When there are missing values for test variables, the within-group-and-stratum sample sizes can differ from variable to variable. In most cases this is not a problem; however, it is possible for all data to be missing for a particular group within a particular stratum. For continuous variables and Freeman-Tukey tests, PROC MULTTEST re-centers the contrast trend coefficients within strata where all data for a particular group are missing. Re-centering the **MEAN** tests could redefine your  $t$  tests in an undesirable fashion; for example, if you specify coefficients to contrast the first and third groups (**contrast -1 0 1**) but the third group is missing, then the re-centered coefficients become  $-0.5$  and  $0.5$ , thus contrasting the first and second groups. If this is the case, you can run your  $t$  tests in separate PROC MULTTEST invocations, then combine the data and adjust the  $p$ -values by using the **INPVALUES=** option. However, you might find this re-centering acceptable for the Freeman-Tukey trend tests, since the contrast still tests for an increasing trend. The Cochran-Armitage and Peto tests are unaffected by this situation.

PROC MULTTEST uses missing values for resampling if they exist in the original data set. If all variables have missing values for any observation, then PROC MULTTEST removes the observation prior to resampling. Otherwise, PROC MULTTEST treats all missing values as ordinary observations in the resampling. This means that different resampled data sets can have different group sizes. In some cases it means that a resampled data set can have all missing values for a particular variable in a particular group/stratum combination, even when values exist for that combination in the original data. For this reason, PROC MULTTEST recomputes all quantities within each pseudo-data set, including such items as centered scoring coefficients and degrees of freedom for  $p$ -values.

While PROC MULTTEST does provide analyses in missing value cases, you should not feel that it completely solves the missing-value problem. If you are concerned about the adverse effects of missing data on a particular analysis, you should consider using imputation and sensitivity analyses to assess the effects of the missing data.

---

## Computational Resources

PROC MULTTEST keeps all of the data in memory to expedite resampling. A large portion of the memory requirement is thus  $8 \times \text{NOBS} \times \text{NVAR}$  bytes, where NOBS is the number of observations in the data set, and NVAR is the number of variables analyzed, including CLASS, FREQ, and STRATA variables.

If you specify PERMUTATION=*number* (for exact permutation distributions), then PROC MULTTEST requires additional memory. This requirement is approximately  $4 \times \text{NTEST} \times \text{NSTRATA} \times \text{CMAX} \times \text{number} \times (\text{number} + 1)$  bytes, where NTEST is the number of contrasts, NSTRATA is the number of STRATA levels, and CMAX is the maximum contrast coefficient.

If you specify the FDRBOOT or FDRPERM option, then saving all the resamples in memory requires  $8 \times \text{NSAMPLE} \times \text{NOBS}$  bytes, where NSAMPLE is the number of resamples used.

The execution time is linear in the number of resamples; that is, 10,000 resamples will take 10 times longer than 1,000 resamples. The execution time is also linear in the sample size; that is, 100 resamples of size  $N$  will take 10 times longer than 100 resamples of size  $10N$ .

---

## Output Data Sets

### OUT= Data Set

The OUT= data set contains contrast names (`_test_`), variable names (`_var_`), the contrast label (`_contrast_`), raw  $p$ -values (`raw_p` or the value specified in the INPVALUES= option), and all requested adjusted  $p$ -values (`bon_p`, `sid_p`, `boot_p`, `perm_p`, `stpbon_p`, `stpsid_p`, `stpbootp`, `stppermp`, `hom_p`, `hoc_p`, `fic_p`, `stouffer_p`, `aholm_p`, `ahoc_p`, `fdr_p`, `dfdr_p`, `fdrbootp`, `ufdbootp`, `fdrpermp`, `ufdpermp`, `afdr_p`, or `pfdr_p`).

If a resampling-based adjusted  $p$ -value is requested, then the simulation standard error is included as either `sim_se`, `stpsimse`, `fdrsimse`, or `ufdsimse`, depending on whether single-step, step-down, or FDR adjustments are requested. The simulation standard errors are used to bound the true resampling-based adjusted  $p$ -value. For example, if the resampling-based estimate is 0.0312 and the simulation standard error is 0.00123, then a 95% confidence interval for the true adjusted  $p$ -value is  $0.0312 \pm 1.96(0.00123)$ , or 0.0288 to 0.0336.

Intermediate statistics used to calculate the  $p$ -values are also written to the OUT= data set. The statistics are separated by the `_strat_` level. When `_strat_` is reported as missing, the statistics refer to the pooled analysis over all `_strat_` levels. The  $p$ -values are provided only for the pooled analyses and are therefore reported as missing for the strata-specific statistics.

For the Peto test, an additional variable, `_tstrat_`, is included to indicate whether the stratum is an incidental occurrence stratum (`_tstrat_=0`) or a fatal occurrence stratum (`_tstrat_=1`).

The statistic `_value_` is the per-strata contribution to the numerator of the overall test statistic. In the case of the MEAN test, this is the contrast function of the sample means multiplied by the total number of observations within the stratum. For the FT test, `_value_` is the contrast function of the double-arcsine transformed proportions, again multiplied by the total number of observations within the stratum. For the CA and Peto tests, `_value_` is the observed value of the trend statistic within that stratum.

When either PETO or CA is requested, the variable `_exp_` is included; this variable contains the expected value of the trend statistic for the given stratum.

The statistic `_se_` is the square root of the variance of the per-strata `_value_` statistic for any of the tests.

For **MEAN** tests, the variable `_nval_` is included. When reported with an individual stratum level (that is, when the `_strat_` value is nonmissing), the value `_nval_` refers to the within-stratum sample size. For the combined analysis (that is, the value of the `_strat_` is missing), the value `_nval_` contains degrees of freedom of the  $t$  distribution used to compute the unadjusted  $p$ -value.

When the **FISHER** test is requested, the `OUT=` data set contains the variables `_xval_`, `_mval_`, `_yval_`, and `_nval_`, which define observations and sample sizes in the two groups defined by the **CONTRAST** statement.

For example, the `OUT=` data set from the drug example in the section “Getting Started: **MULTTEST** Procedure” on page 5167 is displayed in [Figure 61.5](#).

**Figure 61.5** Output Data for the **MULTTEST** Procedure

| Obs | _test_ | _var_     | _contrast_ | _value_ | _exp_ | _se_    | raw_p   | boot_p  | sim_se     |
|-----|--------|-----------|------------|---------|-------|---------|---------|---------|------------|
| 1   | CA     | SideEff1  | Trend      | 8       | 5     | 1.54303 | 0.05187 | 0.33880 | .003346749 |
| 2   | CA     | SideEff2  | Trend      | 7       | 5     | 1.54303 | 0.19492 | 0.84030 | .002590327 |
| 3   | CA     | SideEff3  | Trend      | 10      | 7     | 1.63299 | 0.06619 | 0.51895 | .003532994 |
| 4   | CA     | SideEff4  | Trend      | 10      | 6     | 1.60357 | 0.01262 | 0.08840 | .002007305 |

| 9   | CA     | SideEff9  | Trend      | 7       | 5     | 1.54303 | 0.19492 | 0.84030 | .002590327 |
| 10  | CA     | SideEff10 | Trend      | 8       | 6     | 1.60357 | 0.21232 | 0.90300 | .002092737 |

## OUTPERM= Data Set

The `OUTPERM=` data set contains contrast names (`_contrast_`), variable names (`_var_`), and the associated permutation distributions (`_value_` and `upper_p`). **PROC MULTTEST** computes the permutation distributions when you use the **PERMUTATION=** option with the **CA** or Peto test. The `_value_` variable represents the support of the distributions, and `upper_p` represents their cumulative upper-tail probabilities. The size of this data set depends on the number of variables and the support of their permutation distributions.

For information about how this distribution is computed, see the section “Exact Permutation Test” on page 5189. For an illustration, see [Example 61.1](#).

## OUTSAMP= Data Set

The `OUTSAMP=` data set contains the data sets used in the resampling analysis, if such an analysis is requested. The variable `_sample_` indicates the number of the resampled data set. This variable ranges from 1 to the value of the **NSAMPLE=** option. For each value of the `_sample_` variable, an entire resampled data set is included, with `_stratum_`, `_class_`, and all other variables in the original data set. The values of the original variables are mean-centered for the mean test, if requested. The variable `_obs_` indicates the observation’s position in the original data set.

Each new data set is randomly drawn from the original data set, either with (bootstrap) or without (permutation) replacement. The size of this data set is, thus, the number of observations in the original data set times the number of samples.

---

## Displayed Output

The output produced by PROC MULTTEST is divided into several tables. If the `DATA=` data set is specified, then the following tables are displayed:

- The “Model Information” table provides a list of the options and settings used for that particular invocation of the procedure. This table is not displayed if the `INPVALUES=` data set is specified. Included in this list are the following items:
  - statistical tests
  - support of the exact permutation distribution for the `CA` and `Peto` tests
  - continuity corrections used for the `CA` test
  - test tails
  - strata adjustment
  - $p$ -value adjustments and specified suboptions
  - centering of continuous variables
  - number of samples and seed
- The “Contrast Coefficients” table lists the coefficients used in constructing the statistical tests. These coefficients are either specified in `CONTRAST` statements or generated by default. The coefficients apply to the levels of the `CLASS` statement variable. If a `MEAN` or `FT` test is specified in the `TEST` statement, the centered coefficients are displayed. Patterns of missing values in your data set might affect the coefficients used in your analysis; the displayed contrasts take missing value patterns into account. See the section “Missing Values” on page 5203 for more information.
- The “Variable Tabulations” tables provide summary statistics for each variable listed in the `TEST` statement. Included for discrete variables are the count, sample size, and percentage of occurrences. For continuous variables, the mean, sample standard deviation, and sample size are displayed. All of the previously mentioned statistics are computed for distinct combinations of the `CLASS` and `STRATA` statement variables.

If the `INPVALUES=` data set is specified, then the following tables are displayed:

- The “P-Value Adjustment Information” table provides a list of the specified  $p$ -value adjustments. If an adaptive adjustment is specified (see section “Adaptive Adjustments” on page 5200), then the following settings are also displayed when appropriate:
  - whether the finite-sample version of the PFDR is used (`FINITE`)
  - the number of tuning parameters to check (`NLAMBDA=`), the maximum tuning parameter (`MAXLAMBDA=`), or the specified tuning parameter (`LAMBDA=`)
  - the degrees of freedom of the spline (`DF=`) and the smoothing parameter
  - the number of bootstrap resamples (`NBOOT=`) and the seed (`SEED=`)

- If the `bootstrap` or `spline` method for estimating the number of true null hypotheses  $m_0$  is used and the `PLOTS=` option is specified, the “Lambda Values” table displays the  $m_0$  estimates as a function of the tuning parameter  $\lambda$ . If the `bootstrap` method is used, the table also displays the mean-squared errors, the minimum of which is used to select a specific  $\lambda$ . This table contains the values used in the “Lambda Functions” plot.
- The “Estimated Number of True Null Hypotheses” table displays the  $p$ -value adjustment, the method used to estimate the number of true nulls, and an estimate of the number and proportion of true null hypotheses in the data set.

The following table is displayed unless the `NOPVALUE` option is specified:

- The “p-Values” table is a collection of the raw and adjusted  $p$ -values from the run of PROC MULTTEST. The  $p$ -values are identified by variable and test.

---

## ODS Table Names

PROC MULTTEST assigns a name to each table it creates, and you must use this name to reference the table when using the Output Delivery System (ODS). These names are listed in the following table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 61.3** ODS Tables Produced by PROC MULTTEST

| ODS Table Name | Description                       | Statement or Option               |
|----------------|-----------------------------------|-----------------------------------|
| Continuous     | Continuous variable tabulations   | TEST with MEAN                    |
| Contrasts      | Contrast coefficients             | default                           |
| Discrete       | Discrete variable tabulations     | TEST with CA, FT, PETO, or FISHER |
| LambdaValues   | True null estimates               | AHOLM, AHOC, AFDR, or PFDR        |
| ModelInfo      | Model information                 | default                           |
| NumTrueNull    | Estimates of number of true nulls | AHOLM, AHOC, AFDR, or PFDR        |
| pValues        | $p$ -values from the tests        | default                           |
| pValueInfo     | $p$ -value adjustment information | INPVALUES=                        |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

You must also specify the options in the PROC MULTTEST statement that are indicated in Table 61.4.

PROC MULTTEST assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 61.4.

**Table 61.4** Graphs Produced by PROC MULTTEST

| ODS Graph Name        | Plot Description                                             | Option                                                                      |
|-----------------------|--------------------------------------------------------------|-----------------------------------------------------------------------------|
| AdjPlots              | Panel of adjusted $p$ -value plots                           | PLOTS=ADJUSTED                                                              |
| AdjByRawRank          | Adjusted by rank of raw $p$ -values                          | PLOTS=ADJUSTED(UNPACK)                                                      |
| AdjbyRawP             | Adjusted by raw $p$ -values                                  | PLOTS=ADJUSTED(UNPACK)                                                      |
| AdjBySignificant      | Proportion significant by adjusted                           | PLOTS=ADJUSTED(UNPACK)                                                      |
| FalsePosBySignificant | Expected number of false positives by proportion significant | PLOTS=ADJUSTED(UNPACK)                                                      |
| PByTest               | $p$ -values by test                                          | PLOTS=PBYTEST                                                               |
| LambdaPlot            | MSE or NTRUENULL by lambda                                   | PLOTS=LAMBDA and<br>(NTRUENULL=BOOTSTRAP<br>or NTRUENULL=SPLINE<br>or PFDR) |

| ManhattanPanel        | Panel of Manhattan plots                                     | PLOTS=MANHATTAN                                                             |
| RawUniformPlot        | Raw $p$ -values by rank and histogram                        | PLOTS=RAWPROB or<br>AHOLM or AHOC or AFDR or PFDR                           |
| RawUniformPlot        | Raw $p$ -values by rank                                      | PLOTS=RAWPROB(UNPACK) and<br>AHOLM or AHOC or AFDR or PFDR                  |
| RawUniformHist        | Histogram of raw $p$ -values                                 | PLOTS=RAWPROB(UNPACK) and<br>AHOLM or AHOC or AFDR or PFDR                  |

## Examples: MULTTEST Procedure

### Example 61.1: Cochran-Armitage Test with Permutation Resampling

This example, from Keith Soper at Merck, illustrates the exact permutation Cochran-Armitage test carried out on permutation resamples. In the following data set, each observation represents an animal. The binary variables S1 and S2 indicate two tumor types, with 0s indicating no tumor (failure) and 1 indicating a tumor (success); note that they have perfect negative association. The grouping variable is Dose.

```
data a;
 input S1 S2 Dose @@;
 datalines;
0 1 1 1 0 1 0 1 1
0 1 1 0 1 1 1 0 1
1 0 2 1 0 2 0 1 2
1 0 2 0 1 2 1 0 2
```

```

1 0 3 1 0 3 1 0 3
0 1 3 0 1 3 1 0 3
;

proc multtest data=a permutation nsample=10000 seed=36607 outperm=pmt;
 test ca(S1 S2 / permutation=10 uppertailed);
 class Dose;
 contrast 'CA Linear Trend' 0 1 2;
run;
proc print data=pmt;
run;

```

The PROC MULTTEST statement requests 10,000 permutation resamples. The **OUTPERM=** option creates an output SAS data set **pmt** used for the exact permutation distribution computed for the **CA** test.

The **TEST** statement specifies an upper-tailed Cochran-Armitage linear trend test for **S1** and **S2**. The cutoff for exact permutation calculations is 10, as specified with the **PERMUTATION=** option in the **TEST** statement. Since **S1** and **S2** have 10 and 8 successes, respectively, PROC MULTTEST uses exact permutation distributions to compute the *p*-values for both variables.

The groups for the **CA** test are the levels of **Dose** from the **CLASS** statement. The trend coefficients applied to these groups are 0, 1, and 2, respectively, as specified in the **CONTRAST** statement.

Finally, the PROC PRINT statement displays the SAS data set **pmt**, which contains the permutation distributions.

The results from this analysis are displayed in [Output 61.1.1](#) through [Output 61.1.5](#). You should check the “Model Information” table to verify that the analysis specifications are correct.

### Output 61.1.1 Cochran-Armitage Test with Permutation Resampling

| The Multtest Procedure              |                  |
|-------------------------------------|------------------|
| Model Information                   |                  |
| Test for discrete variables         | Cochran-Armitage |
| Exact permutation distribution used | Everywhere       |
| Tails for discrete tests            | Upper-tailed     |
| Strata weights                      | None             |
| P-value adjustment                  | Permutation      |
| Number of resamples                 | 10000            |
| Seed                                | 36607            |

The label and coefficients from the **CONTRAST** statement are shown in [Output 61.1.2](#).

**Output 61.1.2** Contrast Coefficients

| Contrast Coefficients |      |   |   |
|-----------------------|------|---|---|
|                       | Dose |   |   |
| Contrast              | 1    | 2 | 3 |
| CA Linear Trend       | 0    | 1 | 2 |

Output 61.1.3 displays summary statistics for the two test variables, S1 and S2. The Count column lists the number of successes for each level of the CLASS variable, Dose. The NumObs column lists the sample size, and the Percent column lists the percentage of successes in the sample.

**Output 61.1.3** Summary Statistics

| Discrete Variable Tabulations |      |       |        |         |
|-------------------------------|------|-------|--------|---------|
| Variable                      | Dose | Count | NumObs | Percent |
| S1                            | 1    | 2     | 6      | 33.33   |
| S1                            | 2    | 4     | 6      | 66.67   |
| S1                            | 3    | 4     | 6      | 66.67   |
| S2                            | 1    | 4     | 6      | 66.67   |
| S2                            | 2    | 2     | 6      | 33.33   |
| S2                            | 3    | 2     | 6      | 33.33   |

The Raw column in Output 61.1.4 contains the  $p$ -values from the CA test, and the Permutation column contains the permutation-adjusted  $p$ -values.

**Output 61.1.4** Resulting  $p$ -Values

| p-Values |                 |        |             |
|----------|-----------------|--------|-------------|
| Variable | Contrast        | Raw    | Permutation |
| S1       | CA Linear Trend | 0.1993 | 0.4009      |
| S2       | CA Linear Trend | 0.9220 | 1.0000      |

This table shows that, for S1, the adjusted  $p$ -value is approximately twice the raw  $p$ -value. In fact, resamples with small (large)  $p$ -values for S1 have large (small)  $p$ -values for S2 due to the perfect negative association of the variables, and hence the permutation-adjusted  $p$ -value for S1 should be  $2 \times 0.1993 = 0.3986$ ; the difference is due to resampling error. For the same reason, since the raw  $p$ -value for S2 is 0.9220, the adjusted  $p$ -value equals 1. The permutation  $p$ -values for S1 and S2 also happen to be the Bonferroni-adjusted  $p$ -values for this example.

The OUTPERM= data set is displayed in Output 61.1.5, which contains the exact permutation distributions for S1 and S2 in terms of cumulative probabilities.

**Output 61.1.5** Exact Permutation Distribution

| Obs | _contrast_      | _var_ | _value_ | upper_p |

## Example 61.2: Freeman-Tukey and $t$ Tests with Bootstrap Resampling

The data for this example are the same as for [Example 61.1](#), except that a continuous variable T, which indicates the time of death of the animal, has been added.

```
data a;
 input S1 S2 T Dose @@;
 datalines;
0 1 104 1 1 0 80 1 0 1 104 1
0 1 104 1 0 1 100 1 1 0 104 1
1 0 85 2 1 0 60 2 0 1 89 2
1 0 96 2 0 1 96 2 1 0 99 2
1 0 60 3 1 0 50 3 1 0 80 3
0 1 98 3 0 1 99 3 1 0 50 3
;

proc multtest data=a bootstrap nsample=10000 seed=37081 outsamp=res;
 test ft(S1 S2 / lowertailed) mean(T / lowertailed);
 class Dose;
 contrast 'Linear Trend' 0 1 2;
run;

proc print data=res(obs=36);
run;
```

The **BOOTSTRAP** option in the PROC MULTTEST statement requests bootstrap resampling, and **NSAMPLE=10000** requests 10,000 bootstrap samples. The **SEED=37081** option provides a starting value for the random number generator. The **OUTSAMP=res** option creates an output SAS data set res containing the 10,000 bootstrap samples.

The **TEST** statement specifies the Freeman-Tukey test for S1 and S2 and specifies the  $t$  test for T. Both tests are lower-tailed. The grouping variable in the **CLASS** statement is Dose, and the coefficients across the levels of Dose are 0, 1, and 2, as specified in the **CONTRAST** statement. The PROC PRINT statement displays the first 36 observations of the res data set containing the bootstrap samples.

The results from this analysis are listed in [Output 61.2.1](#) through [Output 61.2.5](#).

The “Model Information” table in [Output 61.2.1](#) corresponds to the specifications in the invocation of PROC MULTTEST.

**Output 61.2.1** FT and *t* tests with Bootstrap Resampling

| The Multtest Procedure        |               |
|-------------------------------|---------------|
| Model Information             |               |
| Test for discrete variables   | Freeman-Tukey |
| Test for continuous variables | Mean t-test   |
| Degrees of Freedom Method     | Pooled        |
| Tails for discrete tests      | Lower-tailed  |
| Tails for continuous tests    | Lower-tailed  |
| Strata weights                | None          |
| P-value adjustment            | Bootstrap     |
| Center continuous variables   | Yes           |
| Number of resamples           | 10000         |
| Seed                          | 37081         |

The “Contrast Coefficients” table in [Output 61.2.2](#) shows the coefficients from the `CONTRAST` statement after centering, and they model a linear trend.

**Output 61.2.2** Contrast Coefficients

| Contrast Coefficients |          |      |   |   |
|-----------------------|----------|------|---|---|
|                       |          | Dose |   |   |
| Contrast              |          | 1    | 2 | 3 |
| Linear Trend          | Centered | -1   | 0 | 1 |

The summary statistics are displayed in [Output 61.2.3](#). The values for the discrete variables S1 and S2 are the same as those from [Example 61.1](#). The mean, standard deviation, and sample size for the continuous variable T at each level of Dose are displayed in the “Continuous Variable Tabulations” table.

**Output 61.2.3** Summary Statistics

| Discrete Variable Tabulations |      |       |        |         |
|-------------------------------|------|-------|--------|---------|
| Variable                      | Dose | Count | NumObs | Percent |
| S1                            | 1    | 2     | 6      | 33.33   |
| S1                            | 2    | 4     | 6      | 66.67   |
| S1                            | 3    | 4     | 6      | 66.67   |
| S2                            | 1    | 4     | 6      | 66.67   |
| S2                            | 2    | 2     | 6      | 33.33   |
| S2                            | 3    | 2     | 6      | 33.33   |

**Output 61.2.3** *continued*

| Continuous Variable Tabulations |      |        |         |                    |
|---------------------------------|------|--------|---------|--------------------|
| Variable                        | Dose | NumObs | Mean    | Standard Deviation |
| T                               | 1    | 6      | 99.3333 | 9.6056             |
| T                               | 2    | 6      | 87.5000 | 14.4326            |
| T                               | 3    | 6      | 72.8333 | 22.7017            |

The  $p$ -values, displayed in [Output 61.2.4](#), are from the Freeman-Tukey test for S1 and S2, and are from the  $t$  test for T.

**Output 61.2.4**  $p$ -Values

| p-Values |              |        |           |
|----------|--------------|--------|-----------|
| Variable | Contrast     | Raw    | Bootstrap |
| S1       | Linear Trend | 0.8547 | 1.0000    |
| S2       | Linear Trend | 0.1453 | 0.4605    |
| T        | Linear Trend | 0.0070 | 0.0281    |

The Raw column in [Output 61.2.4](#) contains the results from the tests on the original data, while the Bootstrap column contains the bootstrap resampled adjustment to raw\_p. Note that the adjusted  $p$ -values are larger than the raw  $p$ -values for all three variables. The adjusted  $p$ -values more accurately reflect the correlation of the raw  $p$ -values, the small size of the data, and the multiple testing.

[Output 61.2.5](#) displays the first 36 observations of the SAS data set resulting from the OUTSAMP=RES option in the PROC MULTTEST statement. The entire data set has 180,000 observations, which is 10,000 times the number of observations in the data set.

**Output 61.2.5** Resampling Data Set

| Obs | _sample_ | _class_ | _obs_ | S1 | S2 | T        |
|-----|----------|---------|-------|----|----|----------|
| 1   | 1        | 1       | 17    | 0  | 1  | 26.1667  |
| 2   | 1        | 1       | 8     | 1  | 0  | -27.5000 |

| 15  | 1        | 3       | 14    | 1  | 0  | -22.8333 |
| 16  | 1        | 3       | 15    | 1  | 0  | 7.1667   |
| 17  | 1        | 3       | 15    | 1  | 0  | 7.1667   |
| 18  | 1        | 3       | 6     | 1  | 0  | 4.6667   |
| 19  | 2        | 1       | 6     | 1  | 0  | 4.6667   |
| 20  | 2        | 1       | 17    | 0  | 1  | 26.1667  |
| 21  | 2        | 1       | 8     | 1  | 0  | -27.5000 |
| 22  | 2        | 1       | 13    | 1  | 0  | -12.8333 |
| 23  | 2        | 1       | 9     | 0  | 1  | 1.5000   |
| 24  | 2        | 1       | 8     | 1  | 0  | -27.5000 |
| 25  | 2        | 2       | 9     | 0  | 1  | 1.5000   |
| 26  | 2        | 2       | 18    | 1  | 0  | -22.8333 |
| 27  | 2        | 2       | 15    | 1  | 0  | 7.1667   |
| 28  | 2        | 2       | 14    | 1  | 0  | -22.8333 |
| 29  | 2        | 2       | 9     | 0  | 1  | 1.5000   |
| 30  | 2        | 2       | 17    | 0  | 1  | 26.1667  |
| 31  | 2        | 3       | 16    | 0  | 1  | 25.1667  |
| 32  | 2        | 3       | 11    | 0  | 1  | 8.5000   |
| 33  | 2        | 3       | 14    | 1  | 0  | -22.8333 |
| 34  | 2        | 3       | 18    | 1  | 0  | -22.8333 |
| 35  | 2        | 3       | 18    | 1  | 0  | -22.8333 |
| 36  | 2        | 3       | 10    | 1  | 0  | 8.5000   |

The `_sample_` variable is the sample indicator and `_class_` indicates the resampling group—that is, the level of the `CLASS` variable Dose assigned to the new observation. The number of the observation in the original data set is represented by `_obs_`. Also listed are the values of the original test variables, S1 and S2, and the mean-centered values of T.

### Example 61.3: Peto Mortality-Prevalence Test

This example illustrates the use of the Peto mortality-prevalence test. The test is a combination of analyses about the prevalence of incidental tumors in the population and mortality due to fatal tumors.

In the following data set, each observation represents an animal. The variables S1–S3 are three tumor types, with a value of 0 indicating no tumor, 1 indicating an incidental (nonlethal) tumor, and 2 indicating a lethal tumor. The time variable T indicates the time of death of the animal, a strata variable B is constructed from T, and the grouping variable Dose is drug dosage.

```
data a;
 input S1-S3 T Dose @@;
 if T<=90 then B=1; else B=2;
 datalines;
0 0 0 104 0 2 0 1 80 0 0 0 1 104 0
0 0 0 104 0 0 2 0 100 0 1 0 0 104 0
2 0 0 85 1 2 1 0 60 1 0 1 0 89 1
2 0 1 96 1 0 0 0 96 1 2 0 1 99 1
2 1 1 60 2 2 0 0 50 2 2 0 1 80 2
0 0 2 98 2 0 0 1 99 2 2 1 1 50 2
;

proc multtest data=a notables out=p stepsid;
 test peto(S1-S3 / permutation=20 time=T uppertailed);
 class Dose;
 strata B;
 contrast 'mort-prev' 0 1 2;
run;
proc print data=p;
run;
```

The **NOTABLES** option in the PROC MULTTEST statement suppresses the display of the summary statistics for each variable. The **OUT=** option creates an output SAS data set *p* containing all *p*-values and intermediate statistics. The **STEPSID** option is used to adjust the *p*-values.

The **TEST** statement specifies an upper-tailed Peto test for S1–S3. The mortality strata are defined by **TIME=T**, the death times. The **CLASS** statement contains the grouping variable Dose. The prevalence strata are defined by the **STRATA** statement as the blocking variable B. The **CONTRAST** statement lists the default linear trend coefficients. The PROC PRINT statement displays the requested *p*-value data set.

The results from this analysis are listed in [Output 61.3.1](#) through [Output 61.3.4](#).

The “Model Information” table in [Output 61.3.1](#) displays information corresponding to the PROC MULTTEST invocation. In this case the totals for all prevalence and fatality strata are less than 20, so exact permutation tests are used everywhere, and the STEPSID adjustments are computed from these permutation distributions.

**Output 61.3.1** Peto Test

| The Multtest Procedure              |                |
|-------------------------------------|----------------|
| Model Information                   |                |
| Test for discrete variables         | Peto           |
| Exact permutation distribution used | Everywhere     |
| Tails for discrete tests            | Upper-tailed   |
| Strata weights                      | Sample size    |
| P-value adjustment                  | Stepdown Sidak |

The contrast trend coefficients are listed in [Output 61.3.2](#). They happen to be the same as the levels of the Dose variable.

**Output 61.3.2** Contrast Coefficients

| Contrast Coefficients |      |   |   |
|-----------------------|------|---|---|
|                       | Dose |   |   |
| Contrast              | 0    | 1 | 2 |
| mort-prev             | 0    | 1 | 2 |

In the “*p*-Values” table in [Output 61.3.3](#), the *p*-values for the Peto tests are listed in the Raw column, and the step-down Šidák adjusted *p*-values are in the Stepdown Šidák column.

**Output 61.3.3** *p*-Values

| p-Values |           |        |                |
|----------|-----------|--------|----------------|
| Variable | Contrast  | Raw    | Stepdown Sidak |
| S1       | mort-prev | 0.0681 | 0.0814         |
| S2       | mort-prev | 0.5000 | 0.5000         |
| S3       | mort-prev | 0.0363 | 0.0781         |

Significant *p*-values in the preceding table support the claim that higher dosage levels lead to higher mortality and prevalence. The raw Peto test is significant at the 5% level for S3, but the adjusted S3 test is no longer significant at 5%. The raw and adjusted *p*-values for S2 are the same because of the step-down technique.

The OUT= data set is displayed in [Output 61.3.4](#).

The first 30 observations correspond to intermediate statistics used to compute the Peto  $p$ -values. The `_test_` variable lists the name of the test, the `_var_` variable lists the name of the TEST variables, and the `_contrast_` variable lists the CONTRAST label. The `_strat_` variable lists the level of the STRATA variable, and the `_tsrat_` variable indicates whether or not the stratum corresponds to values of the TIME= variable. The `_value_` variable is the observed contrast for a stratum, and the `_exp_` variable is its expected value. The variable `_se_` contains the square root of the variance terms summed to form the denominator of the Peto statistics.

The final three observations correspond to the three Peto tests, with their  $p$ -values listed under the `raw_p` variable. The `stpsid_p` variable contains the step-down Šidák-adjusted  $p$ -values.

## Example 61.4: Fisher Test with Permutation Resampling

The following data, from Brown and Fears (1981), are the results of an 80-week carcinogenesis bioassay with female mice. Six tissue sites are examined at necropsy; 1 indicates the presence of a tumor and 0 the absence. A frequency variable Freq is included. A control and four different doses of a drug (in parts per milliliter) make up the levels of the grouping variable Dose.

proc multtest data=a order=data notables out=p
 permutation nsample=1000 seed=764511;
 test fisher(Liver Lung Lymph Cardio Pitui Ovary /
 lowertailed);
 class Dose;
 freq Freq;
run;
proc print data=p;
run;
```

In the PROC MULTTEST statement, the **ORDER=DATA** option is required to keep the levels of Dose in the order in which they appear in the data set. Without this option, the levels are sorted by their formatted value, resulting in an alphabetic ordering. The **NOTABLES** option suppresses the display of summary statistics, and the **OUT=** option produces an output data set p containing the  $p$ -values. The **PERMUTATION** option specifies permutation resampling, **NSAMPLE=1000** requests 1000 samples, and **SEED=764511** option provides a starting value for the random number generator. You should specify a seed if you need to duplicate resampling results.

To test for higher rates of tumor occurrence in the treatment groups compared to the control group, the **LOWERTAILED** option is specified in the **FISHER** option of the **TEST** statement to produce a lower-tailed Fisher exact test for the six tissue sites. The Fisher test is appropriate for comparing a treatment and a control, but multiple testing can be a problem. Brown and Fears (1981) use a multivariate permutation to evaluate the entire collection of tests. PROC MULTTEST adjusts the  $p$ -values by simulation.

The treatments make up the levels of the grouping variable Dose, listed in the **CLASS** statement. Since no **CONTRAST** statement is specified, PROC MULTTEST uses the default pairwise contrasts with the first level of Dose. The **FREQ** statement is used since these are summary data containing frequency counts of occurrences.

The results from this analysis are listed in [Output 61.4.1](#) through [Output 61.4.4](#). First, the PROC MULTTEST specifications are displayed in [Output 61.4.1](#).

**Output 61.4.1** Fisher Test with Permutation Resampling

| The Multtest Procedure      |              |
|-----------------------------|--------------|
| Model Information           |              |
| Test for discrete variables | Fisher       |
| Tails for discrete tests    | Lower-tailed |
| Strata weights              | None         |
| P-value adjustment          | Permutation  |
| Number of resamples         | 1000         |
| Seed                        | 764511       |

The default contrasts for the Fisher test are displayed in [Output 61.4.2](#). Note that each dose is compared with the control.

**Output 61.4.2** Default Contrast Coefficients

| Contrast       | Contrast Coefficients |      |      |       |       |
|----------------|-----------------------|------|------|-------|-------|
|                | Dose                  |      |      |       |       |

| Ovary    | CTRL vs. 50PPM | 0.3689 | 0.9930      |  |

As noted by Brown and Fears, only one of the 24 tests is significant at the 5% level (Lymph, CTRL vs. 16PPM). Brown and Fears report a 12% chance of observing at least one significant raw *p*-value for 16PPM and a 9% chance of observing at least one significant raw *p*-value for Lymph (both at the 5% level). Adjusted *p*-values exhibit much lower chances of false significances. For this example, none of the adjusted *p*-values are close to significant.

The OUT= data set is displayed in [Output 61.4.4](#).

The test, var, and contrast variables provide the TEST name, TEST variable, and CONTRAST label, respectively. The xval, mval, yval, and nval variables contain the components used to compute the Fisher exact tests from the hypergeometric distribution. The raw\_p variable contains the  $p$ -values from the Fisher exact tests, and the perm\_p variable contains their permutation-based adjustments. The variable sim\_se is the simulation standard error from the permutation resampling.

## Example 61.5: Inputting Raw $p$ -Values

This example illustrates how to use PROC MULTTEST to multiplicity-adjust a collection of raw  $p$ -values obtained from some other source. This is a valuable option for those cases where PROC MULTTEST cannot compute the raw  $p$ -values directly. The data set `a`, which follows, contains the unadjusted  $p$ -values computed in Example 61.4. Note that the data set needs to have one variable containing the  $p$ -values, but the data set can contain other variables as well.

```
data a;
 input Test$ Raw_P @@;
 datalines;
test01 0.28282 test02 0.30688 test03 0.71022
test04 0.77175 test05 0.78180 test06 0.88581
test07 0.54685 test08 0.84978 test09 0.24228
test10 0.58977 test11 0.03498 test12 0.41607
test13 0.31631 test14 0.05254 test15 0.45061
test16 0.75758 test17 0.12496 test18 0.49485
test19 0.21572 test20 0.50505 test21 0.94372
test22 0.81260 test23 0.77596 test24 0.36889
;

proc multtest inpvalues=a holm hoc fdr;
run;
```

Note that the PROC MULTTEST statement is the only statement that can be specified with the  $p$ -value input mode. In this example, the raw  $p$ -values are adjusted by the [Holm](#), [Hochberg](#), and [FDR](#) methods.

The “P-Value Adjustment Information” table, displayed in [Output 61.5.1](#), provides information about the requested adjustments and replaces the usual “Model Information” table. The adjusted  $p$ -values are displayed in [Output 61.5.2](#)

### Output 61.5.1 Inputting Raw $p$ -Values

Note that the adjusted  $p$ -values for the Hochberg method are less than or equal to those for the Holm (Step-down Bonferroni) method. In turn, the adjusted  $p$ -values for the FDR method (False Discovery Rate) are less than or equal to those for the Hochberg method. These comparisons hold generally for all  $p$ -value configurations. The FDR method controls the false discovery rate and not the familywise error rate. The Hochberg method controls the familywise error rate under independence. The Holm method controls the familywise error rate without assuming independence.

---

### Example 61.6: Adaptive Adjustments and ODS Graphics

An experiment was performed using Affymetrix<sup>®</sup> gene chips on the CD4 lymphocyte white blood cells of patients with and without a hereditary allergy (atopy) and possibly with asthma. The Asthma-Atopy microarray data set and analysis are discussed in Gibson and Wolfinger (2004): a one-way ANOVA model of the  $\log_2\text{mas5}$  variable ( $\log_2(\text{MAS 5.0 summary statistics})$ ) is fit against a classification variable  $\text{trt}$  describing different asthma-atopy combinations in the patients, and the least squares means of the  $\text{trt}$  variable are computed.

For this example, a 1% random sample of least squares means having  $p$ -values exceeding  $1E-6$  is taken. The resulting data are recorded in the test data set, where the Probe\_Set\_ID variable identifies the probe and the Probt variable contains the  $p$ -values for the  $m = 121$  tests, as follows:

```
data test;
 length Probe_Set_ID $9.;

The following statements adjust the  $p$ -values in the test data set by using the adaptive adjustments ([ADAPTIVEHOLM](#), [ADAPTIVEHOCHBERG](#), [ADAPTIVEFDR](#), and [PFDR](#)), which require an estimate of the number of true null hypotheses ( $\hat{m}_0$ ) or proportion of true null hypotheses ( $\hat{\pi}_0$ ). This example illustrates some of the features and graphics for computing and evaluating these estimates. The [NOPVALUE](#) option is specified to suppress the display of the “p-Values” table.

```
ods graphics on;
proc multtest inpvalues(Probt)=test plots=all seed=518498000
 aholm ahoc afdr pfdr(positive) nopvalue;
 id Probe_Set_ID;
run;
ods graphics off;
```

Output 61.6.1 lists the requested  $p$ -value adjustments, along with the selected value of the “Lambda” tuning parameter and the seed (specified with the `SEED=` option) used in the `bootstrap` method of estimating the number of true null hypotheses. The “Lambda Values” table lists the estimated number of true nulls for each value of  $\lambda$ , where you can see that the minimum MSE (0.002315) occurs at  $\lambda = 0.4$ . Output 61.6.2 shows that the `SPLINE` method failed due to a large slope at  $\lambda = 0.95$ , so the bootstrap method is used and the MSE plot is displayed.

**Output 61.6.1**  $p$  and Lambda Values

**Output 61.6.2** Tuning Parameter Plots

Output 61.6.3 also shows that the bootstrap estimate is used for the PFDR adjustment. The other adjustments have different default methods for estimating the number of true nulls.

**Output 61.6.3** Adjustments and Their Default Estimation Method

| Estimated Number of True Null Hypotheses |                 |          |            |
|------------------------------------------|-----------------|----------|------------|
| P-Value Adjustment                       | Method          | Estimate | Proportion |
| Adaptive Holm                            | Decreased Slope | 26       | 0.21488    |
| Adaptive Hochberg                        | Decreased Slope | 26       | 0.21488    |
| Adaptive FDR                             | Lowest Slope    | 43       | 0.35537    |
| Positive FDR                             | Bootstrap       | 23.3333  | 0.19284    |

Output 61.6.4 displays the estimated number of true nulls  $\hat{m}_0$  against a uniform probability plot of the unadjusted  $p$ -values (if the  $p$ -values are distributed uniformly, the points on the plot will all lie on a straight line). According to Schweder and Spjøtvoll (1982) and Hochberg and Benjamini (1990), the points on the

left side of the plot should be approximately linear with slope  $\frac{1}{m_0+1}$ , so you can use this plot to evaluate whether your estimate of  $\hat{m}_0$  seems reasonable.

**Output 61.6.4** *p*-Value Distribution

The `NTRUENULL=` option provides several methods for estimating the number of true null hypotheses; the following table displays each method and its estimate for this example:

| <code>NTRUENULL=</code> | Estimate |
|-------------------------|----------|
| BOOTSTRAP               | 23.3     |
| DECREASESLOPE           | 26       |
| KSTEST                  | 35       |
| LEASTSQUARES            | 28       |
| LOWESTSLOPE             | 43       |
| MEANDIFF                | 42       |
| SPLINE                  | 50.1     |

Another method of estimating the number of true null hypotheses fits a finite mixture model (mixing a uniform with a beta) to the distribution of the unadjusted  $p$ -values (Allison et al. 2002). Osborne (2006) provides the following PROC NLMIXED statements to fit this model:

```
proc nlmixed data=test;
 parameters pi0=0.5 a=.1 b=.1;
 pi1= 1-pi0;
 bounds 0 <= pi0 <= 1;
 loglikelihood= log(pi0+pi1*pdf('beta',Probt,a,b));
 model Probt ~ general(loglikelihood);
run;
```

You might have to change the initial parameter values in the PARAMETERS statement to achieve convergence; see Chapter 64, “The NLMIXED Procedure,” for more information. This mixture model estimates  $\hat{\pi}_0 = 0$ , meaning that the distribution of  $p$ -values is completely specified by a single beta distribution. If the estimate were, say,  $\hat{\pi}_0 = 0.10$ , you could then specify it as follows:

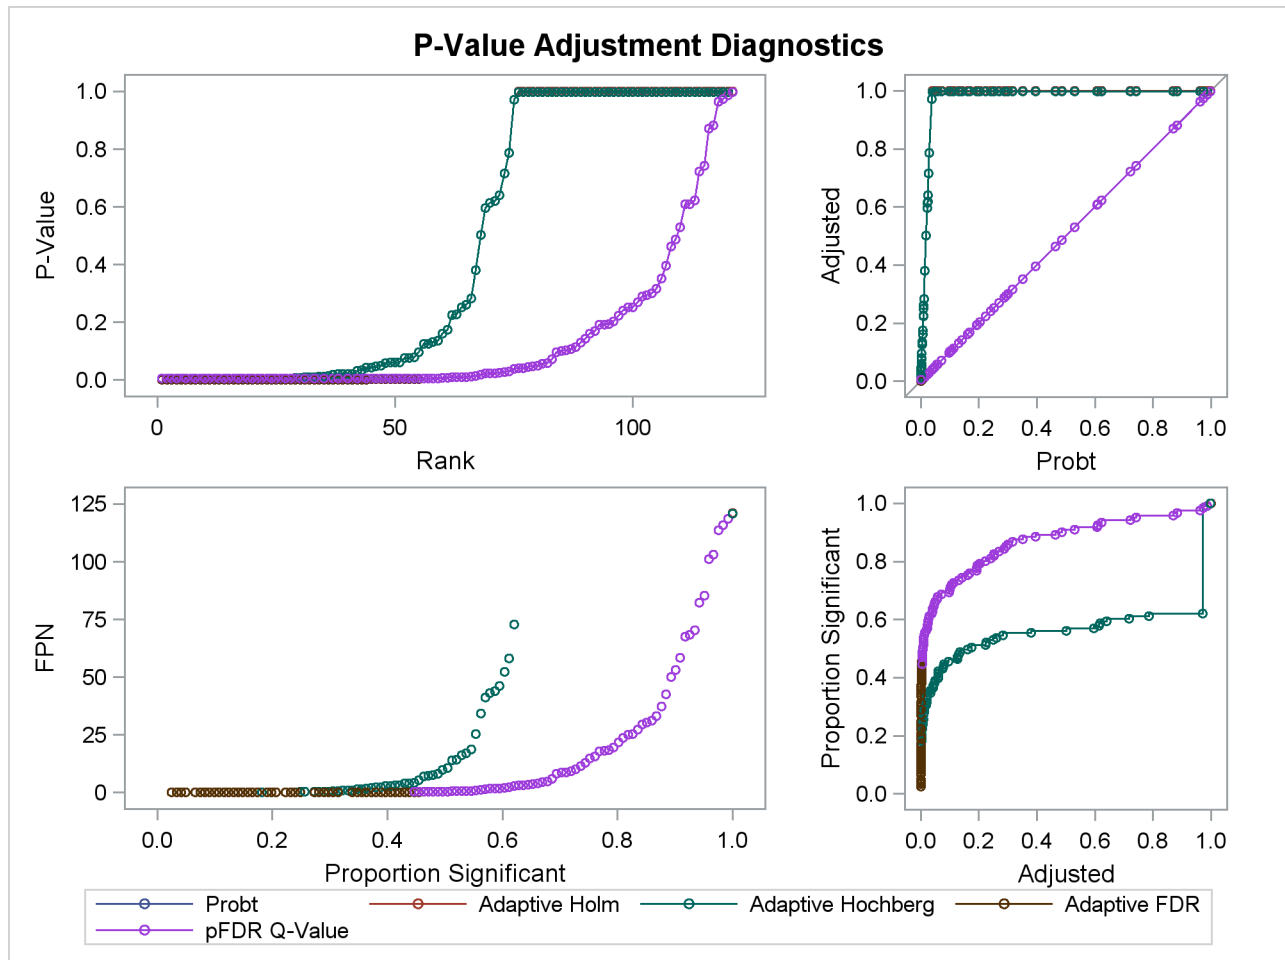

```
proc multtest invalues(Probt)=test ptruennull=0.10
 aholm ahoc afdr pfdr(positive) nopvalue;
 id Probe_Set_ID;
run;
```

A plot of the unadjusted and adjusted  $p$ -values for each test is also produced. Due to the large number of tests and adjustments, the plot is not very informative and is not displayed here.

The top two plots in [Output 61.6.5](#) show how the adjusted values compare with each other and the unadjusted  $p$ -values. The PFDR and AFDR adjustments are eventually smaller than the unadjusted  $p$ -values since they control the false discovery rate. The adaptive Holm and Hochberg adjustments are almost identical, so the adaptive Holm values are mostly obscured in all four plots. The plot of the Proportion Significant versus the Adjusted  $p$ -values tells you how many of the tests are significant for each cutoff, while the plot of the number of false positives (FPN) versus the Proportion Significant tells you how many false positives you can expect for that cutoff.

## Output 61.6.5 Adjustment Diagnostics

A Manhattan plot displays  $-\log_{10}$  of the adjusted  $p$ -values, so the most significant tests stand out at the top of the plot. The default plot is not displayed here. The following statements create a Manhattan plot of the adaptive FDR  $p$ -values, with the most significant tests labeled with their observation number. The ID values are displayed on the X axis, and the `VREF=` option specifies the significance level. This plot is typically created with many more  $p$ -values, and special ODS Graphics options such as the `LABELMAX=` option might be required to display the graph. If memory usage is an issue, you might want to store your  $p$ -values and use the `SGPLOT` procedure to create a similar graph.

```
ods graphics on / labelmax=1000;
proc multtest inpvalues(Probt)=test afdr nopvalue
 plots=Manhattan(label=obs vref=0.0001);
 id Probe_Set_ID;
run;
ods graphics off;
```

Output 61.6.6 Manhattan Plot

If you have a lot of tests, the “Raw and Adjusted  $p$ -Values” and “P-Value Adjustment Diagnostics” plots can be more informative if you suppress some of the tests. In the following statements, the SIGONLY=0.001 option selects tests with adjusted  $p$ -values < 0.001 for display. Output 61.6.7 displays tests with their “significant” adjusted  $p$ -values:

```
ods graphics on;
proc multtest invalues(Probt)=test plots(sigonly=0.001)=PByTest
 aholm ahoc afdr pfdr(positive) nopvalue;
run;
ods graphics off;
```

Output 61.6.7 Raw and Adjusted  $p$ -Values

## Overview: NESTED Procedure

The NESTED procedure performs random-effects analysis of variance for data from an experiment with a nested (hierarchical) structure.<sup>1</sup> A random-effects model for data from a completely nested design with two factors has the form

$$y_{ijr} = \mu + \alpha_i + \beta_{ij} + \epsilon_{ijr}$$

---

<sup>1</sup>PROC NESTED is modeled after the General Purpose Nested Analysis of Variance program of the Dairy Cattle Research Branch of the United States Department of Agriculture. That program was originally written by M. R. Swanson, Statistical Reporting Service, United States Department of Agriculture.

where

- $y_{ijr}$  is the value of the dependent variable observed at the  $r$ th replication with the first factor at its  $i$ th level and the second factor at its  $j$ th level.
- $\mu$  is the overall (fixed) mean of the sampling population.
- $\alpha_i, \beta_{ij}, \epsilon_{ijr}$  are mutually uncorrelated random effects with zero means and respective variances  $\sigma_\alpha^2, \sigma_\beta^2$ , and  $\sigma_\epsilon^2$  (the variance components).

This model is appropriate for an experiment with a multistage nested sampling design. An example of this is given in [Example 62.1](#), where four turnip plants are randomly chosen (the first factor), then three leaves are randomly chosen from each plant (the second factor nested within the first), and then two samples are taken from each leaf (the different replications at fixed levels of the two factors).

Note that PROC NESTED is appropriate for models with only classification effects; it does not handle models that contain continuous covariates. For random effects models with covariates, use either the GLM or MIXED procedure.

---

## Contrasted with Other SAS Procedures

The NESTED procedure performs a computationally efficient analysis of variance for data with a nested design, estimating the different components of variance and also testing for their significance if the design is balanced (see the section “[Unbalanced Data](#)” on page 5243). Although other procedures (such as GLM and MIXED) provide similar analyzes, PROC NESTED is both easier to use and computationally more efficient for this special type of design. This is especially true when the design involves a large number of factors, levels, or observations.

For example, to specify a four-factor completely nested design in the GLM procedure, you use the following form:

```
class a b c d;
model y=a b(a) c(a b) d(a b c);
```

However, to specify the same design in PROC NESTED, you simply use the following form:

```
class a b c d;
var y;
```

In addition, other procedures require TEST statements to perform appropriate tests, whereas the NESTED procedure produces the appropriate tests automatically. However, PROC NESTED makes one assumption about the input data that the other procedures do not: **PROC NESTED assumes that the input data set is sorted by the classification (CLASS) variables defining the effects.** If you use PROC NESTED on data that are not sorted by the CLASS variables, then the results might not be valid.

---

## Getting Started: NESTED Procedure

---

### Reliability of Automobile Models

A study is performed to compare the reliability of several models of automobiles. Three different automobile models (Model) from each of four U.S. automobile manufacturers (Make) are tested. Three different cars of each make and model are subjected to a reliability test and given a score between 1 and 100 (Score), where higher scores indicate greater reliability.

The following statements create the SAS data set auto.

```

title1 'Reliability of Automobile Models';
data auto;
 input Make $ Model Score @@;
 datalines;
a 1 62 a 2 77 a 3 59
a 1 67 a 2 73 a 3 64
a 1 60 a 2 79 a 3 60
b 1 72 b 2 58 b 3 80
b 1 75 b 2 63 b 3 84
b 1 69 b 2 57 b 3 89
c 1 94 c 2 76 c 3 81
c 1 90 c 2 75 c 3 85
c 1 88 c 2 78 c 3 85
d 1 69 d 2 73 d 3 90
d 1 72 d 2 88 d 3 87
d 1 76 d 2 87 d 3 92
;

```

The Make variable contains the make of the automobile, represented here by 'a', 'b', 'c', or 'd', while the Model variable represents the automobile model with a '1', '2', or '3'. The Score variable contains the reliability scores given to the three sampled cars from each Make-Model group. Since the automobile models are nested within their makes, the NESTED procedure is used to analyze these data. The NESTED procedure requires the data to be sorted by Make and, within Make, by Model, so the following statements execute a PROC SORT before completing the analysis.

```

proc sort data=auto;
 by Make Model;
run;

title1 'Reliability of Automobile Models';
proc nested data=auto;
 class Make Model;
 var Score;
run;

```

The Model variable appears after the Make variable in the CLASS statement because it is nested within Make. The VAR statement specifies the response variable. The output is displayed in [Figure 62.1](#).

| Error                                                         | 24   | 350.000000     |         |        |            | 14.583333   | 14.583333          | 11.0583          |
| Score Mean                                                    |      |                |         |        |            | 75.94444444 |                    |                  |
| Standard Error of Score Mean                                  |      |                |         |        |            | 3.97794848  |                    |                  |

Figure 62.1 first displays the coefficients of the variance components that make up each of the expected mean squares, and then it displays the ANOVA table. The results do not indicate significant variation between the different automobile makes ( $F = 2.15$ ,  $p = 0.1719$ ). However, they do suggest that there is significant variation between the different models within the makes ( $F = 18.16$ ,  $p < 0.0001$ ). This is evident in the fact that the make of car accounts for only 25.7% of the total variation in the data, while the car model accounts for 63.3% (as shown in the Percent of Total column). The estimated variance components are shown in the Variance Component column.

## Syntax: NESTED Procedure

The following statements are available in the NESTED procedure:

```
PROC NESTED < options > ;
 CLASS variables < / option > ;
 VAR variables ;
 BY variables ;
```

The PROC NESTED and CLASS statements are required. The BY, CLASS, and VAR statements are described after the PROC NESTED statement.

---

## PROC NESTED Statement

**PROC NESTED** < options > ;

The PROC NESTED statement invokes the NESTED procedure. Table 62.1 summarizes the options available in the PROC NESTED statement.

**Table 62.1** PROC NESTED Statement Options

| Option | Description                                       |
|--------|---------------------------------------------------|
| AOV    | Displays only the analysis of variance statistics |
| DATA=  | Names the SAS data set                            |

The PROC NESTED statement has the following options:

### AOV

displays only the analysis of variance statistics when there is more than one dependent variable. The “analysis of covariation” statistics are suppressed (see the section “[Analysis of Covariation](#)” on page 5244).

### DATA=SAS-data-set

names the SAS data set to be used by PROC NESTED. By default, the procedure uses the most recently created SAS data set.

---

## BY Statement

**BY** variables ;

You can specify a BY statement with PROC NESTED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NESTED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variables* </ option > ;

You must include a CLASS statement with PROC NESTED specifying the classification variables for the analysis.

Values of a variable in the CLASS statement denote the levels of an effect. The name of that variable is also the name of the corresponding effect. The second effect is assumed to be nested within the first effect, the third effect is assumed to be nested within the second effect, and so on.

By default, class levels are determined from the entire formatted values of the CLASS variables. Note that this represents a slight change from previous releases in the way in which class levels are determined. Prior to SAS 9, class levels were determined using no more than the first eight characters of the formatted values, except for numeric variables with no explicit format, for which class levels were determined from the raw numeric values. If you want to revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement. In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide*, and the discussions for the FORMAT statement and SAS formats in *SAS Statements: Reference*.

**NOTE:** The data set must be sorted by the classification variables in the order in which they are given in the CLASS statement. Use PROC SORT to sort the data if they are not already sorted.

You can specify the following option in the CLASS statement after a slash (/):

### TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement lists the dependent variables for the analysis. The dependent variables must be numeric variables. If you do not specify a VAR statement, PROC NESTED performs an analysis of variance for all numeric variables in the data set, except those already specified in the CLASS statement.

---

## Details: NESTED Procedure

---

### Missing Values

An observation with missing values for any of the variables used by PROC NESTED is omitted from the analysis. Blank values of CLASS character variables are treated as missing values.

---

### Unbalanced Data

A completely nested design is defined to be unbalanced if the groups corresponding to the levels of some classification variable are not all of the same size. The NESTED procedure can compute unbiased estimates for the variance components in an unbalanced design, but because the sums of squares on which these estimates are based no longer have  $\chi^2$  distributions under a Gaussian model for the data,  $F$  tests for the significance of the variance components cannot be computed. PROC NESTED checks to see that the design is balanced. If it is not, a warning to that effect appears in the log, and the columns corresponding to the  $F$  tests in the analysis of variance are left blank.

---

### General Random-Effects Model

A random-effects model for data from a completely nested design with  $n$  factors has the general form

$$y_{i_1 i_2 \dots i_n r} = \mu + \alpha_{i_1} + \beta_{i_1 i_2} + \dots + \epsilon_{i_1 i_2 \dots i_n r}$$

where

$y_{i_1 i_2 \dots i_n r}$  is the value of the dependent variable observed at the  $r$ th replication with factor  $j$  at level  $i_j$ , for  $j = 1, \dots, n$ .

$\mu$  is the overall (fixed) mean of the sampled population.

$\alpha_{i_1}, \beta_{i_1 i_2}, \dots, \epsilon_{i_1 i_2 \dots i_n r}$  are mutually uncorrelated random effects with zero means and respective variances  $\sigma_\alpha^2, \sigma_\beta^2, \dots, \sigma_\epsilon^2$ .

---

## Analysis of Covariation

When you specify more than one dependent variable, the NESTED procedure produces a descriptive analysis of the covariance between each pair of dependent variables in addition to a separate analysis of variance for each variable. The analysis of covariation is computed under the basic random-effects model for each pair of dependent variables:

$$y_{i_1 i_2 \dots i_n r} = \mu + \alpha_{i_1} + \beta_{i_1 i_2} + \dots + \epsilon_{i_1 i_2 \dots i_n r}$$

$$y'_{i_1 i_2 \dots i_n r} = \mu' + \alpha'_{i_1} + \beta'_{i_1 i_2} + \dots + \epsilon'_{i_1 i_2 \dots i_n r}$$

where the notation is the same as that used in the preceding general random-effects model.

There is an additional assumption that all the random effects in the two models are mutually uncorrelated except for corresponding effects, for which

$$\begin{aligned} \text{Corr}(\alpha_{i_1}, \alpha'_{i_1}) &= \rho_\alpha \\ \text{Corr}(\beta_{i_1 i_2}, \beta'_{i_1 i_2}) &= \rho_\beta \\ &\vdots \\ \text{Corr}(\epsilon_{i_1 i_2 \dots i_n r}, \epsilon'_{i_1 i_2 \dots i_n r}) &= \rho_\epsilon \end{aligned}$$

---

## Error Terms in *F* Tests

Random-effects ANOVAs are distinguished from fixed-effects ANOVAs by which error mean squares are used as the denominator for *F* tests. Under a fixed-effects model, there is only one true error term in the model, and the corresponding mean square is used as the denominator for all tests. This is how the usual analysis is computed in PROC ANOVA, for example. However, in a random-effects model for a nested experiment, mean squares are compared sequentially. The correct denominator in the test for the first factor is the mean square due to the second factor; the correct denominator in the test for the second factor is the mean square due to the third factor; and so on. Only the mean square due to the last factor, the one at the bottom of the nesting order, should be compared to the error mean square.

## Computational Method

The building blocks of the analysis are the sums of squares for the dependent variables for each classification variable within the factors that precede it in the model, corrected for the factors that follow it. For example, for a two-factor nested design, PROC NESTED computes the following sums of squares:

$$\begin{aligned} \text{Total SS} & \quad \sum_{ijr} (y_{ijr} - y_{\dots})^2 \\ \text{SS for Factor 1} & \quad \sum_i n_{i\cdot} \left( \frac{y_{i\cdot}}{n_{i\cdot}} - \frac{y_{\dots}}{n_{\dots}} \right)^2 \\ \text{SS for Factor 2 within Factor 1} & \quad \sum_{ij} n_{ij} \left( \frac{y_{ij\cdot}}{n_{ij}} - \frac{y_{i\cdot}}{n_{i\cdot}} \right)^2 \\ \text{Error SS} & \quad \sum_{ijr} \left( y_{ijr} - \frac{y_{ij\cdot}}{n_{ij}} \right)^2 \end{aligned}$$

where  $y_{ijr}$  is the  $r$ th replication,  $n_{ij}$  is the number of replications at level  $i$  of the first factor and level  $j$  of the second, and a dot as a subscript indicates summation over the corresponding index. If there is more than one dependent variable, PROC NESTED also computes the corresponding sums of crossproducts for each pair. The expected value of the sum of squares for a given classification factor is a linear combination of the variance components corresponding to this factor and to the factors that are nested within it. For each factor, the coefficients of this linear combination are computed. (The efficiency of PROC NESTED is partly due to the fact that these various sums can be accumulated with just one pass through the data, assuming that the data have been sorted by the classification variables.) Finally, estimates of the variance components are derived as the solution to the set of linear equations that arise from equating the mean squares to their expected values.

## Displayed Output

PROC NESTED displays the following items for each dependent variable:

- Coefficients of Expected Mean Squares, which are the coefficients of the  $n + 1$  variance components making up the expected mean square. Denoting the element in the  $i$ th row and  $j$ th column of this matrix by  $C_{ij}$ , the expected value of the mean square due to the  $i$ th classification factor is

$$C_{i1}\sigma_1^2 + \cdots + C_{in}\sigma_n^2 + C_{i,n+1}\sigma_\epsilon^2$$

$C_{ij}$  is always zero for  $i > j$ , and if the design is balanced,  $C_{ij}$  is equal to the common size of all classification groups of the  $j$ th factor for  $i \leq j$ . Finally, the mean square for error is always an unbiased estimate of  $\sigma_\epsilon^2$ . In other words,  $C_{n+1,n+1} = 1$ .

For every dependent variable, PROC NESTED displays an analysis of variance table. Each table contains the following:

- each Variance Source in the model (the different components of variance) and the total variance
- degrees of freedom (DF) for the corresponding sum of squares
- Sum of Squares for each classification factor. The sum of squares for a given classification factor is the sum of squares in the dependent variable within the factors that precede it in the model, corrected for the factors that follow it. (See the section “[Computational Method](#)” on page 5245.)
- *F* Value for a factor, which is the ratio of its mean square to the appropriate error mean square. The next column, labeled *PR > F*, gives the significance levels that result from testing the hypothesis that each variance component equals zero.
- the appropriate Error Term for an *F* test, which is the mean square due to the next classification factor in the nesting order. (See the section “[Error Terms in \*F\* Tests](#)” on page 5244.)
- Mean Square due to a factor, which is the corresponding sum of squares divided by the degrees of freedom
- estimates of the Variance Components. These are computed by equating the mean squares to their expected values and solving for the variance terms. (See the section “[Computational Method](#)” on page 5245.)
- Percent of Total, the proportion of variance due to each source. For the *i*th factor, the value is

$$100 \times \frac{\text{source variance component}}{\text{total variance component}}$$

- Mean, the overall average of the dependent variable. This gives an unbiased estimate of the mean of the population. Its variance is estimated by a certain linear combination of the estimated variance components, which is identical to the mean square due to the first factor in the model divided by the total number of observations when the design is balanced.

If there is more than one dependent variable, then the NESTED procedure displays an “analysis of covariation” table for each pair of dependent variables (unless the AOV option is specified in the PROC NESTED statement). See the section “[Analysis of Covariation](#)” on page 5244 for details. For each source of variation, this table includes the following:

- Degrees of Freedom
- Sum of Products

- Mean Products
- Covariance Component, the estimate of the covariance component

Items in the analysis of covariation table are computed analogously to their counterparts in the analysis of variance table. The analysis of covariation table also includes the following:

- Variance Component Correlation for a given factor. This is an estimate of the correlation between corresponding effects due to this factor. This correlation is the ratio of the covariance component for this factor to the square root of the product of the variance components for the factor for the two different dependent variables. (See the section “[Analysis of Covariation](#)” on page 5244.)
- Mean Square Correlation for a given classification factor. This is the ratio of the Mean Products for this factor to the square root of the product of the Mean Squares for the factor for the two different dependent variables.

---

## ODS Table Names

PROC NESTED assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “[Using the Output Delivery System.](#)”

**Table 62.2** ODS Tables Produced by PROC NESTED

| ODS Table Name | Description                           | Statement                                     |
|----------------|---------------------------------------|-----------------------------------------------|
| ANCOVA         | Analysis of covariance                | default with more than one dependent variable |
| ANOVA          | Analysis of variance                  | default                                       |
| EMSCoef        | Coefficients of expected mean squares | default                                       |
| Statistics     | Overall statistics for fit            | default                                       |

## Example: NESTED Procedure

### Example 62.1: Variability of Calcium Concentration in Turnip Greens

In the following example from Snedecor and Cochran (1976), an experiment is conducted to study the variability of calcium concentration in turnip greens. Four plants are selected at random; then three leaves are randomly selected from each plant. Two 100-mg samples are taken from each leaf. The amount of calcium is determined by microchemical methods.

Because the data are read in sorted order, it is not necessary to use PROC SORT on the CLASS variables. Leaf is nested in Plant; Sample is nested in Leaf and is left for the residual term. All the effects are random effects. The following statements read the data and invoke PROC NESTED. These statements produce Output 62.1.1.

```

title 'Calcium Concentration in Turnip Leaves--Nested Random Model';

 class plant leaf;
 var calcium;
run;

```

**Output 62.1.1** Analysis of Calcium Concentration in Turnip Greens Using PROC NESTED

Calcium Concentration in Turnip Leaves--Nested Random Model  
Snedecor and Cochran, 'Statistical Methods', 1976, p. 286

The NESTED Procedure

Coefficients of Expected Mean Squares

| Source | Plant | Leaf | Error |
|--------|-------|------|-------|
| Plant  | 6     | 2    | 1     |
| Leaf   | 0     | 2    | 1     |
| Error  | 0     | 0    | 1     |

Output 62.1.1 *continued*

| Nested Random Effects Analysis of Variance for Variable Calcium |    |                |         |        |            |             |                    |                  |
|-----------------------------------------------------------------|----|----------------|---------|--------|------------|-------------|--------------------|------------------|
| Variance Source                                                 | DF | Sum of Squares | F Value | Pr > F | Error Term | Mean Square | Variance Component | Percent of Total |
| Total                                                           | 23 | 10.270396      |         |        |            | 0.446539    | 0.532938           | 100.0000         |
| Plant                                                           | 3  | 7.560346       | 7.67    | 0.0097 | Leaf       | 2.520115    | 0.365223           | 68.5302          |
| Leaf                                                            | 8  | 2.630200       | 49.41   | <.0001 | Error      | 0.328775    | 0.161060           | 30.2212          |
| Error                                                           | 12 | 0.079850       |         |        |            | 0.006654    | 0.006654           | 1.2486           |
| Calcium Mean                                                    |    |                |         |        |            | 3.01208333  |                    |                  |
| Standard Error of Calcium Mean                                  |    |                |         |        |            | 0.32404445  |                    |                  |

The results indicate that there is significant (nonzero) variation from plant to plant ( $Pr > F$  is 0.0097) and from leaf to leaf within a plant ( $Pr > F$  is less than 0.0001). Notice that the variance component for Plant uses the Leaf mean square as an error term in the model rather than the error mean square.

## Overview: NLIN Procedure

The NLIN procedure fits nonlinear regression models and estimates the parameters by nonlinear least squares or weighted nonlinear least squares. You specify the model with programming statements. This gives you great flexibility in modeling the relationship between the response variable and independent (regressor) variables. It does, however, require additional coding compared to model specifications in linear modeling procedures such as the REG, GLM, and MIXED procedures.

Estimating parameters in a nonlinear model is an iterative process that commences from starting values. You need to declare the parameters in your model and supply their initial values for the NLIN procedure. You do not need to specify derivatives of the model equation with respect to the parameters. Although facilities for specifying first and second derivatives exist in the NLIN procedure, it is not recommended that you specify derivatives this way. Obtaining derivatives from user-specified expressions predates the high-quality automatic differentiator that is now used by the NLIN procedure.

Nonlinear least-squares estimation involves finding those values in the parameter space that minimize the (weighted) residual sum of squares. In a sense, this is a “distribution-free” estimation criterion since the distribution of the data does not need to be fully specified. Instead, the assumption of homoscedastic and uncorrelated model errors with zero mean is sufficient. You can relax the homoscedasticity assumption by using a weighted residual sum of squares criterion. The assumption of uncorrelated errors (independent observations) cannot be relaxed in the NLIN procedure. In summary, the primary assumptions for analyses with the NLIN procedure are as follows:

- The structure in the response variable can be decomposed additively into a mean function and an error component.
- The model errors are uncorrelated and have zero mean. Unless a weighted analysis is performed, the errors are also assumed to be homoscedastic (have equal variance).
- The mean function consists of known regressor (independent) variables and unknown constants (the parameters).

Fitting nonlinear models can be a difficult undertaking. There is no closed-form solution for the parameter estimates, and the process is iterative. There can be one or more local minima in the residual sum of squares surface, and the process depends on the starting values supplied by the user. You can reduce the dependence on the starting values and reduce the chance to arrive at a local minimum by specifying a grid of starting values. The NLIN procedure then computes the residual sum of squares at each point on the grid and starts the iterative process from the point that yields the lowest sum of squares. Even in this case, however, convergence does not guarantee that a global minimum has been found.

The numerical behavior of a model and a model–data combination can depend on the way in which you parameterize the model—for example, whether parameters are expressed on the logarithmic scale or not. Parameterization also has bearing on the interpretation of the estimated quantities and the statistical properties of the parameter estimators. Inferential procedures in nonlinear regression models are typically approximate in that they rely on the asymptotic properties of the parameter estimators that are obtained as the sample size grows without bound. Such asymptotic inference can be questionable in small samples, especially if the behavior of the parameter estimators is “far-from-linear.” Reparameterization of the model can yield parameters whose behavior is akin to that of estimators in linear models. These parameters exhibit close-to-linear behavior.

The NLIN procedure solves the nonlinear least squares problem by one of the following four algorithms (methods):

- steepest-descent or gradient method
- Newton method
- modified Gauss-Newton method
- Marquardt method

These methods use derivatives or approximations to derivatives of the SSE with respect to the parameters to guide the search for the parameters producing the smallest SSE. Derivatives computed automatically by the NLIN procedure are analytic, unless the model contains functions for which an analytic derivative is not available.

Using PROC NLIN, you can also do the following:

- confine the estimation procedure to a certain range of values of the parameters by imposing bounds on the estimates
- produce new SAS data sets containing predicted values, parameter estimates, residuals and other model diagnostics, estimates at each iteration, and so forth.

You can use the NLIN procedure for segmented models (see [Example 63.1](#)) or robust regression (see [Example 63.2](#)). You can also use it to compute maximum-likelihood estimates for certain models (see Jennrich and Moore 1975; Charnes, Frome, and Yu 1976). For maximum likelihood estimation in a model with a linear predictor and binomial error distribution, see the LOGISTIC, PROBIT, GENMOD, GLIMMIX, and CATMOD procedures. For a linear model with a Poisson, gamma, or inverse Gaussian error distribution, see the GENMOD and GLIMMIX procedures. For likelihood estimation in a linear model with a normal error distribution, see the MIXED, GENMOD, and GLIMMIX procedures. The PHREG and LIFEREG procedures fit survival models by maximum likelihood. For general maximum likelihood estimation, see the NLP procedure in the *SAS/OR User's Guide: Mathematical Programming* and the NLMIXED procedure. These procedures are recommended over the NLIN procedure for solving maximum likelihood problems.

PROC NLIN uses the Output Delivery System (ODS). ODS enables you to convert any of the output from PROC NLIN into a SAS data set. See the section “[ODS Table Names](#)” on page 5305 for a listing of the ODS tables that are produced by the NLIN procedure.

In addition, PROC NLIN can produce graphs when ODS Graphics is enabled. For more information, see the [PLOTS](#) option and the section “[ODS Graphics](#)” on page 5305 for a listing of the ODS graphs.

---

## Getting Started: NLIN Procedure

---

### Nonlinear or Linear Model

The NLIN procedure performs univariate nonlinear regression by using the least squares method. Nonlinear regression analysis is indicated when the functional relationship between the response variable and the predictor variables is nonlinear. Nonlinearity in this context refers to a nonlinear relationship in the *parameters*. Many linear regression models exhibit a relationship in the regressor (predictor) variables that is not simply a straight line. This does not make the models nonlinear. A model is nonlinear in the parameters if the derivative of the model with respect to a parameter depends on this or other parameters.

Consider, for example the models

$$E[Y|x] = \beta_0 + \beta_1 x$$

$$E[Y|x] = \beta_0 + \beta_1 x + \beta_2 x^2$$

$$E[Y|x] = \beta + x/\alpha$$

In these expressions,  $E[Y|x]$  denotes the expected value of the response variable  $Y$  at the fixed value of  $x$ . (The conditioning on  $x$  simply indicates that the predictor variables are assumed to be non-random in models fit by the NLIN procedure. Conditioning is often omitted for brevity in this chapter.)

Only the third model is a nonlinear model. The first model is a simple linear regression. It is linear in the parameters  $\beta_0$  and  $\beta_1$  since the model derivatives do not depend on unknowns:

$$\frac{\partial}{\partial \beta_0} (\beta_0 + \beta_1 x) = 1$$

$$\frac{\partial}{\partial \beta_1} (\beta_0 + \beta_1 x) = x$$

The model is also linear in its relationship with  $x$  (a straight line). The second model is also linear in the parameters, since

$$\frac{\partial}{\partial \beta_0} (\beta_0 + \beta_1 x + \beta_2 x^2) = 1$$

$$\frac{\partial}{\partial \beta_1} (\beta_0 + \beta_1 x + \beta_2 x^2) = x$$

$$\frac{\partial}{\partial \beta_2} (\beta_0 + \beta_1 x + \beta_2 x^2) = x^2$$

It is a *curvilinear* model since it exhibits a curved relationship when plotted against  $x$ . The third model, finally, is a nonlinear model since

$$\frac{\partial}{\partial \beta} (\beta + x/\alpha) = 1$$

$$\frac{\partial}{\partial \alpha} (\beta + x/\alpha) = -\frac{x}{\alpha^2}$$

The second of these derivatives depends on a parameter  $\alpha$ . A model is nonlinear if it is not linear in at least one parameter.

