, the “Type 3 Analysis of Effects” table and the “Odds Ratio” table remain the same as in [Output 54.2.5](#). With effect coding, the treatment A parameter estimate (0.8772) estimates the effect of treatment A compared to the average effect of treatments A, B, and placebo. The treatment A estimate (3.1790) under the reference coding estimates the difference in effect of treatment A and the placebo treatment.

| Intercept                                | 1  | 15.8669  | 6.4056         | 6.1357          | 0.0132     |
| Treatment A                              | 1  | 3.1790   | 1.0135         | 9.8375          | 0.0017     |
| Treatment B                              | 1  | 3.7264   | 1.1339         | 10.8006         | 0.0010     |
| Sex F                                    | 1  | 1.8235   | 0.7920         | 5.3013          | 0.0213     |
| Age                                      | 1  | -0.2650  | 0.0959         | 7.6314          | 0.0057     |

The **ODDSRATIO** statement results are shown in [Output 54.2.8](#), and the resulting plot is displayed in [Output 54.2.9](#). Note in [Output 54.2.9](#) that the odds ratio confidence limits are truncated due to specifying the **RANGE=CLIP** option; this enables you to see which intervals contain “1” more clearly. The odds ratios are identical to those shown in the “Odds Ratio Estimates” table in [Output 54.2.7](#) with the addition of the odds ratio for “Treatment A vs B”. Both treatments A and B are highly effective over placebo in reducing pain, as can be seen from the odds ratios comparing treatment A against P and treatment B against P (the second

and third rows in the table). However, the 95% confidence interval for the odds ratio comparing treatment A to B is (0.0932, 3.5889), indicating that the pain reduction effects of these two test treatments are not very different. Again, the 'Sex F vs M' odds ratio shows that female patients fared better in obtaining relief from pain than male patients. The odds ratio for Age shows that a patient one year older is 0.77 times as likely to show no pain; that is, younger patients have more improvement than older patients.

**Output 54.2.8** Results from the ODDS RATIO Statements

| Odds Ratio Estimates and Wald Confidence Intervals |          |                       |         |
|----------------------------------------------------|----------|-----------------------|---------|
| Label                                              | Estimate | 95% Confidence Limits |         |
| Treatment A vs B                                   | 0.578    | 0.093                 | 3.589   |
| Treatment A vs P                                   | 24.022   | 3.295                 | 175.121 |
| Treatment B vs P                                   | 41.528   | 4.500                 | 383.262 |
| Sex F vs M                                         | 6.194    | 1.312                 | 29.248  |
| Age                                                | 0.767    | 0.636                 | 0.926   |

**Output 54.2.9** Plot of the ODDS RATIO Statement Results

Output 54.2.10 contains two tables: the “Contrast Test Results” table and the “Contrast Estimation and Testing Results by Row” table. The former contains the overall Wald test for each CONTRAST statement. The latter table contains estimates and tests of individual contrast rows. The estimates for the first two rows of the ‘Pairwise’ CONTRAST statements are the same as those given in the two preceding odds ratio tables (Output 54.2.7 and Output 54.2.8). The third row estimates the odds ratio comparing A to B, agreeing with Output 54.2.8, and the last row computes the odds ratio comparing pain relief for females to that for males.

**Output 54.2.10** Results of CONTRAST Statements

ANCOVA-style plots of the model-predicted probabilities against the Age variable for each combination of Treatment and Sex are displayed in Output 54.2.11 and Output 54.2.12. These plots confirm that females always have a higher probability of pain reduction in each treatment group, the placebo treatment has a lower probability of success than the other treatments, and younger patients respond to treatment better than older patients.

**Output 54.2.11** Model-Predicted Probabilities by Sex

**Output 54.2.12** Model-Predicted Probabilities by Treatment

### Example 54.3: Ordinal Logistic Regression

Consider a study of the effects on taste of various cheese additives. Researchers tested four cheese additives and obtained 52 response ratings for each additive. Each response was measured on a scale of nine categories ranging from strong dislike (1) to excellent taste (9). The data, given in McCullagh and Nelder (1989, p. 175) in the form of a two-way frequency table of additive by rating, are saved in the data set `Cheese` by using the following program. The variable `y` contains the response rating. The variable `Additive` specifies the cheese additive (1, 2, 3, or 4). The variable `freq` gives the frequency with which each additive received each rating.

```
data Cheese;
 do Additive = 1 to 4;
 do y = 1 to 9;
 input freq @@;
 output;
 end;
 end;
 label y='Taste Rating';
 datalines;
```

```

0 0 1 7 8 8 19 8 1
6 9 12 11 7 6 1 0 0
1 1 6 8 23 7 5 1 0
0 0 0 1 3 7 14 16 11
;

```

The response variable  $y$  is ordinally scaled. A cumulative logit model is used to investigate the effects of the cheese additives on taste. The following statements invoke PROC LOGISTIC to fit this model with  $y$  as the response variable and three indicator variables as explanatory variables, with the fourth additive as the reference level. With this parameterization, each Additive parameter compares an additive to the fourth additive. The COVB option displays the estimated covariance matrix. The ODDSRATIO statement computes odds ratios for all combinations of the Additive levels. The PLOTS option produces a graphical display of the odds ratios, and the EFFECTPLOT statement displays the predicted probabilities.

```

ods graphics on;
proc logistic data=Cheese plots(only)=oddsratio(range=clip);
 freq freq;
 class Additive (param=ref ref='4');
 model y=Additive / covb;
 oddsratio Additive;
 effectplot / polybar;
 title 'Multiple Response Cheese Tasting Experiment';
run;
ods graphics off;

```

The “Response Profile” table in [Output 54.3.1](#) shows that the strong dislike ( $y=1$ ) end of the rating scale is associated with lower Ordered Values in the “Response Profile” table; hence the probability of disliking the additives is modeled.

The score chi-square for testing the proportional odds assumption is 17.287, which is not significant with respect to a chi-square distribution with 21 degrees of freedom ( $p = 0.694$ ). This indicates that the proportional odds assumption is reasonable. The positive value (1.6128) for the parameter estimate for Additive1 indicates a tendency toward the lower-numbered categories of the first cheese additive relative to the fourth. In other words, the fourth additive tastes better than the first additive. The second and third additives are both less favorable than the fourth additive. The relative magnitudes of these slope estimates imply the preference ordering: fourth, first, third, second.

Response Profile

| Ordered Value | y | Total Frequency |
|---------------|---|-----------------|
| 1             | 1 | 7               |
| 2             | 2 | 10              |
| 3             | 3 | 19              |
| 4             | 4 | 27              |
| 5             | 5 | 41              |
| 6             | 6 | 28              |
| 7             | 7 | 39              |
| 8             | 8 | 25              |
| 9             | 9 | 12              |

Probabilities modeled are cumulated over the lower Ordered Values.

NOTE: 8 observations having nonpositive frequencies or weights were excluded since they do not contribute to the analysis.

Class Level Information

| Class    | Value | Design Variables |   |   |
|----------|-------|------------------|---|---|
| Additive | 1     | 1                | 0 | 0 |
|          | 2     | 0                | 1 | 0 |
|          | 3     | 0                | 0 | 1 |
|          | 4     | 0                | 0 | 0 |

Model Convergence Status

Convergence criterion (GCONV=1E-8) satisfied.

Score Test for the Proportional Odds Assumption

| Chi-Square | DF | Pr > ChiSq |

The odds ratio results in [Output 54.3.2](#) show the preferences more clearly. For example, the “Additive 1 vs 4” odds ratio says that the first additive has 5.017 times the odds of receiving a lower score than the fourth

additive; that is, the first additive is 5.017 times more likely than the fourth additive to receive a lower score. [Output 54.3.3](#) displays the odds ratios graphically; the range of the confidence limits is truncated by the `RANGE=CLIP` option, so you can see that “1” is not contained in any of the intervals.

**Output 54.3.2** Odds Ratios of All Pairs of Additive Levels

Output 54.3.5 displays the probability of each taste rating  $y$  within each additive. You can see that Additive=1 mostly receives ratings of 5 to 7, Additive=2 mostly receives ratings of 2 to 5, Additive=3 mostly receives ratings of 4 to 6, and Additive=4 mostly receives ratings of 7 to 9, which also confirms the previously discussed preference orderings.

**Output 54.3.5** Model-Predicted Probabilities

### Example 54.4: Nominal Response Data: Generalized Logits Model

Over the course of one school year, third graders from three different schools are exposed to three different styles of mathematics instruction: a self-paced computer-learning style, a team approach, and a traditional class approach. The students are asked which style they prefer and their responses, classified by the type of program they are in (a regular school day versus a regular day supplemented with an afternoon school program), are displayed in Table 54.15. The data set is from Stokes, Davis, and Koch (2012), and is also analyzed in the section “Generalized Logits Model” on page 1784 of Chapter 30, “The CATMOD Procedure.”

**Table 54.15** School Program Data

| School | Program   | Learning Style Preference |      |       |
|--------|-----------|---------------------------|------|-------|
|        |           | Self                      | Team | Class |
| 1      | Regular   | 10                        | 17   | 26    |
| 1      | Afternoon | 5                         | 12   | 50    |
| 2      | Regular   | 21                        | 17   | 26    |
| 2      | Afternoon | 16                        | 12   | 36    |
| 3      | Regular   | 15                        | 15   | 16    |
| 3      | Afternoon | 12                        | 12   | 20    |

The levels of the response variable (self, team, and class) have no essential ordering, so a logistic regression is performed on the generalized logits. The model to be fit is

$$\log\left(\frac{\pi_{hij}}{\pi_{hir}}\right) = \alpha_j + \mathbf{x}'_{hi}\boldsymbol{\beta}_j$$

where  $\pi_{hij}$  is the probability that a student in school  $h$  and program  $i$  prefers teaching style  $j$ ,  $j \neq r$ , and style  $r$  is the baseline style (in this case, class). There are separate sets of intercept parameters  $\alpha_j$  and regression parameters  $\boldsymbol{\beta}_j$  for each logit, and the vector  $\mathbf{x}_{hi}$  is the set of explanatory variables for the  $h$ th population. Thus, two logits are modeled for each school and program combination: the logit comparing self to class and the logit comparing team to class.

The following statements create the data set `school` and request the analysis. The `LINK=GLOGIT` option forms the generalized logits. The response variable option `ORDER=DATA` means that the response variable levels are ordered as they exist in the data set: self, team, and class; thus, the logits are formed by comparing self to class and by comparing team to class. The `ODDSRATIO` statement produces odds ratios in the presence of interactions, and a graphical display of the requested odds ratios is produced when ODS Graphics is enabled.

| School*Program 2 regular                 | self  | 1  | -0.0998  | 0.1919            | 0.2702             | 0.6032     |  |
| School*Program 2 regular                 | team  | 1  | -0.0168  | 0.1898            | 0.0079             | 0.9293     |  |

The table produced by the `ODDSRATIO` statement is displayed in [Output 54.4.4](#). The differences between the program preferences are small across all the styles (logits) compared to their variability as displayed by the confidence limits in [Output 54.4.5](#), confirming that the interaction effect is nonsignificant.

**Output 54.4.4** Odds Ratios for Style

| Odds Ratio Estimates and Wald Confidence Intervals   |          |                       |        |
|------------------------------------------------------|----------|-----------------------|--------|
| Label                                                | Estimate | 95% Confidence Limits |        |
| Style self: Program regular vs afternoon at School=1 | 3.846    | 1.190                 | 12.435 |
| Style team: Program regular vs afternoon at School=1 | 2.724    | 1.132                 | 6.554  |
| Style self: Program regular vs afternoon at School=2 | 1.817    | 0.798                 | 4.139  |
| Style team: Program regular vs afternoon at School=2 | 1.962    | 0.802                 | 4.799  |
| Style self: Program regular vs afternoon at School=3 | 1.562    | 0.572                 | 4.265  |
| Style team: Program regular vs afternoon at School=3 | 1.562    | 0.572                 | 4.265  |

**Output 54.4.5** Plot of Odds Ratios for Style

Since the interaction effect is clearly nonsignificant, a main-effects model is fit with the following statements. The `EFFECTPLOT` statement creates a plot of the predicted values versus the levels of the School

variable at each level of the Program variables. The **CLM** option adds confidence bars, and the **NOOBS** option suppresses the display of the observations.

```
ods graphics on;
proc logistic data=school;
 freq Count;
 class School Program(ref=first);
 model Style(order=data)=School Program / link=glogit;
 effectplot interaction(plotby=Program) / clm noobs;
run;
ods graphics off;
```

All of the global fit tests in [Output 54.4.6](#) suggest the model is significant, and the Type 3 tests show that the school and program effects are also significant.

**Output 54.4.6** Analysis of Main-Effects Model

The interaction plots in [Output 54.4.8](#) show that School=1 and Program=afternoon have a preference for the traditional classroom style. Of course, since these are not simultaneous confidence intervals, the nonoverlapping 95% confidence limits do not take the place of an actual test.

**Output 54.4.8** Model-Predicted Probabilities

### Example 54.5: Stratified Sampling

Consider the hypothetical example in Fleiss (1981, pp. 6–7), in which a test is applied to a sample of 1,000 people known to have a disease and to another sample of 1,000 people known not to have the same disease. In the diseased sample, 950 test positive; in the nondiseased sample, only 10 test positive. If the true disease rate in the population is 1 in 100, specifying `PEVENT=0.01` results in the correct false positive and negative rates for the stratified sampling scheme. Omitting the `PEVENT=` option is equivalent to using the overall sample disease rate ( $1000/2000 = 0.5$ ) as the value of the `PEVENT=` option, which would ignore the stratified sampling.

The statements to create the data set and perform the analysis are as follows:

```
data Screen;
 do Disease='Present', 'Absent';
 do Test=1,0;
 input Count @@;
 output;
 end;
 end;
end;
```

```

 datalines;
950 50
10 990
;

proc logistic data=Screen;
 freq Count;
 model Disease(event='Present')=Test
 / pevent=.5 .01 ctable pprob=.5;
run;

```

The response variable option `EVENT=` indicates that `Disease='Present'` is the event. The `CTABLE` option is specified to produce a classification table. Specifying `PPROB=0.5` indicates a cutoff probability of 0.5. A list of two probabilities, 0.5 and 0.01, is specified for the `PEVENT=` option; 0.5 corresponds to the overall sample disease rate, and 0.01 corresponds to a true disease rate of 1 in 100.

The classification table is shown in [Output 54.5.1](#).

**Output 54.5.1** False Positive and False Negative Rates

| The LOGISTIC Procedure |               |         |               |           |               |             |                  |                  |              |              |

| Prob<br>Event          | Prob<br>Level | Correct |               | Incorrect |               | Percentages |                  |                  |              |              |
|                        |               | Event   | Non-<br>Event | Event     | Non-<br>Event | Correct     | Sensi-<br>tivity | Speci-<br>ficity | False<br>POS | False<br>NEG |
| 0.500                  | 0.500         | 950     | 990           | 10        | 50            | 97.0        | 95.0             | 99.0             | 1.0          | 4.8          |
| 0.010                  | 0.500         | 950     | 990           | 10        | 50            | 99.0        | 95.0             | 99.0             | 51.0         | 0.1          |

In the classification table, the column “Prob Level” represents the cutoff values (the settings of the `PPROB=` option) for predicting whether an observation is an event. The “Correct” columns list the numbers of subjects that are correctly predicted as events and nonevents, respectively, and the “Incorrect” columns list the number of nonevents incorrectly predicted as events and the number of events incorrectly predicted as nonevents, respectively. For `PEVENT=0.5`, the false positive rate is 1% and the false negative rate is 4.8%. These results ignore the fact that the samples were stratified and incorrectly assume that the overall sample proportion of disease (which is 0.5) estimates the true disease rate. For a true disease rate of 0.01, the false positive rate and the false negative rate are 51% and 0.1%, respectively, as shown in the second line of the classification table.

## Example 54.6: Logistic Regression Diagnostics

In a controlled experiment to study the effect of the rate and volume of air intake on a transient reflex vasoconstriction in the skin of the digits, 39 tests under various combinations of rate and volume of air intake were obtained (Finney 1947). The endpoint of each test is whether or not vasoconstriction occurred. Pregibon (1981) uses this set of data to illustrate the diagnostic measures he proposes for detecting influential observations and to quantify their effects on various aspects of the maximum likelihood fit.

The vasoconstriction data are saved in the data set vaso:

```

data vaso;
 length Response $12;
 input Volume Rate Response @@;
 LogVolume=log(Volume);
 LogRate=log(Rate);
 datalines;

0.95 1.90 no_constrict 0.75 1.90 no_constrict
1.30 1.625 constrict
;

```

In the data set vaso, the variable Response represents the outcome of a test. The variable LogVolume represents the log of the volume of air intake, and the variable LogRate represents the log of the rate of air intake.

The following statements invoke PROC LOGISTIC to fit a logistic regression model to the vasoconstriction data, where Response is the response variable, and LogRate and LogVolume are the explanatory variables. Regression diagnostics are displayed when ODS Graphics is enabled, and the INFLUENCE option is specified to display a table of the regression diagnostics.

```

ods graphics on;
title 'Occurrence of Vasoconstriction';
proc logistic data=vaso;
 model Response=LogRate LogVolume/influence iplots;
run;
ods graphics off;

```

Results of the model fit are shown in [Output 54.6.1](#). Both LogRate and LogVolume are statistically significant to the occurrence of vasoconstriction ( $p = 0.0131$  and  $p = 0.0055$ , respectively). Their positive parameter estimates indicate that a higher inspiration rate or a larger volume of air intake is likely to increase the probability of vasoconstriction.

The index plots produced by the IPLOTS option are essentially the same line-printer plots as those produced by the INFLUENCE option, but with a 90-degree rotation and perhaps on a more refined scale. Since ODS Graphics is enabled, the line-printer plots from the INFLUENCE and IPLOTS options are suppressed and ODS Graphics versions of the plots are displayed in Outputs 54.6.3 through 54.6.5. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the LOGISTIC procedure, see the section “ODS Graphics” on page 4294. The vertical axis of an index plot represents the value of the diagnostic, and the horizontal axis represents the sequence (case number) of the observation. The index plots are useful for identification of extreme values.

The index plots of the Pearson residuals and the deviance residuals (Output 54.6.3) indicate that case 4 and case 18 are poorly accounted for by the model. The index plot of the diagonal elements of the hat matrix (Output 54.6.3) suggests that case 31 is an extreme point in the design space. The index plots of DFBETAS (Output 54.6.5) indicate that case 4 and case 18 are causing instability in all three parameter estimates. The other four index plots in Outputs 54.6.3 and 54.6.4 also point to these two cases as having a large impact on the coefficients and goodness of fit.

**Output 54.6.3** Residuals, Hat Matrix, and CI Displacement C

**Output 54.6.4** CI Displacement CBar, Change in Deviance and Pearson Chi-Square

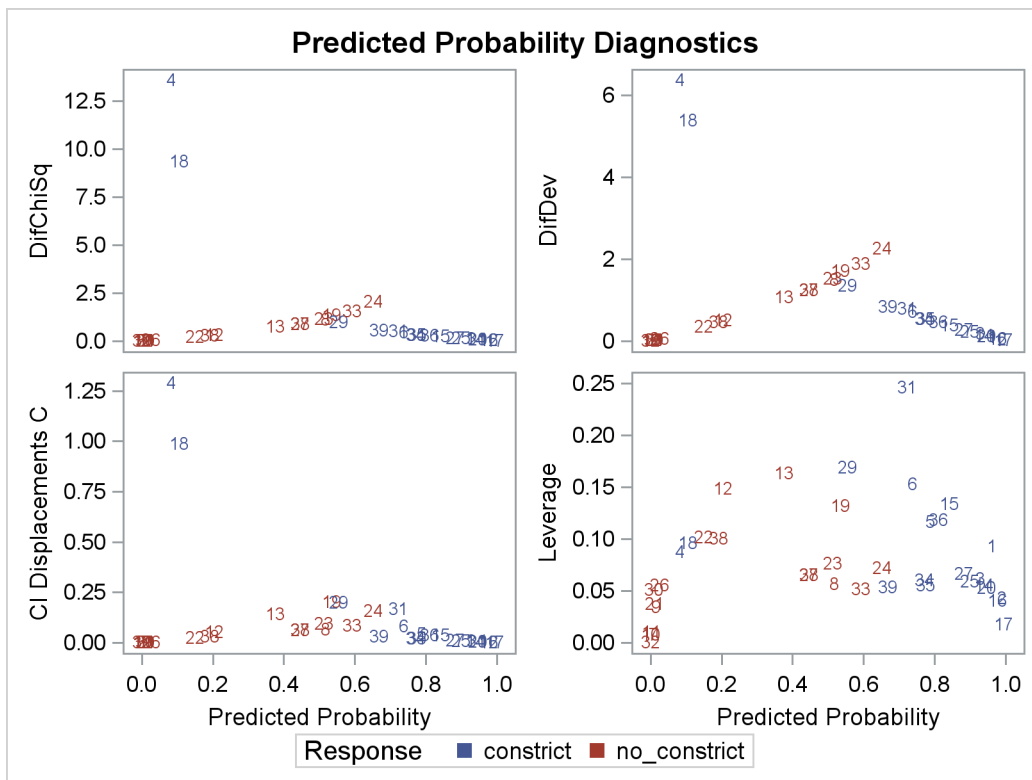

**Output 54.6.5** DFBETAS Plots

Other versions of diagnostic plots can be requested by specifying the appropriate options in the `PLOTS=` option. For example, the following statements produce three other sets of influence diagnostic plots: the `PHAT` option plots several diagnostics against the predicted probabilities ([Output 54.6.6](#)), the `LEVERAGE` option plots several diagnostics against the leverage ([Output 54.6.7](#)), and the `DPC` option plots the deletion diagnostics against the predicted probabilities and colors the observations according to the confidence interval displacement diagnostic ([Output 54.6.8](#)). The `LABEL` option displays the observation numbers on the plots. In all plots, you are looking for the outlying observations, and again cases 4 and 18 are noted.

```
ods graphics on;
proc logistic data=vaso plots(only label)=(phat leverage dpc);
 model Response=LogRate LogVolume;
run;
ods graphics off;
```

**Output 54.6.6** Diagnostics versus Predicted Probability

**Output 54.6.7** Diagnostics versus Leverage

**Output 54.6.8** Three Diagnostics

## Example 54.7: ROC Curve, Customized Odds Ratios, Goodness-of-Fit Statistics, R-Square, and Confidence Limits

This example plots an ROC curve, estimates a customized odds ratio, produces the traditional goodness-of-fit analysis, displays the generalized R Square measures for the fitted model, calculates the normal confidence intervals for the regression parameters, and produces a display of the probability function and prediction curves for the fitted model. The data consist of three variables: *n* (number of subjects in the sample), *disease* (number of diseased subjects in the sample), and *age* (age for the sample). A linear logistic regression model is used to study the effect of age on the probability of contracting the disease. The statements to produce the data set and perform the analysis are as follows:

```
data Data1;
 input disease n age;
 datalines;
0 14 25
0 20 35
0 19 45
7 18 55
6 12 65
17 17 75
;

ods graphics on;
proc logistic data=Data1 plots(only)=roc(id=obs);
 model disease/n=age / scale=none
 clparm=wald
 clodds=pl
 rsquare;

 units age=10;
 effectplot;
run;
ods graphics off;
```

The option **SCALE=NONE** is specified to produce the deviance and Pearson goodness-of-fit analysis without adjusting for overdispersion. The **RSQUARE** option is specified to produce generalized R Square measures of the fitted model. The **CLPARM=WALD** option is specified to produce the Wald confidence intervals for the regression parameters. The **UNITS** statement is specified to produce customized odds ratio estimates for a change of 10 years in the age variable, and the **CLODDS=PL** option is specified to produce profile-likelihood confidence limits for the odds ratio. The **PLOTS=** option with ODS Graphics enabled produces a graphical display of the ROC curve, and the **EFFECTPLOT** statement displays the model fit.