---

## Notation for Nonlinear Regression Models

This section briefly introduces the basic notation for nonlinear regression models that applies in this chapter. Additional notation is introduced throughout as needed.

The  $(n \times 1)$  vector of observed responses is denoted as  $\mathbf{y}$ . This vector is the realization of an  $(n \times 1)$  random vector  $\mathbf{Y}$ . The NLIN procedure assumes that the variance matrix of this random vector is  $\sigma^2\mathbf{I}$ . In other words, the observations have equal variance (are homoscedastic) and are uncorrelated. By defining the special variable `_WEIGHT_` in your NLIN programming statements, you can introduce heterogeneous variances. If a `_WEIGHT_` variable is present, then  $\text{Var}[\mathbf{Y}] = \sigma^2\mathbf{W}^{-1}$ , where  $\mathbf{W}$  is a diagonal matrix containing the values of the `_WEIGHT_` variable.

The mean of the random vector is represented by a nonlinear model that depends on parameters  $\beta_1, \dots, \beta_p$  and regressor (independent) variables  $z_1, \dots, z_k$ :

$$E[Y_i] = f(\beta_1, \beta_2, \dots, \beta_p; z_{i1}, \dots, z_{ik})$$

In contrast to linear models, the number of regressor variables ( $k$ ) does not necessarily equal the number of parameters ( $p$ ) in the mean function  $f(\cdot)$ . For example, the model fitted in the next subsection contains a single regressor and two parameters.

To represent the mean of the vector of observations, boldface notation is used in an obvious extension of the previous equation:

$$E[\mathbf{Y}] = \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \dots, \mathbf{z}_k)$$

The vector  $\mathbf{z}_1$ , for example, is an  $(n \times 1)$  vector of the values for the first regressor variables. The explicit dependence of the mean function on  $\boldsymbol{\beta}$  and/or the  $\mathbf{z}$  vectors is often omitted for brevity.

In summary, the stochastic structure of models fit with the NLIN procedure is mathematically captured by

$$\begin{aligned} \mathbf{Y} &= \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \dots, \mathbf{z}_k) + \boldsymbol{\epsilon} \\ E[\boldsymbol{\epsilon}] &= \mathbf{0} \\ \text{Var}[\boldsymbol{\epsilon}] &= \sigma^2\mathbf{I} \end{aligned}$$

Note that the residual variance  $\sigma^2$  is typically also unknown. Since it is not estimated in the same fashion as the other  $p$  parameters, it is often not counted in the number of parameters of the nonlinear regression. An estimate of  $\sigma^2$  is obtained after the model fit by the method of moments based on the residual sum of squares.

A matrix that plays an important role in fitting nonlinear regression models is the  $(n \times p)$  matrix of the first partial derivatives of the mean function  $\mathbf{f}$  with respect to the  $p$  model parameters. It is frequently denoted as

$$\mathbf{X} = \frac{\partial \mathbf{f}(\boldsymbol{\beta}; \mathbf{z}_1, \dots, \mathbf{z}_k)}{\partial \boldsymbol{\beta}}$$

The use of the symbol  $\mathbf{X}$ —common in linear statistical modeling—is no accident here. The first derivative matrix plays a similar role in nonlinear regression to that of the  $\mathbf{X}$  matrix in a linear model. For example, the

asymptotic variance of the nonlinear least-squares estimators is proportional to  $(\mathbf{X}'\mathbf{X})^{-1}$ , and projection-type matrices in nonlinear regressions are based on  $\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$ . Also, fitting a nonlinear regression model can be cast as an iterative process where a nonlinear model is approximated by a series of linear models in which the derivative matrix is the regressor matrix. An important difference between linear and nonlinear models is that the derivatives in a linear model do not depend on any parameters (see previous subsection). In contrast, the derivative matrix  $\partial f(\boldsymbol{\beta})/\partial \boldsymbol{\beta}$  is a function of at least one element of  $\boldsymbol{\beta}$ . It is this dependence that lies at the core of the fact that estimating the parameters in a nonlinear model cannot be accomplished in closed form, but it is an iterative process that commences with user-supplied starting values and attempts to continually improve on the parameter estimates.

---

## Estimating the Parameters in the Nonlinear Model

As an example of a nonlinear regression analysis, consider the following theoretical model of enzyme kinetics. The model relates the initial velocity of an enzymatic reaction to the substrate concentration.

$$f(\mathbf{x}, \boldsymbol{\theta}) = \frac{\theta_1 x_i}{\theta_2 + x_i}, \quad \text{for } i = 1, 2, \dots, n$$

where  $x_i$  represents the amount of substrate for  $n$  trials and  $f(\mathbf{x}, \boldsymbol{\theta})$  is the velocity of the reaction. The vector  $\boldsymbol{\theta}$  contains the rate parameters. This model is known as the Michaelis-Menten model in biochemistry (Ratkowsky 1990, p. 59). The model exists in many parameterizations. In the form shown here,  $\theta_1$  is the maximum velocity of the reaction that is theoretically attainable. The parameter  $\theta_2$  is the substrate concentration at which the velocity is 50% of the maximum.

Suppose that you want to study the relationship between concentration and velocity for a particular enzyme/substrate pair. You record the reaction rate (velocity) observed at different substrate concentrations.

A SAS data set is created for this experiment in the following DATA step:

```
data Enzyme;
 input Concentration Velocity @@;
 datalines;
0.26 124.7 0.30 126.9
0.48 135.9 0.50 137.6
0.54 139.6 0.68 141.1
0.82 142.8 1.14 147.6
1.28 149.8 1.38 149.4
1.80 153.9 2.30 152.5
2.44 154.5 2.48 154.7
;
```

The SAS data set Enzyme contains the two variables Concentration (substrate concentration) and Velocity (reaction rate). The following statements fit the Michaelis-Menten model by nonlinear least squares:

```
proc nlin data=Enzyme method=marquardt hougard;
 parms theta1=155
 theta2=0 to 0.07 by 0.01;
 model Velocity = theta1*Concentration / (theta2 + Concentration);
run;
```

The **DATA=** option specifies that the SAS data set `Enzyme` be used in the analysis. The **METHOD=** option directs PROC NLIN to use the MARQUARDT iterative method. The **HOUGAARD** option requests that a skewness measure be calculated for the parameters.

The **PARMS** statement declares the parameters and specifies their initial values. Suppose that  $V$  represents the velocity and  $C$  represents the substrate concentration. In this example, the initial estimates listed in the **PARMS** statement for  $\theta_1$  and  $\theta_2$  are obtained as follows:

$\theta_1$ : Because the model is a monotonic increasing function in  $C$ , and because

$$\lim_{C \rightarrow \infty} \left( \frac{\theta_1 C}{\theta_2 + C} \right) = \theta_1$$

you can take the largest observed value of the variable `Velocity` (154.7) as the initial value for the parameter `Theta1`. Thus, the **PARMS** statement specifies 155 as the initial value for `Theta1`, which is approximately equal to the maximum observed velocity.

$\theta_2$ : To obtain an initial value for the parameter  $\theta_2$ , first rearrange the model equation to solve for  $\theta_2$ :

$$\theta_2 = \frac{\theta_1 C}{V} - C$$

By substituting the initial value of `Theta1` for  $\theta_1$  and taking each pair of observed values of `Concentration` and `Velocity` for  $C$  and  $V$ , respectively, you obtain a set of possible starting values for `Theta2` ranging from about 0.01 to 0.07.

You can choose any value within this range as a starting value for `Theta2`, or you can direct PROC NLIN to perform a preliminary search for the best initial `Theta2` value within that range of values. The **PARMS** statement specifies a range of values for `Theta2`, resulting in a search over the grid points from 0 to 0.07 in increments of 0.01.

The **MODEL** statement specifies the enzymatic reaction model

$$V = \frac{\theta_1 C}{\theta_2 + C}$$

in terms of the data set variables `Velocity` and `Concentration` and in terms of the parameters in the **PARMS** statement.

The results from this PROC NLIN invocation are displayed in the following figures.

PROC NLIN evaluates the model at each point on the specified grid for the `Theta2` parameter. [Figure 63.1](#) displays the calculations resulting from the grid search.

**Figure 63.1** Nonlinear Least-Squares Grid Search

| The NLIN Procedure          |        |                |
|-----------------------------|--------|----------------|
| Dependent Variable Velocity |        |                |
| Grid Search                 |        |                |
| theta1                      | theta2 | Sum of Squares |
| 155.0                       | 0      | 3075.4         |
| 155.0                       | 0.0100 | 2074.1         |
| 155.0                       | 0.0200 | 1310.3         |
| 155.0                       | 0.0300 | 752.0          |
| 155.0                       | 0.0400 | 371.9          |
| 155.0                       | 0.0500 | 147.2          |
| 155.0                       | 0.0600 | 58.1130        |
| 155.0                       | 0.0700 | 87.9662        |

The parameter Theta1 is held constant at its specified initial value of 155, the grid is traversed, and the residual sum of squares is computed at each point. The “best” starting value is the point that corresponds to the smallest value of the residual sum of squares. The best set of starting values is obtained for  $\theta_1 = 155$ ,  $\theta_2 = 0.06$  (Figure 63.1). PROC NLIN uses this point from which to start the following, iterative phase of nonlinear least-squares estimation.

Figure 63.2 displays the iteration history. Note that the first entry in the “Iterative Phase” table echoes the starting values and the residual sum of squares for the best value combination in Figure 63.1. The subsequent rows of the table show the updates of the parameter estimates and the improvement (decrease) in the residual sum of squares. For this data-and-model combination, the first iteration yielded a large improvement in the sum of squares (from 58.113 to 19.7017). Further steps were necessary to improve the estimates in order to achieve the convergence criterion. The NLIN procedure by default determines convergence by using R, the relative offset measure of Bates and Watts (1981). Convergence is declared when this measure is less than  $10^{-5}$ —in this example, after three iterations.

**Figure 63.2** Iteration History and Convergence Status

| The NLIN Procedure          |        |        |                |
|-----------------------------|--------|--------|----------------|
| Dependent Variable Velocity |        |        |                |
| Method: Marquardt           |        |        |                |
| Iterative Phase             |        |        |                |
| Iter                        | theta1 | theta2 | Sum of Squares |
| 0                           | 155.0  | 0.0600 | 58.1130        |
| 1                           | 158.0  | 0.0736 | 19.7017        |
| 2                           | 158.1  | 0.0741 | 19.6606        |
| 3                           | 158.1  | 0.0741 | 19.6606        |

**NOTE:** Convergence criterion met.

**Figure 63.3** Estimation Summary

| Estimation Summary   |           |
|----------------------|-----------|
| Method               | Marquardt |
| Iterations           | 3         |
| R                    | 5.861E-6  |
| PPC(theta2)          | 8.569E-7  |
| RPC(theta2)          | 0.000078  |
| Object               | 2.902E-7  |
| Objective            | 19.66059  |
| Observations Read    | 14        |
| Observations Used    | 14        |
| Observations Missing | 0         |

A summary of the estimation including several convergence measures (R, PPC, RPC, and Object) is displayed in Figure 63.3.

The “R” measure in Figure 63.3 is the relative offset convergence measure of Bates and Watts. A “PPC” value of 8.569E-7 indicates that the parameter Theta2 (which has the largest PPC value of the parameters) would change by that relative amount, if PROC NLIN were to take an additional iteration step. The “RPC” value indicates that Theta2 changed by 0.000078, relative to its value in the last iteration. These changes are measured before step length adjustments are made. The “Object” measure indicates that the objective function changed by 2.902E-7 in relative value from the last iteration.

Figure 63.4 displays the analysis of variance table for the model. The table displays the degrees of freedom, sums of squares, and mean squares along with the model *F* test.

**Figure 63.4** Nonlinear Least-Squares Analysis of Variance

NOTE: An intercept was not specified for this model.

| Source            | DF | Sum of Squares | Mean Square | F Value | Approx Pr > F |
|-------------------|----|----------------|-------------|---------|---------------|
| Model             | 2  | 290116         | 145058      | 88537.2 | <.0001        |
| Error             | 12 | 19.6606        | 1.6384      |         |               |
| Uncorrected Total | 14 | 290135         |             |         |               |

**Figure 63.5** Parameter Estimates and Approximate 95% Confidence Intervals

| Parameter | Estimate | Approx Std Error | Approximate 95% Confidence Limits |        | Skewness |
|-----------|----------|------------------|-----------------------------------|--------|----------|
| theta1    | 158.1    | 0.6737           | 156.6                             | 159.6  | 0.0152   |
| theta2    | 0.0741   | 0.00313          | 0.0673                            | 0.0809 | 0.0362   |

Figure 63.5 displays the estimates for each parameter, the associated asymptotic standard error, and the upper and lower values for the asymptotic 95% confidence interval. PROC NLIN also displays the asymptotic

correlations between the estimated parameters (not shown).

The skewness measures of 0.0152 and 0.0362 indicate that the parameter estimators exhibit close-to-linear behavior and that their standard errors and confidence intervals can be safely used for inferences.

Thus, the estimated nonlinear model relating reaction velocity and substrate concentration can be written as

$$\hat{V} = \frac{158.1C}{0.0741 + C}$$

where  $\hat{V}$  represents the predicted velocity or rate of the reaction, and  $C$  represents the substrate concentration.

## Syntax: NLIN Procedure

The following statements are available in the NLIN procedure:

```

PROC NLIN < options > ;
 BOUNDS inequality < , ... , inequality > ;
 BY variables ;
 CONTROL variable < =values > < ... variable < =values > > ;
 DER. parameter=expression ;
 DER. parameter.parameter=expression ;
 ID variables ;
 MODEL dependent = expression ;
 OUTPUT OUT=SAS-data-set keyword=names < ... keyword=names > ;
 PARAMETERS < parameter-specification > < , ... , parameter-specification >
 < / PDATA=SAS-data-set > ;
 PROFILE parameter < ... parameter > < / options > ;
 RETAIN variable < =values > < ... variable < =values > > ;
 Programming statements ;

```

The statements in the NLIN procedure, in addition to the **PROC NLIN** statement, are as follows:

|                               |                                                                                                                                                                    |
|-------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>BOUNDS</b>                 | constrains the parameter estimates within specified bounds                                                                                                         |
| <b>BY</b>                     | specifies variables to define subgroups for the analysis                                                                                                           |
| <b>DER</b>                    | specifies the first or second partial derivatives                                                                                                                  |
| <b>ID</b>                     | specifies additional variables to add to the output data set                                                                                                       |
| <b>MODEL</b>                  | defines the relationship between the dependent and independent variables (the mean function)                                                                       |
| <b>OUTPUT</b>                 | creates an output data set containing observation-wise statistics                                                                                                  |
| <b>PARAMETERS</b>             | identifies parameters to be estimated and their starting values                                                                                                    |
| <b>PROFILE</b>                | identifies parameters to be profiled                                                                                                                               |
| <i>Programming Statements</i> | includes assignment statements, <b>ARRAY</b> statements, <b>DO</b> loops, and other program control statements. These are valid SAS expressions that can appear in |

the DATA step. PROC NLIN enables you to create new variables within the procedure and use them in the nonlinear analysis. These programming statements can appear anywhere in the PROC NLIN code, but new variables must be created before they appear in other statements. The NLIN procedure automatically creates several variables that are also available for use in the analysis. See the section “Special Variables” on page 5291 for more information.

The PROC NLIN, PARAMETERS, and MODEL statements are required.

---

## PROC NLIN Statement

**PROC NLIN** < options > ;

The PROC NLIN statement invokes the NLIN procedure.

Table 63.1 summarizes the options available in the PROC NLIN statement. All options are subsequently discussed in alphabetical order.

**Table 63.1** Summary of Options in PROC NLIN Statement

| Option                                      | Description                                                                                     |
|---------------------------------------------|-------------------------------------------------------------------------------------------------|
| <b>Options Related to Data Sets</b>         |                                                                                                 |
| DATA=                                       | Specifies the input data set                                                                    |
| OUTEST=                                     | Specifies the output data set for parameter estimates, covariance matrix, and so on             |
| SAVE                                        | Requests that final estimates be added to the OUTEST= data set                                  |
| <b>Optimization Options</b>                 |                                                                                                 |
| BEST=                                       | Limits display of grid search                                                                   |
| METHOD=                                     | Chooses the optimization method                                                                 |
| MAXITER=                                    | Specifies the maximum number of iterations                                                      |
| MAXSUBIT=                                   | Specifies the maximum number of step halvings                                                   |
| NOHALVE                                     | Allows the objective function to increase between iterations                                    |
| RHO=                                        | Controls the step-size search                                                                   |
| SMETHOD=                                    | Specifies the step-size search method                                                           |
| TAU=                                        | Controls the step-size search                                                                   |
| G4                                          | Uses the Moore-Penrose inverse                                                                  |
| UNCORRECTEDDF                               | Does not expense degrees of freedom when bounds are active                                      |
| SIGSQ=                                      | Specifies the fixed value for residual variance                                                 |
| <b>Singularity and Convergence Criteria</b> |                                                                                                 |
| CONVERGE=                                   | Tunes the convergence criterion                                                                 |
| CONVERGEOBJ=                                | Uses the change in loss function as the convergence criterion and tunes its value               |
| CONVERGEPARM=                               | Uses the maximum change in parameter estimates as the convergence criterion and tunes its value |
| SINGULAR=                                   | Tunes the singularity criterion used in matrix inversions                                       |

---

Table 63.1 *continued*

| Option                       | Description                                                                              |
|------------------------------|------------------------------------------------------------------------------------------|
| <b>ODS Graphics Options</b>  |                                                                                          |
| PLOTS=                       | Produces ODS graphical displays                                                          |
| <b>Displayed Output</b>      |                                                                                          |
| HOUGAARD                     | Adds Hougaard's skewness measure to the "Parameter Estimates" table                      |
| BIAS                         | Adds Box's bias measure to the "Parameter Estimates" table                               |
| NOITPRINT                    | Suppresses the "Iteration History" table                                                 |
| NOPRINT                      | Suppresses displayed output                                                              |
| LIST                         | Displays the model program and variable list                                             |
| LISTALL                      | Selects the LIST, LISTDEP, LISTDER, and LISTCODE options                                 |
| LISTCODE                     | Displays the model program code                                                          |
| LISTDEP                      | Displays dependencies of model variables                                                 |
| LISTDER                      | Displays the derivative table                                                            |
| NLINMEASURES                 | Displays the global nonlinearity measures table                                          |
| TOTALSS                      | Adds the uncorrected or corrected total sum of squares to the analysis of variance table |
| XREF                         | Displays the cross-reference of variables                                                |
| <b>Trace Model Execution</b> |                                                                                          |
| FLOW                         | Displays execution messages for program statements                                       |
| PRINT                        | Displays results of statements in model program                                          |
| TRACE                        | Displays results of operations in model program                                          |

**ALPHA= $\alpha$** 

specifies the level of significance  $\alpha$  used in the construction of  $100(1 - \alpha)\%$  confidence intervals. The value must be strictly between 0 and 1; the default value of  $\alpha = 0.05$  results in 95% intervals. This value is used as the default confidence level for limits computed in the "Parameter Estimates" table and with the LCLM, LCL, UCLM, and UCL options in the OUTPUT statement.

**BEST= $n$** 

requests that PROC NLIN display the residual sums of squares only for the best  $n$  combinations of possible starting values from the grid. If you do not specify the BEST= option, PROC NLIN displays the residual sum of squares for every combination of possible parameter starting values.

**BIAS**

adds Box's bias and percentage bias measures to the "Parameter Estimates" table (Box 1971). Box's bias measure, along with Hougaard's measure of skewness, is used for assessing a parameter estimator's close-to-linear behavior (Ratkowsky 1983, 1990). Hence, it is useful for identifying problematic parameters (Seber and Wild 1989, sec. 4.7.1). When you specify the BIAS option, Box's bias measure (Box 1971) and the percentage bias (the bias expressed as a percentage of the least-squares estimator) are added for each parameter to the "Parameter Estimates" table. Ratkowsky (1983, p. 21) takes a percentage bias in excess of 1% to be a good rule of thumb for indicating nonlinear behavior.

See the section "Box's Measure of Bias" on page 5286 for further details. Example 63.4 shows how to use this measure, along with Hougaard's measure of skewness, to evaluate changes in the

parameterization of a nonlinear model. Computation of the Box's bias measure requires first and second derivatives. If you do not provide derivatives with the **DER** statement—and it is recommended that you do not—the analytic derivatives are computed for you.

### **CONVERGE=c**

specifies the convergence criterion for PROC NLIN. For all iterative methods the relative offset convergence measure of Bates and Watts is used by default to determine convergence. This measure is labeled “R” in the “Estimation Summary” table. The iterations are said to have converged for **CONVERGE=c** if

$$\sqrt{\frac{\mathbf{r}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r}}{\text{LOSS}^{(i)}}} < c$$

where  $\mathbf{r}$  is the residual vector and  $\mathbf{X}$  is the  $(n \times p)$  matrix of first derivatives with respect to the parameters. The default LOSS function is the sum of squared errors (SSE), and  $\text{LOSS}^{(i)}$  denotes the value of the loss function at the  $i$ th iteration. By default, **CONVERGE**= $10^{-5}$ . The R convergence measure cannot be computed accurately in the special case of a perfect fit (residuals close to zero). When the SSE is less than the value of the **SINGULAR=** criterion, convergence is assumed.

### **CONVERGEOBJ=c**

uses the change in the LOSS function as the convergence criterion and tunes the criterion. The iterations are said to have converged for **CONVERGEOBJ=c** if

$$\frac{|\text{LOSS}^{(i-1)} - \text{LOSS}^{(i)}|}{|\text{LOSS}^{(i-1)} + 10^{-6}|} < c$$

where  $\text{LOSS}^{(i)}$  is the LOSS for the  $i$ th iteration. The default LOSS function is the sum of squared errors (SSE), the residual sum of squares. The constant  $c$  should be a small positive number. For more details about the LOSS function, see the section “[Special Variable Used to Determine Convergence Criteria](#)” on page 5292. For more details about the computational methods in the NIN procedure, see the section “[Computational Methods](#)” on page 5294.

Note that in SAS 6 the **CONVERGE=** and **CONVERGEOBJ=** options both requested that convergence be tracked by the relative change in the loss function. If you specify the **CONVERGEOBJ=** option in newer releases, the **CONVERGE=** option is disabled. This enables you to track convergence as in SAS 6.

### **CONVERGEPARM=c**

uses the maximum change among parameter estimates as the convergence criterion and tunes the criterion. The iterations are said to have converged for **CONVERGEPARM=c** if

$$\max_j \left( \frac{|\beta_j^{(i-1)} - \beta_j^{(i)}|}{|\beta_j^{(i-1)}|} \right) < c$$

where  $\beta_j^{(i)}$  is the value of the  $j$ th parameter at the  $i$ th iteration.

The default convergence criterion is **CONVERGE**. If you specify **CONVERGEPARM=c**, the maximum change in parameters is used as the convergence criterion. If you specify both the **CONVERGEOBJ=** and **CONVERGEPARM=** options, PROC NLIN continues to iterate until the decrease in LOSS is sufficiently small (as determined by the **CONVERGEOBJ=** option) and the maximum change among the parameters is sufficiently small (as determined by the **CONVERGEPARM=** option).

**DATA=SAS-data-set**

specifies the input SAS data set to be analyzed by PROC NLIN. If you omit the DATA= option, the most recently created SAS data set is used.

**FLOW**

displays a message for each statement in the model program as it is executed. This debugging option is rarely needed, and it produces large amounts of output.

**G4**

uses a Moore-Penrose inverse ( $g_4$ -inverse) in parameter estimation. See Kennedy and Gentle (1980) for details.

**HOUGAARD**

adds Hougaard's measure of skewness to the "Parameter Estimates" table (Hougaard 1982, 1985). The skewness measure is one method of assessing a parameter estimator's close-to-linear behavior in the sense of Ratkowsky (1983, 1990). The behavior of estimators that are close to linear approaches that of least squares estimators in linear models, which are unbiased and have minimum variance. When you specify the HOUGAARD option, the standardized skewness measure of Hougaard (1985) is added for each parameter to the "Parameter Estimates" table. Because of the linkage between nonlinear behavior of a parameter estimator in nonlinear regression and the nonnormality of the estimator's sampling distribution, Ratkowsky (1990, p. 28) provides the following rules to interpret the (standardized) Hougaard skewness measure:

- Values less than 0.1 in absolute value indicate very close-to-linear behavior.
- Values between 0.1 and 0.25 in absolute value indicate reasonably close-to-linear behavior.
- The nonlinear behavior is apparent for absolute values above 0.25 and is considerable for absolute values above 1.

See the section "[Hougaard's Measure of Skewness](#)" on page 5286 for further details. [Example 63.4](#) shows how to use this measure to evaluate changes in the parameterization of a nonlinear model. Computation of the Hougaard skewness measure requires first and second derivatives. If you do not provide derivatives with the [DER](#) statement—and it is recommended that you do not—the analytic derivatives are computed for you.

**LIST**

displays the model program and variable lists, including the statements added by macros. Note that the expressions displayed by the LIST option do not necessarily represent the way the expression is actually calculated—because intermediate results for common subexpressions can be reused—but are shown in expanded form. To see how the expression is actually evaluated, use the [LISTCODE](#) option.

**LISTALL**

selects the [LIST](#), [LISTDEP](#), [LISTDER](#), and [LISTCODE](#) options.

**LISTCODE**

displays the derivative tables and the compiled model program code. The LISTCODE option is a debugging feature and is not normally needed.

**LISTDEP**

produces a report that lists, for each variable in the model program, the variables that depend on it and the variables on which it depends.

**LISTDER**

displays a table of derivatives. The derivatives table lists each nonzero derivative computed for the problem. The derivative listed can be a constant, a variable in the model program, or a special derivative variable created to hold the result of an expression.

**MAXITER=*n***

specifies the maximum number *n* of iterations in the optimization process. The default is *n* = 100.

**MAXSUBIT=*n***

places a limit on the number of step halvings. The value of MAXSUBIT must be a positive integer and the default value is *n* = 30.

**METHOD=GAUSS****METHOD=MARQUARDT****METHOD=NEWTON****METHOD=GRADIENT**

specifies the iterative method employed by the NLIN procedure in solving the nonlinear least squares problem. The GAUSS, MARQUARDT, and NEWTON methods are more robust than the GRADIENT method. If you omit the METHOD= option, METHOD=GAUSS is used. See the section “Computational Methods” on page 5294 for more information.

**NLINMEASURES**

displays the global nonlinearity measures table. These measures include the maximum intrinsic and parameter-effects curvatures (Bates and Watts 1980), the root mean square (RMS) intrinsic and parameter-effects curvatures and the critical curvature value (Bates and Watts 1980). In addition, the variances of the ordinary and projected residuals are included. According to Bates and Watts (1980), both intrinsic and parameter-effects curvatures are deemed negligible if they are less than the critical curvature value. This critical value is given by  $1/(\sqrt{F})$  where  $F = F(p, n - p; \alpha)$ . The value  $1/\sqrt{F}$  can be considered as the radius of curvature of the 100(1 -  $\alpha$ ) percent confidence region (Bates and Watts 1980).

**NOITPRINT**

suppresses the display of the “Iteration History” table.

**NOHALVE**

removes the restriction that the objective value must decrease at every iteration. Step halving is still used to satisfy **BOUNDS** and to ensure that the number of observations that can be evaluated does not decrease. The NOHALVE option can be useful in weighted nonlinear least squares problems where the weights depend on the parameters, such as in iteratively reweighted least squares (IRLS) fitting. See [Example 63.2](#) for an application of IRLS fitting.

**NOPRINT**

suppresses the display of the output. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “Using the Output Delivery System.”

**OUTEST=SAS-data-set**

specifies an output data set that contains the parameter estimates produced at each iteration. See the section “[Output Data Sets](#)” for details. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

**PLOTS** <(global-plot-option)> <= (plot-request <(options)> <... plot-request <(options)> >)>

controls most of the plots that are produced through ODS Graphics (other plots are controlled by the [PROFILE](#) statement). When you specify only one *plot-request*, you can omit the parentheses around it. Here are some examples:

```
plots
plots = none
plots = diagnostics(unpack)
plots = fit(stats=none)
plots = residuals(residualtype=proj unpack smooth)
plots(stats=all) = (diagnostics(stats=(maxincurv maxpecurv)) fit)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc nlin plots=diagnostics(stats=all);
 model y = alpha - beta*(gamma**x);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled and if you specify the PLOTS option without any *global-plot-option* or *plot-requests*, PROC NLIN produces the plots listed in [Table 63.2](#) with the default set of statistics and options. If you do not specify the PLOTS option, PROC NLIN does not produce any of these graphs.

**Table 63.2** Graphs Produced When the PLOTS Option Is Specified

| Plot                | Conditional On            |
|---------------------|---------------------------|
| ContourFitPlot      | Model with two regressors |
| FitDiagnosticsPanel | Unconditional             |
| FitPlot             | Model with one regressor  |
| LeveragePlot        | Unconditional             |
| LocalInfluencePlot  | Unconditional             |
| ResidualPanel       | Unconditional             |

You can request additional plots by specifying *plot-requests*. For a listing of all the plots that PROC NLIN produces, see the section “[ODS Graphics](#)” on page 5305. Each *global-plot-option* applies to all plots that are generated by the NLIN procedure except for plots that are controlled by the **PROFILE** statement. The *global-plot-option* can be overridden by a specific *option* after a *plot-request*.

The following *global-plot-options* are available:

**RESIDUALTYPE=RAW | PROJ | BOTH**

specifies the residual type to be plotted in the fit diagnostics and residual plots. RESIDUALTYPE=RAW requests that only the ordinary residuals be included in the plots; RESIDUALTYPE=PROJ sets the choice to projected residuals. By default, both residual types are included, which can also be effected by setting RESIDUALTYPE=BOTH. See the section “[Residuals in Nonlinear Regression](#)” on page 5289 for details about the properties of ordinary and projected residuals in nonlinear regression.

**STATS=ALL | DEFAULT | NONE | (*plot-statistics*)**

requests the statistics to be included in all plots, except the ResidualPlots and the unpacked diagnostics plots. [Table 63.3](#) lists the statistics that you can request. STATS=ALL requests all these statistics, STATS=NONE suppresses all statistics, and STATS=DEFAULT selects the default statistics. You request statistics in addition to the default set by including the keyword DEFAULT in the *plot-statistics* list.

**Table 63.3** Statistics Available in Plots

| Keyword    | Default | Description                                                              |
|------------|---------|--------------------------------------------------------------------------|
| DEFAULT    |         | All default statistics                                                   |
| MAXINCURV  |         | Maximum intrinsic curvature                                              |
| MAXPECURV  |         | Maximum parameter-effects curvature                                      |
| MSE        | x       | Mean squared error, estimated or set by the <a href="#">SIGSQ</a> option |
| NOBS       | x       | Number of observations used                                              |
| NPARAM     | x       | Number of parameters in the model                                        |
| PVAR       | x       | Estimated variance of the projected residuals                            |
| RMSNINCURV |         | Root mean square intrinsic curvature                                     |
| RMSPECURV  |         | Root mean square parameter-effects curvature                             |
| VAR        | x       | Estimated variance of the ordinary residuals                             |

Along with the maximum intrinsic and parameter-effects curvatures, the critical curvature (CURVCRIT) value,  $1/\sqrt{F}$  where  $F = F(p, n - p; \alpha)$ , is also displayed. You do not need to specify any option for it. See the section “[Relative Curvature Measures of Nonlinearity](#)” on page 5287 for details about curvature measures of nonlinearity.

**UNPACK**

suppresses paneling.

You can specify the following *plot-requests* in the PLOTS= option:

**ALL**

produces all appropriate plots.

**NONE**

suppresses all plots.

**DIAGNOSTICS** < (*diagnostics-options*) >

produces a summary panel of fit diagnostics, leverage plots, and local-influence plots. The fit diagnostics panel includes:

- histogram of the ordinary residuals
- histogram of the projected residuals
- response variable values versus the predicted values
- expectation or mean of the ordinary residuals versus the predicted values
- ordinary and projected residuals versus the predicted values
- standardized ordinary and projected residuals versus the predicted values
- standardized ordinary and projected residuals versus the tangential leverage
- standardized ordinary and projected residuals versus the Jacobian leverage
- box plot of the ordinary and projected residuals if you specify the STATS=NONE suboption

The leverage and local influence plots are produced separately. The leverage plot is an index plot of the tangential and Jacobian leverages (by observation), and the local-influence plot contains the local influence by observation for a perturbation of the response variable. See the sections “[Leverage in Nonlinear Regression](#)” on page 5288 and “[Local Influence in Nonlinear Regression](#)” on page 5288 for a some details about leverages and local-influence in nonlinear regression.

You can specify the following *diagnostics-options*:

**RESIDUALTYPE=RAW | PROJ | BOTH**

specifies the residual type to be plotted in the panel. See the RESIDUALTYPE= *global-plot-option* for details. This *diagnostics-option* overrides the PLOTS RESIDUALTYPE *global-plot-option*. Only the plots that overlay both ordinary and projected residuals in the same plot are affected by this option.

**LEVERAGETYPE=TAN | JAC | BOTH**

specifies the leverage type to be plotted in the leverage plot. LEVERAGETYPE=TAN specifies that only the tangential leverage be included in the leverage plot, and LEVERAGETYPE=JAC specifies that only the Jacobian leverage be included. By default, both are displayed in the leverage plot. The same result can be effected by setting LEVERAGETYPE=BOTH. Only the leverage plot is affected by this option.

**LABELOBS**

specifies that the leverage and local-influence plots be labeled with the observation number. Only these two plots are affected by this option.

**STATS=stats-options**

determines which statistics are included in the panel. See the *STATS= global-plot-option* for details. This *diagnostics-option* overrides the *PLOTS STATS global-plot-option*.

**UNPACK**

produces the plots in the diagnostics panel as individual plots. The statistics panel is not included in the individual plots, even if *STATS= global-plot-option* or *STATS= diagnostics-option* or both are specified.

**FITPLOT | FIT <(fit-options)>**

produces, depending on the number of regressors, a scatter or contour fit plot. For a single-regressor model, a scatter plot of the data overlaid with the regression curve, confidence, and prediction bands is produced. For two-regressor models, a contour fit plot of the model with overlaid data is produced. If the model contains more than two regressors, no fit plot is produced.

You can specify the following *fit-options*:

**NOCLI**

suppresses the prediction limits for single-regressor models.

**NOCLM**

suppresses the confidence limits for single-regressor models.

**NOLIMITS**

suppresses the confidence and prediction limits for single-regressor models.

**OBS=GRADIENT | NONE | OUTLINE | OUTLINEGRADIENT**

controls how the observations are displayed. The suboptions are as follows:

**OBS=GRADIENT** specifies that observations be displayed as circles colored by the observed response. The same color gradient is used to display the fitted surface and the observations. Observations for which the predicted response is close to the observed response have similar colors—the greater the contrast between the color of an observation and the surface, the larger the residual is at that point. **OBS=GRADIENT** is the default.

**OBS=NONE** suppresses the observations.

**OBS=OUTLINE** specifies that observations be displayed as circles with a border but with a completely transparent fill.

**OBS=OUTLINEGRADIENT** is the same as **OBS=GRADIENT** except that a border is shown around each observation. This option is useful for identifying the location observations for which the residuals are small, because at these points the color of the observations and the color of the surface are indistinguishable.

**CONTLEG**

specifies that a continuous legend be included in the contour fit plot of a two-regressor model.

**STATS=stats-options**

determines which model fit statistics are included in the panel. See the `STATS= global-plot-option` for details. This *fit-option* overrides the `PLOTS STATS global-plot-option`.

**RESIDUALS < residual-options >**

produces panels of the ordinary and projected residuals versus the regressors in the model. Each panel contains at most six plots, and multiple panels are used in the case where there are more than six regressors in the model.

The following *residual-options* are available:

**RESIDUALTYPE=RAW | PROJ | BOTH**

specifies the residual type to be plotted in the panel. See the `RESIDUALTYPE= global-plot-option` for details. This *residual-option* overrides the `PLOTS RESIDUALTYPE global-plot-option`.

**SMOOTH**

requests a nonparametric smooth of the residuals for each regressor. Each nonparametric fit is a loess fit that uses local linear polynomials, linear interpolation, and a smoothing parameter selected that yields a local minimum of the corrected Akaike information criterion (AICC). See Chapter 53, “[The LOESS Procedure](#),” for details.

**UNPACK**

suppresses paneling.

**PRINT**

displays the result of each statement in the program as it is executed. This option is a debugging feature that produces large amounts of output and is normally not needed.

**RHO=value**

specifies a value that controls the step-size search. By default `RHO=0.1`, except when `METHOD=MARQUARDT`. In that case, `RHO=10`. See the section “[Step-Size Search](#)” on page 5299 for more details.

**SAVE**

specifies that, when the iteration limit is exceeded, the parameter estimates from the final iteration be output to the `OUTEST=` data set. These parameter estimates are associated with the observation for which `_TYPE_="FINAL"`. If you omit the `SAVE` option, the parameter estimates from the final iteration are not output to the data set unless convergence has been attained.

**SIGSQ=value**

specifies a value to use as the estimate of the residual variance in lieu of the estimated mean-squared error. This value is used in computing the standard errors of the estimates. Fixing the value of the residual variance can be useful, for example, in maximum likelihood estimation.

**SINGULAR=s**

specifies the singularity criterion, `s`, which is the absolute magnitude of the smallest pivot value allowed when inverting the Hessian or the approximation to the Hessian. The default value is `1E4` times the machine epsilon; this product is approximately `1E-12` on most computers.

**SMETHOD=HALVE****SMETHOD=GOLDEN****SMETHOD=CUBIC**

specifies the step-size search method. The default is **SMETHOD=HALVE**. See the section “[Step-Size Search](#)” on page 5299 for details.

**TAU=value**

specifies a value that is used to control the step-size search. The default is **TAU=1**, except when **METHOD=MARQUARDT**. In that case the default is **TAU=0.01**. See the section “[Step-Size Search](#)” on page 5299 for details.

**TOTALSS**

adds to the analysis of variance table the uncorrected total sum of squares in models that have an (implied) intercept, and adds the corrected total sum of squares in models that do not have an (implied) intercept.

**TRACE**

displays the result of each operation in each statement in the model program as it is executed, in addition to the information displayed by the **FLOW** and **PRINT** options. This debugging option is needed very rarely, and it produces even more output than the **FLOW** and **PRINT** options.

**XREF**

displays a cross-reference of the variables in the model program showing where each variable is referenced or given a value. The XREF listing does not include derivative variables.

**UNCORRECTEDDF**

specifies that no degrees of freedom be lost when a bound is active. When the **UNCORRECTEDDF** option is not specified, an active bound is treated as if a restriction were applied to the set of parameters, so one parameter degree of freedom is deducted.

---

## BOUNDS Statement

**BOUNDS** *inequality* <, ..., *inequality* > ;

The **BOUNDS** statement restricts the parameter estimates so that they lie within specified regions. In each **BOUNDS** statement, you can specify a series of boundary values separated by commas. The series of bounds is applied simultaneously. Each boundary specification consists of a list of parameters, an inequality comparison operator, and a value. In a single-bounded expression, these three elements follow one another in the order described. The following are examples of valid single-bounded expressions:

```
bounds a1-a10 <= 20;
bounds c > 30;
bounds a b c > 0;
```

Multiple-bounded expressions are also permitted. For example:

```
bounds 0 <= B<= 10;
bounds 15 < x1 <= 30;
bounds r <= s <= p < q;
```

If you need to restrict an expression involving several parameters (for example,  $\alpha + \beta < 1$ ), you can reparameterize the model so that the expression becomes a parameter or so that the boundary constraint can be expressed as a simple relationship between two parameters. For example, the boundary constraint  $\alpha + \beta < 1$  in the model

```
model y = alpha + beta*x;
```

can be achieved by parameterizing  $\theta = 1 - \beta$  as follows:

```
bounds alpha < theta;
model y = alpha + (1-theta)*x;
```

Starting with SAS 7.01, Lagrange multipliers are reported for all bounds that are enforced (active) when the estimation terminates. In the “Parameter Estimates” table, the Lagrange multiplier estimates are identified with names *Bound1*, *Bound2*, and so forth. An active bound is treated as if a restriction were applied to the set of parameters so that one parameter degree of freedom is deducted. You can use the `UNCORRECTEDDF` option to prevent the loss of degrees of freedom when bounds are active.

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC NLIN to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NLIN procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## CONTROL Statement

**CONTROL** *variable* <=*values*> <... *variable* <=*values*>> ;

The CONTROL statement declares control variables and specifies their values. A control variable is like a retained variable (see the section “RETAIN Statement” on page 5282) except that it is retained *across* iterations, and the derivative of the model with respect to a control variable is always zero.

---

## DER Statement

**DER.** *parameter=expression ;*

**DER.** *parameter.parameter=expression ;*

The DER statement specifies first or second partial derivatives. By default, analytical derivatives are automatically computed. However, you can specify the derivatives yourself by using the DER.parm syntax. Use the first form shown to specify first partial derivatives, and use the second form to specify second partial derivatives. Note that the DER.parm syntax is retained for backward compatibility. The automatic analytical derivatives are, in general, a better choice. For additional information about automatic analytical derivatives, see the section “Automatic Derivatives” on page 5284.

For most of the computational methods, you need only specify the first partial derivative with respect to each parameter to be estimated. For the NEWTON method, specify both the first and the second derivatives. If any needed derivatives are not specified, they are automatically computed.

The expression can be an algebraic representation of the partial derivative of the expression in the MODEL statement with respect to the parameter or parameters that appear on the left side of the DER statement. Numerical derivatives can also be used. The expression in the DER statement must conform to the rules for a valid SAS expression, and it can include any quantities that the MODEL statement expression contains.

---

## ID Statement

**ID** *variables ;*

The ID statement specifies additional variables to place in the output data set created by the OUTPUT statement. Any variable on the left side of any assignment statement is eligible. Also, the special variables created by the procedure can be specified. Variables in the input data set do not need to be specified in the ID statement since they are automatically included in the output data set.

---

## MODEL Statement

**MODEL** *dependent = expression ;*

The MODEL statement defines the prediction equation by declaring the dependent variable and defining an expression that evaluates predicted values. The expression can be any valid SAS expression that yields a numeric result. The expression can include parameter names, variables in the data set, and variables created by programming statements in the NLIN procedure. Any operators or functions that can be used in a DATA step can also be used in the MODEL statement.

A statement such as

```
model y=expression;
```

is translated into the form

```
model .y=expression;
```

using the compound variable name `model.y` to hold the predicted value. You can use this assignment directly as an alternative to the `MODEL` statement. Either a `MODEL` statement or an assignment to a compound variable such as `model.y` must appear.

## OUTPUT Statement

**OUTPUT** **OUT**=*SAS-data-set keyword=names* <... *keyword=names*> </ *options* > ;

The `OUTPUT` statement specifies an output data set to contain statistics calculated for each observation. For each statistic, specify the keyword, an equal sign, and a variable name for the statistic in the output data set. All of the names appearing in the `OUTPUT` statement must be valid SAS names, and none of the new variable names can match a variable already existing in the data set to which `PROC NLIN` is applied.

If an observation includes a missing value for one of the independent variables, both the predicted value and the residual value are missing for that observation. If the iterations fail to converge, all the values of all the variables named in the `OUTPUT` statement are missing values.

Table 63.4 summarizes the options available in the `OUTPUT` statement.

**Table 63.4** OUTPUT Statement Options

| Option                                              | Description                                                                                      |
|-----------------------------------------------------|--------------------------------------------------------------------------------------------------|
| <b>Output data set and OUTPUT statement options</b> |                                                                                                  |
| <code>ALPHA=</code>                                 | Specifies the level of significance $\alpha$                                                     |
| <code>DER</code>                                    | Saves the first derivatives of the model                                                         |
| <code>OUT=</code>                                   | Specifies the output data set                                                                    |
| <b>Keyword options</b>                              |                                                                                                  |
| <code>H=</code>                                     | Specifies the tangential leverage                                                                |
| <code>J=</code>                                     | Specifies the Jacobian leverage                                                                  |
| <code>L95=</code>                                   | Specifies the lower bound of an approximate 95% prediction interval                              |
| <code>L95M=</code>                                  | Specifies the lower bound of an approximate 95% confidence interval for the mean                 |
| <code>LCL=</code>                                   | Specifies the lower bound of an approximate $100(1 - \alpha)\%$ prediction interval              |
| <code>LCLM=</code>                                  | Specifies the lower bound of an approximate $100(1 - \alpha)\%$ confidence interval for the mean |
| <code>LMAX=</code>                                  | Specifies the direction of maximum local influence                                               |
| <code>PARMS=</code>                                 | Specifies the parameter estimates                                                                |
| <code>PREDICTED=</code>                             | Specifies the predicted values                                                                   |
| <code>PROJRES=</code>                               | Specifies the projected residuals                                                                |
| <code>PROJSTUDENT=</code>                           | Specifies the standardized projected residuals                                                   |
| <code>RESEXPEC=</code>                              | Specifies the mean of the residuals                                                              |
| <code>RESIDUAL=</code>                              | Specifies the residuals                                                                          |
| <code>SSE=</code>                                   | Specifies the residual sum of squares                                                            |
| <code>STDI=</code>                                  | Specifies the standard error of the individual predicted value                                   |
| <code>STDP=</code>                                  | Specifies the standard error of the mean predicted value                                         |
| <code>STDR=</code>                                  | Specifies the standard error of the residual                                                     |
| <code>STUDENT=</code>                               | Specifies the standardized residuals                                                             |

Table 63.4 *continued*

| Option  | Description                                                                                      |
|---------|--------------------------------------------------------------------------------------------------|
| U95=    | Specifies the upper bound of an approximate 95% prediction interval                              |
| U95M=   | Specifies the upper bound of an approximate 95% confidence interval for the mean                 |
| UCL=    | Specifies the upper bound of an approximate $100(1 - \alpha)\%$ prediction interval              |
| UCLM=   | Specifies the upper bound of an approximate $100(1 - \alpha)\%$ confidence interval for the mean |
| WEIGHT= | Specifies the special variable <code>_WEIGHT_</code>                                             |

You can specify the following options in the OUTPUT statement. For a description of computational formulas, see Chapter 4, “Introduction to Regression Procedures.”

**OUT=SAS-data-set**

specifies the SAS data set to be created by PROC NLIN when an OUTPUT statement is included. The new data set includes the variables in the input data set. Also included are any **ID** variables specified in the **ID** statement, plus new variables with names that are specified in the OUTPUT statement.

The following values can be calculated and output to the new data set.

**H=name**

specifies a variable that contains the tangential leverage. See the section “Leverage in Nonlinear Regression” on page 5288 for details.

**J=name**

specifies a variable that contains the Jacobian leverage. See the section “Leverage in Nonlinear Regression” on page 5288 for details.

**L95=name**

specifies a variable that contains the lower bound of an approximate 95% confidence interval for an individual prediction. This includes the variance of the error as well as the variance of the parameter estimates. See also the description for the **U95=** option later in this section.

**L95M=name**

specifies a variable that contains the lower bound of an approximate 95% confidence interval for the expected value (mean). See also the description for the **U95M=** option later in this section.

**LCL=name**

specifies a variable that contains the lower bound of an approximate  $100(1 - \alpha)\%$  confidence interval for an individual prediction. The  $\alpha$  level is equal to the value of the **ALPHA=** option in the OUTPUT statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then  $\alpha = 0.05$  by default, resulting in a lower bound for an approximate 95% confidence interval. For the corresponding upper bound, see the **UCL** keyword.

**LCLM=***name*

specifies a variable that contains the lower bound of an approximate  $100(1 - \alpha)\%$  confidence interval for the expected value (mean). The  $\alpha$  level is equal to the value of the **ALPHA=** option in the **OUTPUT** statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then  $\alpha = 0.05$  by default, resulting in a lower bound for an approximate 95% confidence interval. For the corresponding lower bound, see the **UCLM** keyword.

**LMAX=***name*

specifies a variable that contains the direction of maximum local influence of an additive perturbation of the response variable. See the section “[Local Influence in Nonlinear Regression](#)” on page 5288 for details.

**PARMS=***names*

specifies variables in the output data set that contains parameter estimates. These can be the same variable names that are listed in the **PARAMETERS** statement; however, you can choose new names for the parameters identified in the sequence from the parameter estimates table. A note in the log indicates which variable in the output data set is associated with which parameter name. Note that, for each of these new variables, the values are the same for every observation in the new data set.

**PREDICTED=***name***P=***name*

specifies a variable in the output data set that contains the predicted values of the dependent variable.

**PROJRES=***name*

specifies a variable that contains the projected residuals obtained by projecting the residuals (ordinary residuals) into the null space of  $(X|H)$ . For the ordinary residuals, see the **RESIDUAL=** option later in this section. The section “[Residuals in Nonlinear Regression](#)” on page 5289 describes the statistical properties of projected residuals in nonlinear regression.

**PROJSTUDENT=***name*

specifies a variable that contains the standardized projected residuals. See the section “[Residuals in Nonlinear Regression](#)” on page 5289 for details and the **STUDENT=** option later in this section.

**RESEXPEC=***name*

specifies a variable that contains the mean of the residuals. In contrast to linear regressions where the mean of the residuals is zero, in nonlinear regression the residuals have a nonzero mean value and show a negative covariance with the mean response. See the section “[Residuals in Nonlinear Regression](#)” on page 5289 for details.

**RESIDUAL=***name***R=***name*

specifies a variable in the output data set that contains the residuals. See also the description of **PROJRES=** option stated previously in this section and the section “[Residuals in Nonlinear Regression](#)” on page 5289 for the statistical properties of residuals and projected residuals.

**SSE=***name***ESS=***name*

specifies a variable in the output data set that contains the residual sum of squares finally determined by the procedure. The value of the variable is the same for every observation in the new data set.

**STDI=***name*

specifies a variable that contains the standard error of the individual predicted value.

**STDP=***name*

specifies a variable that contains the standard error of the mean predicted value.

**STDR=***name*

specifies a variable that contains the standard error of the residual.

**STUDENT=***name*

specifies a variable that contains the standardized residuals. These are residuals divided by their estimated standard deviation. See the **PROJSTUDENT=** option defined previously in this section and the section “Residuals in Nonlinear Regression” on page 5289 for the statistical properties of residuals and projected residuals.

**U95=***name*

specifies a variable that contains the upper bound of an approximate 95% confidence interval for an individual prediction. See also the description for the **L95=** option.

**U95M=***name*

specifies a variable that contains the upper bound of an approximate 95% confidence interval for the expected value (mean). See also the description for the **L95M=** option.

**UCL=***name*

specifies a variable that contains the upper bound of an approximate  $100(1 - \alpha)\%$  confidence interval for an individual prediction. The  $\alpha$  level is equal to the value of the **ALPHA=** option in the **OUTPUT** statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then  $\alpha = 0.05$  by default, resulting in an upper bound for an approximate 95% confidence interval. For the corresponding lower bound, see the **LCL** keyword.

**UCLM=***name*

specifies a variable that contains the upper bound of an approximate  $100(1 - \alpha)\%$  confidence interval for the expected value (mean). The  $\alpha$  level is equal to the value of the **ALPHA=** option in the **OUTPUT** statement or, if this option is not specified, to the value of the **ALPHA=** option in the **PROC NLIN** statement. If neither of these options is specified, then  $\alpha = 0.05$  by default, resulting in an upper bound for an approximate 95% confidence interval. For the corresponding lower bound, see the **LCLM** keyword.

**WEIGHT=***name*

specifies a variable in the output data set that contains values of the special variable **\_WEIGHT\_**.

You can specify the following options in the **OUTPUT** statement after a slash (/):

**ALPHA= $\alpha$** 

specifies the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals. By default,  $\alpha$  is equal to the value of the **ALPHA=** option in the **PROC NLIN** statement or 0.05 if that option is not specified. You can supply values that are strictly between 0 and 1.

**DER**

saves the first derivatives of the model with respect to the parameters to the **OUTPUT** data set. The derivatives are named **DER\_parmname**, where “parmname” is the name of the model parameter in your **NLIN** statements. You can use the **DER** option to extract the  $\mathbf{X} = \partial f / \partial \boldsymbol{\beta}$  matrix into a SAS data set. For example, the following statements create the data set **nlinX**, which contains the **X** matrix:

```
proc nlin;
 parms theta1=155 theta3=0.04;
 model v = theta1*c / (theta3 + c);
 output out=nlinout / der;
run;

data nlinX;
 set nlinout (keep=DER_);
run;
```

The derivatives are evaluated at the final parameter estimates.

---

## PARAMETERS Statement

**PARAMETERS** < *parameter-specification* > < , ... , *parameter-specification* >  
< / **PDATA=SAS-data-set** > ;

**PARMS** < *parameter-specification* > < , ... , *parameter-specification* >  
< / **PDATA=SAS-data-set** > ;

A **PARAMETERS** (or **PARMS**) statement is required. The purpose of this statement is to provide starting values for the **NLIN** procedure. You can provide values that define a point in the parameter space or a set of points.

All parameters must be assigned starting values through the **PARAMETERS** statement. The **NLIN** procedure does not assign default starting values to parameters in your model that do not appear in the **PARAMETERS** statement. However, it is not necessary to supply parameters and starting values explicitly through a *parameter-specification*. Starting values can also be provided through a data set. The names assigned to parameters must be valid SAS names and must not coincide with names of variables in the input data set (see the **DATA=** option in the **PROC NLIN** statement). Parameters that are assigned starting values through the **PARAMETERS** statement can be omitted from the estimation, for example, if the expression in the **MODEL** statement does not depend on them.

### Assigning Starting Values with Parameter-Specification

A *parameter-specification* has the general form

*name* = *value-list*

where *name* identifies the parameter and *value-list* provides the set of starting values for the parameter.

Very often, the *value-list* contains only a single value, but more general and flexible list specifications are possible:

|                                                   |                                                                                                                      |
|---------------------------------------------------|----------------------------------------------------------------------------------------------------------------------|
| <i>m</i>                                          | a single value                                                                                                       |
| <i>m</i> 1, <i>m</i> 2, . . . , <i>m</i> <i>n</i> | several values                                                                                                       |
| <i>m</i> TO <i>n</i>                              | a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals 1    |
| <i>m</i> TO <i>n</i> BY <i>i</i>                  | a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment is <i>i</i> |
| <i>m</i> 1, <i>m</i> 2 TO <i>m</i> 3              | mixed values and sequences                                                                                           |

When you specify more than one value for a parameter, PROC NLIN sorts the values in ascending sequence and removes duplicate values from the parameter list before forming the grid for the parameter search. If you specify several values for each parameter, PROC NLIN evaluates the model at each point on the grid. The iterations then commence from the point on the grid that yields the smallest objective function value.

For example, the following PARMs statement specifies five parameters and sets their possible starting values as shown in the table:

```
parms b0 = 0
 b1 = 4 to 8
 b2 = 0 to .6 by .2
 b3 = 1, 10, 100
 b4 = 0, .5, 1 to 4;
```

| Possible starting values |    |     |     |     |
|--------------------------|----|-----|-----|-----|
| B0                       | B1 | B2  | B3  | B4  |
| 0                        | 4  | 0.0 | 1   | 0.0 |
|                          | 5  | 0.2 | 10  | 0.5 |
|                          | 6  | 0.4 | 100 | 1.0 |
|                          | 7  | 0.6 |     | 2.0 |
|                          | 8  |     |     | 3.0 |
|                          |    |     |     | 4.0 |

Residual sums of squares are calculated for each of the  $1 \times 5 \times 4 \times 3 \times 6 = 360$  combinations of possible starting values. (Specifying a large grid of values can take considerable computing time.)

If you specify a starting value with a *parameter-specification*, any starting values provided for this parameter through the PDATA= data set are ignored. The *parameter-specification* overrides the information in the PDATA= data set. When you specify a BY statement, the same *parameter-specification* is applied in each BY group. To vary starting values with BY groups, use the PDATA= option in the PARAMETERS statement as described in the following paragraphs.

## Assigning Starting Values from a SAS Data Set

The PDATA= option in the PARAMETERS statement enables you to assign starting values for parameters through a SAS data set. The data set must contain at least two variables that identify the parameter and contain starting values, respectively. The *character* variable identifying the parameters must be named Parameter or Parm. The *numeric* variable containing the starting value must be named Estimate or Est. This enables you, for example, to use the contents of the “ParameterEstimates” table from one PROC NLIN run to supply starting values for a subsequent run, as in the following example:

```
proc nlin data=FirstData;
 parameters alpha=100 beta=3 gamma=4;
 < other NLIN statements >
 model y = ... ;
 ods output ParameterEstimates=pest;
run;

proc nlin data=SecondData;
 parameters / pdata=pest;
 Switch = 1/(1+gamma*exp(beta*log(dose)));
 model y = alpha*Switch;
run;
```

You can specify multiple values for a parameter in the PDATA= data set, and the parameters can appear in any order. The starting values are collected by parameter and arranged in ascending order, and duplicate values are removed. The parameter names in the PDATA= data set are not case sensitive. For example, the following DATA step defines starting values for three parameters and a starting grid with  $1 \times 3 \times 1 = 3$  points:

```
data test;
 input Parameter $ Estimate;
 datalines;
alpha 100
BETA 4
beta 4.1
beta 4.2
beta 4.1
gamma 30
;
```

If starting values for a parameter are provided through the PDATA= data set and through an explicit *parameter-specification*, the latter takes precedence.

When you specify a BY statement, you can control whether the same starting values are applied to each BY group or whether the starting values are varied. If the BY variables are not present in the PDATA= data set, the entire contents of the PDATA= data set are applied in each BY group. If the BY variables are present in the PDATA= data set, then BY-group-specific starting values are assigned.

## PROFILE Statement

**PROFILE** *parameter* <...*parameter*> </*options*> ;

A PROFILE statement selects parameters for profiling to assess their nonlinear characteristics. It can also gauge the influence of each observation on the selected parameters. To produce the plots that are controlled by the PROFILE statement, ODS Graphics must be enabled. PROC NLIN ignores PROFILE statements for nonconvergent and singular models.

Table 63.6 summarizes the *options* available in the PROFILE statement.

**Table 63.6** Summary of Options in PROFILE Statement

| Option    | Description                                                                                        |
|-----------|----------------------------------------------------------------------------------------------------|
| ALL       | Produces all profiling related plots and statistics                                                |
| CONFCURV  | Produces confidence curves for the listed parameters                                               |
| JACKKNIFE | Produces plots of the absolute relative percentage change by observation for the listed parameters |
| PROFDATA= | Specifies the profile output data set                                                              |
| RANGE=    | Specifies a profiling range                                                                        |
| TPLOT     | Produces profile <i>t</i> plots for the listed parameters                                          |

### ALL

produces all appropriate plots for the parameters that are listed in the PROFILE statement. This option overrides all other *options*. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set.

### CONFCURV

produces confidence curves for each parameter listed in the PROFILE statement. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set. See the section “Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates” on page 5290 for details.

### JACKKNIFE

produces, for each parameter listed in the PROFILE statement, plots of absolute relative percentage change in the value of the parameter that results from a fit to a jackknife-resampled datum versus observation number. The jackknife resampling is performed with a leave-one-out method. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set. See the section “Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates” on page 5290 for details.

### PROFDATA=*SAS-data-set*

specifies the SAS data set to be created by PROC NLIN when a PROFILE statement is included. See the section “Output Data Sets” on page 5299 for details about this data set.

**RANGE=** $\beta_f$  to  $\beta_t$  by  $\beta_b$ 

specifies a profiling range for each parameter listed in the PROFILE statement.  $\beta_f$ ,  $\beta_t$  and  $\beta_b$  represent the starting, final, and consecutive incremental values of the range in terms of the standard errors of the parameters to be profiled. If you do not specify the RANGE= option, PROC NLIN uses  $-2$ ,  $2$ , and  $0.2$  as default values for  $\beta_f$ ,  $\beta_t$ , and  $\beta_b$ , respectively. For example, if parameter  $\theta$  is in the PROFILE statement, then during the profiling of  $\theta$ , PROC NLIN performs approximately  $(\beta_t - \beta_f)/\beta_b$  number of constrained optimizations. At the  $i$ th constrained optimization, the value of  $\theta$  is constrained to  $\theta_i$ ,

$$\theta_i = \hat{\theta} + \text{stderr}_\theta \left( \beta_f + i \frac{(\beta_t - \beta_f)}{\beta_b} \right)$$

and the rest of the parameters are freely optimized. In the preceding expression,  $\hat{\theta}$  and  $\text{stderr}_\theta$  are the estimated value and standard error, respectively, for  $\theta$ . If parameter bounds are specified with BOUNDS statements, PROC NLIN enforces those bounds during the profiling optimizations.

**NOTE:** The profiling optimizations are performed using quasi-Newton algorithm. During these optimizations, any optimization options specified in the PROC NLIN statement and the `_LOSS_` variable are ignored.

**TPLOT**

produces profile  $t$  plots for each parameter listed in the PROFILE statement. If the PROFDATA= option is specified, the values of the corresponding statistics are written to the data set. See the section “Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates” on page 5290 for details.

**RETAIN Statement**

**RETAIN** *variable* <=*values*> <... *variable* <=*values*>> ;

The RETAIN statement declares retained variables and specifies their values. A retained variable is like a control variable (see the section “CONTROL Statement” on page 5272) except that it is retained only *within* iterations. An iteration involves a single pass through the data set.

**Other Programming Statements**

PROC NLIN supports many statements that are similar to SAS programming statements used in a DATA step. However, there are some differences in capabilities; for additional information, see also the section “Incompatibilities with SAS 6.11 and Earlier Versions of PROC NLIN” on page 5303.

Several SAS programming statements can be used after the PROC NLIN statement. These statements can appear anywhere in the PROC NLIN code, but new variables must be created before they appear in other statements. For example, the following statements are valid since they create the variable `temp` before it is used in the MODEL statement:

```
proc nlin;
 parms b0=0 to 2 by 0.5 b1=0.01 to 0.09 by 0.01;
 temp = exp(-b1*x);
 model y=b0*(1-temp);
run;
```

The following statements result in missing values for y because the variable temp is undefined before it is used:

```
proc nlin;
 parms b0=0 to 2 by 0.5 b1=0.01 to 0.09 by 0.01;
 model y = b0*(1-temp);
 temp = exp(-b1*x);
run;
```

PROC NLIN can process assignment statements, explicitly or implicitly subscripted ARRAY statements, explicitly or implicitly subscripted array references, IF statements, SAS functions, and program control statements. You can use programming statements to create new SAS variables for the duration of the procedure. These variables are not included in the data set to which PROC NLIN is applied. Program statements can include variables in the **DATA=** data set, parameter names, variables created by preceding programming statements within PROC NLIN, and special variables used by PROC NLIN. The following SAS programming statements can be used in PROC NLIN:

```
ABORT;
ARRAY arrayname < [dimensions] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
 < , expression < TO expression > < BY expression > > ...
 < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
 ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
 OTHERWISE program-statement;
```

These statements can use the special variables created by PROC NLIN. See the section “Special Variables” on page 5291 for more information.

## Details: NLIN Procedure

### Automatic Derivatives

Depending on the optimization method you select, analytical first- and second-order derivatives are computed automatically. Derivatives can still be supplied using the DER.parm syntax. These DER.parm derivatives are not verified by the differentiator. If any needed derivatives are not supplied, they are computed and added to the programming statements. To view the computed derivatives, use the [LISTDER](#) or [LIST](#) option.

The following model is solved using Newton's method. Analytical first- and second-order derivatives are automatically computed. The compiled program code is shown in [Figure 63.6](#).