The results in [Output 54.7.1](#) show that the deviance and Pearson statistics indicate no lack of fit in the model.

**Output 54.7.1** Deviance and Pearson Goodness-of-Fit Analysis

| The LOGISTIC Procedure                          |        |    |          |            |
|-------------------------------------------------|--------|----|----------|------------|
| Deviance and Pearson Goodness-of-Fit Statistics |        |    |          |            |
| Criterion                                       | Value  | DF | Value/DF | Pr > ChiSq |
| Deviance                                        | 7.7756 | 4  | 1.9439   | 0.1002     |
| Pearson                                         | 6.6020 | 4  | 1.6505   | 0.1585     |
| Number of events/trials observations: 6         |        |    |          |            |

Output 54.7.2 shows that the R-square for the model is 0.74. The odds of an event increases by a factor of 7.9 for each 10-year increase in age.

Since ODS Graphics is enabled, a graphical display of the ROC curve is produced as shown in [Output 54.7.3](#).

**Output 54.7.3** Receiver Operating Characteristic Curve

Note that the area under the ROC curve is estimated by the statistic  $c$  in the “Association of Predicted Probabilities and Observed Responses” table. In this example, the area under the ROC curve is 0.953.

Since there is only one continuous covariate and since ODS Graphics is enabled, the `EFFECTPLOT` statement produces a graphical display of the predicted probability curve with bounding 95% confidence limits as shown in [Output 54.7.4](#).

**Output 54.7.4** Predicted Probability and 95% Prediction Limits

### Example 54.8: Comparing Receiver Operating Characteristic Curves

DeLong, DeLong, and Clarke-Pearson (1988) report on 49 patients with ovarian cancer who also suffer from an intestinal obstruction. Three (correlated) screening tests are measured to determine whether a patient will benefit from surgery. The three tests are the K-G score and two measures of nutritional status: total protein and albumin. The data are as follows:

```

data roc;
 input alb tp totscore popind @@;
 totscore = 10 - totscore;
 datalines;
3.0 5.8 10 0 3.2 6.3 5 1 3.9 6.8 3 1 2.8 4.8 6 0
3.2 5.8 3 1 0.9 4.0 5 0 2.5 5.7 8 0 1.6 5.6 5 1
3.8 5.7 5 1 3.7 6.7 6 1 3.2 5.4 4 1 3.8 6.6 6 1
4.1 6.6 5 1 3.6 5.7 5 1 4.3 7.0 4 1 3.6 6.7 4 0
2.3 4.4 6 1 4.2 7.6 4 0 4.0 6.6 6 0 3.5 5.8 6 1
3.8 6.8 7 1 3.0 4.7 8 0 4.5 7.4 5 1 3.7 7.4 5 1
3.1 6.6 6 1 4.1 8.2 6 1 4.3 7.0 5 1 4.3 6.5 4 1
3.2 5.1 5 1 2.6 4.7 6 1 3.3 6.8 6 0 1.7 4.0 7 0

```

```

3.7 6.1 5 1 3.3 6.3 7 1 4.2 7.7 6 1 3.5 6.2 5 1
2.9 5.7 9 0 2.1 4.8 7 1 2.8 6.2 8 0 4.0 7.0 7 1
3.3 5.7 6 1 3.7 6.9 5 1 3.6 6.6 5 1
;

```

In the following statements, the **NOFIT** option is specified in the **MODEL** statement to prevent PROC LOGISTIC from fitting the model with three covariates. Each **ROC** statement lists one of the covariates, and PROC LOGISTIC then fits the model with that single covariate. Note that the original data set contains six more records with missing values for one of the tests, but PROC LOGISTIC ignores all records with missing values; hence there is a common sample size for each of the three models. The **ROCCONTRAST** statement implements the nonparameteric approach of DeLong, DeLong, and Clarke-Pearson (1988) to compare the three ROC curves, the **REFERENCE** option specifies that the K-G Score curve is used as the reference curve in the contrast, the **E** option displays the contrast coefficients, and the **ESTIMATE** option computes and tests each comparison. With ODS Graphics enabled, the **plots=roc(id=prob)** specification in the PROC LOGISTIC statement displays several plots, and the plots of individual ROC curves have certain points labeled with their predicted probabilities.

```

ods graphics on;
proc logistic data=roc plots=roc(id=prob);
 model popind(event='0') = alb tp totscore / nofit;
 roc 'Albumin' alb;
 roc 'K-G Score' totscore;
 roc 'Total Protein' tp;
 roccontrast reference('K-G Score') / estimate e;
run;
ods graphics off;

```

The initial model information is displayed in [Output 54.8.1](#).

**Output 54.8.1** Initial LOGISTIC Output

| Probability modeled is popind=0. |        |                  |

**Output 54.8.1** *continued*

| Score Test for Global Null Hypothesis |    |            |
|---------------------------------------|----|------------|
| Chi-Square                            | DF | Pr > ChiSq |
| 10.7939                               | 3  | 0.0129     |

For each ROC model, the model fitting details in Outputs 54.8.2, 54.8.4, and 54.8.6 can be suppressed with the `ROCOPTIONS(NODETAILS)` option; however, the convergence status is always displayed.

The ROC curves for the three models are displayed in Outputs 54.8.3, 54.8.5, and 54.8.7. Note that the labels on the ROC curve are produced by specifying the `ID=PROB` option, and are the predicted probabilities for the cutpoints.

**Output 54.8.7** ROC Curve for Popind=Tp

All ROC curves being compared are also overlaid on the same plot, as shown in Output 54.8.8.

**Output 54.8.8** Overlay of All Models Being Compared

Output 54.8.9 displays the association statistics, and displays the area under the ROC curve along with its standard error and a confidence interval for each model in the comparison. The confidence interval for Total Protein contains 0.50; hence it is not significantly different from random guessing, which is represented by the diagonal line in the preceding ROC plots.

**Output 54.8.9** ROC Association Table

| ROC Association Statistics |        |                |                            |                     |        |        |  |
|----------------------------|--------|----------------|----------------------------|---------------------|--------|--------|--|
| ROC Model                  | Area   | Mann-Whitney   |                            | Somers' D<br>(Gini) | Gamma  | Tau-a  |  |
|                            |        | Standard Error | 95% Wald Confidence Limits |                     |        |        |  |
| Albumin                    | 0.7366 | 0.0927         | 0.5549 0.9182              | 0.4731              | 0.4809 | 0.1949 |  |
| K-G Score                  | 0.7258 | 0.1028         | 0.5243 0.9273              | 0.4516              | 0.5217 | 0.1860 |  |
| Total Protein              | 0.6478 | 0.1000         | 0.4518 0.8439              | 0.2957              | 0.3107 | 0.1218 |  |

Output 54.8.10 shows that the contrast used 'K-G Score' as the reference level. This table is produced by specifying the E option in the ROCCONTRAST statement.

**Output 54.8.10** ROC Contrast Coefficients

| ROC Contrast Coefficients |      |      |
|---------------------------|------|------|
| ROC Model                 | Row1 | Row2 |
| Albumin                   | 1    | 0    |
| K-G Score                 | -1   | -1   |
| Total Protein             | 0    | 1    |

Output 54.8.11 shows that the 2-degrees-of-freedom test that the 'K-G Score' is different from at least one other test is not significant at the 0.05 level.

**Output 54.8.11** ROC Test Results (2 Degrees of Freedom)

| ROC Contrast Test Results |    |            |            |
|---------------------------|----|------------|------------|
| Contrast                  | DF | Chi-Square | Pr > ChiSq |
| Reference = K-G Score     | 2  | 2.5340     | 0.2817     |

Output 54.8.12 is produced by specifying the ESTIMATE option in the ROCCONTRAST statement. Each row shows that the curves are not significantly different.

## Example 54.9: Goodness-of-Fit Tests and Subpopulations

A study is done to investigate the effects of two binary factors, A and B, on a binary response, Y. Subjects are randomly selected from subpopulations defined by the four possible combinations of levels of A and B. The number of subjects responding with each level of Y is recorded, and the following DATA step creates the data set One:

```

data One;
 do A=0,1;
 do B=0,1;
 do Y=1,2;
 input F @@;
 output;
 end;
 end;
 end;
 datalines;
23 63 31 70 67 100 70 104
;

```

The following statements fit a full model to examine the main effects of A and B as well as the interaction effect of A and B:

```

proc logistic data=One;
 freq F;
 model Y=A B A*B;
run;

```

Results of the model fit are shown in [Output 54.9.1](#). Notice that neither the A\*B interaction nor the B main effect is significant.

Pearson and deviance goodness-of-fit tests cannot be obtained for this model since a full model containing four parameters is fit, leaving no residual degrees of freedom. For a binary response model, the goodness-of-fit tests have  $m - q$  degrees of freedom, where  $m$  is the number of subpopulations and  $q$  is the number of model parameters. In the preceding model,  $m = q = 4$ , resulting in zero degrees of freedom for the tests.

The following statements fit a reduced model containing only the A effect, so two degrees of freedom become available for testing goodness of fit. Specifying the `SCALE=NONE` option requests the Pearson and deviance statistics. With single-trial syntax, the `AGGREGATE=` option is needed to define the subpopulations in the study. Specifying `AGGREGATE=(A B)` creates subpopulations of the four combinations of levels of A and B. Although the B effect is being dropped from the model, it is still needed to define the original subpopulations in the study. If `AGGREGATE=(A)` were specified, only two subpopulations would be created from the levels of A, resulting in  $m = q = 2$  and zero degrees of freedom for the tests.

```
proc logistic data=One;
 freq F;
 model Y=A / scale=none aggregate=(A B);
run;
```

The goodness-of-fit tests in [Output 54.9.2](#) show that dropping the B main effect and the A\*B interaction simultaneously does not result in significant lack of fit of the model. The tests' large  $p$ -values indicate insufficient evidence for rejecting the null hypothesis that the model fits.

**Output 54.9.2** Reduced Model Fit

| The LOGISTIC Procedure                          |        |    |          |            |

## Example 54.10: Overdispersion

In a seed germination test, seeds of two cultivars were planted in pots of two soil conditions. The following statements create the data set `seeds`, which contains the observed proportion of seeds that germinated for various combinations of cultivar and soil condition. The variable `n` represents the number of seeds planted in a pot, and the variable `r` represents the number germinated. The indicator variables `cult` and `soil` represent the cultivar and soil condition, respectively.

```
data seeds;
 input pot n r cult soil;
 datalines;
 1 16 8 0 0
 2 51 26 0 0
 3 45 23 0 0
 4 39 10 0 0
 5 36 9 0 0
 6 81 23 1 0
 7 30 10 1 0
 8 39 17 1 0
 9 28 8 1 0
 10 62 23 1 0
 11 51 32 0 1
 12 72 55 0 1
 13 41 22 0 1
 14 12 3 0 1
 15 13 10 0 1
 16 79 46 1 1
 17 30 15 1 1
 18 51 32 1 1
 19 74 53 1 1
 20 56 12 1 1
 ;
```

PROC LOGISTIC is used as follows to fit a logit model to the data, with cult, soil, and cult × soil interaction as explanatory variables. The option `SCALE=NONE` is specified to display goodness-of-fit statistics.

```
proc logistic data=seeds;
 model r/n=cult soil cult*soil/scale=none;
 title 'Full Model With SCALE=NONE';
run;
```

Results of fitting the full factorial model are shown in [Output 54.10.1](#). Both Pearson  $\chi^2$  and deviance are highly significant ( $p < 0.0001$ ), suggesting that the model does not fit well.

If the link function and the model specification are correct and if there are no outliers, then the lack of fit might be due to overdispersion. Without adjusting for the overdispersion, the standard errors are likely to be underestimated, causing the Wald tests to be too sensitive. In PROC LOGISTIC, there are three `SCALE=` options to accommodate overdispersion. With unequal sample sizes for the observations, `SCALE=WILLIAMS` is preferred. The Williams model estimates a scale parameter  $\phi$  by equating the value of Pearson  $\chi^2$  for the full model to its approximate expected value. The full model considered in the following statements is the model with cultivar, soil condition, and their interaction. Using a full model reduces the risk of contaminating  $\phi$  with lack of fit due to incorrect model specification.

```
proc logistic data=seeds;
 model r/n=cult soil cult*soil / scale=williams;
 title 'Full Model With SCALE=WILLIAMS';
run;
```

Results of using Williams' method are shown in [Output 54.10.2](#). The estimate of  $\phi$  is 0.075941 and is given in the formula for the Weight Variable at the beginning of the displayed output.

| cult*soil                                                                                                                                                                                    | 1              | -0.0532                  | 0.5835              | 0.0083          | 0.9274     |

Since neither cult nor cult  $\times$  soil is statistically significant ( $p = 0.5290$  and  $p = 0.9274$ , respectively), a reduced model that contains only the soil condition factor is fitted, with the observations weighted by  $1/(1 + 0.075941(N - 1))$ . This can be done conveniently in PROC LOGISTIC by including the scale estimate in the SCALE=WILLIAMS option as follows:

```
proc logistic data=seeds;
 model r/n=soil / scale=williams(0.075941);
 title 'Reduced Model With SCALE=WILLIAMS(0.075941)';
run;
```

Results of the reduced model fit are shown in [Output 54.10.3](#). Soil condition remains a significant factor ( $p = 0.0064$ ) for the seed germination.

### Example 54.11: Conditional Logistic Regression for Matched Pairs Data

In matched pairs, or *case-control*, studies, conditional logistic regression is used to investigate the relationship between an outcome of being an event (case) or a nonevent (control) and a set of prognostic factors.

The following data are a subset of the data from the Los Angeles Study of the Endometrial Cancer Data in Breslow and Day (1980). There are 63 matched pairs, each consisting of a case of endometrial cancer (Outcome=1) and a control (Outcome=0). The case and corresponding control have the same ID. Two prognostic factors are included: Gall (an indicator variable for gall bladder disease) and Hyper (an indicator variable for hypertension). The goal of the case-control analysis is to determine the relative risk for gall bladder disease, controlling for the effect of hypertension.

```
data Data1;
 do ID=1 to 63;
 do Outcome = 1 to 0 by -1;
 input Gall Hyper @@;
 output;
 end;
 end;
 datalines;
0 0 0 0 0 0 0 0 0 1 0 1 0 0 1 0 1 0 0 1 1 0 0 1
0 1 0 0 1 0 0 0 1 1 0 1 0 0 0 0 0 0 0 0 0 0 0 0
1 0 0 0 0 0 0 1 1 0 0 1 1 0 1 0 1 0 1 0 0 1 1 0 0 1
0 1 0 0 0 0 1 1 0 0 1 1 0 0 0 1 0 1 0 0 0 1 0 0 0
0 0 1 1 0 1 0 1 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
0 0 0 1 1 0 0 1 0 0 1 0 0 0 1 1 0 0 0 0 0 1 0 0 0
0 1 0 0 0 1 0 0 0 1 0 0 0 0 0 0 0 0 0 0 1 1 1 1
0 0 0 1 0 1 0 0 0 1 0 1 0 1 0 1 0 1 0 1 0 1 0 0 0
0 0 0 0 0 1 1 0 0 0 0 1 0 0 0 0 0 0 0 0 1 0 0 0
0 0 0 0 1 1 0 0 0 1 0 0 0 0 0 0 0 0 0 0 0 1 0 1
0 0 0 0 0 1 0 1 0 1 0 1 0 0 0 1 0 0 0 1 0 0 0 0
0 0 0 0 1 1 1 0 0 0 0 0 0 0 0 0 0 0 0 0 1 1 0 0
1 0 1 0 0 1 0 0 1 0 0 0 0 0 0 0 0 0 0 0 0 0 0 0
;
```

There are several ways to approach this problem with PROC LOGISTIC:

- Specify the **STRATA** statement to perform a conditional logistic regression.
- Specify **EXACT** and **STRATA** statements to perform an exact logistic regression on the original data set, if you believe the data set is too small or too sparse for the usual asymptotics to hold.
- Transform each matched pair into a single observation, and then specify a PROC LOGISTIC statement on this transformed data without a STRATA statement; this also performs a conditional logistic regression and produces essentially the same results.
- Specify an **EXACT** statement on the transformed data.

SAS statements and selected results for these four approaches are given in the remainder of this example.

### Conditional Analysis Using the STRATA Statement

In the following statements, PROC LOGISTIC is invoked with the ID variable declared in the **STRATA** statement to obtain the conditional logistic model estimates for a model containing Gall as the only predictor variable:

```
proc logistic data=Data1;
 strata ID;
 model outcome(event='1')=Gall;
run;
```

Results from the conditional logistic analysis are shown in [Output 54.11.1](#). Note that there is no intercept term in the “Analysis of Maximum Likelihood Estimates” tables.

The odds ratio estimate for Gall is 2.60, which is marginally significant ( $p = 0.0694$ ) and which is an estimate of the relative risk for gall bladder disease. A 95% confidence interval for this relative risk is (0.927, 7.293).

**Exact Analysis Using the STRATA Statement**

When you believe there are not enough data or that the data are too sparse, you can perform a stratified exact logistic regression. The following statements perform stratified exact logistic regressions on the original data set by specifying both the **STRATA** and **EXACT** statements:

```
proc logistic data=Data1 exactonly;
 strata ID;
 model outcome(event='1')=Gall;
 exact Gall / estimate=both;
run;
```

**Output 54.11.2** Exact Logistic Regression (Gall as Risk Factor)

| Gall                       | 2.600       | 0.870                 | 9.315                 | 0.0963            |                   |

Note that the score statistic in the “Conditional Exact Tests” table in [Output 54.11.2](#) is identical to the score statistic in [Output 54.11.1](#) from the conditional analysis. The exact odds ratio confidence interval is much wider than its conditional analysis counterpart, but the parameter estimates are similar. The exact analysis confirms the marginal significance of Gall as a predictor variable.

### Conditional Analysis Using Transformed Data

When each matched set consists of one event and one nonevent, the conditional likelihood is given by

$$\prod_i (1 + \exp(-\beta'(x_{i1} - x_{i0})))^{-1}$$

where  $x_{i1}$  and  $x_{i0}$  are vectors representing the prognostic factors for the event and nonevent, respectively, of the  $i$ th matched set. This likelihood is identical to the likelihood of fitting a logistic regression model to a set of data with constant response, where the model contains no intercept term and has explanatory variables given by  $d_i = x_{i1} - x_{i0}$  (Breslow 1982).

To apply this method, the following DATA step transforms each matched pair into a single observation, where the variables Gall and Hyper contain the differences between the corresponding values for the case and the control (case-control). The variable Outcome, which will be used as the response variable in the logistic regression model, is given a constant value of 0 (which is the Outcome value for the control, although any constant, numeric or character, will suffice).

```
data Data2;
 set Data1;
 drop id1 gall1 hyper1;
 retain id1 gall1 hyper1 0;
 if (ID = id1) then do;
 Gall=gall1-Gall; Hyper=hyper1-Hyper;
 output;
 end;
 else do;
 id1=ID; gall1=Gall; hyper1=Hyper;
 end;
run;
```

Note that there are 63 observations in the data set, one for each matched pair. Since the number of observations  $n$  is halved, statistics that depend on  $n$  such as R Square (see the “[Generalized Coefficient of Determination](#)” on page 4246 section) will be incorrect. The variable Outcome has a constant value of 0.