```
proc nlin data=Enzyme method=newton list;
 parms x1=4 x2=2;
 model Velocity = x1 * exp (x2 * Concentration);
run;
```

**Figure 63.6** Model and Derivative Code Output

| 1                                | 1429:4   | @MODEL.Velocity/@x2 = x1 * Concentration<br>* EXP(x2 * Concentration);                         |
| 1                                | 1429:4   | @@MODEL.Velocity/@x1/@x2 = Concentration<br>* EXP(x2 * Concentration);                         |
| 1                                | 1429:4   | @@MODEL.Velocity/@x2/@x1 = Concentration<br>* EXP(x2 * Concentration);                         |
| 1                                | 1429:4   | @@MODEL.Velocity/@x2/@x2 = x1<br>* Concentration * Concentration<br>* EXP(x2 * Concentration); |

Note that all the derivatives require the evaluation of EXP(X2 \* Concentration). The actual machine-level code is displayed if you specify the [LISTCODE](#) option, as in the following statements:

```
proc nlin data=Enzyme method=newton listcode;
 parms x1=4 x2=2;
 model Velocity = x1 * exp (x2 * Concentration);
run;
```

Note that, in the generated code, only one exponentiation is performed ([Figure 63.7](#)). The generated code reuses previous operations to be more efficient.

Figure 63.7 LISTCODE Output

## Measures of Nonlinearity and Diagnostics

A “close-to-linear” nonlinear regression model, in the sense of Ratkowsky (1983, 1990), is a model in which parameter estimators have properties similar to those in a linear regression model. That is, the least squares estimators of the parameters are close to being unbiased and normally distributed, and they have minimum variance.

A nonlinear regression model sometimes fails to be close to linear due to the properties of one or several parameters. When this occurs, bias in the parameter estimates can render inferences that use the reported standard errors and confidence limits invalid.

PROC NLIN provides various measures of nonlinearity. To assess the nonlinearity of a model-data combination, you can use both of the following complementary sets of measures:

- Box’s bias (Box 1971) and Hougaard’s skewness (Hougaard 1982, 1985) of the least squares parameter estimates
- curvature measures of nonlinearity (Bates and Watts 1980).

Furthermore, PROC NLIN provides residual, leverage, and local-influence diagnostics (St. Laurent and Cook 1993).

In the following several sections, these nonlinearity measures and diagnostics are discussed. For this material, several basic definitions are required. Let  $\mathbf{X}$  be the Jacobian matrix for the model,  $\mathbf{X} = \frac{\partial \mathbf{f}}{\partial \boldsymbol{\beta}}$ , and let  $\mathbf{Q}$  and  $\mathbf{R}$  be the components of the QR decomposition of  $\mathbf{X} = \mathbf{QR}$  of  $\mathbf{X}$ , where  $\mathbf{Q}$  is an  $(n \times n)$  orthogonal matrix. Finally, let  $\mathbf{B}$  be the inverse of the matrix constructed from the first  $p$  rows of the  $(n \times p)$  dimensional matrix  $\mathbf{R}$  (that is,  $\mathbf{B} = \mathbf{R}_p^{-1}$ ). Next define

$$\begin{aligned} [\mathbf{H}_j]_{kl} &= \frac{\partial^2 f_j}{\partial \beta_k \partial \beta_l} \\ [\mathbf{U}_j]_{kl} &= \sum_{mn} \mathbf{B}'_{km} [\mathbf{H}_j]_{mn} \mathbf{B}_{nl} \\ [\mathbf{A}_j]_{kl} &= \sqrt{p \times \text{mse}} \sum_m \mathbf{Q}'_{jm} [\mathbf{U}_m]_{kl}, \end{aligned}$$

where  $\mathbf{H}$ ,  $\mathbf{U}$  and the acceleration array  $\mathbf{A}$  are three-dimensional  $(n \times p \times p)$  matrices. The first  $p$  faces of the acceleration array constitute a  $(p \times p \times p)$  parameter-effects array and the last  $(n - p)$  faces constitute the  $(n - p \times p \times p)$  intrinsic curvature array (Bates and Watts 1980). The previous and subsequent quantities are computed at the least squares parameter estimators.

### Box's Measure of Bias

The degree to which parameter estimators exhibit close-to-linear behavior can be assessed with Box's bias (Box 1971) and Hougaard's measure of skewness (Hougaard 1982, 1985). The bias and percentage bias measures are available through the **BIAS** option in the **PROC NLIN** statement. Box's bias measure is defined as

$$\widehat{\text{E}}[\widehat{\theta} - \theta] = -\frac{\sigma^2}{2} (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \sum_{i=1}^n w_i \mathbf{x}'_i \text{Tr} \left( (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} [\mathbf{H}_i] \right)$$

where  $\sigma^2 = \text{mse}$  if the **SIGSQ** option is not set. Otherwise,  $\sigma^2$  is the value you set with the **SIGSQ** option.  $\mathbf{W}$  is the diagonal weight matrix specified with the **\_WEIGHT\_** variable (or the identity matrix if **\_WEIGHT\_** is not defined) and  $[\mathbf{H}_i]$  is the  $(p \times p)$  Hessian matrix at the  $i$ th observation. In the case of unweighted least squares, the bias formula can be expressed in terms of the acceleration array  $\mathbf{A}$ ,

$$\widehat{\text{E}}[\widehat{\theta}_i - \theta_i] = -\frac{\sigma^2}{2p \times \text{mse}} \sum_{j,k=1}^p \mathbf{B}_{ij} [\mathbf{A}_j]_{kk}$$

As the preceding formulas illustrate, the bias depends solely on the parameter-effects array, thereby permitting its reduction through reparameterization. **Example 63.4** shows how changing the parameterization of a four-parameter logistic model can reduce the bias. Ratkowsky (1983, p. 21) recommends that you consider reparameterization if the percentage bias exceeds 1%.

### Hougaard's Measure of Skewness

In addition to Box's bias, Hougaard's measure of skewness,  $g_{1i}$  (Hougaard 1982, 1985), is also provided in PROC NLIN to assess the close-to-linear behavior of parameter estimators. This measure is available

through the **HOUGAARD** option in the **PROC NLIN** statement. Hougaard's skewness measure for the  $i$ th parameter is based on the third central moment, defined as

$$E \left[ \widehat{\theta}_i - E(\widehat{\theta}_i) \right]^3 = -(\sigma^2)^2 \sum_{jkl} [\mathbf{L}]_{ij} [\mathbf{L}]_{ik} [\mathbf{L}]_{il} \left( [\mathbf{V}_j]_{kl} + [\mathbf{V}_k]_{jl} + [\mathbf{V}_l]_{jk} \right)$$

where the sum is a triple sum over the number of parameters and

$$\mathbf{L} = (\mathbf{X}'\mathbf{X})^{-1} = \left( \frac{\partial \mathbf{f}}{\partial \boldsymbol{\beta}'} \frac{\partial \mathbf{f}}{\partial \boldsymbol{\beta}} \right)^{-1}$$

The term  $[\mathbf{L}]_{ij}$  denotes the value in row  $i$ , column  $j$  of the matrix  $\mathbf{L}$ . (Hougaard (1985) uses superscript notation to denote elements in this inverse.) The matrix  $\mathbf{V}$  is a three-dimensional ( $p \times p \times p$ ) array

$$[\mathbf{V}_j]_{kl} = \sum_{m=1}^n \frac{\partial F_m}{\partial \beta_j} \frac{\partial^2 F_m}{\partial \beta_k \partial \beta_l}$$

The third central moment is then normalized using the standard error as

$$G_{1i} = E \left[ \widehat{\theta}_i - E(\widehat{\theta}_i) \right]^3 / (\sigma^2 \times [\mathbf{L}]_{ii})^{3/2}$$

The previous expressions depend on the unknown values of the parameters and on the residual variance  $\sigma^2$ . In order to evaluate the Hougaard measure in a particular data set, the NLIN procedure computes

$$g_{1i} = \widehat{E} \left[ \widehat{\theta}_i - E(\widehat{\theta}_i) \right]^3 / \left( \text{mse} \times [\widehat{\mathbf{L}}]_{ii} \right)^{3/2}$$

$$\widehat{E} \left[ \widehat{\theta}_i - E(\widehat{\theta}_i) \right]^3 = -\text{mse}^2 \sum_{jkl} [\widehat{\mathbf{L}}]_{ij} [\widehat{\mathbf{L}}]_{ik} [\widehat{\mathbf{L}}]_{il} \left( [\widehat{\mathbf{V}}_j]_{kl} + [\widehat{\mathbf{V}}_k]_{jl} + [\widehat{\mathbf{V}}_l]_{jk} \right)$$

Following Ratkowsky (1990, p. 28), the parameter  $\theta_i$  is considered to be very close to linear, reasonably close, skewed, or quite nonlinear according to the absolute value of the Hougaard measure  $|g_{1i}|$  being less than 0.1, between 0.1 and 0.25, between 0.25 and 1, or greater than 1, respectively.

## Relative Curvature Measures of Nonlinearity

Bates and Watts (1980) formulated the maximum parameter-effects and maximum intrinsic curvature measures of nonlinearity to assess the close-to-linear behavior of nonlinear models. Ratkowsky (1990) notes that of the two curvature components in a nonlinear model, the parameter-effects curvature is typically larger. It is this component that you can affect by changing the parameterization of a model. PROC NLIN provides these two measures of curvature both through the **STATS plot-option** and through the **NLINMEASURES** option in the **PROC NLIN** statement.

The maximum parameter-effects and intrinsic curvatures are defined, in a compact form, as

$$\mathbf{T}^\tau = \max_{\boldsymbol{\theta}} \left\| \boldsymbol{\theta}' \mathbf{A}^\tau \boldsymbol{\theta} \right\|$$

$$\mathbf{T}^\eta = \max_{\boldsymbol{\theta}} \left\| \boldsymbol{\theta}' \mathbf{A}^\eta \boldsymbol{\theta} \right\|$$

where  $\mathbf{T}^\tau$  and  $\mathbf{T}^\eta$  denote the maximum parameter-effects and intrinsic curvatures, while  $\mathbf{A}^\tau$  and  $\mathbf{A}^\eta$  stand for the parameter-effects and intrinsic curvature arrays. The maximization is carried out over a unit-vector

of the parameter values (Bates and Watts 1980). In line with Bates and Watts (1980), PROC NLIN takes  $10^{-4}$  as the convergence tolerance for the maximum intrinsic and parameter-effects curvatures. Note that the preceding matrix products involve contraction of the faces of the three-dimensional acceleration arrays with the normalized parameter vector,  $\theta$ . The corresponding expressions for the RMS (root mean square) parameter-effects and intrinsic curvatures can be found in Bates and Watts (1980).

The statistical significance of  $T^\tau$  and  $T^\eta$  and the corresponding RMS values can be assessed by comparing these values with  $1/\sqrt{F}$ , where  $F$  is the upper  $\alpha \times 100\%$  quantile of an  $F$  distribution with  $p$  and  $n - p$  degrees of freedom (Bates and Watts 1980).

One motivation for fitting a nonlinear model in a different parameterization is to obtain a particular interpretation and to give parameter estimators more close-to-linear behavior. [Example 63.4](#) shows how changing the parameterization of a four-parameter logistic model can reduce the parameter-effects curvature and can yield a useful parameter interpretation at the same time. In addition, [Example 63.6](#) shows a nonlinear model with a high intrinsic curvature and the corresponding diagnostics.

## Leverage in Nonlinear Regression

In contrast to linear regression, there are several measures of leverage in nonlinear regression. Furthermore, in nonlinear regression, the effect of a change in the  $i$ th response on the  $i$ th predicted value might depend on both the size of the change and the  $i$ th response itself (St. Laurent and Cook 1992). As a result, some observations might show superleverage —namely, leverages in excess of one (St. Laurent and Cook 1992).

PROC NLIN provides two measures of leverages: tangential and Jacobian leverages through the PLOTS option in the PROC NLIN statement and the H= and J= options of OUTPUT statement. Tangential leverage,  $H_i$ , is based on approximating the nonlinear model with a linear model that parameterizes the tangent plane at the least squares parameter estimators. In contrast, Jacobian leverage,  $J_i$ , is simply defined as the instantaneous rate of change in the  $i$ th predicted value with respect to the  $i$ th response (St. Laurent and Cook 1992).

The mathematical formulas for tangential and Jacobian leverages are

$$H_i = w_i \mathbf{x}_i (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{x}_i'$$

$$J_i = w_i \mathbf{x}_i (\mathbf{X}'\mathbf{W}\mathbf{X} - [\mathbf{W} \mathbf{e}] [\mathbf{H}])^{-1} \mathbf{x}_i',$$

where  $\mathbf{e}$  is the vector of residuals,  $\mathbf{W}$  is the diagonal weight matrix if you specify the special variable `_WEIGHT_` and otherwise the identity matrix, and  $i$  indexes the corresponding quantities for the  $i$ th observation. The brackets `[.][.]` indicate column multiplication as defined in Bates and Watts (1980). The preceding formula for tangential leverage holds if the gradient, Marquardt, or Gauss methods are used. For the Newton method, the tangential leverage is set equal to the Jacobian leverage.

In a model with a large intrinsic curvature, the Jacobian and tangential leverages can be very different. In fact, the two leverages are identical only if the model provides an exact fit to the data ( $\mathbf{e} = 0$ ) or the model is intrinsically linear (St. Laurent and Cook 1993). This is also illustrated by the leverage plot and nonlinearity measures provided in [Example 63.6](#).

## Local Influence in Nonlinear Regression

St. Laurent and Cook (1993) suggest using  $l_{\max}$ , the direction that yields the maximum normal curvature, to assess the local influence of an additive perturbation to the response variable on the estimation of the

parameters and variance of a nonlinear model. Defining the normal curvature components

$$C_\theta = \max_l \frac{2}{\sigma^2} l' \mathbf{J} l$$

$$C_\sigma = \max_l \frac{4}{\sigma^2} l' \mathbf{P}_e l$$

where  $\mathbf{J}$  is the Jacobian leverage matrix and  $\mathbf{P}_e = \mathbf{e}\mathbf{e}'/(\mathbf{e}'\mathbf{e})$ , you choose the  $l_{\max}$  that results in the maximum of the two curvature components (St. Laurent and Cook 1993). PROC NLIN provides  $l_{\max}$  through the PLOTS option in the PROC NLIN statement and the LMAX= option in the OUTPUT statement. Example 63.6 shows a plot of  $l_{\max}$  for a model with high intrinsic curvature.

## Residuals in Nonlinear Regression

If a nonlinear model is intrinsically nonlinear, using the residuals  $\mathbf{e} = \mathbf{y} - \hat{\mathbf{y}}$  for diagnostics can be misleading (Cook and Tsai 1985). This is due to the fact that in correctly specified intrinsically nonlinear models, the residuals have nonzero means and different variances, even when the original error terms have identical variances. Furthermore, the covariance between the residuals and the predicted values tends to be negative semidefinite, complicating the interpretation of plots based on  $\mathbf{e}$  (Cook and Tsai 1985).

Projected residuals are proposed by Cook and Tsai (1985) to overcome these shortcomings of residuals, which are henceforth called raw (ordinary) residuals to differentiate them from their projected counterparts. Projected residuals have zero means and are uncorrelated with the predicted values. In fact, projected residuals are identical to the raw residuals in intrinsically linear models.

PROC NLIN provides raw and projected residuals, along with their standardized forms. In addition, the mean or expectation of the raw residuals is available. These can be accessed with the PLOTS option in the PROC NLIN statement and the OUTPUT statement options PROJRES=, PROJSTUDENT=, RESEXPEC=, RESIDUAL= and STUDENT=.

Denote the projected residuals by  $\mathbf{e}_p$  and the expectation of the raw residuals by  $E[\mathbf{e}]$ . Then

$$\mathbf{e}_p = (\mathbf{I}_n - \mathbf{P}_{xh}) \mathbf{e}$$

$$E[\mathbf{e}_i] = -\frac{\sigma^2}{2} \sum_{j=1}^n \tilde{\mathbf{P}}_{x,ij} \text{Tr} \left( [\mathbf{H}_j] (\mathbf{X}'\mathbf{X})^{-1} \right)$$

where  $\mathbf{e}_i$  is the  $i$ th observation raw residual,  $\mathbf{I}_n$  is an  $n$ -dimensional identity matrix,  $\mathbf{P}_{xh}$  is the projector onto the column space of  $(\mathbf{X}|\mathbf{H})$ , and  $\tilde{\mathbf{P}}_x = \mathbf{I}_n - \mathbf{P}_x$ . The preceding formulas are general with the projectors defined accordingly to take the weighting into consideration. In unweighted least squares,  $E[\mathbf{e}]$  reduces to

$$E[\mathbf{e}] = -\frac{1}{2} \sigma^2 \tilde{\mathbf{Q}} \mathbf{a}$$

with  $\tilde{\mathbf{Q}}$  being the last  $n - p$  columns of the  $\mathbf{Q}$  matrix in the QR decomposition of  $\mathbf{X}$  and the  $(n - p)$  dimensional vector  $\mathbf{a}$  being defined in terms of the intrinsic acceleration array

$$\mathbf{a}_i = \sum_{j=1}^p [\mathbf{A}_{i+p}]_{jj}$$

Standardization of the projected residuals requires the variance of the projected residuals. This is estimated using the formula (Cook and Tsai 1985)

$$\sigma_p^2 = \frac{\mathbf{e}_p' \mathbf{e}_p}{\text{Tr}(\mathbf{I}_n - \mathbf{P}_{xh})}$$

The standardized raw and projected residuals, denoted by  $\tilde{\mathbf{e}}$  and  $\tilde{\mathbf{e}}_p$  respectively, are given by

$$\tilde{\mathbf{e}} = \frac{\sqrt{w_i} \mathbf{e}}{\sigma \sqrt{1 - \mathbf{P}_{x,ii}}}$$

$$\tilde{\mathbf{e}}_p = \frac{\sqrt{w_i} \mathbf{e}_p}{\sigma \sqrt{1 - \mathbf{P}_{xh,ii}}}$$

The use of raw and projected residuals for diagnostics in nonlinear regression is illustrated in [Example 63.6](#).

### Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates

The global measures of nonlinearity, discussed in the preceding section, are very useful for assessing the overall nonlinearity of the model. However, the impact of global nonlinearity on inference regarding subsets of the parameter set cannot be easily determined (Cook and Tsai 1985). The impact of the nonlinearity on the uncertainty of individual parameters can be efficiently described by profile  $t$  plots and confidence curves (Bates and Watts 1988; Cook and Weisberg 1990).

A profile  $t$  plot for parameter  $\theta$  is a plot of the likelihood ratio pivotal statistic,  $\tau(\theta)$ , and the corresponding Wald pivotal statistic,  $\sigma(\theta)$  (Bates and Watts 1988). The likelihood ratio pivotal statistic is defined as

$$\tau(\theta) = \text{sign}(\theta - \hat{\theta}) L(\theta)$$

with

$$L(\theta) = \left( \frac{\text{SSE}(\theta, \tilde{\Theta}) - \text{SSE}(\hat{\theta}, \hat{\Theta})}{\text{mse}} \right)^{1/2}$$

where  $\theta$  is the profile parameter and  $\Theta$  refers to the remaining parameters.  $\text{SSE}(\theta, \tilde{\Theta})$  is the sum of square errors where the profile parameter  $\theta$  is constrained at a given value and  $\tilde{\Theta}$  is the least squares estimate of  $\Theta$  conditional on a given value of  $\theta$ . In contrast,  $\text{SSE}(\hat{\theta}, \hat{\Theta})$  is the sum of square errors for the full model. For linear models,  $\tau(\theta)$  matches  $\sigma(\theta)$ , which is defined as

$$\sigma(\theta) = \frac{\theta - \hat{\theta}}{\text{stderr}_\theta}$$

where  $\theta$  is the constrained value,  $\hat{\theta}$  is the estimated value for the parameter, and  $\text{stderr}_\theta$  is the standard error for the parameter. Usually a profile  $t$  plot is overlaid with a reference line that passes through the origin and has a slope of 1. PROC NLIN follows this convention.

A confidence curve for a particular parameter is useful for validating Wald-based confidence intervals for the parameter against likelihood-based confidence intervals (Cook and Weisberg 1990). A confidence curve contains a scatter plot of the constrained parameter value versus  $L(\theta)$ . The Wald-based confidence intervals are overlaid as two straight lines that pass through  $(0, \hat{\theta})$  with a slope of  $\pm \text{stderr}_\theta$ . Hence, for different levels of significance, you can easily compare the Wald-based confidence intervals against the corresponding confidence intervals that are based on the likelihood ratio. Cook and Weisberg (1990) recommend that you report a single Wald-based confidence interval only if there is a good agreement between the Wald and likelihood intervals up to at least the 99% confidence level.

Compared to local influence, the leave-one-out method performs a more complete analysis of the influence of observations on the values of parameter estimates. In this method, jackknife resampling removes each

observation in turn and fits the model to the remaining data set. Hence, a data set with  $n$  observations will have  $n$  corresponding data sets with  $n-1$  observations. The impact of each observation on a parameter is assessed by the absolute relative percentage change in the value of the parameter compared with the reference value from the full data.

---

## Missing Values

If the value of any one of the SAS variables involved in the model is missing from an observation, that observation is omitted from the analysis. If only the value of the dependent variable is missing, that observation has a predicted value calculated for it when you use an **OUTPUT** statement and specify the **PREDICTED=** option.

If an observation includes a missing value for one of the independent variables, both the predicted value and the residual value are missing for that observation. If the iterations fail to converge, the values for all variables named in the **OUTPUT** statement are set to missing.

---

## Special Variables

Several special variables are created automatically and can be used in PROC NLIN programming statements.

### Special Variables with Values That Are Set by PROC NLIN

The values of the following six special variables are set by PROC NLIN and should not be reset to a different value by programming statements:

- \_ERROR\_** is set to 1 if a numerical error or invalid argument to a function occurs during the current execution of the program. It is reset to 0 before each new execution.
- \_ITER\_** represents the current iteration number. The variable **\_ITER\_** is set to -1 during the grid search phase.
- \_MODEL\_** is set to 1 for passes through the data when only the predicted values are needed, and not the derivatives. It is 0 when both predicted values and derivatives are needed. If your derivative calculations consume a lot of time, you can save resources by using the following statement after your **MODEL** statement but before your derivative calculations:

```
if _model_ then return;
```

The derivatives generated by PROC NLIN do this automatically.

- \_N\_** indicates the number of times the PROC NLIN step has been executed. It is never reset for successive passes through the data set.
- \_OBS\_** indicates the observation number in the data set for the current program execution. It is reset to 1 to start each pass through the data set (unlike the **\_N\_** variable).
- \_SSE\_** contains the error sum of squares of the last iteration. During the grid search phase, the **\_SSE\_** variable is set to 0. For iteration 0, the **\_SSE\_** variable is set to the SSE associated with the point chosen from the grid search.

`_P_WEIGHTED_SSE_` contains the error sum of squares for the optimization tasks that are required for profiling parameters and assessing the influence of each observation on the estimate of each profiled parameter.

### Special Variable Used to Determine Convergence Criteria

The special variable `_LOSS_` can be used to determine the criterion function for convergence and step shortening. PROC NLIN looks for the variable `_LOSS_` in the programming statements and, if it is defined, uses the (weighted) sum of this value instead of the residual sum of squares to determine the criterion function for convergence and step shortening. This feature is useful in certain types of maximum-likelihood estimation.

**NOTE:** Even if you specify the `_LOSS_` variable in your programming statements, the NLIN procedure continues to solve a least squares problem. The specified `_LOSS_` variable does **not** define or alter the objective function for parameter estimation.

### Weighted Regression with the Special Variable `_WEIGHT_`

To obtain weighted nonlinear least squares estimates of parameters, make an assignment to the `_WEIGHT_` variable as in the following statement:

```
weight = expression;
```

When this statement is included, the expression on the right side of the assignment statement is evaluated for each observation in the data set. The values multiplied by  $1/\sigma^2$  are then taken as inverse elements of the diagonal variance-covariance matrix of the dependent variable.

When a variable name is given after the equal sign, the values of the variable are taken as the inverse elements of the variance-covariance matrix. The larger the `_WEIGHT_` value, the more importance the observation is given.

The `_WEIGHT_` variable can be a function of the estimated parameters. For estimation purposes, the derivative of the `_WEIGHT_` variable with respect to the parameters is not included in the gradient and the Hessian of the loss function. This is normally the desired approach for iteratively reweighted least squares estimation. When the `_WEIGHT_` variable is a function of the parameters, the gradient and the Hessian used can lead to poor convergence or nonconvergence of the requested estimation. To have the derivative of the `_WEIGHT_` variable with respect to the parameters included in the gradient and the Hessian of the loss function, do not use the `_WEIGHT_` variable. Instead, redefine the model as

$$(y - f(x, \beta)) \times \sqrt{\text{wgt}(\beta)}$$

where  $y$  is the original dependent variable,  $f(x, \beta)$  is the nonlinear model, and  $\text{wgt}(\beta)$  is the weight that is a function of the parameters.

If the `_WEIGHT_ =` statement is not used, the default value of 1 is used, and regular least squares estimates are obtained.

---

## Troubleshooting

This section describes a number of problems that might occur in your analysis with PROC NLIN.

## Excessive Computing Time

If you specify a grid of starting values that contains many points, the analysis might take excessive time since the procedure must go through the entire data set for each point on the grid.

The analysis might also take excessive time if your problem takes many iterations to converge, since each iteration requires as much time as a linear regression with predicted values and residuals calculated.

## Dependencies

The matrix of partial derivatives can be singular, possibly indicating an overparameterized model. For example, if  $b_0$  starts at zero in the following model, the derivatives for  $b_1$  are all zero for the first iteration:

```
parms b0=0 b1=.022;
model pop=b0*exp(b1*(year-1790));
der.b0=exp(b1*(year-1790));
der.b1=(year-1790)*b0*exp(b1*(year-1790));
```

The first iteration changes a subset of the parameters; then the procedure can make progress in succeeding iterations. This singularity problem is local. The next example displays a global problem. The term  $b_2$  in the exponent is not identifiable since it trades roles with  $b_0$ .

```
parms b0=3.9 b1=.022 b2=0;
model pop=b0*exp(b1*(year-1790)+b2);
der.b0 = exp(b1*(year-1790)+b2);
der.b1 = (year-1790)*b0*exp(b1*(year-1790)+b2);
der.b2 = b0*exp(b1*(year-1790)+b2);
```

## Unable to Improve

The method can lead to steps that do not improve the estimates even after a series of step halvings. If this happens, the procedure issues a message stating that it is unable to make further progress, but it then displays the following warning message:

```
PROC NLIN failed to converge
```

Then it displays the results. This often means that the procedure has not converged at all. If you provided your own derivatives, check them carefully and then examine the residual sum of squares surface. If PROC NLIN has not converged, try a different set of starting values, a different METHOD= specification, the G4 option, or a different model.

## Divergence

The iterative process might diverge, resulting in overflows in computations. It is also possible that parameters enter a space where arguments to such functions as LOG and SQRT become invalid. For example, consider the following model:

```
parms b=0;
model y = x / b;
```

Suppose that  $y$  contains only zeros, and suppose that the values for variable  $x$  are not zero. There is no least squares estimate for  $b$  since the SSE declines as  $b$  approaches infinity or minus infinity. To avoid the problem, the same model could be parameterized as  $y = a \cdot x$ .

If you have divergence problems, try reparameterizing the model, selecting different starting values, increasing the maximum allowed number of iterations (the `MAXITER=` option), specifying an alternative `METHOD=` option, or including a `BOUNDS` statement.

## Local Minimum

The program might converge to a local rather than a global minimum. For example, consider the following model:

```
parms a=1 b=-1;
model y=(1-a*x) * (1-b*x);
```

Once a solution is found, an equivalent solution with the same SSE can be obtained by swapping the values of  $a$  and  $b$ .

## Discontinuities

The computational methods assume that the model is a continuous and smooth function of the parameters. If this is not true, the method does not work. For example, the following models do not work:

```
model y=a+int(b*x);

model y=a+b*x+4*(z>c);
```

## Responding to Trouble

PROC NLIN does not necessarily produce a good solution the first time. Much depends on specifying good initial values for the parameters. You can specify a grid of values in the `PARMS` statement to search for good starting values. While most practical models should give you no trouble, other models can require switching to a different iteration method or a different computational method for matrix inversion. Specifying the option `METHOD=MARQUARDT` sometimes works when the default method (Gauss-Newton) does not work.

## Computational Methods

### Nonlinear Least Squares

Recall the basic notation for the nonlinear regression model from the section “Notation for Nonlinear Regression Models” on page 5255. The parameter vector  $\beta$  belongs to  $\Omega$ , a subset of  $R^p$ . Two points of this set are of particular interest: the true value  $\tilde{\beta}$  and the least squares estimate  $\hat{\beta}$ . The general nonlinear model fit with the NLIN procedure is represented by the equation

$$Y = f(\tilde{\beta}_0, \tilde{\beta}_1, \dots, \tilde{\beta}_p; z_1, z_2, \dots, z_k) + \epsilon = f(\tilde{\beta}; z_1, z_2, \dots, z_k) + \epsilon$$

where  $z_j$  denotes the  $(n \times 1)$  vector of the  $j$ th regressor (independent) variable,  $\tilde{\beta}$  is the true value of the parameter vector, and  $\epsilon$  is the  $(n \times 1)$  vector of homoscedastic and uncorrelated model errors with zero mean.

To write the model for the  $i$ th observation, the  $i$ th elements of  $\mathbf{z}_1, \dots, \mathbf{z}_k$  are collected in the row vector  $\mathbf{z}'_i$ , and the model equation becomes

$$Y_i = f(\boldsymbol{\beta}; \mathbf{z}'_i) + \epsilon_i$$

The shorthand  $f_i(\boldsymbol{\beta})$  will also be used throughout to denote the mean of the  $i$ th observation.

For any given value  $\boldsymbol{\beta}$  we can compute the residual sum of squares

$$\begin{aligned} \text{SSE}(\boldsymbol{\beta}) &= \sum_{i=1}^n (y_i - f(\boldsymbol{\beta}; \mathbf{z}'_i))^2 \\ &= \sum_{i=1}^n (y_i - f_i(\boldsymbol{\beta}))^2 = \mathbf{r}(\boldsymbol{\beta})' \mathbf{r}(\boldsymbol{\beta}) \end{aligned}$$

The aim of nonlinear least squares estimation is to find the value  $\widehat{\boldsymbol{\beta}}$  that minimizes  $\text{SSE}(\boldsymbol{\beta})$ . Because  $\mathbf{f}$  is a nonlinear function of  $\boldsymbol{\beta}$ , a closed-form solution does not exist for this minimization problem. An iterative process is used instead. The iterative techniques that PROC NLIN uses are similar to a series of linear regressions involving the matrix  $\mathbf{X}$  and the residual vector  $\mathbf{r} = \mathbf{y} - \mathbf{f}(\boldsymbol{\beta})$ , evaluated at the current values of  $\boldsymbol{\beta}$ .

It is more insightful, however, to describe the algorithms in terms of their approach to minimizing the residual sum of squares and in terms of their updating formulas. If  $\widehat{\boldsymbol{\beta}}^{(u)}$  denotes the value of the parameter estimates at the  $u$ th iteration, and  $\widehat{\boldsymbol{\beta}}^{(0)}$  are your starting values, then the NLIN procedure attempts to find values  $k$  and  $\boldsymbol{\Delta}$  such that

$$\widehat{\boldsymbol{\beta}}^{(u+1)} = \widehat{\boldsymbol{\beta}}^{(u)} + k \boldsymbol{\Delta}$$

and

$$\text{SSE}(\widehat{\boldsymbol{\beta}}^{(u+1)}) < \text{SSE}(\widehat{\boldsymbol{\beta}}^{(u)})$$

The various methods to fit a nonlinear regression model—which you can select with the `METHOD=` option in the `PROC NLIN` statement—differ in the calculation of the update vector  $\boldsymbol{\Delta}$ .

The gradient and Hessian of the residual sum of squares with respect to individual parameters and pairs of parameters are, respectively,

$$\begin{aligned} \mathbf{g}(\boldsymbol{\beta}_j) &= \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \beta_j} = -2 \sum_{i=1}^n (y_i - f_i(\boldsymbol{\beta})) \frac{\partial f_i(\boldsymbol{\beta})}{\partial \beta_j} \\ [\mathbf{H}(\boldsymbol{\beta})]_{jk} &= \frac{\partial^2 \text{SSE}(\boldsymbol{\beta})}{\partial \beta_j \partial \beta_k} = 2 \sum_{i=1}^n \frac{\partial f_i(\boldsymbol{\beta})}{\partial \beta_j} \frac{\partial f_i(\boldsymbol{\beta})}{\partial \beta_k} - (y_i - f_i(\boldsymbol{\beta})) \frac{\partial^2 f_i(\boldsymbol{\beta})}{\partial \beta_j \partial \beta_k} \end{aligned}$$

Denote as  $\mathbf{H}_i^*(\boldsymbol{\beta})$  the Hessian matrix of the mean function,

$$[\mathbf{H}_i^*(\boldsymbol{\beta})]_{jk} = \left[ \frac{\partial^2 f_i(\boldsymbol{\beta})}{\partial \beta_j \partial \beta_k} \right]_{jk}$$

Collecting the derivatives across all parameters leads to the expressions

$$\mathbf{g}(\boldsymbol{\beta}) = \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = -2\mathbf{X}'\mathbf{r}(\boldsymbol{\beta})$$

$$\mathbf{H}(\boldsymbol{\beta}) = \frac{\partial^2 \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta} \partial \boldsymbol{\beta}'} = 2 \left( \mathbf{X}'\mathbf{X} - \sum_{i=1}^n r_i(\boldsymbol{\beta}) \mathbf{H}_i^*(\boldsymbol{\beta}) \right)$$

The change in the vector of parameter estimates is computed as follows, depending on the estimation method:

$$\text{Gauss-Newton: } \boldsymbol{\Delta} = (-\mathbf{E}[\mathbf{H}(\boldsymbol{\beta})])^{-1} \mathbf{g}(\boldsymbol{\beta}) = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}'\mathbf{r}$$

$$\text{Marquardt: } \boldsymbol{\Delta} = (\mathbf{X}'\mathbf{X} + \lambda \text{diag}(\mathbf{X}'\mathbf{X}))^{-1} \mathbf{X}'\mathbf{r}$$

$$\text{Newton: } \boldsymbol{\Delta} = -\mathbf{H}(\boldsymbol{\beta})^{-1} \mathbf{g}(\boldsymbol{\beta}) = \mathbf{H}(\boldsymbol{\beta})^{-1} \mathbf{X}'\mathbf{r}$$

$$\text{Steepest descent: } \boldsymbol{\Delta} = -\frac{1}{2} \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = \mathbf{X}'\mathbf{r}$$

The Gauss-Newton and Marquardt iterative methods regress the residuals onto the partial derivatives of the model with respect to the parameters until the estimates converge. You can view the Marquardt algorithm as a Gauss-Newton algorithm with a ridgeing penalty. The Newton iterative method regresses the residuals onto a function of the first and second derivatives of the model with respect to the parameters until the estimates converge. Analytical first- and second-order derivatives are automatically computed as needed.

The default method used to compute  $(\mathbf{X}'\mathbf{X})^{-1}$  is the sweep (Goodnight 1979). It produces a reflexive generalized inverse (a  $g_2$ -inverse, Pringle and Rayner 1971). In some cases it might be preferable to use a Moore-Penrose inverse (a  $g_4$ -inverse) instead. If you specify the **G4** option in the **PROC NLIN** statement, a  $g_4$ -inverse is used to calculate  $\boldsymbol{\Delta}$  on each iteration.

The four algorithms are now described in greater detail.

## Algorithmic Details

### **Gauss-Newton and Newton Methods**

From the preceding set of equations you can see that the Marquardt method is a ridged version of the Gauss-Newton method. If the ridge parameter  $\lambda$  equals zero, the Marquardt step is identical to the Gauss-Newton step. An important difference between the Newton methods and the Gauss-Newton-type algorithms lies in the use of second derivatives. To motivate this distinctive element between Gauss-Newton and the Newton method, focus first on the objective function in nonlinear least squares. To numerically find the minimum of

$$\text{SSE}(\boldsymbol{\beta}) = \mathbf{r}(\boldsymbol{\beta})'\mathbf{r}(\boldsymbol{\beta})$$

you can approach the problem by approximating the sum of squares criterion by a criterion for which you can compute a closed-form solution. Following Seber and Wild (1989, Sect. 2.1.3), we can achieve that by doing the following:

- approximating the model and substituting the approximation into  $SSE(\boldsymbol{\beta})$
- approximating  $SSE(\boldsymbol{\beta})$  directly

The first method, approximating the nonlinear model with a first-order Taylor series, is the purview of the Gauss-Newton method. Approximating the residual sum of squares directly is the realm of the Newton method.

The first-order Taylor series of the residual  $\mathbf{r}(\boldsymbol{\beta})$  at the point  $\hat{\boldsymbol{\beta}}$  is

$$\mathbf{r}(\boldsymbol{\beta}) \approx \mathbf{r}(\hat{\boldsymbol{\beta}}) - \hat{\mathbf{X}}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})$$

Substitution into  $SSE(\boldsymbol{\beta})$  leads to the objective function for the Gauss-Newton step:

$$SSE(\boldsymbol{\beta}) \approx S_G(\boldsymbol{\beta}) = \mathbf{r}(\hat{\boldsymbol{\beta}})' - 2\mathbf{r}'(\hat{\boldsymbol{\beta}})\hat{\mathbf{X}}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}}) + (\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})'(\hat{\mathbf{X}}'\hat{\mathbf{X}})(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})$$

“Hat” notation is used here to indicate that the quantity in question is evaluated at  $\hat{\boldsymbol{\beta}}$ .

To motivate the Newton method, take a second-order Taylor series of  $SSE(\boldsymbol{\beta})$  around the value  $\hat{\boldsymbol{\beta}}$ :

$$SSE(\boldsymbol{\beta}) \approx S_N(\boldsymbol{\beta}) = SSE(\hat{\boldsymbol{\beta}}) + \mathbf{g}(\hat{\boldsymbol{\beta}})'(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}}) + \frac{1}{2}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})' \mathbf{H}(\hat{\boldsymbol{\beta}})(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})$$

Both  $S_G(\boldsymbol{\beta})$  and  $S_N(\boldsymbol{\beta})$  are quadratic functions in  $\boldsymbol{\beta}$  and are easily minimized. The minima occur when

$$\text{Gauss-Newton: } \boldsymbol{\beta} - \hat{\boldsymbol{\beta}} = (\hat{\mathbf{X}}'\hat{\mathbf{X}})^{-1} \hat{\mathbf{X}}'\mathbf{r}(\hat{\boldsymbol{\beta}})$$

$$\text{Newton: } \boldsymbol{\beta} - \hat{\boldsymbol{\beta}} = -\mathbf{H}(\hat{\boldsymbol{\beta}})^{-1} \mathbf{g}(\hat{\boldsymbol{\beta}})$$

and these terms define the preceding  $\boldsymbol{\Delta}$  update vectors.

### **Gauss-Newton Method**

Since the Gauss-Newton method is based on an approximation of the model, you can also derive the update vector by first considering the “normal” equations of the nonlinear model

$$\mathbf{X}'\mathbf{f}(\boldsymbol{\beta}) = \mathbf{X}'\mathbf{Y}$$

and then substituting the Taylor approximation

$$\mathbf{f}(\boldsymbol{\beta}) \approx \mathbf{f}(\hat{\boldsymbol{\beta}}) + \mathbf{X}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})$$

for  $\mathbf{f}(\boldsymbol{\beta})$ . This leads to

$$\mathbf{X}'(\mathbf{f}(\hat{\boldsymbol{\beta}}) + \mathbf{X}(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}})) = \mathbf{X}'\mathbf{Y}$$

$$(\mathbf{X}'\mathbf{X})(\boldsymbol{\beta} - \hat{\boldsymbol{\beta}}) = \mathbf{X}'\mathbf{Y} - \mathbf{X}'\mathbf{f}(\hat{\boldsymbol{\beta}})$$

$$(\mathbf{X}'\mathbf{X})\boldsymbol{\Delta} = \mathbf{X}'\mathbf{r}(\hat{\boldsymbol{\beta}})$$

and the update vector becomes

$$\boldsymbol{\Delta} = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}'\mathbf{r}(\hat{\boldsymbol{\beta}})$$

**NOTE:** If  $\mathbf{X}'\mathbf{X}$  is singular or becomes singular, PROC NLIN computes  $\boldsymbol{\Delta}$  by using a generalized inverse for the iterations after singularity occurs. If  $\mathbf{X}'\mathbf{X}$  is still singular for the last iteration, the solution should be examined.

**Newton Method**

The Newton method uses the second derivatives and solves the equation

$$\Delta = \mathbf{H}^{-1} \mathbf{X}' \mathbf{r}$$

If the automatic variables `_WEIGHT_`, `_WGTJPJ_`, and `_RESID_` are used, then

$$\Delta = \mathbf{H}^{-1} \mathbf{X}' \mathbf{W}^{\text{SSE}} \mathbf{r}^*$$

is the direction, where

$$\mathbf{H} = \mathbf{X}' \mathbf{W}^{\text{XPX}} \mathbf{X} - \sum_{i=1}^n \mathbf{H}_i^*(\boldsymbol{\beta}) w_i^{\text{XPX}} r_i^*$$

and

$\mathbf{W}^{\text{SSE}}$  is an  $n \times n$  diagonal matrix with elements  $w_i^{\text{SSE}}$  of weights from the `_WEIGHT_` variable. Each element  $w_i^{\text{SSE}}$  contains the value of `_WEIGHT_` for the  $i$ th observation.

$\mathbf{W}^{\text{XPX}}$  is an  $n \times n$  diagonal matrix with elements  $w_i^{\text{XPX}}$  of weights from the `_WGTJPJ_` variable. Each element  $w_i^{\text{XPX}}$  contains the value of `_WGTJPJ_` for the  $i$ th observation.

$\mathbf{r}^*$  is a vector with elements  $r_i^*$  from the `_RESID_` variable. Each element  $r_i^*$  contains the value of `_RESID_` evaluated for the  $i$ th observation.

**Marquardt Method**

The updating formula for the Marquardt method is as follows:

$$\Delta = (\mathbf{X}' \mathbf{X} + \lambda \text{diag}(\mathbf{X}' \mathbf{X}))^{-1} \mathbf{X}' \mathbf{e}$$

The Marquardt method is a compromise between the Gauss-Newton and steepest descent methods (Marquardt 1963). As  $\lambda \rightarrow 0$ , the direction approaches Gauss-Newton. As  $\lambda \rightarrow \infty$ , the direction approaches steepest descent.

Marquardt's studies indicate that the average angle between Gauss-Newton and steepest descent directions is about  $90^\circ$ . A choice of  $\lambda$  between 0 and infinity produces a compromise direction.

By default, PROC NLIN chooses  $\lambda = 10^{-7}$  to start and computes  $\Delta$ . If  $\text{SSE}(\boldsymbol{\beta}_0 + \Delta) < \text{SSE}(\boldsymbol{\beta}_0)$ , then  $\lambda = \lambda/10$  for the next iteration. Each time  $\text{SSE}(\boldsymbol{\beta}_0 + \Delta) > \text{SSE}(\boldsymbol{\beta}_0)$ , then  $\lambda = 10\lambda$ .

**NOTE:** If the SSE decreases on each iteration, then  $\lambda \rightarrow 0$ , and you are essentially using the Gauss-Newton method. If SSE does not improve, then  $\lambda$  is increased until you are moving in the steepest descent direction.

Marquardt's method is equivalent to performing a series of ridge regressions, and it is useful when the parameter estimates are highly correlated or the objective function is not well approximated by a quadratic.

**Steepest Descent (Gradient) Method**

The steepest descent method is based directly on the gradient of  $0.5\mathbf{r}(\boldsymbol{\beta})' \mathbf{r}(\boldsymbol{\beta})$ :

$$\frac{1}{2} \frac{\partial \text{SSE}(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = -\mathbf{X}' \mathbf{r}$$

The quantity  $-\mathbf{X}'\mathbf{r}$  is the gradient along which  $\epsilon'\epsilon$  increases. Thus  $\mathbf{\Delta} = \mathbf{X}'\mathbf{r}$  is the direction of steepest descent.

If the automatic variables `_WEIGHT_` and `_RESID_` are used, then

$$\mathbf{\Delta} = \mathbf{X}'\mathbf{W}^{\text{SSE}}\mathbf{r}^*$$

is the direction, where

$\mathbf{W}^{\text{SSE}}$  is an  $n \times n$  diagonal matrix with elements  $w_i^{\text{SSE}}$  of weights from the `_WEIGHT_` variable. Each element  $w_i^{\text{SSE}}$  contains the value of `_WEIGHT_` for the  $i$ th observation.

$\mathbf{r}^*$  is a vector with elements  $r_i^*$  from `_RESID_`. Each element  $r_i^*$  contains the value of `_RESID_` evaluated for the  $i$ th observation.

Using the method of steepest descent, let

$$\boldsymbol{\beta}^{(k+1)} = \boldsymbol{\beta}^{(k)} + \alpha \mathbf{\Delta}$$

where the scalar  $\alpha$  is chosen such that

$$\text{SSE}(\boldsymbol{\beta}_i + \alpha \mathbf{\Delta}) < \text{SSE}(\boldsymbol{\beta}_i)$$

**NOTE:** The steepest-descent method can converge very slowly and is therefore not generally recommended. It is sometimes useful when the initial values are poor.

### Step-Size Search

The default method of finding the step size  $k$  is step halving by using `SMETHOD=HALVE`. If  $\text{SSE}(\boldsymbol{\beta}^{(u)} + \mathbf{\Delta}) > \text{SSE}(\boldsymbol{\beta}^{(u)})$ , compute  $\text{SSE}(\boldsymbol{\beta}^{(u)} + 0.5\mathbf{\Delta})$ ,  $\text{SSE}(\boldsymbol{\beta}^{(u)} + 0.25\mathbf{\Delta})$ , . . . , until a smaller SSE is found.

If you specify `SMETHOD=GOLDEN`, the step size  $k$  is determined by a golden section search. The parameter `TAU` determines the length of the initial interval to be searched, with the interval having length `TAU` (or  $2 \times \text{TAU}$ ), depending on  $\text{SSE}(\boldsymbol{\beta}^{(u)} + \mathbf{\Delta})$ . The `RHO` parameter specifies how fine the search is to be. The SSE at each endpoint of the interval is evaluated, and a new subinterval is chosen. The size of the interval is reduced until its length is less than `RHO`. One pass through the data is required each time the interval is reduced. Hence, if `RHO` is very small relative to `TAU`, a large amount of time can be spent determining a step size. For more information about the golden section search, see Kennedy and Gentle (1980).

If you specify `SMETHOD=CUBIC`, the NLIN procedure performs a cubic interpolation to estimate the step size. If the estimated step size does not result in a decrease in SSE, step halving is used.

---

## Output Data Sets

The data set produced by the `OUTEST=` option in the `PROC NLIN` statement contains the parameter estimates on each iteration, including the grid search.

The variable `_ITER_` contains the iteration number. The variable `_TYPE_` denotes whether the observation contains iteration parameter estimates (“ITER”), final parameter estimates (“FINAL”), or covariance estimates (“COVB”). The variable `_NAME_` contains the parameter name for covariances, and the variable

`_SSE_` contains the objective function value for the parameter estimates. The variable `_STATUS_` indicates whether the estimates have converged.

The data set produced by the `OUTPUT` statement contains statistics calculated for each observation. In addition, the data set contains the variables from the input data set and any `ID` variables that are specified in the `ID` statement.

The data set that is produced by the `PROFDATA=` option in the `PROFILE` statement contains statistics that are calculated during parameter profiling. The variable `_TYPE_` denotes whether the observation is from a profiling task (set as `PROF`) or jackknife resampling task (set as `JACK`). The variable `_PROF_PARM_` refers to the name of the profiled parameter for profiling tasks. The variable `_OBS_INF_MEAS_` is the observation index of the deleted observation for jackknife resampling tasks, and the variables `_L_STAT_` and `_W_STAT_` contain the likelihood ratio pivotal statistic and the Wald pivotal statistic, respectively. The rest of the variables are the parameter estimates.

## Confidence Intervals

### Parameter Confidence Intervals

The parameter confidence intervals are computed using the Wald-based formula:

$$\hat{\beta}_i \pm \text{stderr}_i \times t(n - p, 1 - \alpha/2)$$

where  $\hat{\beta}_i$  is the  $i$ th parameter estimate,  $\text{stderr}_i$  is its estimated approximate standard error,  $t(n - p, 1 - \alpha/2)$  is a  $t$  statistic with  $n - p$  degrees of freedom,  $n$  is the number of observations, and  $p$  is the number of parameters. You can specify the significance level  $\alpha$  used in the construction of these confidence limits with the `ALPHA=` option in the `PROC NLIN` statement; the default value is  $\alpha = 0.05$ . Because Wald-based confidence intervals are only asymptotically valid, you should use confidence curves for a more accurate and complete inference on confidence intervals. See the section “[Profiling Parameters and Assessing the Influence of Observations on Parameter Estimates](#)” on page 5290 for details.

### Model Confidence Intervals

Model confidence intervals are output when an `OUT=` data set is specified and one or more of the keywords `LCLM`, `UCLM`, `LCL`, `UCL`, `L95M=`, `U95M=`, `L95=`, and `U95=` is specified. The expressions for these terms are as follows:

$$\text{LCLM} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE} \times h_i/w_i} \times t(n - p, 1 - \alpha/2)$$

$$\text{UCLM} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE} \times h_i/w_i} \times t(n - p, 1 - \alpha/2)$$

$$\text{LCL} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - \alpha/2)$$

$$\text{UCL} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - \alpha/2)$$

$$\text{L95M} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE} \times h_i/w_i} \times t(n - p, 1 - 0.05/2)$$

$$\text{U95M} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE} \times h_i/w_i} \times t(n - p, 1 - 0.05/2)$$

$$\text{L95} = f(\boldsymbol{\beta}, \mathbf{z}_i) - \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - 0.05/2)$$

$$\text{U95} = f(\boldsymbol{\beta}, \mathbf{z}_i) + \sqrt{\text{MSE}(h_i + 1/w_i)} \times t(n - p, 1 - 0.05/2)$$

where  $h_i = w_i x_i (\mathbf{X}'\mathbf{W}\mathbf{X})^{-1} \mathbf{x}'_i$  is the leverage,  $\mathbf{X} = \partial \mathbf{f} / \partial \boldsymbol{\beta}$ , and  $\mathbf{x}_i$  is the  $i$ th row of  $\mathbf{X}$ . These results are derived for linear systems. The intervals are approximate for nonlinear models. The value  $\alpha$  in the preceding formulas for **LCLM**, **UCLM**, **LCL**, and **UCL** can be set with the **ALPHA=** option in the **PROC NLIN** statement or with the **ALPHA=** option in the **OUTPUT** statement. If both **ALPHA=** options are specified, the option in the **OUTPUT** takes precedence.

---

## Covariance Matrix of Parameter Estimates

For unconstrained estimates (no active bounds), the covariance matrix of the parameter estimates is

$$\text{mse} \times (\mathbf{X}'\mathbf{X})^{-1}$$

for the gradient, Marquardt, and Gauss methods and

$$\text{mse} \times \mathbf{H}^{-1}$$

for the Newton method. Recall that  $\mathbf{X}$  is the matrix of the first partial derivatives of the nonlinear model with respect to the parameters. The matrices are evaluated at the final parameter estimates. The mean squared error, the estimate of the residual variance  $\sigma^2$ , is computed as

$$\text{mse} = \mathbf{r}'\mathbf{r} / (n - p)$$

where  $n$  is the number of nonmissing (used) observations and  $p$  is the number of estimable parameters. The standard error reported for the parameter estimates is the square root of the corresponding diagonal element of this matrix. If you specify a value for the residual variance with the **SIGSQ=** option, then that value replaces **mse** in the preceding expressions.

Now suppose that restrictions or bounds are active. Equality restrictions can be written as a vector function,  $h(\boldsymbol{\theta}) = \mathbf{0}$ . Inequality restrictions are either active or inactive. When an inequality restriction is active, it is treated as an equality restriction.

Assume that the vector  $h(\boldsymbol{\theta})$  contains the current active restrictions. The constraint matrix  $\mathbf{A}$  is then

$$\mathbf{A}(\hat{\boldsymbol{\theta}}) = \frac{\partial h(\hat{\boldsymbol{\theta}})}{\partial \hat{\boldsymbol{\theta}}}$$

The covariance matrix for the restricted parameter estimates is computed as

$$\mathbf{Z}(\mathbf{Z}'\mathbf{H}\mathbf{Z})^{-1}\mathbf{Z}'$$

where  $\mathbf{H}$  is the Hessian (or approximation to the Hessian) and  $\mathbf{Z}$  collects the last  $(p - n_c)$  columns of  $\mathbf{Q}$  from an LQ factorization of the constraint matrix. Further,  $n_c$  is the number of active constraints, and  $p$  denotes the number of parameters. See Gill, Murray, and Wright (1981) for more details about the LQ factorization. The covariance matrix for the Lagrange multipliers is computed as

$$(\mathbf{A}\mathbf{H}^{-1}\mathbf{A}')^{-1}$$

## Convergence Measures

The NLIN procedure computes and reports four convergence measures, labeled R, PPC, RPC, and OBJECT.

**R** is the primary convergence measure for the parameters. It measures the degree to which the residuals are orthogonal to the columns of  $\mathbf{X}$ , and it approaches 0 as the gradient of the objective function becomes small. R is defined as

$$\sqrt{\frac{\mathbf{r}'\mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{r}}{\text{LOSS}^i}}$$

**PPC** is the prospective parameter change measure. PPC measures the maximum relative change in the parameters implied by the parameter-change vector computed for the next iteration. At the  $k$ th iteration, PPC is the maximum over the parameters

$$\frac{|\widehat{\theta}_i^{(k+1)} - \widehat{\theta}_i^{(k)}|}{|\widehat{\theta}_i^{(k)}| + 1\text{E} - 6}$$

where  $\widehat{\theta}_i^{(k)}$  is the current value of the  $i$ th parameter and  $\widehat{\theta}_i^{(k+1)}$  is the prospective value of this parameter after adding the change vector computed for the next iteration. These changes are measured before step length adjustments are made. The parameter with the maximum prospective relative change is displayed with the value of PPC, unless the PPC is nearly 0.

**RPC** is the retrospective parameter change measure. RPC measures the maximum relative change in the parameters from the previous iteration. At the  $k$ th iteration, RPC is the maximum over  $i$  of

$$\frac{|\widehat{\theta}_i^{(k)} - \widehat{\theta}_i^{(k-1)}|}{|\widehat{\theta}_i^{(k-1)}| + 1\text{E} - 6}$$

where  $\widehat{\theta}_i^{(k)}$  is the current value of the  $i$ th parameter and  $\widehat{\theta}_i^{(k-1)}$  is the previous value of this parameter. These changes are measured before step length adjustments are made. The name of the parameter with the maximum retrospective relative change is displayed with the value of RPC, unless the RPC is nearly 0.

**OBJECT** measures the relative change in the objective function value between iterations:

$$\frac{|O^{(k)} - O^{(k-1)}|}{|O^{(k-1)}| + 1\text{E} - 6}$$

where  $O^{(k-1)}$  is the value of the objective function ( $O^{(k)}$ ) from the previous iteration. This is the old **CONVERGEOBJ=** criterion.

---

## Displayed Output

In addition to the output data sets, PROC NLIN also produces the following output objects:

- the residual sums of squares associated with all or some of the combinations of possible starting values of the parameters
- the estimates of the parameters and the residual sums of squares at each iteration
- the estimation summary table, which displays information about the estimation method, the number of observations in the analysis, the objective function, and convergence measures
- the analysis of variance table, including sums of squares for the “Model,” “Residual,” and “Total” sources of variation (“Corrected Total” or “Uncorrected Total”), and the model  $F$  test. Note that beginning in SAS<sup>®</sup> 9, only the uncorrected total SS is reported and the respective  $F$  test is based on the uncorrected total SS if PROC NLIN determines the model does not include an intercept. If PROC NLIN determines the model does include an intercept, only the corrected total SS is reported and the respective  $F$  test is based on the corrected total SS.
- the table of parameter estimates, which contains for each parameter in the model its estimate, the approximate standard error of the estimate, and a 95% confidence interval based on the approximate standard error. The confidence level can be changed with the `ALPHA=` option in the `PROC NLIN` statement. The `HOUGAARD` option in the `PROC NLIN` statement requests that Hougaard’s skewness measure be added for each parameter. The standard errors and confidence limits are labeled approximate because they are valid asymptotically as the number of observations grows. If your model is linear in the parameters, the standard errors and confidence intervals are not approximate.
- the approximate correlation matrix of the parameter estimates. This correlation matrix is labeled approximate because it is computed from the approximate covariance matrix of the parameter estimates. If your model is linear in the parameters, the correlation matrix is not approximate.

---

## Incompatibilities with SAS 6.11 and Earlier Versions of PROC NLIN

The NLIN procedure now uses a compiler that is different from the DATA step compiler. The compiler was changed so that analytical derivatives could be computed automatically. For the most part, the syntax accepted by the old NLIN procedure can be used in the new NLIN procedure. However, there are several differences that should be noted:

- You cannot specify a character index variable in the DO statement, and you cannot specify a character test in the IF statement. Thus `do i=1,2,3;` is supported, but `do i='ONE','TWO','THREE';` is not supported. And `if 'THIS' < 'THAT' then ...;` is supported, but `if 'THIS' THEN ...;` is not supported.
- The PUT statement, which is used mostly for program debugging in PROC NLIN, supports only some of the features of the DATA step PUT statement, and it has some new features that the DATA step PUT statement does not.

- The PUT statement does not support line pointers, factored lists, iteration factors, overprinting, the `_INFILE_` option, the ‘.’ format modifier, or the symbol ‘\$’.
  - The PUT statement does support expressions inside of parentheses. For example, `put (sqrt(x));` produces the square root of X.
  - The PUT statement also supports the option `_PDV_` to display a formatted listing of all the variables in the program. The statement `put _pdv_;` prints a much more readable listing of the variables than `put _all_;` does.
- You cannot use the ‘\*’ subscript, but you can specify an array name in a PUT statement without subscripts. Thus, `array a ...; put a;` is acceptable, but `put a[*];` is not. The statement `put a;` displays all the elements of the array a. The `put a=;` statement displays all the elements of A with each value labeled by the name of the element variable.
  - You cannot specify arguments in the ABORT statement.
  - You can specify more than one target statement in the WHEN and OTHERWISE statements. That is, DO/END groups are not necessary for multiple WHEN statements, such as `select; when(exp1); stmt1; stmt2; when(exp2); stmt3; stmt4; end;`
  - You can specify only the options LOG, PRINT, and LIST in the FILE statement.
  - The RETAIN statement retains only values across one pass through the data set. If you need to retain values across iterations, use the CONTROL statement to make a control variable.

The ARRAY statement in PROC NLIN is similar to, but not the same as, the ARRAY statement in the DATA step. The ARRAY statement is used to associate a name (of no more than 8 characters) with a list of variables and constants. The array name can then be used with subscripts in the program to refer to the items in the list.

The ARRAY statement supported by PROC NLIN does not support all the features of the DATA step ARRAY statement. You cannot specify implicit indexing variables; all array references must have explicit subscript expressions. You can specify simple array dimensions; lower bound specifications are not supported. A maximum of six dimensions are accepted.

On the other hand, the ARRAY statement supported by PROC NLIN does accept both variables and constants as array elements. In the following statements, b is a constant array and c is a variable array. Note that the constant array elements cannot be changed with assignment statements.

```
proc nlin data=nld;
array b[4] 1 2 3 4; /* Constant array */
array c[4] (1 2 3 4); /* Numeric array with initial values */

b[1] = 2; /* This is an ERROR, b is a constant array*/
c[2] = 7.5; /* This is allowed */
```

Both dimension specification and the list of elements are optional, but at least one must be specified. When the list of elements is not specified, or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

If the array is used as a pure array in the program rather than a list of symbols (the individual symbols of the array are not referenced in the code), the array is converted to a numerical array. A pure array is literally

a vector of numbers that are accessed only by index. Using these types of arrays results in faster derivatives and compiled code. The assignment to `c1` in the following statements forces the array to be treated as a list of symbols:

```
proc nlin data=nld;
 array c[4] (1 2 3 4); /* Numeric array with initial values */

 c[2] = 7.5; /* This is C used as a pure array */
 c1 = -92.5; /* This forces C to be a list of symbols */
```

---

## ODS Table Names

PROC NLIN assigns a name to each table it creates. You can use these names to refer to the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 63.7. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 63.7** ODS Tables Produced by PROC NLIN

| ODS Table Name       | Description                             | Statement    |
|----------------------|-----------------------------------------|--------------|
| ANOVA                | Analysis of variance                    | default      |
| CodeDependency       | Variable cross reference                | LISTDEP      |
| CodeList             | Listing of program statements           | LISTCODE     |
| ConvergenceStatus    | Convergence status                      | default      |
| CorrB                | Correlation of the parameters           | default      |
| EstSummary           | Summary of the estimation               | default      |
| FirstDerivatives     | First derivative table                  | LISTDER      |
| IterHistory          | Iteration output                        | default      |
| MissingValues        | Missing values generated by the program | default      |
| NonlinearityMeasures | Global nonlinearity measures            | NLINMEASURES |
| ParameterEstimates   | Parameter estimates                     | default      |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

PROC NLIN assigns a name to each graph it creates using ODS. You can use these names to refer to the graphs when using ODS. The graphs that are controlled by the **PLOTS** option in the **PROC NLIN** statement are listed in Table 63.8 and those that are controlled by the options in **PROFILE** statement are in Table 63.9.

**Table 63.8** Graphs Controlled by the PLOTS option in the PROC NLIN Statement

| ODS Graph Name             | Plot Description                                                     | PLOTS Option        |
|----------------------------|----------------------------------------------------------------------|---------------------|
| ContourFitPlot             | Contour fit plot for models with two regressors                      | FIT                 |
| FitPlot                    | Fit plot for models with one regressor                               | FIT                 |
| FitDiagnosticsPanel        | Panel of fit diagnostics                                             | DIAGNOSTICS         |
| LeveragePlot               | Tangential and Jacobian leverages versus observation number          | DIAGNOSTICS         |
| LocalInfluencePlot         | Local influence versus observation number                            | DIAGNOSTICS         |
| ObservedByPredictedPlot    | Dependent variable versus predicted values                           | DIAGNOSTICS(UNPACK) |
| ProjectedResidualHistogram | A histogram of the projected residuals                               | DIAGNOSTICS(UNPACK) |
| RawResidualExpectationPlot | Raw residual expectation versus predicted values                     | DIAGNOSTICS(UNPACK) |
| RawResidualHistogram       | A histogram of the raw residuals                                     | DIAGNOSTICS(UNPACK) |
| ResidualBoxPlot            | A box plot of the raw and projected residuals                        | DIAGNOSTICS(UNPACK) |
| ResidualPanel              | A panel of the raw and projected residuals versus the regressors     | RESIDUALS           |
| ResidualPlot               | A plot of the raw and projected residuals versus the regressors      | RESIDUALS(UNPACK)   |
| ResidualByPredictedPlot    | Raw and projected residuals versus the predicted values              | DIAGNOSTICS(UNPACK) |
| RStudentByJacLeveragePlot  | Standardized raw and projected residuals versus Jacobian leverage    | DIAGNOSTICS(UNPACK) |
| RStudentByPredictedPlot    | Standardized raw and projected residuals versus the predicted values | DIAGNOSTICS(UNPACK) |
| RStudentByTanLeveragePlot  | Standardized raw and projected residuals versus tangential leverage  | DIAGNOSTICS(UNPACK) |

**Table 63.9** Graphs Controlled by the PROFILE Statement

| ODS Graph Name  | Plot Description                                                  | PROFILE Option |
|-----------------|-------------------------------------------------------------------|----------------|
| ConfidenceCurve | Parameter value versus $t$ value                                  | CONF CURV      |
| JackknifePlot   | Absolute relative percentage difference versus observation number | JACKKNIFE      |
| ProfiletPlot    | Likelihood ratio pivotal statistic versus Wald pivotal statistic  | T PLOT         |

## Convergence Status Table

The “Convergence Status” table can be used to programmatically check the status of an estimation. This table contains the `Status` variable that takes on the value 0, 1, 2, or 3. If `Status` takes on a value less than 3, the convergence criterion was met. Specifically, the values mean the following:

|          |                                                                                                                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Status=0 | indicates that the convergence criterion was met and no warning or error messages were issued during the PROC NLIN run. Also, no notes that could indicate a problem with the model were issued. |
| Status=1 | indicates that the convergence criterion was met and notes were written to the log that might indicate a problem with the model.                                                                 |
| Status=2 | indicates that the convergence criterion was met and one or more warning messages were produced during the PROC NLIN run.                                                                        |
| Status=3 | indicates that the convergence criterion was not met.                                                                                                                                            |

The following sample program demonstrates how the “Convergence Status” table can be used:

```
ods output ConvergenceStatus=ConvStatus;
proc nlin data=YourData;
 parameters a=1 b=1 c=1;
 model wgt = a + x / (b*y+c*z);
run;

data _null_;
 set ConvStatus;
 if status > 0 then put "A problem occurred";
run;
```

---

## Examples: NLIN Procedure

---

### Example 63.1: Segmented Model

Suppose you are interested in fitting a model that consists of two segments that connect in a smooth fashion. For example, the following model states that for values of  $x$  less than  $x_0$  the mean of  $Y$  is a quadratic function in  $x$ , and for values of  $x$  greater than  $x_0$  the mean of  $Y$  is constant:

$$E[Y|x] = \begin{cases} \alpha + \beta x + \gamma x^2 & \text{if } x < x_0 \\ c & \text{if } x \geq x_0 \end{cases}$$

In this model equation  $\alpha$ ,  $\beta$ , and  $\gamma$  are the coefficients of the quadratic segment, and  $c$  is the plateau of the mean function. The NLIN procedure can fit such a segmented model even when the join point,  $x_0$ , is unknown.

We also want to impose conditions on the two segments of the model. First, the curve should be continuous—that is, the quadratic and the plateau section need to meet at  $x_0$ . Second, the curve should be smooth—that is, the first derivative of the two segments with respect to  $x$  need to coincide at  $x_0$ .

The continuity condition requires that

$$p = E[Y|x_0] = \alpha + \beta x_0 + \gamma x_0^2$$

The smoothness condition requires that

$$\frac{\partial E[Y|x_0]}{\partial x} = \beta + 2\gamma x_0 \equiv 0$$

If you solve for  $x_0$  and substitute into the expression for  $c$ , the two conditions jointly imply that

$$\begin{aligned} x_0 &= -\beta/2\gamma \\ c &= \alpha - \beta^2/4\gamma \end{aligned}$$

Although there are apparently four unknowns, the model contains only three parameters. The continuity and smoothness restrictions together completely determine one parameter given the other three.

The following DATA step creates the SAS data set for this example:

```
data a;
 input y x @@;
 datalines;
.46 1 .47 2 .57 3 .61 4 .62 5 .68 6 .69 7
.78 8 .70 9 .74 10 .77 11 .78 12 .74 13 .80 13
.80 15 .78 16
;
```

The following PROC NLIN statements fit this segmented model:

```
title 'Quadratic Model with Plateau';
proc nlin data=a;
 parms alpha=.45 beta=.05 gamma=-.0025;

 x0 = -.5*beta / gamma;

 if (x < x0) then
 mean = alpha + beta*x + gamma*x*x;
 else mean = alpha + beta*x0 + gamma*x0*x0;
 model y = mean;

 if _obs_=1 and _iter_ =. then do;
 plateau =alpha + beta*x0 + gamma*x0*x0;
 put / x0= plateau= ;
 end;
 output out=b predicted=yp;
run;
```

The parameters of the model are  $\alpha$ ,  $\beta$ , and  $\gamma$ , respectively. They are represented in the PROC NLIN statements by the variables alpha, beta, and gamma, respectively. In order to model the two segments, a conditional statement is used that assigns the appropriate expression to the mean function depending on the value of  $x_0$ . A PUT statement is used to print the constrained parameters every time the program is executed for the first observation. The OUTPUT statement computes predicted values for plotting and saves them to data set b.

Note that there are other ways in which you can write the conditional expressions for this model. For example, you could formulate a condition with two model statements, as follows:

```
proc nlin data=a;
 parms alpha=.45 beta=.05 gamma=-.0025;
 x0 = -.5*beta / gamma;
 if (x < x0) then
 model y = alpha+beta*x+gamma*x*x;
 else model y = alpha+beta*x0+gamma*x0*x0;
run;
```

Or you could use a single expression with a conditional evaluation, as in the following statements:

```
proc nlin data=a;
 parms alpha=.45 beta=.05 gamma=-.0025;
 x0 = -.5*beta / gamma;
 model y = (x <x0)*(alpha+beta*x +gamma*x*x) +
 (x>=x0)*(alpha+beta*x0+gamma*x0*x0);
run;
```

The results from fitting this model with PROC NLIN are shown in [Output 63.1.1–Output 63.1.3](#). The iterative optimization converges after six iterations ([Output 63.1.1](#)). [Output 63.1.1](#) indicates that the join point is 12.747 and the plateau value is 0.777.

The following statements produce a graph of the observed and predicted values with reference lines for the join point and plateau estimates ([Output 63.1.4](#)):

```
proc sgplot data=b noautolegend;
 yaxis label='Observed or Predicted';
 refline 0.777 / axis=y label="Plateau" labelpos=min;
 refline 12.747 / axis=x label="Join point" labelpos=min;
 scatter y=y x=x;
 series y=yp x=x;
run;
```

**Output 63.1.4** Observed and Predicted Values for the Quadratic Model

If you want to estimate the join point directly, you can use the relationship between the parameters to change the parameterization of the model in such a way that the mean function depends directly on  $x_0$ . Using the smoothness condition that relates  $x_0$  to  $\gamma$ ,

$$x_0 = -\beta/2\gamma$$

you can express  $\gamma$  as a function of  $\beta$  and  $x_0$ :

$$\gamma = -\beta/(2x_0)$$

Substituting for  $\gamma$  in the model equation

$$E[Y|x] = \begin{cases} \alpha + \beta x + \gamma x^2 & \text{if } x < x_0 \\ \alpha - \beta^2/(4\gamma) & \text{if } x \geq x_0 \end{cases}$$

yields the reparameterized model

$$E[Y|x] = \begin{cases} \alpha + \beta x(1 - x/(2x_0)) & \text{if } x < x_0 \\ \alpha + \beta x_0/2 & \text{if } x \geq x_0 \end{cases}$$

This model is fit with the following PROC NLIN statements:

```

proc nlin data=a;
 parms alpha=.45 beta=.05 x0=10;
 if (x<x0) then
 mean = alpha + beta*x *(1-x/(2*x0));
 else mean = alpha + beta*x0/2;
 model y = mean;
run;

```

The analysis of variance table in the reparameterized model is the same as in the earlier analysis (compare [Output 63.1.5](#) and [Output 63.1.3](#)). Changing the parameterization of a model does not affect the fit. The “Parameter Estimates” table now shows  $x_0$  as a parameter in the model. The estimate agrees with the earlier result that uses the PUT statement ([Output 63.1.2](#)). Since  $x_0$  is now a model parameter, the NLIN procedure also reports its asymptotic standard error and its approximate 95% confidence interval.

## Example 63.2: Iteratively Reweighted Least Squares

With the NLIN procedure you can perform weighted nonlinear least squares regression in situations where the weights are functions of the parameters. To minimize a weighted sum of squares, you assign an expression to the `_WEIGHT_` variable in your PROC NLIN statements. When the `_WEIGHT_` variable depends on the model parameters, the estimation technique is known as iteratively reweighted least squares (IRLS). In this situation you should employ the `NOHALVE` option in the PROC NLIN statement. Because the weights change from iteration to iteration, it is not reasonable to expect the *weighted* residual sum of squares to decrease between iterations. The `NOHALVE` option removes that restriction.

Examples where IRLS estimation is used include robust regression via M-estimation (Huber 1964, 1973), generalized linear models (McCullagh and Nelder 1989), and semivariogram fitting in spatial statistics (Schabenberger and Pierce 2002, Sect. 9.2). There are dedicated SAS/STAT procedures for robust regression (the ROBUSTREG procedure) and generalized linear models (the GENMOD and GLIMMIX procedures). Examples of weighted least squares fitting of a semivariogram function can be found in Chapter 102, “The VARIOGRAM Procedure.”

In this example we show an application of PROC NLIN for M-estimation only to illustrate the connection between robust regression and weighted least squares. The ROBUSTREG procedure is the appropriate tool to fit these models with SAS/STAT software.

M-estimation was introduced by Huber (1964, 1973) to estimate location parameters robustly. Beaton and Tukey (1974) applied the idea of M-estimation in regression models and introduced the biweight (or bisquare) weight function. See Holland and Welsch (1977) for this and other robust methods. Consider a linear regression model of the form

$$E[Y_i|x] = \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i$$

In weighted least squares estimation you seek the parameters  $\hat{\boldsymbol{\beta}}$  that minimize

$$\sum_{i=1}^n w_i (y_i - \mathbf{x}'_i \boldsymbol{\beta})^2 = \sum_{i=1}^n w_i e_i^2$$

where  $w_i$  is the weight associated with the  $i$ th observation. The *normal* equations of this minimization problem can be written as

$$\sum_{i=1}^n w_i e_i \mathbf{x}_i = \mathbf{0}$$

In M-estimation the corresponding equations take on the form

$$\sum_{i=1}^n \psi(e_i) \mathbf{x}_i = \mathbf{0}$$

where  $\psi(\cdot)$  is a weighing function. The Beaton-Tukey biweight, for example, can be written as

$$\psi(e_i) = \begin{cases} e_i \left(1 - \left(\frac{e_i}{\sigma k}\right)^2\right)^2 & |e_i/\sigma| \leq k \\ 0 & |e_i/\sigma| > k \end{cases}$$

Substitution into the estimating equation for M-estimation yields weighted least squares equations

$$\sum_{i=1}^n \psi(e_i) \mathbf{x}_i = \sum_{i=1}^n w_i e_i \mathbf{x}_i = \mathbf{0}$$

$$w_i = \begin{cases} \left(1 - \left(\frac{e_i}{\sigma k}\right)^2\right)^2 & |e_i/\sigma| \leq k \\ 0 & |e_i/\sigma| > k \end{cases}$$

The biweight function involves two constants,  $\sigma$  and  $k$ . The scale  $\sigma$  can be fixed or estimated from the fit in the previous iteration. If  $\sigma$  is estimated, a robust estimator of scale is typically used. In this example  $\sigma$  is fixed at 2. A common value for the constant  $k$  is  $k = 4.685$ .

The following DATA step creates a SAS data set of the population of the United States (in millions), recorded at 10-year intervals starting in 1790 and ending in 1990. The aim is to fit a quadratic linear model to the population over time.

```

title 'U.S. Population Growth';

226542 248710
;

```

The PROC NLIN code that follows fits this linear model by M-estimation and IRLS. The weight function is set to a zero or nonzero value depending on the value of the scaled residual. The **NOHALVE** option removes the requirement that the (weighted) residual sum of squares must decrease between iterations.

```

You can obtain this analysis more conveniently with PROC ROBUSTREG. The procedure re-estimates the scale parameter robustly between iterations. To obtain an analysis with a fixed scale parameter as in this example, use the following PROC ROBUSTREG statements:

```

proc robustreg data=uspop method=m(scale=2);
 model pop = year year*year;
 output out=weights weight=w;
run;

proc print data=weights;
run;

```

Note that the computation of standard errors in the ROBUSTREG procedure is different from the calculations in the NLIN procedure.

---

### Example 63.3: Probit Model with Likelihood Function

The data in this example, taken from Lee (1974), consist of patient characteristics and a variable indicating whether cancer remission occurred. This example demonstrates how to use PROC NLIN with a likelihood function. In this case, twice the negative of the log-likelihood function is to be minimized. This is the objective function for the analysis:

$$-2 \log L = -2 \sum_{i=1}^n \log \{ \pi_i(y_i, \mathbf{x}_i) \}$$

In this expression,  $\pi_i$  denotes the success probability of the  $n$  Bernoulli trials, and  $\log L$  is the log likelihood of  $n$  independent binary (Bernoulli) observations. The probability  $\pi_i$  depends on the observations through the linear predictor  $\eta_i$ ,

$$\pi_i(y_i, \mathbf{x}_i) = \begin{cases} 1 - \Phi(\eta_i) & y_i = 1 \\ \Phi(\eta_i) & y_i = 0 \end{cases}$$

The linear predictor takes the form of a regression equation that is linear in the parameters,

$$\eta_i = \beta_0 + \beta_1 z_{1i} + \beta_2 z_{2i} + \cdots + \beta_k z_{ki} = \mathbf{z}_i \boldsymbol{\beta}$$

Despite this linearity of  $\eta$  in the  $z$  variables, the probit model is nonlinear, because the linear predictor appears inside the nonlinear probit function.

In order to use the NLIN procedure to minimize the function, the estimation problem must be cast in terms of a nonlinear least squares problem with objective function

$$\sum_{i=1}^n (y_i - f(\boldsymbol{\beta}, \mathbf{z}'_i))^2$$

This can be accomplished by setting  $y_i = 0$  and  $f(\boldsymbol{\beta}, \mathbf{z}'_i) = \sqrt{-2 \log \{ \pi_i \}}$ . Because  $0 \leq \pi \leq 1$ , the function  $-2 \log \{ \pi_i \}$  is strictly positive and the square root can be taken safely.

The following DATA step creates the data for the probit analysis. The variable like is created in the DATA step, and it contains the value 0 throughout. This variable serves as the “dummy” response variable in the PROC NLIN step. The variable remiss indicates whether cancer remission occurred. It is the binary outcome variable of interest and is used to determine the relevant probability for observation  $i$  as the success or failure probability of a Bernoulli experiment.

```

data remiss;
 input remiss cell smear infil li blast temp;
 label remiss = 'complete remission';

1 1 .69 .69 0.9 0.398 .986
0 1 .73 .73 0.7 0.398 .986
;

```

The following NLIN statements fit the probit model:

```

proc nlin data=remiss method=newton sigsq=1;
 parms int=-10 a = -2 b = -1 c=6;

 linp = int + a*cell + b*li + c*temp;
 p = probnorm(linp);

 if (remiss = 1) then pi = 1-p;
 else pi = p;

 model.like = sqrt(- 2 * log(pi));
 output out=p p=predict;
run;

```

The assignment to the variable `linp` creates the linear predictor of the generalized linear model,

$$\eta = \beta_0 + \beta_1 \text{cell}_i + \beta_2 \text{li}_i + \beta_3 * \text{temp}_i$$

In this example, the variables cell, li, and temp are used as regressors.

By default, the NLIN procedure computes the covariance matrix of the parameter estimates based on the nonlinear least squares assumption. That is, the procedure computes the estimate of the residual variance as the mean squared error and uses that to multiply the inverse crossproduct matrix or the inverse Hessian matrix. (See the section “Covariance Matrix of Parameter Estimates” on page 5301 for details.) In the probit model, there is no residual variance. In addition, standard errors in maximum likelihood estimation are based on the inverse Hessian matrix. The `METHOD=NEWTON` option in the `PROC NLIN` statement is used to employ the Hessian matrix in computing the covariance matrix of the parameter estimates. The `SIGSQ=1` option replaces the residual variance estimate that PROC NLIN would use by default as a multiplier of the inverse Hessian with the value 1.0.

**Output 63.3.1** shows the results of this analysis. The analysis of variance table shows an apparently strange result. The total sum of squares is zero, and the model sum of squares is negative. Recall that the values of the response variable were set to zero and the mean function was constructed as  $-2 \log\{\pi_i\}$  in order for the NLIN procedure to minimize a log-likelihood function in terms of a nonlinear least squares problem. The value 21.9002 shown as the “Error” sum of squares is the value of the function  $-2 \log L$ .

**Output 63.3.1** Nonlinear Least-Squares Analysis from PROC NLIN

The problem can be more simply solved using dedicated procedures for generalized linear models:

```
proc glimmix data=remiss;
 model remiss = cell li temp / dist=binary link=probit s;
run;

proc genmod data=remiss;
 model remiss = cell li temp / dist=bin link=probit;
run;

proc logistic data=remiss;
 model remiss = cell li temp / link=probit technique=newton;
run;
```

---

### Example 63.4: Affecting Curvature through Parameterization

The work of Ratkowsky (1983, 1990) has brought into focus the importance of close-to-linear behavior of parameters in nonlinear regression models. The curvature in a nonlinear model consists of two components: the intrinsic curvature and the parameter-effects curvature. See the section “[Relative Curvature Measures of Nonlinearity](#)” on page 5287 for details. Intrinsic curvature expresses the degree to which the nonlinear model bends as values of the *parameters* change. This is not the same as the curviness of the model as a function of the covariates (the  $x$  variables). Intrinsic curvature is a function of the type of model you are fitting and the data. This curvature component cannot be affected by reparameterization of the model. According to Ratkowsky (1983), the intrinsic curvature component is typically smaller than the parameter-effects curvature, which can be affected by altering the parameterization of the model.

In models with low curvature, the nonlinear least squares parameter estimators behave similarly to least squares estimators in linear regression models, which have a number of desirable properties. If the model is correct, they are best linear unbiased estimators and are normally distributed if the model errors are normal (otherwise they are asymptotically normal). As you lower the curvature of a nonlinear model, you can expect that the parameter estimators approach the behavior of the linear regression model estimators: they behave “close to linear.”

This example uses a simple data set and a commonly applied model for dose-response relationships to examine how the parameter-effects curvature can be reduced. The statistics by which an estimator’s behavior is judged are Box’s bias (Box 1971) and Hougaard’s measure of skewness (Hougaard 1982, 1985).

The log-logistic model

$$E[Y|x] = \delta + \frac{\alpha - \delta}{1 + \gamma \exp\{\beta \ln(x)\}}$$

is a popular model to express the response  $Y$  as a function of dose  $x$ . The response is bounded between the asymptotes  $\alpha$  and  $\delta$ . The term in the denominator governs the transition between the asymptotes and depends on two parameters,  $\gamma$  and  $\beta$ . The log-logistic model can be viewed as a member of a broader class of dose-response functions, those relying on *switch-on* or *switch-off* mechanisms (see, for example, Schabenberger and Pierce 2002, sec. 5.8.6). A switch function is usually a monotonic function  $S(x, \boldsymbol{\theta})$  that takes values between 0 and 1. A switch-on function increases in  $x$ ; a switch-off function decreases in  $x$ . In the log-logistic case, the function

$$S(x, [\beta, \gamma]) = \frac{1}{1 + \gamma \exp\{\beta \ln(x)\}}$$

is a switch-off function for  $\beta > 0$  and a switch-on function for  $\beta < 0$ . You can write general dose-response functions with asymptotes simply as

$$E[Y|x] = \mu_{\min} + (\mu_{\max} - \mu_{\min})S(x, \theta)$$

The following DATA step creates a small data set from a dose-response experiment with response y:

```
data logistic;
 input dose y;
 logdose = log(dose);
 datalines;
0.009 106.56
0.035 94.12
0.07 89.76
0.15 60.21
0.20 39.95
0.28 21.88
0.50 7.46
;
```

A graph of these data is produced with the following statements:

```
proc sgplot data=logistic;
 scatter y=y x=dose;
 xaxis type=log logstyle=linear;
run;
```

**Output 63.4.1** Observed Data in Dose-Response Experiment

When dose is expressed on the log scale, the sigmoidal shape of the dose-response relationship is clearly visible (Output 63.4.1). The log-logistic switching model in the preceding parameterization is fit with the following statements in the NLIN procedure:

```
proc nlin data=logistic bias hougaard nlinmeasures;
 parameters alpha=100 beta=3 gamma=300;
 delta = 0;
 Switch = 1/(1+gamma*exp(beta*log(dose)));
 model y = delta + (alpha - delta)*Switch;
run;
```

The lower asymptote  $\delta$  is assumed to be 0 in this case. Since  $\delta$  is not listed in the **PARAMETERS** statement and is assigned a value in the program, it is assumed to be constant. Note that the term **Switch** is the switch-off function in the log-logistic model. The **BIAS** and **HOUGAARD** options in the **PROC NLIN** statement request that Box's bias, percentage bias, and Hougaard's skewness measure be added to the table of parameter estimates, and the **NLINMEASURES** option requests that the global nonlinearity measures be produced.