In the following statements, PROC LOGISTIC is invoked with the NOINT option to obtain the conditional logistic model estimates. Because the option CLODDS=PL is specified, PROC LOGISTIC computes a 95% profile-likelihood confidence interval for the odds ratio for each predictor variable; note that profile-likelihood confidence intervals are not currently available when a STRATA statement is specified.

```
proc logistic data=Data2;
 model outcome=Gall / noint clodds=PL;
run;
```

The results are not displayed here.

## Exact Analysis Using Transformed Data

Sometimes the original data set in a matched-pairs study is too large for the exact methods to handle. In such cases it might be possible to use the transformed data set. The following statements perform exact logistic regressions on the transformed data set. The results are not displayed here.

```
proc logistic data=Data2 exactonly;
 model outcome=Gall / noint;
 exact Gall / estimate=both;
run;
```

---

## Example 54.12: Firth's Penalized Likelihood Compared with Other Approaches

Firth's penalized likelihood approach is a method of addressing issues of separability, small sample sizes, and bias of the parameter estimates. This example performs some comparisons between results from using the `FIRTH` option to results from the usual unconditional, conditional, and exact logistic regression analyses. When the sample size is large enough, the unconditional estimates and the Firth penalized-likelihood estimates should be nearly the same. These examples show that Firth's penalized likelihood approach compares favorably with unconditional, conditional, and exact logistic regression; however, this is not an exhaustive analysis of Firth's method. For more detailed analyses with separable data sets, see Heinze (2006, 1999) and Heinze and Schemper (2002).

### Comparison on 2x2 Tables with One Zero Cell

A  $2 \times 2$  table with one cell having zero frequency, where the rows of the table are the levels of a covariate while the columns are the levels of the response variable, is an example of a quasi-completely separated data set. The parameter estimate for the covariate under unconditional logistic regression will move off to infinity, although PROC LOGISTIC will stop the iterations at an earlier point in the process. An exact logistic regression is sometimes performed to determine the importance of the covariate in describing the variation in the data, but the median-unbiased parameter estimate, while finite, might not be near the true value, and one confidence limit (for this example, the upper) is always infinite.

The following DATA step produces 1000 different  $2 \times 2$  tables, all following an underlying probability structure, with one cell having a near zero probability of being observed:

```
%let beta0=-15;
%let beta1=16;
data one;
 keep sample X y pry;
 do sample=1 to 1000;
 do i=1 to 100;
 X=rantbl(987987, .4, .6)-1;
 xb= &beta0 + X*&beta1;
 exb=exp(xb);
 pry= exb/(1+exb);
 cut= ranuni(393993);
 if (pry < cut) then y=1; else y=0;
 output;
 end;
 end;
```

```
end;
run;
```

The following statements perform the bias-corrected and exact logistic regression on each of the 1000 different data sets, output the odds ratio tables by using the ODS OUTPUT statement, and compute various statistics across the data sets by using the MEANS procedure:

```
ods exclude all;
proc logistic data=one;
 by sample;
 class X(param=ref);
 model y(event='1')=X / firth clodds=pl;
 ods output cloddspl=firth;
run;
proc logistic data=one exactonly;
 by sample;
 class X(param=ref);
 model y(event='1')=X;
 exact X / estimate=odds;
 ods output exactoddsratio=exact;
run;
ods select all;
proc means data=firth;
 var LowerCL OddsRatioEst UpperCL;
run;
proc means data=exact;
 var LowerCL Estimate UpperCL;
run;
```

The results of the PROC MEANS statements are summarized in [Table 54.16](#). You can see that the odds ratios are all quite large; the confidence limits on every table suggest that the covariate X is a significant factor in explaining the variability in the data.

**Table 54.16** Odds Ratio Results

| Method | Mean Estimate | Standard Error | Minimum Lower CL | Maximum Upper CL |
|--------|---------------|----------------|------------------|------------------|
| Firth  | 231.59        | 83.57          | 10.40            | 111317           |
| Exact  | 152.02        | 52.30          | 11.16            | ∞                |

### Comparison on Case-Control Data

Case-control models contain an intercept term for every case-control pair in the data set. This means that there are a large number of parameters compared to the number of observations. Breslow and Day (1980) note that the estimates from unconditional logistic regression are biased with the corresponding odds ratios off by a power of 2 from the true value; conditional logistic regression was developed to remedy this.

The following DATA step produces 1000 case-control data sets, with pair indicating the strata:

```

%let beta0=1;
%let beta1=2;
data one;
 do sample=1 to 1000;
 do pair=1 to 20;
 ran=ranuni(939393);
 a=3*ranuni(9384984)-1;
 pdf0= pdf('NORMAL', a, .4, 1);
 pdf1= pdf('NORMAL', a, 1, 1);
 pry0= pdf0/(pdf0+pdf1);
 pry1= 1-pry0;
 xb= log(pry0/pry1);
 x= (xb-&beta0*pair/100) / &beta1;
 y=0;
 output;
 x= (-xb-&beta0*pair/100) / &beta1;
 y=1;
 output;
 end;
 end;
run;

```

Unconditional, conditional, exact, and Firth-adjusted analyses are performed on the data sets, and the mean, minimum, and maximum odds ratios and the mean upper and lower limits for the odds ratios are displayed in Table 54.17. **CAUTION:** Due to the exact analyses, this program takes a long time and a lot of resources to run. You might want to reduce the number of samples generated.

```

ods exclude all;
proc logistic data=one;
 by sample;
 class pair / param=ref;
 model y=x pair / clodds=pl;
 ods output cloddspl=oru;
run;
data oru;
 set oru;
 if Effect='x';
 rename lowercl=lclu uppercl=uclu oddsratioest=orestu;
run;
proc logistic data=one;
 by sample;
 strata pair;
 model y=x / clodds=wald;
 ods output cloddswald=orc;
run;
data orc;
 set orc;
 if Effect='x';
 rename lowercl=lclc uppercl=uclc oddsratioest=orestc;
run;
proc logistic data=one exactonly;
 by sample;
 strata pair;

```

```

model y=x;
exact x / estimate=both;
ods output ExactOddsRatio=ore;
run;
proc logistic data=one;
by sample;
class pair / param=ref;
model y=x pair / firth clodds=pl;
ods output cloddspl=orf;
run;
data orf;
set orf;
if Effect='x';
rename lowercl=lclf uppercl=uclf oddsratioest=orestf;
run;
data all;
merge oru orc ore orf;
run;
ods select all;
proc means data=all;
run;

```

You can see from Table 54.17 that the conditional, exact, and Firth-adjusted results are all comparable, while the unconditional results are several orders of magnitude different.

**Table 54.17** Odds Ratio Estimates

| Method        | N    | Minimum | Mean   | Maximum |
|---------------|------|---------|--------|---------|
| Unconditional | 1000 | 0.00045 | 112.09 | 38038   |
| Conditional   | 1000 | 0.021   | 4.20   | 195     |
| Exact         | 1000 | 0.021   | 4.20   | 195     |
| Firth         | 1000 | 0.018   | 4.89   | 71      |

Further examination of the data set all shows that the differences between the square root of the unconditional odds ratio estimates and the conditional estimates have mean  $-0.00019$  and standard deviation  $0.0008$ , verifying that the unconditional odds ratio is about the square of the conditional odds ratio. The conditional and exact conditional odds ratios are also nearly equal, with their differences having mean  $3E-7$  and standard deviation  $6E-6$ . The differences between the Firth and the conditional odds ratios can be large (mean  $0.69$ , standard deviation  $5.40$ ), but their relative differences,  $\frac{\text{Firth} - \text{Conditional}}{\text{Conditional}}$ , have mean  $0.20$  with standard deviation  $0.19$ , so the largest differences occur with the larger estimates.

### Example 54.13: Complementary Log-Log Model for Infection Rates

Antibodies produced in response to an infectious disease like malaria remain in the body after the individual has recovered from the disease. A serological test detects the presence or absence of such antibodies. An individual with such antibodies is called seropositive. In geographic areas where the disease is endemic, the inhabitants are at fairly constant risk of infection. The probability of an individual never having been

infected in  $Y$  years is  $\exp(-\mu Y)$ , where  $\mu$  is the mean number of infections per year (see the appendix of Draper, Voller, and Carpenter 1972). Rather than estimating the unknown  $\mu$ , epidemiologists want to estimate the probability of a person living in the area being infected in one year. This infection rate  $\gamma$  is given by

$$\gamma = 1 - e^{-\mu}$$

The following statements create the data set `sero`, which contains the results of a serological survey of malarial infection. Individuals of nine age groups (Group) were tested. The variable `A` represents the midpoint of the age range for each age group. The variable `N` represents the number of individuals tested in each age group, and the variable `R` represents the number of individuals that are seropositive.

```
data sero;
 input Group A N R;
 X=log(A);
 label X='Log of Midpoint of Age Range';
 datalines;
1 1.5 123 8
2 4.0 132 6
3 7.5 182 18
4 12.5 140 14
5 17.5 138 20
6 25.0 161 39
7 35.0 133 19
8 47.0 92 25
9 60.0 74 44
;
```

For the  $i$ th group with the age midpoint  $A_i$ , the probability of being seropositive is  $p_i = 1 - \exp(-\mu A_i)$ . It follows that

$$\log(-\log(1 - p_i)) = \log(\mu) + \log(A_i)$$

By fitting a binomial model with a complementary log-log link function and by using `X=log(A)` as an offset term, you can estimate  $\alpha = \log(\mu)$  as an intercept parameter. The following statements invoke PROC LOGISTIC to compute the maximum likelihood estimate of  $\alpha$ . The `LINK=CLOGLOG` option is specified to request the complementary log-log link function. Also specified is the `CLPARM=PL` option, which requests the profile-likelihood confidence limits for  $\alpha$ .

```
proc logistic data=sero;
 model R/N= / offset=X
 link=cloglog
 clparm=pl
 scale=none;
 title 'Constant Risk of Infection';
run;
```

Results of fitting this constant risk model are shown in [Output 54.13.1](#).

**Output 54.13.1** Modeling Constant Risk of Infection

| Constant Risk of Infection                      |                  |                              |                 |            |

| Parameter Estimates and Profile-Likelihood Confidence Intervals |          |                       |         |
|-----------------------------------------------------------------|----------|-----------------------|---------|
| Parameter                                                       | Estimate | 95% Confidence Limits |         |
| Intercept                                                       | -4.6605  | -4.8057               | -4.5219 |

Output 54.13.1 shows that the maximum likelihood estimate of  $\alpha = \log(\mu)$  and its estimated standard error are  $\hat{\alpha} = -4.6605$  and  $\hat{\sigma}_{\hat{\alpha}} = 0.0725$ , respectively. The infection rate is estimated as

$$\hat{\gamma} = 1 - e^{-\hat{\mu}} = 1 - e^{-e^{\hat{\beta}_0}} = 1 - e^{-e^{-4.6605}} = 0.00942$$

The 95% confidence interval for  $\gamma$ , obtained by back-transforming the 95% confidence interval for  $\alpha$ , is (0.0082, 0.0108); that is, there is a 95% chance that, in repeated sampling, the interval of 8 to 11 infections per thousand individuals contains the true infection rate.

The goodness-of-fit statistics for the constant risk model are statistically significant ( $p < 0.0001$ ), indicating that the assumption of constant risk of infection is not correct. You can fit a more extensive model by allowing a separate risk of infection for each age group. Suppose  $\mu_i$  is the mean number of infections per year for the  $i$ th age group. The probability of seropositive for the  $i$ th group with the age midpoint  $A_i$  is  $p_i = 1 - \exp(-\mu_i A_i)$ , so that

$$\log(-\log(1 - p_i)) = \log(\mu_i) + \log(A_i)$$

In the following statements, a complementary log-log model is fit containing Group as an explanatory classification variable with the GLM coding (so that a dummy variable is created for each age group), no intercept term, and X=log(A) as an offset term. The ODS OUTPUT statement saves the estimates and their 95% profile-likelihood confidence limits to the ClparmPL data set. Note that  $\log(\mu_i)$  is the regression parameter associated with Group=  $i$ .

```
proc logistic data=sero;
 ods output ClparmPL=ClparmPL;
 class Group / param=glm;
 model R/N=Group / noint
 offset=X
 link=cloglog
 clparm=pl;
 title 'Infectious Rates and 95% Confidence Intervals';
run;
```

Results of fitting the model with a separate risk of infection are shown in Output 54.13.2.

| Group 8                                                         | 8 | -4.9987  | -5.4195               | -4.6289 |
| Group 9                                                         | 9 | -4.1965  | -4.5164               | -3.9037 |

For the first age group (Group=1), the point estimate of  $\log(\mu_1)$  is  $-3.1048$ , which transforms into an infection rate of  $1 - \exp(-\exp(-3.1048)) = 0.0438$ . A 95% confidence interval for this infection rate is obtained by transforming the 95% confidence interval for  $\log(\mu_1)$ . For the first age group, the lower and upper confidence limits are  $1 - \exp(-\exp(-3.8880)) = 0.0203$  and  $1 - \exp(-\exp(-2.4833)) = 0.0801$ , respectively; that is, there is a 95% chance that, in repeated sampling, the interval of 20 to 80 infections per thousand individuals contains the true infection rate. The following statements perform this transformation on the estimates and confidence limits saved in the ClparmPL data set; the resulting estimated infection rates in one year's time for each age group are displayed in Table 54.18. Note that the infection rate for the first age group is high compared to that of the other age groups.

```
data ClparmPL;
 set ClparmPL;
 Estimate=round(1000*(1-exp(-exp(Estimate))));
 LowerCL =round(1000*(1-exp(-exp(LowerCL)));
 UpperCL =round(1000*(1-exp(-exp(UpperCL)));
run;
```

**Table 54.18** Infection Rate in One Year

| Age Group | Number Infected per 1,000 People |           |           |
|-----------|----------------------------------|-----------|-----------|
|           | Point Estimate                   | 95% Lower | 95% Upper |

### Example 54.14: Complementary Log-Log Model for Interval-Censored Survival Times

Often survival times are not observed more precisely than the interval (for instance, a day) within which the event occurred. Survival data of this form are known as grouped or interval-censored data. A discrete analog of the continuous proportional hazards model (Prentice and Gloeckler 1978; Allison 1982) is used to investigate the relationship between these survival times and a set of explanatory variables.

Suppose  $T_i$  is the discrete survival time variable of the  $i$ th subject with covariates  $\mathbf{x}_i$ . The discrete-time hazard rate  $\lambda_{it}$  is defined as

$$\lambda_{it} = \Pr(T_i = t \mid T_i \geq t, \mathbf{x}_i), \quad t = 1, 2, \dots$$

Using elementary properties of conditional probabilities, it can be shown that

$$\Pr(T_i = t) = \lambda_{it} \prod_{j=1}^{t-1} (1 - \lambda_{ij}) \quad \text{and} \quad \Pr(T_i > t) = \prod_{j=1}^t (1 - \lambda_{ij})$$

Suppose  $t_i$  is the observed survival time of the  $i$ th subject. Suppose  $\delta_i = 1$  if  $T_i = t_i$  is an event time and 0 otherwise. The likelihood for the grouped survival data is given by

$$\begin{aligned} L &= \prod_i [\Pr(T_i = t_i)]^{\delta_i} [\Pr(T_i > t_i)]^{1-\delta_i} \\ &= \prod_i \left( \frac{\lambda_{it_i}}{1 - \lambda_{it_i}} \right)^{\delta_i} \prod_{j=1}^{t_i} (1 - \lambda_{ij}) \\ &= \prod_i \prod_{j=1}^{t_i} \left( \frac{\lambda_{ij}}{1 - \lambda_{ij}} \right)^{y_{ij}} (1 - \lambda_{ij}) \end{aligned}$$

where  $y_{ij} = 1$  if the  $i$ th subject experienced an event at time  $T_i = j$  and 0 otherwise.

Note that the likelihood  $L$  for the grouped survival data is the same as the likelihood of a binary response model with event probabilities  $\lambda_{ij}$ . If the data are generated by a continuous-time proportional hazards model, Prentice and Gloeckler (1978) have shown that

$$\lambda_{ij} = 1 - \exp(-\exp(\alpha_j + \boldsymbol{\beta}'\mathbf{x}_i))$$

which can be rewritten as

$$\log(-\log(1 - \lambda_{ij})) = \alpha_j + \boldsymbol{\beta}'\mathbf{x}_i$$

where the coefficient vector  $\boldsymbol{\beta}$  is identical to that of the continuous-time proportional hazards model, and  $\alpha_j$  is a constant related to the conditional survival probability in the interval defined by  $T_i = j$  at  $\mathbf{x}_i = \mathbf{0}$ . The grouped data survival model is therefore equivalent to the binary response model with complementary log-log link function. To fit the grouped survival model by using PROC LOGISTIC, you must treat each discrete time unit for each subject as a separate observation. For each of these observations, the response is dichotomous, corresponding to whether or not the subject died in the time unit.

Consider a study of the effect of insecticide on flour beetles. Four different concentrations of an insecticide were sprayed on separate groups of flour beetles. The following DATA step saves the number of male and female flour beetles dying in successive intervals in the data set Beetles:

```
data Beetles(keep=time sex conc freq);

 13 1 0 0 0 0 1 0 0
 14 101 126 19 47 7 17 2 4
 ;
```

The data set Beetles contains four variables: time, sex, conc, and freq. The variable time represents the interval death time; for example, time=2 is the interval between day 1 and day 2. Insects surviving the duration (13 days) of the experiment are given a time value of 14. The variable sex represents the sex of the insects (1=male, 2=female), conc represents the concentration of the insecticide (mg/cm<sup>2</sup>), and freq represents the frequency of the observations.

To use PROC LOGISTIC with the grouped survival data, you must expand the data so that each beetle has a separate record for each day of survival. A beetle that died in the third day (`time=3`) would contribute three observations to the analysis, one for each day it was alive at the beginning of the day. A beetle that survives the 13-day duration of the experiment (`time=14`) would contribute 13 observations.

The following DATA step creates a new data set named `Days` containing the beetle-day observations from the data set `Beetles`. In addition to the variables `sex`, `conc`, and `freq`, the data set contains an outcome variable `y` and a classification variable `day`. The variable `y` has a value of 1 if the observation corresponds to the day that the beetle died, and it has a value of 0 otherwise. An observation for the first day will have a value of 1 for `day`; an observation for the second day will have a value of 2 for `day`, and so on. For instance, [Output 54.14.1](#) shows an observation in the `Beetles` data set with `time=3`, and [Output 54.14.2](#) shows the corresponding beetle-day observations in the data set `Days`.

```
data Days;
 set Beetles;
 do day=1 to time;
 if (day < 14) then do;
 y= (day=time);
 output;
 end;
 end;
run;
```

**Output 54.14.1** An Observation with Time=3 in Beetles Data Set

| Obs | time | conc | freq | sex |
|-----|------|------|------|-----|
| 17  | 3    | 0.2  | 10   | 1   |

**Output 54.14.2** Corresponding Beetle-Day Observations in Days

| Obs | time | conc | freq | sex | day | y |
|-----|------|------|------|-----|-----|---|
| 25  | 3    | 0.2  | 10   | 1   | 1   | 0 |
| 26  | 3    | 0.2  | 10   | 1   | 2   | 0 |
| 27  | 3    | 0.2  | 10   | 1   | 3   | 1 |

The following statements invoke PROC LOGISTIC to fit a complementary log-log model for binary data with the response variable `Y` and the explanatory variables `day`, `sex`, and `Variableconc`. Specifying the `EVENT=` option ensures that the event (`y=1`) probability is modeled. The GLM coding in the `CLASS` statement creates an indicator column in the design matrix for each level of `day`. The coefficients of the indicator effects for `day` can be used to estimate the baseline survival function. The `NOINT` option is specified to prevent any redundancy in estimating the coefficients of `day`. The Newton-Raphson algorithm is used for the maximum likelihood estimation of the parameters.

```
proc logistic data=Days outest=est1;
 class day / param=glm;
 model y(event='1')= day sex conc
 / noint link=cloglog technique=newton;
 freq freq;
run;
```

Results of the model fit are given in [Output 54.14.3](#). Both sex and conc are statistically significant for the survival of beetles sprayed by the insecticide. Female beetles are more resilient to the chemical than male beetles, and increased concentration of the insecticide increases its effectiveness.

**Output 54.14.3** Parameter Estimates for the Grouped Proportional Hazards Model

| conc                                     | 1  | 3.0918   | 0.2288         | 182.5665        | <.0001     |

The coefficients of parameters for the day variable are the maximum likelihood estimates of  $\alpha_1, \dots, \alpha_{13}$ , respectively. The baseline survivor function  $S_0(t)$  is estimated by

$$\hat{S}_0(t) = \widehat{\Pr}(T > t) = \prod_{j \leq t} \exp(-\exp(\hat{\alpha}_j))$$

and the survivor function for a given covariate pattern (sex= $x_1$  and conc= $x_2$ ) is estimated by

$$\hat{S}(t) = [\hat{S}_0(t)]^{\exp(-0.5651x_1 + 3.0918x_2)}$$

The following statements compute the survival curves for male and female flour beetles exposed to the insecticide in concentrations of 0.20 mg/cm<sup>2</sup> and 0.80 mg/cm<sup>2</sup>:

```

data one (keep=day survival element s_m20 s_f20 s_m80 s_f80);
 array dd day1-day13;
 array sc[4] m20 f20 m80 f80;
 array s_sc[4] s_m20 s_f20 s_m80 s_f80 (1 1 1 1);
 set est1;
 m20= exp(sex + .20 * conc);
 f20= exp(2 * sex + .20 * conc);
 m80= exp(sex + .80 * conc);
 f80= exp(2 * sex + .80 * conc);
 survival=1;
 day=0;
 output;
 do over dd;
 element= exp(-exp(dd));
 survival= survival * element;
 do i=1 to 4;
 s_sc[i] = survival ** sc[i];
 end;
 day + 1;
 output;
 end;
run;

```

Instead of plotting the curves as step functions, the following statements use the PBSPLINE statement in the SGPLOT procedure to smooth the curves with a penalized B-spline. See Chapter 97, “The TRANSREG Procedure,” for details about the implementation of the penalized B-spline method. The SAS autocall macro %MODSTYLE is specified to change the marker symbols for the plot. For more information about the %MODSTYLE macro, see the section “Style Template Modification Macro” on page 667 in Chapter 21, “Statistical Graphics Using ODS.” The smoothed survival curves are displayed in Output 54.14.4.

```

%modstyle(name=LogiStyle,parent=htmlblue,markers=circlefilled);
ods listing style=LogiStyle;
proc sgplot data=one;
 title 'Flour Beetles Sprayed with Insecticide';
 xaxis grid integer;
 yaxis grid label='Survival Function';
 pbspline y=s_m20 x=day /
 legendlabel = "Male at 0.20 conc." name="pred1";
 pbspline y=s_m80 x=day /
 legendlabel = "Male at 0.80 conc." name="pred2";
 pbspline y=s_f20 x=day /
 legendlabel = "Female at 0.20 conc." name="pred3";
 pbspline y=s_f80 x=day /
 legendlabel = "Female at 0.80 conc." name="pred4";
 discretelegend "pred1" "pred2" "pred3" "pred4" / across=2;
run;

```

**Output 54.14.4** Predicted Survival at Insecticide Concentrations of 0.20 and 0.80 mg/cm<sup>2</sup>

The probability of survival is displayed on the vertical axis. Notice that most of the insecticide effect occurs by day 6 for both the high and low concentrations.

## Example 54.15: Scoring Data Sets

This example first illustrates the syntax used for scoring data sets, then uses a previously scored data set to score a new data set. A generalized logit model is fit to the remote-sensing data set used in the section “[Example 33.4: Linear Discriminant Analysis of Remote-Sensing Data on Crops](#)” on page 2146 of Chapter 33, “[The DISCRIM Procedure](#),” to illustrate discrimination and classification methods. In the following DATA step, the response variable is Crop and the prognostic factors are x1 through x4:

```
data Crops;
 length Crop $ 10;
 infile datalines truncover;
 input Crop $ @@;
 do i=1 to 3;
 input x1-x4 @@;
 if (x1 ^= .) then output;
```

```

end;
input;
datalines;
Corn 16 27 31 33 15 23 30 30 16 27 27 26
Corn 18 20 25 23 15 15 31 32 15 32 32 15
Corn 12 15 16 73
Soybeans 20 23 23 25 24 24 25 32 21 25 23 24
Soybeans 27 45 24 12 12 13 15 42 22 32 31 43
Cotton 31 32 33 34 29 24 26 28 34 32 28 45
Cotton 26 25 23 24 53 48 75 26 34 35 25 78
Sugarbeets 22 23 25 42 25 25 24 26 34 25 16 52
Sugarbeets 54 23 21 54 25 43 32 15 26 54 2 54
Clover 12 45 32 54 24 58 25 34 87 54 61 21
Clover 51 31 31 16 96 48 54 62 31 31 11 11
Clover 56 13 13 71 32 13 27 32 36 26 54 32
Clover 53 08 06 54 32 32 62 16
;

```

In the following statements, you specify a **SCORE** statement to use the fitted model to score the Crops data. The data together with the predicted values are saved in the data set Score1. The output from the **EFFECTPLOT** statement is discussed at the end of this section.

```

ods graphics on;
proc logistic data=Crops;
 model Crop=x1-x4 / link=glogit;
 score out=Score1;
 effectplot slicefit (x=x3);
run;
ods graphics off;

```

In the following statements, the model is fit again, and the data and the predicted values are saved into the data set Score2. The **OUTMODEL=** option saves the fitted model information in the permanent SAS data set sasuser.CropModel, and the **STORE** statement saves the fitted model information into the SAS data set CropModel2. Both the **OUTMODEL=** option and the **STORE** statement are specified to illustrate their use; you would usually specify only one of these model-storing methods.

```

proc logistic data=Crops outmodel=sasuser.CropModel;
 model Crop=x1-x4 / link=glogit;
 score data=Crops out=Score2;
 store CropModel2;
run;

```

To score data without refitting the model, specify the **INMODEL=** option to identify a previously saved SAS data set of model information. In the following statements, the model is read from the sasuser.CropModel data set, and the data and the predicted values are saved in the data set Score3. Note that the data set being scored does not have to include the response variable.

```

proc logistic inmodel=sasuser.CropModel;
 score data=Crops out=Score3;
run;

```

Another method available to score the data without refitting the model is to invoke the PLM procedure. In the following statements, the stored model is named in the **SOURCE=** option. The **PREDICTED=** option computes the linear predictors, and the **ILINK** option transforms the linear predictors to the probability

scale. The SCORE statement scores the Crops data set, and the predicted probabilities are saved in the data set ScorePLM. See Chapter 69, “The PLM Procedure,” for more information.

```
proc plm source=CropModel2;
 score data=Crops out=ScorePLM predicted=p / ilink;
run;
```

For each observation in the Crops data set, the ScorePLM data set contains 5 observations—one for each level of the response variable. The following statements transform this data set into a form that is similar to the other scored data sets in this example:

```
proc transpose data=ScorePLM out=Score4 prefix=P_ let;
 id _LEVEL_;
 var p;
 by x1-x4 notsorted;
run;
data Score4(drop=_NAME_ _LABEL_);
 merge Score4 Crops(keep=Crop x1-x4);
 F_Crop=Crop;
run;
proc summary data=ScorePLM nway;
 by x1-x4 notsorted;
 var p;
 output out=into maxid(p(_LEVEL_))=I_Crop;
run;
data Score4;
 merge Score4 into(keep=I_Crop);
run;
```

To set prior probabilities on the responses, specify the **PRIOR=** option to identify a SAS data set containing the response levels and their priors. In the following statements, the Prior data set contains the values of the response variable (because this example uses single-trial MODEL statement syntax) and a **\_PRIOR\_** variable containing values proportional to the default priors. The data and the predicted values are saved in the data set Score5.

```
data Prior;
 length Crop $10.;
 input Crop _PRIOR_;
 datalines;
Clover 11
Corn 7
Cotton 6
Soybeans 6
Sugarbeets 6
;

proc logistic inmodel=sasuser.CropModel;
 score data=Crops prior=prior out=Score5 fitstat;
run;
```

The “Fit Statistics for SCORE Data” table displayed in [Output 54.15.1](#) shows that 47.22% of the observations are misclassified.

**Output 54.15.1** Fit Statistics for Data Set Prior

| Fit Statistics for SCORE Data |                 |                |                       |          |             |          |

The **EFFECTPLOT** statement that is specified in the first PROC LOGISTIC invocation produces a plot of the model-predicted probabilities versus X3 while holding the other three covariates at their means (Output 54.15.4). This plot shows how the value of X3 affects the probabilities of the various crops when the other prognostic factors are fixed at their means. If you are interested in the effect of X3 when the other covariates are fixed at a certain level—say, 10—specify the following EFFECTPLOT statement.

```

effectplot slicefit(x=x3) / at(x1=10 x2=10 x4=10)

```

Output 54.15.4 Model-Predicted Probabilities

### Example 54.16: Using the LSMEANS Statement

Recall the main-effects model fit to the Neuralgia data set in [Example 54.2](#). The Treatment\*Sex interaction, which was previously shown to be nonsignificant, is added back into the model for this discussion.

In the following statements, the **ODDSRATIO** statement is specified to produce odds ratios of pairwise differences of the Treatment parameters in the presence of the Sex interaction. The **LSMEANS** statement is specified with several options: the **E** option displays the coefficients that are used to compute the LS-means for each Treatment level, the **DIFF** option takes all pairwise differences of the LS-means for the levels of the Treatment variable, the **ODDSRATIO** option computes odds ratios of these differences, the **CL** option produces confidence intervals for the differences and odds ratios, and the **ADJUST=BON** option performs a very conservative adjustment of the *p*-values and confidence intervals.

```
proc logistic data=Neuralgia;
 class Treatment Sex / param=glm;
 model Pain= Treatment|Sex Age;
 oddsratio Treatment;
 lsmeans Treatment / e diff oddsratio cl adjust=bon;
run;
```

The results from the **ODDSRATIO** statement are displayed in [Output 54.16.1](#). All pairwise differences of levels of the Treatment effect are compared. However, because of the interaction between the Treatment and Sex variables, each difference is computed at each of the two levels of the Sex variable. These results show that the difference between Treatment levels A and B is insignificant for both genders.

To compute these odds ratios, you must first construct a linear combination of the parameters,  $l'\beta$ , for each level that is compared with all other levels fixed at some value. For example, to compare Treatment=A with B for Sex=F, you fix the Age variable at its mean, 70.05, and construct the following  $l$  vectors:

|               | Intercept | Treatment |    |   | Sex |   | Treatment*Sex |    |    |    |    |    | Age   |
|---------------|-----------|-----------|----|---|-----|---|---------------|----|----|----|----|----|-------|
|               |           | A         | B  | P | F   | M | AF            | AM | BF | BM | PF | PM |       |
| $l'_A$        | 1         | 1         | 0  | 0 | 1   | 0 | 1             | 0  | 0  | 0  | 0  | 0  | 70.05 |
| $l'_B$        | 1         | 0         | 1  | 0 | 1   | 0 | 0             | 0  | 1  | 0  | 0  | 0  | 70.05 |
| $l'_A - l'_B$ | 0         | 1         | -1 | 0 | 0   | 0 | 1             | 0  | -1 | 0  | 0  | 0  | 0     |

Then the odds ratio for Treatment A versus B at Sex=F is computed as  $\exp((l'_A - l'_B)\beta)$ . Different  $l$  vectors must be similarly constructed when Sex=M because the resulting odds ratio will be different due to the interaction.

**Output 54.16.1** Odds Ratios from the ODDSRATIO Statement

| Odds Ratio Estimates and Wald Confidence Intervals |          |                       |          |
|----------------------------------------------------|----------|-----------------------|----------|
| Label                                              | Estimate | 95% Confidence Limits |          |
| Treatment A vs B at Sex=F                          | 0.398    | 0.016                 | 9.722    |
| Treatment A vs P at Sex=F                          | 16.892   | 1.269                 | 224.838  |
| Treatment B vs P at Sex=F                          | 42.492   | 2.276                 | 793.254  |
| Treatment A vs B at Sex=M                          | 0.663    | 0.078                 | 5.623    |
| Treatment A vs P at Sex=M                          | 34.766   | 1.807                 | 668.724  |
| Treatment B vs P at Sex=M                          | 52.458   | 2.258                 | >999.999 |

The results from the **LSMEANS** statement are displayed in [Output 54.16.2](#) through [Output 54.16.4](#).

The LS-means are computed by constructing each of the  $l$  coefficient vectors shown in [Output 54.16.2](#), and then computing  $l'\beta$ . The LS-means are not estimates of the event probabilities; they are estimates of the linear predictors on the logit scale. In order to obtain event probabilities, you need to apply the inverse-link transformation by specifying the **ILINK** option in the **LSMEANS** statement. Notice in [Output 54.16.2](#) that the Sex rows do not indicate either Sex=F or Sex=M. Instead, the LS-means are computed at an average of these two levels, so only one result needs to be reported. For more information about the construction of LS-means, see the section “[Construction of Least Squares Means](#)” on page 3363 of Chapter 42, “[The GLM Procedure](#).”

**Output 54.16.2** Treatment LS-Means Coefficients

| Coefficients for Treatment Least Squares Means |           |     |       |       |       |
|------------------------------------------------|-----------|-----|-------|-------|-------|
| Parameter                                      | Treatment | Sex | Row1  | Row2  | Row3  |
| Intercept: Pain=No                             |           |     | 1     | 1     | 1     |
| Treatment A                                    | A         |     | 1     |       |       |
| Treatment B                                    | B         |     |       | 1     |       |
| Treatment P                                    | P         |     |       |       | 1     |
| Sex F                                          |           | F   | 0.5   | 0.5   | 0.5   |
| Sex M                                          |           | M   | 0.5   | 0.5   | 0.5   |
| Treatment A * Sex F                            | A         | F   | 0.5   |       |       |
| Treatment A * Sex M                            | A         | M   | 0.5   |       |       |
| Treatment B * Sex F                            | B         | F   |       | 0.5   |       |
| Treatment B * Sex M                            | B         | M   |       | 0.5   |       |
| Treatment P * Sex F                            | P         | F   |       |       | 0.5   |
| Treatment P * Sex M                            | P         | M   |       |       | 0.5   |
| Age                                            |           |     | 70.05 | 70.05 | 70.05 |

The Treatment LS-means shown in [Output 54.16.3](#) are all significantly nonzero at the 0.05 level. These LS-means are *predicted population margins* of the logits; that is, they estimate the marginal means over a balanced population, and they are effectively the within-Treatment means appropriately adjusted for the other effects in the model. The LS-means are not event probabilities; in order to obtain event probabilities, you need to apply the inverse-link transformation by specifying the ILINK option in the LSMEANS statement. For more information about LS-means, see the section “LSMEANS Statement” on page 453 of Chapter 19, “Shared Concepts and Topics.”

**Output 54.16.3** Treatment LS-Means

| Treatment Least Squares Means |          |                |         |         |       |         |         |
|-------------------------------|----------|----------------|---------|---------|-------|---------|---------|
| Treatment                     | Estimate | Standard Error | z Value | Pr >  z | Alpha | Lower   | Upper   |
| A                             | 1.3195   | 0.6664         | 1.98    | 0.0477  | 0.05  | 0.01331 | 2.6257  |
| B                             | 1.9864   | 0.7874         | 2.52    | 0.0116  | 0.05  | 0.4431  | 3.5297  |
| P                             | -1.8682  | 0.7620         | -2.45   | 0.0142  | 0.05  | -3.3618 | -0.3747 |

Pairwise differences between the Treatment LS-means, requested with the DIFF option, are displayed in [Output 54.16.4](#). The LS-mean for the level that is displayed in the \_Treatment column is subtracted from the LS-mean for the level in the Treatment column, so the first row displays the LS-mean for Treatment level A minus the LS-mean for Treatment level B. The Pr > |z| column indicates that the A and B levels are not significantly different; however, both of these levels are different from level P. If the inverse-link transformation is specified with the ILINK option, then these differences do not transform back to differences in probabilities.

There are two odds ratios for Treatment level A versus B in [Output 54.16.1](#); these are constructed at each level of the interacting covariate Sex. In contrast, there is only one LS-means odds ratio for Treatment level A versus B in [Output 54.16.4](#). This odds ratio is computed at an average of the interacting effects by creating the  $l$  vectors shown in [Output 54.16.2](#) (the Row1 column corresponds to  $l_A$  and the Row2 column corresponds to  $l_B$ ) and computing  $\exp(l'_A \beta - l'_B \beta)$ .

Since multiple tests are performed, you can protect yourself from falsely significant results by adjusting your *p*-values for multiplicity. The **ADJUST=BON** option performs the very conservative Bonferroni adjustment, and adds the columns labeled with ‘Adj’ to [Output 54.16.4](#). Comparing the Pr > |z| column to the Adj P column, you can see that the *p*-values are adjusted upwards; in this case, there is no change in your conclusions. The confidence intervals are also adjusted for multiplicity—all adjusted intervals are wider than the unadjusted intervals, but again your conclusions in this example are unchanged.

**Output 54.16.4** Differences and Odds Ratios for the Treatment LS-Means

| Differences of Treatment Least Squares Means<br>Adjustment for Multiple Comparisons: Bonferroni |            |          |                |         |         |        |       |

| B                                                                                               | P          | 4.384                                 | 508.441                               | 2.590                | 860.612              |

If you want to jointly test whether the active treatments are different from the placebo, you can specify a custom hypothesis test with the **LSMESTIMATE** statement. In the following statements, the LS-means for the two treatments are contrasted against the LS-mean of the placebo, and the **JOINT** option performs a joint test that the two treatments are not different from placebo.

```
proc logistic data=Neuralgia;
 class Treatment Sex / param=glm;
 model Pain= Treatment|Sex Age;
 lsmestimate treatment 1 0 -1, 0 1 -1 / joint;
run;
```

[Output 54.16.5](#) displays the results from the **LSMESTIMATE** statement. The “Least Squares Means Es-

imate” table displays the differences of the two active treatments against the placebo, and the results are identical to the second and third rows of [Output 54.16.3](#). The “Chi-Square Test for Least Squares Means Estimates” table displays the joint test. In all of these tests, you reject the null hypothesis that the treatment has the same effect as the placebo.

**Output 54.16.5** Custom LS-Mean Tests

| Least Squares Means Estimates                     |        |            |                |         |         |
|---------------------------------------------------|--------|------------|----------------|---------|---------|
| Effect                                            | Label  | Estimate   | Standard Error | z Value | Pr >  z |
| Treatment                                         | Row 1  | 3.1877     | 1.0376         | 3.07    | 0.0021  |
| Treatment                                         | Row 2  | 3.8547     | 1.2126         | 3.18    | 0.0015  |
| Chi-Square Test for Least Squares Means Estimates |        |            |                |         |         |
| Effect                                            | Num DF | Chi-Square | Pr > ChiSq     |         |         |
| Treatment                                         | 2      | 12.13      | 0.0023         |         |         |

If you want to work with LS-means but you prefer to compute the Treatment odds ratios within the Sex levels in the same fashion as the [ODDSRATIO](#) statement does, you can specify the [SLICE](#) statement. In the following statements, you specify the same options in the [SLICE](#) statement as you do in the [LSMEANS](#) statement, except that you also specify the [SLICEBY=](#) option to perform an LS-means analysis partitioned into sets that are defined by the Sex variable:

```
proc logistic data=Neuralgia;
 class Treatment Sex / param=glm;
 model Pain= Treatment|Sex Age;
 slice Treatment*Sex / sliceby=Sex diff oddsratio cl adjust=bon;
run;
```

The results for Sex=F are displayed in [Output 54.16.6](#) and [Output 54.16.7](#). The joint test in [Output 54.16.6](#) tests the equality of the LS-means of the levels of Treatment for Sex=F, and rejects equality at level 0.05. In [Output 54.16.7](#), the odds ratios and confidence intervals match those reported for Sex=F in [Output 54.16.1](#), and multiplicity adjustments are performed.

**Output 54.16.6** Joint Test of Treatment Equality for Females

| Chi-Square Test for Treatment*Sex<br>Least Squares Means Slice |        |            |            |
|----------------------------------------------------------------|--------|------------|------------|
| Slice                                                          | Num DF | Chi-Square | Pr > ChiSq |
| Sex F                                                          | 2      | 8.22       | 0.0164     |

## Example 54.17: Partial Proportional Odds Model

Cameron and Trivedi (1998, p. 68) studied the number of doctor visits from the Australian Health Survey 1977–78. The data set contains a dependent variable, `dvisits`, which contains the number of doctor visits in the past two weeks (0, 1, or 2, where 2 represents two or more visits) and the following explanatory variables: `sex`, which indicates whether the patient is female; `age`, which contains the patient’s age in years divided by 100; `income`, which contains the patient’s annual income (in units of \$10,000); `levyplus`, which indicates whether the patient has private health insurance; `freepoor`, which indicates that the patient has free government health insurance due to low income; `freerepa`, which indicates that the patient has free government health insurance for other reasons; `illness`, which contains the number of illnesses in the past two weeks; `actdays`, which contains the number of days the illness caused reduced activity; `hscore`, which is a questionnaire score; `chcond1`, which indicates a chronic condition that does not limit activity; and `chcond2`, which indicates a chronic condition that limits activity.

```
data docvisit;
 input sex age agesq income levyplus freepoor freerepa
 illness actdays hscore chcond1 chcond2 dvisits;
 if (dvisits > 2) then dvisits = 2;
datalines;
1 0.19 0.0361 0.55 1 0 0 1 4 1 0 0 1
1 0.19 0.0361 0.45 1 0 0 1 2 1 0 0 1
0 0.19 0.0361 0.90 0 0 0 3 0 0 0 0 1

... more lines ...

1 0.37 0.1369 0.25 0 0 1 1 0 1 0 0 0
1 0.52 0.2704 0.65 0 0 0 0 0 0 0 0 0
0 0.72 0.5184 0.25 0 0 1 0 0 0 0 0 0
;
```

Because the response variable `dvisits` has three levels, the proportional odds model constructs two response functions. There is an intercept parameter for each of the two response functions,  $\alpha_1 < \alpha_2$ , and common slope parameters  $\beta = (\beta_1, \dots, \beta_{12})$  across the functions. The model can be written as

$$\text{logit}(\Pr(Y \leq i | \mathbf{x})) = \alpha_i + \beta' \mathbf{x}, \quad i = 1, 2$$

The following statements fit a proportional odds model to this data:

```
proc logistic data=docvisit;
 model dvisits = sex age agesq income levyplus
 freepoor freerepa illness actdays hscore
 chcond1 chcond2;
run;
```

Selected results are displayed in [Output 54.17.1](#).

| Score                                           | 811.8964   | 12         | <.0001     |
| Wald                                            | 690.7156   | 12         | <.0001     |

The test of the proportional odds assumption in [Output 54.17.1](#) rejects the null hypothesis that all the slopes are equal across the two response functions. This test is very anticonservative; that is, it tends to reject the null hypothesis even when the proportional odds assumption is reasonable.