The NLIN procedure converges after 10 iterations and achieves a residual mean squared error of 15.1869 (Output 63.4.2). This value is not that important by itself, but it is worth noting since this model fit is compared to the fit with other parameterizations later on.

#### Output 63.4.2 Iteration History and Analysis of Variance

NOTE: An intercept was not specified for this model.

| Source            | DF | Sum of Squares | Mean Square | F Value | Approx Pr > F |
|-------------------|----|----------------|-------------|---------|---------------|
| Model             | 3  | 33965.4        | 11321.8     | 745.50  | <.0001        |
| Error             | 4  | 60.7475        | 15.1869     |         |               |
| Uncorrected Total | 7  | 34026.1        |             |         |               |

The table of parameter estimates displays the estimates of the three model parameters, their approximate standard errors, 95% confidence limits, Hougaard's skewness measure, Box's bias, and percentage bias (Output 63.4.3). Parameters for which the skewness measure is less than 0.1 in absolute value and with percentage bias less than 1% exhibit very close-to-linear behavior, and skewness values less than 0.25 in absolute value indicate reasonably close-to-linear behavior (Ratkowsky 1990). According to these rules, the estimators  $\hat{\beta}$  and  $\hat{\gamma}$  suffer from substantial curvature. The estimator  $\hat{\gamma}$  is especially "far-from-linear." Inferences that involve  $\hat{\gamma}$  and rely on the reported standard errors or confidence limits (or both) for this parameter might be questionable.

**Output 63.4.3** Parameter Estimates, Hougaard’s Skewness, and Box’s Bias

| Parameter | Estimate | Approx Std Error | Approximate 95% Confidence Limits | Skewness | Bias    | Percent Bias |
|-----------|----------|------------------|-----------------------------------|----------|---------|--------------|
| alpha     | 101.8    | 3.0034           | 93.4751 110.2                     | 0.1415   | 0.1512  | 0.15         |
| beta      | 2.3570   | 0.2928           | 1.5440 3.1699                     | 0.4987   | 0.0303  | 1.29         |
| gamma     | 66.8892  | 31.6146          | -20.8870 154.7                    | 1.9200   | 10.9230 | 16.3         |

The related global nonlinearity measures output table (Output 63.4.4) shows that both the maximum and RMS parameter-effects curvature are substantially larger than the critical curvature value recommended by Bates and Watts (1980). In contrast, the intrinsic curvatures of the model are less than the critical value. This implies that most of the nonlinearity can be removed by reparameterization.

**Output 63.4.4** Global Nonlinearity Measures

| Global Nonlinearity Measures    |        |
|---------------------------------|--------|
| Max Intrinsic Curvature         | 0.2397 |
| RMS Intrinsic Curvature         | 0.1154 |
| Max Parameter-Effects Curvature | 4.0842 |
| RMS Parameter-Effects Curvature | 1.8198 |
| Curvature Critical Value        | 0.3895 |
| Raw Residual Variance           | 15.187 |
| Projected Residual Variance     | 5.922  |

One method of reducing the parameter-effects curvature, and thereby reduce the bias and skewness of the parameter estimators, is to replace a parameter with its expected-value parameterization. Schabenberger et al. (1999) and Schabenberger and Pierce (2002, sec. 5.7.2) refer to this method as *reparameterization through defining relationships*. A defining relationship is obtained by equating the mean response at a chosen value of  $x$  (say,  $x^*$ ) to the model:

$$E[Y|x^*] = \delta + \frac{\alpha - \delta}{1 + \gamma \exp\{\beta \ln(x^*)\}}$$

This equation is then solved for a parameter that is subsequently replaced in the original equation. This method is particularly useful if  $x^*$  has an interesting interpretation. For example, let  $\lambda_K$  denote the value that reduces the response by  $K \times 100\%$ ,

$$E[Y|\lambda_K] = \delta + \left(\frac{100 - K}{100}\right)(\alpha - \delta)$$

Because  $\gamma$  exhibits large bias and skewness, it is the target in the first round of reparameterization. Setting the expression for the conditional mean at  $\lambda_K$  equal to the mean function when  $x = \lambda_K$  yields the following expression:

$$\delta + \left(\frac{100 - K}{100}\right)(\alpha - \delta) = \delta + \frac{\alpha - \delta}{1 + \gamma \exp\{\beta \ln(\lambda_K)\}}$$

This expression is solved for  $\gamma$ , and the result is substituted back into the model equation. This leads to a log-logistic model in which  $\gamma$  is replaced by the parameter  $\lambda_K$ , the dose at which the response was reduced by  $K \times 100\%$ . The new model equation is

$$E[Y|x] = \delta + \frac{\alpha - \delta}{1 + K/(100 - K) \exp\{\beta \ln(x/\lambda_K)\}}$$

A particularly interesting choice is  $K = 50$ , since  $\lambda_{50}$  is the dose at which the response is halved. In studies of mortality, this concentration is also known as the LD50. For the special case of  $\lambda_{50}$  the model equation becomes

$$E[Y|x] = \delta + \frac{\alpha - \delta}{1 + \exp\{\beta \ln(x/\lambda_{50})\}}$$

You can fit the model in the LD50 parameterization with the following statements:

```
proc nlin data=logistic bias hougard;
 parameters alpha=100 beta=3 LD50=0.15;
 delta = 0;
 Switch = 1/(1+exp(beta*log(dose/LD50)));
 model y = delta + (alpha - delta)*Switch;
 output out=nlinout pred=p lcl=lcl ucl=ucl;
run;
```

Partial results from this NLIN run are shown in [Output 63.4.5](#). The analysis of variance tables in [Output 63.4.2](#) and [Output 63.4.5](#) are identical. Changing the parameterization of a model does not affect the model fit. It does, however, affect the interpretation of the parameters and the statistical properties (close-to-linear behavior) of the parameter estimators. The skewness and bias measures of the parameter LD50 is considerably reduced compared to those values for the parameter  $\gamma$  in the previous parameterization. Also,  $\gamma$  has been replaced by a parameter with a useful interpretation, the dose that yields a 50% reduction in mean response. Also notice that the bias and skewness measures of  $\alpha$  and  $\beta$  are not affected by the  $\gamma \rightarrow$  LD50 reparameterization.

To reduce the parameter-effects curvature of the  $\beta$  parameter, you can use the technique of defining relationships again. This can be done generically, by solving

$$\mu^* = \delta + \frac{\alpha - \delta}{1 + \exp\{\beta \ln(x/\lambda)\}}$$

for  $\beta$ , treating  $\mu^*$  as the new parameter (in lieu of  $\beta$ ), and choosing a value for  $x^*$  that leads to low skewness. This results in the expected-value parameterization of  $\beta$ . Solving for  $\beta$  yields

$$\beta = \frac{\log\left(\frac{\alpha - \mu^*}{\mu^* - \delta}\right)}{\log(x^*/\lambda)}$$

The interpretation of the parameter  $\mu^*$  that replaces  $\beta$  in the model equation is simple: it is the mean dose response when the dose is  $x^*$ . Fixing  $x^* = 0.3$ , the following PROC NLIN statements fit this model:

```
proc nlin data=logistic bias hougaard nlinmeasures;
 parameters alpha=100 mustar=20 LD50=0.15;
 delta = 0;
 xstar = 0.3;
 beta = log((alpha - mustar)/(mustar - delta)) / log(xstar/LD50);
 Switch = 1/(1+exp(beta*log(dose/LD50)));
 model y = delta + (alpha - delta)*Switch;
 output out=nlinout pred=p lcl=lcl ucl=ucl;
run;
```

Note that the switch-off function continues to be written in terms of  $\beta$  and the LD50. The only difference from the previous model is that  $\beta$  is now expressed as a function of the parameter  $\mu^*$ . Using expected-value parameterizations is a simple mechanism to lower the curvature in a model and to arrive at starting values. The starting value for  $\mu^*$  can be gleaned from [Output 63.4.1](#) at  $x = 0.3$ .

[Output 63.4.6](#) shows selected results from this NLIN run. The ANOVA table is again unaffected by the change in parameterization. The skewness for  $\mu^*$  is significantly reduced in comparison to those of the  $\beta$  parameter in the previous model (compare [Output 63.4.6](#) and [Output 63.4.5](#)), while its bias remains on the same scale from [Output 63.4.5](#) to [Output 63.4.6](#). Also note the substantial reduction in the parameter-effects curvature values. As expected, the intrinsic curvature values remain intact.

**Example 63.5: Comparing Nonlinear Trends among Groups**

When you model nonlinear trends in the presence of group (classification) variables, two questions often arise: whether the trends should be varied by group, and how to decide which parameters should be varied across groups. A large battery of tools is available on linear statistical models to test hypotheses involving the model parameters, especially to test linear hypotheses. To test similar hypotheses in nonlinear models, you can draw on analogous tools. Especially important in this regard are comparisons of nested models by contrasting their residual sums of squares.

In this example, a two-group model from a pharmacokinetic application is fit to data that are in part based on the theophylline data from Pinheiro and Bates (1995) and the first example in the documentation for the NLMIXED procedure. In a pharmacokinetic application you study how a drug is dispersed through a living organism. The following data represent concentrations of the drug theophylline over a 25-hour period following oral administration. The data are derived by collapsing and averaging the subject-specific data from Pinheiro and Bates (1995) in a particular, yet unimportant, way. The purpose of arranging the data in this way is purely to demonstrate the methodology.

The following code plots the theophylline concentration data over time for the two groups (Output 63.5.1). In each group the concentration tends to rise sharply right after the drug is administered, followed by a prolonged tapering of the concentration.

```
proc sgplot data=theop;
 scatter x=time y=conc / group=group;
 yaxis label='Concentration';
 xaxis label='Time';
run;
```

**Output 63.5.1** Observed Responses in Two Groups

In the context of nonlinear mixed models, Pinheiro and Bates (1995) consider a first-order compartment model for these data. In terms of two fixed treatment groups, the model can be written as

$$C_{it} = \frac{Dk_{e_i}k_{a_i}}{Cl_i(k_{a_i} - k_{e_i})} [\exp(-k_{e_i}t) - \exp(-k_{a_i}t)] + \epsilon_{it}$$

where  $C_{it}$  is the observed concentration in group  $i$  at time  $t$ ,  $D$  is the dose of theophylline,  $k_{e_i}$  is the elimination rate in group  $i$ ,  $k_{a_i}$  is the absorption rate in group  $i$ ,  $Cl_i$  is the clearance in group  $i$ , and  $\epsilon_{it}$

denotes the model error. Because the rates and the clearance must be positive, you can parameterize the model in terms of log rates and the log clearance:

$$\begin{aligned} Cl_i &= \exp\{\beta_{1i}\} \\ k_{a_i} &= \exp\{\beta_{2i}\} \\ k_{e_i} &= \exp\{\beta_{3i}\} \end{aligned}$$

In this parameterization the model contains six parameters, and the rates and clearance vary by group. This produces two separate response profiles, one for each group. On the other extreme, you could model the trends as if there were no differences among the groups:

$$\begin{aligned} Cl_i &= \exp\{\beta_1\} \\ k_{a_i} &= \exp\{\beta_2\} \\ k_{e_i} &= \exp\{\beta_3\} \end{aligned}$$

In between these two extremes lie other models, such as a model where both groups have the same absorption and elimination rate, but different clearances. The question then becomes how to go about building a model in an organized manner.

To test hypotheses about nested nonlinear models, you can apply the idea of a “Sum of Squares Reduction Test.” A reduced model is nested within a full model if you can impose  $q$  constraints on the full model to obtain the reduced model. Then, if  $SSE_r$  and  $SSE_f$  denote the residual sum of squares in the reduced and the full model, respectively, the test statistic is

$$F_R = \frac{(SSE_r - SSE_f) / q}{SSE_f / (n - p)} = \frac{(SSE_r - SSE_f) / q}{MSE_f}$$

where  $n$  are the number of observations used and  $p$  are the number of parameters in the full model. The numerator of the  $F_R$  statistic is the average reduction in residual sum of squares per constraint. The mean squared error of the full model is used to scale this average because it is less likely to be a biased estimator of the residual variance than the variance estimate from a constrained (reduced) model. The  $F_R$  statistic is then compared against quantiles from an  $F$  distribution with  $q$  numerator and  $n - p$  denominator degrees of freedom. Schabenberger and Pierce (2002) discuss the justification for this test and compare it to other tests in nonlinear models.

In the present application we might phrase the initial question akin to the overall  $F$  test for a factor in a linear model: Should any parameters be varied between the two groups? The corresponding null hypothesis is

$$H: \begin{cases} \beta_{11} = \beta_{12} \\ \beta_{21} = \beta_{22} \\ \beta_{31} = \beta_{32} \end{cases}$$

where the first subscript identifies the type of the parameter and the second subscript identifies the group. Note that this hypothesis implies

$$H: \begin{cases} Cl_1 = Cl_2 \\ k_{a_1} = k_{a_2} \\ k_{e_1} = k_{e_2} \end{cases}$$

If you fail to reject this hypothesis, there is no need to further examine individual parameter differences.

The reduced model—the model subject to the null hypothesis—is fit with the following PROC NLIN statements:

```
proc nlin data=theop;
 parms beta1=-3.22 beta2=0.47 beta3=-2.45;
 c1 = exp(beta1);
 ka = exp(beta2);
 ke = exp(beta3);
 mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
 model conc = mean;
 ods output Anova=aovred(rename=(ss=ssred ms=msred df=dfred));
run;
```

The clearance, the rates, and the mean function are formed independently of the group membership. The analysis of variance table is saved to the data set aovred, and some of its variables are renamed. This is done so that the data set can be merged easily with the analysis of variance table for the full model (see following).

The converged model has a residual sum of square of  $SSE_r = 286.4$  and a mean squared error of 3.0142 (Output 63.5.2). The table of parameter estimates gives the values for the estimated log clearance ( $\hat{\beta}_1 = -3.2991$ ), the estimated log absorption rate ( $\hat{\beta}_2 = 0.4769$ ), and the estimated log elimination rate ( $\hat{\beta}_3 = -2.5555$ ).

The full model, in which all three parameters are varied by group, can be fit with the following statements in the NLIN procedure:

```
proc nlin data=theop;
 parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
 beta1_2=-3.22 beta2_2=0.47 beta3_2=-2.45;
 if (group=1) then do;
 c1 = exp(beta1_1);
 ka = exp(beta2_1);
 ke = exp(beta3_1);
 end; else do;
 c1 = exp(beta1_2);
 ka = exp(beta2_2);
 ke = exp(beta3_2);
 end;
 mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
 model conc = mean;
 ods output Anova=aovfull;
run;
```

Separate parameters for the groups are now specified in the **PARMS** statement, and the value of the model variables *c1*, *ka*, and *ke* is assigned conditional on the group membership of an observation. Notice that the same expression as in the previous run can be used to model the mean function.

The results from this PROC NLIN run are shown in **Output 63.5.3**. The residual sum of squares in the full model is only  $SSE_f = 138.9$ , compared to  $SSE_r = 286.4$  in the reduced model (**Output 63.5.3**).

Whether this reduction in sum of squares is sufficient to declare that the full model provides a significantly better fit than the reduced model depends on the number of constraints imposed on the full model and on the variability in the data. In other words, before drawing any conclusions, you have to take into account how many parameters have been dropped from the model and how much variation around the regression trends the data exhibit. The  $F_R$  statistic sets these quantities into relation. The following macro merges the analysis of variance tables from the full and reduced model, and computes  $F_R$  and its  $p$ -value:

```
%macro SSReductionTest;
 data aov; merge aovred aovfull;
 if (Source='Error') then do;
 Fstat = ((SSred-SS)/(dfred-df))/ms;
 pvalue = 1-ProbF(Fstat,dfred-df,df);
 output;
 end;
run;
proc print data=aov label noobs;
 label Fstat = 'F Value'
 pValue = 'Prob > F';
 format pvalue pvalue8.;
 var Fstat pValue;
run;
%mend;
%SSReductionTest;
```

#### Output 63.5.4 F Statistic and P-value for Hypothesis of Equal Trends

|  | F Value | Prob > F |
|--|---------|----------|
|  | 32.5589 | <.000001 |

There is clear evidence that the model with separate trends fits these data significantly better (Output 63.5.4). To decide whether all parameters should be varied between the groups or only one or two of them, we first refit the model in a slightly different parameterization:

```
proc nlin data=theop;
 parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
 beta1_diff=0 beta2_diff=0 beta3_diff=0;
 if (group=1) then do;
 c1 = exp(beta1_1);
 ka = exp(beta2_1);
 ke = exp(beta3_1);
 end; else do;
 c1 = exp(beta1_1 + beta1_diff);
 ka = exp(beta2_1 + beta2_diff);
 ke = exp(beta3_1 + beta3_diff);
 end;
 mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
 model conc = mean;
run;
```

In the preceding statements, the parameters in the second group were expressed using offsets from parameters in the first group. For example, the parameter `beta1_diff` measures the change in log clearance between group 2 and group 1.

This simple reparameterization does not affect the model fit. The analysis of variance tables in [Output 63.5.5](#) and [Output 63.5.3](#) are identical. It does, however, affect the interpretation of the estimated quantities. Since the parameter `beta1_diff` measures the change in the log clearance rates between the groups, you can use the approximate 95% confidence limits in [Output 63.5.5](#) to assess whether that quantity in the pharmacokinetic equation varies between groups. Only the confidence interval for the difference in the log clearances excludes 0. The intervals for `beta2_diff` and `beta3_diff` include 0.

**Output 63.5.5** Fit Results for the Full Model in Difference Parameterization

This suggests as the final model one where the absorption and elimination rates are the same for both groups and only the clearances are varied. The following statements fit this model and perform the sum of squares reduction test:

```
proc nlin data=theop;
 parms beta1_1=-3.22 beta2_1=0.47 beta3_1=-2.45
 beta1_diff=0;
 ka = exp(beta2_1);
 ke = exp(beta3_1);
 if (group=1) then do;
 cl = exp(beta1_1);
 end; else do;
 cl = exp(beta1_1 + beta1_diff);
 end;
 mean = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
 model conc = mean;
 ods output Anova=aovred(rename=(ss=ssred ms=msred df=dfred));
```

```

output out=predvals predicted=p;
run;
%SSReductionTest;

```

The results for this model with common absorption and elimination rates are shown in [Output 63.5.6](#). The sum-of-squares reduction test comparing this model against the full model with six parameters shows—as expected—that the full model does not fit the data significantly better ( $p = 0.6193$ , [Output 63.5.7](#)).

**Output 63.5.7** F Statistic and P-value for Hypothesis of Common Rates

| F Value | Prob > F |
|---------|----------|
| 0.48151 | 0.619398 |

A plot of the observed and predicted values for this final model is obtained with the following statements:

```

proc sgplot data=predvals;
 scatter x=time y=conc / group=group;
 series x=time y=p / group=group name='fit';
 keylegend 'fit' / across=2 title='Group';
 yaxis label='Concentration';
 xaxis label='Time';
run;

```

The plot is shown in [Output 63.5.8](#).

**Output 63.5.8** Observed and Fitted Values for Theophylline Data

The sum-of-squares reduction test is not the only possibility of performing linear-model style hypothesis testing in nonlinear models. You can also perform Wald-type testing of linear hypotheses about the parameter estimates. See [Example 41.17](#) in Chapter 41, “The GLIMMIX Procedure,” for an application of this example that uses the NLIN and GLIMMIX procedures to compare the parameters across groups and adjusts  $p$ -values for multiplicity.

## Example 63.6: ODS Graphics and Diagnostics

The model in this example, taken from St. Laurent and Cook (1993), shows an unusual behavior in that the intrinsic curvature is substantially larger than the parameter-effects curvature. This example demonstrates how the diagnostics features of PROC NLIN can be used to perform postconvergence diagnostics.

The model takes the form

$$E[Y|x_1, x_2] = \alpha x_1 + \exp\{\gamma x_2\}$$

The following DATA step creates a small data set to be used in this example:

```

data contrived;
 input x1 x2 y;
 datalines;
-4.0 -2.5 -10.0
-3.0 -2.0 -5.0
-2.0 -1.5 -2.0
-1.0 -1.0 -1.0
 0.0 0.0 1.5
 1.0 1.0 4.0
 2.0 1.5 5.0
 3.0 2.0 6.0
 4.0 2.5 7.0
-3.5 -2.2 -7.1
-3.5 -1.7 -5.1
 3.5 0.7 6.1
 2.5 1.2 7.5
;

```

The model is fit with the following statements in the NLIN procedure:

```

ods graphics on;
proc nlin data=contrived bias hougaard
 NLINMEASURES plots(stats=all)=(diagnostics);
 parms alpha=2.0
 gamma=0.0;
 model y = alpha*x1 + exp(gamma*x2);
run;
ods graphics off;

```

#### Output 63.6.1 Bias, Skewness, and Global Nonlinearity Measures

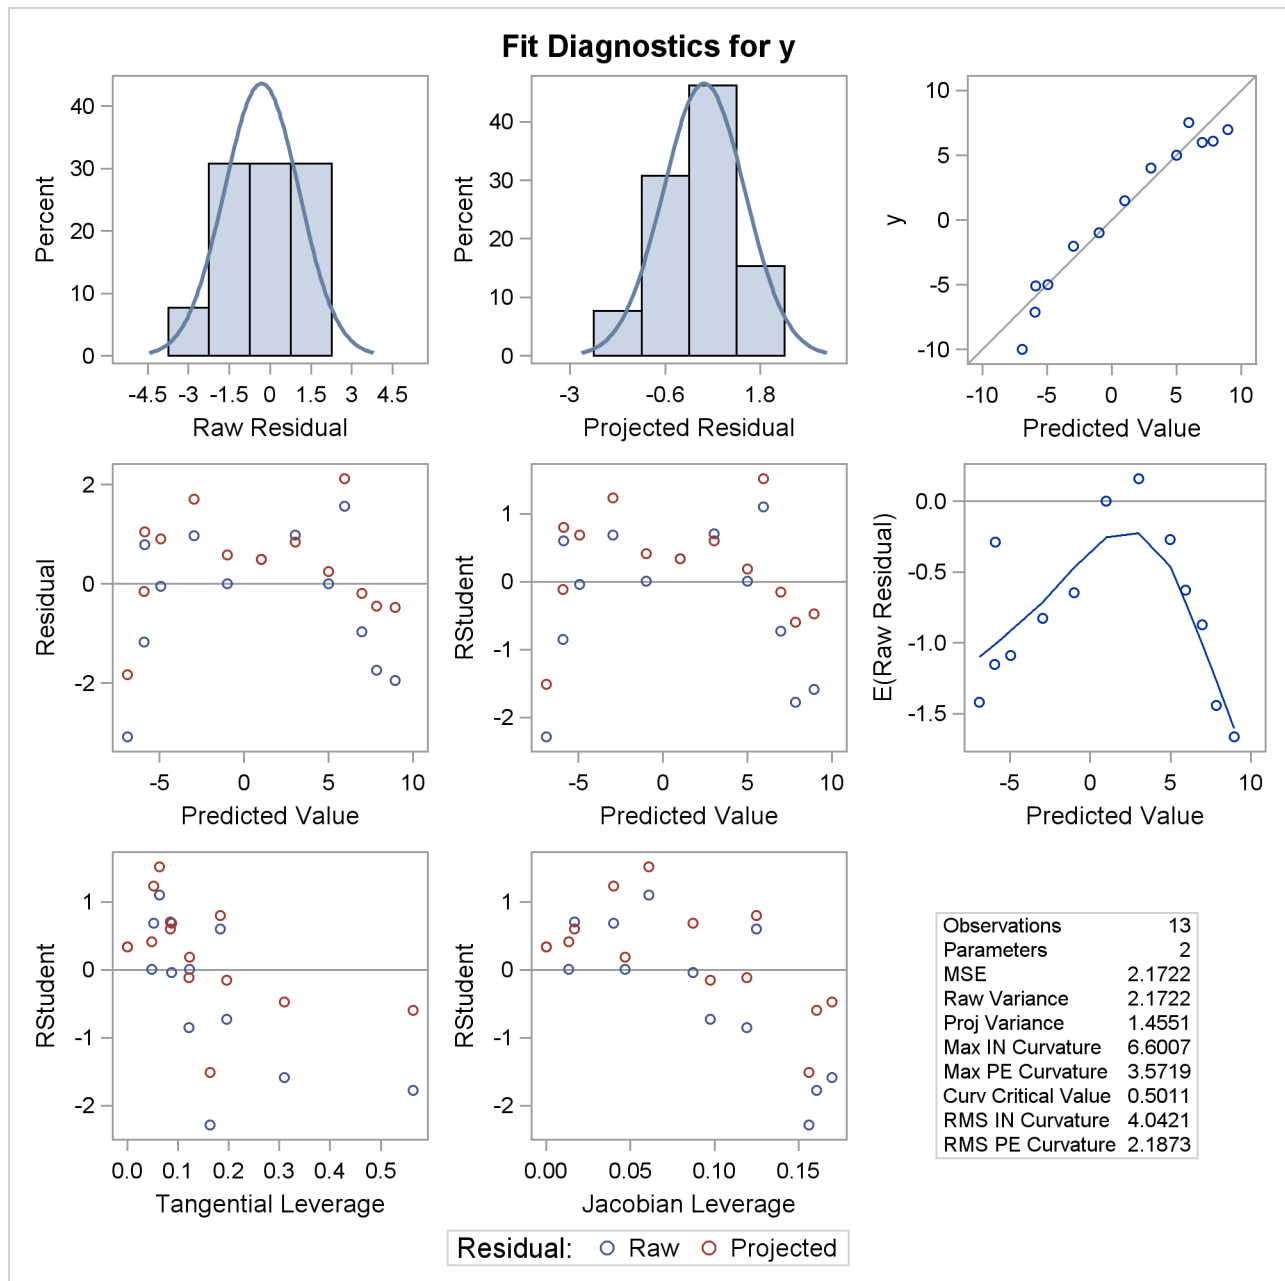

| The NLIN Procedure           |                                 |                  |                                   |        |          |         |              |

|                              | Curvature Critical Value        |                  |                                   |        | 0.5011   |         |              |
|                              | Raw Residual Variance           |                  |                                   |        | 2.1722   |         |              |
|                              | Projected Residual Variance     |                  |                                   |        | 1.4551   |         |              |

The bias, skewness, and both the maximum and RMS intrinsic curvatures, compared to the critical curvature value, show that the model is highly nonlinear (Output 63.6.1). As such, performing diagnostics with the

raw residuals can be problematic because they might have undesirable statistical properties: a nonzero mean and a negative semidefinite (instead of zero) covariance with the predicted values and different variances. In addition, the use of tangential leverage is questionable in this case.

The partial results from this NLIN run are shown in [Output 63.6.2](#), [Output 63.6.3](#), and [Output 63.6.4](#). The diagnostics plots corroborate the previously mentioned expectations: highly correlated raw residuals (with the predicted values), significant differences between tangential and Jacobian leverages and projected residuals which overcome some of the shortcomings of the raw residuals. Finally, considering the large intrinsic curvature, reparameterization might not make the model close-to-linear, perhaps necessitating the construction of another model.

**Output 63.6.2** Diagnostics Panel

Output 63.6.3 Leverage Plots

Output 63.6.4 Local Influence Plot

## Example 63.7: Parameter Profiling

The following model, taken from Clarke (1987a), demonstrates the benefits of parameter profiling and confidence curves to identify the nonlinear characteristics of parameters that occur in the model. The profiling is also augmented with a plot that shows the influence of each observation on the parameter estimates.

The model takes the form

$$E[Y|x] = \theta_3 + \theta_2 \exp\{\theta_1 x\}$$

The data set used in this example is taken from Clarke (1987a). The following DATA step creates this data set:

```
data clarke1987a;
 input x y;
 datalines;
1 3.183
2 3.059
3 2.871
4 2.622
5 2.541
6 2.184
7 2.110
8 2.075
9 2.018
10 1.903
11 1.770
12 1.762
13 1.550
;
```

The model is fit with the following statements in the NLIN procedure:

```
ods graphics on;
proc nlin data=clarke1987a plots(stats=none)=diagnostics;
 parms theta1=-0.15
 theta2=2.0
 theta3=0.80;
 profile theta3 / range = -6 to 2 by 0.2 all;
 model y = theta3 + theta2*exp(theta1*x);
run;
ods graphics off;
```

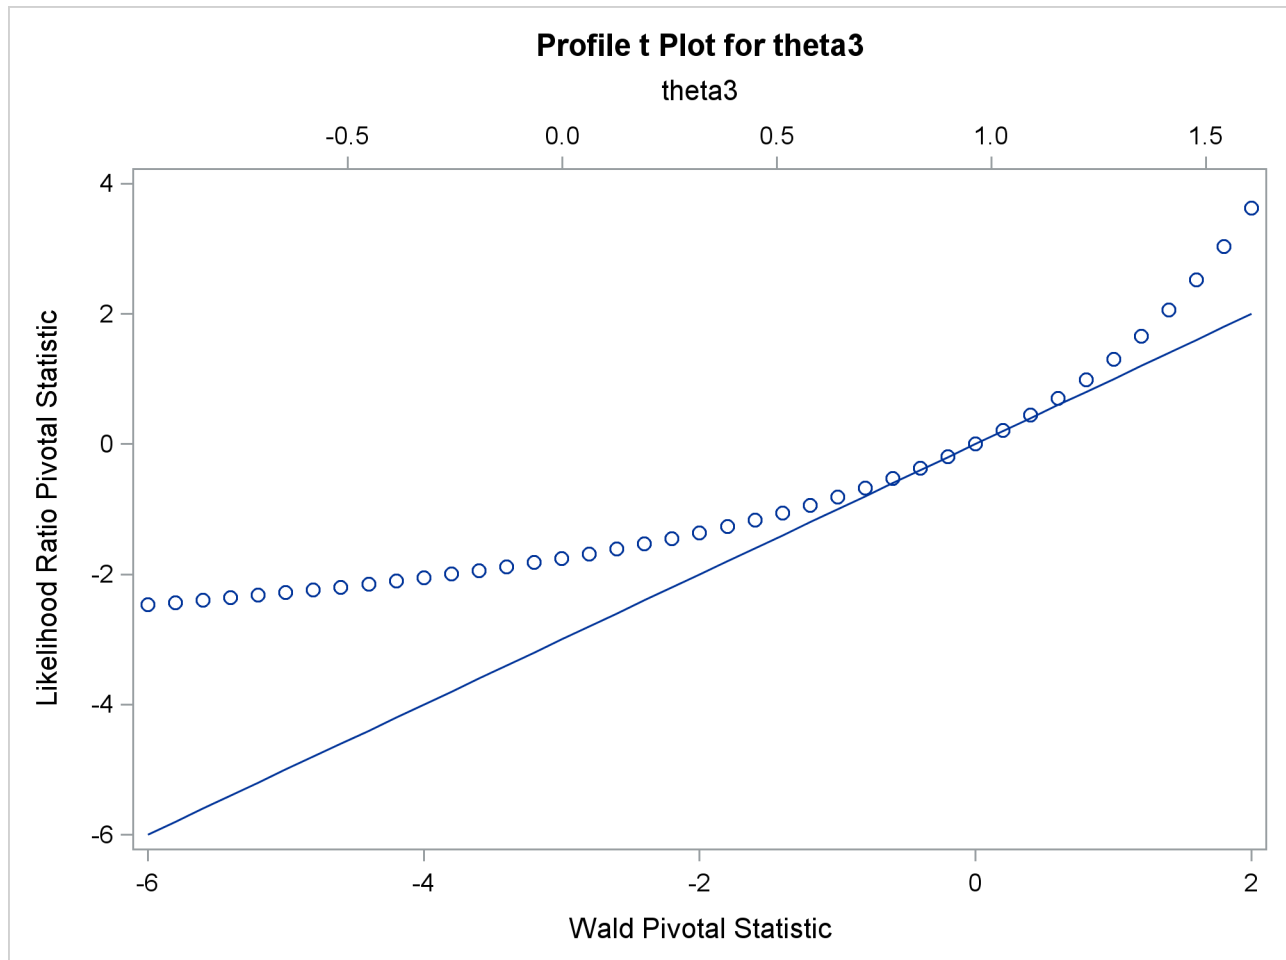

The profile  $t$  plot, [Output 63.7.1](#), for parameter  $\theta_3$  shows a definite deviation from the linear reference line that has a slope of 1 and passes through the origin. Hence, Wald-based inference for  $\theta_3$  is not appropriate. The confidence curve for  $\theta_3$  validates this conclusion.

[Output 63.7.2](#) shows the confidence curve for  $\theta_3$ . You can see that there is a significant difference between the Wald-based confidence interval and the corresponding likelihood-based interval. In such cases, the likelihood-based intervals are preferred because their coverage rate is much closer to the nominal values than the coverage rate of the Wald-based intervals (Donaldson and Schnabel 1987; Cook and Weisberg 1990). Furthermore, this example shows that the adequacy of a linear approximation with regards to a certain parameter cannot be inferred directly from the model. If it could,  $\theta_3$ , which enters the model linearly,

would have a completely linear behavior. For a detailed discussion about this issue, see Cook and Weisberg (1990).

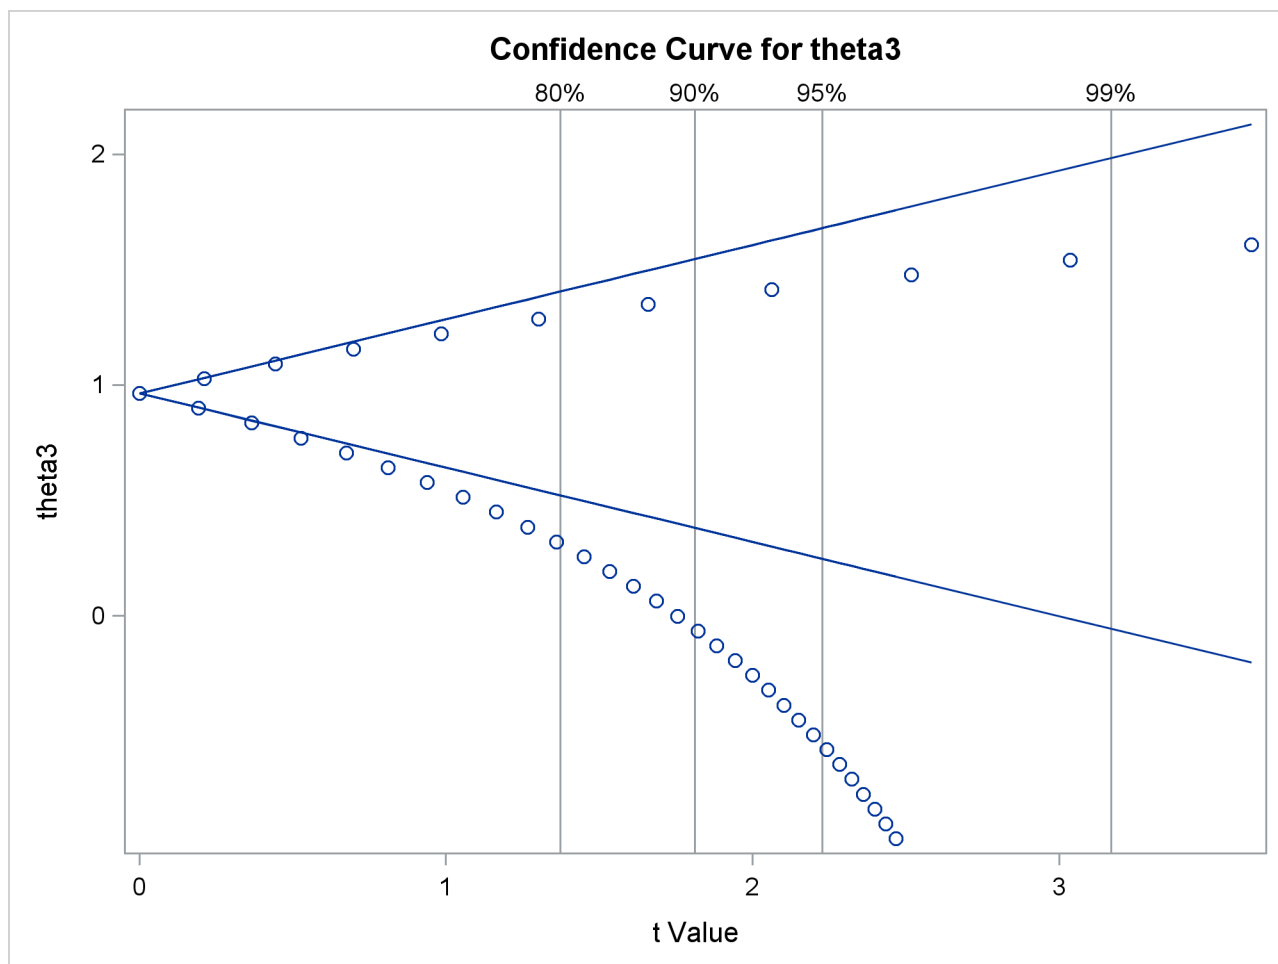

Finally, [Output 63.7.3](#) depicts the influence of each observation on the value of  $\theta_3$ . Observations 6 and 13 have the most influence on the value of this parameter. The plot is generated using the leave-one-out method and should be contrasted with the local influence plot, [Output 63.7.4](#), which is based on assessing the influence of an additive perturbation of the response variable.

**Output 63.7.1** Profile  $t$  Plot

Output 63.7.2 Confidence Curve

**Output 63.7.3** Observation Influence on Parameter Estimate

**Output 63.7.4** Local Influence Plot

## Overview: NLMIXED Procedure

---

### Introduction

The NLMIXED procedure fits nonlinear mixed models—that is, models in which both fixed and random effects enter nonlinearly. These models have a wide variety of applications, two of the most common being pharmacokinetics and overdispersed binomial data. PROC NLMIXED enables you to specify a conditional distribution for your data (given the random effects) having either a standard form (normal, binomial, Poisson) or a general distribution that you code using SAS programming statements.

PROC NLMIXED fits nonlinear mixed models by maximizing an approximation to the likelihood integrated over the random effects. Different integral approximations are available, the principal ones being adaptive Gaussian quadrature and a first-order Taylor series approximation. A variety of alternative optimization techniques are available to carry out the maximization; the default is a dual quasi-Newton algorithm.

Successful convergence of the optimization problem results in parameter estimates along with their approximate standard errors based on the second derivative matrix of the likelihood function. PROC NLMIXED enables you to use the estimated model to construct predictions of arbitrary functions by using empirical Bayes estimates of the random effects. You can also estimate arbitrary functions of the nonrandom parameters, and PROC NLMIXED computes their approximate standard errors by using the delta method.

### Literature on Nonlinear Mixed Models

Davidian and Giltinan (1995) and Vonesh and Chinchilli (1997) provide good overviews as well as general theoretical developments and examples of nonlinear mixed models. Pinheiro and Bates (1995) is a primary reference for the theory and computational techniques of PROC NLMIXED. They describe and compare several different integrated likelihood approximations and provide evidence that adaptive Gaussian quadrature is one of the best methods. Davidian and Gallant (1993) also use Gaussian quadrature for nonlinear mixed models, although the smooth nonparametric density they advocate for the random effects is currently not available in PROC NLMIXED.

Traditional approaches to fitting nonlinear mixed models involve Taylor series expansions, expanding around either zero or the empirical best linear unbiased predictions of the random effects. The former is the basis for the well-known first-order method (Beal and Sheiner 1982, 1988; Sheiner and Beal 1985),

and it is optionally available in PROC NL MIXED. The latter is the basis for the estimation method of Lindstrom and Bates (1990), and it is not available in PROC NL MIXED. However, the closely related Laplacian approximation is an option; it is equivalent to adaptive Gaussian quadrature with only one quadrature point. The Laplacian approximation and its relationship to the Lindstrom-Bates method are discussed by: Beal and Sheiner (1992); Wolfinger (1993); Vonesh (1992, 1996); Vonesh and Chinchilli (1997); Wolfinger and Lin (1997).

A parallel literature exists in the area of generalized linear mixed models, in which random effects appear as a part of the linear predictor inside a link function. Taylor-series methods similar to those just described are discussed in articles such as: Harville and Mee (1984); Stiratelli, Laird, and Ware (1984); Gilmour, Anderson, and Rae (1985); Goldstein (1991); Schall (1991); Engel and Keen (1992); Breslow and Clayton (1993); Wolfinger and O'Connell (1993); McGilchrist (1994), but such methods have not been implemented in PROC NL MIXED because they can produce biased results in certain binary data situations (Rodriguez and Goldman 1995; Lin and Breslow 1996). Instead, a numerical quadrature approach is available in PROC NL MIXED, as discussed in: Pierce and Sands (1975); Anderson and Aitkin (1985); Hedeker and Gibbons (1994); Crouch and Spiegelman (1990); Longford (1994); McCulloch (1994); Liu and Pierce (1994); Diggle, Liang, and Zeger (1994).

Nonlinear mixed models have important applications in pharmacokinetics, and Roe (1997) provides a wide-ranging comparison of many popular techniques. Yuh et al. (1994) provide an extensive bibliography on nonlinear mixed models and their use in pharmacokinetics.

---

## PROC NL MIXED Compared with Other SAS Procedures and Macros

The models fit by PROC NL MIXED can be viewed as generalizations of the random coefficient models fit by the MIXED procedure. This generalization allows the random coefficients to enter the model nonlinearly, whereas in PROC MIXED they enter linearly. With PROC MIXED you can perform both maximum likelihood and restricted maximum likelihood (REML) estimation, whereas PROC NL MIXED implements only maximum likelihood. This is because the analog to the REML method in PROC NL MIXED would involve a high-dimensional integral over all of the fixed-effects parameters, and this integral is typically not available in closed form. Finally, PROC MIXED assumes the data to be normally distributed, whereas PROC NL MIXED enables you to analyze data that are normal, binomial, or Poisson or that have any likelihood programmable with SAS statements.

PROC NL MIXED does not implement the same estimation techniques available with the NLINMIX macro or the default estimation method of the GLIMMIX procedure. These are based on the estimation methods of: Lindstrom and Bates (1990); Breslow and Clayton (1993); Wolfinger and O'Connell (1993), and they iteratively fit a set of generalized estimating equations (see Chapters 14 and 15 of Littell et al. 2006; Wolfinger 1997). In contrast, PROC NL MIXED directly maximizes an approximate integrated likelihood. This remark also applies to the SAS/IML macros MIXNLIN (Vonesh and Chinchilli 1997) and NLMEM (Galecki 1998).

The GLIMMIX procedure also fits mixed models for nonnormal data with nonlinearity in the conditional mean function. In contrast to the NL MIXED procedure, PROC GLIMMIX assumes that the model contains a linear predictor that links covariates to the conditional mean of the response. The NL MIXED procedure is designed to handle general conditional mean functions, whether they contain a linear component or not. As mentioned earlier, the GLIMMIX procedure by default estimates parameters in generalized linear mixed models by pseudo-likelihood techniques, whereas PROC NL MIXED by default performs maximum likeli-

hood estimation by adaptive Gauss-Hermite quadrature. This estimation method is also available with the GLIMMIX procedure (METHOD=QUAD in the PROC GLIMMIX statement).

PROC NLMIXED has close ties with the NLP procedure in SAS/OR software. PROC NLMIXED uses a subset of the optimization code underlying PROC NLP and has many of the same optimization-based options. Also, the programming statement functionality used by PROC NLMIXED is the same as that used by PROC NLP and the MODEL procedure in SAS/ETS software.

## Getting Started: NLMIXED Procedure

### Nonlinear Growth Curves with Gaussian Data

As an introductory example, consider the orange tree data of Draper and Smith (1981). These data consist of seven measurements of the trunk circumference (in millimeters) on each of five orange trees. You can input these data into a SAS data set as follows:

```
data tree;
 input tree day y;
 datalines;
1 118 30
1 484 58
1 664 87

... more lines ...

5 1582 177
;
```

Lindstrom and Bates (1990) and Pinheiro and Bates (1995) propose the following logistic nonlinear mixed model for these data:

$$y_{ij} = \frac{b_1 + u_{i1}}{1 + \exp[-(d_{ij} - b_2)/b_3]} + e_{ij}$$

Here,  $y_{ij}$  represents the  $j$ th measurement on the  $i$ th tree ( $i = 1, \dots, 5; j = 1, \dots, 7$ ),  $d_{ij}$  is the corresponding day,  $b_1, b_2, b_3$  are the fixed-effects parameters,  $u_{i1}$  are the random-effect parameters assumed to be iid  $N(0, \sigma_u^2)$ , and  $e_{ij}$  are the residual errors assumed to be iid  $N(0, \sigma_e^2)$  and independent of the  $u_{i1}$ . This model has a logistic form, and the random-effect parameters  $u_{i1}$  enter the model linearly.

The statements to fit this nonlinear mixed model are as follows:

```
proc nlmixed data=tree;
 parms b1=190 b2=700 b3=350 s2u=1000 s2e=60;
 num = b1+u1;
 ex = exp(-(day-b2)/b3);
 den = 1 + ex;
 model y ~ normal(num/den, s2e);
 random u1 ~ normal(0, s2u) subject=tree;
run;
```

The **PROC NLMIXED** statement invokes the procedure and inputs the tree data set. The **PARMS** statement identifies the unknown parameters and their starting values. Here there are three fixed-effects parameters ( $b_1$ ,  $b_2$ ,  $b_3$ ) and two variance components ( $s^2u$ ,  $s^2e$ ).

The next three statements are SAS programming statements specifying the logistic mixed model. A new variable  $u_1$  is included to identify the random effect. These statements are evaluated for every observation in the data set when the NLMIXED procedure computes the log likelihood function and its derivatives.

The **MODEL** statement defines the dependent variable and its conditional distribution given the random effects. Here a normal (Gaussian) conditional distribution is specified with mean  $\text{num}/\text{den}$  and variance  $s^2e$ .

The **RANDOM** statement defines the single random effect to be  $u_1$ , and specifies that it follow a normal distribution with mean 0 and variance  $s^2u$ . The **SUBJECT=** argument in the **RANDOM** statement defines a variable indicating when the random effect obtains new realizations; in this case, it changes according to the values of the *tree* variable. PROC NLMIXED assumes that the input data set is clustered according to the levels of the *tree* variable; that is, all observations from the same tree occur sequentially in the input data set.

The output from this analysis is as follows.

**Figure 64.1** Model Specifications

| The NLMIXED Procedure               |                                 |
|-------------------------------------|---------------------------------|
| Specifications                      |                                 |
| Data Set                            | WORK.TREE                       |
| Dependent Variable                  | Y                               |
| Distribution for Dependent Variable | Normal                          |
| Random Effects                      | $u_1$                           |
| Distribution for Random Effects     | Normal                          |
| Subject Variable                    | tree                            |
| Optimization Technique              | Dual Quasi-Newton               |
| Integration Method                  | Adaptive Gaussian<br>Quadrature |

The “Specifications” table lists basic information about the nonlinear mixed model you have specified (Figure 64.1). Included are the input data set, the dependent and subject variables, the random effects, the relevant distributions, and the type of optimization. The “Dimensions” table lists various counts related to the model, including the number of observations, subjects, and parameters (Figure 64.2). These quantities are useful for checking that you have specified your data set and model correctly. Also listed is the number of quadrature points that PROC NLMIXED has selected based on the evaluation of the log likelihood at the starting values of the parameters. Here, only one quadrature point is necessary because the random-effect parameters  $u_{i1}$  enter the model linearly. (The Gauss-Hermite quadrature with a single quadrature point results in the Laplace approximation of the log likelihood.)

**Figure 64.2** Dimensions Table for Growth Curve Model

| Dimensions            |    |
|-----------------------|----|
| Observations Used     | 35 |
| Observations Not Used | 0  |
| Total Observations    | 35 |
| Subjects              | 5  |
| Max Obs Per Subject   | 7  |
| Parameters            | 5  |
| Quadrature Points     | 1  |

**Figure 64.3** Starting Values of Parameter Estimates and Negative Log Likelihood

| Parameters |     |     |      |     |            |
|------------|-----|-----|------|-----|------------|
| b1         | b2  | b3  | s2u  | s2e | NegLogLike |
| 190        | 700 | 350 | 1000 | 60  | 132.491787 |

The “Parameters” table lists the parameters to be estimated, their starting values, and the negative log likelihood evaluated at the starting values (Figure 64.3).

**Figure 64.4** Iteration History for Growth Curve Model

| Iteration History |       |            |          |          |          |
|-------------------|-------|------------|----------|----------|----------|
| Iter              | Calls | NegLogLike | Diff     | MaxGrad  | Slope    |
| 1                 | 4     | 131.686742 | 0.805045 | 0.010269 | -0.633   |

| 4                 | 10    | 131.572522 | 0.041555 | 0.001186 | -0.01344 |
| 5                 | 11    | 131.571895 | 0.000627 | 0.0002   | -0.00121 |
| 6                 | 13    | 131.571889 | 5.549E-6 | 0.000092 | -7.68E-6 |
| 7                 | 15    | 131.571888 | 1.096E-6 | 6.097E-6 | -1.29E-6 |

NOTE: GCONV convergence criterion satisfied.

The “Iteration History” table records the history of the minimization of the negative log likelihood (Figure 64.4). For each iteration of the quasi-Newton optimization, values are listed for the number of function calls, the value of the negative log likelihood, the difference from the previous iteration, the absolute value of the largest gradient, and the slope of the search direction. The note at the bottom of the table indicates that the algorithm has converged successfully according to the **GCONV** convergence criterion, a standard criterion computed using a quadratic form in the gradient and the inverse Hessian.

The final maximized value of the log likelihood as well as the information criterion of Akaike (AIC), its small sample bias corrected version (AICC), and the Bayesian information criterion (BIC) in the “smaller is better” form appear in the “Fit Statistics” table (Figure 64.5). These statistics can be used to compare different nonlinear mixed models.

**Figure 64.5** Fit Statistics for Growth Curve Model

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Log Likelihood        | 263.1 |
| AIC (smaller is better)  | 273.1 |
| AICC (smaller is better) | 275.2 |
| BIC (smaller is better)  | 271.2 |

**Figure 64.6** Parameter Estimates at Convergence

| Parameter Estimates |          |                |    |         |         |       |         |
|---------------------|----------|----------------|----|---------|---------|-------|---------|
| Parameter           | Estimate | Standard Error | DF | t Value | Pr >  t | Alpha | Lower   |
| b1                  | 192.05   | 15.6473        | 4  | 12.27   | 0.0003  | 0.05  | 148.61  |
| b2                  | 727.90   | 35.2472        | 4  | 20.65   | <.0001  | 0.05  | 630.04  |
| b3                  | 348.07   | 27.0790        | 4  | 12.85   | 0.0002  | 0.05  | 272.88  |
| s2u                 | 999.88   | 647.44         | 4  | 1.54    | 0.1974  | 0.05  | -797.70 |
| s2e                 | 61.5139  | 15.8831        | 4  | 3.87    | 0.0179  | 0.05  | 17.4153 |

| Parameter Estimates |         |          |
|---------------------|---------|----------|
| Parameter           | Upper   | Gradient |
| b1                  | 235.50  | 1.154E-6 |
| b2                  | 825.76  | 5.289E-6 |
| b3                  | 423.25  | -6.1E-6  |
| s2u                 | 2797.45 | -3.84E-6 |
| s2e                 | 105.61  | 2.892E-6 |

The maximum likelihood estimates of the five parameters and their approximate standard errors computed using the final Hessian matrix are displayed in the “Parameter Estimates” table (Figure 64.6). Approximate *t*-values and Wald-type confidence limits are also provided, with degrees of freedom equal to the number of subjects minus the number of random effects. You should interpret these statistics cautiously for variance parameters like s2u and s2e. The final column in the output shows the gradient vector at the optimization solution. Each element appears to be sufficiently small to indicate a stationary point.

Since the random-effect parameters  $u_{i1}$  enter the model linearly, you can obtain equivalent results by using the first-order method (specify `METHOD=FIRO` in the `PROC NL MIXED` statement).

## Logistic-Normal Model with Binomial Data

This example analyzes the data from Beitler and Landis (1985), which represent results from a multi-center clinical trial investigating the effectiveness of two topical cream treatments (active drug, control) in curing an infection. For each of eight clinics, the number of trials and favorable cures are recorded for each treatment. The SAS data set is as follows.

```
data infection;
 input clinic t x n;
 datalines;
1 1 11 36
1 0 10 37
2 1 16 20
2 0 22 32
3 1 14 19
3 0 7 19
4 1 2 16
4 0 1 17
5 1 6 17
5 0 0 12
6 1 1 11
6 0 0 10
7 1 1 5
7 0 1 9
8 1 4 6
8 0 6 7
;
```

Suppose  $n_{ij}$  denotes the number of trials for the  $i$ th clinic and the  $j$ th treatment ( $i = 1, \dots, 8; j = 0, 1$ ), and  $x_{ij}$  denotes the corresponding number of favorable cures. Then a reasonable model for the preceding data is the following logistic model with random effects:

$$x_{ij}|u_i \sim \text{Binomial}(n_{ij}, p_{ij})$$

and

$$\eta_{ij} = \log\left(\frac{p_{ij}}{1 - p_{ij}}\right) = \beta_0 + \beta_1 t_j + u_i$$

The notation  $t_j$  indicates the  $j$ th treatment, and the  $u_i$  are assumed to be iid  $N(0, \sigma_u^2)$ .

The PROC NLMIXED statements to fit this model are as follows:

```
proc nlmixed data=infection;
 parms beta0=-1 beta1=1 s2u=2;
 eta = beta0 + beta1*t + u;
 expeta = exp(eta);
 p = expeta/(1+expeta);
 model x ~ binomial(n,p);
 random u ~ normal(0,s2u) subject=clinic;
 predict eta out=eta;
 estimate '1/beta1' 1/beta1;
run;
```

The **PROC NL MIXED** statement invokes the procedure, and the **PARMS** statement defines the parameters and their starting values. The next three statements define  $p_{ij}$ , and the **MODEL** statement defines the conditional distribution of  $x_{ij}$  to be binomial. The **RANDOM** statement defines  $u$  to be the random effect with subjects defined by the clinic variable.

The **PREDICT** statement constructs predictions for each observation in the input data set. For this example, predictions of  $\eta_{ij}$  and approximate standard errors of prediction are output to a data set named eta. These predictions include empirical Bayes estimates of the random effects  $u_i$ .

The **ESTIMATE** statement requests an estimate of the reciprocal of  $\beta_1$ .

The output for this model is as follows.

**Figure 64.7** Model Information and Dimensions for Logistic-Normal Model

| The NL MIXED Procedure              |                              |
|-------------------------------------|------------------------------|
| Specifications                      |                              |
| Data Set                            | WORK.INFECTION               |
| Dependent Variable                  | x                            |
| Distribution for Dependent Variable | Binomial                     |
| Random Effects                      | u                            |
| Distribution for Random Effects     | Normal                       |
| Subject Variable                    | clinic                       |
| Optimization Technique              | Dual Quasi-Newton            |
| Integration Method                  | Adaptive Gaussian Quadrature |
| Dimensions                          |                              |
| Observations Used                   | 16                           |
| Observations Not Used               | 0                            |
| Total Observations                  | 16                           |
| Subjects                            | 8                            |
| Max Obs Per Subject                 | 2                            |
| Parameters                          | 3                            |
| Quadrature Points                   | 5                            |

The “Specifications” table provides basic information about the nonlinear mixed model (Figure 64.7). For example, the distribution of the response variable, conditional on normally distributed random effects, is binomial. The “Dimensions” table provides counts of various variables. You should check this table to make sure the data set and model have been entered properly. PROC NL MIXED selects five quadrature points to achieve the default accuracy in the likelihood calculations.

**Figure 64.8** Starting Values of Parameter Estimates

| Parameters |       |     |            |
|------------|-------|-----|------------|
| beta0      | beta1 | s2u | NegLogLike |
| -1         | 1     | 2   | 37.5945925 |

The “Parameters” table lists the starting point of the optimization and the negative log likelihood at the starting values (Figure 64.8).

**Figure 64.9** Iteration History and Fit Statistics for Logistic-Normal Model

| Iteration History |       |            |          |          |          |
|-------------------|-------|------------|----------|----------|----------|
| Iter              | Calls | NegLogLike | Diff     | MaxGrad  | Slope    |
| 1                 | 2     | 37.3622692 | 0.232323 | 2.882077 | -19.3762 |
| 2                 | 3     | 37.1460375 | 0.216232 | 0.921926 | -0.82852 |
| 3                 | 5     | 37.0300936 | 0.115944 | 0.315897 | -0.59175 |
| 4                 | 6     | 37.0223017 | 0.007792 | 0.01906  | -0.01615 |
| 5                 | 7     | 37.0222472 | 0.000054 | 0.001743 | -0.00011 |
| 6                 | 9     | 37.0222466 | 6.57E-7  | 0.000091 | -1.28E-6 |
| 7                 | 11    | 37.0222466 | 5.38E-10 | 2.078E-6 | -1.1E-9  |

NOTE: GCONV convergence criterion satisfied.

| Fit Statistics           |      |
|--------------------------|------|
| -2 Log Likelihood        | 74.0 |
| AIC (smaller is better)  | 80.0 |
| AICC (smaller is better) | 82.0 |
| BIC (smaller is better)  | 80.3 |

The “Iteration History” table indicates successful convergence in seven iterations (Figure 64.9). The “Fit Statistics” table lists some useful statistics based on the maximized value of the log likelihood.

**Figure 64.10** Parameter Estimates for Logistic-Normal Model

| Parameter Estimates |          |                |    |         |         |       |         |
|---------------------|----------|----------------|----|---------|---------|-------|---------|
| Parameter           | Estimate | Standard Error | DF | t Value | Pr >  t | Alpha | Lower   |
| beta0               | -1.1974  | 0.5561         | 7  | -2.15   | 0.0683  | 0.05  | -2.5123 |
| beta1               | 0.7385   | 0.3004         | 7  | 2.46    | 0.0436  | 0.05  | 0.02806 |
| s2u                 | 1.9591   | 1.1903         | 7  | 1.65    | 0.1438  | 0.05  | -0.8554 |

| Parameter Estimates |        |          |
|---------------------|--------|----------|
| Parameter           | Upper  | Gradient |
| beta0               | 0.1175 | -3.1E-7  |
| beta1               | 1.4488 | -2.08E-6 |
| s2u                 | 4.7736 | -2.48E-7 |

The “Parameter Estimates” table indicates marginal significance of the two fixed-effects parameters (Figure 64.10). The positive value of the estimate of  $\beta_1$  indicates that the treatment significantly increases the chance of a favorable cure.

**Figure 64.11** Table of Additional Estimates

| Additional Estimates |          |                |    |         |         |       |         |        |
|----------------------|----------|----------------|----|---------|---------|-------|---------|--------|
| Label                | Estimate | Standard Error | DF | t Value | Pr >  t | Alpha | Lower   | Upper  |
| 1/beta1              | 1.3542   | 0.5509         | 7  | 2.46    | 0.0436  | 0.05  | 0.05146 | 2.6569 |

The “Additional Estimates” table displays results from the `ESTIMATE` statement (Figure 64.11). The estimate of  $1/\beta_1$  equals  $1/0.7385 = 1.3542$  and its standard error equals  $0.3004/0.7385^2 = 0.5509$  by the delta method (Billingsley 1986; Cox 1998). Note that this particular approximation produces a  $t$ -statistic identical to that for the estimate of  $\beta_1$ .

Not shown is the eta data set, which contains the original 16 observations and predictions of the  $\eta_{ij}$ .

---

## Syntax: NLMIXED Procedure

The following statements are available in the NLMIXED procedure:

```

PROC NLMIXED < options > ;
 ARRAY array-specification ;
 BOUNDS boundary-constraints ;
 BY variables ;
 CONTRAST 'label' expression <, expression > < options > ;
 ESTIMATE 'label' expression < options > ;
 ID names ;
 MODEL model-specification ;
 PARMS parameters-and-starting-values ;
 PREDICT expression OUT=SAS-data-set < options > ;
 RANDOM random-effects-specification ;
 REPLICATE variable ;
 Programming statements ;

```

The following sections provide a detailed description of each of these statements.

---

## PROC NLMIXED Statement

```

PROC NLMIXED < options > ;

```

The `PROC NLMIXED` statement invokes the NLMIXED procedure. Table 64.1 summarizes the options available in the `PROC NLMIXED` statement.

**Table 64.1** PROC NLMIXED Statement Options

| Option                                 | Description                                                            |
|----------------------------------------|------------------------------------------------------------------------|
| <b>Basic Options</b>                   |                                                                        |
| DATA=                                  | Specifies the input data set                                           |
| METHOD=                                | Specifies the integration method                                       |
| <b>Displayed Output Specifications</b> |                                                                        |
| ALPHA=                                 | Specifies $\alpha$ for confidence limits                               |
| CORR                                   | Requests the correlation matrix                                        |
| COV                                    | Requests the covariance matrix                                         |
| DF=                                    | Specifies the degrees of freedom for $p$ -values and confidence limits |
| ECORR                                  | Requests the correlation matrix of additional estimates                |
| ECOV                                   | Requests the covariance matrix of additional estimates                 |
| EDER                                   | Requests derivatives of additional estimates                           |
| EMPIRICAL                              | Requests the empirical (“sandwich”) estimator of covariance matrix     |
| HESS                                   | Requests the Hessian matrix                                            |
| ITDETAILS                              | Requests iteration details                                             |
| START                                  | Specifies the gradient at starting values                              |
| <b>Debugging Output</b>                |                                                                        |
| FLOW                                   | Displays the model execution messages                                  |
| LISTCODE                               | Displays compiled model program                                        |
| LISTDEP                                | Produces a model dependency listing                                    |
| LISTDER                                | Displays the model derivatives                                         |
| LIST                                   | Displays the model program and variables                               |
| TRACE                                  | Displays detailed model execution messages                             |
| XREF                                   | Displays the model cross references                                    |
| <b>Quadrature Options</b>              |                                                                        |
| NOADSCALE                              | Requests no adaptive scaling                                           |
| NOAD                                   | Requests no adaptive centering                                         |
| OUTQ=                                  | Displays output data set                                               |
| QFAC=                                  | Specifies the search factor                                            |
| QMAX=                                  | Specifies the maximum points                                           |
| QPOINTS=                               | Specifies the number of points                                         |
| QSCALEFAC=                             | Specifies the scale factor                                             |
| QTOL=                                  | Specifies the tolerance                                                |
| <b>Empirical Bayes Options</b>         |                                                                        |
| EBOPT                                  | Requests comprehensive optimization                                    |
| EBSSFRAC=                              | Specifies the step-shortening fraction                                 |
| EBSTOL=                                | Specifies the step-shortening tolerance                                |
| EBSTEPS=                               | Specifies the number of Newton steps                                   |
| EBSUBSTEPS=                            | Specifies the number of substeps                                       |
| EBTOL=                                 | Specifies the convergence tolerance                                    |
| EBZSTART                               | Requests zero as the starting values                                   |

Table 64.1 *continued*

| Option                                     | Description                                                                                       |
|--------------------------------------------|---------------------------------------------------------------------------------------------------|
| <b>Optimization Specifications</b>         |                                                                                                   |
| HESCAL=                                    | Specifies the type of Hessian scaling                                                             |
| INHESIAN<=>                                | Specifies the start for approximated Hessian                                                      |
| LINESEARCH=                                | Specifies the line-search method                                                                  |
| LSPRECISION=                               | Specifies the line-search precision                                                               |
| OPTCHECK<=>                                | Checks optimality in a neighborhood                                                               |
| RESTART=                                   | Specifies the iteration number for update restart                                                 |
| TECHNIQUE=                                 | Specifies the minimization technique                                                              |
| UPDATE=                                    | Specifies the update technique                                                                    |
| <b>Derivatives Specifications</b>          |                                                                                                   |
| DIAHES                                     | Uses only the diagonal of Hessian                                                                 |
| FDHESSIAN<=>                               | Specifies the finite-difference second derivatives                                                |
| FD<=>                                      | Specifies the finite-difference derivatives                                                       |
| <b>Constraint Specifications</b>           |                                                                                                   |
| LCDEACT=                                   | Specifies the Lagrange multiplier tolerance for deactivating                                      |
| LCEPSILON=                                 | Specifies the range for active constraints                                                        |
| LCSINGULAR=                                | Specifies the tolerance for dependent constraints                                                 |
| <b>Termination Criteria Specifications</b> |                                                                                                   |
| ABSCONV=                                   | Specifies the absolute function convergence criterion                                             |
| ABSFCONV=                                  | Specifies the absolute function difference convergence criterion                                  |
| ABSGCONV=                                  | Specifies the absolute gradient convergence criterion                                             |
| ABSXCONV=                                  | Specifies the absolute parameter convergence criterion                                            |
| FCONV=                                     | Specifies the relative function convergence criterion                                             |
| FCONV2=                                    | Specifies another relative function convergence criterion                                         |
| FDIGITS=                                   | Specifies the number accurate digits in objective function                                        |
| FSIZE=                                     | Specifies the FSIZE parameter of the relative function and relative gradient termination criteria |
| GCONV=                                     | Specifies the relative gradient convergence criterion                                             |
| MAXFUNC=                                   | Specifies the maximum number of function calls                                                    |
| MAXITER=                                   | Specifies the maximum number of iterations                                                        |
| MAXTIME=                                   | Specifies the upper limit seconds of CPU time                                                     |
| MINITER=                                   | Specifies the minimum number of iterations                                                        |
| XCONV=                                     | Specifies the relative parameter convergence criterion                                            |
| XSIZE=                                     | Used in XCONV criterion                                                                           |
| <b>Step Length Specifications</b>          |                                                                                                   |
| DAMPSTEP<=>                                | Specifies the damped steps in line search                                                         |
| INSTEP=                                    | Specifies the initial trust-region radius                                                         |
| MAXSTEP=                                   | Specifies the maximum trust-region radius                                                         |
| <b>Singularity Tolerances</b>              |                                                                                                   |
| SINGCHOL=                                  | Specifies the tolerance for Cholesky roots                                                        |

Table 64.1 *continued*

| Option                              | Description                                        |
|-------------------------------------|----------------------------------------------------|
| SINGHESS=                           | Specifies the tolerance for Hessian                |
| SINGSWEEP=                          | Specifies the tolerance for sweep                  |
| SINGVAR=                            | Specifies the tolerance for variances              |
| <b>Covariance Matrix Tolerances</b> |                                                    |
| ASINGULAR=                          | Specifies the absolute singularity for inertia     |
| CFACTOR=                            | Specifies the multiplication factor for COV matrix |
| COVSING=                            | Specifies the tolerance for singular COV matrix    |
| G4=                                 | Specifies the threshold for Moore-Penrose inverse  |
| MSINGULAR=                          | Specifies the relative M singularity for inertia   |
| VSINGULAR=                          | Specifies the relative V singularity for inertia   |

These options are described in alphabetical order. For a description of the mathematical notation used in the following sections, see the section “[Modeling Assumptions and Notation](#)” on page 5383.

**ABSCONV=r**

**ABSTOL=r**

specifies an absolute function convergence criterion. For minimization, termination requires  $f(\boldsymbol{\theta}^{(k)}) \leq r$ . The default value of  $r$  is the negative square root of the largest double-precision value, which serves only as a protection against overflows.

**ABSFCONV=r<[n]>**

**ABSFTOL=r<[n]>**

specifies an absolute function difference convergence criterion. For all techniques except NMSIMP, termination requires a small change of the function value in successive iterations:

$$|f(\boldsymbol{\theta}^{(k-1)}) - f(\boldsymbol{\theta}^{(k)})| \leq r$$

The same formula is used for the NMSIMP technique, but  $\boldsymbol{\theta}^{(k)}$  is defined as the vertex with the lowest function value, and  $\boldsymbol{\theta}^{(k-1)}$  is defined as the vertex with the highest function value in the simplex. The default value is  $r = 0$ . The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

**ABSGCONV=r<[n]>**

**ABSGTOL=r<[n]>**

specifies an absolute gradient convergence criterion. Termination requires the maximum absolute gradient element to be small:

$$\max_j |g_j(\boldsymbol{\theta}^{(k)})| \leq r$$

This criterion is not used by the NMSIMP technique. The default value is  $r = 1\text{E-}5$ . The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

**ABSXCONV**= $r < [n] >$ **ABSXTOL**= $r < [n] >$ 

specifies an absolute parameter convergence criterion. For all techniques except NMSIMP, termination requires a small Euclidean distance between successive parameter vectors,

$$\| \boldsymbol{\theta}^{(k)} - \boldsymbol{\theta}^{(k-1)} \|_2 \leq r$$

For the NMSIMP technique, termination requires either a small length  $\alpha^{(k)}$  of the vertices of a restart simplex,

$$\alpha^{(k)} \leq r$$

or a small simplex size,

$$\delta^{(k)} \leq r$$

where the simplex size  $\delta^{(k)}$  is defined as the L1 distance from the simplex vertex  $\boldsymbol{\xi}^{(k)}$  with the smallest function value to the other  $n$  simplex points  $\boldsymbol{\theta}_l^{(k)} \neq \boldsymbol{\xi}^{(k)}$ :

$$\delta^{(k)} = \sum_{\boldsymbol{\theta}_l^{(k)} \neq \boldsymbol{\xi}^{(k)}} \| \boldsymbol{\theta}_l^{(k)} - \boldsymbol{\xi}^{(k)} \|_1$$

The default is  $r = 1\text{E-}8$  for the NMSIMP technique and  $r = 0$  otherwise. The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

**ALPHA**= $\alpha$ 

specifies the alpha level to be used in computing confidence limits. The default value is 0.05.

**ASINGULAR**= $r$ **ASING**= $r$ 

specifies an absolute singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is the square root of the smallest positive double-precision value.

**CFACTOR**= $f$ 

specifies a multiplication factor  $f$  for the estimated covariance matrix of the parameter estimates.

**COV**

requests the approximate covariance matrix for the parameter estimates.

**CORR**

requests the approximate correlation matrix for the parameter estimates.

**COVSING**= $r > 0$ 

specifies a nonnegative threshold that determines whether the eigenvalues of a singular Hessian matrix are considered to be zero.

**DAMPSTEP** $\langle =r \rangle$ **DS** $\langle =r \rangle$ 

specifies that the initial step-size value  $\alpha^{(0)}$  for each line search (used by the QUANEW, CONGRA, or NEWRAP technique) cannot be larger than  $r$  times the step-size value used in the former iteration. If you specify the DAMPSTEP option without factor  $r$ , the default value is  $r = 2$ . The DAMPSTEP= $r$  option can prevent the line-search algorithm from repeatedly stepping into regions where some objective functions are difficult to compute or where they could lead to floating-point overflows during the computation of objective functions and their derivatives. The DAMPSTEP= $r$  option can save time-costly function calls that result in very small step sizes  $\alpha$ . For more details on setting the start values of each line search, see the section “Restricting the Step Length” on page 5398.

**DATA**=SAS-data-set

specifies the input data set. Observations in this data set are used to compute the log likelihood function that you specify with PROC NLMIXED statements.

**NOTE:** If you are using a **RANDOM** statement, the input data set must be clustered according to the **SUBJECT=** variable. One easy way to accomplish this is to sort your data by the **SUBJECT=** variable prior to calling PROC NLMIXED. PROC NLMIXED does not sort the input data set for you.

**DF**= $d$ 

specifies the degrees of freedom to be used in computing  $p$  values and confidence limits. The default value is the number of subjects minus the number of random effects for random effects models, and the number of observations otherwise.

**DIAHES**

specifies that only the diagonal of the Hessian is used.

**EBOPT**

requests that a more comprehensive optimization be carried out if the default empirical Bayes optimization fails to converge.

**EBSSFRAC**= $r > 0$ 

specifies the step-shortening fraction to be used while computing empirical Bayes estimates of the random effects. The default value is 0.8.

**EBSSTOL**= $r \geq 0$ 

specifies the objective function tolerance for determining the cessation of step-shortening while computing empirical Bayes estimates of the random effects. The default value is  $r = 1\text{E}-8$ .

**EBSTEPS**= $n \geq 0$ 

specifies the maximum number of Newton steps for computing empirical Bayes estimates of random effects. The default value is  $n = 50$ .

**EBSUBSTEPS**= $n \geq 0$ 

specifies the maximum number of step-shortenings for computing empirical Bayes estimates of random effects. The default value is  $n = 20$ .

**EBTOL**= $r \geq 0$ 

specifies the convergence tolerance for empirical Bayes estimation. The default value is  $r = \epsilon\text{E}4$ , where  $\epsilon$  is the machine precision. This default value equals approximately  $1\text{E}-12$  on most machines.