The proportional odds assumption for ordinal response models can be relaxed by specifying the `UNEQUALSLOPES` option in the `MODEL` statement. A fully nonproportional odds model has different slope parameters  $\beta_i = (\beta_{1,i}, \dots, \beta_{12,i})$  for every logit  $i$ :

$$\text{logit}(\Pr(Y \leq i | \mathbf{x})) = \alpha_i + \beta'_i \mathbf{x}, \quad i = 1, 2$$

The nonproportional odds model is fit with the following statements. The `TEST` statements test the proportional odds assumption for each of the covariates in the model.

```
proc logistic data=docvisit;
 model dvisits = sex age agesq income levyplus
 freepoor freerepa illness actdays hscore
 chcond1 chcond2 / unequalslopes;
 sex: test sex_0 =sex_1;
 age: test age_0 =age_1;
 agesq: test agesq_0 =agesq_1;
 income: test income_0 =income_1;
 levyplus: test levyplus_0 =levyplus_1;
 freepoor: test freepoor_0 =freepoor_1;
 freerepa: test freerepa_0 =freerepa_1;
 illness: test illness_0 =illness_1;
 actdays: test actdays_0 =actdays_1;
 hscore: test hscore_0 =hscore_1;
 chcond1: test chcond1_0 =chcond1_1;
 chcond2: test chcond2_0 =chcond2_1;
run;
```

Selected results from fitting the nonproportional odds model to the data are displayed in [Output 54.17.2](#).

The preceding nonproportional odds model fits  $12 \times 2 = 24$  slope parameters, and the model seems to overfit the data. You can obtain a more parsimonious model by specifying a subset of the parameters to have nonproportional odds. The following statements allow the parameters for the variables in the “Linear Hypotheses Testing Results” table that have  $p$ -values less than 0.1 (actdays, agesq, and income) to vary across the response functions:

```
proc logistic data=docvisit;
 model dvisits= sex age agesq income levyplus freepoor
 freerepa illness actdays hscore chcond1 chcond2
 / unequalslopes=(actdays agesq income);
run;
```

Selected results from fitting this partial proportional odds model are displayed in [Output 54.17.3](#).

The partial proportional odds model can be written in the same form as the nonproportional odds model by letting  $\mathbf{x} = (x_1, \dots, x_q, x_{q+1}, \dots, x_{12})$  and  $\boldsymbol{\beta}_i = (\beta_1, \dots, \beta_q, \beta_{q+1,i}, \dots, \beta_{12,i})$ , so the first  $q$  parameters have proportional odds and the remaining parameters do not. The last  $12-q$  parameters can be rewritten to have a common slope:  $\beta_{q+j} + \gamma_{q+j,i}$ ,  $j = 1, \dots, 12 - q$ , where the new parameters  $\gamma_i$  contain the increments from the common slopes. The model in this form makes it obvious that the proportional odds model is a submodel of the partial proportional odds models, and both of these are submodels of the nonproportional odds model. This means that you can use likelihood ratio tests to compare models.

You can use the following statements to compute the likelihood ratio tests from the Likelihood Ratio row of the “Testing Global Null hypothesis: BETA=0” tables in the preceding outputs:

```
data a;
 label p='Pr>ChiSq';
 format p 8.6;
 input Test $10. ChiSq1 DF1 ChiSq2 DF2;
 ChiSq= ChiSq1-ChiSq2;
 DF= DF1-DF2;
 p=1-probchi(ChiSq,DF);
 keep Test ChiSq DF p;
 datalines;
Non vs PO 761.4797 24 734.2971 12
PPO vs PO 752.5512 15 734.2971 12
Non vs PPO 761.4797 24 752.5512 15
;

proc print data=a label noobs;
 var Test ChiSq DF p;
run;
```

**Output 54.17.4** Likelihood Ratio Tests

| Test       | ChiSq   | DF | Pr>ChiSq |
|------------|---------|----|----------|
| Non vs PO  | 27.1826 | 12 | 0.007273 |
| PPO vs PO  | 18.2541 | 3  | 0.000390 |
| Non vs PPO | 8.9285  | 9  | 0.443900 |

Therefore, you reject the proportional odds model in favor of both the nonproportional odds model and the partial proportional odds model, and the partial proportional odds model fits as well as the nonproportional odds model. The likelihood ratio test of the nonproportional odds model versus the proportional odds model is very similar to the score test of the proportional odds assumption in [Output 54.17.1](#) because of the large sample size (Stokes, Davis, and Koch 2000, p. 249).

**NOTE:** The proportional odds model has increasing intercepts, which ensures the increasing nature of the cumulative response functions. However, none of the parameters in the partial or nonproportional odds models are constrained. Because of this, sometimes during the optimization process a predicted individual probability can be negative; the optimization continues because it might recover from this situation. Sometimes your final model will predict negative individual probabilities for some of the observations; in this case a message is displayed, and you should check your data for outliers and possibly redefine your model. Other times the model fits your data well, but if you try to score new data you can get negative individual probabilities. This means the model is not appropriate for the data you are trying to score, a message is displayed, and the estimates are set to missing.

## Overview: MCMC Procedure

The MCMC procedure is a general purpose Markov chain Monte Carlo (MCMC) simulation procedure that is designed to fit Bayesian models. Bayesian statistics is different from traditional statistical methods such as frequentist or classical methods. For a short introduction to Bayesian analysis and related basic concepts, see Chapter 7, “[Introduction to Bayesian Analysis Procedures](#).” Also see the section “[A Bayesian Reading List](#)” on page 156 for a guide to Bayesian textbooks of varying degrees of difficulty.

In essence, Bayesian statistics treats parameters as unknown random variables, and it makes inferences based on the posterior distributions of the parameters. There are several advantages associated with this approach to statistical inference. Some of the advantages include its ability to use prior information and to directly answer specific scientific questions that can be easily understood. For further discussions of the relative advantages and disadvantages of Bayesian analysis, see the section “[Bayesian Analysis: Advantages and Disadvantages](#)” on page 132.

It follows from Bayes’ theorem that a posterior distribution is the product of the likelihood function and the prior distribution of the parameter. In all but the simplest cases, it is very difficult to obtain the posterior distribution directly and analytically. Often, Bayesian methods rely on simulations to generate sample from the desired posterior distribution and use the simulated draws to approximate the distribution and to make all of the inferences.

PROC MCMC is a flexible, simulation-based procedure that is suitable for fitting a wide range of Bayesian models. To use PROC MCMC, you need to specify a likelihood function for the data and a prior distribution for the parameters. If you are fitting hierarchical models, you can specify a hyperprior distribution or distributions for the random-effects parameters. PROC MCMC then obtains samples from the corresponding posterior distributions, produces summary and diagnostic statistics, and saves the posterior samples in an output data set that can be used for further analysis. Although PROC MCMC supports a suite of standard distributions, you can analyze data that have any likelihood, prior, or hyperprior, as long as these functions are programmable using the SAS DATA step functions. There are no constraints on how the parameters can enter the model, in either linear or any nonlinear functional form.

The **MODEL** statement in PROC MCMC can automatically model missing data, response variables, or covariates. In releases before SAS/STAT 12.1, observations with missing values were discarded prior to the analysis. Now, PROC MCMC treats the missing values as unknown parameters and incorporates the sampling of the missing values as part of the simulation.

PROC MCMC selects a sampling method for each parameter or a block of parameters. For example, when conjugacy is available, samples are drawn directly from the full conditional distribution by using standard random number generators. In other cases, PROC MCMC uses an adaptive blocked random walk Metropolis algorithm that uses a normal proposal distribution. You can also choose alternative sampling algorithms, such as the slice sampler.

---

## PROC MCMC Compared with Other SAS Procedures

PROC MCMC is unlike most other SAS/STAT procedures in that the nature of the statistical inference is Bayesian. You specify prior distributions for the parameters with **PRIOR** statements and the likelihood function for the data with **MODEL** statements. PROC MCMC derives inferences from simulation rather than through analytic or numerical methods. You should expect slightly different answers from each run

for the same problem, unless the same random number seed is used. The model specification is similar to PROC NLIN, and PROC MCMC shares some of the syntax of PROC NLMIXED.

You can also carry out a Bayesian analysis with the GENMOD, PHREG, LIFEREG, and FMM procedures for generalized linear models, accelerated life failure models, Cox regression models, piecewise constant baseline hazard models (also known as piecewise exponential models), and finite mixture models. See Chapter 40, “The GENMOD Procedure,” Chapter 67, “The PHREG Procedure,” Chapter 51, “The LIFEREG Procedure,” and Chapter 37, “The FMM Procedure.”

## Getting Started: MCMC Procedure

There are three examples in this “Getting Started” section: a simple linear regression, the Behrens-Fisher estimation problem, and a random-effects model. The regression model is chosen for its simplicity; the Behrens-Fisher problem illustrates some advantages of the Bayesian approach; and the random-effects model is one of the most prevalently used models.

Keep in mind that **PARMS** statements declare the parameters in the model, **PRIOR** statements declare the prior distributions, **MODEL** statements declare the likelihood for the data, and **RANDOM** statements declare the random effects. In most cases, you do not need to supply initial values. PROC MCMC advises you if it is unable to generate starting values for the Markov chain.

### Simple Linear Regression

This section illustrates some basic features of PROC MCMC by using a linear regression model. The model is as follows:

$$Y_i = \beta_0 + \beta_1 X_i + \epsilon_i$$

for the observations  $i = 1, 2, \dots, n$ .

The following statements create a SAS data set with measurements of Height and Weight for a group of children:

```

title 'Simple Linear Regression';

data Class;
 input Name $ Height Weight @@;
 datalines;
Alfred 69.0 112.5 Alice 56.5 84.0 Barbara 65.3 98.0
Carol 62.8 102.5 Henry 63.5 102.5 James 57.3 83.0
Jane 59.8 84.5 Janet 62.5 112.5 Jeffrey 62.5 84.0
John 59.0 99.5 Joyce 51.3 50.5 Judy 64.3 90.0
Louise 56.3 77.0 Mary 66.5 112.0 Philip 72.0 150.0
Robert 64.8 128.0 Ronald 67.0 133.0 Thomas 57.5 85.0
William 66.5 112.0
;

```

The equation of interest is as follows:

$$\text{Weight}_i = \beta_0 + \beta_1 \text{Height}_i + \epsilon_i$$

The observation errors,  $\epsilon_i$ , are assumed to be independent and identically distributed with a normal distribution with mean zero and variance  $\sigma^2$ .

$$\text{Weight}_i \sim \text{normal}(\beta_0 + \beta_1 \text{Height}_i, \sigma^2)$$

The likelihood function for each of the `Weight`, which is specified in the `MODEL` statement, is as follows:

$$p(\text{Weight}|\beta_0, \beta_1, \sigma^2, \text{Height}_i) = \phi(\beta_0 + \beta_1 \text{Height}_i, \sigma^2)$$

where  $p(\cdot|\cdot)$  denotes a conditional probability density and  $\phi$  is the normal density. There are three parameters in the likelihood:  $\beta_0$ ,  $\beta_1$ , and  $\sigma^2$ . You use the `PARMS` statement to indicate that these are the parameters in the model.

Suppose you want to use the following three prior distributions on each of the parameters:

$$\begin{aligned} \pi(\beta_0) &= \phi(0, \text{var} = 1e6) \\ \pi(\beta_1) &= \phi(0, \text{var} = 1e6) \\ \pi(\sigma^2) &= f_{i\Gamma}(\text{shape} = 3/10, \text{scale} = 10/3) \end{aligned}$$

where  $\pi(\cdot)$  indicates a prior distribution and  $f_{i\Gamma}$  is the density function for the inverse-gamma distribution. The normal priors on  $\beta_0$  and  $\beta_1$  have large variances, expressing your lack of knowledge about the regression coefficients. The priors correspond to an equal-tail 95% credible intervals of approximately (-2000, 2000) for  $\beta_0$  and  $\beta_1$ . Priors of this type are often called *vague* or *diffuse* priors. See the section “[Prior Distributions](#)” on page 127 for more information. Typically diffuse prior distributions have little influence on the posterior distribution and are appropriate when stronger prior information about the parameters is not available.

A frequently used prior for the variance parameter  $\sigma^2$  is the inverse-gamma distribution. See [Table 55.22](#) in the section “[Standard Distributions](#)” on page 4476 for the density definition. The inverse-gamma distribution is a conjugate prior (see the section “[Conjugate Sampling](#)” on page 4472) for the variance parameter in a normal distribution. Also see the section “[Gamma and Inverse-Gamma Distributions](#)” on page 4512 for typical usages of the gamma and inverse-gamma prior distributions. With a shape parameter of 3/10 and a scale parameter of 10/3, this prior corresponds to an equal-tail 95% credible interval of (1.7, 1E6), with the mode at 2.5641 for  $\sigma^2$ . Alternatively, you can use any other prior distribution with positive support on this variance component. For example, you can use the gamma prior.

According to Bayes’ theorem, the likelihood function and prior distributions determine the posterior (joint) distribution of  $\beta_0$ ,  $\beta_1$ , and  $\sigma^2$  as follows:

$$\pi(\beta_0, \beta_1, \sigma^2 | \text{Weight}, \text{Height}) \propto \pi(\beta_0)\pi(\beta_1)\pi(\sigma^2)p(\text{Weight}|\beta_0, \beta_1, \sigma^2, \text{Height})$$

You do not need to know the form of the posterior distribution when you use PROC MCMC. PROC MCMC automatically obtains samples from the desired posterior distribution, which is determined by the prior and likelihood you supply.

The following statements fit this linear regression model with diffuse prior information:

```
ods graphics on;
proc mcmc data=class outpost=classout nmc=10000 thin=2 seed=246810;
 parms beta0 0 beta1 0;
 parms sigma2 1;
 prior beta0 beta1 ~ normal(mean = 0, var = 1e6);
 prior sigma2 ~ igamma(shape = 3/10, scale = 10/3);
 mu = beta0 + beta1*height;
 model weight ~ n(mu, var = sigma2);
run;
ods graphics off;
```

When ODS Graphics is enabled, diagnostic plots, such as the trace and autocorrelation function plots of the posterior samples, are displayed. For more information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).”

The PROC MCMC statement invokes the procedure and specifies the input data set `Class`. The output data set `Classout` contains the posterior samples for all of the model parameters. The `NMC=` option specifies the number of posterior simulation iterations. The `THIN=` option controls the thinning of the Markov chain and specifies that one of every 2 samples is kept. Thinning is often used to reduce the correlations among posterior sample draws. In this example, 5,000 simulated values are saved in the `Classout` data set. The `SEED=` option specifies a seed for the random number generator, which guarantees the reproducibility of the random stream. For more information about Markov chain sample size, burn-in, and thinning, see the section “[Burn-in, Thinning, and Markov Chain Samples](#)” on page 138.

The `PARMS` statements identify the three parameters in the model: `beta0`, `beta1`, and `sigma2`. Each statement also forms a block of parameters, where the parameters are updated simultaneously in each iteration. In this example, `beta0` and `beta1` are sampled jointly, conditional on `sigma2`; and `sigma2` is sampled conditional on fixed values of `beta0` and `beta1`. In simple regression models such as this, you expect the parameters `beta0` and `beta1` to have high posterior correlations, and placing them both in the same block improves the mixing of the chain—that is, the efficiency that the posterior parameter space is explored by the Markov chain. For more information, see the section “[Blocking of Parameters](#)” on page 4466. The `PARMS` statements also assign initial values to the parameters (see the section “[Initial Values of the Markov Chains](#)” on page 4474). The regression parameters are given 0 as their initial values, and the scale parameter `sigma2` starts at value 1. If you do not provide initial values, PROC MCMC chooses starting values for every parameter.

The `PRIOR` statements specify prior distributions for the parameters. The parameters `beta0` and `beta1` both share the same prior—a normal prior with mean 0 and variance 1e6. The parameter `sigma2` has an inverse-gamma distribution with a shape parameter of 3/10 and a scale parameter of 10/3. For a list of standard distributions that PROC MCMC supports, see the section “[Standard Distributions](#)” on page 4476.

The `MU` assignment statement calculates the expected value of `Weight` as a linear function of `Height`. The `MODEL` statement uses the shorthand notation, `n`, for the normal distribution to indicate that the response variable, `Weight`, is normally distributed with parameters `mu` and `sigma2`. The functional argument `MEAN=` in the normal distribution is optional, but you have to indicate whether `sigma2` is a variance (`VAR=`), a standard deviation (`SD=`), or a precision (`PRECISION=`) parameter. See [Table 55.2](#) in the section “[MODEL Statement](#)” on page 4443 for distribution specifications.

The distribution parameters can contain expressions. For example, you can write the `MODEL` statement as follows:

```
model weight ~ n(beta0 + beta1*height, var = sigma2);
```

Before you do any posterior inference, it is essential that you examine the convergence of the Markov chain (see the section “[Assessing Markov Chain Convergence](#)” on page 139). You cannot make valid inferences if the Markov chain has not converged. A very effective convergence diagnostic tool is the trace plot. Although PROC MCMC produces graphs at the end of the procedure output (see [Figure 55.5](#)), you should visually examine the convergence graph first.

The first table that PROC MCMC produces is the “Number of Observations” table, as shown in [Figure 55.1](#). This table lists the number of observations read from the `DATA=` data set and the number of observations used in the analysis.

**Figure 55.1** Observation Information

| Simple Linear Regression    |    |
|-----------------------------|----|
| The MCMC Procedure          |    |
| Number of Observations Read | 19 |
| Number of Observations Used | 19 |

The “Parameters” table, shown in [Figure 55.2](#), lists the names of the parameters, the blocking information, the sampling method used, the starting values, and the prior distributions. For more information about blocking information, see the section “[Blocking of Parameters](#)” on page 4466; for more information about starting values, see the section “[Initial Values of the Markov Chains](#)” on page 4474. The first block, which consists of the parameters `beta0` and `beta1`, uses a random walk Metropolis algorithm. The second block, which consists of the parameter `sigma2`, is updated via its full conditional distribution in conjugacy. You should check this table to ensure that you have specified the parameters correctly, especially for complicated models.

**Figure 55.2** Parameter Information

| Parameters |                     |                 |               |                                    |
|------------|---------------------|-----------------|---------------|------------------------------------|
| Block      | Parameter           | Sampling Method | Initial Value | Prior Distribution                 |
| 1          | <code>beta0</code>  | N-Metropolis    | 0             | normal(mean = 0, var = 1e6)        |
|            | <code>beta1</code>  |                 | 0             | normal(mean = 0, var = 1e6)        |
| 2          | <code>sigma2</code> | Conjugate       | 1.0000        | igamma(shape = 3/10, scale = 10/3) |

For each posterior distribution, PROC MCMC also reports summary statistics (posterior means, standard deviations, and quantiles) and interval statistics (95% equal-tail and highest posterior density credible intervals), as shown in [Figure 55.3](#). For more information about posterior statistics, see the section “[Summary Statistics](#)” on page 153.

**Figure 55.3** MCMC Summary and Interval Statistics

| Simple Linear Regression |      |        |                       |             |        |        |
|--------------------------|------|--------|-----------------------|-------------|--------|--------|
| The MCMC Procedure       |      |        |                       |             |        |        |
| Posterior Summaries      |      |        |                       |             |        |        |

| beta0                    | 5000 | -142.8 | 33.4326               | -164.8      | -142.3 | -120.0 |
| beta1                    | 5000 | 3.8924 | 0.5333                | 3.5361      | 3.8826 | 4.2395 |
| sigma2                   | 5000 | 137.3  | 51.1030               | 101.9       | 127.2  | 161.2  |

| Posterior Intervals |       |                     |        |              |          |
|---------------------|-------|---------------------|--------|--------------|----------|
| Parameter           | Alpha | Equal-Tail Interval |        | HPD Interval |          |
|                     |       | beta0               | 0.050  | -208.9       | -78.7305 |
| beta1               | 0.050 | 2.8790              | 4.9449 | 2.9056       | 4.9545   |
| sigma2              | 0.050 | 69.1351             | 259.8  | 59.2362      | 236.3    |

By default, PROC MCMC also computes a number of convergence diagnostics to help you determine whether the chain has converged. These are the Monte Carlo standard errors, the autocorrelations at selected lags, the Geweke diagnostics, and the effective sample sizes. These statistics are shown in [Figure 55.4](#). For details and interpretations of these diagnostics, see the section “[Assessing Markov Chain Convergence](#)” on page 139.

The “Monte Carlo Standard Errors” table indicates that the standard errors of the mean estimates for each of the parameters are relatively small, with respect to the posterior standard deviations. The values in the “MCSE/SD” column (ratios of the standard errors and the standard deviations) are small, around 0.03. This means that only a fraction of the posterior variability is due to the simulation. The “Autocorrelations of the Posterior Samples” table shows that the autocorrelations among posterior samples reduce quickly and become almost nonexistent after a few lags. The “Geweke Diagnostics” table indicates that no parameter failed the test, and the “Effective Sample Sizes” table reports the number of effective sample sizes of the Markov chain.

**Figure 55.4** MCMC Convergence Diagnostics

PROC MCMC produces a number of graphs, shown in Figure 55.5, which also aid convergence diagnostic checks. With the trace plots, there are two important aspects to examine. First, you want to check whether the mean of the Markov chain has stabilized and appears constant over the graph. Second, you want to check whether the chain has good mixing and is “dense,” in the sense that it quickly traverses the support of the distribution to explore both the tails and the mode areas efficiently. The plots show that the chains appear to have reached their stationary distributions.

Next, you should examine the autocorrelation plots, which indicate the degree of autocorrelation for each of the posterior samples. High correlations usually imply slow mixing. Finally, the kernel density plots estimate the posterior marginal distributions for each parameter.

**Figure 55.5** Diagnostic Plots for  $\beta_0$ ,  $\beta_1$  and  $\sigma^2$

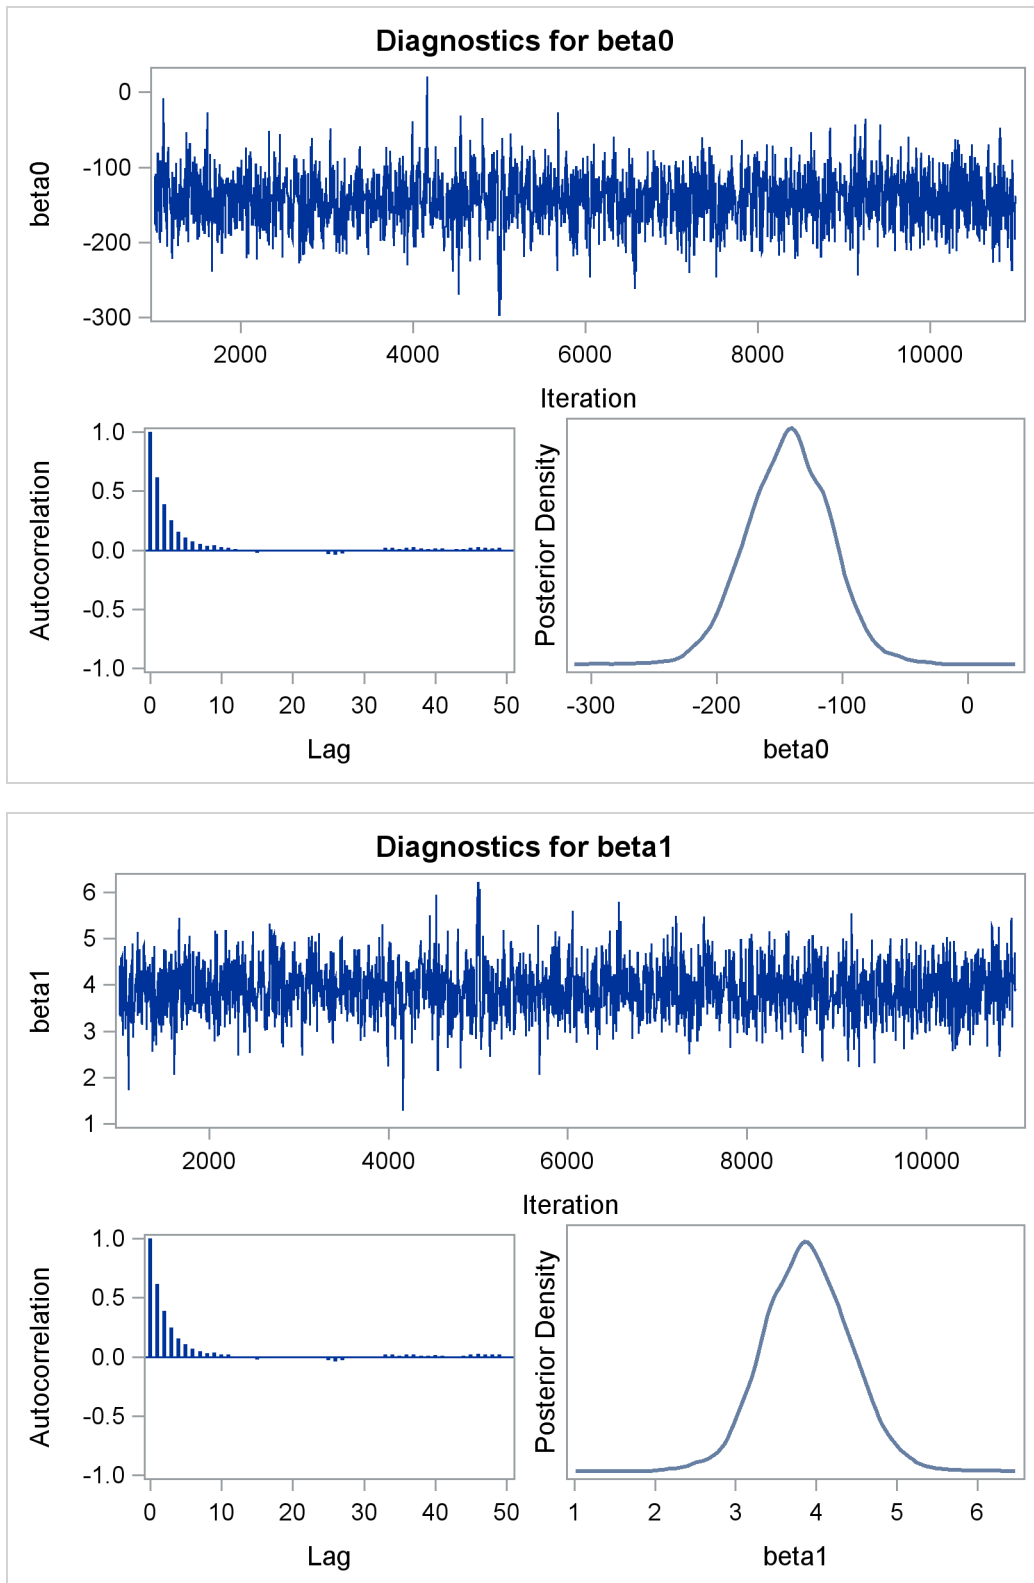

Figure 55.5 continued

In regression models such as this, you expect the posterior estimates to be very similar to the maximum likelihood estimators with noninformative priors on the parameters. The REG procedure produces the following fitted model (code not shown):

$$\text{Weight} = -143.0 + 3.9 \times \text{Height}$$

These are very similar to the means show in Figure 55.3. With PROC MCMC, you can carry out informative analysis that uses specifications to indicate prior knowledge on the parameters. Informative analysis is likely to produce different posterior estimates, which are the result of information from both the likelihood and the prior distributions. Incorporating additional information in the analysis is one major difference between the classical and Bayesian approaches to statistical inference.

---

## The Behrens-Fisher Problem

One of the famous examples in the history of statistics is the Behrens-Fisher problem (Fisher 1935). Consider the situation where there are two independent samples from two different normal distributions:

$$y_{11}, y_{12}, \dots, y_{1n_1} \sim \text{normal}(\mu_1, \sigma_1^2)$$

$$y_{21}, y_{22}, \dots, y_{2n_2} \sim \text{normal}(\mu_2, \sigma_2^2)$$

Note that  $n_1 \neq n_2$ . When you do not want to assume that the variances are equal, testing the hypothesis  $H_0 : \mu_1 = \mu_2$  is a difficult problem in the classical statistics framework, because the distribution under  $H_0$

is not known. Within the Bayesian framework, this problem is straightforward because you can estimate the posterior distribution of  $\mu_1 - \mu_2$  while taking into account the uncertainties in all of parameters by treating them as random variables.

Suppose you have the following set of data:

```

title 'The Behrens-Fisher Problem';

data behrens;
 input y ind @@;
 datalines;
121 1 94 1 119 1 122 1 142 1 168 1 116 1
172 1 155 1 107 1 180 1 119 1 157 1 101 1
145 1 148 1 120 1 147 1 125 1 126 2 125 2
130 2 130 2 122 2 118 2 118 2 111 2 123 2
126 2 127 2 111 2 112 2 121 2
 ;

```

The response variable is  $y$ , and the  $\text{ind}$  variable is the group indicator, which takes two values: 1 and 2. There are 19 observations that belong to group 1 and 14 that belong to group 2.

The likelihood functions for the two samples are as follows:

$$\begin{aligned}
 p(y_{1i} | \mu_1, \sigma_1^2) &= \phi(y_{1i}; \mu_1, \sigma_1^2) \quad \text{for } i = 1, \dots, 19 \\
 p(y_{2j} | \mu_2, \sigma_2^2) &= \phi(y_{2j}; \mu_2, \sigma_2^2) \quad \text{for } j = 1, \dots, 14
 \end{aligned}$$

Berger (1985) showed that a uniform prior on the support of the location parameter is a noninformative prior. The distribution is invariant under location transformations—that is,  $\theta = \mu + c$ . You can use this prior for the mean parameters in the model:

$$\begin{aligned}
 \pi(\mu_1) &\propto 1 \\
 \pi(\mu_2) &\propto 1
 \end{aligned}$$

In addition, Berger (1985) showed that a prior of the form  $1/\sigma^2$  is noninformative for the scale parameter, and it is invariant under scale transformations (that is  $\tau = c\sigma^2$ ). You can use this prior for the variance parameters in the model:

$$\begin{aligned}
 \pi(\sigma_1^2) &\propto 1/\sigma_1^2 \\
 \pi(\sigma_2^2) &\propto 1/\sigma_2^2
 \end{aligned}$$

The log densities of the prior distributions on  $\sigma_1^2$  and  $\sigma_2^2$  are:

$$\begin{aligned}
 \log(\pi(\sigma_1^2)) &= -\log(\sigma_1^2) \\
 \log(\pi(\sigma_2^2)) &= -\log(\sigma_2^2)
 \end{aligned}$$

The following statements generate posterior samples of  $\mu_1, \mu_2, \sigma_1^2, \sigma_2^2$ , and the difference in the means:  $\mu_1 - \mu_2$ :

```

proc mcmc data=behrens outpost=postout seed=123
 nmc=40000 thin=10 monitor=(_parms_ mudif)
 statistics(alpha=0.01)=(summary interval);
ods select PostSummaries PostIntervals;
parm mu1 0 mu2 0;
parm sig21 1;
parm sig22 1;
prior mu: ~ general(0);
prior sig21 ~ general(-log(sig21), lower=0);
prior sig22 ~ general(-log(sig22), lower=0);
mudif = mu1 - mu2;
if ind = 1 then do;
 mu = mu1;
 s2 = sig21;
end;
else do;
 mu = mu2;
 s2 = sig22;
end;
model y ~ normal(mu, var=s2);
run;

```

The PROC MCMC statement specifies an input data set (Behrens), an output data set containing the posterior samples (Postout), a random number seed, the simulation size, and the thinning rate. The **MONITOR=** option specifies a list of symbols, which can be either parameters or functions of the parameters in the model, for which inference is to be done. The symbol `_parms_` is a shorthand for all model parameters—in this case,  $\mu_1$ ,  $\mu_2$ ,  $\text{sig21}$ , and  $\text{sig22}$ . The symbol `mudif` is defined in the program as the difference between  $\mu_1$  and  $\mu_2$ .

The **STATISTICS=** option requests the calculation of summary and interval statistics. The global suboption `ALPHA=0.01` specifies 99% equal-tail and highest posterior density (HPD) credible intervals for all parameters.

The ODS SELECT statement displays the summary statistics and interval statistics tables while excluding all other output. For a complete list of ODS tables that PROC MCMC can produce, see the sections “[Displayed Output](#)” on page 4533 and “[ODS Table Names](#)” on page 4537.

The **PARMS** statements assign the parameters  $\mu_1$  and  $\mu_2$  to the same block, and  $\text{sig21}$  and  $\text{sig22}$  each to their own separate blocks. There are a total of three blocks. The **PARMS** statements also assign an initial value to each parameter.

The **PRIOR** statements specify prior distributions for the parameters. Because the priors are all nonstandard (uniform on the real axis for  $\mu_1$  and  $\mu_2$  and  $1/\sigma^2$  for  $\sigma_1^2$  and  $\sigma_2^2$ ), you must use the **GENERAL** function here. The argument in the **GENERAL** function is an expression for the log of the distribution, up to an additive constant. This distribution can have any functional form, as long as it is programmable using SAS functions and expressions. The function specifies a distribution on the log scale, not on the original scale. The log of the prior on  $\mu_1$  and  $\mu_2$  is 0, and the log of the priors on  $\text{sig21}$  and  $\text{sig22}$  are  $-\log(\text{sig21})$  and  $-\log(\text{sig22})$  respectively. See the section “[Specifying a New Distribution](#)” on page 4490 for more information about how to specify an arbitrary distribution. The **LOWER=** option indicates that both variance terms must be strictly positive.

The MUDIF assignment statement calculates the difference between  $\mu_1$  and  $\mu_2$ . The IF-ELSE statements enable different  $y$ 's to have different mean and variance, depending on their group indicator *ind*. The MODEL statement specifies the normal likelihood function for each observation in the model.

Figure 55.6 displays the posterior summary and interval statistics.

| sig22               | 0.010 | 18.5883             | 158.8   | 16.3730      | 140.5   |
| mudif               | 0.010 | -3.2537             | 29.9987 | -3.1915      | 30.0558 |

The mean difference has a posterior mean value of 13.36, and the lower endpoints of the 99% credible intervals are negative. This suggests that the mean difference is positive with a high probability. However, if you want to estimate the probability that  $\mu_1 - \mu_2 > 0$ , you can do so as follows.

The following statements produce Figure 55.7:

```
proc format;
 value diffmt low=0 = 'mu1 - mu2 <= 0' 0<-high = 'mu1 - mu2 > 0';
run;

proc freq data = postout;
 tables mudif /nocum;
 format mudif diffmt.;
run;
```

The sample estimate of the posterior probability that  $\mu_1 - \mu_2 > 0$  is 0.98. This example illustrates an advantage of Bayesian analysis. You are not limited to making inferences based on model parameters only. You can accurately quantify uncertainties with respect to any function of the parameters, and this allows for flexibility and easy interpretations in answering many scientific questions.

**Figure 55.7** Estimated Probability of  $\mu_1 - \mu_2 > 0$ .

| The Behrens-Fisher Problem |           |         |
|----------------------------|-----------|---------|

| mudif                      | Frequency | Percent |
| mu1 - mu2 <= 0             | 77        | 1.93    |
| mu1 - mu2 > 0              | 3923      | 98.08   |

## Random-Effects Model

This example illustrates how you can fit a normal likelihood random-effects model in PROC MCMC. PROC MCMC offers you the ability to model beyond the normal likelihood (see “Example 55.7: Logistic Regression Random-Effects Model” on page 4579, “Example 55.8: Nonlinear Poisson Regression Multilevel Random-Effects Model” on page 4581, and “Example 55.16: Piecewise Exponential Frailty Model” on page 4631).

Consider a scenario in which data are collected in groups and you want to model group-specific effects. You can use a random-effects model (sometimes also known as a variance-components model):

$$y_{ij} = \beta_0 + \beta_1 x_{ij} + \gamma_i + e_{ij}, \quad e_{ij} \sim \text{normal}(0, \sigma^2)$$

where  $i = 1, 2, \dots, I$  is the group index and  $j = 1, 2, \dots, n_i$  indexes the observations in the  $i$ th group. In the regression model, the fixed effects  $\beta_0$  and  $\beta_1$  are the intercept and the coefficient for variable  $x_{ij}$ , respectively. The random effect  $\gamma_i$  is the mean for the  $i$ th group, and  $e_{ij}$  are the error term.

Consider the following SAS data set:

```

title 'Random-Effects Model';

data heights;
 input Family G$ Height @@;
 datalines;
1 F 67 1 F 66 1 F 64 1 M 71 1 M 72 2 F 63
2 F 63 2 F 67 2 M 69 2 M 68 2 M 70 3 F 63
3 M 64 4 F 67 4 F 66 4 M 67 4 M 67 4 M 69
;

```

The response variable Height measures the heights (in inches) of 18 individuals. The covariate  $x$  is the gender (variable G), and the individuals are grouped according to Family (group index). Since the variable G is a character variable and PROC MCMC does not support a CLASS statement, you need to create the corresponding design matrix. In this example, the design matrix for a factor variable of level 2 (M and F) can be constructed using the following statement:

```

data input;
 set heights;
 if g eq 'F' then gf = 1;
 else gf = 0;
 drop g;
run;

```

The data set variable `gf` is a numeric variable and can be used in the regression model in PROC MCMC.

In data sets with factor variables that have more levels, you can consider using PROC TRANSREG to construct the design matrix. See the section “[Create Design Matrix](#)” on page 4502 for more information.

To model the data, you can assume that Height is normally distributed:

$$y_{ij} \sim \text{normal}(\mu_{ij}, \sigma^2), \quad \mu_{ij} = \beta_0 + \beta_1 \text{gf}_{ij} + \gamma_i$$

The priors on the parameters  $\beta_0$ ,  $\beta_1$ ,  $\gamma_i$  are also assumed to be normal:

$$\begin{aligned} \beta_0 &\sim \text{normal}(0, \text{var} = 1e5) \\ \beta_1 &\sim \text{normal}(0, \text{var} = 1e5) \\ \gamma_i &\sim \text{normal}(0, \text{var} = \sigma_\gamma^2) \end{aligned}$$

Priors on the variance terms,  $\sigma^2$  and  $\sigma_\gamma^2$ , are inverse-gamma:

$$\begin{aligned} \sigma^2 &\sim \text{igamma}(\text{shape} = 0.01, \text{scale} = 0.01) \\ \sigma_\gamma^2 &\sim \text{igamma}(\text{shape} = 0.01, \text{scale} = 0.01) \end{aligned}$$

The inverse-gamma distribution is a conjugate prior for the variance in the normal likelihood and the variance in the prior distribution of the random effect.

The following statements fit a linear random-effects model to the data and produce the output shown in [Figure 55.9](#) and [Figure 55.10](#):

```

ods graphics on;
proc mcmc data=input outpost=postout nmc=50000 thin=5 seed=7893 plots=trace;
 ods select Parameters REparameters PostSummaries PostIntervals
 tracepanel;
 parms b0 0 b1 0 s2 1 s2g 1;

 prior b: ~ normal(0, var = 10000);
 prior s: ~ igamma(0.01, scale = 0.01);
 random gamma ~ normal(0, var = s2g) subject=family monitor=(gamma);
 mu = b0 + b1 * gf + gamma;
 model height ~ normal(mu, var = s2);
run;
ods graphics off;

```

Some of the statements are very similar to those shown in the previous two examples. The ODS GRAPHICS ON statement enables ODS Graphics. The PROC MCMC statement specifies the input and output data sets, the simulation size, the thinning rate, and a random number seed. The ODS SELECT statement displays

the model parameter and random-effects parameter information tables, summary statistics table, the interval statistics table, and the trace plots.

The **PARMS** statement lumps all four model parameters in a single block. They are  $b_0$  (overall intercept),  $b_1$  (main effect for *gf*),  $s_2$  (variance of the likelihood function), and  $s_{2g}$  (variance of the random effect). If a random walk Metropolis sampler is the only applicable sampler for all parameters, then these four parameters are updated in a single block. However, because PROC MCMC updates the parameters  $s_2$  and  $s_{2g}$  via conjugacy, these parameters are separated into individual blocks. (See the Block column in “Parameters” table in Figure 55.8.)

The **PRIOR** statements specify priors for all the parameters. The notation  $b:$  is a shorthand for all symbols that start with the letter ‘ $b$ ’. In this example,  $b:$  includes  $b_0$  and  $b_1$ . Similarly,  $s:$  stands for both  $s_2$  and  $s_{2g}$ . This shorthand notation can save you some typing, and it keeps your statements tidy.

The **RANDOM** statement specifies a single random effect to be  $\gamma$ , and specifies that it has a normal prior centered at 0 with variance  $s_{2g}$ . The **SUBJECT=** argument in the **RANDOM** statement defines a group index (family) in the model, where all observations from the same family should have the same group indicator value. The **MONITOR=** option outputs analysis for all the random-effects parameters.

Finally, the **MU** assignment statement calculates the expected value of the height of the model. The calculation includes the random-effects term  $\gamma$ . The **MODEL** statement specifies the likelihood function for height.

The “Parameters” and “Random-Effects Parameters” tables, shown in Figure 55.8, contain information about the model parameters and the four random-effects parameters.

**Figure 55.8** Model and Random-Effects Parameter Information

| gamma_2             | 0.050 | -2.5942             | 2.5279  | -2.5357      | 2.5636  |
| gamma_3             | 0.050 | -5.4957             | 0.6638  | -4.7168      | 1.0677  |
| gamma_4             | 0.050 | -2.4901             | 2.7349  | -2.5895      | 2.5888  |

Trace plots for all the parameters are shown in [Figure 55.10](#). The mixing looks very reasonable, suggesting convergence.

**Figure 55.10** Plots for  $b_1$  and Log of the Posterior Density

Figure 55.10 continued

From the interval statistics table, you see that both the equal-tail and HPD intervals for  $\beta_0$  are positive, strongly indicating the positive effect of the parameter. On the other hand, both intervals for  $\beta_1$  cover the value zero, indicating that  $gf$  does not have a strong impact on predicting height in this model.