**EBZSTART**

requests that a zero be used as starting values during empirical Bayes estimation. By default, the starting values are set equal to the estimates from the previous iteration (or zero for the first iteration).

**ECOV**

requests the approximate covariance matrix for all expressions specified in **ESTIMATE** statements.

**ECORR**

requests the approximate correlation matrix for all expressions specified in **ESTIMATE** statements.

**EDER**

requests the derivatives of all expressions specified in **ESTIMATE** statements with respect to each of the model parameters.

**EMPIRICAL**

requests that the covariance matrix of the parameter estimates be computed as a likelihood-based empirical (“sandwich”) estimator (White 1982). If  $f(\boldsymbol{\theta}) = -\log\{m(\boldsymbol{\theta})\}$  is the objective function for the optimization and  $m(\boldsymbol{\theta})$  denotes the marginal log likelihood (see the section “**Modeling Assumptions and Notation**” on page 5383 for notation and further definitions) the empirical estimator is computed as

$$\mathbf{H}(\hat{\boldsymbol{\theta}})^{-1} \left( \sum_{i=1}^s \mathbf{g}_i(\hat{\boldsymbol{\theta}}) \mathbf{g}_i(\hat{\boldsymbol{\theta}})' \right) \mathbf{H}(\hat{\boldsymbol{\theta}})^{-1}$$

where  $\mathbf{H}$  is the second derivative matrix of  $f$  and  $\mathbf{g}_i$  is the first derivative of the contribution to  $f$  by the  $i$ th subject. If you choose the **EMPIRICAL** option, this estimator of the covariance matrix of the parameter estimates replaces the model-based estimator  $\mathbf{H}(\hat{\boldsymbol{\theta}})^{-1}$  in subsequent calculations. You can output the subject-specific gradients  $\mathbf{g}_i$  to a SAS data set with the **SUBGRADIENT** option in the **PROC NL MIXED** statement.

The **EMPIRICAL** option requires the presence of a **RANDOM** statement and is available for **METHOD=GAUSS** and **METHOD=ISAMP** only.

**FCONV=r<[n]>****FTOL=r<[n]>**

specifies a relative function convergence criterion. For all techniques except **NMSIMP**, termination requires a small relative change of the function value in successive iterations,

$$\frac{|f(\boldsymbol{\theta}^{(k)}) - f(\boldsymbol{\theta}^{(k-1)})|}{\max(|f(\boldsymbol{\theta}^{(k-1)})|, \text{FSIZE})} \leq r$$

where **FSIZE** is defined by the **FSIZE=** option. The same formula is used for the **NMSIMP** technique, but  $\boldsymbol{\theta}^{(k)}$  is defined as the vertex with the lowest function value, and  $\boldsymbol{\theta}^{(k-1)}$  is defined as the vertex with the highest function value in the simplex. The default is  $r = 10^{-\text{FDIGITS}}$ , where **FDIGITS** is the value of the **FDIGITS=** option. The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

**FCONV2**= $r$ <[ $n$ ]>

**FTOL2**= $r$ <[ $n$ ]>

specifies another function convergence criterion. For all techniques except NMSIMP, termination requires a small predicted reduction

$$df^{(k)} \approx f(\boldsymbol{\theta}^{(k)}) - f(\boldsymbol{\theta}^{(k)} + \mathbf{s}^{(k)})$$

of the objective function. The predicted reduction

$$\begin{aligned} df^{(k)} &= -\mathbf{g}^{(k)'} \mathbf{s}^{(k)} - \frac{1}{2} \mathbf{s}^{(k)'} \mathbf{H}^{(k)} \mathbf{s}^{(k)} \\ &= -\frac{1}{2} \mathbf{s}^{(k)'} \mathbf{g}^{(k)} \\ &\leq r \end{aligned}$$

is computed by approximating the objective function  $f$  by the first two terms of the Taylor series and substituting the Newton step:

$$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1} \mathbf{g}^{(k)}$$

For the NMSIMP technique, termination requires a small standard deviation of the function values of the  $n + 1$  simplex vertices  $\boldsymbol{\theta}_l^{(k)}$ ,  $l = 0, \dots, n$ ,

$$\sqrt{\frac{1}{n+1} \sum_l \left[ f(\boldsymbol{\theta}_l^{(k)}) - \bar{f}(\boldsymbol{\theta}^{(k)}) \right]^2} \leq r$$

where  $\bar{f}(\boldsymbol{\theta}^{(k)}) = \frac{1}{n+1} \sum_l f(\boldsymbol{\theta}_l^{(k)})$ . If there are  $n_{act}$  boundary constraints active at  $\boldsymbol{\theta}^{(k)}$ , the mean and standard deviation are computed only for the  $n + 1 - n_{act}$  unconstrained vertices. The default value is  $r = 1\text{E-}6$  for the NMSIMP technique and  $r = 0$  otherwise. The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

**FD** <= **FORWARD** | **CENTRAL** |  $r$ >

specifies that all derivatives be computed using finite difference approximations. The following specifications are permitted:

**FD** is equivalent to **FD**=100.

**FD**=**CENTRAL** uses central differences.

**FD**=**FORWARD** uses forward differences.

**FD**= $r$  uses central differences for the initial and final evaluations of the gradient and for the Hessian. During iteration, start with forward differences and switch to a corresponding central-difference formula during the iteration process when one of the following two criteria is satisfied:

- The absolute maximum gradient element is less than or equal to  $r$  times the **ABSGCONV**= threshold.
- The normalized predicted function reduction (see the **GTOL** option) is less than or equal to  $\max(1\text{E-}6, r \times \text{GTOL})$ . The  $1\text{E-}6$  ensures that the switch is done, even if you set the **GTOL** threshold to zero.

Note that the FD and FDHESSIAN options cannot apply at the same time. The FDHESSIAN option is ignored when only first-order derivatives are used. See the section “[Finite-Difference Approximations of Derivatives](#)” on page 5393 for more information.

**FDHESSIAN**<=**FORWARD** | **CENTRAL**>

**FDHES**<=**FORWARD** | **CENTRAL**>

**FDH**<=**FORWARD** | **CENTRAL**>

specifies that second-order derivatives be computed using finite difference approximations based on evaluations of the gradients.

FDHESSIAN=FORWARD uses forward differences.

FDHESSIAN=CENTRAL uses central differences.

FDHESSIAN uses forward differences for the Hessian except for the initial and final output.

Note that the FD and FDHESSIAN options cannot apply at the same time. See the section “[Finite-Difference Approximations of Derivatives](#)” on page 5393 for more information.

**FDIGITS**=*r*

specifies the number of accurate digits in evaluations of the objective function. Fractional values such as FDIGITS=4.7 are allowed. The default value is  $r = -\log_{10} \epsilon$ , where  $\epsilon$  is the machine precision. The value of  $r$  is used to compute the interval size  $h$  for the computation of finite-difference approximations of the derivatives of the objective function and for the default value of the **FCONV**= option.

**FLOW**

displays a message for each statement in the model program as it is executed. This debugging option is very rarely needed and produces voluminous output.

**FSIZE**=*r*

specifies the FSIZE parameter of the relative function and relative gradient termination criteria. The default value is  $r = 0$ . For more details, see the **FCONV**= and **GCONV**= options.

**G4**= $n > 0$

specifies a dimension to determine the type of generalized inverse to use when the approximate covariance matrix of the parameter estimates is singular. The default value of  $n$  is 60. See the section “[Covariance Matrix](#)” on page 5402 for more information.

**GCONV**=*r*< [*n*]>

**GTOL**=*r*< [*n*]>

specifies a relative gradient convergence criterion. For all techniques except CONGRA and NMSIMP, termination requires that the normalized predicted function reduction is small,

$$\frac{\mathbf{g}(\boldsymbol{\theta}^{(k)})' [\mathbf{H}^{(k)}]^{-1} \mathbf{g}(\boldsymbol{\theta}^{(k)})}{\max(|f(\boldsymbol{\theta}^{(k)})|, \text{FSIZE})} \leq r$$

where FSIZE is defined by the FSIZE= option. For the CONGRA technique (where a reliable Hessian estimate  $H$  is not available), the following criterion is used:

$$\frac{\|\mathbf{g}(\boldsymbol{\theta}^{(k)})\|_2^2 \|\mathbf{s}(\boldsymbol{\theta}^{(k)})\|_2}{\|\mathbf{g}(\boldsymbol{\theta}^{(k)}) - \mathbf{g}(\boldsymbol{\theta}^{(k-1)})\|_2 \max(|f(\boldsymbol{\theta}^{(k)})|, \text{FSIZE})} \leq r$$

This criterion is not used by the NMSIMP technique.

The default value is  $r = 1\text{E-}8$ . The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can terminate.

**HESCAL=0|1|2|3**

**HS=0|1|2|3**

specifies the scaling version of the Hessian matrix used in NRRIDG, TRUREG, NEWRAP, or DBLDOG optimization.

If HS is not equal to 0, the first iteration and each restart iteration sets the diagonal scaling matrix  $\mathbf{D}^{(0)} = \text{diag}(d_i^{(0)})$ :

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

where  $H_{i,i}^{(0)}$  are the diagonal elements of the Hessian. In every other iteration, the diagonal scaling matrix  $\mathbf{D}^{(0)} = \text{diag}(d_i^{(0)})$  is updated depending on the HS option:

HS=0 specifies that no scaling is done.

HS=1 specifies the Moré (1978) scaling update:

$$d_i^{(k+1)} = \max \left[ d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

HS=2 specifies the Dennis, Gay, and Welsch (1981) scaling update:

$$d_i^{(k+1)} = \max \left[ 0.6 * d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

HS=3 specifies that  $d_i$  is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In each scaling update,  $\epsilon$  is the relative machine precision. The default value is HS=0. Scaling of the Hessian can be time-consuming in the case where general linear constraints are active.

## HESS

requests the display of the final Hessian matrix after optimization. If you also specify the **START** option, then the Hessian at the starting values is also printed.

**INHESIAN<=r>**

**INHES<=r>**

specifies how the initial estimate of the approximate Hessian is defined for the quasi-Newton techniques QUANEW and DBLDOG. There are two alternatives:

- If you do not use the  $r$  specification, the initial estimate of the approximate Hessian is set to the Hessian at  $\theta^{(0)}$ .
- If you do use the  $r$  specification, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix,  $r\mathbf{I}$ .

By default, if you do not specify the option **INHESIAN=r**, the initial estimate of the approximate Hessian is set to the multiple of the identity matrix  $r\mathbf{I}$ , where the scalar  $r$  is computed from the magnitude of the initial gradient.

**INSTEP=*r***

reduces the length of the first trial step during the line search of the first iterations. For highly nonlinear objective functions, such as the EXP function, the default initial radius of the trust-region algorithm TRUREG or DBLDOG or the default step length of the line-search algorithms can result in arithmetic overflows. If this occurs, you should specify decreasing values of  $0 < r < 1$  such as INSTEP=1E-1, INSTEP=1E-2, INSTEP=1E-4, and so on, until the iteration starts successfully.

- For trust-region algorithms (TRUREG, DBLDOG), the INSTEP= option specifies a factor  $r > 0$  for the initial radius  $\Delta^{(0)}$  of the trust region. The default initial trust-region radius is the length of the scaled gradient. This step corresponds to the default radius factor of  $r = 1$ .
- For line-search algorithms (NEWRAP, CONGRA, QUANEW), the INSTEP= option specifies an upper bound for the initial step length for the line search during the first five iterations. The default initial step length is  $r = 1$ .
- For the Nelder-Mead simplex algorithm, using TECH=NMSIMP, the INSTEP=*r* option defines the size of the start simplex.

For more details, see the section “[Computational Problems](#)” on page 5399.

**ITDETAILS**

requests a more complete iteration history, including the current values of the parameter estimates, their gradients, and additional optimization statistics. For further details, see the section “[Iterations](#)” on page 5405.

**LCDEACT=*r*****LCD=*r***

specifies a threshold  $r$  for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. During minimization, an active inequality constraint can be deactivated only if its Lagrange multiplier is less than the threshold value  $r < 0$ . The default value is

$$r = -\min(0.01, \max(0.1 \times \text{ABSGCONV}, 0.001 \times \text{gmax}^{(k)}))$$

where ABSGCONV is the value of the absolute gradient criterion, and  $\text{gmax}^{(k)}$  is the maximum absolute element of the (projected) gradient  $\mathbf{g}^{(k)}$  or  $\mathbf{Z}'\mathbf{g}^{(k)}$ . (See the section “[Active Set Methods](#)” for a definition of  $\mathbf{Z}$ .)

**LCEPSILON=*r* > 0****LCEPS=*r* > 0****LCE=*r* > 0**

specifies the range for active and violated boundary constraints. The default value is  $r = 1\text{E}-8$ . During the optimization process, the introduction of rounding errors can force PROC NL MIXED to increase the value of  $r$  by a factor of 10, 100, . . . . If this happens, it is indicated by a message displayed in the log.

**LCSINGULAR= $r > 0$** **LCSING= $r > 0$** **LCS= $r > 0$** 

specifies a criterion  $r$ , used in the update of the QR decomposition, that determines whether an active constraint is linearly dependent on a set of other active constraints. The default value is  $r = 1\text{E-}8$ . The larger  $r$  becomes, the more the active constraints are recognized as being linearly dependent. If the value of  $r$  is larger than 0.1, it is reset to 0.1.

**LINESEARCH= $i$** **LIS= $i$** 

specifies the line-search method for the CONGRA, QUANEW, and NEWRAP optimization techniques. See Fletcher (1987) for an introduction to line-search techniques. The value of  $i$  can be  $1, \dots, 8$ . For CONGRA, QUANEW and NEWRAP, the default value is  $i = 2$ .

- |       |                                                                                                                                                                                                                                                                                 |
|-------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LIS=1 | specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is similar to one used by the Harwell subroutine library.                                                                 |
| LIS=2 | specifies a line-search method that needs more function than gradient calls for quadratic and cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option. |
| LIS=3 | specifies a line-search method that needs the same number of function and gradient calls for cubic interpolation and cubic extrapolation; this method is implemented as shown in Fletcher (1987) and can be modified to an exact line search by using the LSPRECISION= option.  |
| LIS=4 | specifies a line-search method that needs the same number of function and gradient calls for stepwise extrapolation and cubic interpolation.                                                                                                                                    |
| LIS=5 | specifies a line-search method that is a modified version of LIS=4.                                                                                                                                                                                                             |
| LIS=6 | specifies golden section line search (Polak 1971), which uses only function values for linear approximation.                                                                                                                                                                    |
| LIS=7 | specifies bisection line search (Polak 1971), which uses only function values for linear approximation.                                                                                                                                                                         |
| LIS=8 | specifies the Armijo line-search technique (Polak 1971), which uses only function values for linear approximation.                                                                                                                                                              |

**LIST**

displays the model program and variable lists. The LIST option is a debugging feature and is not normally needed.

**LISTCODE**

displays the derivative tables and the compiled program code. The LISTCODE option is a debugging feature and is not normally needed.

**LISTDEP**

produces a report that lists, for each variable in the program, the variables that depend on it and on which it depends. The LISTDEP option is a debugging feature and is not normally needed.

**LISTDER**

displays a table of derivatives. This table lists each nonzero derivative computed for the problem. The LISTDER option is a debugging feature and is not normally needed.

**LOGNOTE**<=*n*>

writes periodic notes to the log that describe the current status of computations. It is designed for use with analyses requiring extensive CPU resources. The optional integer value *n* specifies the desired level of reporting detail. The default is *n* = 1. Choosing *n* = 2 adds information about the objective function values at the end of each iteration. The most detail is obtained with *n* = 3, which also reports the results of function evaluations within iterations.

**LSPRECISION**=*r***LSP**=*r*

specifies the degree of accuracy that should be obtained by the line-search algorithms LIS=2 and LIS=3. Usually an imprecise line search is inexpensive and successful. For more difficult optimization problems, a more precise and expensive line search might be necessary (Fletcher 1987). The second line-search method (which is the default for the NEWRAP, QUANEW, and CONGRA techniques) and the third line-search method approach exact line search for small LSPRECISION= values. If you have numerical problems, you should try to decrease the LSPRECISION= value to obtain a more precise line search. The default values are shown in the following table.

| <b>TECH=</b> | <b>UPDATE=</b> | <b>LSP default</b> |
|--------------|----------------|--------------------|
| QUANEW       | DBFGS, BFGS    | <i>r</i> = 0.4     |
| QUANEW       | DDFP, DFP      | <i>r</i> = 0.06    |
| CONGRA       | all            | <i>r</i> = 0.1     |
| NEWRAP       | no update      | <i>r</i> = 0.9     |

For more details, see Fletcher (1987).

**MAXFUNC**=*i***MAXFU**=*i*

specifies the maximum number *i* of function calls in the optimization process. The default values are as follows:

- TRUREG, NRRIDG, NEWRAP: 125
- QUANEW, DBLDOG: 500
- CONGRA: 1000
- NMSIMP: 3000

Note that the optimization can terminate only after completing a full iteration. Therefore, the number of function calls that is actually performed can exceed the number that is specified by the MAXFUNC= option.

**MAXITER=*i*****MAXIT=*i***

specifies the maximum number *i* of iterations in the optimization process. The default values are as follows:

- TRUREG, NRRIDG, NEWRAP: 50
- QUANEW, DBLDOG: 200
- CONGRA: 400
- NMSIMP: 1000

These default values are also valid when *i* is specified as a missing value.

**MAXSTEP=*r*<[*n*]>**

specifies an upper bound for the step length of the line-search algorithms during the first *n* iterations. By default, *r* is the largest double-precision value and *n* is the largest integer available. Setting this option can improve the speed of convergence for the CONGRA, QUANEW, and NEWRAP techniques.

**MAXTIME=*r***

specifies an upper limit of *r* seconds of CPU time for the optimization process. The default value is the largest floating-point double representation of your computer. Note that the time specified by the MAXTIME= option is checked only once at the end of each iteration. Therefore, the actual running time can be much longer than that specified by the MAXTIME= option. The actual running time includes the rest of the time needed to finish the iteration and the time needed to generate the output of the results.

**METHOD=*value***

specifies the method for approximating the integral of the likelihood over the random effects. Valid values are as follows:

**FIRO**

specifies the first-order method of Beal and Sheiner (1982). When using METHOD=FIRO, you must specify the NORMAL distribution in the MODEL statement and you must also specify a RANDOM statement.

**GAUSS**

specifies adaptive Gauss-Hermite quadrature (Pinheiro and Bates 1995). You can prevent the adaptation with the NOAD option or prevent adaptive scaling with the NOADSCALE option. This is the default integration method.

**HARDY**

specifies Hardy quadrature based on an adaptive trapezoidal rule. This method is available only for one-dimensional integrals; that is, you must specify only one random effect.

**ISAMP**

specifies adaptive importance sampling (Pinheiro and Bates 1995). You can prevent the adaptation with the NOAD option or prevent adaptive scaling with the NOADSCALE option. You can use the SEED= option to specify a starting seed for the random number generation used in the importance sampling. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock.

**MINITER=*i*****MINIT=*i***

specifies the minimum number of iterations. The default value is 0. If you request more iterations than are actually needed for convergence to a stationary point, the optimization algorithms can behave strangely. For example, the effect of rounding errors can prevent the algorithm from continuing for the required number of iterations.

**MSINGULAR= $r > 0$** **MSING= $r > 0$** 

specifies a relative singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is  $1E-12$  if you do not specify the SINGHESS= option; otherwise, the default value is  $\max(10\epsilon, (1E-4) \times \text{SINGHESS})$ . See the section “Covariance Matrix” on page 5402 for more information.

**NOAD**

requests that the Gaussian quadrature be nonadaptive; that is, the quadrature points are centered at zero for each of the random effects and the current random-effects variance matrix is used as the scale matrix.

**NOADSCALE**

requests nonadaptive scaling for adaptive Gaussian quadrature; that is, the quadrature points are centered at the empirical Bayes estimates for the random effects, but the current random-effects variance matrix is used as the scale matrix. By default, the observed Hessian from the current empirical Bayes estimates is used as the scale matrix.

**OPTCHECK $\langle =r > 0 \rangle$** 

computes the function values  $f(\theta_l)$  of a grid of points  $\theta_l$  in a ball of radius of  $r$  about  $\theta^*$ . If you specify the OPTCHECK option without factor  $r$ , the default value is  $r = 0.1$  at the starting point and  $r = 0.01$  at the terminating point. If a point  $\theta_l^*$  is found with a better function value than  $f(\theta^*)$ , then optimization is restarted at  $\theta_l^*$ .

**OUTQ=*SAS-data-set***

specifies an output data set containing the quadrature points used for numerical integration.

**QFAC= $r > 0$** 

specifies the additive factor used to adaptively search for the number of quadrature points. For **METHOD=GAUSS**, the search sequence is 1, 3, 5, 7, 9, 11,  $11 + r$ ,  $11 + 2r$ , ..., where the default value of  $r$  is 10. For **METHOD=ISAMP**, the search sequence is 10,  $10 + r$ ,  $10 + 2r$ , ..., where the default value of  $r$  is 50.

**QMAX= $r > 0$** 

specifies the maximum number of quadrature points permitted before the adaptive search is aborted. The default values are 31 for adaptive Gaussian quadrature, 61 for nonadaptive Gaussian quadrature, 160 for adaptive importance sampling, and 310 for nonadaptive importance sampling.

**QPOINTS= $n > 0$** 

specifies the number of quadrature points to be used during evaluation of integrals. For **METHOD=GAUSS**,  $n$  equals the number of points used in each dimension of the random effects, resulting in a total of  $n^r$  points, where  $r$  is the number of dimensions. For **METHOD=ISAMP**,  $n$  specifies the total number of quadrature points regardless of the dimension of the random effects.

By default, the number of quadrature points is selected adaptively, and this option disables the adaptive search.

**QSCALEFAC= $r > 0$** 

specifies a multiplier for the scale matrix used during quadrature calculations. The default value is 1.0.

**QTOL= $r > 0$** 

specifies the tolerance used to adaptively select the number of quadrature points. When the relative difference between two successive likelihood calculations is less than  $r$ , then the search terminates and the lesser number of quadrature points is used during the subsequent optimization process. The default value is  $1E-4$ .

**RESTART= $i > 0$** **REST= $i > 0$** 

specifies that the QUANEW or CONGRA algorithm is restarted with a steepest descent/ascent search direction after, at most,  $i$  iterations. Default values are as follows:

- CONGRA: UPDATE=PB: restart is performed automatically,  $i$  is not used.
- CONGRA: UPDATE $\neq$ PB:  $i = \min(10n, 80)$ , where  $n$  is the number of parameters.
- QUANEW:  $i$  is the largest integer available.

**SEED= $i$** 

specifies the random number seed for **METHOD=ISAMP**. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. The value must be less than  $2^{31} - 1$ .

**SINGCHOL= $r > 0$** 

specifies the singularity criterion  $r$  for Cholesky roots of the random-effects variance matrix and scale matrix for adaptive Gaussian quadrature. The default value is  $1E4$  times the machine epsilon; this product is approximately  $1E-12$  on most computers.

**SINGHESS= $r > 0$** 

specifies the singularity criterion  $r$  for the inversion of the Hessian matrix. The default value is  $1E-8$ . See the ASINGULAR, MSINGULAR=, and VSINGULAR= options for more information.

**SINGSWEEP= $r > 0$** 

specifies the singularity criterion  $r$  for inverting the variance matrix in the first-order method and the empirical Bayes Hessian matrix. The default value is  $1E4$  times the machine epsilon; this product is approximately  $1E-12$  on most computers.

**SINGVAR= $r > 0$** 

specifies the singularity criterion  $r$  below which statistical variances are considered to equal zero. The default value is  $1E4$  times the machine epsilon; this product is approximately  $1E-12$  on most computers.

**START**

requests that the gradient of the log likelihood at the starting values be displayed. If you also specify the **HESS** option, then the starting Hessian is displayed as well.

**SUBGRADIENT**=*SAS-data-set*

**SUBGRAD**=*SAS-data-set*

specifies a SAS data set to save in models with **RANDOM** statement the subject-specific gradients of the integrated, marginal log-likelihood with respect to all parameters. The sum of the subject-specific gradients equals the gradient reported in the “Parameter Estimates” table. The data set contains a variable identifying the subjects.

In models without **RANDOM** statement the **SUBGRADIENT**= data set contains the observation-wise gradient. The variable identifying the **SUBJECT**= is then replaced with the Observation. This observation counter includes observations not used in the analysis and is reset in each **BY**-group.

Saving disaggregated gradient information with the **SUBGRADIENT**= option requires **METHOD**=**GAUSS** or **METHOD**=**ISAMP**.

**TECHNIQUE**=*value*

**TECH**=*value*

specifies the optimization technique. By default, **TECH** = **QUANEW**. Valid values are as follows:

- **CONGRA**  
performs a conjugate-gradient optimization, which can be more precisely specified with the **UPDATE**= option and modified with the **LINESEARCH**= option. When you specify this option, **UPDATE**=**PB** by default.
- **DBLDOG**  
performs a version of double-dogleg optimization, which can be more precisely specified with the **UPDATE**= option. When you specify this option, **UPDATE**=**DBFGS** by default.
- **NMSIMP**  
performs a Nelder-Mead simplex optimization.
- **NONE**  
does not perform any optimization. This option can be used as follows:
  - to perform a grid search without optimization
  - to compute estimates and predictions that cannot be obtained efficiently with any of the optimization techniques
- **NEWRAP**  
performs a Newton-Raphson optimization combining a line-search algorithm with ridging. The line-search algorithm **LIS**=**2** is the default method.
- **NRRIDG**  
performs a Newton-Raphson optimization with ridging.
- **QUANEW**  
performs a quasi-Newton optimization, which can be defined more precisely with the **UPDATE**= option and modified with the **LINESEARCH**= option. This is the default estimation method.
- **TRUREG**  
performs a trust region optimization.

**TRACE**

displays the result of each operation in each statement in the model program as it is executed. This debugging option is very rarely needed, and it produces voluminous output.

**UPDATE=method****UPD=method**

specifies the update method for the quasi-Newton, double-dogleg, or conjugate-gradient optimization technique. Not every update method can be used with each optimizer. See the section “[Optimization Algorithms](#)” on page 5388 for more information.

Valid methods are as follows:

- **BFGS**  
performs the original Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the inverse Hessian matrix.
- **DBFGS**  
performs the dual BFGS update of the Cholesky factor of the Hessian matrix. This is the default update method.
- **DDFP**  
performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- **DFP**  
performs the original DFP update of the inverse Hessian matrix.
- **PB**  
performs the automatic restart update method of Powell (1977) and Beale (1972).
- **FR**  
performs the Fletcher-Reeves update (Fletcher 1987).
- **PR**  
performs the Polak-Ribiere update (Fletcher 1987).
- **CD**  
performs a conjugate-descent update of Fletcher (1987).

**VSINGULAR=r > 0****VSING=r > 0**

specifies a relative singularity criterion for the computation of the inertia (number of positive, negative, and zero eigenvalues) of the Hessian and its projected forms. The default value is  $r = 1\text{E-}8$  if the **SINGHESS=** option is not specified, and it is the value of **SINGHESS=** option otherwise. See the section “[Covariance Matrix](#)” on page 5402 for more information.

**XCONV=r < [n] >****XTOL=r < [n] >**

specifies the relative parameter convergence criterion. For all techniques except NMSIMP, termination requires a small relative parameter change in subsequent iterations:

$$\frac{\max_j |\theta_j^{(k)} - \theta_j^{(k-1)}|}{\max(|\theta_j^{(k)}|, |\theta_j^{(k-1)}|, \text{XSIZE})} \leq r$$

For the NMSIMP technique, the same formula is used, but  $\theta^{(k)}$  is defined as the vertex with the lowest function value and  $\theta^{(k-1)}$  is defined as the vertex with the highest function value in the simplex.

The default value is  $r = 1E-8$  for the NMSIMP technique and  $r = 0$  otherwise. The optional integer value  $n$  specifies the number of successive iterations for which the criterion must be satisfied before the process can be terminated.

#### **XREF**

displays a cross-reference of the variables in the program showing where each variable is referenced or given a value. The XREF listing does not include derivative variables. This option is a debugging feature and is not normally needed.

#### **XSIZE= $r > 0$**

specifies the XSIZE parameter of the relative parameter termination criterion. The default value is  $r = 0$ . For more details, see the **XCONV=** option.

---

## **ARRAY Statement**

**ARRAY** *arrayname* [ *dimensions* ] <\$> <*variables-and-constants*> ;

The ARRAY statement is similar to, but not exactly the same as, the ARRAY statement in the SAS DATA step, and it is exactly the same as the ARRAY statements in the NLIN, NLP, and MODEL procedures. The ARRAY statement is used to associate a name (of no more than eight characters) with a list of variables and constants. The array name is used with subscripts in the program to refer to the array elements. The following statements illustrate this:

```
array r[8] r1-r8;

do i = 1 to 8;
 r[i] = 0;
end;
```

The ARRAY statement does not support all the features of the ARRAY statement in the DATA step. It cannot be used to assign initial values to array elements. Implicit indexing of variables cannot be used; all array references must have explicit subscript expressions. Only exact array dimensions are allowed; lower-bound specifications are not supported. A maximum of six dimensions is allowed.

On the other hand, the ARRAY statement does allow both variables and constants to be used as array elements. (Constant array elements cannot have values assigned to them.) Both dimension specification and the list of elements are optional, but at least one must be specified. When the list of elements is not specified or fewer elements than the size of the array are listed, array variables are created by suffixing element numbers to the array name to complete the element list.

---

## BOUNDS Statement

**BOUNDS** *b-con* <, *b-con* ... >;

where *b-con* := number *operator* parameter\_list *operator* number  
 or *b-con* := number *operator* parameter\_list  
 or *b-con* := parameter\_list *operator* number  
 and *operator* := <=, <, >=, or >

Boundary constraints are specified with a BOUNDS statement. One- or two-sided boundary constraints are allowed. The list of boundary constraints are separated by commas. For example:

```
bounds 0 <= a1-a9 x <= 1, -1 <= c2-c5;
bounds b1-b10 y >= 0;
```

You can specify more than one BOUNDS statement. If you specify more than one lower (upper) bound for the same parameter, the maximum (minimum) of these is taken.

If the maximum  $l_j$  of all lower bounds is larger than the minimum of all upper bounds  $u_j$  for the same parameter  $\theta_j$ , the boundary constraint is replaced by  $\theta_j := l_j := \min(u_j)$  defined by the minimum of all upper bounds specified for  $\theta_j$ .

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC NLMIXED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NLMIXED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

An optimization problem is solved for each BY group separately unless the **TECH=NONE** option is specified.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CONTRAST Statement

**CONTRAST** *'label'* *expression* < , *expression* > < *options* > ;

The CONTRAST statement enables you to conduct a statistical test that several expressions simultaneously equal zero. The expressions are typically contrasts—that is, differences whose expected values equal zero under the hypothesis of interest.

In the CONTRAST statement you must provide a quoted string to identify the contrast and then a list of valid SAS expressions separated by commas. Multiple CONTRAST statements are permitted, and results from all statements are listed in a common table. PROC NL MIXED constructs approximate  $F$  tests for each statement using the delta method (Cox 1998) to approximate the variance-covariance matrix of the constituent expressions.

The following option is available in the CONTRAST statement:

**DF=*d***

specifies the denominator degrees of freedom to be used in computing  $p$  values for the  $F$  statistics. The default value corresponds to the **DF=** option in the PROC NL MIXED statement.

---

## ESTIMATE Statement

**ESTIMATE** *'label'* *expression* < *options* > ;

The ESTIMATE statement enables you to compute an additional estimate that is a function of the parameter values. You must provide a quoted string to identify the estimate and then a valid SAS expression. Multiple ESTIMATE statements are permitted, and results from all statements are listed in a common table. PROC NL MIXED computes approximate standard errors for the estimates using the delta method (Billingsley 1986). It uses these standard errors to compute corresponding  $t$  statistics,  $p$ -values, and confidence limits.

The **ECOV** option in the PROC NL MIXED statement produces a table containing the approximate covariance matrix of all the additional estimates you specify. The **ECORR** option produces the corresponding correlation matrix. The **EDER** option produces a table of the derivatives of the additional estimates with respect to each of the model parameters.

The following options are available in the ESTIMATE statement:

**ALPHA= $\alpha$**

specifies the alpha level to be used in computing confidence limits. The default value corresponds to the **ALPHA=** option in the PROC NL MIXED statement.

**DF=*d***

specifies the degrees of freedom to be used in computing  $p$ -values and confidence limits. The default value corresponds to the **DF=** option in the PROC NL MIXED statement.

---

## ID Statement

**ID** *names* ;

The ID statement identifies additional quantities to be included in the **OUT=** data set of the **PREDICT** statement. These can be any symbols you have defined with SAS programming statements.

---

## MODEL Statement

**MODEL** *dependent-variable* ~ *distribution* ;

The MODEL statement is the mechanism for specifying the conditional distribution of the data given the random effects. You must specify a single dependent variable from the input data set, a tilde ~, and then a distribution with its parameters. Valid distributions are as follows.

- *normal(m,v)* specifies a normal (Gaussian) distribution with mean *m* and variance *v*.
- *binary(p)* specifies a binary (Bernoulli) distribution with probability *p*.
- *binomial(n,p)* specifies a binomial distribution with count *n* and probability *p*.
- *gamma(a,b)* specifies a gamma distribution with shape *a* and scale *b*.
- *negbin(n,p)* specifies a negative binomial distribution with count *n* and probability *p*.
- *poisson(m)* specifies a Poisson distribution with mean *m*.
- *general(ll)* specifies a general log likelihood function that you construct using SAS programming statements.

The MODEL statement must follow any SAS programming statements you specify for computing parameters of the preceding distributions. See the section “[Built-in Log-Likelihood Functions](#)” on page 5386 for expressions of the built-in conditional log-likelihood functions.

---

## PARMS Statement

**PARMS** < *name-list* <=*numbers*> > < , *name-list* <=*numbers*> ... >  
< / *options* > ;

The PARMS statement lists names of parameters and specifies initial values, possibly over a grid. You can specify the parameters and values directly in a list, or you can provide the name of a SAS data set that contains them by using the **DATA=** option.

While the PARMS statement is not required, you are encouraged to use it to provide PROC NLMIXED with accurate starting values. Parameters not listed in the PARMS statement are assigned an initial value of 1.

PROC NLMIXED considers all symbols not assigned values to be parameters, so you should specify your modeling statements carefully and check the output from the “Parameters” table to make sure the proper parameters are identified.

A list of parameter names in the PARMs statement is not separated by commas and is followed by an equal sign and a list of numbers. If the number list consists of only one number, this number defines the initial value for all the parameters listed to the left of the equal sign.

If the number list consists of more than one number, these numbers specify the grid locations for each of the parameters listed to the left of the equal sign. You can use the TO and BY keywords to specify a number list for a grid search. If you specify a grid of points in a PARMs statement, PROC NLMIXED computes the objective function value at each grid point and chooses the best (feasible) grid point as an initial point for the optimization process. You can use the BEST= option to save memory for the storing and sorting of all grid point information.

The following options are available in the PARMs statement after a slash (/):

**BEST=*i* > 0**

specifies the maximum number of points displayed in the “Parameters” table, selected as the points with the maximum likelihood values. By default, all grid values are displayed.

**BYDATA**

enables you to assign different starting values for each BY group by using the DATA=SAS-*data-set* option during BY processing. By default, BY groups are ignored in the PARMs data set. For the BYDATA option to be effective, the DATA= data set must contain the BY variables and the same BY groups as the primary input data set. When you supply a grid of starting values with the DATA= data set and the BYDATA option is in effect, the size of the grid is determined by the first BY group.

**DATA=SAS-*data-set***

specifies a SAS data set containing parameter names and starting values. The data set should be in one of two forms: narrow or wide. The narrow-form data set contains the variables Parameter and Estimate, with parameters and values listed as distinct observations. The wide-form data set has the parameters themselves as variables, and each observation provides a different set of starting values. By default, BY groups are ignored in this data set, so the same starting grid is evaluated for each BY group. You can vary the starting values for BY groups by using the BYDATA option.

---

## PREDICT Statement

**PREDICT** *expression* **OUT=SAS-*data-set*** < *options* > ;

The PREDICT statement enables you to construct predictions of an expression across all of the observations in the input data set. Any valid SAS programming expression involving the input data set variables, parameters, and random effects is valid. Predicted values are computed using the parameter estimates and empirical Bayes estimates of the random effects. Standard errors of prediction are computed using the delta method (Billingsley 1986; Cox 1998). Results are placed in an output data set that you specify with the OUT= option. Besides all variables from the input data set, the OUT= data set contains the following variables: Pred, StdErrPred, DF, tValue, Probt, Alpha, Lower, Upper. You can also add other computed quantities to this data set with the ID statement.

The following options are available in the PREDICT statement:

**ALPHA= $\alpha$** 

specifies the alpha level to be used in computing  $t$  statistics and intervals. The default value corresponds to the ALPHA= option in the PROC NLMIXED statement.

**DER**

requests that derivatives of the predicted expression with respect to all parameters be included in the OUT= data set. The variable names for the derivatives are the same as the parameter names with the prefix “Der\_” appended. All of the derivatives are evaluated at the final estimates of the parameters and the empirical Bayes estimates of the random effects.

**DF= $d$** 

specifies the degrees of freedom to be used in computing  $t$  statistics and intervals in the OUT= data set. The default value corresponds to the DF= option in the PROC NLMIXED statement.

---

## RANDOM Statement

**RANDOM** *random-effects* ~ *distribution* **SUBJECT=***variable* < *options* > ;

The RANDOM statement defines the random effects and their distribution. The random effects must be represented by symbols that appear in your SAS programming statements. They typically influence the mean value of the distribution specified in the MODEL statement. The RANDOM statement consists of a list of the random effects (usually just one or two symbols), a tilde ~, the distribution for the random effects, and then a SUBJECT= variable.

**NOTE:** The input data set must be clustered according to the SUBJECT= variable. One easy way to accomplish this is to sort your data by the SUBJECT= variable prior to calling PROC NLMIXED. PROC NLMIXED does not sort the input data set for you; rather, it processes the data sequentially and considers an observation to be from a new subject whenever the value of its SUBJECT= variable changes from the previous observation.

The only distribution available for the random effects is normal( $m,v$ ) with mean  $m$  and variance  $v$ .

This syntax is illustrated as follows for one effect:

```
random u ~ normal(0,s2u) subject=clinic;
```

For multiple effects, you should specify bracketed vectors for  $m$  and  $v$ , the latter consisting of the lower triangle of the random-effects variance matrix listed in row order. This is illustrated for two and three random effects as follows:

```
random b1 b2 ~ normal([0,0],[g11,g21,g22]) subject=person;
random b1 b2 b3 ~ normal([0,0,0],[g11,g21,g22,g31,g32,g33])
subject=person;
```

The SUBJECT= variable determines when new realizations of the random effects are assumed to occur. PROC NLMIXED assumes that a new realization occurs whenever the value of the SUBJECT= variable changes from the previous observation, so your input data set should be clustered according to this variable. One easy way to accomplish this is to run PROC SORT prior to calling PROC NLMIXED by using the SUBJECT= variable as the BY variable.

Only one RANDOM statement is permitted, so multilevel nonlinear mixed models are not accommodated. However, you can specify certain nested random effects structure with a single RANDOM statement (see Chapter 15 of Littell et al. (2006) for an example).

The following options are available in the RANDOM statement:

**ALPHA= $\alpha$**

specifies the alpha level to be used in computing  $t$  statistics and intervals. The default value corresponds to the ALPHA= option in the PROC NL MIXED statement.

**DF= $d$**

specifies the degrees of freedom to be used in computing  $t$  statistics and intervals in the OUT= data set. The default value corresponds to the DF= option in the PROC NL MIXED statement.

**OUT=*SAS-data-set***

requests an output data set containing empirical Bayes estimates of the random effects and their approximate standard errors of prediction.

---

## REPLICATE Statement

**REPLICATE** *variable* ;

The REPLICATE statement provides a way to accommodate models in which different subjects have identical data. This occurs most commonly when the dependent variable is binary. When you specify a REPLICATE variable, PROC NL MIXED treats its value as the number of subjects that have data identical to the data for the current value of the SUBJECT= variable (specified in the RANDOM statement). Only the last observation of the REPLICATE variable for each subject is used, and the replicate variable must have only positive values.

The function of a REPLICATE statement is related to but not quite the same as the function of either a FREQ or a WEIGHT statement in other statistical modeling procedures, such as the GLM, GENMOD, GLIMMIX, and LOGISTIC procedures. A FREQ or a WEIGHT value essentially multiplies the log likelihood or sum of squares contribution for each observation. On the other hand, a REPLICATE value multiplies the log likelihood contribution of each subject, which consists of one or more observations. When no SUBJECT= variable is specified, the REPLICATE value behaves like a weight, multiplying each observation's log likelihood contribution.

---

## Programming Statements

This section lists the programming statements used to code the log-likelihood function in PROC NL MIXED. It also documents the differences between programming statements in PROC NL MIXED and programming statements in the SAS DATA step. The syntax of programming statements used in PROC NL MIXED is identical to that used in the CALIS and GENMOD procedures (see Chapter 27 and Chapter 40, respectively), and the MODEL procedure (see the *SAS/ETS User's Guide*). Most of the programming statements that can be used in the SAS DATA step can also be used in the NL MIXED procedure. See *SAS Language Reference: Dictionary* for a description of SAS programming statements. The following are valid statements:

```

ABORT;
ARRAY arrayname < [dimensions] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
 < , expression < TO expression > < BY expression > > ...
 < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
 ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
 OTHERWISE program-statement;

```

For the most part, the SAS programming statements work the same as they do in the SAS DATA step, as documented in *SAS Language Reference: Concepts*; however, there are the following differences:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus

```
do i = 1,2,3;
```

is supported, but the following statement is not supported:

```
do i = 'A', 'B', 'C';
```

- The LAG function does work appropriately with PROC NLMIXED, but you can use the ZLAG function instead.
- The PUT statement, used mostly for program debugging in PROC NLMIXED, supports only some of the features of the DATA step PUT statement, and it has some new features that the DATA step PUT statement does not.
  - The PROC NLMIXED PUT statement does not support line pointers, factored lists, iteration factors, overprinting, `_INFILE_`, the colon (:) format modifier, or “\$”.
  - The PROC NLMIXED PUT statement does support expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of x:
 

```
put (sqrt(x));
```

- The PROC NLMIXED PUT statement supports the item `_PDV_` to display a formatted listing of all variables in the program. For example, the following statement displays a much more readable listing of the variables than the `_ALL_` print item:

```
put _pdv_;
```

- The WHEN and OTHERWISE statements enable you to specify more than one target statement. That is, DO/END groups are not necessary for multiple statement WHENs. For example, the following syntax is valid:

```
select;
 when (exp1) stmt1;
 stmt2;
 when (exp2) stmt3;
 stmt4;
end;
```

When coding your programming statements, you should avoid defining variables that begin with an underscore (`_`), because they might conflict with internal variables created by PROC NLMIXED. The `MODEL` statement must come after any SAS programming statements that define or modify terms used in the construction of the log-likelihood.

## Details: NLMIXED Procedure

This section contains details about the underlying theory and computations of PROC NLMIXED.

### Modeling Assumptions and Notation

PROC NLMIXED operates under the following general framework for nonlinear mixed models. Assume that you have an observed data vector  $\mathbf{y}_i$  for each of  $i$  subjects,  $i = 1, \dots, s$ . The  $\mathbf{y}_i$  are assumed to be independent across  $i$ , but within-subject covariance is likely to exist because each of the elements of  $\mathbf{y}_i$  is measured on the same subject. As a statistical mechanism for modeling this within-subject covariance, assume that there exist latent random-effect vectors  $\mathbf{u}_i$  of small dimension (typically one or two) that are also independent across  $i$ . Assume also that an appropriate model linking  $\mathbf{y}_i$  and  $\mathbf{u}_i$  exists, leading to the joint probability density function

$$p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)q(\mathbf{u}_i | \boldsymbol{\xi})$$

where  $\mathbf{X}_i$  is a matrix of observed explanatory variables and  $\boldsymbol{\phi}$  and  $\boldsymbol{\xi}$  are vectors of unknown parameters.

Let  $\boldsymbol{\theta} = [\boldsymbol{\phi}, \boldsymbol{\xi}]$  and assume that it is of dimension  $n$ . Then inferences about  $\boldsymbol{\theta}$  are based on the marginal likelihood function

$$m(\boldsymbol{\theta}) = \prod_{i=1}^s \int p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)q(\mathbf{u}_i | \boldsymbol{\xi})d\mathbf{u}_i$$

In particular, the function

$$f(\boldsymbol{\theta}) = -\log m(\boldsymbol{\theta})$$

is minimized over  $\boldsymbol{\theta}$  numerically in order to estimate  $\boldsymbol{\theta}$ , and the inverse Hessian (second derivative) matrix at the estimates provides an approximate variance-covariance matrix for the estimate of  $\boldsymbol{\theta}$ . The function  $f(\boldsymbol{\theta})$  is referred to both as the negative log likelihood function and as the objective function for optimization.

As an example of the preceding general framework, consider the nonlinear growth curve example in the section “Getting Started: NLMIXED Procedure” on page 5350. Here, the conditional distribution  $p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, u_i)$  is normal with mean

$$\frac{b_1 + u_{i1}}{1 + \exp[-(d_{ij} - b_2)/b_3]}$$

and variance  $\sigma_e^2$ ; thus  $\boldsymbol{\phi} = [b_1, b_2, b_3, \sigma_e^2]$ . Also,  $u_i$  is a scalar and  $q(u_i | \xi)$  is normal with mean 0 and variance  $\sigma_u^2$ ; thus  $\xi = \sigma_u^2$ .

The following additional notation is also found in this chapter. The quantity  $\boldsymbol{\theta}^{(k)}$  refers to the parameter vector at the  $k$ th iteration, the vector  $\mathbf{g}(\boldsymbol{\theta})$  refers to the gradient vector  $\nabla f(\boldsymbol{\theta})$ , and the matrix  $\mathbf{H}(\boldsymbol{\theta})$  refers to the Hessian  $\nabla^2 f(\boldsymbol{\theta})$ . Other symbols are used to denote various constants or option values.

## Integral Approximations

An important part of the marginal maximum likelihood method described previously is the computation of the integral over the random effects. The default method in PROC NLMIXED for computing this integral is adaptive Gaussian quadrature as described in Pinheiro and Bates (1995). Another approximation method is the first-order method of Beal and Sheiner (1982, 1988). A description of these two methods follows.

### Adaptive Gaussian Quadrature

A quadrature method approximates a given integral by a weighted sum over predefined abscissas for the random effects. A good approximation can usually be obtained with an adequate number of quadrature points as well as appropriate centering and scaling of the abscissas. Adaptive Gaussian quadrature for the integral over  $\mathbf{u}_i$  centers the integral at the empirical Bayes estimate of  $\mathbf{u}_i$ , defined as the vector  $\hat{\mathbf{u}}_i$  that minimizes

$$-\log [p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)q(\mathbf{u}_i | \boldsymbol{\xi})]$$

with  $\boldsymbol{\phi}$  and  $\boldsymbol{\xi}$  set equal to their current estimates. The final Hessian matrix from this optimization can be used to scale the quadrature abscissas.

Suppose  $(z_j, w_j; j = 1, \dots, p)$  denote the standard Gauss-Hermite abscissas and weights (Golub and Welsch 1969, or Table 25.10 of Abramowitz and Stegun 1972). The adaptive Gaussian quadrature integral approximation is as follows:

$$\int p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)q(\mathbf{u}_i | \boldsymbol{\xi})d\mathbf{u}_i \approx 2^{r/2} |\boldsymbol{\Gamma}(\mathbf{X}_i, \boldsymbol{\theta})|^{-1/2} \sum_{j_1=1}^p \cdots \sum_{j_r=1}^p \left[ p(y_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{a}_{j_1, \dots, j_r})q(\mathbf{a}_{j_1, \dots, j_r} | \boldsymbol{\xi}) \prod_{k=1}^r w_{j_k} \exp z_{j_k}^2 \right]$$

where  $r$  is the dimension of  $u_i$ ,  $\Gamma(\mathbf{X}_i, \boldsymbol{\theta})$  is the Hessian matrix from the empirical Bayes minimization,  $\mathbf{z}_{j_1, \dots, j_r}$  is a vector with elements  $(z_{j_1}, \dots, z_{j_r})$ , and

$$\mathbf{a}_{j_1, \dots, j_r} = \hat{\mathbf{u}}_i + 2^{1/2} \Gamma(\mathbf{X}_i, \boldsymbol{\theta})^{-1/2} \mathbf{z}_{j_1, \dots, j_r}$$

PROC NL MIXED selects the number of quadrature points adaptively by evaluating the log-likelihood function at the starting values of the parameters until two successive evaluations have a relative difference less than the value of the QTOL= option. The specific search sequence is described under the QFAC= option. Using the QPOINTS= option, you can adjust the number of quadrature points  $p$  to obtain different levels of accuracy. Setting  $p = 1$  results in the Laplacian approximation as described in: Beal and Sheiner (1992); Wolfinger (1993); Vonesh (1992, 1996); Vonesh and Chinchilli (1997); Wolfinger and Lin (1997).

The NOAD option in the PROC NL MIXED statement requests nonadaptive Gaussian quadrature. Here all  $\hat{\mathbf{u}}_i$  are set equal to zero, and the Cholesky root of the estimated variance matrix of the random effects is substituted for  $\Gamma(\mathbf{X}_i, \boldsymbol{\theta})^{-1/2}$  in the preceding expression for  $\mathbf{a}_{j_1, \dots, j_r}$ . In this case derivatives are computed using the algorithm of Smith (1995). The NOADSCALE option requests the same scaling substitution but with the empirical Bayes  $\hat{\mathbf{u}}_i$ .

PROC NL MIXED computes the derivatives of the adaptive Gaussian quadrature approximation when carrying out the default dual quasi-Newton optimization.

## First-Order Method

Another integral approximation available in PROC NL MIXED is the first-order method of Beal and Sheiner (1982, 1988) and Sheiner and Beal (1985). This approximation is used only in the case where  $p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)$  is normal—that is,

$$p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) = (2\pi)^{-n_i/2} |\mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})|^{-1/2} \exp \left\{ -(1/2) [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)]' \mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})^{-1} [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)] \right\}$$

where  $n_i$  is the dimension of  $\mathbf{y}_i$ ,  $\mathbf{R}_i$  is a diagonal variance matrix, and  $\mathbf{m}_i$  is the conditional mean vector of  $\mathbf{y}_i$ .

The first-order approximation is obtained by expanding  $\mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i)$  with a one-term Taylor series expansion about  $\mathbf{u}_i = \mathbf{0}$ , resulting in the approximation

$$p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) \approx (2\pi)^{-n_i/2} |\mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})|^{-1/2} \exp \left( -(1/2) [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0}) - \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi}) \mathbf{u}_i]' \mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})^{-1} [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0}) - \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi}) \mathbf{u}_i] \right)$$

where  $\mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi})$  is the Jacobian matrix  $\partial \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) / \partial \mathbf{u}_i$  evaluated at  $\mathbf{u}_i = \mathbf{0}$ .

Assuming that  $q(\mathbf{u}_i | \boldsymbol{\xi})$  is normal with mean  $\mathbf{0}$  and variance matrix  $\mathbf{G}(\boldsymbol{\xi})$ , the first-order integral approximation is computable in closed form after completing the square:

$$\int p(\mathbf{y}_i | \mathbf{X}_i, \boldsymbol{\phi}, \mathbf{u}_i) q(\mathbf{u}_i | \boldsymbol{\xi}) d\mathbf{u}_i \approx (2\pi)^{-n_i/2} |\mathbf{V}_i(\mathbf{X}_i, \boldsymbol{\theta})|^{-1/2} \exp \left( -(1/2) [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0})]' \mathbf{V}_i(\mathbf{X}_i, \boldsymbol{\theta})^{-1} [\mathbf{y}_i - \mathbf{m}_i(\mathbf{X}_i, \boldsymbol{\phi}, \mathbf{0})] \right)$$

where  $\mathbf{V}_i(\mathbf{X}_i, \boldsymbol{\theta}) = \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi}) \mathbf{G}(\boldsymbol{\xi}) \mathbf{Z}_i(\mathbf{X}_i, \boldsymbol{\phi})' + \mathbf{R}_i(\mathbf{X}_i, \boldsymbol{\phi})$ . The resulting approximation for  $f(\boldsymbol{\theta})$  is then minimized over  $\boldsymbol{\theta} = [\boldsymbol{\phi}, \boldsymbol{\xi}]$  to obtain the first-order estimates. PROC NL MIXED uses finite-difference derivatives of the first-order integral approximation when carrying out the default dual quasi-Newton optimization.

## Built-in Log-Likelihood Functions

This section displays the basic formulas used by the NLMIXED procedure to compute the conditional log-likelihood functions of the data given the random effects. Note, however, that in addition to these basic equations, the NLMIXED procedure employs a number of checks for missing values and floating-point arithmetic. You can see the entire program used by the NLMIXED procedure to compute the conditional log-likelihood functions  $l(\phi; y)$  by adding the **LIST** debugging option to the **PROC NLMIXED** statement.

$Y \sim \text{normal}(m, v)$

$$l(m, v; y) = -\frac{1}{2} \left( \log\{2\pi\} + \frac{(y - m)^2}{v} + \log\{v\} \right)$$

$$E[Y] = m$$

$$\text{Var}[Y] = v$$

$$v > 0$$

$Y \sim \text{binary}(p)$

$$l_1(p; y) = \begin{cases} y \log\{p\} & y > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$l_2(p; y) = \begin{cases} (1 - y) \log\{1 - p\} & y < 1 \\ 0 & \text{otherwise} \end{cases}$$

$$l(p; y) = l_1(p; y) + l_2(p; y)$$

$$E[Y] = p$$

$$\text{Var}[Y] = p(1 - p)$$

$$0 < p < 1$$

$Y \sim \text{binomial}(n, p)$

$$l_c = \log\{\Gamma(n + 1)\} - \log\{\Gamma(y + 1)\} - \log\{\Gamma(n - y + 1)\}$$

$$l_1(n, p; y) = \begin{cases} y \log\{p\} & y > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$l_2(n, p; y) = \begin{cases} (n - y) \log\{1 - p\} & n - y > 0 \\ 0 & \text{otherwise} \end{cases}$$

$$l(n, p; y) = l_c + l_1(n, p; y) + l_2(n, p; y)$$

$$E[Y] = n p$$

$$\text{Var}[Y] = n p(1 - p)$$

$$0 < p < 1$$

$Y \sim \text{gamma}(a, b)$

$$l(a, b; y) = -a \log\{b\} - \log\{\Gamma(a)\} + (a - 1) \log\{y\} - y/b$$

$$E[Y] = ab$$

$$\text{Var}[Y] = ab^2$$

$$a > 0$$

$$b > 0$$

This parameterization of the gamma distribution differs from the parameterization used in the GLIMMIX and GENMOD procedures. The following statements show the equivalent reparameterization in the NLMIXED procedure that fits a generalized linear model for gamma-distributed data in the parameterization of the GLIMMIX procedure:

```
proc glimmix;
 model y = x / dist=gamma s;
run;

proc nlmixed;
 parms b0=1 b1=0 scale=14;
 linp = b0 + b1*x;
 mu = exp(linp);
 b = mu/scale;
 model y ~ gamma(scale,b);
run;
```

$Y \sim \text{negbin}(n, p)$

$$l(n, p; y) = \log\{\Gamma(n + y)\} - \log\{\Gamma(n)\} - \log\{\Gamma(y + 1)\} \\ + n \log\{p\} + y \log\{1 - p\}$$

$$E[Y] = nP = n \left( \frac{1 - p}{p} \right)$$

$$\text{Var}[Y] = nP(1 - P) = n \left( \frac{1 - p}{p} \right) \frac{1}{p}$$

$$n \geq 0$$

$$0 < p < 1$$

This form of the negative binomial distribution is one of the many parameterizations in which the mass function or log-likelihood function appears. Another common parameterization uses

$$l(n, p; y) = \log\{\Gamma(n + y)\} - \log\{\Gamma(n)\} - \log\{\Gamma(y + 1)\} \\ + n \log\{1 - P/(1 + P)\} + y \log\{P/(1 + P)\}$$

with  $P = (1 - p)/p$ ,  $P > 0$ .

Note that the parameter  $n$  can be real-numbered; it does not have to be integer-valued. The parameterization of the negative binomial distribution in the NLMIXED procedure differs from that in the GLIMMIX and GENMOD procedures. The following statements show the equivalent formulations for maximum likelihood estimation in the GLIMMIX and NLMIXED procedures in a negative binomial regression model:

```
proc glimmix;
 model y = x / dist=negbin s;
run;
```

```

proc nlmixed;
 parms b0=3, b1=1, k=0.8;
 linp = b0 + b1*x;
 mu = exp(linp);
 p = 1/(1+mu*k);
 model y ~ negbin(1/k, p);
run;

```

$Y \sim \text{Poisson}(m)$

$$l(m; y) = y \log\{m\} - m - \log\{\Gamma(y + 1)\}$$

$$E[Y] = m$$

$$\text{Var}[Y] = m$$

$$m > 0$$

---

## Optimization Algorithms

There are several optimization techniques available in PROC NLMIXED. You can choose a particular optimizer with the **TECH=** option in the **PROC NLMIXED** statement.

| Algorithm                                     | TECH=  |
|-----------------------------------------------|--------|
| trust region method                           | TRUREG |

No algorithm for optimizing general nonlinear functions exists that always finds the global optimum for a general nonlinear minimization problem in a reasonable amount of time. Since no single optimization technique is invariably superior to others, PROC NLMIXED provides a variety of optimization techniques that work well in various circumstances. However, you can devise problems for which none of the techniques in PROC NLMIXED can find the correct solution. Moreover, nonlinear optimization can be computationally expensive in terms of time and memory, so you must be careful when matching an algorithm to a problem.

All optimization techniques in PROC NLMIXED use  $O(n^2)$  memory except the conjugate gradient methods, which use only  $O(n)$  of memory and are designed to optimize problems with many parameters. Since the techniques are iterative, they require the repeated computation of the following:

- the function value (optimization criterion)
- the gradient vector (first-order partial derivatives)
- for some techniques, the (approximate) Hessian matrix (second-order partial derivatives)

However, since each of the optimizers requires different derivatives, some computational efficiencies can be gained. The following table shows, for each optimization technique, which derivatives are required (FOD: first-order derivatives; SOD: second-order derivatives).

| Algorithm | FOD | SOD |
|-----------|-----|-----|
| TRUREG    | x   | x   |
| NEWRAP    | x   | x   |
| NRRIDG    | x   | x   |
| QUANEW    | x   | -   |
| DBLDOG    | x   | -   |
| CONGRA    | x   | -   |
| NMSIMP    | -   | -   |

Each optimization method employs one or more convergence criteria that determine when it has converged. The various termination criteria are listed and described in the “**PROC NLMIXED Statement**” section. An algorithm is considered to have converged when any one of the convergence criteria is satisfied. For example, under the default settings, the QUANEW algorithm will converge if  $ABSGCONV < 1E-5$ ,  $FCONV < 10^{-FDIGITS}$ , or  $GCONV < 1E-8$ .

### Choosing an Optimization Algorithm

The factors that go into choosing a particular optimization technique for a particular problem are complex and can involve trial and error.

For many optimization problems, computing the gradient takes more computer time than computing the function value, and computing the Hessian sometimes takes *much* more computer time and memory than computing the gradient, especially when there are many decision variables. Unfortunately, optimization techniques that do not use some kind of Hessian approximation usually require many more iterations than techniques that do use a Hessian matrix, and as a result the total run time of these techniques is often longer. Techniques that do not use the Hessian also tend to be less reliable. For example, they can more easily terminate at stationary points rather than at global optima.

A few general remarks about the various optimization techniques follow:

- The second-derivative methods TRUREG, NEWRAP, and NRRIDG are best for small problems where the Hessian matrix is not expensive to compute. Sometimes the NRRIDG algorithm can be faster than the TRUREG algorithm, but TRUREG can be more stable. The NRRIDG algorithm requires only one matrix with  $n(n + 1)/2$  double words; TRUREG and NEWRAP require two such matrices.
- The first-derivative methods QUANEW and DBLDOG are best for medium-sized problems where the objective function and the gradient are much faster to evaluate than the Hessian. The QUANEW and DBLDOG algorithms, in general, require more iterations than TRUREG, NRRIDG, and NEWRAP, but each iteration can be much faster. The QUANEW and DBLDOG algorithms require only the gradient to update an approximate Hessian, and they require slightly less memory than TRUREG or NEWRAP (essentially one matrix with  $n(n + 1)/2$  double words). QUANEW is the default optimization method.

- The first-derivative method CONGRA is best for large problems where the objective function and the gradient can be computed much faster than the Hessian and where too much memory is required to store the (approximate) Hessian. The CONGRA algorithm, in general, requires more iterations than QUANEW or DBLDOG, but each iteration can be much faster. Since CONGRA requires only a factor of  $n$  double-word memory, many large applications of PROC NLMIXED can be solved only by CONGRA.
- The no-derivative method NMSIMP is best for small problems where derivatives are not continuous or are very difficult to compute.

## Algorithm Descriptions

Some details about the optimization techniques follow.

### **Trust Region Optimization (TRUREG)**

The trust region method uses the gradient  $\mathbf{g}(\boldsymbol{\theta}^{(k)})$  and the Hessian matrix  $\mathbf{H}(\boldsymbol{\theta}^{(k)})$ ; thus, it requires that the objective function  $f(\boldsymbol{\theta})$  have continuous first- and second-order derivatives inside the feasible region.

The trust region method iteratively optimizes a quadratic approximation to the nonlinear objective function within a hyperelliptic trust region with radius  $\Delta$  that constrains the step size corresponding to the quality of the quadratic approximation. The trust region method is implemented using: Dennis, Gay, and Welsch (1981); Gay (1983); Moré and Sorensen (1983).

The trust region method performs well for small- to medium-sized problems, and it does not need many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

### **Newton-Raphson Optimization with Line Search (NEWRAP)**

The NEWRAP technique uses the gradient  $\mathbf{g}(\boldsymbol{\theta}^{(k)})$  and the Hessian matrix  $\mathbf{H}(\boldsymbol{\theta}^{(k)})$ ; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region. If second-order derivatives are computed efficiently and precisely, the NEWRAP method can perform well for medium-sized to large problems, and it does not need many function, gradient, and Hessian calls.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. Otherwise, a combination of ridging and line search is performed to compute successful steps. If the Hessian is not positive definite, a multiple of the identity matrix is added to the Hessian matrix to make it positive definite (Eskow and Schnabel 1991).

In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation (LINESEARCH=2).

### **Newton-Raphson Ridge Optimization (NRRIDG)**

The NRRIDG technique uses the gradient  $\mathbf{g}(\boldsymbol{\theta}^{(k)})$  and the Hessian matrix  $\mathbf{H}(\boldsymbol{\theta}^{(k)})$ ; thus, it requires that the objective function have continuous first- and second-order derivatives inside the feasible region.

This algorithm uses a pure Newton step when the Hessian is positive definite and when the Newton step reduces the value of the objective function successfully. If at least one of these two conditions is not satisfied, a multiple of the identity matrix is added to the Hessian matrix.

The NRRIDG method performs well for small- to medium-sized problems, and it does not require many function, gradient, and Hessian calls. However, if the computation of the Hessian matrix is computationally expensive, one of the (dual) quasi-Newton or conjugate gradient algorithms might be more efficient.

Since the NRRIDG technique uses an orthogonal decomposition of the approximate Hessian, each iteration of NRRIDG can be slower than that of the NEWRAP technique, which works with Cholesky decomposition. Usually, however, NRRIDG requires fewer iterations than NEWRAP.

### **Quasi-Newton Optimization (QUANEW)**

The (dual) quasi-Newton method uses the gradient  $g(\theta^{(k)})$ , and it does not need to compute second-order derivatives since they are approximated. It works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian; but, in general, it requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which compute second-order derivatives. QUANEW is the default optimization algorithm because it provides an appropriate balance between the speed and stability required for most nonlinear mixed model applications.

The QUANEW technique is one of the following, depending on the value of the `UPDATE=` option.

- the original quasi-Newton algorithm, which updates an approximation of the inverse Hessian
- the dual quasi-Newton algorithm, which updates the Cholesky factor of an approximate Hessian (default)

You can specify four update formulas with the `UPDATE=` option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno (BFGS) update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell (DFP) update of the Cholesky factor of the Hessian matrix.
- BFGS performs the original BFGS update of the inverse Hessian matrix.
- DFP performs the original DFP update of the inverse Hessian matrix.

In each iteration, a line search is performed along the search direction to find an approximate optimum. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size  $\alpha$  satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit of the step size. Violating the left-side Goldstein condition can affect the positive definiteness of the quasi-Newton update. In that case, either the update is skipped or the iterations are restarted with an identity matrix, resulting in the steepest descent or ascent search direction. You can specify line-search algorithms other than the default with the `LINESEARCH=` option.

The QUANEW algorithm uses its own line-search technique. No options and parameters (except the `INSTEP=` option) controlling the line search in the other algorithms apply here. In several applications, large steps in the first iterations are troublesome. You can use the `INSTEP=` option to impose an upper bound for the step size  $\alpha$  during the first five iterations. You can also use the `INHESIAN=r` option to specify a different starting approximation for the Hessian. If you specify only the `INHESIAN` option, the Cholesky factor of a (possibly ridged) finite difference approximation of the Hessian is used to initialize the quasi-Newton update process. The values of the `LCSINGULAR=`, `LCEPSILON=`, and `LCDEACT=`

options, which control the processing of linear and boundary constraints, are valid only for the quadratic programming subroutine used in each iteration of the QUANEW algorithm.

### **Double-Dogleg Optimization (DBLDOG)**

The double-dogleg optimization method combines the ideas of the quasi-Newton and trust region methods. In each iteration, the double-dogleg algorithm computes the step  $s^{(k)}$  as the linear combination of the steepest descent or ascent search direction  $s_1^{(k)}$  and a quasi-Newton search direction  $s_2^{(k)}$ :

$$s^{(k)} = \alpha_1 s_1^{(k)} + \alpha_2 s_2^{(k)}$$

The step is requested to remain within a prespecified trust region radius; see Fletcher (1987, p. 107). Thus, the DBLDOG subroutine uses the dual quasi-Newton update but does not perform a line search. You can specify two update formulas with the `UPDATE=` option:

- DBFGS performs the dual Broyden, Fletcher, Goldfarb, and Shanno update of the Cholesky factor of the Hessian matrix. This is the default.
- DDFP performs the dual Davidon, Fletcher, and Powell update of the Cholesky factor of the Hessian matrix.

The double-dogleg optimization technique works well for medium to moderately large optimization problems where the objective function and the gradient are much faster to compute than the Hessian. The implementation is based on Dennis and Mei (1979) and Gay (1983), but it is extended for dealing with boundary and linear constraints. The DBLDOG technique generally requires more iterations than the TRUREG, NEWRAP, and NRRIDG techniques, which require second-order derivatives; however, each of the DBLDOG iterations is computationally cheap. Furthermore, the DBLDOG technique requires only gradient calls for the update of the Cholesky factor of an approximate Hessian.

### **Conjugate Gradient Optimization (CONGRA)**

Second-order derivatives are not required by the CONGRA algorithm and are not even approximated. The CONGRA algorithm can be expensive in function and gradient calls, but it requires only  $O(n)$  memory for unconstrained optimization. In general, many iterations are required to obtain a precise solution, but each of the CONGRA iterations is computationally cheap. You can specify four different update formulas for generating the conjugate directions by using the `UPDATE=` option:

- PB performs the automatic restart update method of Powell (1977) and Beale (1972). This is the default.
- FR performs the Fletcher-Reeves update (Fletcher 1987).
- PR performs the Polak-Ribiere update (Fletcher 1987).
- CD performs a conjugate-descent update of Fletcher (1987).

The default, `UPDATE=PB`, behaved best in most test examples. You are advised to avoid the option `UPDATE=CD`, which behaved worst in most test examples.

The CONGRA subroutine should be used for optimization problems with large  $n$ . For the unconstrained or boundary constrained case, CONGRA requires only  $O(n)$  bytes of working memory, whereas all other

optimization methods require order  $O(n^2)$  bytes of working memory. During  $n$  successive iterations, uninterrupted by restarts or changes in the working set, the conjugate gradient algorithm computes a cycle of  $n$  conjugate search directions. In each iteration, a line search is performed along the search direction to find an approximate optimum of the objective function. The default line-search method uses quadratic interpolation and cubic extrapolation to obtain a step size  $\alpha$  satisfying the Goldstein conditions. One of the Goldstein conditions can be violated if the feasible region defines an upper limit for the step size. Other line-search algorithms can be specified with the `LINESEARCH=` option.

### **Nelder-Mead Simplex Optimization (NMSIMP)**

The Nelder-Mead simplex method does not use any derivatives and does not assume that the objective function has continuous derivatives. The objective function itself needs to be continuous. This technique is quite expensive in the number of function calls, and it might be unable to generate precise results for  $n \gg 40$ .

The original Nelder-Mead simplex algorithm is implemented and extended to boundary constraints. This algorithm does not compute the objective for infeasible points, but it changes the shape of the simplex adapting to the nonlinearities of the objective function, which contributes to an increased speed of convergence. It uses a special termination criterion.

---

## **Finite-Difference Approximations of Derivatives**

The `FD=` and `FDHESSIAN=` options specify the use of finite-difference approximations of the derivatives. The `FD=` option specifies that all derivatives are approximated using function evaluations, and the `FDHESSIAN=` option specifies that second-order derivatives are approximated using gradient evaluations.

Computing derivatives by finite-difference approximations can be very time-consuming, especially for second-order derivatives based only on values of the objective function (`FD=` option). If analytical derivatives are difficult to obtain (for example, if a function is computed by an iterative process), you might consider one of the optimization techniques that use first-order derivatives only (`QUANEW`, `DBLDOG`, or `CONGRA`). In the expressions that follow,  $\boldsymbol{\theta}$  denotes the parameter vector,  $h_i$  denotes the step size for the  $i$ th parameter, and  $\mathbf{e}_i$  is a vector of zeros with a 1 in the  $i$ th position.

### **Forward-Difference Approximations**

The forward-difference derivative approximations consume less computer time, but they are usually not as precise as approximations that use central-difference formulas.

- For first-order derivatives,  $n$  additional function calls are required:

$$g_i = \frac{\partial f}{\partial \theta_i} \approx \frac{f(\boldsymbol{\theta} + h_i \mathbf{e}_i) - f(\boldsymbol{\theta})}{h_i}$$

- For second-order derivatives based on function calls only (Dennis and Schnabel 1983, p. 80),  $n + n^2/2$  additional function calls are required for dense Hessian:

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{f(\boldsymbol{\theta} + h_i \mathbf{e}_i + h_j \mathbf{e}_j) - f(\boldsymbol{\theta} + h_i \mathbf{e}_i) - f(\boldsymbol{\theta} + h_j \mathbf{e}_j) + f(\boldsymbol{\theta})}{h_i h_j}$$

- For second-order derivatives based on gradient calls (Dennis and Schnabel 1983, p. 103),  $n$  additional gradient calls are required:

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{g_i(\boldsymbol{\theta} + h_j \mathbf{e}_j) - g_i(\boldsymbol{\theta})}{2h_j} + \frac{g_j(\boldsymbol{\theta} + h_i \mathbf{e}_i) - g_j(\boldsymbol{\theta})}{2h_i}$$

### Central-Difference Approximations

Central-difference approximations are usually more precise, but they consume more computer time than approximations that use forward-difference derivative formulas.

- For first-order derivatives,  $2n$  additional function calls are required:

$$g_i = \frac{\partial f}{\partial \theta_i} \approx \frac{f(\boldsymbol{\theta} + h_i \mathbf{e}_i) - f(\boldsymbol{\theta} - h_i \mathbf{e}_i)}{2h_i}$$

- For second-order derivatives based on function calls only (Abramowitz and Stegun 1972, p. 884),  $2n + 4n^2/2$  additional function calls are required.

$$\frac{\partial^2 f}{\partial \theta_i^2} \approx \frac{-f(\boldsymbol{\theta} + 2h_i \mathbf{e}_i) + 16f(\boldsymbol{\theta} + h_i \mathbf{e}_i) - 30f(\boldsymbol{\theta}) + 16f(\boldsymbol{\theta} - h_i \mathbf{e}_i) - f(\boldsymbol{\theta} - 2h_i \mathbf{e}_i)}{12h_i^2}$$

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{f(\boldsymbol{\theta} + h_i \mathbf{e}_i + h_j \mathbf{e}_j) - f(\boldsymbol{\theta} + h_i \mathbf{e}_i - h_j \mathbf{e}_j) - f(\boldsymbol{\theta} - h_i \mathbf{e}_i + h_j \mathbf{e}_j) + f(\boldsymbol{\theta} - h_i \mathbf{e}_i - h_j \mathbf{e}_j)}{4h_i h_j}$$

- For second-order derivatives based on gradient calls,  $2n$  additional gradient calls are required:

$$\frac{\partial^2 f}{\partial \theta_i \partial \theta_j} \approx \frac{g_i(\boldsymbol{\theta} + h_j \mathbf{e}_j) - g_i(\boldsymbol{\theta} - h_j \mathbf{e}_j)}{4h_j} + \frac{g_j(\boldsymbol{\theta} + h_i \mathbf{e}_i) - g_j(\boldsymbol{\theta} - h_i \mathbf{e}_i)}{4h_i}$$

You can use the `FDIGITS=` option to specify the number of accurate digits in the evaluation of the objective function. This specification is helpful in determining an appropriate interval size  $h$  to be used in the finite-difference formulas.

The step sizes  $h_j$ ,  $j = 1, \dots, n$  are defined as follows:

- For the forward-difference approximation of first-order derivatives that use function calls and second-order derivatives that use gradient calls,  $h_j = \sqrt[2]{\eta}(1 + |\theta_j|)$ .
- For the forward-difference approximation of second-order derivatives that use only function calls and all central-difference formulas,  $h_j = \sqrt[3]{\eta}(1 + |\theta_j|)$ .

The value of  $\eta$  is defined by the `FDIGITS=` option:

- If you specify the number of accurate digits by using `FDIGITS=r`,  $\eta$  is set to  $10^{-r}$ .
- If you do not specify the `FDIGITS=` option,  $\eta$  is set to the machine precision  $\epsilon$ .

## Hessian Scaling

The rows and columns of the Hessian matrix can be scaled when you use the trust region, Newton-Raphson, and double-dogleg optimization techniques. Each element  $H_{i,j}$ ,  $i, j = 1, \dots, n$  is divided by the scaling factor  $d_i d_j$ , where the scaling vector  $d = (d_1, \dots, d_n)$  is iteratively updated in a way specified by the HESCAL= $i$  option, as follows:

$i = 0$  : No scaling is done (equivalent to  $d_i = 1$ ).

$i \neq 0$  : First iteration and each restart iteration sets:

$$d_i^{(0)} = \sqrt{\max(|H_{i,i}^{(0)}|, \epsilon)}$$

$i = 1$  : See Moré (1978):

$$d_i^{(k+1)} = \max \left[ d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

$i = 2$  : See Dennis, Gay, and Welsch (1981):

$$d_i^{(k+1)} = \max \left[ 0.6d_i^{(k)}, \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)} \right]$$

$i = 3$  :  $d_i$  is reset in each iteration:

$$d_i^{(k+1)} = \sqrt{\max(|H_{i,i}^{(k)}|, \epsilon)}$$

In the preceding equations,  $\epsilon$  is the relative machine precision or, equivalently, the largest double-precision value that, when added to 1, results in 1.

## Active Set Methods

The parameter vector  $\theta \in \mathcal{R}^n$  can be subject to a set of  $m$  linear equality and inequality constraints:

$$\begin{aligned} \sum_{j=1}^n a_{ij} \theta_j &= b_i & i = 1, \dots, m_e \\ \sum_{j=1}^n a_{ij} \theta_j &\geq b_i & i = m_e + 1, \dots, m \end{aligned}$$

The coefficients  $a_{ij}$  and right-hand sides  $b_i$  of the equality and inequality constraints are collected in the  $m \times n$  matrix  $\mathbf{A}$  and the  $m$  vector  $\mathbf{b}$ .

The  $m$  linear constraints define a feasible region  $\mathcal{G}$  in  $\mathcal{R}^n$  that must contain the point  $\theta_*$  that minimizes the problem. If the feasible region  $\mathcal{G}$  is empty, no solution to the optimization problem exists.

In PROC NLMIXED, all optimization techniques use *active set methods*. The iteration starts with a feasible point  $\theta^{(0)}$ , which you can provide or which can be computed by the Schittkowski and Stoer (1979) algorithm

implemented in PROC NLMIXED. The algorithm then moves from one feasible point  $\theta^{(k-1)}$  to a better feasible point  $\theta^{(k)}$  along a feasible search direction  $s^{(k)}$ ,

$$\theta^{(k)} = \theta^{(k-1)} + \alpha^{(k)} s^{(k)}, \quad \alpha^{(k)} > 0$$

Theoretically, the path of points  $\theta^{(k)}$  never leaves the feasible region  $\mathcal{G}$  of the optimization problem, but it can reach its boundaries. The active set  $\mathcal{A}^{(k)}$  of point  $\theta^{(k)}$  is defined as the index set of all linear equality constraints and those inequality constraints that are satisfied at  $\theta^{(k)}$ . If no constraint is active at  $\theta^{(k)}$ , the point is located in the interior of  $\mathcal{G}$ , and the active set  $\mathcal{A}^{(k)} = \emptyset$  is empty. If the point  $\theta^{(k)}$  in iteration  $k$  hits the boundary of inequality constraint  $i$ , this constraint  $i$  becomes active and is added to  $\mathcal{A}^{(k)}$ . Each equality constraint and each active inequality constraint reduce the dimension (degrees of freedom) of the optimization problem.

In practice, the active constraints can be satisfied only with finite precision. The `LCEPSILON=r` option specifies the range for active and violated linear constraints. If the point  $\theta^{(k)}$  satisfies the condition

$$\left| \sum_{j=1}^n a_{ij} \theta_j^{(k)} - b_i \right| \leq t$$

where  $t = r(|b_i| + 1)$ , the constraint  $i$  is recognized as an active constraint. Otherwise, the constraint  $i$  is either an inactive inequality or a violated inequality or equality constraint. Due to rounding errors in computing the projected search direction, error can be accumulated so that an iterate  $\theta^{(k)}$  steps out of the feasible region.

In those cases, PROC NLMIXED might try to pull the iterate  $\theta^{(k)}$  back into the feasible region. However, in some cases the algorithm needs to increase the feasible region by increasing the `LCEPSILON=r` value. If this happens, a message is displayed in the log output.

If the algorithm cannot improve the value of the objective function by moving from an active constraint back into the interior of the feasible region, it makes this inequality constraint an equality constraint in the next iteration. This means that the active set  $\mathcal{A}^{(k+1)}$  still contains the constraint  $i$ . Otherwise, it releases the active inequality constraint and increases the dimension of the optimization problem in the next iteration.

A serious numerical problem can arise when some of the active constraints become (nearly) linearly dependent. PROC NLMIXED removes linearly dependent equality constraints before starting optimization. You can use the `LCSINGULAR=` option to specify a criterion  $r$  used in the update of the QR decomposition that determines whether an active constraint is linearly dependent relative to a set of other active constraints.

If the solution  $\theta^*$  is subjected to  $n_{act}$  linear equality or active inequality constraints, the QR decomposition of the  $n \times n_{act}$  matrix  $\hat{\mathbf{A}}'$  of the linear constraints is computed by  $\hat{\mathbf{A}}' = \mathbf{QR}$ , where  $\mathbf{Q}$  is an  $n \times n$  orthogonal matrix and  $\mathbf{R}$  is an  $n \times n_{act}$  upper triangular matrix. The  $n$  columns of matrix  $\mathbf{Q}$  can be separated into two matrices,  $\mathbf{Q} = [\mathbf{Y}, \mathbf{Z}]$ , where  $\mathbf{Y}$  contains the first  $n_{act}$  orthogonal columns of  $\mathbf{Q}$  and  $\mathbf{Z}$  contains the last  $n - n_{act}$  orthogonal columns of  $\mathbf{Q}$ . The  $n \times (n - n_{act})$  column-orthogonal matrix  $\mathbf{Z}$  is also called the *null-space matrix* of the active linear constraints  $\hat{\mathbf{A}}'$ . The  $n - n_{act}$  columns of the  $n \times (n - n_{act})$  matrix  $\mathbf{Z}$  form a basis orthogonal to the rows of the  $n_{act} \times n$  matrix  $\hat{\mathbf{A}}$ .

At the end of the iterating, PROC NLMIXED computes the *projected gradient*  $\mathbf{gz}$ ,

$$\mathbf{gz} = \mathbf{Z}'\mathbf{g}$$

In the case of boundary-constrained optimization, the elements of the projected gradient correspond to the gradient elements of the free parameters. A necessary condition for  $\theta^*$  to be a local minimum of the optimization problem is

$$\mathbf{gz}(\theta^*) = \mathbf{Z}'\mathbf{g}(\theta^*) = \mathbf{0}$$

The symmetric  $n_{act} \times n_{act}$  matrix  $\mathbf{G}_Z$ ,

$$\mathbf{G}_Z = \mathbf{Z}'\mathbf{G}\mathbf{Z}$$

is called a *projected Hessian matrix*. A second-order necessary condition for  $\boldsymbol{\theta}^*$  to be a local minimizer requires that the projected Hessian matrix is positive semidefinite.

Those elements of the  $n_{act}$  vector of first-order estimates of *Lagrange multipliers*,

$$\lambda = (\hat{\mathbf{A}}\hat{\mathbf{A}}')^{-1}\hat{\mathbf{A}}\mathbf{Z}\mathbf{Z}'\mathbf{g}$$

that correspond to active inequality constraints indicate whether an improvement of the objective function can be obtained by releasing this active constraint. For minimization, a significant negative Lagrange multiplier indicates that a possible reduction of the objective function can be achieved by releasing this active linear constraint. The `LCDEACT=r` option specifies a threshold  $r$  for the Lagrange multiplier that determines whether an active inequality constraint remains active or can be deactivated. (In the case of boundary-constrained optimization, the Lagrange multipliers for active lower (upper) constraints are the negative (positive) gradient elements corresponding to the active parameters.)

## Line-Search Methods

In each iteration  $k$ , the (dual) quasi-Newton, conjugate gradient, and Newton-Raphson minimization techniques use iterative line-search algorithms that try to optimize a linear, quadratic, or cubic approximation of  $f$  along a feasible descent search direction  $\mathbf{s}^{(k)}$ ,

$$\boldsymbol{\theta}^{(k+1)} = \boldsymbol{\theta}^{(k)} + \alpha^{(k)}\mathbf{s}^{(k)}, \quad \alpha^{(k)} > 0$$

by computing an approximately optimal scalar  $\alpha^{(k)}$ .

Therefore, a line-search algorithm is an iterative process that optimizes a nonlinear function  $f(\alpha)$  of one parameter ( $\alpha$ ) within each iteration  $k$  of the optimization technique. Since the outside iteration process is based only on the approximation of the objective function, the inside iteration of the line-search algorithm does not have to be perfect. Usually, it is satisfactory that the choice of  $\alpha$  significantly reduces (in a minimization) the objective function. Criteria often used for termination of line-search algorithms are the Goldstein conditions (see Fletcher 1987).

You can select various line-search algorithms by specifying the `LINESEARCH=` option. The line-search method `LINESEARCH=2` seems to be superior when function evaluation consumes significantly less computation time than gradient evaluation. Therefore, `LINESEARCH=2` is the default method for Newton-Raphson, (dual) quasi-Newton, and conjugate gradient optimizations.

You can modify the line-search methods `LINESEARCH=2` and `LINESEARCH=3` to be exact line searches by using the `LSPRECISION=` option and specifying the  $\sigma$  parameter described in Fletcher (1987). The line-search methods `LINESEARCH=1`, `LINESEARCH=2`, and `LINESEARCH=3` satisfy the left-side and right-side Goldstein conditions (see Fletcher 1987). When derivatives are available, the line-search methods `LINESEARCH=6`, `LINESEARCH=7`, and `LINESEARCH=8` try to satisfy the right-side Goldstein condition; if derivatives are not available, these line-search algorithms use only function calls.

## Restricting the Step Length

Almost all line-search algorithms use iterative extrapolation techniques that can easily lead them to (feasible) points where the objective function  $f$  is no longer defined or is difficult to compute. Therefore, PROC NLMIXED provides options restricting the step length  $\alpha$  or trust region radius  $\Delta$ , especially during the first main iterations.

The inner product  $\mathbf{g}'\mathbf{s}$  of the gradient  $\mathbf{g}$  and the search direction  $\mathbf{s}$  is the slope of  $f(\alpha) = f(\boldsymbol{\theta} + \alpha\mathbf{s})$  along the search direction  $\mathbf{s}$ . The default starting value  $\alpha^{(0)} = \alpha^{(k,0)}$  in each line-search algorithm ( $\min_{\alpha>0} f(\boldsymbol{\theta} + \alpha\mathbf{s})$ ) during the main iteration  $k$  is computed in three steps:

1. The first step uses either the difference  $|\Delta f| = |f^{(k)} - f^{(k-1)}|$  of the function values during the last two consecutive iterations or the final step-size value  $\alpha^-$  of the last iteration  $k - 1$  to compute a first value of  $\alpha_1^{(0)}$ .

- If the **DAMPSTEP** option is not used,

$$\alpha_1^{(0)} = \begin{cases} \text{step} & \text{if } 0.1 \leq \text{step} \leq 10 \\ 10 & \text{if } \text{step} > 10 \\ 0.1 & \text{if } \text{step} < 0.1 \end{cases}$$

with

$$\text{step} = \begin{cases} |\Delta f|/|\mathbf{g}'\mathbf{s}| & \text{if } |\mathbf{g}'\mathbf{s}| \geq \epsilon \max(100 \times |\Delta f|, 1) \\ 1 & \text{otherwise} \end{cases}$$

This value of  $\alpha_1^{(0)}$  can be too large and can lead to a difficult or impossible function evaluation, especially for highly nonlinear functions such as the EXP function.

- If the **DAMPSTEP=r** option is used,

$$\alpha_1^{(0)} = \min(1, r\alpha^-)$$

The initial value for the new step length can be no larger than  $r$  times the final step length  $\alpha^-$  of the former iteration. The default value is  $r = 2$ .

2. During the first five iterations, the second step enables you to reduce  $\alpha_1^{(0)}$  to a smaller starting value  $\alpha_2^{(0)}$  by using the **INSTEP=r** option:

$$\alpha_2^{(0)} = \min(\alpha_1^{(0)}, r)$$

After more than five iterations,  $\alpha_2^{(0)}$  is set to  $\alpha_1^{(0)}$ .

3. The third step can further reduce the step length by

$$\alpha_3^{(0)} = \min(\alpha_2^{(0)}, \min(10, u))$$

where  $u$  is the maximum length of a step inside the feasible region.

The `INSTEP=r` option enables you to specify a smaller or larger radius  $\Delta$  of the trust region used in the first iteration of the trust region and double-dogleg algorithms. The default initial trust region radius  $\Delta^{(0)}$  is the length of the scaled gradient (Moré 1978). This step corresponds to the default radius factor of  $r = 1$ . In most practical applications of the TRUREG and DBLDOG algorithms, this choice is successful. However, for bad initial values and highly nonlinear objective functions (such as the EXP function), the default start radius can result in arithmetic overflows. If this happens, you can try decreasing values of `INSTEP=r`,  $0 < r < 1$ , until the iteration starts successfully. A small factor  $r$  also affects the trust region radius  $\Delta^{(k+1)}$  of the next steps because the radius is changed in each iteration by a factor  $0 < c \leq 4$ , depending on the ratio  $\rho$  expressing the goodness of quadratic function approximation. Reducing the radius  $\Delta$  corresponds to increasing the ridge parameter  $\lambda$ , producing smaller steps aimed more closely toward the (negative) gradient direction.

---

## Computational Problems

### Floating-Point Errors and Overflows

Numerical optimization of a numerically integrated function is a difficult task, and the computation of the objective function and its derivatives can lead to arithmetic exceptions and overflows. A typical cause of these problems is parameters with widely varying scales. If the scaling of your parameters varies by more than a few orders of magnitude, the numerical stability of the optimization problem can be seriously reduced and can result in computational difficulties. A simple remedy is to rescale each parameter so that its final estimated value has a magnitude near 1.

If parameter rescaling does not help, consider the following actions:

- Specify the `ITDETAILS` option in the `PROC NLMIXED` statement to obtain more detailed information about when and where the problem is occurring.
- Provide different initial values or try a grid search of values.
- Use boundary constraints to avoid the region where overflows can happen.
- Delete outlying observations or subjects from the input data, if this is reasonable.
- Change the algorithm (specified in programming statements) that computes the objective function.

The line-search algorithms that work with cubic extrapolation are especially sensitive to arithmetic overflows. If an overflow occurs during a line search, you can use the `INSTEP=` option to reduce the length of the first trial step during the first five iterations, or you can use the `DAMPSTEP` or `MAXSTEP` option to restrict the step length of the initial  $\alpha$  in subsequent iterations. If an arithmetic overflow occurs in the first iteration of the trust region or double-dogleg algorithm, you can use the `INSTEP=` option to reduce the default trust region radius of the first iteration. You can also change the optimization technique or the line-search method.

### Long Run Times

`PROC NLMIXED` can take a long time to run for problems involving complex models, many parameters, or large input data sets. Although the optimization techniques used by `PROC NLMIXED` are some of the best ones available, they are not guaranteed to converge quickly for all problems. Ill-posed or misspecified

models can cause the algorithms to use more extensive calculations designed to achieve convergence, and this can result in longer run times. So first make sure that your model is specified correctly, that your parameters are scaled to be of the same order of magnitude, and that your data reasonably match the model you are contemplating.

If you are using the default adaptive Gaussian quadrature algorithm and no iteration history is printing at all, then PROC NLMIXED might be bogged down trying to determine the number of quadrature points at the first set of starting values. Specifying the `QPOINTS=` option will bypass this stage and proceed directly to iterations; however, be aware that the likelihood approximation might not be accurate if there are too few quadrature points.

PROC NLMIXED can also have difficulty determining the number of quadrature points if the initial starting values are far from the optimum values. To obtain more accurate starting values for the model parameters, one easy method is to fit a model with no `RANDOM` statement. You can then use these estimates as starting values, although you will still need to specify values for the random-effects distribution. For normal-normal models, another strategy is to use `METHOD=FIRO`. If you can obtain estimates by using this approximate method, then they can be used as starting values for more accurate likelihood approximations.

If you are running PROC NLMIXED multiple times, you will probably want to include a statement like the following in your program:

```
ods output ParameterEstimates=pe;
```

This statement creates a SAS data set named PE upon completion of the run. In your next invocation of PROC NLMIXED, you can then specify

```
parms / data=pe;
```

to read in the previous estimates as starting values.

To speed general computations, you should double-check your programming statements to minimize the number of floating-point operations. Using auxiliary variables and factoring amenable expressions can be useful changes in this regard.

## Problems Evaluating Code for Objective Function

The starting point  $\theta^{(0)}$  must be a point for which the programming statements can be evaluated. However, during optimization, the optimizer might iterate to a point  $\theta^{(k)}$  where the objective function or its derivatives cannot be evaluated. In some cases, the specification of boundary for parameters can avoid such situations. In many other cases, you can indicate that the point  $\theta^{(0)}$  is a bad point simply by returning an extremely large value for the objective function. In these cases, the optimization algorithm reduces the step length and stays closer to the point that has been evaluated successfully in the former iteration.

## No Convergence

There are a number of things to try if the optimizer fails to converge.

- Change the initial values by using a grid search specification to obtain a set of good feasible starting values.
- Change or modify the update technique or the line-search algorithm.

This method applies only to `TECH=QUANEW` and `TECH=CONGRA`. For example, if you use the default update formula and the default line-search algorithm, you can do the following:

- change the update formula with the `UPDATE=` option
  - change the line-search algorithm with the `LINESEARCH=` option
  - specify a more precise line search with the `LSPRECISION=` option, if you use `LINESEARCH=2` or `LINESEARCH=3`
- Change the optimization technique.  
For example, if you use the default option, `TECH=QUANEW`, you can try one of the second-derivative methods if your problem is small or the conjugate gradient method if it is large.
  - Adjust finite-difference derivatives.  
The forward-difference derivatives specified with the `FD=` or `FDHESSIAN=` option might not be precise enough to satisfy strong gradient termination criteria. You might need to specify the more expensive central-difference formulas. The finite-difference intervals might be too small or too big, and the finite-difference derivatives might be erroneous.
  - Double-check the data entry and program specification.

### Convergence to Stationary Point

The gradient at a stationary point is the null vector, which always leads to a zero search direction. This point satisfies the first-order termination criterion. Search directions that are based on the gradient are zero, so the algorithm terminates. There are two ways to avoid this situation:

- Use the `PARMS` statement to specify a grid of feasible initial points.
- Use the `OPTCHECK=r` option to avoid terminating at the stationary point.

The signs of the eigenvalues of the (reduced) Hessian matrix contain the following information regarding a stationary point:

- If all of the eigenvalues are positive, the Hessian matrix is positive definite, and the point is a minimum point.
- If some of the eigenvalues are positive and all remaining eigenvalues are zero, the Hessian matrix is positive semidefinite, and the point is a minimum or saddle point.
- If all of the eigenvalues are negative, the Hessian matrix is negative definite, and the point is a maximum point.
- If some of the eigenvalues are negative and all remaining eigenvalues are zero, the Hessian matrix is negative semidefinite, and the point is a maximum or saddle point.
- If all of the eigenvalues are zero, the point can be a minimum, maximum, or saddle point.

## Precision of Solution

In some applications, PROC NLMIXED can result in parameter values that are not precise enough. Usually, this means that the procedure terminated at a point too far from the optimal point. The termination criteria define the size of the termination region around the optimal point. Any point inside this region can be accepted for terminating the optimization process. The default values of the termination criteria are set to satisfy a reasonable compromise between the computational effort (computer time) and the precision of the computed estimates for the most common applications. However, there are a number of circumstances in which the default values of the termination criteria specify a region that is either too large or too small.

If the termination region is too large, then it can contain points with low precision. In such cases, you should determine which termination criterion stopped the optimization process. In many applications, you can obtain a solution with higher precision simply by using the old parameter estimates as starting values in a subsequent run in which you specify a smaller value for the termination criterion that was satisfied at the former run.

If the termination region is too small, the optimization process might take longer to find a point inside such a region, or it might not even find such a point due to rounding errors in function values and derivatives. This can easily happen in applications in which finite-difference approximations of derivatives are used and the `GCONV` and `ABSGCONV` termination criteria are too small to respect rounding errors in the gradient values.

---

## Covariance Matrix

The estimated covariance matrix of the parameter estimates is computed as the inverse Hessian matrix, and for unconstrained problems it should be positive definite. If the final parameter estimates are subjected to  $n_{act} > 0$  active linear inequality constraints, the formulas of the covariance matrices are modified similar to Gallant (1987) and Cramer (1986, p. 38) and additionally generalized for applications with singular matrices.

There are several steps available that enable you to tune the rank calculations of the covariance matrix.

1. You can use the `ASINGULAR=`, `MSINGULAR=`, and `VSINGULAR=` options to set three singularity criteria for the inversion of the Hessian matrix **H**. The singularity criterion used for the inversion is

$$|d_{j,j}| \leq \max(\text{ASING}, \text{VSING} * |H_{j,j}|, \text{MSING} * \max(|H_{1,1}|, \dots, |H_{n,n}|))$$

where  $d_{j,j}$  is the diagonal pivot of the matrix **H**, and `ASING`, `VSING`, and `MSING` are the specified values of the `ASINGULAR=`, `VSINGULAR=`, and `MSINGULAR=` options, respectively. The default values are as follows:

- `ASING`: the square root of the smallest positive double-precision value
- `MSING`:  $1\text{E}-12$  if you do not specify the `SINGHESS=` option and  $\max(10\epsilon, 1\text{E} - 4 \times \text{SINGHESS})$  otherwise, where  $\epsilon$  is the machine precision
- `VSING`:  $1\text{E}-8$  if you do not specify the `SINGHESS=` option and the value of `SINGHESS` otherwise

Note that, in many cases, a normalized matrix  $\mathbf{D}^{-1}\mathbf{AD}^{-1}$  is decomposed, and the singularity criteria are modified correspondingly.

2. If the matrix  $\mathbf{H}$  is found to be singular in the first step, a generalized inverse is computed. Depending on the `G4=` option, either a generalized inverse satisfying all four Moore-Penrose conditions is computed (a  $g_4$ -inverse) or a generalized inverse satisfying only two Moore-Penrose conditions is computed (a  $g_2$ -inverse, Pringle and Rayner 1971). If the number of parameters  $n$  of the application is less than or equal to `G4=i`, a  $g_4$ -inverse is computed; otherwise, only a  $g_2$ -inverse is computed. The  $g_4$ -inverse is computed by the (computationally very expensive but numerically stable) eigenvalue decomposition, and the  $g_2$ -inverse is computed by Gauss transformation. The  $g_4$ -inverse is computed using the eigenvalue decomposition  $\mathbf{A} = \mathbf{Z}\mathbf{\Lambda}\mathbf{Z}'$ , where  $\mathbf{Z}$  is the orthogonal matrix of eigenvectors and  $\mathbf{\Lambda}$  is the diagonal matrix of eigenvalues,  $\mathbf{\Lambda} = \text{diag}(\lambda_1, \dots, \lambda_n)$ . The  $g_4$ -inverse of  $\mathbf{H}$  is set to

$$\mathbf{A}^- = \mathbf{Z}\mathbf{\Lambda}^- \mathbf{Z}'$$

where the diagonal matrix  $\mathbf{\Lambda}^- = \text{diag}(\lambda_1^-, \dots, \lambda_n^-)$  is defined using the `COVSING=` option:

$$\lambda_i^- = \begin{cases} 1/\lambda_i & \text{if } |\lambda_i| > \text{COVSING} \\ 0 & \text{if } |\lambda_i| \leq \text{COVSING} \end{cases}$$

If you do not specify the `COVSING=` option, the  $nr$  smallest eigenvalues are set to zero, where  $nr$  is the number of rank deficiencies found in the first step.

For optimization techniques that do not use second-order derivatives, the covariance matrix is computed using finite-difference approximations of the derivatives.

---

## Prediction

The nonlinear mixed model is a useful tool for statistical prediction. Assuming a prediction is to be made regarding the  $i$ th subject, suppose that  $f(\boldsymbol{\theta}, \mathbf{u}_i)$  is a differentiable function predicting some quantity of interest. Recall that  $\boldsymbol{\theta}$  denotes the vector of unknown parameters and  $\mathbf{u}_i$  denotes the vector of random effects for the  $i$ th subject. A natural point prediction is  $f(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$ , where  $\hat{\boldsymbol{\theta}}$  is the maximum likelihood estimate of  $\boldsymbol{\theta}$  and  $\hat{\mathbf{u}}_i$  is the empirical Bayes estimate of  $\mathbf{u}_i$  described previously in the section “Integral Approximations” on page 5384.

An approximate prediction variance matrix for  $(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$  is

$$\mathbf{P} = \begin{bmatrix} \hat{\mathbf{H}}^{-1} & \hat{\mathbf{H}}^{-1} \left( \frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right)' \\ \left( \frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right) \hat{\mathbf{H}}^{-1} & \hat{\mathbf{\Gamma}}^{-1} + \left( \frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right) \hat{\mathbf{H}}^{-1} \left( \frac{\partial \hat{\mathbf{u}}_i}{\partial \boldsymbol{\theta}} \right)' \end{bmatrix}$$

where  $\hat{\mathbf{H}}$  is the approximate Hessian matrix from the optimization for  $\hat{\boldsymbol{\theta}}$ ,  $\hat{\mathbf{\Gamma}}$  is the approximate Hessian matrix from the optimization for  $\hat{\mathbf{u}}_i$ , and  $(\partial \hat{\mathbf{u}}_i / \partial \boldsymbol{\theta})$  is the derivative of  $\hat{\mathbf{u}}_i$  with respect to  $\boldsymbol{\theta}$ , evaluated at  $(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$ . The approximate variance matrix for  $\hat{\boldsymbol{\theta}}$  is the standard one discussed in the previous section, and that for  $\hat{\mathbf{u}}_i$  is an approximation to the conditional mean squared error of prediction described by Booth and Hobert (1998).

The prediction variance for a general scalar function  $f(\boldsymbol{\theta}, \mathbf{u}_i)$  is defined as the expected squared difference  $E[f(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i) - f(\boldsymbol{\theta}, \mathbf{u}_i)]^2$ . PROC NL MIXED computes an approximation to it as follows. The derivative of  $f(\boldsymbol{\theta}, \mathbf{u}_i)$  is computed with respect to each element of  $(\boldsymbol{\theta}, \mathbf{u}_i)$  and evaluated at  $(\hat{\boldsymbol{\theta}}, \hat{\mathbf{u}}_i)$ . If  $\mathbf{a}_i$  is the resulting vector, then the approximate prediction variance is  $\mathbf{a}_i' \mathbf{P} \mathbf{a}_i$ . This approximation is known as the delta method (Billingsley 1986; Cox 1998).

## Computational Resources

Since nonlinear optimization is an iterative process that depends on many factors, it is difficult to estimate how much computer time is necessary to find an optimal solution satisfying one of the termination criteria. You can use the `MAXTIME=`, `MAXITER=`, and `MAXFUNC=` options to restrict the amount of CPU time, the number of iterations, and the number of function calls in a single run of PROC NLMIXED.

In each iteration  $k$ , the NRRIDG technique uses a symmetric Householder transformation to decompose the  $n \times n$  Hessian matrix  $\mathbf{H}$ ,

$$\mathbf{H} = \mathbf{V}'\mathbf{T}\mathbf{V}, \quad \mathbf{V}: \text{orthogonal}, \quad \mathbf{T}: \text{tridiagonal}$$

to compute the (Newton) search direction  $\mathbf{s}$ ,

$$\mathbf{s}^{(k)} = -[\mathbf{H}^{(k)}]^{-1}\mathbf{g}^{(k)} \quad k = 1, 2, 3, \dots$$

The TRUREG and NEWRAP techniques use the Cholesky decomposition to solve the same linear system while computing the search direction. The QUANEW, DBLDOG, CONGRA, and NMSIMP techniques do not need to invert or decompose a Hessian matrix; thus, they require less computational resources than the other techniques.

The larger the problem, the more time is needed to compute function values and derivatives. Therefore, you might want to compare optimization techniques by counting and comparing the respective numbers of function, gradient, and Hessian evaluations.

Finite-difference approximations of the derivatives are expensive because they require additional function or gradient calls:

- forward-difference formulas
  - For first-order derivatives,  $n$  additional function calls are required.
  - For second-order derivatives based on function calls only, for a dense Hessian,  $n + n^2/2$  additional function calls are required.
  - For second-order derivatives based on gradient calls,  $n$  additional gradient calls are required.
- central-difference formulas
  - For first-order derivatives,  $2n$  additional function calls are required.
  - For second-order derivatives based on function calls only, for a dense Hessian,  $2n + 2n^2$  additional function calls are required.
  - For second-order derivatives based on gradient calls,  $2n$  additional gradient calls are required.

Many applications need considerably more time for computing second-order derivatives (Hessian matrix) than for computing first-order derivatives (gradient). In such cases, a dual quasi-Newton technique is recommended, which does not require second-order derivatives.

---

## Displayed Output

This section describes the displayed output from PROC NLMIXED. See the section “ODS Table Names” on page 5407 for details about how this output interfaces with the Output Delivery System.

### **Specifications**

The NLMIXED procedure first displays the “Specifications” table, listing basic information about the nonlinear mixed model that you have specified. It includes the principal variables and estimation methods.

### **Dimensions**

The “Dimensions” table lists counts of important quantities in your nonlinear mixed model, including the number of observations, subjects, parameters, and quadrature points.

### **Parameters**

The “Parameters” table displays the information you provided with the **PARMS** statement and the value of the negative log-likelihood function evaluated at the starting values.

### **Starting Gradient and Hessian**

The **START** option in the **PROC NLMIXED** statement displays the gradient of the negative log-likelihood function at the starting values of the parameters. If you also specify the **HESS** option, then the starting Hessian is displayed as well.

### **Iterations**

The iteration history consists of one line of output for each iteration in the optimization process. The iteration history is displayed by default because it is important that you check for possible convergence problems. The default iteration history includes the following variables:

- Iter, the iteration number
- Calls, the number of function calls
- NegLogLike, the value of the objective function
- Diff, the difference between adjacent function values
- MaxGrad, the maximum of the absolute (projected) gradient components (except NMSIMP)
- Slope, the slope  $g'$ s of the search direction  $s$  at the current parameter iterate  $\theta^{(k)}$  (QUANEW only)
- Rho, the ratio between the achieved and predicted values of Diff (NRRIDG only)
- Radius, the radius of the trust region (TRUREG only)
- StdDev, the standard deviation of the simplex values (NMSIMP only)
- Delta, the vertex length of the simplex (NMSIMP only)
- Size, the size of the simplex (NMSIMP only)

For the QUANEW method, the value of Slope should be significantly negative. Otherwise, the line-search algorithm has difficulty reducing the function value sufficiently. If this difficulty is encountered, an asterisk (\*) appears after the iteration number. If there is a tilde ~ after the iteration number, the BFGS update is skipped, and very high values of the Lagrange function are produced. A backslash ( \ ) after the iteration number indicates that Powell's correction for the BFGS update is used.

For methods using second derivatives, an asterisk (\*) after the iteration number means that the computed Hessian approximation was singular and had to be ridged with a positive value.

For the NMSIMP method, only one line is displayed for several internal iterations. This technique skips the output for some iterations because some of the termination tests (StdDev and Size) are rather time-consuming compared to the simplex operations, and they are performed only every five simplex operations.

The ITDETAILS option in the PROC NLMIXED statement provides a more detailed iteration history. Besides listing the current values of the parameters and their gradients, the ITDETAILS option provides the following values in addition to the default output:

- Restart, the number of iteration restarts
- Active, the number of active constraints
- Lambda, the value of the Lagrange multiplier (TRUREG and DBLDOG only)
- Ridge, the ridge value (NRRIDG only)
- Alpha, the line-search step size (QUANEW only)

An apostrophe (') trailing the number of active constraints indicates that at least one of the active constraints was released from the active set due to a significant Lagrange multiplier.

### Convergence Status

The "Convergence Status" table contains a status message describing the reason for termination of the optimization. The ODS name of this table is ConvergenceStatus, and you can query the nonprinting numeric variable Status to check for a successful optimization. This is useful in batch processing, or when processing BY groups, for example, in simulations. Successful convergence is indicated by Status=0.

### Fitting Information

The "Fitting Information" table lists the final minimized value of  $-2$  times the log likelihood as well as the information criteria of Akaike (AIC) and Schwarz (BIC), as well as a finite-sample corrected version of AIC (AICC). The criteria are computed as follows:

$$\text{AIC} = 2f(\hat{\theta}) + 2p$$

$$\text{AICC} = 2f(\hat{\theta}) + 2pn/(n - p - 1)$$

$$\text{BIC} = 2f(\hat{\theta}) + p \log(s)$$

where  $f()$  is the negative of the marginal log-likelihood function,  $\hat{\theta}$  is the vector of parameter estimates,  $p$  is the number of parameters,  $n$  is the number of observations, and  $s$  is the number of subjects. See Hurvich and Tsai (1989) and Burnham and Anderson (1998) for additional details.

### Parameter Estimates

The “Parameter Estimates” table lists the estimates of the parameter values after successful convergence of the optimization problem or the final values of the parameters under nonconvergence. If the problem did converge, standard errors are computed from the final Hessian matrix. The ratio of the estimate with its standard error produces a  $t$  value, with approximate degrees of freedom computed as the number of subjects minus the number of random effects. A  $p$ -value and confidence limits based on this  $t$  distribution are also provided. Finally, the gradient of the negative log-likelihood function is displayed for each parameter, and you should verify that they each are sufficiently small for unconstrained parameters.

### Covariance and Correlation Matrices

Following standard maximum likelihood theory (for example, Serfling 1980), the asymptotic variance-covariance matrix of the parameter estimates equals the inverse of the Hessian matrix. You can display this matrix with the **COV** option in the **PROC NL MIXED** statement. The corresponding correlation form is available with the **CORR** option.

### Additional Estimates

The “Additional Estimates” table displays the results of all **ESTIMATE** statements that you specify, with the same columns as the “Parameter Estimates” table. The **ECOV** and **ECORR** options in the **PROC NL MIXED** statement produce tables displaying the approximate covariance and correlation matrices of the additional estimates. They are computed using the delta method (Billingsley 1986; Cox 1998). The **EDER** option in the **PROC NL MIXED** statement produces a table that displays the derivatives of the additional estimates with respect to the model parameters evaluated at their final estimated values.

---

## ODS Table Names

**PROC NL MIXED** assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 64.2. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 64.2** ODS Tables Produced by **PROC NL MIXED**

| ODS Table Name      | Description                                | Statement or Option |
|---------------------|--------------------------------------------|---------------------|
| AdditionalEstimates | Results from <b>ESTIMATE</b> statements    | <b>ESTIMATE</b>     |
| Contrasts           | Results from <b>CONTRAST</b> statements    | <b>CONTRAST</b>     |
| ConvergenceStatus   | Convergence status                         | default             |
| CorrMatAddEst       | Correlation matrix of additional estimates | <b>ECORR</b>        |
| CorrMatParmEst      | Correlation matrix of parameter estimates  | <b>CORR</b>         |
| CovMatAddEst        | Covariance matrix of additional estimates  | <b>ECOV</b>         |
| CovMatParmEst       | Covariance matrix of parameter estimates   | <b>COV</b>          |
| DerAddEst           | Derivatives of additional estimates        | <b>EDER</b>         |
| Dimensions          | Dimensions of the problem                  | default             |
| FitStatistics       | Fit statistics                             | default             |
| Hessian             | Second derivative matrix                   | <b>HESS</b>         |
| IterHistory         | Iteration history                          | default             |
| Parameters          | Parameters                                 | default             |
| ParameterEstimates  | Parameter estimates                        | default             |

Table 64.2 continued

## Examples: NLMIXED Procedure

### Example 64.1: One-Compartment Model with Pharmacokinetic Data

A popular application of nonlinear mixed models is in the field of pharmacokinetics, which studies how a drug disperses through a living individual. This example considers the theophylline data from Pinheiro and Bates (1995). Serum concentrations of the drug theophylline are measured in 12 subjects over a 25-hour period after oral administration. The data are as follows.

```
data theoph;
 input subject time conc dose wt;
 datalines;
 1 0.00 0.74 4.02 79.6
 1 0.25 2.84 4.02 79.6
 1 0.57 6.57 4.02 79.6
 1 1.12 10.50 4.02 79.6
 1 2.02 9.66 4.02 79.6
 1 3.82 8.58 4.02 79.6
 1 5.10 8.36 4.02 79.6

Pinheiro and Bates (1995) consider the following first-order compartment model for these data:

$$C_{it} = \frac{Dk_{e_i}k_{a_i}}{Cl_i(k_{a_i} - k_{e_i})} [\exp(-k_{e_i}t) - \exp(-k_{a_i}t)] + e_{it}$$

where  $C_{it}$  is the observed concentration of the  $i$ th subject at time  $t$ ,  $D$  is the dose of theophylline,  $k_{e_i}$  is the elimination rate constant for subject  $i$ ,  $k_{a_i}$  is the absorption rate constant for subject  $i$ ,  $Cl_i$  is the clearance for subject  $i$ , and  $e_{it}$  are normal errors. To allow for random variability between subjects, they assume

$$\begin{aligned} Cl_i &= \exp(\beta_1 + b_{i1}) \\ k_{a_i} &= \exp(\beta_2 + b_{i2}) \\ k_{e_i} &= \exp(\beta_3) \end{aligned}$$

where the  $\beta$ s denote fixed-effects parameters and the  $b_i$ s denote random-effects parameters with an unknown covariance matrix.

The PROC NL MIXED statements to fit this model are as follows:

```
proc nlmixed data=theoph;
 parms beta1=-3.22 beta2=0.47 beta3=-2.45
 s2b1 =0.03 cb12 =0 s2b2 =0.4 s2=0.5;
 cl = exp(beta1 + b1);
 ka = exp(beta2 + b2);
 ke = exp(beta3);
 pred = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/cl/(ka-ke);
 model conc ~ normal(pred,s2);
 random b1 b2 ~ normal([0,0],[s2b1,cb12,s2b2]) subject=subject;
run;
```

The **PARMS** statement specifies starting values for the three  $\beta$ s and four variance-covariance parameters. The clearance and rate constants are defined using SAS programming statements, and the conditional model for the data is defined to be normal with mean `pred` and variance `s2`. The two random effects are `b1` and `b2`, and their joint distribution is defined in the **RANDOM** statement. Brackets are used in defining their mean vector (two zeros) and the lower triangle of their variance-covariance matrix (a general  $2 \times 2$  matrix). The **SUBJECT=** variable is `subject`.

The results from this analysis are as follows.

#### Output 64.1.1 Model Specification for One-Compartment Model

| The NL MIXED Procedure              |                                 |
|-------------------------------------|---------------------------------|

The “Specifications” table lists the setup of the model (Output 64.1.1). The “Dimensions” table indicates that there are 132 observations, 12 subjects, and 7 parameters. PROC NL MIXED selects 5 quadrature points for each random effect, producing a total grid of 25 points over which quadrature is performed (Output 64.1.2).

**Output 64.1.2** Dimensions Table for One-Compartment Model

| Dimensions            |     |
|-----------------------|-----|
| Observations Used     | 132 |
| Observations Not Used | 0   |
| Total Observations    | 132 |
| Subjects              | 12  |
| Max Obs Per Subject   | 11  |
| Parameters            | 7   |
| Quadrature Points     | 5   |

The “Parameters” table lists the 7 parameters, their starting values, and the initial evaluation of the negative log likelihood using adaptive Gaussian quadrature (Output 64.1.3). The “Iteration History” table indicates that 10 steps are required for the dual quasi-Newton algorithm to achieve convergence.

**Output 64.1.3** Starting Values and Iteration History

| Parameters |       |       |      |      |      |                |

| s2                  | 0.5016   | 0.06837        | 10 | 7.34    | <.0001  | 0.05  | 0.3493   |

| Parameter Estimates |         |          |
|---------------------|---------|----------|
| Parameter           | Upper   | Gradient |
| beta1               | -3.0942 | -0.00009 |
| beta2               | 0.9238  | 3.645E-7 |
| beta3               | -2.3449 | 0.000039 |
| s2b1                | 0.05523 | -0.00014 |
| cb12                | 0.07458 | -0.00007 |
| s2b2                | 0.8798  | -6.98E-6 |
| s2                  | 0.6540  | 6.133E-6 |

The “Parameter Estimates” table contains the maximum likelihood estimates of the parameters (Output 64.1.5). Both s2b1 and s2b2 are marginally significant, indicating between-subject variability in the clearances and absorption rate constants, respectively. There does not appear to be a significant covariance between them, as seen by the estimate of cb12.

The estimates of  $\beta_1$ ,  $\beta_2$ , and  $\beta_3$  are close to the adaptive quadrature estimates listed in Table 3 of Pinheiro and Bates (1995). However, Pinheiro and Bates use a Cholesky-root parameterization for the random-effects variance matrix and a logarithmic parameterization for the residual variance. The PROC NL MIXED statements using their parameterization are as follows, and results are similar.

```

proc nlmixed data=theoph;
 parms l11=-1.5 l2=0 l13=-0.1 beta1=-3 beta2=0.5 beta3=-2.5 ls2=-0.7;
 s2 = exp(ls2);
 l1 = exp(l11);
 l3 = exp(l13);
 s2b1 = l1*l1*s2;
 cb12 = l2*l1*s2;
 s2b2 = (l2*l2 + l3*l3)*s2;
 c1 = exp(beta1 + b1);
 ka = exp(beta2 + b2);
 ke = exp(beta3);
 pred = dose*ke*ka*(exp(-ke*time)-exp(-ka*time))/c1/(ka-ke);
 model conc ~ normal(pred, s2);
 random b1 b2 ~ normal([0,0], [s2b1, cb12, s2b2]) subject=subject;
run;

```

## Example 64.2: Probit-Normal Model with Binomial Data

For this example, consider the data from Weil (1970), also studied by: Williams (1975); Ochi and Prentice (1984); McCulloch (1994). In this experiment 16 pregnant rats receive a control diet and 16 receive a chemically treated diet, and the litter size for each rat is recorded after 4 and 21 days. The SAS data set follows:

```

data rats;
 input trt $ m x @@;
 if (trt='c') then do;
 x1 = 1;
 x2 = 0;
 end;
 else do;
 x1 = 0;
 x2 = 1;
 end;
 litter = _n_;
 datalines;
c 13 13 c 12 12 c 9 9 c 9 9 c 8 8 c 8 8 c 13 12 c 12 11
c 10 9 c 10 9 c 9 8 c 13 11 c 5 4 c 7 5 c 10 7 c 10 7
t 12 12 t 11 11 t 10 10 t 9 9 t 11 10 t 10 9 t 10 9 t 9 8
t 9 8 t 5 4 t 9 7 t 7 4 t 10 5 t 6 3 t 10 3 t 7 0
;

```

Here,  $m$  represents the size of the litter after 4 days, and  $x$  represents the size of the litter after 21 days. Also, indicator variables  $x_1$  and  $x_2$  are constructed for the two treatment levels.

Following McCulloch (1994), assume a latent survival model of the form

$$y_{ijk} = t_i + \alpha_{ij} + e_{ijk}$$

where  $i$  indexes treatment,  $j$  indexes litter, and  $k$  indexes newborn rats within a litter. The  $t_i$  represent treatment means, the  $\alpha_{ij}$  represent random litter effects assumed to be iid  $N(0, s_i^2)$ , and the  $e_{ijk}$  represent iid residual errors, all on the latent scale.

Instead of observing the survival times  $y_{ijk}$ , assume that only the binary variable indicating whether  $y_{ijk}$  exceeds 0 is observed. If  $x_{ij}$  denotes the sum of these binary variables for the  $i$ th treatment and the  $j$ th litter,

then the preceding assumptions lead to the following generalized linear mixed model:

$$x_{ij} | \alpha_{ij} \sim \text{Binomial}(m_{ij}, p_{ij})$$

where  $m_{ij}$  is the size of each litter after 4 days and

$$p_{ij} = \Phi(t_i + \alpha_{ij})$$

The PROC NLMIXED statements to fit this model are as follows:

```
proc nlmixed data=rats;
 parms t1=1 t2=1 s1=.05 s2=1;
 eta = x1*t1 + x2*t2 + alpha;
 p = probnorm(eta);
 model x ~ binomial(m,p);
 random alpha ~ normal(0,x1*s1*s1+x2*s2*s2) subject=litter;
 estimate 'gamma2' t2/sqrt(1+s2*s2);
 predict p out=p;
run;
```

As in [Example 64.1](#), the PROC NLMIXED statement invokes the procedure and the PARMS statement defines the parameters. The parameters for this example are the two treatment means,  $t_1$  and  $t_2$ , and the two random-effect standard deviations,  $s_1$  and  $s_2$ .

The indicator variables  $x_1$  and  $x_2$  are used in the program to assign the proper mean to each observation in the input data set as well as the proper variance to the random effects. Note that programming expressions are permitted inside the distributional specifications, as illustrated by the random-effects variance specified here.

The ESTIMATE statement requests an estimate of  $\gamma_2 = t_2 / \sqrt{1 + s_2^2}$ , which is a location-scale parameter from Ochi and Prentice (1984).

The PREDICT statement constructs predictions for each observation in the input data set. For this example, predictions of  $p$  and approximate standard errors of prediction are output to a SAS data set named P. These predictions are functions of the parameter estimates and the empirical Bayes estimates of the random effects  $\alpha_i$ .

The output for this model is as follows.

#### Output 64.2.1 Specifications, Dimensions, and Starting Values

| Quadrature Points     |    |      |    |            | 7  |
| Parameters            |    |      |    |            |    |
| t1                    | t2 | s1   | s2 | NegLogLike |    |
| 1                     | 1  | 0.05 | 1  | 54.9362323 |    |

The “Specifications” table provides basic information about this nonlinear mixed model (Output 64.2.1). The “Dimensions” table provides counts of various variables. Note that each observation in the data comprises a separate subject. Using the starting values in the “Parameters” table, PROC NLMIXED determines that the log-likelihood function can be approximated with sufficient accuracy with a seven-point quadrature rule.

**Output 64.2.2** Iteration History for Probit-Normal Model

| Iteration History                            |       |            |          |          |          |
|----------------------------------------------|-------|------------|----------|----------|----------|
| Iter                                         | Calls | NegLogLike | Diff     | MaxGrad  | Slope    |

| t2                  | 0.9475   | 0.3055         | 31 | 3.10    | 0.0041  | 0.05  | 0.3244  |
| s1                  | 0.2403   | 0.3015         | 31 | 0.80    | 0.4315  | 0.05  | -0.3746 |
| s2                  | 1.0292   | 0.2988         | 31 | 3.44    | 0.0017  | 0.05  | 0.4198  |

| Parameter Estimates |        |          |
|---------------------|--------|----------|
| Parameter           | Upper  | Gradient |
| t1                  | 1.6499 | -0.00002 |
| t2                  | 1.5705 | 9.283E-6 |
| s1                  | 0.8552 | 0.000014 |
| s2                  | 1.6385 | -3.16E-6 |

The “Parameter Estimates” table indicates significance of all the parameters except S1 (Output 64.2.4).

**Output 64.2.5** Additional Estimates

| Additional Estimates |          |                |    |         |         |       |        |        |
|----------------------|----------|----------------|----|---------|---------|-------|--------|--------|
| Label                | Estimate | Standard Error | DF | t Value | Pr >  t | Alpha | Lower  | Upper  |
| gamma2               | 0.6603   | 0.2165         | 31 | 3.05    | 0.0047  | 0.05  | 0.2186 | 1.1019 |

The “Additional Estimates” table displays results from the ESTIMATE statement (Output 64.2.5). The estimate of  $\gamma_2$  equals 0.66, agreeing with that obtained by McCulloch (1994). The standard error 0.22 is computed using the delta method (Billingsley 1986; Cox 1998).

Not shown is the P data set, which contains the original 32 observations and predictions of the  $p_{ij}$ .

### Example 64.3: Probit-Normal Model with Ordinal Data

The data for this example are from Ezzet and Whitehead (1991), who describe a crossover experiment on two groups of patients using two different inhaler devices (A and B). Patients from group 1 used device A for one week and then device B for another week. Patients from group 2 used the devices in reverse order. The data entered as a SAS data set are as follows:

```
data inhaler;
 input clarity group time freq @@;
 gt = group*time;
 sub = floor((_n_+1)/2);
 datalines;
1 0 0 59 1 0 1 59 1 0 0 35 2 0 1 35 1 0 0 3 3 0 1 3 1 0 0 2
4 0 1 2 2 0 0 11 1 0 1 11 2 0 0 27 2 0 1 27 2 0 0 2 3 0 1 2
2 0 0 1 4 0 1 1 4 0 0 1 1 0 1 1 4 0 0 1 2 0 1 1 1 1 0 63
1 1 1 63 1 1 0 13 2 1 1 13 2 1 0 40 1 1 1 40 2 1 0 15 2 1 1 15
3 1 0 7 1 1 1 7 3 1 0 2 2 1 1 2 3 1 0 1 3 1 1 1 4 1 0 2
1 1 1 2 4 1 0 1 3 1 1 1
;
```

The response measurement, clarity, is the patients' assessment on the clarity of the leaflet instructions for the devices. The clarity variable is on an ordinal scale, with 1=easy, 2=only clear after rereading, 3=not very clear, and 4=confusing. The group variable indicates the treatment group, and the time variable indicates the time of measurement. The freq variable indicates the number of patients with exactly the same responses. A variable gt is created to indicate a group-by-time interaction, and a variable sub is created to indicate patients.

As in the previous example and in Hedeker and Gibbons (1994), assume an underlying latent continuous variable, here with the form

$$y_{ij} = \beta_0 + \beta_1 g_i + \beta_2 t_j + \beta_3 g_i t_j + u_i + e_{ij}$$

where  $i$  indexes patient and  $j$  indexes the time period,  $g_i$  indicates groups,  $t_j$  indicates time,  $u_i$  is a patient-level normal random effect, and  $e_{ij}$  are iid normal errors. The  $\beta$ s are unknown coefficients to be estimated.

Instead of observing  $y_{ij}$ , however, you observe only whether it falls in one of the four intervals:  $(-\infty, 0)$ ,  $(0, I_1)$ ,  $(I_1, I_1 + I_2)$ , or  $(I_1 + I_2, \infty)$ , where  $I_1$  and  $I_2$  are both positive. The resulting category is the value assigned to the clarity variable.

The following code sets up and fits this ordinal probit model:

```
proc nlmixed data=inhaler corr ecorr;
 parms b0=0 b1=0 b2=0 b3=0 sd=1 i1=1 i2=1;
 bounds i1 > 0, i2 > 0;
 eta = b0 + b1*group + b2*time + b3*gt + u;
 if (clarity=1) then p = probnorm(-eta);
 else if (clarity=2) then
 p = probnorm(i1-eta) - probnorm(-eta);
 else if (clarity=3) then
 p = probnorm(i1+i2-eta) - probnorm(i1-eta);
 else p = 1 - probnorm(i1+i2-eta);
 if (p > 1e-8) then ll = log(p);
 else ll = -1e20;
```

```

model clarity ~ general(11);
random u ~ normal(0,sd*sd) subject=sub;
replicate freq;
estimate 'thresh2' i1;
estimate 'thresh3' i1 + i2;
estimate 'icc' sd*sd/(1+sd*sd);
run;

```

The **PROC NLMIXED** statement specifies the input data set and requests correlations both for the parameter estimates (**CORR** option) and for the additional estimates specified with **ESTIMATE** statements (**ECORR** option).

The parameters as defined in the **PARMS** statement are as follows: **b0** (overall intercept), **b1** (group main effect), **B2** (time main effect), **b3** (group-by-time interaction), **sd** (standard deviation of the random effect), **i1** (increment between first and second thresholds), and **i2** (increment between second and third thresholds). The **BOUNDS** statement restricts **i1** and **i2** to be positive.

The SAS programming statements begin by defining the linear predictor **eta**, which is a linear combination of the **b** parameters and a single random effect **u**. The next statements define the ordinal likelihood according to the **clarity** variable, **eta**, and the increment variables. An error trap is included in case the likelihood becomes too small.

A general log-likelihood specification is used in the **MODEL** statement, and the **RANDOM** statement defines the random effect **u** to have standard deviation **sd** and subject variable **sub**. The **REPLICATE** statement indicates that data for each subject should be replicated according to the **freq** variable.

The **ESTIMATE** statements specify the second and third thresholds in terms of the increment variables (the first threshold is assumed to equal zero for model identifiability). Also computed is the intraclass correlation.

The output is as follows.

### Output 64.3.1 Specifications for Ordinal Data Model

| The NLMIXED Procedure               |                              |
|-------------------------------------|------------------------------|
| Specifications                      |                              |
| Data Set                            | WORK.INHALER                 |
| Dependent Variable                  | clarity                      |
| Distribution for Dependent Variable | General                      |
| Random Effects                      | u                            |
| Distribution for Random Effects     | Normal                       |
| Subject Variable                    | sub                          |
| Replicate Variable                  | freq                         |
| Optimization Technique              | Dual Quasi-Newton            |
| Integration Method                  | Adaptive Gaussian Quadrature |

The “Specifications” table echoes some primary information specified for this nonlinear mixed model (Output 64.3.1). Because the log-likelihood function was expressed with SAS programming statements, the distribution is displayed as *General* in the “Specifications” table.

The “Dimensions” table reveals a total of 286 subjects, which is the sum of the values of the FREQ variable for the second time point. Five quadrature points are selected for log-likelihood evaluation (Output 64.3.2).

**Output 64.3.2** Dimensions Table for Ordinal Data Model

| Dimensions            |     |
|-----------------------|-----|
| Observations Used     | 38  |
| Observations Not Used | 0   |
| Total Observations    | 38  |
| Subjects              | 286 |
| Max Obs Per Subject   | 2   |
| Parameters            | 7   |
| Quadrature Points     | 5   |

**Output 64.3.3** Parameter Starting Values and Negative Log Likelihood

| Parameters |    |    |    |    |    |    |            |
|------------|----|----|----|----|----|----|------------|
| b0         | b1 | b2 | b3 | sd | i1 | i2 | NegLogLike |
| 0          | 0  | 0  | 0  | 1  | 1  | 1  | 538.484276 |

The “Parameters” table lists the simple starting values for this problem (Output 64.3.3). The “Iteration History” table indicates successful convergence in 13 iterations (Output 64.3.4).

**Output 64.3.4** Iteration History

| Iteration History |       |            |          |          |          |

| Label                | Estimate | Standard Error | DF  | t Value | Pr >  t | Alpha | Lower  | Upper  |
| thresh2              | 1.7450   | 0.1474         | 285 | 11.84   | <.0001  | 0.05  | 1.4548 | 2.0352 |
| thresh3              | 2.3435   | 0.2073         | 285 | 11.31   | <.0001  | 0.05  | 1.9355 | 2.7515 |
| icc                  | 0.3034   | 0.08402        | 285 | 3.61    | 0.0004  | 0.05  | 0.1380 | 0.4687 |

The “Additional Estimates” table displays results from the ESTIMATE statements (Output 64.3.7).

### Example 64.4: Poisson-Normal Model with Count Data

This example uses the pump failure data of Gaver and O’Muircheartaigh (1987). The number of failures and the time of operation are recorded for 10 pumps. Each of the pumps is classified into one of two groups corresponding to either continuous or intermittent operation. The data are as follows:

```
data pump;
 input y t group;
 pump = _n_;
 logtstd = log(t) - 2.4564900;
 datalines;
5 94.320 1
1 15.720 2
5 62.880 1
14 125.760 1
3 5.240 2
19 31.440 1
1 1.048 2
1 1.048 2
4 2.096 2
22 10.480 2
;
```

Each row denotes data for a single pump, and the variable logtstd contains the centered operation times.

Letting  $y_{ij}$  denote the number of failures for the  $j$ th pump in the  $i$ th group, Draper (1996) considers the following hierarchical model for these data:

$$y_{ij} | \lambda_{ij} \sim \text{Poisson}(\lambda_{ij})$$

$$\log \lambda_{ij} = \alpha_i + \beta_i (\log t_{ij} - \overline{\log t}) + e_{ij}$$

$$e_{ij} | \sigma^2 \sim \text{Normal}(0, \sigma^2)$$

The model specifies different intercepts and slopes for each group, and the random effect is a mechanism for accounting for overdispersion.

The corresponding PROC NL MIXED statements are as follows:

```
proc nlmixed data=pump;
 parms logsig 0 beta1 1 beta2 1 alpha1 1 alpha2 1;
 if (group = 1) then eta = alpha1 + beta1*logtstd + e;
 else eta = alpha2 + beta2*logtstd + e;
 lambda = exp(eta);
 model y ~ poisson(lambda);
 random e ~ normal(0,exp(2*logsig)) subject=pump;
 estimate 'alpha1-alpha2' alpha1-alpha2;
 estimate 'beta1-beta2' beta1-beta2;
run;
```

The selected output is as follows.

**Output 64.4.1** Dimensions Table for Poisson-Normal Model

| The NL MIXED Procedure |    |
|------------------------|----|
| Dimensions             |    |
| Observations Used      | 10 |
| Observations Not Used  | 0  |
| Total Observations     | 10 |
| Subjects               | 10 |
| Max Obs Per Subject    | 1  |
| Parameters             | 5  |
| Quadrature Points      | 5  |

The “Dimensions” table indicates that data for 10 pumps are used with one observation for each (Output 64.4.1).

**Output 64.4.2** Iteration History for Poisson-Normal Model

| Iteration History |       |            |          |          |          |
|-------------------|-------|------------|----------|----------|----------|
| Iter              | Calls | NegLogLike | Diff     | MaxGrad  | Slope    |
| 1                 | 2     | 30.6986932 | 2.162768 | 5.107253 | -91.602  |
| 2                 | 5     | 30.0255468 | 0.673146 | 2.761738 | -11.0489 |

| beta1-beta2          | 0.8623 |

The “Parameter Estimates” and “Additional Estimates” tables list the maximum likelihood estimates for each of the parameters and two differences (Output 64.4.4). The point estimates for the mean parameters agree fairly closely with the Bayesian posterior means reported by Draper (1996); however, the likelihood-based standard errors are roughly half the Bayesian posterior standard deviations. This is most likely due to the fact that the Bayesian standard deviations account for the uncertainty in estimating  $\sigma^2$ , whereas the likelihood values plug in its estimated value. This downward bias can be corrected somewhat by using the  $t_9$  distribution shown here.

## Example 64.5: Failure Time and Frailty Model

In this example an accelerated failure time model with proportional hazard is fitted with and without random effects. The data are from the “Getting Started” example of PROC LIFEREG; see Chapter 51, “The LIFEREG Procedure.” Thirty-eight patients are divided into two groups of equal size, and different pain relievers are assigned to each group. The outcome reported is the time in minutes until headache relief. The variable `sensor` indicates whether relief was observed during the course of the observation period (`sensor = 0`) or whether the observation is censored (`sensor = 1`). The SAS DATA step for these data is as follows:

```
data headache;
 input minutes group sensor @@;
 patient = _n_;
 datalines;
11 1 0 12 1 0 19 1 0 19 1 0
19 1 0 19 1 0 21 1 0 20 1 0
21 1 0 21 1 0 20 1 0 21 1 0
20 1 0 21 1 0 25 1 0 27 1 0
30 1 0 21 1 1 24 1 1 14 2 0
16 2 0 16 2 0 21 2 0 21 2 0
23 2 0 23 2 0 23 2 0 23 2 0
25 2 1 23 2 0 24 2 0 24 2 0
26 2 1 32 2 1 30 2 1 30 2 0
32 2 1 20 2 1
;
```

In modeling survival data, censoring of observations must be taken into account carefully. In this example, only right censoring occurs. If  $g(t, \boldsymbol{\beta})$ ,  $h(t, \boldsymbol{\beta})$ , and  $G(t, \boldsymbol{\beta})$  denote the density of failure, the hazard function, and the survival distribution function at time  $t$ , respectively, then the log likelihood can be written as

$$\begin{aligned} l(\boldsymbol{\beta}; \mathbf{t}) &= \sum_{i \in U_u} \log g(t_i, \boldsymbol{\beta}) + \sum_{i \in U_c} \log G(t_i, \boldsymbol{\beta}) \\ &= \sum_{i \in U_u} \log h(t_i, \boldsymbol{\beta}) + \sum_{i=1}^n \log G(t_i, \boldsymbol{\beta}) \end{aligned}$$

(See Cox and Oakes 1984, Ch. 3.) In these expressions  $U_u$  is the set of uncensored observations,  $U_c$  is the set of censored observations, and  $n$  denotes the total sample size.

The proportional hazards specification expresses the hazard in terms of a baseline hazard, multiplied by a constant. In this example the hazard is that of a Weibull model and is parameterized as  $h(t, \boldsymbol{\beta}) = \gamma \alpha (\alpha t)^{\gamma-1}$  and  $\alpha = \exp\{-\mathbf{x}'\boldsymbol{\beta}\}$ .

The linear predictor is set equal to the intercept in the reference group (`group = 2`); this defines the baseline hazard. The corresponding distribution of survival past time  $t$  is  $G(t, \beta) = \exp\{-(\alpha t)^\gamma\}$ . See Cox and Oakes (1984, Table 2.1) and the section “Supported Distributions” in Chapter 51, “The LIFEREG Procedure,” for this and other survival distribution models and various parameterizations.

The following NLMIXED statements fit this accelerated failure time model and estimate the cumulative distribution function of time to headache relief:

```
proc nlmixed data=headache;
 bounds gamma > 0;
 linp = b0 - b1*(group-2);
 alpha = exp(-linp);
 G_t = exp(-(alpha*minutes)**gamma);
 g = gamma*alpha*(alpha*minutes)**(gamma-1)*G_t;
 ll = (censor=0)*log(g) + (censor=1)*log(G_t);
 model minutes ~ general(ll);
 predict 1-G_t out=cdf;
run;
```

**Output 64.5.1** Specifications Table for Fixed-Effects Failure Time Model

| The NLMIXED Procedure               |                   |
|-------------------------------------|-------------------|
| Specifications                      |                   |
| Data Set                            | WORK.HEADACHE     |
| Dependent Variable                  | minutes           |
| Distribution for Dependent Variable | General           |
| Optimization Technique              | Dual Quasi-Newton |
| Integration Method                  | None              |

The “Specifications” table shows that no integration is required, since the model does not contain random effects (Output 64.5.1).

**Output 64.5.2** Negative Log Likelihood with Default Starting Values

| Parameters |    |    |            |
|------------|----|----|------------|
| gamma      | b0 | b1 | NegLogLike |
| 1          | 1  | 1  | 263.990327 |

No starting values were given for the three parameters. The NLMIXED procedure assigns the default value of 1.0 in this case. The negative log likelihood based on these starting values is shown in Output 64.5.2.

**Output 64.5.3** Iteration History for Fixed-Effects Failure Time Model

| Iteration History |       |            |          |          |          |
|-------------------|-------|------------|----------|----------|----------|
| Iter              | Calls | NegLogLike | Diff     | MaxGrad  | Slope    |
| 1                 | 2     | 169.244311 | 94.74602 | 22.5599  | -2230.83 |
| 2                 | 4     | 142.873508 | 26.3708  | 14.88631 | -3.64643 |

| 5                 | 9     | 121.396959 | 1.493699 | 13.85584 | -4.55427 |
| 6                 | 11    | 120.623843 | 0.773116 | 13.67062 | -1.38064 |
| 7                 | 12    | 119.278196 | 1.345647 | 15.78014 | -1.69072 |
| 8                 | 14    | 116.271325 | 3.006871 | 26.94029 | -3.2529  |
| 9                 | 16    | 109.427401 | 6.843925 | 19.88382 | -6.9289  |
| 10                | 19    | 103.298102 | 6.129298 | 12.15647 | -4.96054 |
| 11                | 22    | 101.686239 | 1.611863 | 14.24868 | -4.34059 |
| 12                | 23    | 100.027875 | 1.658364 | 11.69853 | -13.2049 |
| 13                | 26    | 99.9189048 | 0.108971 | 3.602552 | -0.55176 |
| 14                | 28    | 99.8738836 | 0.045021 | 0.170712 | -0.16645 |
| 15                | 30    | 99.8736392 | 0.000244 | 0.050822 | -0.00041 |
| 16                | 32    | 99.8736351 | 4.071E-6 | 0.000705 | -6.9E-6  |
| 17                | 34    | 99.8736351 | 6.1E-10  | 4.768E-6 | -1.23E-9 |

NOTE: GCONV convergence criterion satisfied.

The “Iteration History” table shows that the procedure converges after 17 iterations and 34 evaluations of the objective function (Output 64.5.3).

**Output 64.5.4** Fit Statistics and Parameter Estimates

| Fit Statistics |                          |  |  |  |  |  |       |
|----------------|--------------------------|--|--|--|--|--|-------|
|                | -2 Log Likelihood        |  |  |  |  |  | 199.7 |
|                | AIC (smaller is better)  |  |  |  |  |  | 205.7 |
|                | AICC (smaller is better) |  |  |  |  |  | 206.5 |
|                | BIC (smaller is better)  |  |  |  |  |  | 210.7 |

| Parameter Estimates |          |                |    |         |         |       |         |
|---------------------|----------|----------------|----|---------|---------|-------|---------|
| Parameter           | Estimate | Standard Error | DF | t Value | Pr >  t | Alpha | Lower   |
| gamma               | 4.7128   | 0.6742         | 38 | 6.99    | <.0001  | 0.05  | 3.3479  |
| b0                  | 3.3091   | 0.05885        | 38 | 56.23   | <.0001  | 0.05  | 3.1900  |
| b1                  | -0.1933  | 0.07856        | 38 | -2.46   | 0.0185  | 0.05  | -0.3523 |

| Parameter Estimates |          |          |
|---------------------|----------|----------|
| Parameter           | Upper    | Gradient |
| gamma               | 6.0777   | 5.327E-8 |
| b0                  | 3.4283   | -4.77E-6 |
| b1                  | -0.03426 | -1.22E-6 |

The parameter estimates and their standard errors shown in [Output 64.5.4](#) are identical to those obtained with the LIFEREG procedure and the following statements:

```
proc lifereg data=headache;
 class group;
 model minutes*censor(1) = group / dist=weibull;
 output out=new cdf=prob;
run;
```

The  $t$  statistic and confidence limits are based on 38 degrees of freedom. The LIFEREG procedure computes  $z$  intervals for the parameter estimates.

For the two groups you obtain

$$\hat{\alpha}(\text{group} = 1) = \exp\{-3.3091 + 0.1933\} = 0.04434$$

$$\hat{\alpha}(\text{group} = 2) = \exp\{-3.3091\} = 0.03655$$

The probabilities of headache relief by  $t$  minutes are estimated as

$$1 - G(t, \text{group} = 1) = 1 - \exp\{-(0.04434 * t)^{4.7128}\}$$

$$1 - G(t, \text{group} = 2) = 1 - \exp\{-(0.03655 * t)^{4.7128}\}$$

These probabilities, calculated at the observed times, are shown for the two groups in [Output 64.5.5](#) and printed with the following statements:

```
proc print data=cdf;
 var group censor patient minutes pred;
run;
```

Since the slope estimate is negative with  $p$ -value of 0.0185, you can infer that pain reliever 1 leads to overall significantly faster relief, but the estimated probabilities give no information about patient-to-patient variation within and between groups. For example, while pain reliever 1 provides faster relief overall, some patients in group 2 might respond more quickly than some patients in group 1. A frailty model enables you to accommodate and estimate patient-to-patient variation in health status by introducing random effects into a subject's hazard function.

**Output 64.5.5** Estimated Cumulative Distribution Function

| Obs | group | ensor | patient | minutes | Pred    |

| 36  | 2     | 0     | 36      | 30      | 0.78633 |
| 37  | 2     | 1     | 37      | 32      | 0.87656 |
| 38  | 2     | 1     | 38      | 20      | 0.20414 |

The following statements model the hazard for patient  $i$  in terms of  $\alpha_i = \exp\{-\mathbf{x}_i' \boldsymbol{\beta} - z_i\}$ , where  $z_i$  is a (normal) random patient effect. Notice that the only difference from the previous NLMIXED statements are the **RANDOM** statement and the addition of  $z$  in the linear predictor. The empirical Bayes estimates of the random effect (**RANDOM** statement), the parameter estimates (**ODS OUTPUT** statement), and the estimated cumulative distribution function (**PREDICT** statement) are saved to subsequently graph the patient-specific distribution functions.