## Syntax: MCMC Procedure

The following statements are available in the MCMC procedure. Items within  $\langle \rangle$  are optional.

```

PROC MCMC $\langle options \rangle$;
 ARRAY arrayname [dimensions] $\langle \$ \rangle$ $\langle variables-and-constants \rangle$;
 BEGINCNST/ENDCNST ;
 BEGINNODATA/ENDNODATA ;
 BY variables ;
 MODEL variable \sim distribution $\langle options \rangle$;
 PARMS parameter $\langle = \rangle$ number $\langle / options \rangle$;
 PREDDIST $\langle 'label' \rangle$ OUTPRED=SAS-data-set $\langle options \rangle$;
 PRIOR/HYPERPRIOR parameter \sim distribution ;
 Programming statements ;
 RANDOM random-effects-specification $\langle / options \rangle$;
 UDS subroutine-name (subroutine-argument-list) ;

```

The **PARMS** statements declare parameters in the model and assign optional starting values for the Markov chain. The **PRIOR/HYPERPRIOR** statements specify the prior distributions of the parameters. The **MODEL** statements specify the log-likelihood functions for the response variables. These statements form the basis of most Bayesian models.

In addition, you can use the **ARRAY** statement to define constant or parameter arrays, the **BEGINCNST/ENDCNST** and **BEGINNODATA/ENDNODATA** statements to omit unnecessary evaluation and reduce simulation time, the **PREDDIST** statement to generate samples from the posterior predictive distribution, the **program statements** to specify more complicated models that you want to fit, the **RANDOM** statement to specify random effects and their prior distributions, and the **UDS** statement to define your own Gibbs samplers to sample parameters in the model.

The following sections provide a description of each of these statements.

---

## PROC MCMC Statement

**PROC MCMC options ;**

The PROC MCMC statement invokes the MCMC procedure. [Table 55.1](#) summarizes the options available in the PROC MCMC statement.

**Table 55.1** PROC MCMC Statement Options

| Option                                   | Description                                                                              |
|------------------------------------------|------------------------------------------------------------------------------------------|
| <b>Basic options</b>                     |                                                                                          |
| <b>DATA=</b>                             | Names the input data set                                                                 |
| <b>OUTPOST=</b>                          | Names the output data set for posterior samples of parameters                            |
| <b>Debugging output</b>                  |                                                                                          |
| <b>LIST</b>                              | Displays model program and variables                                                     |
| <b>LISTCODE</b>                          | Displays compiled model program                                                          |
| <b>TRACE</b>                             | Displays detailed model execution messages                                               |
| <b>Frequently used MCMC options</b>      |                                                                                          |
| <b>MAXTUNE=</b>                          | Specifies the maximum number of tuning loops                                             |
| <b>MINTUNE=</b>                          | Specifies the minimum number of tuning loops                                             |
| <b>NBI=</b>                              | Specifies the number of burn-in iterations                                               |
| <b>NMC=</b>                              | Specifies the number of MCMC iterations, excluding the burn-in iterations                |
| <b>NTU=</b>                              | Specifies the number of tuning iterations                                                |
| <b>PROPCOV=</b>                          | Controls options for constructing the initial proposal covariance matrix                 |
| <b>SEED=</b>                             | Specifies the random seed for simulation                                                 |
| <b>THIN=</b>                             | Specifies the thinning rate                                                              |
| <b>Less frequently used MCMC options</b> |                                                                                          |
| <b>ACCEPTTOL=</b>                        | Specifies the acceptance rate tolerance                                                  |
| <b>DISCRETE=</b>                         | Controls sampling discrete parameters                                                    |
| <b>INIT=</b>                             | Controls generating initial values                                                       |
| <b>MCHISTORY=</b>                        | Displays Markov chain sampling history                                                   |
| <b>MAXINDEXPRINT=</b>                    | Specifies the maximum number of observation indices to print in models with missing data |

---

Table 55.1 (continued)

| Option                                            | Description                                                                                                |
|---------------------------------------------------|------------------------------------------------------------------------------------------------------------|
| MAXSUBVALUEPRINT=                                 | Specifies the maximum number of subject values to print in the “Random Effects Parameters” table           |
| PROPDIST=                                         | Specifies the proposal distribution                                                                        |
| REOBSINFO                                         | Displays more detailed information about each random effect                                                |
| SCALE=                                            | Specifies the initial scale applied to the proposal distribution                                           |
| TARGACCEPT=                                       | Specifies the target acceptance rate for random walk sampler                                               |
| TARGACCEPTI=                                      | Specifies the target acceptance rate for independence sampler                                              |
| TUNEWT=                                           | Specifies the weight used in covariance updating                                                           |
| <b>Summary, diagnostics, and plotting options</b> |                                                                                                            |
| AUTOCORLAG=                                       | Specifies the number of autocorrelation lags used to compute effective sample sizes and Monte Carlo errors |
| DIAGNOSTICS=                                      | Controls the convergence diagnostics                                                                       |
| DIC                                               | Computes deviance information criterion (DIC)                                                              |
| MONITOR=                                          | Outputs analysis for a list of symbols of interest                                                         |
| PLOTS=                                            | Controls plotting                                                                                          |
| STATISTICS=                                       | Controls posterior statistics                                                                              |
| <b>Other Options</b>                              |                                                                                                            |
| INF=                                              | Specifies the machine numerical limit for infinity                                                         |
| JOINTMODEL                                        | Specifies joint log-likelihood function                                                                    |
| MISSING=                                          | Indicates how missing values are handled.                                                                  |
| NOLOGDIST                                         | Omits the calculation of the logarithm of the joint distribution of the parameters                         |
| SIMREPORT=                                        | Controls the frequency of report for expected run time                                                     |
| SINGDEN=                                          | Specifies the singularity tolerance                                                                        |

These options are described in alphabetical order.

**ACCEPTTOL=*n***

specifies a tolerance for acceptance probabilities. By default, ACCEPTTOL=0.075.

**AUTOCORLAG=*n*****ACLAG=*n***

specifies the maximum number of autocorrelation lags used in computing the effective sample size; see the section “Effective Sample Size” on page 152 for more details. The value is used in the calculation of the Monte Carlo standard error; see the section “Standard Error of the Mean Estimate” on page 153. By default, AUTOCORLAG=MIN(500, MCsample/4), where MCsample is the Markov chain sample size kept after thinning—that is,  $MCsample = \left\lceil \frac{NMC}{NTHIN} \right\rceil$ . If AUTOCORLAG= is set too low, you might observe significant lags, and the effective sample size cannot be calculated accurately. A WARNING message appears, and you can either increase AUTOCORLAG= or NMC=, accordingly.

**DISCRETE=***keyword*

specifies the proposal distribution used in sampling discrete parameters. The default is DISCRETE=BINNING.

The *keyword* values are as follows:

**BINNING**

uses continuous proposal distributions for all discrete parameter blocks. The proposed sample is then discretized (binned) before further calculations. This sampling method approximates the correlation structure among the discrete parameters in the block and could improve mixing in some cases.

**GEO**

uses independent symmetric geometric proposal distributions for all discrete parameter blocks. This proposal does not take parameter correlations into account. However, it can work better than the BINNING option in cases where the range of the parameters is relatively small and a normal approximation can perform poorly.

**DIAGNOSTICS=NONE** | (*keyword-list*)**DIAG=NONE** | (*keyword-list*)

specifies options for MCMC convergence diagnostics. By default, PROC MCMC computes the Geweke test, sample autocorrelations, effective sample sizes, and Monte Carlo errors. The Raftery-Lewis and Heidelberger-Welch tests are also available. See the section “[Assessing Markov Chain Convergence](#)” on page 139 for more details on convergence diagnostics. You can request all of the diagnostic tests by specifying DIAGNOSTICS=ALL. You can suppress all the tests by specifying DIAGNOSTICS=NONE.

You can use postprocessing autocall macros to calculate convergence diagnostics of the posterior samples after PROC MCMC has exited. See the section “[Autocall Macros for Postprocessing](#)” on page 4510.

The following *options* are available.

**ALL**

computes all diagnostic tests and statistics. You can combine the option ALL with any other specific tests to modify test options. For example DIAGNOSTICS=(ALL AUTOCORR(LAGS=(1 5 35))) computes all tests with default settings and autocorrelations at lags 1, 5, and 35.

**AUTOCORR** < (*autocorr-options*) >

computes default autocorrelations at lags 1, 5, 10, and 50 for each variable. You can choose other lags by using the following *autocorr-options*:

**LAGS** | **AC=***numeric-list*

specifies autocorrelation lags. The *numeric-list* must take positive integer values.

**ESS**

computes the effective sample sizes (Kass et al. (1998)) of the posterior samples of each parameter. It also computes the correlation time and the efficiency of the chain for each parameter. Small values of ESS might indicate a lack of convergence. See the section “[Effective Sample Size](#)” on page 152 for more details.

**GEWEKE** < (*Geweke-options*) >

computes the Geweke spectral density diagnostics; this is a two-sample  $t$ -test between the first  $f_1$  portion and the last  $f_2$  portion of the chain. See the section “[Geweke Diagnostics](#)” on page 146 for more details. The default is  $\text{FRAC1}=0.1$  and  $\text{FRAC2}=0.5$ , but you can choose other fractions by using the following *Geweke-options*:

**FRAC1** | **F1**=*value*

specifies the beginning  $\text{FRAC1}$  proportion of the Markov chain. By default,  $\text{FRAC1}=0.1$ .

**FRAC2** | **F2**=*value*

specifies the end  $\text{FRAC2}$  proportion of the Markov chain. By default,  $\text{FRAC2}=0.5$ .

**HEIDELBERGER** | **HEIDEL** < (*Heidel-options*) >

computes the Heidelberg and Welch diagnostic (which consists of a stationarity test and a halfwidth test) for each variable. The stationary diagnostic test tests the null hypothesis that the posterior samples are generated from a stationary process. If the stationarity test is passed, a halfwidth test is then carried out. See the section “[Heidelberg and Welch Diagnostics](#)” on page 148 for more details.

These diagnostics are not performed by default. You can specify the `DIAGNOSTICS=HEIDELBERGER` option to request these diagnostics, and you can also specify suboptions, such as `DIAGNOSTICS=HEIDELBERGER(EPS=0.05)`, as follows:

**SALPHA**=*value*

specifies the  $\alpha$  level ( $0 < \alpha < 1$ ) for the stationarity test. By default,  $\text{SALPHA}=0.05$ .

**HALPHA**=*value*

specifies the  $\alpha$  level ( $0 < \alpha < 1$ ) for the halfwidth test. By default,  $\text{HALPHA}=0.05$ .

**EPS**=*value*

specifies a small positive number  $\epsilon$  such that if the halfwidth is less than  $\epsilon$  times the sample mean of the retaining iterates, the halfwidth test is passed. By default,  $\text{EPS}=0.1$ .

**MCSE****MCERROR**

computes the Monte Carlo standard error for the posterior samples of each parameter.

**NONE**

suppresses all of the diagnostic tests and statistics. This is not recommended.

**RAFTERY** | **RL** < (*Raftery-options*) >

computes the Raftery and Lewis diagnostics, which evaluate the accuracy of the estimated quantile ( $\hat{\theta}_Q$  for a given  $Q \in (0, 1)$ ) of a chain.  $\hat{\theta}_Q$  can achieve any degree of accuracy when the chain is allowed to run for a long time. The algorithm stops when the estimated probability  $\hat{P}_Q = \Pr(\theta \leq \hat{\theta}_Q)$  reaches within  $\pm R$  of the value  $Q$  with probability  $S$ ; that is,  $\Pr(Q - R \leq \hat{P}_Q \leq Q + R) = S$ . See the section “[Raftery and Lewis Diagnostics](#)” on page 149

for more details. The *Raftery-options* enable you to specify Q, R, S, and a precision level  $\epsilon$  for a stationary test.

These diagnostics are not performed by default. You can specify the `DIAGNOSTICS=RAFERTY` option to request these diagnostics, and you can also specify suboptions, such as `DIAGNOSTICS=RAFERTY(QUANTILE=0.05)`, as follows:

**QUANTILE | Q=value**

specifies the order (a value between 0 and 1) of the quantile of interest. By default, `QUANTILE=0.025`.

**ACCURACY | R=value**

specifies a small positive number as the margin of error for measuring the accuracy of estimation of the quantile. By default, `ACCURACY=0.005`.

**PROB | S=value**

specifies the probability of attaining the accuracy of the estimation of the quantile. By default, `PROB=0.95`.

**EPS=value**

specifies the tolerance level (a small positive number) for the stationary test. By default, `EPS=0.001`.

**DIC**

computes the Deviance Information Criterion (DIC). DIC is calculated using the posterior mean estimates of the parameters. See the section “[Deviance Information Criterion \(DIC\)](#)” on page 155 for more details.

**DATA=SAS-data-set**

specifies the input data set. Observations in this data set are used to compute the log-likelihood function that you specify with PROC MCMC statements.

**INF=value**

specifies the numerical definition of infinity in PROC MCMC. The default is `INF=1E15`. For example, PROC MCMC considers `1E16` to be outside of the support of the normal distribution and assigns a missing value to the log density evaluation. You can select a larger value with the `INF=` option. The minimum value allowed is `1E10`.

**INIT=(keyword-list)**

specifies options for generating the initial values for the parameters. These options apply only to prior distributions that are recognized by PROC MCMC. See the section “[Standard Distributions](#)” on page 4476 for a list of these distributions. If either of the functions `GENERAL` or `DGENERAL` is used, you must supply explicit initial values for the parameters. By default, `INIT=MODE`. The following keywords are used:

**MODE**

uses the mode of the prior density as the initial value of the parameter, if you did not provide one. If the mode does not exist or if it is on the boundary of the support of the density, the mean value is used. If the mean is outside of the support or on the boundary, which can happen if the prior distribution is truncated, a random number drawn from the prior is used as the initial value.

**PINIT**

tabulates parameter values after the tuning phase. This option also tabulates the tuned proposal parameters used by the Metropolis algorithm. These proposal parameters include covariance matrices for continuous parameters and probability vectors for discrete parameters for each block. By default, PROC MCMC does not display the initial values or the tuned proposal parameters after the tuning phase.

**RANDOM**

generates a random number from the prior density and uses it as the initial value of the parameter, if you did not provide one.

**REINIT**

resets the parameters, after the tuning phase, with the initial values that you provided explicitly or that were assigned by PROC MCMC. By default, PROC MCMC does not reset the parameters because the tuning phase usually moves the Markov chains to a more favorable place in the posterior distribution.

**LIST**

displays the model program and variable lists. The LIST option is a debugging feature and is not normally needed.

**LISTCODE**

displays the compiled program code. The LISTCODE option is a debugging feature and is not normally needed.

**JOINTMODEL****JOINTLLIKE**

specifies how the likelihood function is calculated. By default, PROC MCMC assumes that the observations in the data set are independent so that the joint log-likelihood function is the sum of the individual log-likelihood functions for the observations, where the individual log-likelihood function is specified in the [MODEL](#) statement. When your data are not independent, you can specify the JOINTMODEL option to modify the way that PROC MCMC computes the joint log-likelihood function. In this situation, PROC MCMC no longer steps through the input data set to sum the individual log likelihood.

To use this option correctly, you need to do the following two things:

- create ARRAY symbols to store all data set variables that are used in the program. This can be accomplished with the [BEGINCNST](#) and [ENDCNST](#) statements.
- program the joint log-likelihood function by using these ARRAY symbols only. The [MODEL](#) statement specifies the joint log-likelihood function for the entire data set. Typically, you use the function [GENERAL](#) in the [MODEL](#) statement.

See the sections “[BEGINCNST/ENDCNST Statement](#)” on page 4441 and “[Modeling Joint Likelihood](#)” on page 4504 for details.

**MAXTUNE=*n***

specifies an upper limit for the number of proposal tuning loops. By default, MAXTUNE=24. See the section “[Covariance Tuning](#)” on page 4470 for more details.

**MAXINDEXPRINT=*number* | ALL****MAXIPRINT=*number* | ALL**

specifies the maximum number of observation indices to print in the ODS tables “Missing Response Information” table and “Missing Covariates Information” table. This option applies only to programs that model missing data. The default value is 20. MAXINDEXPRINT=ALL prints all observation indices for every missing variable that is modeled in PROC MCMC.

**MAXSUBVALUEPRINT=*number* | ALL****MAXSVPRINT=*number* | ALL**

specifies the maximum number of subject values to display in the “Subject Values” column of the ODS table “Random Effects Parameters.” This option applies only to programs that have RANDOM statements. The default value is 20. MAXSUBVALUEPRINT=ALL prints all subject values for every random effect in the program.

**MCHISTORY=*keyword*****MCHIST=*keyword***

controls the display of the Markov chain sampling history.

**BRIEF**

produces a summary output for the tuning, burn-in, and sampling history tables. The tables show the following when applicable:

- “RWM Scale” shows the scale, or the range of the scales, used in each random walk Metropolis block that is normal or is based on a *t* distribution.
- “Probability” shows the proposal probability parameter, or the range of the parameters, used in each random walk Metropolis block that is based on a geometric distribution.
- “RWM Acceptance Rate” shows the acceptance rate, or the range of the acceptance rates, for each random walk Metropolis block.
- “IM Acceptance Rate” shows the acceptance rate, or the range of the acceptance rates, for each independent Metropolis block.

**DETAILED**

produces detailed output of the tuning, burn-in, and sampling history tables, including scale values, acceptance probabilities, blocking information, and so on. Use this option with caution, especially in random-effects models that have a large number of random-effects groups. This option can produce copious output.

**NONE**

produces none of the tuning history, burn-in history, and sampling history tables.

The default is MCHISTORY=NONE.

**MINTUNE=*n***

specifies a lower limit for the number of proposal tuning loops. By default, MINTUNE=2. See the section “[Covariance Tuning](#)” on page 4470 for more details.

**MISSING=keyword**

**MISS=keyword**

specifies how missing values are handled (see the section “Handling of Missing Data” on page 4518 for more details). The default is MISSING=COMPLETECASE.

**ALLCASE | AC**

gives you the option to model the missing values in an all-case analysis. You can use any techniques that you see fit, for example, fully Bayesian or multiple imputation.

**COMPLETECASE | CC**

assumes a complete case analysis, so all observations with missing variable values are discarded prior to the simulation.

**MONITOR= (symbol-list)**

outputs analysis for selected symbols of interest in the program. The symbols can be any of the following: model parameters (symbols in the **PARMS** statement), secondary parameters (assigned using the operator “=”), the log of the posterior density (**LOGPOST**), the log of the prior density (**LOGPRIOR**), the log of the hyperprior density (**LOGHYPER**) if the **HYPER** statement is used, or the log of the likelihood function (**LOGLIKE**). You can use the keyword **\_PARMS\_** as a shorthand for all of the model parameters. PROC MCMC performs only posterior analyses (such as plotting, diagnostics, and summaries) on the symbols selected with the **MONITOR=** option. You can also choose to monitor an entire array by specifying the name of the array. By default **MONITOR=\_PARMS\_**.

Posterior samples of any secondary parameters listed in the **MONITOR=** option are saved in the **OUTPOST=** data set. Posterior samples of model parameters are always saved to the **OUTPOST=** data set, regardless of whether they appear in the **MONITOR=** option.

**NBI=*n***

specifies the number of burn-in iterations to perform before beginning to save parameter estimate chains. By default, **NBI=1000**. See the section “Burn-in, Thinning, and Markov Chain Samples” on page 138 for more details.

**NMC=*n***

specifies the number of iterations in the main simulation loop. This is the MCMC sample size if **THIN=1**. By default, **NMC=1000**.

**NOLOGDIST**

omits the calculation of the logarithm of the joint distribution of the model parameters at each iteration. The option applies only if all parameters in the model are updated directly from their target distribution, either from the full conditional posterior via conjugacy or from the marginal distribution. Such algorithms do not require the calculation of the joint posterior distribution; hence PROC MCMC runs faster by avoiding these unnecessary calculations. As a result, the **OUTPOST=** data set does not contain the **LOGPRIOR**, **LOGLIKE**, and **LOGPOST** variables.

**NTU=*n***

specifies the number of iterations to use in each proposal tuning phase. By default, **NTU=500**.

**OUTPOST=SAS-data-set**

specifies an output data set that contains the posterior samples of all model parameters, the iteration numbers (variable name **ITERATION**), the log of the posterior density (**LOGPOST**), the log of the

prior density (LOGPRIOR), the log of the hyperprior density (LOGHYPER), if the **HYPER** statement is used, and the log likelihood (LOGLIKE). Any secondary parameters (assigned using the operator “=”) listed in the **MONITOR=** option are saved to this data set. By default, no **OUTPOST=** data set is created.