```
ods output ParameterEstimates=est;
proc nlmixed data=headache;
 bounds gamma > 0;
 linp = b0 - b1*(group-2) + z;
 alpha = exp(-linp);
 G_t = exp(-(alpha*minutes)**gamma);
 g = gamma*alpha*((alpha*minutes)**(gamma-1))*G_t;
 ll = (censor=0)*log(g) + (censor=1)*log(G_t);
 model minutes ~ general(ll);
 random z ~ normal(0,exp(2*logsig)) subject=patient out=EB;
 predict 1-G_t out=cdf;
run;
```

### Output 64.5.6 Specifications for Random Frailty Model

| Distribution for Dependent Variable | General                      |
| Random Effects                      | z                            |
| Distribution for Random Effects     | Normal                       |
| Subject Variable                    | patient                      |
| Optimization Technique              | Dual Quasi-Newton            |
| Integration Method                  | Adaptive Gaussian Quadrature |

The “Specifications” table shows that the objective function is computed by adaptive Gaussian quadrature because of the presence of random effects (compare [Output 64.5.6](#) and [Output 64.5.1](#)). The “Dimensions” table reports that nine quadrature points are being used to integrate over the random effects ([Output 64.5.7](#)).

### Output 64.5.7 Dimensions Table for Random Frailty Model

| Dimensions            |    |
|-----------------------|----|
| Observations Used     | 38 |
| Observations Not Used | 0  |
| Total Observations    | 38 |

| 15                | 31    | 99.2444957 | 9.147E-8 | 0.000271 | -1.84E-7 |

NOTE: GCONV convergence criterion satisfied.

The procedure converges after 15 iterations (Output 64.5.8). The achieved  $-2$  log likelihood is only 1.2 less than that in the model without random effects (compare Output 64.5.9 and Output 64.5.4). Compared to a chi-square distribution with one degree of freedom, the addition of the random effect appears not to improve the model significantly. You must exercise care, however, in interpreting likelihood ratio tests when the value under the null hypothesis falls on the boundary of the parameter space (see, for example, Self and Liang 1987).

**Output 64.5.9** Fit Statistics for Random Frailty Model

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Log Likelihood        | 198.5 |
| AIC (smaller is better)  | 206.5 |
| AICC (smaller is better) | 207.7 |
| BIC (smaller is better)  | 213.0 |

**Output 64.5.10** Parameter Estimates

| logsig              | -0.8343  | 0.000027 |

The estimate of the Weibull parameter has changed drastically from the model without random effects (compare [Output 64.5.10](#) and [Output 64.5.4](#)). The variance of the patient random effect is  $\exp\{-2 \times 1.9027\} = 0.02225$ . The listing in [Output 64.5.11](#) shows the empirical Bayes estimates of the random effects. These are the adjustments made to the linear predictor in order to obtain a patient's survival distribution. The listing is produced with the following statements:

```
proc print data=eb;
 var Patient Effect Estimate StdErrPred;
run;
```

**Output 64.5.11** Empirical Bayes Estimates of Random Effects

| Obs | patient | Effect | Estimate | StdErr<br>Pred |
|-----|---------|--------|----------|----------------|
| 1   | 1       | z      | -0.13597 | 0.23249        |

| 26  | 26      | z      | -0.05797 | 0.13294        |
| 27  | 27      | z      | -0.05797 | 0.13294        |
| 28  | 28      | z      | -0.05797 | 0.13294        |
| 29  | 29      | z      | 0.06420  | 0.13956        |
| 30  | 30      | z      | -0.05797 | 0.13294        |
| 31  | 31      | z      | -0.04266 | 0.12390        |
| 32  | 32      | z      | -0.04266 | 0.12390        |
| 33  | 33      | z      | 0.07618  | 0.14132        |
| 34  | 34      | z      | 0.16292  | 0.16460        |
| 35  | 35      | z      | 0.13193  | 0.15528        |
| 36  | 36      | z      | 0.06327  | 0.12124        |
| 37  | 37      | z      | 0.16292  | 0.16460        |
| 38  | 38      | z      | 0.02074  | 0.14160        |

The predicted values and patient-specific survival distributions can be plotted with the SAS code that follows:

```
proc transpose data=est(keep=estimate)
 out=trest(rename=(col1=gamma col2=b0 col3=b1));
run;

data pred;
 merge eb(keep=estimate) headache(keep=patient group);
 array pp{2} pred1-pred2;
 if _n_ = 1 then set trest(keep=gamma b0 b1);
 do time=11 to 32;
 linp = b0 - b1*(group-2) + estimate;
 pp{group} = 1-exp(- (exp(-linp)*time)**gamma);
 symbolid = patient+1;
 output;
 end;
 keep pred1 pred2 time patient;
run;

data pred;
 merge pred
 cdf(where = (group=1)
 rename = (pred=pcdf1 minutes=minutes1)
 keep = pred minutes group)
 cdf(where = (group=2)
 rename = (pred=pcdf2 minutes=minutes2)
 keep = pred minutes group);
 drop group;
run;

proc sgplot data=pred noautolegend;
 label minutes1='Minutes to Headache Relief'
 pcdf1 ='Estimated Patient-specific CDF';
 series x=time y=pred1 /
 group=patient
 lineattrs=(pattern=solid color=black);
 series x=time y=pred2 /
 group=patient
 lineattrs=(pattern=dash color=black);
 scatter x=minutes1 y=pcdf1 /
 markerattrs=(symbol=CircleFilled size=9);
 scatter x=minutes2 y=pcdf2 /
 markerattrs=(symbol=Circle size=9);
run;
```

The separation of the distribution functions by groups is evident in [Output 64.5.12](#). Most of the distributions of patients in the first group are to the left of the distributions in the second group. The separation is not complete, however. Several patients who are assigned the second pain reliever experience headache relief more quickly than patients assigned to the first group.

**Output 64.5.12** Patient-Specific CDFs and Predicted Values. Pain Reliever 1: Solid Lines, Closed Circles; Pain Reliever 2: Dashed Lines, Open Circles.

## Overview: NPAR1WAY Procedure

The NPAR1WAY procedure performs nonparametric tests for location and scale differences across a one-way classification. PROC NPAR1WAY also provides a standard analysis of variance on the raw data and tests based on the empirical distribution function.

PROC NPAR1WAY performs tests for location and scale differences based on the following scores of a response variable: Wilcoxon, median, Van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and Conover. Additionally, PROC NPAR1WAY provides tests that use the raw input data as scores. When the data are classified into two samples, tests are based on simple linear rank statistics. When the data are classified into more than two samples, tests are based on one-way ANOVA statistics. Both asymptotic and exact  $p$ -values are available for these tests. PROC NPAR1WAY also provides Hodges-Lehmann estimation, including exact confidence limits for the location shift.

PROC NPAR1WAY computes empirical distribution function (EDF) statistics, which test whether the distribution of a variable is the same across different groups. These include the Kolmogorov-Smirnov test, the Cramer-von Mises test, and, when the data are classified into only two samples, the Kuiper test. Exact  $p$ -values are available for the two-sample Kolmogorov-Smirnov test.

PROC NPAR1WAY uses the Output Delivery System (ODS), a SAS subsystem that provides capabilities for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from PROC NPAR1WAY into a SAS data set. See the section “[ODS Table Names](#)” on page 5493 for more information.

PROC NPAR1WAY uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the NPAR1WAY procedure, see the `PLOTS=` option in the PROC NPAR1WAY statement and the section “[ODS Graphics](#)” on page 5495.

## Getting Started: NPAR1WAY Procedure

This example illustrates how you can use PROC NPAR1WAY to perform a one-way nonparametric analysis. The data from Halverson and Sherwood (1930) consist of weight gain measurements for five different levels of gossypol additive in animal feed. Gossypol is a substance contained in cottonseed shells, and these data were collected to study the effect of gossypol on animal nutrition.

The following DATA step statements create the SAS data set Gossypol:

```
data Gossypol;
 input Dose n;
 do i=1 to n;
 input Gain @@;
 output;
 end;
 datalines;
0 16
228 229 218 216 224 208 235 229 233 219 224 220 232 200 208 232
.04 11
186 229 220 208 228 198 222 273 216 198 213
.07 12
179 193 183 180 143 204 114 188 178 134 208 196
.10 17
130 87 135 116 118 165 151 59 126 64 78 94 150 160 122 110 178
.13 11
154 130 130 118 118 104 112 134 98 100 104
;
```

The data set Gossypol contains the variable Dose, which represents the amount of gossypol additive, and the variable Gain, which represents the weight gain.

Researchers are interested in whether there is a difference in weight gain among animals receiving the different dose levels of gossypol. The following statements invoke the NPAR1WAY procedure to perform a nonparametric analysis of this problem:

```
proc npar1way data=Gossypol;
 class Dose;
 var Gain;
run;
```

The variable Dose is the CLASS variable, and the VAR statement specifies the variable Gain is the response variable. The CLASS statement is required, and you must name only one CLASS variable. You can name one or more analysis variables in the VAR statement. If you omit the VAR statement, PROC NPAR1WAY analyzes all numeric variables in the data set except for the CLASS variable, the FREQ variable, and the BY variables.

When no analysis options are specified in the PROC NPAR1WAY statement, the ANOVA, WILCOXON, MEDIAN, VW, SAVAGE, and EDF options are invoked by default. The tables in the following figures show the results of these analyses.

The tables in Figure 65.1 are produced with the ANOVA option. For each level of the CLASS variable Dose, PROC NPAR1WAY displays the number of observations and the mean of the analysis variable Gain. PROC NPAR1WAY displays a standard analysis of variance on the raw data. This gives the same results as the GLM and ANOVA procedures. The  $p$ -value for the  $F$  test is  $<0.0001$ , which indicates that Dose accounts for a significant portion of the variability of the dependent variable Gain.

**Figure 65.1** Analysis of Variance

| Within                                 | 62   | 38901.998997   | 627.45160   |         |        |
| Average scores were used for ties.     |      |                |             |         |        |

The WILCOXON option produces the output in Figure 65.2. PROC NPAR1WAY first provides a summary of the Wilcoxon scores for the analysis variable Gain by class level. For each level of the CLASS variable Dose, PROC NPAR1WAY displays the following information: number of observations, sum of the Wilcoxon scores, expected sum under the null hypothesis of no difference among class levels, standard deviation under the null hypothesis, and mean score.

Next PROC NPAR1WAY displays the one-way ANOVA statistic, which for Wilcoxon scores is known as the Kruskal-Wallis test. The statistic equals 52.6656, with four degrees of freedom, which is the number of class levels minus one. The  $p$ -value (probability of a larger statistic under the null hypothesis) is  $<0.0001$ . This leads to rejection of the null hypothesis that there is no difference in location for Gain among the levels of Dose. This  $p$ -value is asymptotic, computed from the asymptotic chi-square distribution of the test statistic. For certain data sets it might also be useful to compute the exact  $p$ -value—for example, for small data sets or for data sets that are sparse, skewed, or heavily tied. You can use the EXACT statement to request exact  $p$ -values for any of the location or scale tests available in PROC NPAR1WAY.

**Figure 65.2** Wilcoxon Score Analysis

| 0.13                                                                         | 11 | 161.50           | 374.0                | 59.063588           | 14.681818     |

Average scores were used for ties.

**Kruskal-Wallis Test**

|                 |         |
|-----------------|---------|
| Chi-Square      | 52.6656 |
| DF              | 4       |
| Pr > Chi-Square | <.0001  |

Figure 65.3 through Figure 65.5 display the analyses produced by the MEDIAN, VW, and SAVAGE options. For each score type, PROC NPAR1WAY provides a summary of scores and the one-way ANOVA statistic, as previously described for Wilcoxon scores. Other score types available in PROC NPAR1WAY are Siegel-Tukey, Ansari-Bradley, Klotz, and Mood, which can be used to test for scale differences. Conover scores can be used to test for differences in both location and scale. Additionally, you can specify the SCORES=DATA option, which uses the input data as scores. This option gives you the flexibility to construct any scores for your data with the DATA step and then analyze these scores with PROC NPAR1WAY.

PROC NPAR1WAY uses ODS Graphics to create graphs as part of its output. The following statements produce a box plot of Wilcoxon scores for Gain classified by Dose. ODS Graphics must be enabled before producing graphs.

```
ods graphics on;
proc npar1way data=Gossypol plots(only)=wilcoxonboxplot;
 class Dose;
 var Gain;
run;
ods graphics off;
```

Figure 65.7 displays the box plot of Wilcoxon scores. This graph corresponds to the Wilcoxon scores analysis shown in Figure 65.2. To remove the  $p$ -value from the box plot display, you can specify the NOSTATS plot option in parentheses following the WILCOXONBOXPLOT option.

Box plots are available for all PROC NPAR1WAY score types except median scores, which are displayed in a stacked bar chart. If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC NPAR1WAY produces all plots that are associated with the analyses that you request.

**Figure 65.7** Box Plot of Wilcoxon Scores

In the preceding example, the CLASS variable Dose has five levels, and the analyses examine possible differences among these five levels (samples). The following statements invoke the NPAR1WAY procedure to perform a nonparametric analysis of the two lowest levels of Dose:

```
proc npar1way data=Gossypol;
 where Dose <= .04;
 class Dose;
 var Gain;
run;
```

The tables in the following figures show the results of this two-sample analysis. The tables in [Figure 65.8](#) are produced by the ANOVA option.

[Figure 65.9](#) displays the output produced by the WILCOXON option. PROC NPAR1WAY provides a summary of the Wilcoxon scores for the analysis variable Gain for each of the two class levels. Since there are only two levels, PROC NPAR1WAY displays the two-sample test, based on the simple linear rank statistic with Wilcoxon scores. The normal approximation includes a continuity correction. To remove the continuity correction, you can specify the CORRECT=NO option. PROC NPAR1WAY also gives a *t* approximation for the Wilcoxon two-sample test. Like the multisample analysis, PROC NPAR1WAY computes a one-way ANOVA statistic, which for Wilcoxon scores is known as the Kruskal-Wallis test. All these *p*-values show no difference in Gain for the two Dose levels at the 0.05 level of significance.

[Figure 65.10](#) through [Figure 65.12](#) display the two-sample analyses produced by the MEDIAN, VW, and SAVAGE options.

The tables in [Figure 65.13](#) display the empirical distribution function statistics, comparing the distribution of Gain for the two levels of Dose. The  $p$ -value for the Kolmogorov-Smirnov two-sample test is 0.6199, which indicates no rejection of the null hypothesis that the Gain distributions are identical for the two levels of Dose.

## Syntax: NPAR1WAY Procedure

The following statements are available in the NPAR1WAY procedure:

```
PROC NPAR1WAY < options > ;
 BY variables ;
 CLASS variable ;
 EXACT statistic-options < / computation-options > ;
 FREQ variable ;
 OUTPUT < OUT=SAS-data-set > < options > ;
 VAR variables ;
```

The **PROC NPAR1WAY** statement invokes the NPAR1WAY procedure. The **PROC NPAR1WAY** and **CLASS** statements are required. Table 65.1 summarizes the statements available in the NPAR1WAY procedure.

The rest of this section gives detailed syntax information for the **BY**, **CLASS**, **EXACT**, **FREQ**, **OUTPUT**, and **VAR** statements in alphabetical order after the description of the **PROC NPAR1WAY** statement.

**Table 65.1** Summary of PROC NPAR1WAY Statements

| Statement     | Description                                  |
|---------------|----------------------------------------------|
| <b>BY</b>     | Provides separate analyses for each BY group |
| <b>CLASS</b>  | Identifies the classification variable       |
| <b>EXACT</b>  | Requests exact tests                         |
| <b>FREQ</b>   | Identifies a frequency variable              |
| <b>OUTPUT</b> | Requests an output data set                  |
| <b>VAR</b>    | Identifies analysis variables                |

---

## PROC NPAR1WAY Statement

```
PROC NPAR1WAY < options > ;
```

The **PROC NPAR1WAY** statement invokes the NPAR1WAY procedure. Optionally, it identifies the input data set and requests analyses. By default, the procedure uses the most recently created SAS data set and omits missing values from the analysis. If you do not specify any analysis *options*, **PROC NPAR1WAY** performs an analysis of variance (**ANOVA** option), tests for location differences (**WILCOXON**, **MEDIAN**, **SAVAGE**, and **VW** options), and empirical distribution function tests (**EDF** option).

Table 65.2 summarizes the *options* available in the **PROC NPAR1WAY** statement. Descriptions of the *options* follow in alphabetical order.

**Table 65.2** PROC NPAR1WAY Statement Options

| Option                  | Description                                                                         |
|-------------------------|-------------------------------------------------------------------------------------|
| <b>Input Data Set</b>   |                                                                                     |
| DATA=                   | Names the input SAS data set                                                        |
| <b>Missing Values</b>   |                                                                                     |
| MISSING                 | Treats missing CLASS values as a valid class                                        |
| <b>Analyses</b>         |                                                                                     |
| AB                      | Requests analysis of Ansari-Bradley scores                                          |
| ANOVA                   | Requests standard analysis of variance                                              |
| CONOVER                 | Requests analysis of Conover scores                                                 |
| D                       | Requests one-sided Kolmogorov-Smirnov statistics                                    |
| DSCF                    | Requests pairwise multiple comparison analysis                                      |
| EDF                     | Requests empirical distribution function statistics                                 |
| FP                      | Requests the Fligner-Policello test                                                 |
| HL                      | Requests Hodges-Lehmann estimation for two-sample data                              |
| KLOTZ                   | Requests analysis of Klotz scores                                                   |
| MEDIAN                  | Requests analysis of median scores                                                  |
| MOOD                    | Requests analysis of Mood scores                                                    |
| SAVAGE                  | Requests analysis of Savage scores                                                  |
| SCORES=DATA             | Requests analysis of input data scores                                              |
| ST                      | Requests analysis of Siegel-Tukey scores                                            |
| VW   NORMAL             | Requests analysis of Van der Waerden (normal) scores                                |
| WILCOXON                | Requests analysis of Wilcoxon scores                                                |
| <b>Analysis Details</b> |                                                                                     |
| ADJUST                  | Requests median adjustment for scale analyses                                       |
| ALPHA=                  | Specifies the confidence level for Hodges-Lehmann estimation                        |
| CORRECT=NO              | Suppresses the continuity correction for Wilcoxon and Siegel-Tukey two-sample tests |
| <b>Displayed Output</b> |                                                                                     |
| NOPRINT                 | Suppresses the display of all output                                                |
| <b>Plots</b>            |                                                                                     |
| PLOTS=                  | Requests plots from ODS Graphics                                                    |

You can specify the following *options* in the PROC NPAR1WAY statement.

**AB < (ADJUST) >**

requests an analysis of Ansari-Bradley scores. See the section “[Ansari-Bradley Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

**ADJUST**

adjusts for location differences among classes before performing tests for scale differences. The ADJUST option applies to the following analyses: Ansari-Bradley (**AB**), Klotz (**KLOTZ**), Mood (**MOOD**), and Siegel-Tukey (**ST**). If you specify the ADJUST option, PROC NPAR1WAY subtracts the corresponding class median from each observation before scoring the data and performing the scale tests that you request.

You can also request adjustment for an individual scale test by specifying ADJUST in parentheses after the scale test option; for example, you can specify **ST(ADJUST)** to adjust by class medians before performing the Siegel-Tukey test.

**ALPHA= $\alpha$** 

specifies the level of the confidence limits for location shift, which you request with the **HL** option. The value of  $\alpha$  must be between 0 and 1, and the default is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits for the Hodges-Lehmann estimate.

**ANOVA**

requests a standard analysis of variance on the raw data.

**CONOVER**

requests an analysis of Conover scores. See the section “[Conover Scores](#)” on page 5472 for more information.

**CORRECT=NO**

suppresses the continuity correction for the Wilcoxon two-sample test and the Siegel-Tukey two-sample test. See the section “[Continuity Correction](#)” on page 5469 for more information.

**D**

requests the one-sided Kolmogorov-Smirnov  $D+$  and  $D-$  statistics and their asymptotic  $p$ -values, in addition to the two-sided  $D$  statistic produced by the **EDF** option for two-sample data. The **D** option invokes the **EDF** option. The statistics  $D+$  and  $D-$  are provided by default if you request exact Kolmogorov-Smirnov statistics with the **KS** option in the **EXACT** statement for two-sample data. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for details about Kolmogorov-Smirnov statistics.

**DATA=SAS-data-set**

names the SAS data set to be analyzed by PROC NPAR1WAY. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**DSCF**

requests the Dwass, Steel, Critchlow-Fligner multiple comparison procedure, which is based on pairwise two-sample rankings. This procedure is available for multisample data, where the number of **CLASS** variable levels is greater than 2. See the section “[Multiple Comparisons Based on Pairwise Rankings](#)” on page 5476 for more information.

**EDF**

requests statistics based on the empirical distribution function. These include the Kolmogorov-Smirnov and Cramér-von Mises tests and, if there are only two classification levels, the Kuiper test. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for more information.

The EDF option produces the Kolmogorov-Smirnov  $D$  statistic for two-sample data. You can request the one-sided  $D+$  and  $D-$  statistics for two-sample data with the **D** option.

**FP < (REFCLASS = class-number | 'class-value' ) >**

requests the Fligner-Policello test for two-sample data. See the section “[Fligner-Policello Test](#)” on page 5475 for more information.

The REFCLASS= option specifies which of the two **CLASS** variable levels (samples) to use as the reference class  $X$  for the difference between class placement sums,  $P_Y - P_X$ . REFCLASS=1 refers to the first class that is listed in the “Fligner-Policello Placements” table, and REFCLASS=2 refers to the second class listed. The table displays class levels in the order in which they appear in the input data set. REFCLASS=*class-value* identifies the reference class by the formatted value of the **CLASS** variable. By default, the reference class is the second class listed in the “Fligner-Policello Placements” table (REFCLASS=2).

**HL < (REFCLASS = class-number | 'class-value' ) >**

requests Hodges-Lehmann estimation of the location shift for two-sample data. The HL option provides asymptotic confidence limits for the location shift. These are sometimes known as Moses confidence limits. See the section “[Hodges-Lehmann Estimation of Location Shift](#)” on page 5473 for details. You can specify the level of the confidence limits by using the **ALPHA=** option. The default of ALPHA=0.5 produces 95% confidence limits for the location shift.

The REFCLASS= option specifies which of the two **CLASS** variable levels (samples) to use as the reference class  $X$  for the location shift,  $Y - X$ . REFCLASS=1 refers to the first class that is listed in the “Wilcoxon Scores” table, and REFCLASS=2 refers to the second class listed. The table displays class levels in the order in which they appear in the input data set. REFCLASS=*class-value* identifies the reference class by the formatted value of the **CLASS** variable.

By default, PROC NPAR1WAY uses the larger of the two classes as the reference class  $X$  to compute the Hodges-Lehmann location shift,  $Y - X$ . If both class have the same number of observations, PROC NPAR1WAY uses the class that appears second in the input data set as the reference class.

**KLOTZ < (ADJUST) >**

requests an analysis of Klotz scores. See the section “[Klotz Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

**MEDIAN**

requests an analysis of median scores. When there are two classification levels, this option produces the two-sample median test. When there are more than two samples, this option produces the multi-sample median test, which is also known as the Brown-Mood test. See the section “[Median Scores](#)” on page 5471 for more information.

**MISSING**

treats missing values of the **CLASS** variable as a valid class level.

**MOOD < (ADJUST) >**

requests an analysis of Mood scores. See the section “[Mood Scores](#)” on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

**NOPRINT**

suppresses the display of all output. You can use the NOPRINT option when you only want to create an output data set. Note that this option temporarily disables the Output Delivery System (ODS). For more information, see Chapter 20, “Using the Output Delivery System.”

**PLOTS** < ( *global-plot-options* ) > < = *plot-request* < ( *plot-option* ) > >

**PLOTS** < ( *global-plot-options* ) > < = ( *plot-request* < ( *plot-option* ) > <...*plot-request* < ( *plot-option* ) >> ) >

controls the plots that are produced through ODS Graphics. *Plot-requests* specify the plots to produce, and *plot-options* control the appearance and content of the plots. You can specify *plot-options* in parentheses after a *plot-request*. A *global-plot-option* applies to all plots for which it is available, unless it is altered by a specific *plot-option*. You can specify *global-plot-options* in parentheses after the PLOTS option.

When you specify only one *plot-request*, you can omit the parentheses around the request. For example:

```
plots=all
plots=wilcoxonboxplot
plots=(wilcoxonboxplot edfplot)
plots(only)=(medianplot normalboxplot)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc npar1way plots=wilcoxonboxplot;
 variable response;
 class treatment;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

If ODS Graphics is enabled but you do not specify the PLOTS= option, PROC NPAR1WAY produces all plots that are associated with the analyses that you request. If you request a plot with the PLOTS= option but do not request the corresponding analysis, PROC NPAR1WAY automatically invokes that analysis. For example, if you specify PLOTS=CONOVERBOXPLOT but do not also specify the CONOVER option in the PROC NPAR1WAY statement, PROC NPAR1WAY produces the Conover scores analysis in addition to the box plot.

You can suppress default plots and request specific plots by using the PLOTS(ONLY)= option; PLOTS(ONLY)=(*plot-requests*) produces only the plots that are specified as *plot-requests*. You can suppress all plots with the PLOTS=NONE option. The PLOTS= option has no effect when you specify the NOPRINT option.

PROC NPAR1WAY provides box plots of scored data, median plots, and empirical distribution plots. See Figure 65.7, Output 65.1.2, Output 65.1.4, and Output 65.2.2 for examples of plots that PROC NPAR1WAY produces. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

**Global Plot Options**

A *Global-plot-option* applies to all plots for which the option is available unless it is altered by a specific *plot-option*. You can specify the following *global-plot-options* in parentheses after the PLOTS option. You cannot specify both STATS and NOSTATS as *global-plot-options* in the same statement.

**NOSTATS**

suppresses the  $p$ -values that are displayed by default in the plots.

**ONLY**

suppresses the default plots and requests only the plots that are specified as *plot-requests*.

**STATS**

displays  $p$ -values in the plots. This is the default.

**Plot Requests**

The following *plot-requests* are available with the PLOTS= option.

**ABBOXPLOT | AB**

requests a box plot of Ansari-Bradley scores. This plot is associated with the Ansari-Bradley analysis, which you request by specifying the **AB** option.

**ALL**

requests all plots that are associated with the specified analyses. This is the default if you do not specify the **ONLY** *global-plot-option*.

**ANOVABOXPLOT | ANOVA**

requests a box plot of the raw data. This plot is associated with the analysis of variance based on the raw data, which you request by specifying the **ANOVA** option.

**CONOVERBOXPLOT | CONOVER**

requests a box plot of Conover scores. This plot is associated with the Conover analysis, which you request by specifying the **CONOVER** option.

**DATASCORESBXPLOT | DATASCORES**

requests a box plot of raw data scores. This plot is associated with the analysis that uses input data as scores, which you request by specifying the **SCORES=DATA** option.

**EDFPLOT | EDF**

requests an empirical distribution plot. This plot is associated with the analyses based on the empirical distribution function, which you request by specifying the **EDF** option.

**FPBOXPLOT | FP**

requests a box plot of Fligner-Policello placements. This plot is associated with the Fligner-Policello analysis, which you request by specifying the **FP** option.

**KLOTZBOXPLOT | KLOTZ**

requests a box plot of Klotz scores. This plot is associated with the Klotz analysis, which you request by specifying the **KLOTZ** option.

**MEDIANPLOT | MEDIAN**

requests a stacked bar chart showing the frequencies above and below the overall median. This plot is associated with the median score analysis, which you request by specifying the **MEDIAN** option.

**MOODBOXPLOT | MOOD**

requests a box plot of Mood scores. This plot is associated with the Mood analysis, which you request by specifying the **MOOD** option.

**NONE**

suppresses all plots.

**SAVAGEBOXPLOT | SAVAGE**

requests a box plot of Savage scores. This plot is associated with the Savage analysis, which you request by specifying the **SAVAGE** option.

**STBOXPLOT | ST**

requests a box plot of Siegel-Tukey scores. This plot is associated with the Siegel-Tukey analysis, which you request by specifying the **ST** option.

**VWBOXPLOT | VW****NORMALBOXPLOT | NORMAL**

requests a box plot of Van der Waerden (normal) scores. This plot is associated with the Van der Waerden analysis, which you request by specifying the **VW** or **NORMAL** option.

**WILCOXONBOXPLOT | WILCOXON**

requests a box plot of Wilcoxon scores. This plot is associated with the Wilcoxon analysis, which you request by specifying the **WILCOXON** option.

**Plot Options**

The following *plot-options* are available for any *plot-request*. You cannot specify both **STATS** and **NOSTATS** as *plot-options* for the same plot. If you specify **NOSTATS** as a *global-plot-option*, specifying **STATS** as an individual *plot-option* overrides the *global-plot-option* for the individual plot and displays statistics in the plot.

**NOSTATS**

suppresses the *p*-values that are displayed in the plot by default.

**STATS**

displays *p*-values in the plot. This is the default.

**SAVAGE**

requests an analysis of Savage scores. See the section “[Savage Scores](#)” on page 5471 for more information.

**SCORES=DATA**

requests an analysis that uses input data as scores. This option gives you the flexibility to construct any scores for your data with the **DATA** step and then analyze these scores with PROC NPAR1WAY. See the section “[Scores for Linear Rank and One-Way ANOVA Tests](#)” on page 5470 for more information.

To produce the two-sample permutation test that is known as Pitman's test, provide raw (unscored) data in the input data set and specify the SCORES=DATA option in the EXACT statement. See the section "Exact Tests" on page 5479 for more information.

#### ST < (ADJUST) >

requests an analysis of Siegel-Tukey scores. See the section "Siegel-Tukey Scores" on page 5472 for more information. The ADJUST option subtracts class medians from the input observations before performing the analysis.

#### VW | NORMAL

requests an analysis of Van der Waerden (normal) scores. See the section "Van der Waerden (Normal) Scores" on page 5471 for more information.

#### WILCOXON

requests an analysis of Wilcoxon scores. When there are two classification levels (samples), this option produces the Wilcoxon rank-sum test. For any number of classification levels, this option produces the Kruskal-Wallis test. See the section "Wilcoxon Scores" on page 5471 for more information.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC NPARIWAY to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the NPARIWAY procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* ;

The CLASS statement, which is required, names one and only one classification variable. The variable can be character or numeric. The CLASS variable identifies groups (samples) in the data, and PROC NPAR1WAY provides analyses to examine differences among these groups. There can be two or more groups in the data.

---

## EXACT Statement

**EXACT** *statistic-options* < / *computation-options* > ;

The EXACT statement requests exact tests and confidence limits for selected statistics. The *statistic-options* identify which statistics to compute, and the *computation-options* specify options for computing exact statistics. See the section “Exact Tests” on page 5479 for details.

**NOTE:** PROC NPAR1WAY computes exact tests by using fast and efficient algorithms that are superior to direct enumeration. Exact tests are appropriate when a data set is small, sparse, skewed, or heavily tied. For some large problems, computation of exact tests might require a large amount of time and memory. Consider using asymptotic tests for such problems. Alternatively, when asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact  $p$ -values. You can request Monte Carlo estimation by specifying the **MC** *computation-option* in the EXACT statement. See the section “Computational Resources” on page 5481 for more information.

## Statistic Options

The *statistic-options* specify which exact tests to compute. Table 65.3 lists the available *statistic-options* and the exact statistics that are computed. Descriptions of the *statistic-options* follow Table 65.3 in alphabetical order.

Exact  $p$ -values are available for all nonparametric tests of location and scale differences that are produced by PROC NPAR1WAY. These include tests based on the following scores: Wilcoxon, median, Van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and Conover. Additionally, exact  $p$ -values are available for tests that use the raw input data as scores. The procedure computes exact  $p$ -values when the data are classified into two levels (two-sample tests) and when the data are classified into more than two levels (multisample tests). Two-sample tests are based on simple linear rank statistics. Multisample tests are based on one-way ANOVA statistics.

Exact  $p$ -values are also available for the two-sample Kolmogorov-Smirnov test. Exact confidence limits are available for the Hodges-Lehmann estimate of location shift.

If you list no *statistic-options* in the EXACT statement, then PROC NPAR1WAY computes all available exact  $p$ -values for those tests that you request in the PROC NPAR1WAY statement.

**Table 65.3** EXACT Statement Statistic Options

| Statistic Option | Exact Test                                                                       |
|------------------|----------------------------------------------------------------------------------|
| AB               | Ansari-Bradley test                                                              |
| CONOVER          | Conover test                                                                     |
| HL               | Hodges-Lehmann confidence limits                                                 |
| KLOTZ            | Klotz test                                                                       |
| KS   EDF         | Two-sample Kolmogorov-Smirnov test                                               |
| MEDIAN           | Median test                                                                      |
| MOOD             | Mood test                                                                        |
| SAVAGE           | Savage test                                                                      |
| SCORES=DATA      | Test with input data as scores                                                   |
| ST               | Siegel-Tukey test                                                                |
| VW   NORMAL      | Van der Waerden (normal scores) test                                             |
| WILCOXON         | Wilcoxon test for two-sample data or<br>Kruskal-Wallis test for multisample data |

You can specify the following *statistic-options* in the EXACT statement.

**AB**

requests the exact Ansari-Bradley test. See the sections “[Ansari-Bradley Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **AB** option in the PROC NPAR1WAY statement provides Ansari-Bradley score analysis and asymptotic tests.

**CONOVER**

requests the exact Conover test. See the sections “[Conover Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **CONOVER** option in the PROC NPAR1WAY statement provides Conover score analysis and asymptotic tests.

**HL**

requests exact Hodges-Lehmann confidence limits for the location shift for two-sample data. See the section “[Hodges-Lehmann Estimation of Location Shift](#)” on page 5473 for details. The **HL** option in the PROC NPAR1WAY statement provides asymptotic Hodges-Lehmann confidence limits.

You can specify the level of the confidence limits by using the **ALPHA=** option in the PROC NPAR1WAY statement. The default of ALPHA=0.5 produces 95% confidence limits for the location shift.

**KLOTZ**

requests the exact Klotz test. See the sections “[Klotz Scores](#)” on page 5472 and “[Exact Tests](#)” on page 5479 for details. The **KLOTZ** option in the PROC NPAR1WAY statement provides Klotz score analysis and asymptotic tests.

**KS | EDF**

requests the exact Kolmogorov-Smirnov two-sample test. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for details. The **EDF** option in the PROC NPAR1WAY statement provides the asymptotic Kolmogorov-Smirnov test and other statistics that are based on the empirical distribution function. The **D** option in the PROC NPAR1WAY statement provides the asymptotic one-sided Kolmogorov-Smirnov tests for two-sample data.

**MEDIAN**

requests the exact median test. See the sections “Median Scores” on page 5471 and “Exact Tests” on page 5479 for details. The **MEDIAN** option in the PROC NPAR1WAY statement provides median score analysis and asymptotic tests.

**MOOD**

requests the exact Mood test. See the sections “Mood Scores” on page 5472 and “Exact Tests” on page 5479 for details. The **MOOD** option in the PROC NPAR1WAY statement provides Mood score analysis and asymptotic tests.

**SAVAGE**

requests the exact Savage test. See the sections “Savage Scores” on page 5471 and “Exact Tests” on page 5479 for details. The **SAVAGE** option in the PROC NPAR1WAY statement provides Savage score analysis and asymptotic tests.

**SCORES=DATA**

requests the exact test that uses the input data as scores. For two-sample data, the test is based on the rank-sum statistic. For multisample data, the test is based on the one-way ANOVA statistic. See the sections “Scores for Linear Rank and One-Way ANOVA Tests” on page 5470 and “Exact Tests” on page 5479 for details. The **SCORES=DATA** option in the PROC NPAR1WAY statement provides analysis of the data scores and the corresponding asymptotic test.

**ST**

requests the exact Siegel-Tukey test. See the sections “Siegel-Tukey Scores” on page 5472 and “Exact Tests” on page 5479 for details. The **ST** option in the PROC NPAR1WAY statement provides analysis of Siegel-Tukey scores and asymptotic tests.

**VW | NORMAL**

requests the exact Van der Waerden (normal scores) test. See the sections “Van der Waerden (Normal Scores)” on page 5471 and “Exact Tests” on page 5479 for details. The **VW** option in the PROC NPAR1WAY statement provides analysis of Van der Waerden (normal) scores and asymptotic tests.

**WILCOXON**

requests the exact Wilcoxon test. When the data consist of two classification levels (samples), the exact test is based on the Wilcoxon rank-sum statistic. When the data consist of more than two levels (multisample data), the exact test is based on the one-way ANOVA statistic for Wilcoxon scores, which is the Kruskal-Wallis statistic. See the sections “Wilcoxon Scores” on page 5471 and “Exact Tests” on page 5479 for details. The **WILCOXON** option in the PROC NPAR1WAY statement provides analysis of Wilcoxon scores and the asymptotic Wilcoxon and Kruskal-Wallis tests.

**Computation Options**

*Computation-options* specify options for computing exact statistics. You can specify the following *computation-options* in the EXACT statement after a slash (/).

**ALPHA= $\alpha$** 

specifies the level of the confidence limits for Monte Carlo  $p$ -value estimates. The value of  $\alpha$  must be between 0 and 1, and the default is 0.01. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.01 produces 99% confidence limits for the Monte Carlo estimates.

The ALPHA= option invokes the **MC** option.

**MAXTIME=***value*

specifies the maximum clock time (in seconds) that PROC NPAR1WAY can use to compute an exact  $p$ -value. If the procedure does not complete the computation within the specified time, the computation terminates. The value of MAXTIME= must be a positive number. The MAXTIME= option is valid for Monte Carlo estimation of exact  $p$ -values as well as direct exact  $p$ -value computation. See the section “[Computational Resources](#)” on page 5481 for more information.

**MC**

requests Monte Carlo estimation of exact  $p$ -values instead of direct exact  $p$ -value computation. Monte Carlo estimation can be useful for large problems that require a considerable amount of time and memory for exact computations but for which asymptotic approximations might not be sufficient. See the section “[Monte Carlo Estimation](#)” on page 5481 for more information.

The MC option is available for all EXACT *statistic-options* except the HL option, which produces exact Hodges-Lehmann confidence limits. The ALPHA=, N=, and SEED= options also invoke the MC option.

**N=***n*

specifies the number of samples for Monte Carlo estimation. The value of  $n$  must be a positive integer, and the default is 10,000 samples. Larger values of  $n$  produce more precise estimates of exact  $p$ -values. Because larger values of  $n$  generate more samples, the computation time increases.

The N= option invokes the MC option.

**POINT**

requests exact point probabilities for the test statistics.

The POINT option is available for all EXACT statement *statistic-options* except the HL option, which produces exact Hodges-Lehmann confidence limits. The POINT option is not available with the MC option.

**SEED=***number*

specifies the initial seed for random number generation for Monte Carlo estimation. The value of the SEED= option must be an integer. If you do not specify the SEED= option or if the SEED= value is negative or zero, PROC NPAR1WAY uses the time of day from the computer’s clock to obtain the initial seed.

The SEED= option invokes the MC option.

**FREQ Statement**

**FREQ** *variable* ;

The FREQ statement names a numeric variable that provides a frequency for each observation in the input data set. If you use a FREQ statement, PROC NPAR1WAY assumes that an observation occurs  $n$  times, where  $n$  is the value of the FREQ variable for the observation. The sum of the FREQ variable values represents the total number of observations, and the analysis is based on this expanded number of observations.

If the value of the FREQ variable is missing or is less than one, PROC NPAR1WAY does not use that observation in the analysis. If the value of the FREQ variable is not an integer, PROC NPAR1WAY uses only the integer portion as the frequency of the observation.

---

## OUTPUT Statement

**OUTPUT** < **OUT=SAS-data-set** > < *output-options* > ;

The OUTPUT statement creates a SAS data set that contains statistics that PROC NPAR1WAY computes. Table 65.4 lists the statistics that can be stored in the output data set. You identify which statistics to include by specifying *output-options*.

The output data set contains one observation for each analysis variable that you name in the VAR statement. If you use a BY statement, the output data set contains an observation or set of observations for each BY group. See the section “Contents of the Output Data Set” on page 5483 for more information.

As an alternative to the OUTPUT statement, you can use the Output Delivery System (ODS) to store statistics that PROC NPAR1WAY computes. ODS can create a SAS data set from any table that PROC NPAR1WAY produces. For more information, see the section “ODS Table Names” on page 5493 and Chapter 20, “Using the Output Delivery System.”

You can specify the following *options* in the OUTPUT statement:

### **OUT=SAS-data-set**

names the output data set. When you use an OUTPUT statement but do not specify the OUT= option, PROC NPAR1WAY creates a data set and names it by using the DATA*n* convention.

### *output-options*

specifies the statistics to include in the output data set. Table 65.4 lists the *output-options* that are available in the OUTPUT statement. Descriptions of the *output-options* follow the table in alphabetical order.

When you specify an *output-option*, the output data set includes the test statistic and associated values from the analysis that you specify. The associated values might include standardized statistics, one- and two-sided *p*-values, exact *p*-values, degrees of freedom, and confidence limits. See the section “Contents of the Output Data Set” on page 5483 for a list of output data set variables that each *output-option* produces.

If you do not specify any *output-options* in the OUTPUT statement, the output data set includes all available statistics from the analyses that you request in the PROC NPAR1WAY statement. If you request a statistic in the OUTPUT statement but do not request the corresponding analysis in the PROC NPAR1WAY statement, PROC NPAR1WAY performs the corresponding analysis.

**Table 65.4** OUTPUT Statement Output Options

| Output Option | Output Data Set Statistics                                                                |
|---------------|-------------------------------------------------------------------------------------------|
| AB            | Ansari-Bradley test                                                                       |
| ANOVA         | Analysis of variance                                                                      |

You can specify the following *output-options* in the OUTPUT statement.

**AB**

includes statistics from the Ansari-Bradley analysis in the output data set. The **AB** option in the PROC NPAR1WAY statement requests analysis of Ansari-Bradley scores. See the section “[Ansari-Bradley Scores](#)” on page 5472 for more information.

**ANOVA**

includes analysis of variance statistics in the output data set. The **ANOVA** option in the PROC NPAR1WAY statement requests a standard analysis of variance for the raw data.

**CONOVER**

includes statistics from the Conover analysis in the output data set. The **CONOVER** option in the PROC NPAR1WAY statement requests analysis of Conover scores. See the section “[Conover Scores](#)” on page 5472 for more information.

**EDF**

includes empirical distribution function statistics in the output data set. The **EDF** option in the PROC NPAR1WAY statement requests computation of these statistics, which include the Kolmogorov-Smirnov test, the Cramér-von Mises test, and the Kuiper test for two sample-data. See the section “[Tests Based on the Empirical Distribution Function](#)” on page 5477 for more information.

**FP**

includes the Fligner-Policello test in the output data set. The **FP** option in the PROC NPAR1WAY statement requests the Fligner-Policello test, which is available for two-sample data. See the section “[Fligner-Policello Test](#)” on page 5475 for more information.

**HL**

includes the Hodges-Lehmann estimate and confidence limits in the output data set. The **HL** option in the PROC NPAR1WAY statement requests Hodges-Lehmann estimation, which is available for two-sample data. See the section “[Hodges-Lehmann Estimation of Location Shift](#)” on page 5473 for more information.

**KLOTZ**

includes statistics from the Klotz analysis in the output data set. The **KLOTZ** option in the PROC NPAR1WAY statement requests analysis of Klotz scores. See the section “[Klotz Scores](#)” on page 5472 for more information.

**MEDIAN**

includes statistics from the median analysis in the output data set. The **MEDIAN** option in the PROC NPAR1WAY statement requests analysis of median scores. See the section “[Median Scores](#)” on page 5471 for more information.

**MOOD**

includes statistics from the Mood analysis in the output data set. The **MOOD** option in the PROC NPAR1WAY statement requests analysis of Mood scores. See the section “[Mood Scores](#)” on page 5472 for more information.

**SAVAGE**

includes statistics from the Savage analysis in the output data set. The **SAVAGE** option in the PROC NPAR1WAY statement requests analysis of SAVAGE scores. See the section “[Savage Scores](#)” on page 5471 for more information.

**SCORES=DATA**

includes statistics from the analysis of data scores in the output data set. The **SCORES=DATA** option in the PROC NPAR1WAY statement requests an analysis that uses the raw input data as scores.

**ST**

includes statistics from the Siegel-Tukey analysis in the output data set. The **ST** option in the PROC NPAR1WAY statement requests analysis of Siegel-Tukey scores. See the section “[Siegel-Tukey Scores](#)” on page 5472 for more information.

**VW | NORMAL**

includes statistics from the Van der Waerden (normal scores) analysis in the output data set. The **VW** option in the PROC NPAR1WAY statement requests analysis of Van der Waerden scores. See the section “[Van der Waerden \(Normal\) Scores](#)” on page 5471 for more information.

**WILCOXON**

includes statistics from the Wilcoxon analysis in the output data set. The **WILCOXON** option in the PROC NPAR1WAY statement requests analysis of Wilcoxon scores. For two-sample data, this analysis includes the Wilcoxon rank-sum test. For all data (two-sample and multisample), the analysis includes the Kruskal-Wallis test. See the section “[Wilcoxon Scores](#)” on page 5471 for more information.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement names the response (dependent) variables to be included in the analysis. These variables must be numeric. If you omit the VAR statement, the procedure includes all numeric variables in the data set except for the CLASS variable, the FREQ variable, and the BY variables.

---

## Details: NPAR1WAY Procedure

---

### Missing Values

If an observation has a missing value for a response (VAR) variable, PROC NPAR1WAY excludes that observation from the analysis. Any observation with a missing or nonpositive value for the FREQ variable is also excluded from the analysis.

By default, PROC NPAR1WAY also excludes observations with missing values of the CLASS variable. If you specify the MISSING option, PROC NPAR1WAY treats missing values of the CLASS variable as a valid class level and includes these observations in the analysis.

PROC NPAR1WAY treats missing BY variable values like any other BY variable value. The missing values form a separate, valid BY group.

---

### Tied Values

*Tied values* occur when two or more observations are equal, whether the observations occur in the same sample or in different samples. In theory, nonparametric tests were developed for continuous distributions where the probability of a tie is zero. In practice, however, ties often occur. PROC NPAR1WAY uses the same method to handle ties for all score types. The procedure computes the scores as if there were no ties, averages the scores for tied observations, and assigns this average score to each observation with the same value.

When there are tied values, PROC NPAR1WAY first sorts the observations in ascending order and assigns ranks as if there were no ties. Then the procedure computes the scores based on these ranks by using the formula for the specified score type. The procedure averages the scores for tied observations and assigns this average score to each of the tied observations. Thus, all equal data values have the same score value. PROC NPAR1WAY then computes the test statistic from these scores.

Note that the asymptotic tests might be less accurate when the distribution of the data is heavily tied. For such data, it might be appropriate to use the exact tests provided by PROC NPAR1WAY as described in the section “Exact Tests” on page 5479.

When computing empirical distribution function statistics for data with ties, PROC NPAR1WAY uses the formulas given in the section “Tests Based on the Empirical Distribution Function” on page 5477. No special handling of ties is necessary.

PROC NPAR1WAY bases its computations on the internal numeric values of the analysis variables; the procedure does not format or round these values before analysis. When values differ in their internal representation, even slightly, PROC NPAR1WAY does not treat them as tied values. If this is a concern for your data, then round the analysis variables by an appropriate amount before invoking PROC NPAR1WAY. For information about the ROUND function, see the discussion in *SAS Language Reference: Dictionary*.

---

## Statistical Computations

### Simple Linear Rank Tests for Two-Sample Data

Statistics of the form

$$S = \sum_{j=1}^n c_j a(R_j)$$

are called *simple linear rank statistics*, where

$R_j$  is the rank of observation  $j$

$a(R_j)$  is the score based on the rank of observation  $j$

$c_j$  is an indicator variable denoting the class to which the  $j$ th observation belongs

$n$  is the total number of observations

For two-sample data (where the observations are classified into two levels), PROC NPAR1WAY calculates simple linear rank statistics for the scores that you specify. The section “[Scores for Linear Rank and One-Way ANOVA Tests](#)” on page 5470 describes the available scores, which you can use to test for differences in location and differences in scale.

To compute the linear rank statistic  $S$ , PROC NPAR1WAY sums the scores of the observations in the smaller of the two samples. If both samples have the same number of observations, PROC NPAR1WAY sums those scores for the sample that appears first in the input data set.

For each score that you specify, PROC NPAR1WAY computes an asymptotic test of the null hypothesis of no difference between the two classification levels. Exact tests are also available for these two-sample linear rank statistics. PROC NPAR1WAY computes exact tests for each score type that you specify in the **EXACT** statement. See the section “[Exact Tests](#)” on page 5479 for details.

To compute an asymptotic test for a linear rank sum statistic, PROC NPAR1WAY uses a standardized test statistic  $z$ , which has an asymptotic standard normal distribution under the null hypothesis. The standardized test statistic is computed as

$$z = (S - E_0(S)) / \sqrt{\text{Var}_0(S)}$$

where  $E_0(S)$  is the expected value of  $S$  under the null hypothesis, and  $\text{Var}_0(S)$  is the variance under the null hypothesis. As shown in Randles and Wolfe (1979),

$$E_0(S) = \frac{n_1}{n} \sum_{j=1}^n a(R_j)$$

where  $n_1$  is the number of observations in the first (smaller) class level (sample),  $n_2$  is the number of observations in the other class level, and

$$\text{Var}_0(S) = \frac{n_1 n_2}{n(n-1)} \sum_{j=1}^n (a(R_j) - \bar{a})^2$$

where  $\bar{a}$  is the average score,

$$\bar{a} = \frac{1}{n} \sum_{j=1}^n a(R_j)$$

### Definition of $p$ -Values

PROC NPAR1WAY computes one-sided and two-sided asymptotic  $p$ -values for each two-sample linear rank test. When the test statistic  $z$  is greater than its null hypothesis expected value of zero, PROC NPAR1WAY computes the right-sided  $p$ -value, which is the probability of a larger value of the statistic occurring under the null hypothesis. When the test statistic is less than or equal to zero, PROC NPAR1WAY computes the left-sided  $p$ -value, which is the probability of a smaller value of the statistic occurring under the null hypothesis. The one-sided  $p$ -value  $P_1(z)$  can be expressed as

$$P_1(z) = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value  $P_2(z)$  is computed as

$$P_2(z) = \text{Prob}(|Z| > |z|)$$

### Continuity Correction

PROC NPAR1WAY uses a continuity correction for the asymptotic two-sample Wilcoxon and Siegel-Tukey tests by default. You can remove the continuity correction by specifying the `CORRECT=NO` option. PROC NPAR1WAY incorporates the continuity correction when computing the standardized test statistic  $z$  by subtracting 0.5 from the numerator ( $S - E_0(S)$ ) if it is greater than zero. If the numerator is less than zero, PROC NPAR1WAY adds 0.5. Some sources recommend a continuity correction for nonparametric tests that use a continuous distribution to approximate a discrete distribution. (See Sheskin 1997.)

If you specify `CORRECT=NO`, PROC NPAR1WAY does not use a continuity correction for any test.

## One-Way ANOVA Tests

PROC NPAR1WAY computes a one-way ANOVA test for each score type that you specify. Under the null hypothesis of no difference among class levels (samples), this test statistic has an asymptotic chi-square distribution with  $r - 1$  degrees of freedom, where  $r$  is the number of class levels. For Wilcoxon scores, this test is known as the Kruskal-Wallis test.

Exact one-way ANOVA tests are also available for multisample data (where the data are classified into more than two levels). For two-sample data, exact simple linear rank tests are available. PROC NPAR1WAY computes exact tests for each score type that you specify in the `EXACT` statement. See the section “Exact Tests” on page 5479 for details.

PROC NPAR1WAY computes the one-way ANOVA test statistic as

$$C = \left( \sum_{i=1}^r (T_i - E_0(T_i))^2 / n_i \right) / S^2$$

where  $T_i$  is the total of scores for class level  $i$ ,  $E_0(T_i)$  is the expected total for level  $i$  under the null hypothesis of no difference among levels,  $n_i$  is the number of observations in level  $i$ , and  $S^2$  is the sample variance of the scores. The total of scores for class level  $i$  is given by

$$T_i = \sum_{j=1}^n c_{ij} a(R_j)$$

where  $a(R_j)$  is the score for observation  $j$ , and  $c_{ij}$  indicates whether observation  $j$  is in level  $i$ . The expected total of scores for class level  $i$  under the null hypothesis is equal to

$$E_0(T_i) = \frac{n_i}{n} \sum_{j=1}^n a(R_j)$$

The sample variance of the scores is computed as

$$S^2 = \frac{1}{(n-1)} \sum_{j=1}^n (a(R_j) - \bar{a})^2$$

where  $\bar{a}$  is the average score,

$$\bar{a} = \frac{1}{n} \sum_{j=1}^n a(R_j)$$

### Scores for Linear Rank and One-Way ANOVA Tests

For each score type that you specify, PROC NPAR1WAY computes a one-way ANOVA statistic and also a linear rank statistic for two-sample data. The following score types are used primarily to test for differences in location: Wilcoxon, median, Van der Waerden (normal), and Savage. The following scores types are used to test for scale differences: Siegel-Tukey, Ansari-Bradley, Klotz, and Mood. Conover scores can be used to test for differences in both location and scale. This section gives formulas for the score types available in PROC NPAR1WAY. For further information about the formulas and the applicability of each score, see Randles and Wolfe (1979); Gibbons and Chakraborti (2010); Conover (1999); Hollander and Wolfe (1999).

In addition to the score types described in this section, you can specify the **SCORES=DATA** option to use the input data observations as scores. This enables you to produce a wide variety of tests. You can construct any scores by using the DATA step, and then you can use PROC NPAR1WAY to compute the corresponding linear rank and one-way ANOVA tests for these scores. You can also analyze raw (unscored) data with the **SCORES=DATA** option; for two-sample data, the corresponding exact test is a permutation test that is known as Pitman's test.

**Wilcoxon Scores**

Wilcoxon scores are the ranks of the observations, which can be written as

$$a(R_j) = R_j$$

where  $R_j$  is the rank of observation  $j$ , and  $a(R_j)$  is the score of observation  $j$ .

Using Wilcoxon scores in the linear rank statistic for two-sample data produces the rank sum statistic of the Mann-Whitney-Wilcoxon test. Using Wilcoxon scores in the one-way ANOVA statistic produces the Kruskal-Wallis test. Wilcoxon scores are locally most powerful for location shifts of a logistic distribution.

When computing the asymptotic Wilcoxon two-sample test, PROC NPAR1WAY uses a continuity correction by default, as described in the section “[Continuity Correction](#)” on page 5469. If you specify the `CORRECT=NO` option in the PROC NPAR1WAY statement, the procedure does not use a continuity correction.

**Median Scores**

Median scores equal 1 for observations greater than the median, and 0 otherwise. In terms of the observation ranks, median scores are defined as

$$a(R_j) = \begin{cases} 1 & \text{if } R_j > (n + 1)/2 \\ 0 & \text{if } R_j \leq (n + 1)/2 \end{cases}$$

Using median scores in the linear rank statistic for two-sample data produces the two-sample median test. The one-way ANOVA statistic with median scores is equivalent to the Brown-Mood test. Median scores are particularly powerful for distributions that are symmetric and heavy-tailed.

**Van der Waerden (Normal) Scores**

Van der Waerden scores are the quantiles of a standard normal distribution and are also known as *quantile normal scores*. Van der Waerden scores are computed as

$$a(R_j) = \Phi^{-1} \left( \frac{R_j}{n + 1} \right)$$

where  $\Phi$  is the cumulative distribution function of a standard normal distribution. These scores are powerful for normal distributions.

**Savage Scores**

Savage scores are expected values of order statistics from the exponential distribution, with 1 subtracted to center the scores around 0. Savage scores are computed as

$$a(R_j) = \sum_{i=1}^{R_j} \left( \frac{1}{n - i + 1} \right) - 1$$

Savage scores are powerful for comparing scale differences in exponential distributions or location shifts in extreme value distributions (Hajek 1969, p. 83).

**Siegel-Tukey Scores**

Siegel-Tukey scores are defined as

$$\begin{aligned} a(1) &= 1, & a(n) &= 2, & a(n-1) &= 3, & a(2) &= 4, \\ a(3) &= 5, & a(n-2) &= 6, & a(n-3) &= 7, & a(4) &= 8, \dots \end{aligned}$$

where the score values continue to increase in this pattern toward the middle ranks until all observations have been assigned a score.

When computing the asymptotic Siegel-Tukey two-sample test, PROC NPAR1WAY uses a continuity correction by default, as described in the section “[Continuity Correction](#)” on page 5469. If you specify the `CORRECT=NO` option in the PROC NPAR1WAY statement, the procedure does not use a continuity correction.

**Ansari-Bradley Scores**

Ansari-Bradley scores are similar to Siegel-Tukey scores, but Ansari-Bradley scoring assigns the same score value to corresponding extreme ranks. (Siegel-Tukey scores are a permutation of the ranks  $1, 2, \dots, n$ .) Ansari-Bradley scores are defined as

$$\begin{aligned} a(1) &= 1, & a(n) &= 1, \\ a(2) &= 2, & a(n-1) &= 2, \dots \end{aligned}$$

Equivalently, Ansari-Bradley scores are equal to

$$a(R_j) = \frac{n+1}{2} - \left| R_j - \frac{n+1}{2} \right|$$

**Klotz Scores**

Klotz scores are the squares of the Van der Waerden (normal) scores. Klotz scores are computed as

$$a(R_j) = \left( \Phi^{-1} \left( \frac{R_j}{n+1} \right) \right)^2$$

where  $\Phi$  is the cumulative distribution function of a standard normal distribution.

**Mood Scores**

Mood scores are computed as the square of the difference between the observation rank and the average rank. Mood scores can be written as

$$a(R_j) = \left( R_j - \frac{n+1}{2} \right)^2$$

**Conover Scores**

Conover scores are based on the squared ranks of the absolute deviations from the sample means. For observation  $j$  the absolute deviation from the mean is computed as

$$U_j = |X_{j(i)} - \bar{X}_i|$$

where  $X_{j(i)}$  is the value of observation  $j$ , observation  $j$  belongs to sample  $i$ , and  $\bar{X}_i$  is the mean of sample  $i$ . The values of  $U_j$  are ranked, and the Conover score for observation  $j$  is computed as

$$\text{Score}_j = (\text{Rank}(U_j))^2$$

Following Conover (1999), when there are ties among the values of  $U_j$ , PROC NPAR1WAY assigns the average rank to each of the tied observations. To compute the average rank, PROC NPAR1WAY ranks the  $U_j$  as if there were no ties, and then averages the ranks of the tied observations.

The Conover score test is also known as the squared ranks test for variances. See Conover (1999) for more information.

### Hodges-Lehmann Estimation of Location Shift

If you specify the **HL** option, PROC NPAR1WAY computes the Hodges-Lehmann estimate of location shift for two-sample data. PROC NPAR1WAY also provides confidence limits for the location shift. These confidence limits are sometimes called Moses confidence limits. You can set the level of the confidence limits with the **ALPHA=** option. The default is ALPHA=0.05, which produces 95% confidence limits. Additionally, you can request exact confidence limits for the location shift by specifying the HL option in the **EXACT** statement.

The Hodges-Lehmann estimator of location shift is associated with the Wilcoxon linear rank statistic. See Hollander and Wolfe (1999) and Hodges and Lehmann (1983) for details.

PROC NPAR1WAY computes the Hodges-Lehmann estimate  $\hat{\Delta}$  as the median of all paired differences between observations in the two samples (classes), which can be written as

$$\hat{\Delta} = \text{median} \left( (Y_j - X_i) \quad \text{where } j = 1, 2, \dots, n_1; i = 1, 2, \dots, n_2 \right)$$

The  $Y_j$  are observations in class 1, the  $X_i$  are observations in class 2, and  $n_1$  and  $n_2$  denote the number of observations in class 1 and class 2, respectively.

By default, PROC NPAR1WAY uses the larger of the two classes as the reference class  $X$  (class 2). If both classes have the same number of observations, PROC NPAR1WAY uses the class that appears second in the input data set as the reference class. You can specify the reference class by using the **HL(REFCLASS=)** option. REFCLASS=1 refers to the first class that is listed in the “Wilcoxon Scores” table, and REFCLASS=2 refers to the second class in the table. REFCLASS=*class-value* identifies the reference class by the formatted value of the **CLASS** variable.

Let  $m$  denote the total number of differences ( $n_1 \times n_2$ ), and let  $U^{(k)}$  denote the  $k$ th value of  $(Y_j - X_i)$  among the ordered differences. When  $m$  is an odd number, then the median difference is the value with rank  $(m + 1)/2$ ,

$$\hat{\Delta} = U^{(k)} \quad \text{where } k = (m + 1)/2$$

When  $m$  is an even number, the median difference is the average of the values with ranks  $(m/2)$  and  $((m/2) + 1)$ ,

$$\hat{\Delta} = \left( U^{(k)} + U^{(k+1)} \right) / 2 \quad \text{where } k = m/2$$

Following Hollander and Wolfe (1999), the asymptotic lower and upper confidence limits for the location shift are

$$\left( \Delta_L = U^{(C_\alpha)}, \quad \Delta_U = U^{(m+1-C_\alpha)} \right)$$

where  $C_\alpha$  is the largest integer less than or equal to  $C_\alpha^*$ , which is computed as

$$C_\alpha^* = E_0(S) - z_{\alpha/2} \sqrt{\text{Var}_0(S)}$$

where  $E_0(S)$  and  $\text{Var}_0(S)$  are the expected value and variance, respectively, of the Wilcoxon statistic  $S$  under the null hypothesis (as described in the section “Simple Linear Rank Tests for Two-Sample Data” on page 5468), and  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the standard normal distribution. For Wilcoxon rank scores,

$$E_0(S) = n_1 n_2 / 2$$

When there are no tied values,  $\text{Var}_0(S)$  for Wilcoxon scores equals

$$\text{Var}_0(S) = n_1 n_2 (n_1 + n_2 + 1) / 12$$

PROC NPAR1WAY displays the midpoint of the confidence interval  $(\Delta_L, \Delta_U)$ , which can also be used as an estimate of location shift. See Lehmann (1963) for details. Additionally, PROC NPAR1WAY provides an estimate of the asymptotic standard error of  $\hat{\Delta}$  based on the length of the confidence interval, which is computed as

$$\text{se}(\hat{\Delta}) = (\Delta_U - \Delta_L) / (2 z_{\alpha/2})$$

### Exact Confidence Limits

If you specify the HL option in the EXACT statement, PROC NPAR1WAY computes exact confidence limits for the location shift between the two samples. As for the asymptotic confidence limits, you can set the confidence level with the ALPHA= option. The default is ALPHA=0.05, which produces 95% confidence limits.

PROC NPAR1WAY computes exact confidence limits for the location shift as described in Randles and Wolfe (1979, p. 180). PROC NPAR1WAY first generates the exact conditional distribution of the Mann-Whitney  $U$  statistic, which equals the number of pairwise differences  $(Y_i - X_j)$  that are positive, plus half the number of pairwise differences that are zero. The Mann-Whitney statistic is defined as

$$MW = \sum_{i=1}^{n_1} \sum_{j=i}^{n_2} \phi(X_i - Y_j)$$

where

$$\phi(Y_i, X_j) = \begin{cases} 1 & \text{if } Y_i > X_j \\ 1/2 & \text{if } Y_i = X_j \\ 0 & \text{otherwise} \end{cases}$$

From the exact conditional distribution of the Mann-Whitney statistic  $MW$ , PROC NPAR1WAY chooses  $C_{L,\alpha}^*$  as the largest value such that  $\text{Prob}(MW \geq C_{L,\alpha}^*) \geq \alpha/2$ . Rounding  $C_{L,\alpha}^*$  up to the nearest integer  $C_{L,\alpha}$ , the lower confidence limit equals the difference  $(Y_i - X_j)$  that has a rank of  $(n_1 n_2 - C_{L,\alpha} + 1)$ .

To find the upper confidence limit, PROC NPAR1WAY chooses  $C_{U,\alpha}^*$  as the smallest value such that  $\text{Prob}(MW \leq C_{U,\alpha}^*) \geq \alpha/2$ . Rounding  $C_{U,\alpha}^*$  down to the nearest integer  $C_{U,\alpha}$ , the upper confidence limit equals the difference  $(Y_i - X_j)$  that has a rank of  $(n_1 n_2 - C_{U,\alpha})$ .

Because this is a discrete problem, the confidence coefficient for these exact confidence limits is not exactly  $(1 - \alpha)$  but is at least  $(1 - \alpha)$ . Thus, these confidence limits are conservative.

## Fligner-Policello Test

If you specify the `FP` option, PROC `NPARIWAY` computes the Fligner-Policello location test for two-sample data (Fligner and Policello 1981). The null hypothesis for the test is  $H_0 : \theta_X = \theta_Y$ , where  $\theta_X$  and  $\theta_Y$  are the population medians of the two classes. The Fligner-Policello test assumes that the distribution in each class is symmetric around the class median, but it does not require that the two class distributions have the same form or that the class variances be equal. See Hollander and Wolfe (1999) and Juneau (2007) for more information.

The Fligner-Policello test is based on placement scores (Orban and Wolfe 1979). The placement of an observation  $X_i$  from class  $X$ ,  $P(X_i)$ , is defined as the number of observations in class  $Y$  that are less than  $X_i$ . If there are ties, the placement of  $X_i$  is adjusted by adding half the number of observations in class  $Y$  that are equal to  $X_i$ . The placement of an observation  $Y_j$  from class  $Y$ ,  $P(Y_j)$ , is defined in the same way. The placements can be expressed as

$$P(X_i) = \sum_{j=1}^{n_y} (I(Y_j < X_i) + 0.5I(Y_j = X_i))$$

$$P(Y_j) = \sum_{i=1}^{n_x} (I(X_i < Y_j) + 0.5I(X_i = Y_j))$$

where  $I(\cdot)$  is an indicator function and  $n_x$  and  $n_y$  denote the number of observations in class  $X$  and class  $Y$ , respectively.

The average placements for class  $X$  and class  $Y$  are computed as

$$\bar{P}_x = \left( \sum_{i=1}^{n_x} P(X_i) \right) / n_x$$

$$\bar{P}_y = \left( \sum_{j=1}^{n_y} P(Y_j) \right) / n_y$$

The Fligner-Policello test statistic is computed as

$$z = \left( \sum_{j=1}^{n_y} P(Y_j) - \sum_{i=1}^{n_x} P(X_i) \right) / \left( 2\sqrt{V_x + V_y + \bar{P}_x \bar{P}_y} \right)$$

where

$$V_x = \sum_{i=1}^{n_x} (P(X_i) - \bar{P}_x)^2$$

$$V_y = \sum_{j=1}^{n_y} (P(Y_j) - \bar{P}_y)^2$$

and the standard deviation of the placements is  $\sqrt{V_x/(n_x - 1)}$  for class  $X$  and  $\sqrt{V_y/(n_y - 1)}$  for class  $Y$ .

Under the null hypothesis, the Fligner-Policello statistic has an asymptotic standard normal distribution. PROC NPAR1WAY provides one- and two-sided asymptotic  $p$ -values for the Fligner-Policello test. For the one-sided test, PROC NPAR1WAY displays the right-sided  $p$ -value when the test statistic  $z$  is greater than its null hypothesis expected value of zero. PROC NPAR1WAY displays the left-sided  $p$ -value when the test statistic  $z$  is less than or equal to zero. The one-sided  $p$ -value  $P_1(z)$  can be expressed as

$$P_1(z) = \begin{cases} \text{Prob}(Z > z) & \text{if } z > 0 \\ \text{Prob}(Z < z) & \text{if } z \leq 0 \end{cases}$$

where  $Z$  has a standard normal distribution. The two-sided  $p$ -value  $P_2(z)$  is computed as  $\text{Prob}(|Z| > |z|)$ .

When you specify the FP option, PROC NPAR1WAY displays a “Fligner-Policello Placements” table and a “Fligner-Policello Test” table. The “Fligner-Policello Placements” table contains the following information for each of the two classes: number of observations, sum of the placements, average placement, and standard deviation of the placements. The “Fligner-Policello Test” table contains the test statistic  $z$  and the corresponding one- and two-sided  $p$ -values. This table also displays the difference between the class placement sums, which is the numerator of the test statistic. When ODS Graphics is enabled and you specify the FP or PLOTS=FPBOXPLOT option, PROC NPAR1WAY provides a box plot of the Fligner-Policello placements.

PROC NPAR1WAY computes the Fligner-Policello difference (the numerator of the test statistic) as the placement sum for class  $Y$  minus the placement sum for class  $X$  (the reference class). By default, PROC NPAR1WAY uses the first class that is listed in the “Fligner-Policello Placements” table as class  $Y$  and the second class as the reference class  $X$ . The table displays class levels in the order in which they appear in the input data set. To use the first class (instead of the second class) as the reference class for the Fligner-Policello test, you can specify the FP(REFCLASS=1) option. Or you can specify the FP(REFCLASS=*class-value*) option to identify the reference class by the formatted value of the CLASS variable.

## Multiple Comparisons Based on Pairwise Rankings

If you specify the DSCF option, PROC NPAR1WAY computes the Dwass, Steel, Critchlow-Fligner (DSCF) multiple comparison analysis, which is based on pairwise two-sample Wilcoxon comparisons (Dwass 1960; Steel 1960; Critchlow and Fligner 1991). The DSCF analysis is available when the number of CLASS variable levels (samples) is greater than 2. There are  $r(r-1)/2$  pairs of samples, where  $r$  is the total number of samples.

For each pair of samples, PROC NPAR1WAY ranks the observations and computes the standardized Wilcoxon test statistic, which is described in the sections “Simple Linear Rank Tests for Two-Sample Data” on page 5468 and “Wilcoxon Scores” on page 5471. The procedure does not include a continuity correction in the Wilcoxon test statistics that it computes for the DSCF analysis. The DSCF statistic for a pair of samples is computed as  $\sqrt{2}z$ , where  $z$  is the two-sample standardized Wilcoxon statistic. Under the null hypothesis of no location differences among the  $r$  samples, the distribution of the DSCF statistics can be approximated by the studentized range distribution for  $r$  independent standard normal variables. The  $p$ -value for a two-sample DSCF comparison is the percentile of the studentized range distribution that corresponds to the value of the DSCF statistic. See Hollander and Wolfe (1999) and Juneau (2007, 2004) for more information.

When you specify the DSCF option, PROC NPAR1WAY displays the “Pairwise Two-Sided Multiple Comparison Analysis” table, which contains the following information for each two-sample comparison: comparison identification (two class variable levels), two-sample Wilcoxon test statistic, DSCF statistic, and

two-sided DSCF  $p$ -value. You can store these statistics in a SAS data set by using the Output Delivery System (ODS). The ODS name for this table is DSCF. For more information, see the section “ODS Table Names” on page 5493 and Chapter 20, “Using the Output Delivery System.”

## Tests Based on the Empirical Distribution Function

If you specify the **EDF** option, PROC NPAR1WAY computes tests based on the empirical distribution function. These include the Kolmogorov-Smirnov and Cramér–von Mises tests, and also the Kuiper test for two-sample data. This section gives formulas for these test statistics. For further information about the formulas and the interpretation of EDF statistics, see Hollander and Wolfe (1999) and Gibbons and Chakraborti (2010). For details about the  $k$ -sample analogs of the Kolmogorov-Smirnov and Cramér–von Mises statistics, see Kiefer (1959).

The *empirical distribution function* (EDF) of a sample  $\{x_j\}$ ,  $j = 1, 2, \dots, n$ , is defined as

$$F(x) = \frac{1}{n}(\text{number of } x_j \leq x) = \frac{1}{n} \sum_{j=1}^n I(x_j \leq x)$$

where  $I(\cdot)$  is an indicator function. PROC NPAR1WAY uses the subsample of values within the  $i$ th class level to generate an EDF for the class,  $F_i$ . The EDF for the overall sample, pooled over classes, can also be expressed as

$$F(x) = \frac{1}{n} \sum_i (n_i F_i(x))$$

where  $n_i$  is the number of observations in the  $i$ th class level, and  $n$  is the total number of observations.

### Kolmogorov-Smirnov Test

The Kolmogorov-Smirnov statistic measures the maximum deviation of the EDF within the classes from the pooled EDF. PROC NPAR1WAY computes the Kolmogorov-Smirnov statistic as

$$KS = \max_j \sqrt{\frac{1}{n} \sum_i n_i (F_i(x_j) - F(x_j))^2} \quad \text{where } j = 1, 2, \dots, n$$

The asymptotic Kolmogorov-Smirnov statistic is computed as

$$KS_a = KS \times \sqrt{n}$$

For each class level  $i$  and overall, PROC NPAR1WAY displays the value of  $F_i$  at the maximum deviation from  $F$  and the value  $\sqrt{n_i} (F_i - F)$  at the maximum deviation from  $F$ . PROC NPAR1WAY also gives the observation where the maximum deviation occurs.

If there are only two class levels, PROC NPAR1WAY computes the two-sample Kolmogorov-Smirnov test statistic  $D$  as

$$D = \max_j |F_1(x_j) - F_2(x_j)| \quad \text{where } j = 1, 2, \dots, n$$

The  $p$ -value for this test is the probability that  $D$  is greater than the observed value  $d$  under the null hypothesis of no difference between class levels (samples). PROC NPAR1WAY computes the asymptotic  $p$ -value for

$D$  with the approximation

$$\text{Prob}(D > d) = 2 \sum_{i=1}^{\infty} (-1)^{(i-1)} e^{(-2i^2 z^2)}$$

where

$$z = d \sqrt{n_1 n_2 / n}$$

See Hodges (1957) for information about this approximation.

If you specify the **D** option, or if you request exact Kolmogorov-Smirnov  $p$ -values with the **KS** option in the **EXACT** statement, PROC NPAR1WAY also computes the one-sided Kolmogorov-Smirnov statistics  $D+$  and  $D-$  for two-sample data as

$$D+ = \max_j (F_1(x_j) - F_2(x_j)) \quad \text{where } j = 1, 2, \dots, n$$

$$D- = \max_j (F_2(x_j) - F_1(x_j)) \quad \text{where } j = 1, 2, \dots, n$$

The asymptotic probability that  $D+$  is greater than the observed value  $d^+$ , under the null hypothesis of no difference between the two class levels, is computed as

$$\text{Prob}(D+ > d^+) = e^{-2z^2} \quad \text{where } z = d^+ \sqrt{n_1 n_2 / n}$$

Similarly, the asymptotic probability that  $D-$  is greater than the observed value  $d^-$  is computed as

$$\text{Prob}(D- > d^-) = e^{-2z^2} \quad \text{where } z = d^- \sqrt{n_1 n_2 / n}$$

To request exact  $p$ -values for the Kolmogorov-Smirnov statistics, you can specify the **KS** option in the **EXACT** statement. See the section “Exact Tests” on page 5479 for more information.

### **Cramér–von Mises Test**

The Cramér–von Mises statistic is defined as

$$CM = \frac{1}{n^2} \sum_i \left( n_i \sum_{j=1}^p t_j (F_i(x_j) - F(x_j))^2 \right)$$

where  $t_j$  is the number of ties at the  $j$ th distinct value and  $p$  is the number of distinct values. The asymptotic value is computed as

$$CM_a = CM \times n$$

PROC NPAR1WAY displays the contribution of each class level to the sum  $CM_a$ .

**Kuiper Test**

For data with two class levels, PROC NPAR1WAY computes the Kuiper statistic, its scaled value for the asymptotic distribution, and the asymptotic  $p$ -value. The Kuiper statistic is computed as

$$K = \max_j (F_1(x_j) - F_2(x_j)) - \min_j (F_1(x_j) - F_2(x_j)) \quad \text{where } j = 1, 2, \dots, n$$

The asymptotic value is

$$K_a = K \sqrt{n_1 n_2 / n}$$

PROC NPAR1WAY displays the value of  $(\max_j |F_1(x_j) - F_2(x_j)|)$  for each class level.

The  $p$ -value for the Kuiper test is the probability of observing a larger value of  $K_a$  under the null hypothesis of no difference between the two classes. PROC NPAR1WAY computes this  $p$ -value according to Owen (1962, p. 441).

**Exact Tests**

PROC NPAR1WAY provides exact  $p$ -values for tests for location and scale differences based on the following scores: Wilcoxon, median, van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, and Conover. Additionally, PROC NPAR1WAY provides exact  $p$ -values for tests that use the raw data as scores. Exact tests are available for two-sample and multisample data. When the data are classified into two samples, tests are based on simple linear rank statistics. When the data are classified into more than two samples, tests are based on one-way ANOVA statistics.

Exact tests can be useful in situations where the asymptotic assumptions are not met and the asymptotic  $p$ -values are not close approximations for the true  $p$ -values. Standard asymptotic methods involve the assumption that the test statistic follows a particular distribution when the sample size is sufficiently large. When the sample size is not large, asymptotic results might not be valid, with the asymptotic  $p$ -values differing perhaps substantially from the exact  $p$ -values. Asymptotic results might also be unreliable when the distribution of the data is sparse, skewed, or heavily tied. See Agresti (2007) and Bishop, Fienberg, and Holland (1975). Exact computations are based on the statistical theory of exact conditional inference for contingency tables, reviewed by Agresti (1992).