**PLOTS**< (*global-plot-options*)>= (*plot-request* <... *plot-request*>)

**PLOT**< (*global-plot-options*)>= (*plot-request* <... *plot-request*>)

controls the display of diagnostic plots. Three types of plots can be requested: trace plots, autocorrelation function plots, and kernel density plots. By default, the plots are displayed in panels unless the global plot option **UNPACK** is specified. Also when more than one type of plot is specified, the plots are grouped by parameter unless the global plot option **GROUPBY=TYPE** is specified. When you specify only one plot request, you can omit the parentheses around the plot-request, as shown in the following example:

```
plots=none
plots(unpack)=trace
plots=(trace density)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc mcmc data=exi seed=7 outpost=p1 plots=all;
 parm mu;
 prior mu ~ normal(0, sd=10);
 model y ~ normal(mu, sd=1);
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but do not specify the **PLOTS=** option, then PROC MCMC produces, for each parameter, a panel that contains the trace plot, the autocorrelation function plot, and the density plot. This is equivalent to specifying **PLOTS=(TRACE AUTOCORR DENSITY)**.

The *global-plot-options* include the following:

#### **FRINGE**

adds a fringe plot to the horizontal axis of the density plot.

#### **GROUPBY|GROUP=PARAMETER | TYPE**

specifies how the plots are grouped when there is more than one type of plot. **GROUPBY=PARAMETER** is the default. The choices are as follows:

##### **TYPE**

specifies that the plots are grouped by type.

##### **PARAMETER**

specifies that the plots are grouped by parameter.

**LAGS=*n***

specifies the number of autocorrelation lags used in plotting the ACF graph. By default, LAGS=50.

**SMOOTH**

smooths the trace plot with a fitted penalized B-spline curve (Eilers and Marx 1996).

**UNPACKPANEL****UNPACK**

specifies that all paneled plots are to be unpacked, so that each plot in a panel is displayed separately.

The *plot-requests* are as follows:

**ALL**

requests all types of plots. PLOTS=ALL is equivalent to specifying PLOTS=(TRACE AUTO-CORR DENSITY).

**AUTOCORR | ACF**

displays the autocorrelation function plots for the parameters.

**DENSITY | D | KERNEL | K**

displays the kernel density plots for the parameters.

**NONE**

suppresses the display of all plots.

**TRACE | T**

displays the trace plots for the parameters.

Consider a model with four parameters, X1–X4. Displays for various specifications are depicted as follows.

- PLOTS=(TRACE AUTOCORR) displays the trace and autocorrelation plots for each parameter side by side with two parameters per panel:

---

|           |           |              |
|-----------|-----------|--------------|
| Display 1 | Trace(X1) | Autocorr(X1) |
|           | Trace(X2) | Autocorr(X2) |
| Display 2 | Trace(X3) | Autocorr(X3) |
|           | Trace(X4) | Autocorr(X4) |

---

- PLOTS(GROUPBY=TYPE)=(TRACE AUTOCORR) displays all the paneled trace plots, followed by panels of autocorrelation plots:

---

|           |              |              |
|-----------|--------------|--------------|
| Display 1 | Trace(X1)    |              |
|           | Trace(X2)    |              |
| Display 2 | Trace(X3)    |              |
|           | Trace(X4)    |              |
| Display 3 | Autocorr(X1) | Autocorr(X2) |
|           | Autocorr(X3) | Autocorr(X4) |

---

- PLOTS(UNPACK)=(TRACE AUTOCORR) displays a separate trace plot and a separate correlation plot, parameter by parameter:

---

|           |              |
|-----------|--------------|
| Display 1 | Trace(X1)    |
| Display 2 | Autocorr(X1) |
| Display 3 | Trace(X2)    |
| Display 4 | Autocorr(X2) |
| Display 5 | Trace(X3)    |
| Display 6 | Autocorr(X3) |
| Display 7 | Trace(X4)    |
| Display 8 | Autocorr(X4) |

---

- PLOTS(UNPACK GROUPBY=TYPE)=(TRACE AUTOCORR) displays all the separate trace plots followed by the separate autocorrelation plots:

---

|           |              |
|-----------|--------------|
| Display 1 | Trace(X1)    |
| Display 2 | Trace(X2)    |
| Display 3 | Trace(X3)    |
| Display 4 | Trace(X4)    |
| Display 5 | Autocorr(X1) |
| Display 6 | Autocorr(X2) |
| Display 7 | Autocorr(X3) |
| Display 8 | Autocorr(X4) |

---

**PROPCOV=value**

specifies the method used in constructing the initial covariance matrix for the Metropolis-Hastings algorithm. The QUANEW and NMSIMP methods find numerically approximated covariance matrices at the optimum of the posterior density function with respect to all continuous parameters. The optimization does not apply to discrete parameters. The tuning phase starts at the optimized values; in some problems, this can greatly increase convergence performance. If the approximated covariance matrix is not positive definite, then an identity matrix is used instead. Valid values are as follows:

**IND**

uses the identity covariance matrix. This is the default. See the section “[Tuning the Proposal Distribution](#)” on page 4469.

**CONGRA**< (*optimize-options*) >

performs a conjugate-gradient optimization.

**DBLDOG**< (*optimize-options*) >

performs a double-dogleg optimization.

**QUANEW**< (*optimize-options*) >

performs a quasi-Newton optimization.

**NMSIMP | SIMPLEX**< (*optimize-options*) >

performs a Nelder-Mead simplex optimization.

The *optimize-options* are as follows:

**ITPRINT**

prints optimization iteration steps and results.

**PROPDIST**=*value*

specifies a proposal distribution for the Metropolis algorithm. See the section “[Metropolis and Metropolis-Hastings Algorithms](#)” on page 134. You can also use **PARMS** statement option (see the section “[PARMS Statement](#)” on page 4451) to change the proposal distribution for a particular block of parameters. Valid values are as follows:

**NORMAL****N**

specifies a normal distribution as the proposal distribution. This is the default.

**T**< (*df*) >

specifies a *t* distribution with the degrees of freedom *df*. By default, *df* = 3. If *df* > 100, the normal distribution is used since the two distributions are almost identical.

**REOBSINFO** < (*display-options*) >

displays the ODS table “Random Effect Observation Information.” The table lists the name of each random effect, the unique values in the corresponding subject variable, the number of observations in each subject, and the observation indices for each subject value.

To understand how this option works, consider the following statements:

```
data input;
 array names{*} $ n1-n10 ("John" "Mary" "Chris" "Rob" "Greg"
 "Jen" "Henry" "Alice" "James" "Toby");
 call streaminit(17);
 do i = 1 to 20;
 j = ceil(rand("uniform") * 10);
 index = names[j];
 output;
 end;
```

```

drop n: j;
run;

proc print data=input;
run;

```

The input data set (Figure 55.11) contains the index variable, which indicates subjects in a hypothetical random-effects model.

**Figure 55.11** Subject Variable in an Input Data Set

| Obs | i  | index |
|-----|----|-------|
| 1   | 1  | Mary  |
| 2   | 2  | James |
| 3   | 3  | Mary  |
| 4   | 4  | Greg  |
| 5   | 5  | Chris |
| 6   | 6  | James |
| 7   | 7  | James |
| 8   | 8  | Chris |
| 9   | 9  | James |
| 10  | 10 | James |
| 11  | 11 | Chris |
| 12  | 12 | Rob   |
| 13  | 13 | Rob   |
| 14  | 14 | Greg  |
| 15  | 15 | Greg  |
| 16  | 16 | Alice |
| 17  | 17 | Jen   |
| 18  | 18 | Alice |
| 19  | 19 | John  |
| 20  | 20 | Chris |

The following statements illustrate the use of the REOBSINFO option:

```

ods select reobsinfo;
proc mcmc data=input reobsinfo stats=none diag=none;
 random u ~ normal(0, sd=1) subject=index;
 model general(0);
run;

```

Figure 55.12 displays the “Random Effect Observation Information” table. The table contains the name of the random-effect parameter ( $u$ ), the values of the subject variable `index`, the total number of observations, and the row index of these observations in each of the subject values.

Figure 55.12 Random Effect Observation Information

| The MCMC Procedure                    |                |                                   |                     |
|---------------------------------------|----------------|-----------------------------------|---------------------|
| Random Effect Observation Information |                |                                   |                     |
| Parameter                             | Subject Values | Number of Observations in Subject | Observation Indices |
| u                                     | Mary           | 2                                 | 1 3                 |
|                                       | James          | 5                                 | 2 6 7 9 10          |
|                                       | Greg           | 3                                 | 4 14 15             |
|                                       | Chris          | 4                                 | 5 8 11 20           |
|                                       | Rob            | 2                                 | 12 13               |
|                                       | Alice          | 2                                 | 16 18               |
|                                       | Jen            | 1                                 | 17                  |
|                                       | John           | 1                                 | 19                  |

The *display-options* are as follows:

**MAXVALUEPRINT=number | ALL**

**MAXVPRINT=number | ALL**

prints the number of subject values for each random effect (that is, the number of rows that are displayed in the “Random Effect Observation Information” table for each random effect). The default value is 20. MAXVALUEPRINT=ALL displays all subject values.

**MAXOBSPRINT=number | ALL**

**MAXOPRINT=number | ALL**

prints the number of observation indices for each subject value of every random effect (that is, the maximum number of indices that are displayed in the “Observation Indices” column in the “Random Effect Observation Information” table). The default value is 20. MAXOBSPRINT=ALL displays indices for every subject value.

**SCALE=value**

controls the initial multiplicative scale to the covariance matrix of the proposal distribution. By default, SCALE=2.38. See the section “[Scale Tuning](#)” on page 4470 for more details.

**SEED=n**

specifies the random number seed. By default, SEED=0, and PROC MCMC gets a random number seed from the clock.

**SIMREPORT=n**

controls the number of times that PROC MCMC reports the expected run time of the simulation. This can be useful for monitoring the progress of CPU-intensive programs. For example, with SIMREPORT=2, PROC MCMC reports the simulation progress twice. By default, SIMREPORT=0, and there is no reporting. The expected run times are displayed in the log file.

**SINGDEN=***value*

defines the singularity criterion in PROC MCMC. By default, SINGDEN=1E-11. The *value* indicates the exclusion of an endpoint in an interval. The mathematical notation “(0” is equivalent to “[*value*” in PROC MCMC—that is,  $x < 0$  is treated as  $x \leq \textit{value}$  in PROC MCMC. The maximum SINGDEN allowed is 1E-6.

**STATISTICS**< *global-stats-options* > = **NONE** | **ALL** | *stats-request***STATS**< *global-stats-options* > = **NONE** | **ALL** | *stats-request*

specifies options for posterior statistics. By default, PROC MCMC computes the posterior mean, standard deviation, quantiles, and two 95% credible intervals: equal-tail and highest posterior density (HPD). Other available statistics include the posterior correlation and covariance. See the section “[Summary Statistics](#)” on page 153 for more details. You can request all of the posterior statistics by specifying STATS=ALL. You can suppress all the calculations by specifying STATS=NONE.

You can use postprocessing autocall macros to calculate posterior summary statistics of the posterior samples after PROC MCMC has exited. See the section “[Autocall Macros for Postprocessing](#)” on page 4510.

The *global-stats-options* includes the following:

**ALPHA=***numeric-list*

specifies the  $\alpha$  level for the equal-tail and HPD intervals. The value  $\alpha$  must be between 0 and 0.5. By default, ALPHA=0.05.

**PERCENTAGE** | **PERCENT=***numeric-list*

calculates the posterior percentages. The *numeric-list* contains values between 0 and 100. By default, PERCENTAGE=(25 50 75).

The *stats-requests* include the following:

**ALL**

computes all posterior statistics. You can combine the option ALL with any other options. For example STATS(ALPHA=(0.02 0.05 0.1))=ALL computes all statistics with the default settings and intervals at  $\alpha$  levels of 0.02, 0.05, and 0.1.

**CORR**

computes the posterior correlation matrix.

**COV**

computes the posterior covariance matrix.

**SUMMARY****SUM**

computes the posterior means, standard deviations, and percentile points for each variable. By default, the 25th, 50th, and 75th percentile points are produced, but you can use the global PERCENT= option to request specific percentile points.

**INTERVAL****INT**

computes the  $100(1 - \alpha)\%$  equal-tail and HPD credible intervals for each variable. See the sections “[Equal-Tail Credible Interval](#)” on page 154 and “[Highest Posterior Density \(HPD\) Interval](#)” on page 154 for details. By default, ALPHA=0.05, but you can use the global ALPHA= option to request other intervals of any probabilities.

**NONE**

suppresses all of the statistics.

**TARGACCEPT=value**

specifies the target acceptance rate for the random walk based Metropolis algorithm. See the section “[Metropolis and Metropolis-Hastings Algorithms](#)” on page 134. The numeric *value* must be between 0.01 and 0.99. By default, TARGACCEPT=0.45 for models with 1 parameter; TARGACCEPT=0.35 for models with 2, 3, or 4 parameters; and TARGACCEPT=0.234 for models with more than 4 parameters (Roberts, Gelman, and Gilks 1997; Roberts and Rosenthal 2001).

**TARGACCEPTI=value**

specifies the target acceptance rate for the independence sampler algorithm. The independence sampler is used for blocks of binary parameters. See the section “[Independence Sampler](#)” on page 137 for more details. The numeric *value* must be between 0 and 1. By default, TARGACCEPTI=0.6.

**THIN=n****NTHIN=n**

controls the thinning rate of the simulation. PROC MCMC keeps every *n*th simulation sample and discards the rest. All of the posterior statistics and diagnostics are calculated using the thinned samples. By default, THIN=1. See the section “[Burn-in, Thinning, and Markov Chain Samples](#)” on page 138 for more details.

**TRACE**

displays the result of each operation in each statement in the model program as it is executed. This debugging option is very rarely needed, and it produces voluminous output. If you use this option, also use small NMC=, NBI=, MAXTUNE=, and NTU= numbers.

**TUNEWT=value**

specifies the multiplicative weight used in updating the covariance matrix of the proposal distribution. The numeric *value* must be between 0 and 1. By default, TUNEWT=0.75. See the section “[Covariance Tuning](#)” on page 4470 for more details.

---

## ARRAY Statement

```
ARRAY arrayname [dimensions] < $ > < variables-and-constants > ;
```

The ARRAY statement associates a name (of no more than eight characters) with a list of variables and constants. The ARRAY statement is similar to, but not the same as, the ARRAY statement in the DATA step, and it is the same as the ARRAY statements in the NLIN, NLP, NLMIXED, and MODEL procedures. The array name is used with subscripts in the program to refer to the array elements, as illustrated in the following statements:

```
array r[8] r1-r8;

do i = 1 to 8;
 r[i] = 0;
end;
```

The ARRAY statement does not support all the features of the ARRAY statement in the DATA step. Implicit indexing of variables cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

Both variables and constants can be array elements. Constant array elements cannot have values assigned to them while variables can. Both the dimension specification and the list of elements are optional, but at least one must be specified. When the list of elements is not specified or fewer elements than the size of the array are listed, array variables are created by appending element numbers to the array name to complete the element list. You can index array elements by enclosing a subscript in braces ({} ) or brackets ([ ]), but not in parentheses (( )). The parentheses are reserved for function calls only.

For example, the following statement names an array `day`:

```
array day[365];
```

By default, the variables names are `day1` to `day365`. However, since `day` is a SAS function, any subscript that uses parentheses gives you the wrong results. The expression `day(4)` returns the value 5 and does not reference the array element `day4`.

---

## BEGINCNST/ENDCNST Statement

```
BEGINCNST ;
```

```
ENDCNST ;
```

The BEGINCNST and ENDCNST statements define a block within which PROC MCMC processes the programming statements only during the setup stage of the simulation. You can use the BEGINCNST and ENDCNST statements to define constants or import data set variables into arrays. Storing data in arrays enables you to work with data that are not identically distributed (see the section “[Modeling Joint Likelihood](#)” on page 4504) or to implement your own Markov chain sampler (see the section “[UDS Statement](#)” on page 4462). You can also use the BEGINCNST and ENDCNST statements to assign initial values to the parameters (see the section “[Assignments of Parameters](#)” on page 4474).

### Assign Constants

Whenever you have programming statements that calculate constants that do not need to be evaluated multiple times throughout the simulation, you should put them within the BEGINCNST and ENDCNST statements. Using these statements can reduce redundant processing. For example, you can assign a constant to a symbol or fill in an array with numbers:

```
array cnst[17];
begincnst;
 offset = 17;
 do i = 1 to 17;
 cnst[i] = i * i;
 end;
endcnst;
```

During the setup process, PROC MCMC evaluates the programming statements within the BEGINCNST/ENDCNST once for each observation in the data set and ignores the statements in the rest of the simulation.

## READ\_ARRAY Function

Sometimes you might need to store variables, either from the current input data set or from a different data set, in arrays and use these arrays to specify your model. The READ\_ARRAY function is convenient for that purpose.

The following two forms of the READ\_ARRAY function are available:

```
rc = READ_ARRAY (data-set, array) ;
```

```
rc = READ_ARRAY (data-set, array <, "col-name1"> <, "col-name2"> <, ... >);
```

where

- *rc* returns 0 if the function is able to successfully read the data set.
- *data-set* specifies the name of the data set from which the array data is read. The value specified for *data-set* must be a character literal or a variable that contains the member name (libname.memname) of the data set to be read from.
- *array* specifies the PROC MCMC array variable into which the data is read. The value specified for *array* must be a local temporary array variable because the function might need to grow or shrink its size to accommodate the size of the data set.
- *col-name* specifies optional names for the specific columns of the data set that are read. If specified, *col-name* must be a literal string enclosed in quotation marks. In addition, *col-name* cannot be a PROC MCMC variable. If column names are not specified, PROC MCMC reads all of the columns in the data set.

When SAS translates between an array and a data set, the array is indexed as [row,column].

The READ\_ARRAY function attempts to dynamically resize the array to match the dimensions of the input data set. Therefore, the array must be dynamic; that is, the array must be declared with the /NOSYMBOLS option.

For examples that use the READ\_ARRAY function, see “Modeling Joint Likelihood” on page 4504, “Example 55.14: Time Independent Cox Model” on page 4617, and “Example 55.19: Implement a New Sampling Algorithm” on page 4645.

---

## BEGINNODATA/ENDNODATA Statements

```
BEGINNODATA ;
```

```
ENDNODATA ;
```

```
BEGINPRIOR ;
```

```
ENDPRIOR ;
```

The BEGINNODATA and ENDNODATA statements define a block within which PROC MCMC processes the programming statements without stepping through the entire data set. The programming statements are executed only twice: at the first and the last observation of the data set. The BEGINNODATA and ENDNODATA statements are best used to reduce unnecessary observation-level computations. Any computations that are identical to every observation, such as transformation of parameters, should be enclosed in these statements.

At the first observation, PROC MCMC executes all programming statements, including those that are enclosed by these two statements. This enables a quick update of all the symbols enclosed by the BEGINNODATA and ENDNODATA statements. The goal is to ensure that subsequent statements (for example, the MODEL statement) use symbol values that have been calculated correctly. At the last observation, PROC MCMC executes the enclosed programming statements again and adds the log of the prior density to the log of the posterior density.

The BEGINPRIOR and ENDPRIOR statements are aliases for the BEGINNODATA and ENDNODATA statements, respectively. You can enclose PRIOR statements in the BEGINNODATA and ENDNODATA statements.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC MCMC to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MCMC procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## MODEL Statement

**MODEL** *dependent-variable-list* ~ *distribution* < *options* > ;

The MODEL statement specifies the conditional distribution of the data given the parameters (the likelihood function). You specify a single dependent variable or a list of dependent variables, a tilde ~, and then a

distribution with its arguments. The dependent variables can be variables from the input data set or functions of the symbols in the program. You must specify the dependent variables unless you use the **GENERAL** function or the **DGENERAL** function (see the section “Specifying a New Distribution” on page 4490 for more details).

The **MODEL** statement assumes that the observations are independent of each other, conditional on the model parameters. If you want to model dependent data—that is,  $f(y_i|\theta, y_j)$  for  $j \neq i$ —you can use the **JOINTMODEL** option in the **PROC MCMC** statement. See the section “Modeling Joint Likelihood” on page 4504 for more details. By default, the log-likelihood value is the sum of the individual log-likelihood value for each observation.

You can specify multiple **MODEL** statements. You can define likelihood functions that are independent of each other. For example, in the following statements, the dependent variables **y1** and **y2** are independent of each other:

```
model y1 ~ normal(alpha, var=s21);
model y2 ~ normal(beta, var=s22);
```

Alternatively, you can use marginal and conditional distributions to define a joint log-likelihood function for multiple dependent variables. For example, the following statements jointly define a distribution over (**y1**, **y2**). They specify a marginal distribution for the dependent variable **y1** and a conditional distribution for the dependent variable **y2**:

```
model y1 ~ normal(alpha, var=s21);
model y2 ~ normal(beta * y1, var=s22);
```

Every program must have at least one **MODEL** statement. If you want to run a Monte Carlo simulation that does not require a response variable, use the **GENERAL** function in the **MODEL** statement:

```
model general(0);
```

**PROC MCMC** interprets the statement as a flat likelihood function with a constant log-likelihood value of 0.

**PROC MCMC** is a programming language that is similar to the **DATA** step, and the order of statement evaluation is important. For example, the **MODEL** statement must come after any **SAS** programming statements that define or modify arguments used in the construction of the log likelihood. In **PROC MCMC**, a symbol can be defined multiple times and used at different places. Using an expression out of order produces erroneous results that can also be hard to detect.

Do not embed the **MODEL** statement within programming statements. For example, suppose you have three response variables, **y1**, **y2**, and **y3**, and want to model each with a normal distribution. The following statements lead to erroneous output:

```
array Y[3] y1 y2 y3;
do i = 1 to 3;
 model y[i] ~ normal(mu, sd=s);
end;
```

Instead, you should do one of the following.

- Use separate **MODEL** statements:

```

model y1 ~ normal(mu, sd=s);
model y2 ~ normal(mu, sd=s);
model y3 ~ normal(mu, sd=s);

```

- Use the GENERAL function to construct a joint distribution of the three dependent variables and use a single MODEL statement to specify the log-likelihood function:

```

llike = logpdf("normal", y1, mu, s) +
 logpdf("normal", y2, mu, s) +
 logpdf("normal", y3, mu, s);
model y1 y2 y3 ~ general(llike);

```

See the section “[Specifying a New Distribution](#)” on page 4490 for more information about how to use the GENERAL function to specify an arbitrary distribution.