In addition to computation of exact  $p$ -values, PROC NPAR1WAY provides the option of estimating exact  $p$ -values by Monte Carlo simulation. This can be useful for problems that are so large that exact computations require a great amount of time and memory, but for which asymptotic approximations might not be sufficient.

The following sections summarize the exact computational algorithms, define the exact  $p$ -values that PROC NPAR1WAY computes, discuss the computational resource requirements, and describe the Monte Carlo estimation option.

**Computational Algorithms**

PROC NPAR1WAY computes exact  $p$ -values by using the network algorithm developed by Mehta and Patel (1983). This algorithm provides a substantial advantage over direct enumeration, which can be very time-consuming and feasible only for small problems. See Agresti (1992) for a review of algorithms for computation of exact  $p$ -values, and see Mehta, Patel, and Tsiatis (1984) and Mehta, Patel, and Senchaudhuri (1991) for information about the performance of the network algorithm.

PROC NPAR1WAY constructs a contingency table from the input data, with rows formed by the levels of the classification variable and columns formed by the response variable values. The reference set for a given contingency table is the set of all contingency tables with the observed marginal row and column sums. Corresponding to this reference set, the network algorithm forms a directed acyclic network consisting of nodes in a number of stages. A path through the network corresponds to a distinct table in the reference set. The distances between nodes are defined so that the total distance of a path through the network is the corresponding value of the test statistic. At each node, the algorithm computes the shortest and longest path distances for all the paths that pass through that node. For the two-sample linear rank statistics, which can be expressed as linear combinations of cell frequencies multiplied by increasing row and column scores, PROC NPAR1WAY computes shortest and longest path distances by using the algorithm given by Agresti, Mehta, and Patel (1990). For the multisample one-way test statistics, PROC NPAR1WAY computes an upper bound for the longest path and a lower bound for the shortest path by following the approach of Valz and Thompson (1994).

The longest and shortest path distances (bounds) for a node are compared to the value of the test statistic to determine whether all paths through the node contribute to the  $p$ -value, none of the paths through the node contribute to the  $p$ -value, or neither of these situations occurs. If all paths through the node contribute, the  $p$ -value is incremented accordingly, and these paths are eliminated from further analysis. If no paths contribute, these paths are eliminated from the analysis. Otherwise, the algorithm continues, still processing this node and the associated paths. The algorithm finishes when all nodes have been accounted for.

In applying the network algorithm, PROC NPAR1WAY uses full numerical precision to represent all statistics, row and column scores, and other quantities involved in the computations. Although it is possible to use rounding to improve the speed and memory requirements of the algorithm, PROC NPAR1WAY does not do this because it can result in reduced accuracy of the  $p$ -values.

### Definition of $p$ -Values

For two-sample linear rank tests, PROC NPAR1WAY computes exact one-sided and two-sided  $p$ -values for each test that is specified in the EXACT statement. For the one-sided test, PROC NPAR1WAY displays the right-sided  $p$ -value when the observed value of the test statistic is greater than its expected value. The right-sided  $p$ -value is the sum of probabilities for those tables having a test statistic greater than or equal to the observed test statistic. Otherwise, when the test statistic is less than or equal to its expected value, PROC NPAR1WAY displays the left-sided  $p$ -value. The left-sided  $p$ -value is the sum of probabilities for those tables having a test statistic less than or equal to the one observed. The one-sided  $p$ -value  $P_1$  can be expressed as

$$P_1(t) = \begin{cases} \text{Prob}(\text{Test Statistic} \geq t) & \text{if } t > E_0(T) \\ \text{Prob}(\text{Test Statistic} \leq t) & \text{if } t \leq E_0(T) \end{cases}$$

where  $t$  is the observed value of the test statistic and  $E_0(T)$  is the expected value of the test statistic under the null hypothesis. PROC NPAR1WAY computes the two-sided  $p$ -value as the sum of the one-sided  $p$ -value and the corresponding area in the opposite tail of the distribution of the statistic, equidistant from the expected value. The two-sided  $p$ -value  $P_2$  can be expressed as

$$P_2(t) = \text{Prob}(|\text{Test Statistic} - E_0(T)| \geq |t - E_0(T)|)$$

For multisample data, the tests are based on one-way ANOVA statistics. For a test of this form, large values of the test statistic indicate a departure from the null hypothesis; the test is inherently two-sided. The exact

$p$ -value is the sum of probabilities for those tables having a test statistic greater than or equal to the value of the observed test statistic.

If you specify the **POINT** option in the EXACT statement, PROC NPAR1WAY also displays exact point probabilities for the test statistics. The exact point probability is the exact probability that the test statistic equals the observed value.

### **Computational Resources**

PROC NPAR1WAY uses relatively fast and efficient algorithms for exact computations. These algorithms, together with improvements in computer power, now make it feasible to perform exact computations for data sets where previously only asymptotic methods could be applied. Nevertheless, there are still large problems that might require a prohibitive amount of time and memory for exact computations, depending on the speed and memory available on your computer. For large problems, consider whether exact methods are really needed or whether asymptotic methods might give results quite close to the exact results while requiring much less computer time and memory. When asymptotic methods might not be sufficient for such large problems, consider using Monte Carlo estimation of exact  $p$ -values, as described in the section “**Monte Carlo Estimation**” on page 5481.

A formula does not exist that can predict in advance how much time and memory are needed to compute an exact  $p$ -value for a certain problem. The time and memory required depend on several factors, including which test is being performed, the total sample size, the number of rows and columns, and the specific arrangement of the observations into table cells. Generally, larger problems (in terms of total sample size, number of rows, and number of columns) tend to require more time and memory. Additionally, for a fixed total sample size, time and memory requirements tend to increase as the number of rows and columns increase, since this corresponds to an increase in the number of tables in the reference set. Also for a fixed sample size, time and memory requirements increase as the marginal row and column totals become more homogeneous. See Agresti, Mehta, and Patel (1990) and Gail and Mantel (1977) for details.

At any time while PROC NPAR1WAY is computing exact  $p$ -values, you can terminate the computations by pressing the system interrupt key sequence (see the *SAS Companion* for your system) and choosing to stop computations. After you terminate exact computations, PROC NPAR1WAY completes all other remaining tasks. The procedure produces the requested output and reports missing values for any exact  $p$ -values not computed by the time of termination.

You can also use the **MAXTIME=** option in the EXACT statement to limit the amount of time PROC NPAR1WAY uses for exact computations. You specify a **MAXTIME=** value that is the maximum amount of time (in seconds) that PROC NPAR1WAY can use to compute an exact  $p$ -value. If PROC NPAR1WAY does not finish computing the exact  $p$ -value within that time, it terminates the computation and completes all other remaining tasks.

### **Monte Carlo Estimation**

If you specify the **MC** option in the EXACT statement, PROC NPAR1WAY computes Monte Carlo estimates of the exact  $p$ -values instead of directly computing the exact  $p$ -values. Monte Carlo estimation can be useful for large problems that require a great amount of time and memory for exact computations but for which asymptotic approximations might not be sufficient. To describe the precision of each Monte Carlo estimate, PROC NPAR1WAY provides the asymptotic standard error and  $100(1 - \alpha)\%$  confidence limits. The confidence level  $\alpha$  is determined by the **ALPHA=** option in the EXACT statement, which, by default, equals 0.01 and produces 99% confidence limits. The **N=** option in the EXACT statement specifies the

number of samples PROC NPAR1WAY uses for Monte Carlo estimation; the default is 10,000 samples. You can specify a larger value for  $n$  to improve the precision of the Monte Carlo estimates. Because larger values of  $n$  generate more samples, the computation time increases. Or you can specify a smaller value of  $n$  to reduce the computation time.

To compute a Monte Carlo estimate of an exact  $p$ -value, PROC NPAR1WAY generates a random sample of tables with the same total sample size, row totals, and column totals as the observed table. PROC NPAR1WAY uses the algorithm of Agresti, Wackerly, and Boyett (1979), which generates tables in proportion to their hypergeometric probabilities conditional on the marginal frequencies. For each sample table, PROC NPAR1WAY computes the value of the test statistic and compares it to the value for the observed table. When estimating a right-sided  $p$ -value, PROC NPAR1WAY counts all sample tables for which the test statistic is greater than or equal to the observed test statistic. Then the  $p$ -value estimate equals the number of these tables divided by the total number of tables sampled, which can be written as

$$\begin{aligned}\hat{P}_{MC} &= M / N \\ M &= \text{number of samples with (Test Statistic} \geq t) \\ N &= \text{total number of samples} \\ t &= \text{observed Test Statistic}\end{aligned}$$

PROC NPAR1WAY computes left-sided and two-sided  $p$ -value estimates in a similar manner. For left-sided  $p$ -values, PROC NPAR1WAY evaluates whether the test statistic for each sampled table is less than or equal to the observed test statistic. For two-sided  $p$ -values, PROC NPAR1WAY examines the sample test statistics according to the expression for  $P_2(t)$  given in the section “[Definition of  \$p\$ -Values](#)” on page 5480.

The variable  $M$  is a binomial variable with  $N$  trials and success probability  $p$ . It follows that the asymptotic standard error of the Monte Carlo estimate is

$$se(\hat{P}_{MC}) = \sqrt{\hat{P}_{MC} (1 - \hat{P}_{MC}) / (N - 1)}$$

PROC NPAR1WAY constructs asymptotic confidence limits for the  $p$ -values according to

$$\hat{P}_{MC} \pm (z_{\alpha/2} \times se(\hat{P}_{MC}))$$

where  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the standard normal distribution, and the confidence level  $\alpha$  is determined by the ALPHA= option in the EXACT statement.

When the Monte Carlo estimate  $\hat{P}_{MC}$  equals 0, PROC NPAR1WAY computes confidence limits for the  $p$ -value as

$$(0, 1 - \alpha^{(1/N)})$$

When the Monte Carlo estimate  $\hat{P}_{MC}$  equals 1, PROC NPAR1WAY computes the confidence limits as

$$(\alpha^{(1/N)}, 1)$$

## Contents of the Output Data Set

The **OUTPUT** statement creates a SAS data set that contains statistics that PROC NPAR1WAY computes. You identify which statistics to store in the output data set by specifying *output-options* in the OUTPUT statement. See the description of the **OUTPUT** statement for more information.

The output data set contains one observation for each analysis variable for each **BY** group. (You can specify the analysis variables in the **VAR** statement.) The OUTPUT data set includes the following variables:

- BY variables, if you use a **BY** statement
- **\_VAR\_**, which identifies the analysis variable
- variables that contain the statistics

When you specify an *output-option* in the OUTPUT statement, the output data set contains the test statistic and associated values from the analysis that you specify. The associated values might include standardized statistics, one- and two-sided *p*-values, exact *p*-values, degrees of freedom, and confidence limits. If you request an exact test for the specified analysis by using the **EXACT** statement, the output data set includes the exact *p*-values. The statistics that are included also depend on the classification of the data. Some statistics are available only for two-sample data (where the **CLASS** variable groups the data into two classes); other statistics are available only for multisample data.

Table 65.5 lists variable names and descriptions for the statistics that are available in the output data set.

Monte Carlo estimates of exact *p*-values are not available in this output data set. You can store Monte Carlo estimates in a SAS data set by using the Output Delivery System (ODS). ODS can create a SAS data set from any table that PROC NPAR1WAY produces. For more information, see the section “ODS Table Names” on page 5493 and Chapter 20, “Using the Output Delivery System.”

**Table 65.5** Output Data Set Variable Names and Descriptions

| Output Option   | Output Variables                                      | Variable Descriptions                                      |
|-----------------|-------------------------------------------------------|------------------------------------------------------------|
| AB              | <b>_AB_</b>                                           | * Two-sample Ansari-Bradley statistic                      |
|                 | <b>Z_AB</b>                                           | * Ansari-Bradley statistic, standardized                   |
|                 | <b>PL_AB</b>                                          | * <i>p</i> -value (left-sided), Ansari-Bradley test        |
|                 | <b>PR_AB</b>                                          | * <i>p</i> -value (right-sided), Ansari-Bradley test       |
|                 | <b>P2_AB</b>                                          | * <i>p</i> -value (two-sided), Ansari-Bradley test         |
|                 | <b>XPL_AB</b>                                         | * Exact <i>p</i> -value (left-sided), Ansari-Bradley test  |
|                 | <b>XPR_AB</b>                                         | * Exact <i>p</i> -value (right-sided), Ansari-Bradley test |
|                 | <b>XPT_AB</b>                                         | * Exact point probability, Ansari-Bradley test             |
|                 | <b>XP2_AB</b>                                         | * Exact <i>p</i> -value (two-sided), Ansari-Bradley test   |

|               | XP2_WIL                                         | * Exact $p$ -value (two-sided), Wilcoxon test          |
|               | _KW_                                            | Kruskal-Wallis statistic                               |
|               | DF_KW                                           | Degrees of freedom, Kruskal-Wallis test                |
|               | P_KW                                            | $p$ -value, Kruskal-Wallis test                        |
|               | XP_KW                                           | ** Exact $p$ -value, Kruskal-Wallis test               |
| XPT_KW        | ** Exact point probability, Kruskal-Wallis test |                                                        |

\*Statistic included only for two-sample cases.

\*\*Statistic included only for multisample cases.

## Displayed Output

If you specify the ANOVA option, PROC NPAR1WAY displays a “Class Means” table and an “Analysis of Variance” table for each response variable. The “Class Means” table includes the following information for each CLASS variable value (level):

- N, which is the number of observations
- Mean of the response variable

The “Analysis of Variance” table includes the following information for each Source of variation (Among classes and Within classes):

- DF, which is the degrees of freedom associated with the source
- Sum of Squares
- Mean Square, which is the sum of squares divided by the degrees of freedom

The “Analysis of Variance” table also includes the following:

- F Value for testing the hypothesis that the class means are equal, which is computed by dividing the Mean Square (Among) by the Mean Square (Within)
- $Pr > F$ , which is the significance probability corresponding to the F Value

For each score type that you specify, PROC NPAR1WAY displays a “Class Scores” table. The available score types include Wilcoxon, median, Van der Waerden (normal), Savage, Siegel-Tukey, Ansari-Bradley, Klotz, Mood, Conover, and raw data scores. PROC NPAR1WAY computes the scores for the response variable values and classifies the scored observations according to the CLASS variable values. The “Class Scores” table includes the following information for each CLASS variable level:

- N, which is the number of observations
- Sum of Scores
- Expected Under H0, which is the expected sum of scores under the null hypothesis of no difference among classes
- Std Dev Under H0, which is the standard deviation under the null hypothesis
- Mean Score

When there are two levels of the CLASS variable, PROC NPAR1WAY displays a “Two-Sample Test” table for each analysis of scores. The “Two-Sample Test” table includes the following information:

- Statistic, which is the sum of scores for the class with the smaller sample size
- Z, which is the standardized test statistic and has an asymptotic standard normal distribution under the null hypothesis
- One-Sided  $Pr < Z$  or One-Sided  $Pr > Z$ , which is the asymptotic one-sided  $p$ -value. This is displayed as  $Pr < Z$  or  $Pr > Z$ , depending on whether Z is  $\leq 0$  or  $> 0$ .
- Two-Sided  $Pr > |Z|$ , which is the asymptotic two-sided  $p$ -value

For Wilcoxon scores, the “Two-Sample Test” table also includes a  $t$  Approximation for the Wilcoxon two-sample test.

If you request an exact test by specifying the score type in the EXACT statement, the “Two-Sample Test” table also includes the following exact  $p$ -values:

- One-Sided  $Pr \leq S$  or One-Sided  $Pr \geq S$ , which is the exact one-sided  $p$ -value. This is displayed as  $Pr \leq S$  or  $Pr \geq S$ , depending on whether  $S \leq \text{Mean}$  or  $S > \text{Mean}$ , where S is the test statistic and Mean is its expected value under the null hypothesis.

- Point  $Pr = S$ , which is the point probability. This is displayed if you specify the **POINT** option in the **EXACT** statement.
- Two-Sided  $Pr \geq |S - \text{Mean}|$ , which is the exact two-sided  $p$ -value

If you request Monte Carlo estimates for a two-sample exact test by specifying the **MC** option in the **EXACT** statement, PROC NPAR1WAY displays the “Monte Carlo Estimates for the Exact Test” table, which includes the following information:

- Estimate of One-Sided  $Pr \leq S$  or One-Sided  $Pr \geq S$ , which is the exact one-sided  $p$ -value, together with its Lower and Upper Confidence Limits
- Estimate of Two-Sided  $Pr \geq |S - \text{Mean}|$ , which is the exact two-sided  $p$ -value, together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimates
- Initial Seed used to compute the Monte Carlo estimates

For both two-sample and multisample data, PROC NPAR1WAY displays a “One-Way Analysis” table, which includes the following information:

- Chi-Square, which is the one-way ANOVA statistic for testing the null hypothesis of no difference among classes
- DF, which is the degrees of freedom
- $Pr > \text{Chi-Square}$ , which is the asymptotic  $p$ -value

For multisample data, if you request an exact test by specifying the score type in the **EXACT** statement, the “One-Way Analysis” table also displays the exact  $p$ -value as follows:

- Exact  $Pr \geq \text{Chi-Square}$
- Exact  $Pr = \text{Chi-Square}$ , which is the point probability. This is displayed if you specify the **POINT** option in the **EXACT** statement.

For multisample data, if you specify the **MC** option in the **EXACT** statement, PROC NPAR1WAY displays the following information in the “Monte Carlo Estimate for the Exact Test” table:

- Estimate of Exact  $Pr \geq \text{Chi-Square}$ , together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimate
- Initial Seed used to compute the Monte Carlo estimate

If you specify the **HL** option for two-sample data, PROC NPAR1WAY produces a “Hodges-Lehmann Estimation” table, which includes the following information:

- Location Shift estimate
- Confidence Limits for the Location Shift
- Confidence Interval Midpoint
- Asymptotic Standard Error estimate, which is based on the confidence interval

If you request exact Hodges-Lehmann confidence limits by specifying the HL option in the **EXACT** statement, the “Hodges-Lehmann Estimation” table also includes Exact Confidence Limits and the exact Interval Midpoint.

If you specify the **FP** option for two-sample data, PROC NPAR1WAY produces the “Fligner-Policello Placements” table and the “Fligner-Policello Test” table. The “Fligner-Policello Placements” table includes the following information for each **CLASS** variable level:

- N, which is the number of observations
- Sum, which is the sum of the placements
- Mean, which is the average placement
- Std Dev, which is the standard deviation of the placements

The “Fligner-Policello Test” table includes the following information:

- Difference, which is the difference in placement sums between the two **CLASS** levels (samples)
- Statistic ( $Z$ ), which is the standardized test statistic and has an asymptotic standard normal distribution under the null hypothesis
- One-Sided  $\Pr < Z$  or One-Sided  $\Pr > Z$ , which is the one-sided  $p$ -value. This is displayed as  $\Pr < Z$  or  $\Pr > Z$ , depending on whether  $Z$  is  $\leq 0$  or  $> 0$ .
- Two-Sided  $\Pr > |Z|$ , which is the two-sided  $p$ -value

If you specify the **DSCF** option for multisample data, PROC NPAR1WAY produces the “Pairwise Two-Sided Multiple Comparison Analysis” table, which includes the following information for each two-sample comparison:

- Comparison, which identifies the two **CLASS** levels that are compared
- Wilcoxon  $Z$ , which is the standardized two-sample Wilcoxon statistic
- DSCF Value, which is the Dwass, Steel, Critchlow-Fligner statistic
- $\Pr > \text{DSCF}$ , which is the two-sided  $p$ -value

If you specify the **EDF** option, PROC NPAR1WAY produces tables for the Kolmogorov-Smirnov test, the Cramér-von Mises test, and for two-sample data only, the Kuiper test.

The “Kolmogorov-Smirnov Test” table includes the following information for each **CLASS** variable level:

- N, which is the number of observations
- EDF at Maximum, which is the value of the class EDF (empirical distribution function) at its maximum deviation from the pooled EDF
- Deviation from Mean at Maximum, which is the value of  $\sqrt{n_i} \sqrt{F_i - F}$  at its maximum, where  $n_i$  is the class sample size,  $F_i$  is the class EDF, and  $F$  is the pooled EDF

The “Kolmogorov-Smirnov Test” table displays the following statistics:

- KS, which is the Kolmogorov-Smirnov statistic
- KSa, which is the asymptotic Kolmogorov-Smirnov statistic,  $KSa = \sqrt{n}$  KS

For two-sample data, the “Kolmogorov-Smirnov Test” table also displays the following statistics:

- Pr > KSa, which is the asymptotic  $p$ -value for KSa and equals Pr > D
- D, which is the two-sample Kolmogorov-Smirnov statistic,  $\max_j |F_1(x_j) - F_2(x_j)|$

If you specify the **D** option for two-sample data, PROC NPAR1WAY displays the following one-sided Kolmogorov-Smirnov statistics and their asymptotic  $p$ -values in the “Kolmogorov-Smirnov Two-Sample Test” table:

- D+, which is  $\max_j (F_1(x_j) - F_2(x_j))$
- Pr > D+
- D-, which is  $\max_j (F_2(x_j) - F_1(x_j))$
- Pr > D-

For two-sample data, if you request an exact Kolmogorov-Smirnov test by specifying the **KS** option in the **EXACT** statement, PROC NPAR1WAY displays the following exact  $p$ -values in the “Kolmogorov-Smirnov Two-Sample Test” table:

- Exact Pr  $\geq$  D
- Exact Pr  $\geq$  D+
- Exact Pr  $\geq$  D-
- Exact Point Pr = D, Exact Point Pr = D+, and Exact Point Pr = D-, if you specify the **POINT** option in the **EXACT** statement

If you request Monte Carlo estimates for the two-sample exact Kolmogorov-Smirnov test, PROC NPAR1WAY displays the following information in the “Kolmogorov-Smirnov Two-Sample Test” table:

- Estimate of Exact  $\Pr \geq D$ , together with its Lower and Upper Confidence Limits
- Estimate of Exact  $\Pr \geq D+$ , together with its Lower and Upper Confidence Limits
- Estimate of Exact  $\Pr \geq D-$ , together with its Lower and Upper Confidence Limits
- Number of Samples used to compute the Monte Carlo estimates
- Initial Seed used to compute the Monte Carlo estimates

The “Cramér–von Mises Test” table includes the following information for each CLASS variable level:

- N, which is the number of observations
- Summed Deviation from Mean, which is  $(n_i/n) \sum_{j=1}^p t_j (F_i(x_j) - F(x_j))^2$

The “Cramér–von Mises Statistics” table displays the following statistics:

- CM, which is the Cramér–von Mises statistic
- CMa, which is the asymptotic Cramér–von Mises statistic,  $CMa = n CM$

For two-sample data, PROC NPAR1WAY displays the “Kuiper Test” table, which includes the following information for each CLASS variable level:

- N, which is the number of observations
- Deviation from Mean, which is  $\max_j |F_1(x_j) - F_2(x_j)|$

The “Kuiper Two-Sample Statistics” table displays the following statistics:

- K, which is the Kuiper two-sample test statistic
- Ka, which is the asymptotic Kuiper two-sample test statistic,  $Ka = K \sqrt{n_1 n_2 / n}$
- $\Pr > Ka$

---

## ODS Table Names

PROC NPAR1WAY assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 65.6 lists the ODS table names together with their descriptions and the options required to produce the tables. If you do not specify any analysis options in the PROC NPAR1WAY statement, the procedure provides the ANOVA, WILCOXON, MEDIAN, VW (NORMAL), SAVAGE, and EDF analyses by default.

**Table 65.6** ODS Tables Produced by PROC NPAR1WAY

| ODS Table Name     | Description                                                 | Statement | Option           |
|--------------------|-------------------------------------------------------------|-----------|------------------|
| ANOVA              | Analysis of variance                                        | PROC      | ANOVA            |
| ABAnalysis         | Ansari-Bradley one-way analysis                             | PROC      | AB               |
| ABMC               | Monte Carlo estimates for the Ansari-Bradley exact test     | EXACT     | AB / MC          |
| ABScores           | Ansari-Bradley scores                                       | PROC      | AB               |
| ABTest*            | Ansari-Bradley two-sample test                              | PROC      | AB               |

\*\*PROC NPAR1WAY produces this table only for multisample data.

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, you can request specific plots with the PLOTS= option in the PROC NPAR1WAY statement. If you do not specify the PLOTS= option but have enabled ODS Graphics, PROC NPAR1WAY produces all plots that are associated with the analyses that you request.

PROC NPAR1WAY assigns a name to each graph that it creates with ODS Graphics. You can use these names to refer to the graphs. Table 65.7 lists the names of the graphs that PROC NPAR1WAY generates together with their descriptions and the options that are required to produce the graphs.

**Table 65.7** Graphs Produced by PROC NPAR1WAY

| ODS Graph Name    | Description                              | Option      |
|-------------------|------------------------------------------|-------------|
| ABBoxPlot         | Box plot of Ansari-Bradley scores        | AB          |

| WilcoxonBoxPlot   | Box plot of Wilcoxon scores              | WILCOXON    |

## Examples: NPAR1WAY Procedure

### Example 65.1: Two-Sample Location Tests and Plots

Fifty-nine female patients with rheumatoid arthritis who participated in a clinical trial were assigned to two groups, active and placebo. The response status (excellent=5, good=4, moderate=3, fair=2, poor=1) of each patient was recorded.

The following SAS statements create the data set *Arthritis*, which contains the observed status values for all the patients. The variable *Treatment* denotes the treatment received by a patient, and the variable *Response* contains the response status of the patient. The variable *Freq* contains the frequency of the observation, which is the number of patients with the *Treatment* and *Response* combination.

```
data Arthritis;
 input Treatment $ Response Freq @@;
 datalines;
 Active 5 5 Active 4 11 Active 3 5 Active 2 1 Active 1 5
 Placebo 5 2 Placebo 4 4 Placebo 3 7 Placebo 2 7 Placebo 1 12
 ;
```

The following PROC NPAR1WAY statements test the null hypothesis that there is no difference in the patient response status against the alternative hypothesis that the patient response status differs in the two treatment groups. The WILCOXON option requests the Wilcoxon test for difference in location, and the MEDIAN option requests the median test for difference in location. The variable *Treatment* is the CLASS variable, and the VAR statement specifies that the variable *Response* is the analysis variable.

The PLOTS= option requests a box plot of the Wilcoxon scores and a median plot for Response classified by Treatment. ODS Graphics must be enabled before producing plots.

```
ods graphics on;
proc nparlway data=Arthritis wilcoxon median
 plots=(wilcoxonboxplot medianplot);
 class Treatment;
 var Response;
 freq Freq;
run;
ods graphics off;
```

Output 65.1.1 shows the results of the Wilcoxon analysis. The Wilcoxon two-sample test statistic equals 999.0, which is the sum of the Wilcoxon scores for the smaller sample (Active). This sum is greater than 810.0, which is the expected value under the null hypothesis of no difference between the two samples, Active and Placebo. The one-sided  $p$ -value is 0.0016, which indicates that the patient response for the Active treatment is significantly more than for the Placebo group.

### Output 65.1.1 Wilcoxon Two-Sample Test

| The NPAR1WAY Procedure                                                                |    |                  |                      |                     |               |

| Pr > Chi-Square                                                                       |    | 0.0031           |                      |                     |               |

Output 65.1.2 displays the box plot of Wilcoxon scores classified by Treatment, which corresponds to the Wilcoxon analysis in Output 65.1.1. To remove the  $p$ -values from the box plot display, you can specify the NOSTATS plot option in parentheses after the WILCOXONBOXPLOT option.

**Output 65.1.2** Box Plot of Wilcoxon Scores

Output 65.1.3 shows the results of the median two-sample test. The test statistic equals 18.9167, and its standardized  $Z$  value is 3.2667. The one-sided  $p$ -value  $\Pr > Z$  equals 0.0005. This supports the alternative hypothesis that the effect of the Active treatment is greater than that of the Placebo.

Output 65.1.4 displays the median plot for the analysis of Response classified by Treatment. The median plot is a stacked bar chart showing the frequencies above and below the overall median. This plot corresponds to the median scores analysis in Output 65.1.3.

**Output 65.1.3** Median Two-Sample Test

## Example 65.2: EDF Statistics and EDF Plot

This example uses the SAS data set *Arthritis* created in [Example 65.1](#). The data set contains the variable *Treatment*, which denotes the treatment received by a patient, and the variable *Response*, which contains the response status of the patient. The variable *Freq* contains the frequency of the observation, which is the number of patients with the *Treatment* and *Response* combination.

The following statements request empirical distribution function (EDF) statistics, which test whether the distribution of a variable is the same across different groups. The *EDF* option requests the EDF analysis. The variable *Treatment* is the *CLASS* variable, and the variable *Response* specified in the *VAR* statement is the analysis variable. The *FREQ* statement names *Freq* as the frequency variable.

The *PLOTS=* option requests an EDF plot for *Response* classified by *Treatment*. ODS Graphics must be enabled before producing plots.

```
ods graphics on;
proc npar1way edf plots=edfplot data=Arthritis;
 class Treatment;
 var Response;
 freq Freq;
run;
ods graphics off;
```

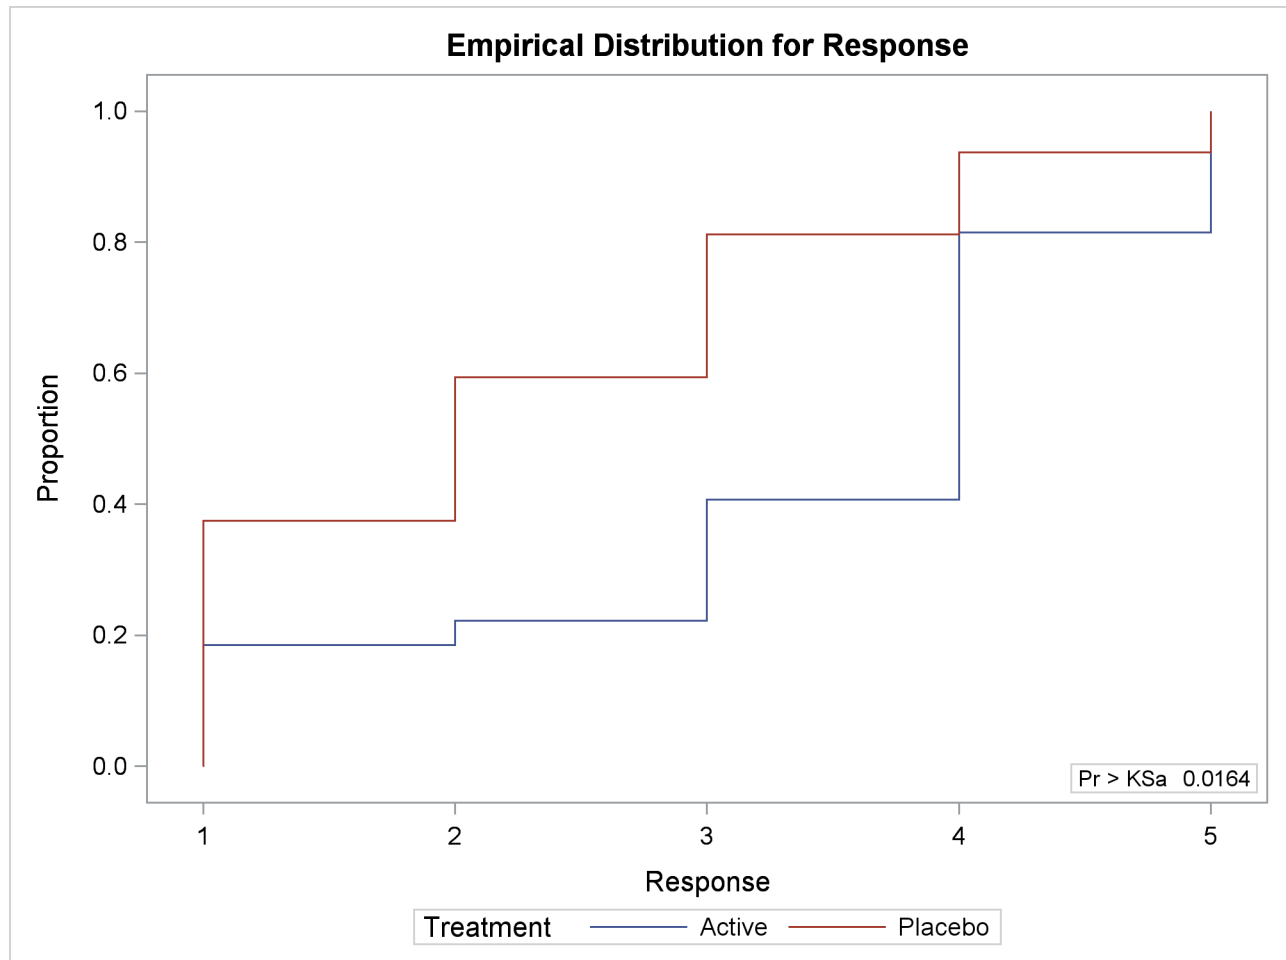

[Output 65.2.1](#) shows EDF statistics that compare the two levels of *Treatment*, *Active* and *Placebo*. The asymptotic *p*-value for the Kolmogorov-Smirnov test is 0.0164. This supports rejection of the null hypothesis that the distributions are the same for the two samples.

[Output 65.2.2](#) shows the EDF plot for *Response* classified by *Treatment*.

**Output 65.2.2** Empirical Distribution Function Plot

### Example 65.3: Exact Wilcoxon Two-Sample Test

Researchers conducted an experiment to compare the effects of two stimulants. Thirteen randomly selected subjects received the first stimulant, and six randomly selected subjects received the second stimulant. The reaction times (in minutes) were measured while the subjects were under the influence of the stimulants.

The following SAS statements create the data set `React`, which contains the observed reaction times for each stimulant. The variable `Stim` represents Stimulant 1 or 2. The variable `Time` contains the reaction times observed for subjects under the stimulant.

```
data React;
 input Stim Time @@;
 datalines;
 1 1.94 1 1.94 1 2.92 1 2.92 1 2.92 1 2.92 1 3.27
 1 3.27 1 3.27 1 3.27 1 3.70 1 3.70 1 3.74
 2 3.27 2 3.27 2 3.27 2 3.70 2 3.70 2 3.74
 ;
```

The following statements request a Wilcoxon test of the null hypothesis that there is no difference between the effects of the two stimulants. `Stim` is the CLASS variable, and `Time` is the analysis variable. The

WILCOXON option requests an analysis of Wilcoxon scores. The CORRECT=NO option removes the continuity correction from the computation of the standardized  $z$  test statistic. The WILCOXON option in the EXACT statement requests exact  $p$ -values for the Wilcoxon test. Because the sample size is small, the large-sample normal approximation might not be adequate, and it is appropriate to compute the exact test. These statements produce the results shown in Output 65.3.1.

```
proc npar1way wilcoxon correct=no data=React;
 class Stim;
 var Time;
 exact wilcoxon;
run;
```

Output 65.3.1 displays the results of the Wilcoxon two-sample test. The Wilcoxon statistic equals 79.50. Since this value is greater than 60.0, the expected value under the null hypothesis, PROC NPAR1WAY displays the right-sided  $p$ -values. The normal approximation for the Wilcoxon two-sample test yields a one-sided  $p$ -value of 0.0382 and a two-sided  $p$ -value of 0.0764. For the exact Wilcoxon test, the one-sided  $p$ -value is 0.0527, and the two-sided  $p$ -value is 0.1054.

**Output 65.3.1** Wilcoxon Two-Sample Test

| The NPAR1WAY Procedure                                                       |    |                  |                      |                     |               |

## Example 65.4: Hodges-Lehmann Estimation

This example uses the SAS data set `React` created in [Example 65.3](#). The data set contains the variable `Stim`, which represents Stimulant 1 or 2, and the variable `Time`, which contains the reaction times observed for subjects under the stimulant.

The following statements request Hodges-Lehmann estimation of the location shift between the two groups. `Stim` is the CLASS variable, and `Time` is the analysis variable. The `HL` option requests Hodges-Lehmann estimation. The `ALPHA=` option sets the confidence level for the Hodges-Lehmann confidence limits. The `HL` option in the `EXACT` statement requests exact confidence limits for the estimate of location shift. The `ODS SELECT` statement selects which tables to display. [Output 65.4.1](#) shows the Hodges-Lehmann results.

```
proc npar1way hl alpha=.02 data=React;
 class Stim;
 var Time;
 exact hl;
 ods select WilcoxonScores HodgesLehmann;
run;
```

The `HL` option invokes the `WILCOXON` option, which produces a table of Wilcoxon scores ([Output 65.4.1](#)). The Hodges-Lehmann estimate of location shift is 0.35, and the asymptotic confidence limits are 0.00 and 0.82. The confidence interval midpoint equals 0.41, which can also be used as an estimate of the location shift. The ASE estimate of 0.1762 is based on the length of the confidence interval. The exact confidence limits are 0.00 and 1.33.

**Output 65.4.1** Hodges-Lehmann Estimate of Location Shift

## Example 65.5: Exact Savage Multisample Test

A researcher conducting a laboratory experiment randomly assigned 15 mice to receive one of three drugs. The survival time (in days) was then recorded.

The following SAS statements create the data set `Mice`, which contains the observed survival times for the mice. The variable `Treatment` denotes the treatment received. The variable `Days` contains the number of days the mouse survived.

```
data Mice;
 input Treatment $ Days @@;
 datalines;
1 1 1 1 1 3 1 3 1 4
2 3 2 4 2 4 2 4 2 15
3 4 3 4 3 10 3 10 3 26
;
```

The following statements request a Savage test of the null hypothesis that there is no difference in survival time among the three drugs. `Treatment` is the CLASS variable, and `Days` is the analysis variable. The SAVAGE option requests an analysis of Savage scores. The SAVAGE option in the EXACT statement requests exact  $p$ -values for the Savage test. Because the sample size is small, the large-sample normal approximation might not be adequate, and it is appropriate to compute the exact test.

PROC NPAR1WAY tests the null hypothesis that there is no difference in the survival times among the three drugs against the alternative hypothesis of difference among the drugs. The SAVAGE option specifies an analysis based on Savage scores. The variable `Treatment` is the CLASS variable, and the variable `Days` is the response variable. The EXACT statement requests the exact Savage test.

```
proc npar1way savage data=Mice;
 class Treatment;
 var Days;
 exact savage;
run;
```

Output 65.5.1 shows the results of the Savage test. The exact  $p$ -value is 0.0445, which supports a difference in survival times among the drugs at the 0.05 level. The asymptotic  $p$ -value based on the chi-square approximation is 0.0638.

## Output 65.5.1 Savage Multisample Exact Test

### Overview: ORTHOREG Procedure

The ORTHOREG procedure fits general linear models by the method of least squares. Other SAS/STAT software procedures, such as the GLM and REG procedures, fit the same types of models, but PROC

ORTHOREG can produce more accurate estimates than other regression procedures when your data are ill-conditioned. Instead of collecting crossproducts, PROC ORTHOREG uses Gentleman-Givens transformations to update and compute the upper triangular matrix  $\mathbf{R}$  of the QR decomposition of the data matrix, with special care for scaling (Gentleman 1972, 1973). This method has the advantage over other orthogonalization methods (for example, Householder transformations) of not requiring the data matrix to be stored in memory.

The standard SAS regression procedures (PROC REG and PROC GLM) are very accurate for most problems. However, if you have very ill-conditioned data, these procedures can produce estimates that yield an error sum of squares very close to the minimum but still different from the exact least squares estimates. Normally, this coincides with estimates that have very high standard errors. In other words, the numerical error is much smaller than the statistical standard error.

PROC ORTHOREG fits models by the method of linear least squares, minimizing the sum of the squared residuals for predicting the responses—that is, the distance between the regression line and the observed  $Y$ s. The “ORTHO” in the name of the procedure refers to the orthogonalization approach to solving the least squares equations. In particular, PROC ORTHOREG does *not* perform the modeling method known as “orthogonal regression,” which minimizes a different criterion (namely, the distance between the regression line and the  $X/Y$  points taken together.)

---

## Getting Started: ORTHOREG Procedure

---

### Longley Data

The labor statistics data set of Longley (1967) is noted for being ill-conditioned. Both the ORTHOREG and GLM procedures are applied for comparison (only portions of the PROC GLM results are shown).

**NOTE:** The results from this example vary from machine to machine, depending on floating-point configuration.

The following statements read the data into the SAS data set Longley:

```

title 'PROC ORTHOREG used with Longley data';
data Longley;
 input Employment Prices GNP Jobless Military PopSize Year;
 datalines;
60323 83.0 234289 2356 1590 107608 1947

68655 112.6 482704 3813 2552 123366 1959

```

```

69564 114.2 502601 3931 2514 125368 1960
69331 115.7 518173 4806 2572 127852 1961
70551 116.9 554894 4007 2827 130081 1962
;

```

The data set contains one dependent variable, Employment (total derived employment), and six independent variables: Prices (GNP implicit price deflator normalized to the value 100 in 1954), GNP (gross national product), Jobless (unemployment), Military (size of armed forces), PopSize (noninstitutional population aged 14 and over), and Year (year).

The following statements use the ORTHOREG procedure to model the Longley data by using a quadratic model in each independent variable, without interaction:

```

proc orthoreg data=Longley;
 model Employment = Prices Prices*Prices
 GNP GNP*GNP
 Jobless Jobless*Jobless
 Military Military*Military
 PopSize PopSize*PopSize
 Year Year*Year;
run;

```

Figure 66.1 shows the resulting analysis.

The estimates in Figure 66.1 compare very well with the best estimates available; for additional information, see Longley (1967) and Beaton, Rubin, and Barone (1976).

The following statements request the same analysis from the GLM procedure:

```
proc glm data=Longley;
 model Employment = Prices Prices*Prices
 GNP GNP*GNP
 Jobless Jobless*Jobless
 Military Military*Military
 PopSize PopSize*PopSize
 Year Year*Year;
 ods select OverallANOVA
 FitStatistics
 ParameterEstimates
 Notes;
run;
```

Figure 66.2 contains the overall ANOVA table and the parameter estimates produced by PROC GLM. Notice that the PROC ORTHOREG fit achieves a somewhat smaller root mean square error (RMSE) and also that the GLM procedure detects spurious singularities.

Figure 66.2 Partial PROC GLM Results

PROC ORTHOREG used with Longley data

The GLM Procedure

Dependent Variable: Employment

| Source          | DF | Sum of Squares | Mean Square | F Value | Pr > F |
|-----------------|----|----------------|-------------|---------|--------|
| Model           | 11 | 184791061.6    | 16799187.4  | 308.58  | <.0001 |
| Error           | 4  | 217764.4       | 54441.1     |         |        |

| PopSize           | -4.246         | 5.156          | -0.82   | 0.4565  |
| PopSize*PopSize   | 0.000 B        | 0.000          | 0.81    | 0.4655  |
| Year              | 0.000 B        | .              | .       | .       |
| Year*Year         | 1.038          | 0.419          | 2.48    | 0.0683  |

NOTE: The X'X matrix has been found to be singular, and a generalized inverse was used to solve the normal equations. Terms whose estimates are followed by the letter 'B' are not uniquely estimable.

## Syntax: ORTHOREG Procedure

The following statements are available in the ORTHOREG procedure:

```

PROC ORTHOREG < options > ;
 CLASS variables < / option > ;
 MODEL dependent-variable = independent-effects < / option > ;
 BY variables ;
 EFFECT name = effect-type (variables < / options >) ;
 EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
 ESTIMATE < 'label' > estimate-specification < / options > ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL= 'label' > ;
 TEST < model-effects > < / options > ;
 WEIGHT variable ;

```

The **BY**, **CLASS**, **MODEL**, and **WEIGHT** statements are described in full after the **PROC ORTHOREG** statement in alphabetical order. The **EFFECT**, **EFFECTPLOT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **SLICE**, **STORE**, and **TEST** statements are common to many procedures. Summary descriptions of functionality and syntax for these statements are also given after the **PROC ORTHOREG** statement in alphabetical order, and full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

## PROC ORTHOREG Statement

```
PROC ORTHOREG < options > ;
```

The **PROC ORTHOREG** statement invokes the ORTHOREG procedure. Table 66.1 summarizes the options available in the **PROC ORTHOREG** statement.

**Table 66.1** PROC ORTHOREG Statement Options

| Option           | Description                                       |
|------------------|---------------------------------------------------|
| <b>DATA=</b>     | Specifies the input SAS data set                  |
| <b>NOPRINT</b>   | Suppresses the normal display of results          |
| <b>ORDER=</b>    | Specifies the order in which to sort class levels |
| <b>OUTEST=</b>   | Produces an output data set                       |
| <b>SINGULAR=</b> | Specifies the singularity criterion               |

The **PROC ORTHOREG** statement has the following options:

**DATA=SAS-data-set**

specifies the input SAS data set to use. By default, the procedure uses the most recently created SAS data set. The data set specified cannot be a **TYPE=CORR**, **TYPE=COV**, or **TYPE=SSCP** data set.

**NOPRINT**

suppresses the normal display of results. This option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System” for more information.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This ordering determines which parameters in the model correspond to each level in the data, so the **ORDER=** option may be useful when you use **ESTIMATE** statement. This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

| Value of <b>ORDER=</b> | Levels Sorted By                                                                                                                       |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>            | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>            | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>        | Unformatted value                                                                                                                      |

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent.

For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of **BY**-group processing in *SAS Language Reference: Concepts*.

**OUTEST=SAS-data-set**

produces an output data set that contains the parameter estimates, the **BY** variables, and the special variables **\_TYPE\_** (value “**PARMS**”), **\_NAME\_** (blank), and **\_RMSE\_** (root mean squared error).

**SINGULAR=s**

specifies a singularity criterion ( $s \geq 0$ ) for the inversion of the triangular matrix **R**. By default, **SINGULAR=1E-12**.

---

## BY Statement

**BY variables ;**

You can specify a **BY** statement with **PROC ORTHOREG** to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the ORTHOREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* <(REF= *option*)> ... <*variable* <(REF= *option*)>> </ *global-options* > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC ORTHOREG statement. You can specify the following REF= option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

### REF= '*level*' | FIRST | LAST

specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC ORTHOREG's singular parameterization. You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify REF=FIRST to designate that the first ordered level serve as the reference, or REF=LAST to designate that the last ordered level serve as the reference. To specify that REF=FIRST or REF=LAST be used for all classification variables, use the REF= *global-option* after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

**REF=FIRST | LAST**

specifies a level of all classification variables to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC ORTHOREG's singular parameterization. Specify REF=FIRST to designate that the first ordered level for each classification variable serve as the reference. Specify REF=LAST to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use REF= options for individual variables.

**TRUNCATE**

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

---

## EFFECT Statement

**EFFECT** *name=effect-type* (*variables* < / *options* >);

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>COLLECTION</b>        | is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.       |
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                           |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                             |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 66.2 summarizes the *options* available in the EFFECT statement.

**Table 66.2** EFFECT Statement Options

| Option                            | Description                                        |
|-----------------------------------|----------------------------------------------------|
| <b>Collection Effects Options</b> |                                                    |
| <b>DETAILS</b>                    | Displays the constituents of the collection effect |

Table 66.2 continued

| Option                             | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Lag Effects Options</b>         |                                                                                                                                                      |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                        |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                            |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                           |
| PERIOD=                            | Names the variable that defines the period                                                                                                           |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                            |
| <b>Multimember Effects Options</b> |                                                                                                                                                      |
| NOEFFECT                           | Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                            |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                      |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                               |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                             |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                              |
| <b>Spline Effects Options</b>      |                                                                                                                                                      |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                              |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                    |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                              |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

## EFFECTPLOT Statement

**EFFECTPLOT** < *plot-type* < (*plot-definition-options*) > > < / *options* > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 66.3 describes the available *plot-types* and their *plot-definition-options*.

**Table 66.3** *Plot-Types and Plot-Definition-Options*

| <b>Plot-Type and Description</b>                                                                                                                                                                                                          | <b>Plot-Definition-Options</b>                                                                                                     |
|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>BOX</b><br/>Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the <b>INTERACTION</b> <i>plot-type</i>.</p>     | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>X=</b> CLASS variable or effect</p>                                              |
| <p><b>CONTOUR</b><br/>Displays a contour plot of predicted values against two continuous covariates.</p>                                                                                                                                  | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>X=</b> continuous variable<br/><b>Y=</b> continuous variable</p>                 |
| <p><b>FIT</b><br/>Displays a curve of predicted values versus a continuous variable.</p>                                                                                                                                                  | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>X=</b> continuous variable</p>                                                   |
| <p><b>INTERACTION</b><br/>Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.</p> | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>SLICEBY=</b> variable or CLASS effect<br/><b>X=</b> CLASS variable or effect</p> |
| <p><b>SLICEFIT</b><br/>Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.</p>                                                                                                     | <p><b>PLOTBY=</b> variable or CLASS effect<br/><b>SLICEBY=</b> variable or CLASS effect<br/><b>X=</b> continuous variable</p>      |

For full details about the syntax and options of the EFFECTPLOT statement, see the section “EFFECTPLOT Statement” on page 411 in Chapter 19, “Shared Concepts and Topics.”

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 <, ... <'label'> estimate-specification <(divisor=n)>>
 </options>;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $\mathbf{L}\boldsymbol{\beta}$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 66.4 summarizes the options available in the ESTIMATE statement.

**Table 66.4** ESTIMATE Statement Options

| Option                                                     | Description                                                               |
|------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                           |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                     |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects |
| SINGULAR=                                                  | Tunes the estimability checking difference                                |
| <b>Degrees of Freedom and <math>p</math>-values</b>        |                                                                           |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates     |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                          |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                |
| STEPDOWN                                                   | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                      |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                |
| <b>Statistical Output</b>                                  |                                                                           |
| CL                                                         | Constructs confidence limits                                              |
| CORR                                                       | Displays the correlation matrix of estimates                              |
| COV                                                        | Displays the covariance matrix of estimates                               |
| E                                                          | Prints the $\mathbf{L}$ matrix                                            |
| JOINT                                                      | Produces a joint $F$ or chi-square test for the estimable functions       |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers         |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## LSMEANS Statement

**LSMEANS** < model-effects > < / options > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 66.5 summarizes the options available in the LSMEANS statement.

**Table 66.5** LSMEANS Statement Options

| Option                                          | Description                                                                                 |
|-------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                                                             |
| AT                                              | Modifies the covariate value in computing LS-means                                          |
| BYLEVEL                                         | Computes separate margins                                                                   |
| DIFF                                            | Requests differences of LS-means                                                            |
| OM=                                             | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| SINGULAR=                                       | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <i>p</i>-values</b>   |                                                                                             |
| ADJUST=                                         | Determines the method for multiple-comparison adjustment of LS-means differences            |
| ALPHA= $\alpha$                                 | Determines the confidence level $(1 - \alpha)$                                              |
| STEPDOWN                                        | Adjusts multiple-comparison <i>p</i> -values further in a step-down fashion                 |
| <b>Statistical Output</b>                       |                                                                                             |
| CL                                              | Constructs confidence limits for means and mean differences                                 |
| CORR                                            | Displays the correlation matrix of LS-means                                                 |
| COV                                             | Displays the covariance matrix of LS-means                                                  |
| E                                               | Prints the L matrix                                                                         |
| LINES                                           | Produces a “Lines” display for pairwise LS-means differences                                |
| MEANS                                           | Prints the LS-means                                                                         |
| PLOTS=                                          | Requests graphs of means and mean comparisons                                               |
| SEED=                                           | Specifies the seed for computations that depend on random numbers                           |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 in Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 66.6 summarizes the options available in the LSMESTIMATE statement.

**Table 66.6** LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level $(1 - \alpha)$                                      |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |
| <b>Statistical Output</b>                           |                                                                                     |
| CL                                                  | Constructs confidence limits for means and mean differences                         |
| CORR                                                | Displays the correlation matrix of LS-means                                         |
| COV                                                 | Displays the covariance matrix of LS-means                                          |
| E                                                   | Prints the <b>L</b> matrix                                                          |
| ELSM                                                | Prints the <b>K</b> matrix                                                          |
| JOINT                                               | Produces a joint $F$ or chi-square test for the LS-means and LS-means differences   |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                   |

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” on page 470 in Chapter 19, “Shared Concepts and Topics.”

---

## MODEL Statement

**MODEL** *dependent-variable = independent-effects* </ option > ;

The MODEL statement names the dependent variable and the independent effects. Only one MODEL statement is allowed. The [specification of effects](#) and the parameterization of the linear model are the same as in the GLM procedure; see Chapter 42, “[The GLM Procedure](#)” for further details.

The following option can be used in the MODEL statement:

### NOINT

omits the intercept term from the model. Often, this omission also changes the total sum of squares in the ANOVA and the value of R square to forms of these statistics that are not corrected for the mean. However, if the model is determined to contain an implicit intercept, in the sense that the all-ones intercept vector is in the column space of the design, then the usual mean-corrected forms of these statistics are used.

---

## SLICE Statement

**SLICE** *model-effect* </ options > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the [LSMEANS](#) statement, which are summarized in [Table 19.21](#). For details about the syntax of the SLICE statement, see the section “[SLICE Statement](#)” on page 498 in Chapter 19, “[Shared Concepts and Topics](#).”

---

## STORE Statement

**STORE** < **OUT=** > *item-store-name* </ **LABEL=** 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “[STORE Statement](#)” on page 501 in Chapter 19, “[Shared Concepts and Topics](#).”

---

## TEST Statement

**TEST** < *model-effects* > </ options > ;

The TEST statement enables you to perform  $F$  tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “[The Four Types of Estimable Functions](#),” for details about the construction of Type I, II, and III estimable functions.

[Table 66.7](#) summarizes the options available in the TEST statement.

**Table 66.7** TEST Statement Options

| Option    | Description                                                |
|-----------|------------------------------------------------------------|
| CHISQ     | Requests chi-square tests                                  |
| DDF=      | Specifies denominator degrees of freedom for fixed effects |
| E         | Requests Type I, Type II, and Type III coefficients        |
| E1        | Requests Type I coefficients                               |
| E2        | Requests Type II coefficients                              |
| E3        | Requests Type III coefficients                             |
| HTYPE=    | Indicates the type of hypothesis test to perform           |
| INTERCEPT | Adds a row that corresponds to the overall intercept       |

For details about the syntax of the TEST statement, see the section “TEST Statement” on page 502 in Chapter 19, “Shared Concepts and Topics.”

---

## WEIGHT Statement

**WEIGHT** *variable* ;

A WEIGHT statement names a variable in the input data set whose values are relative weights for a weighted least squares regression. If the weight value is proportional to the reciprocal of the variance for each observation, the weighted estimates are the best linear unbiased estimates (BLUE). For a more complete description of the WEIGHT statement, see the section “WEIGHT Statement” on page 3323 in the GLM procedure.

---

## Details: ORTHOREG Procedure

---

### Missing Values

If there is a missing value for any model variable in an observation, the entire observation is dropped from the analysis.

---

### Output Data Set

The OUTEST= option produces a TYPE=EST output SAS data set that contains the BY variables, parameter estimates, and four special variables. For each new value of the BY variables, PROC ORTHOREG outputs an observation to the OUTEST= data set. The variables in the data set are as follows:

- parameter estimates for all variables listed in the MODEL statement
- BY variables
- \_TYPE\_, which is a character variable with the value PARMS for every observation

- `_NAME_`, which is a character variable left blank for every observation
- `_RMSE_`, which is the root mean square error (the estimate of the standard deviation of the true errors)
- Intercept, which is the estimated intercept. This variable does not exist in the OUTEST= data set if the `NOINT` option is specified.

---

## Displayed Output

PROC ORTHOREG displays the parameter estimates and associated statistics. These include the following:

- overall model analysis of variance, including the error mean square, which is an estimate of  $\sigma^2$  (the variance of the true errors), and the overall  $F$  test for a model effect.
- root mean square error, which is an estimate of the standard deviation of the true errors. It is calculated as the square root of the mean squared error.
- R square ( $R^2$ ) measures how much variation in the dependent variable can be accounted for by the model. R square, which can range from 0 to 1, is the ratio of the sum of squares for the model to the corrected total sum of squares. In general, the larger the value of R square, the better the model's fit.
- estimates for the parameters in the linear model

The table of parameter estimates consists of the following:

- the terms used as regressors, including the intercept.
- degrees of freedom (DF) for the variable. There is one degree of freedom for each parameter being estimated unless the model is not full rank.
- estimated linear coefficients.
- estimates of the standard errors of the parameter estimates.
- the critical  $t$  values for testing whether the parameters are This is computed as the parameter estimate divided by its standard error.
- the two-sided  $p$ -value for the  $t$  test, which is the probability that a  $t$  statistic would obtain a greater absolute value than that observed given that the true parameter is zero.

---

## ODS Table Names

PROC ORTHOREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in [Table 66.8](#). For more information about ODS, see Chapter 20, “[Using the Output Delivery System.](#)”

Each of the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements also creates tables, which are not listed in Table 66.8. For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

**Table 66.8** ODS Tables Produced by PROC ORTHOREG

| ODS Table Name     | Description                | Statement       |
|--------------------|----------------------------|-----------------|
| ANOVA              | Analysis of variance       | Default         |
| FitStatistics      | Overall statistics for fit | Default         |
| Levels             | Table of class levels      | CLASS statement |
| ParameterEstimates | Parameter estimates        | Default         |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, then each of the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

---

## Examples: ORTHOREG Procedure

---

### Example 66.1: Precise Analysis of Variance

The data for the following example are from Powell, Murphy, and Gramlich (1982). In order to calibrate an instrument for measuring atomic weight, 24 replicate measurements of the atomic weight of silver (chemical symbol Ag) are made with the new instrument and with a reference instrument.

**NOTE:** The results from this example vary from machine to machine, depending on floating-point configuration.

The following statements read the measurements for the two instruments into the SAS data set AgWeight:

```

title 'Atomic Weight of Silver by Two Different Instruments';
data AgWeight;
 input Instrument AgWeight @@;
 datalines;
1 107.8681568 1 107.8681465 1 107.8681572 1 107.8681785
1 107.8681446 1 107.8681903 1 107.8681526 1 107.8681494
1 107.8681616 1 107.8681587 1 107.8681519 1 107.8681486
1 107.8681419 1 107.8681569 1 107.8681508 1 107.8681672
1 107.8681385 1 107.8681518 1 107.8681662 1 107.8681424
1 107.8681360 1 107.8681333 1 107.8681610 1 107.8681477
2 107.8681079 2 107.8681344 2 107.8681513 2 107.8681197
2 107.8681604 2 107.8681385 2 107.8681642 2 107.8681365
2 107.8681151 2 107.8681082 2 107.8681517 2 107.8681448
2 107.8681198 2 107.8681482 2 107.8681334 2 107.8681609
2 107.8681101 2 107.8681512 2 107.8681469 2 107.8681360
2 107.8681254 2 107.8681261 2 107.8681450 2 107.8681368
;

```

Notice that the variation in the atomic weight measurements is several orders of magnitude less than their mean. This is a situation that can be difficult for standard, regression-based analysis-of-variance procedures to handle correctly.

The following statements invoke the ORTHOREG procedure to perform a simple one-way analysis of variance, testing for differences between the two instruments:

```

proc orthoreg data=AgWeight;
 class Instrument;
 model AgWeight = Instrument;
run;

```

Output 66.1.1 shows the resulting analysis.

#### Output 66.1.1 PROC ORTHOREG Results for Atomic Weight Example

| Atomic Weight of Silver by Two Different Instruments |        |          |
|------------------------------------------------------|--------|----------|
| The ORTHOREG Procedure                               |        |          |

Output 66.1.1 *continued*

| Atomic Weight of Silver by Two Different Instruments |    |                    |                |         |         |
|------------------------------------------------------|----|--------------------|----------------|---------|---------|
| The ORTHOREG Procedure                               |    |                    |                |         |         |
| Dependent Variable: AgWeight                         |    |                    |                |         |         |
| Source                                               | DF | Sum of Squares     | Mean Square    | F Value | Pr > F  |
| Model                                                | 1  | 3.6383419E-9       | 3.6383419E-9   | 15.95   | 0.0002  |
| Error                                                | 46 | 1.0495173E-8       | 2.281559E-10   |         |         |
| Corrected Total                                      | 47 | 1.4133515E-8       |                |         |         |
|                                                      |    | Root MSE           | 0.0000151048   |         |         |
|                                                      |    | R-Square           | 0.2574265445   |         |         |
| Parameter                                            | DF | Parameter Estimate | Standard Error | t Value | Pr >  t |
| Intercept                                            | 1  | 107.868136354166   | 3.0832608E-6   | 3.499E7 | <.0001  |
| (Instrument='1')                                     | 1  | 0.00001741249999   | 4.3603893E-6   | 3.99    | 0.0002  |
| (Instrument='2')                                     | 0  | 0                  | .              | .       | .       |

The mean difference between instruments is about  $1.74 \times 10^{-5}$  (the value of the `(Instrument='1')` parameter in the parameter estimates table), whereas the level of background variation in the measurements is about  $1.51 \times 10^{-5}$  (the value of the root mean square error). At this level of error, the difference is significant, with a  $p$ -value of 0.0002.

The National Institute of Standards and Technology (1998) has provided certified ANOVA values for this data set. The following statements use ODS to examine the ANOVA values produced by both the ORTHOREG and GLM procedures more precisely for comparison with the NIST-certified values:

```

ods listing close;

proc orthoreg data=AgWeight;
 class Instrument;
 model AgWeight = Instrument;
 ods output ANOVA = OrthoregANOVA
 FitStatistics = OrthoregFitStat;
run;

proc glm data=AgWeight;
 class Instrument;
 model AgWeight = Instrument;
 ods output OverallANOVA = GLMANOVA
 FitStatistics = GLMFitStat;
run;
ods listing;

data _null_;
 set OrthoregANOVA (in=inANOVA)
 OrthoregFitStat(in=inFitStat);
 if (inANOVA) then do;
 if (Source = 'Model') then put "Model SS: " ss e20.;
 if (Source = 'Error') then put "Error SS: " ss e20.;
 end;
 if (inFitStat) then do;
 if (Statistic = 'Root MSE') then
 put "Root MSE: " nValue1 e20.;
 if (Statistic = 'R-Square') then
 put "R-Square: " nValue1 best20.;
 end;
run;

data _null_;
 set GLMANOVA (in=inANOVA)
 GLMFitStat(in=inFitStat);
 if (inANOVA) then do;
 if (Source = 'Model') then put "Model SS: " ss e20.;
 if (Source = 'Error') then put "Error SS: " ss e20.;
 end;
 if (inFitStat) then put "Root MSE: " RootMSE e20.;
 if (inFitStat) then put "R-Square: " RSquare best20.;
run;

```

In SAS/STAT software prior to SAS 8, PROC GLM gave much less accurate results than PROC ORTHOREG. Table 66.9 and Table 66.10 compare the ANOVA values certified by NIST with those produced by the two procedures.

**Table 66.9** Accuracy Comparison for Sums of Squares

| Values         | Model SS            | Error SS            |
|----------------|---------------------|---------------------|
| NIST-certified | 3.6383418750000E-09 | 1.0495172916667E-08 |
| ORTHOREG       | 3.6383418747907E-09 | 1.0495172916797E-08 |

**Table 66.9** *continued*

| Values            | Model SS            | Error SS            |
|-------------------|---------------------|---------------------|
| GLM, since SAS 8  | 3.6383418747907E-09 | 1.0495172916797E-08 |
| GLM, before SAS 8 | 0                   | 1.0331496763990E-08 |

**Table 66.10** Accuracy Comparison for Fit Statistics

| Values            | Root MSE            | R Square         |
|-------------------|---------------------|------------------|
| NIST-certified    | 1.5104831444641E-05 | 0.25742654453832 |
| ORTHOREG          | 1.5104831444735E-05 | 0.25742654452494 |
| GLM, since SAS 8  | 1.5104831444735E-05 | 0.25742654452494 |
| GLM, before SAS 8 | 1.4986585859992E-05 | 0                |

Although the PROC ORTHOREG values and the PROC GLM values for the current version are quite close to the certified ones, the PROC GLM values for releases prior to SAS 8 are not. In fact, since the model sum of squares is so small, in prior releases the GLM procedure set it (and consequently R square) to zero.

## Example 66.2: Wampler Data

This example applies the ORTHOREG procedure to a collection of data sets noted for being ill-conditioned. The `OUTEST=` data set is used to collect the results for comparison with values certified to be correct by the National Institute of Standards and Technology (1998).

**NOTE:** The results from this example vary from machine to machine, depending on floating-point configuration.

The data are from Wampler (1970). The independent variates for all five data sets are  $x^i$ ,  $i = 1, \dots, 5$ , for  $x = 0, 1, \dots, 20$ . Two of the five dependent variables are exact linear functions of the independent terms:

$$y_1 = 1 + x + x^2 + x^3 + x^4 + x^5$$

$$y_2 = 1 + 0.1x + 0.01x^2 + 0.001x^3 + 0.0001x^4 + 0.00001x^5$$

The other three dependent variables have the same mean value as  $y_1$ , but with nonzero errors:

$$y_3 = y_1 + e$$

$$y_4 = y_1 + 100e$$

$$y_5 = y_1 + 10000e$$

where  $e$  is a vector of values with standard deviation  $\sim 2044$ , chosen to be orthogonal to the mean model for  $y_1$ .

The following statements create a SAS data set Wampler that contains the Wampler data, run a SAS macro program that uses PROC ORTHOREG to fit a fifth-order polynomial in  $x$  to each of the Wampler dependent variables, and collect the results in a data set named ParmEst:

```

data Wampler;
 do x=0 to 20;
 input e @@;
 y1 = 1 + x + x**2 + x**3
 + x**4 + x**5;
 y2 = 1 + .1 *x + .01 *x**2 + .001*x**3
 + .0001*x**4 + .00001*x**5;
 y3 = y1 + e;
 y4 = y1 + 100*e;
 y5 = y1 + 10000*e;
 output;
 end;
 datalines;
759 -2048 2048 -2048 2523 -2048 2048 -2048 1838 -2048 2048
-2048 1838 -2048 2048 -2048 2523 -2048 2048 -2048 759
;

%macro WTest;
 data ParmEst; if (0); run;
 %do i = 1 %to 5;
 proc orthoreg data=Wampler outest=ParmEst&i noprint;
 model y&i = x *x *x*x*x *x*x*x*x*x *x*x*x*x*x*x;
 data ParmEst&i; set ParmEst&i; Dep = "y&i";
 data ParmEst; set ParmEst ParmEst&i;
 label Col1='x' Col2='x**2' Col3='x**3'
 Col4='x**4' Col5='x**5';
 run;
 %end;
%mend;
%WTest;

```

Instead of displaying the raw values of the RMSE and parameter estimates, use an additional DATA step as follows to compute the deviations from the values certified to be correct by the National Institute of Standards and Technology (1998):

```

data ParmEst; set ParmEst;
 if (Dep = 'y1') then
 RMSE = _RMSE_ - 0.000000000000000;
 else if (Dep = 'y2') then
 RMSE = _RMSE_ - 0.000000000000000;
 else if (Dep = 'y3') then
 RMSE = _RMSE_ - 2360.14502379268;
 else if (Dep = 'y4') then
 RMSE = _RMSE_ - 236014.502379268;
 else if (Dep = 'y5') then
 RMSE = _RMSE_ - 23601450.2379268;
 if (Dep ^= 'y2') then do;

```

```

Intercept = Intercept - 1.000000000000000;
Col1 = Col1 - 1.000000000000000;
Col2 = Col2 - 1.000000000000000;
Col3 = Col3 - 1.000000000000000;
Col4 = Col4 - 1.000000000000000;
Col5 = Col5 - 1.000000000000000;
end;
else do;
Intercept = Intercept - 1.000000000000000;
Col1 = Col1 - 0.100000000000000;
Col2 = Col2 - 0.100000000000000e-1;
Col3 = Col3 - 0.100000000000000e-2;
Col4 = Col4 - 0.100000000000000e-3;
Col5 = Col5 - 0.100000000000000e-4;
end;
run;

proc print data=ParmEst label noobs;
 title 'Wampler data: Deviations from Certified Values';
 format _RMSE_ Intercept Col1-Col5 e9.;
 var Dep _RMSE_ Intercept Col1-Col5;
run;

```

The results, shown in [Output 66.2.1](#), indicate that the values computed by PROC ORTHOREG are quite close to the NIST-certified values.

**Output 66.2.1** Wampler Data: Deviations from Certified Values

| Wampler data: Deviations from Certified Values |           |           |           |           |           |           |           |

### Example 66.3: Fitting Polynomials

The extra accuracy of the regression algorithm used by PROC ORTHOREG is most useful when the model contains near-singularities that you want to be able to distinguish from true singularities. This example demonstrates this usefulness in the context of fitting polynomials of high degree.

**NOTE:** The results from this example vary from machine to machine, depending on floating-point configuration.

The following DATA step computes a response  $y$  as an exact ninth-degree polynomial function of a predictor  $x$  evaluated at 0, 0.01, 0.02, ..., 1.

```

title 'Polynomial Data';
data Polynomial;
 do i = 1 to 101;
 x = (i-1)/(101-1);
 y = 10**(9/2);
 do j = 0 to 8;
 y = y * (x - j/8);
 end;
 output;
 end;
run;

```

The polynomial is constructed in such a way that its zeros lie at  $x = i/8$  for  $i = 0, \dots, 8$ . The following statements use the EFFECT statement to fit a ninth-degree polynomial to this data with PROC ORTHOREG. The EFFECT statement makes it easy to specify complicated polynomial models.

```

ods graphics on;

proc orthoreg data=Polynomial;
 effect xMod = polynomial(x / degree=9);
 model y = xMod;
 effectplot fit / obs;
 store OStore;
run;

ods graphics off;

```

The effect xMod defined by the EFFECT statement refers to all nine degrees of freedom in the ninth-degree polynomial (excluding the intercept term). The resulting output is shown in [Output 66.3.1](#). Note that the R square for the fit is 1, indicating that the ninth-degree polynomial has been correctly fit.

**Output 66.3.1** PROC ORTHOREG Results for Ninth-Degree Polynomial

| Polynomial Data        |     |                |              |         |        |

## Output 66.3.1 continued

| Parameter | DF | Parameter Estimate | Standard Error | t Value | Pr >  t |
|-----------|----|--------------------|----------------|---------|---------|
| Intercept | 1  | -3.24572035915E-11 | 8.114115E-12   | -4.00   | 0.0001  |
| x         | 1  | 75.9977312440678   | 4.898326E-10   | 1.55E11 | <.0001  |
| x^2       | 1  | -1652.40781362191  | 9.5027919E-9   | -174E9  | <.0001  |
| x^3       | 1  | 14249.4539769783   | 8.3110512E-8   | 1.71E11 | <.0001  |
| x^4       | 1  | -64932.461575205   | 3.8997072E-7   | -167E9  | <.0001  |
| x^5       | 1  | 173315.359360779   | 1.066611E-6    | 1.62E11 | <.0001  |
| x^6       | 1  | -280158.03646002   | 1.7523078E-6   | -16E10  | <.0001  |
| x^7       | 1  | 269781.812887653   | 1.7021134E-6   | 1.58E11 | <.0001  |
| x^8       | 1  | -142302.494710055  | 9.0027891E-7   | -158E9  | <.0001  |
| x^9       | 1  | 31622.7766022468   | 1.997493E-7    | 1.58E11 | <.0001  |

The fit plot produced by the EFFECTPLOT statement, [Output 66.3.2](#), also demonstrates the perfect fit.

## Output 66.3.2 PROC ORTHOREG Fit Plot for Ninth-Degree Polynomial

Finally, you can use the PLM procedure with the fit model saved by the STORE statement in the item store

OStore to check the predicted values for the known zeros of the polynomial, as shown in the following statements:

```
data Zeros(keep=x);
 do j = 0 to 8;
 x = j/8;
 output;
 end;
run;

proc plm restore=OStore noprint;
 score data=Zeros out=OZeros pred=OPred;
run;

proc print noobs;
run;
```

The predicted values of the zeros, shown in [Output 66.3.3](#), are again all miniscule.

**Output 66.3.3** Predicted Zeros for Ninth-Degree Polynomial

| Polynomial Data |             |
|-----------------|-------------|
| x               | OPred       |
| 0.000           | -3.2457E-11 |
| 0.125           | -2.1262E-11 |
| 0.250           | -9.5867E-12 |
| 0.375           | -2.2895E-11 |
| 0.500           | -5.2154E-11 |
| 0.625           | -1.2329E-10 |
| 0.750           | -2.5329E-10 |
| 0.875           | -3.9836E-10 |
| 1.000           | -5.9663E-10 |

To compare these results with those from a least squares fit produced by an alternative algorithm, consider fitting a polynomial to this data using the GLM procedure. PROC GLM does not have an EFFECT statement, but the familiar bar notation can still be used to specify a ninth-degree polynomial fairly succinctly, as shown in the following statements:

```
proc glm data=Polynomial;
 model y = x|x|x|x|x|x|x|x|x;
 store GStore;
run;
```

Partial results are shown in [Output 66.3.4](#). In this case, the R square for the fit is only about 0.83, indicating that the full ninth-degree polynomial was not correctly fit.

**Output 66.3.4** PROC GLM for Ninth-Degree Polynomial

| Polynomial Data       |          |                |             |           |        |
|-----------------------|----------|----------------|-------------|-----------|--------|
| The GLM Procedure     |          |                |             |           |        |
| Dependent Variable: y |          |                |             |           |        |
| Source                | DF       | Sum of Squares | Mean Square | F Value   | Pr > F |
| Model                 | 8        | 12.91166643    | 1.61395830  | 56.77     | <.0001 |
| Error                 | 92       | 2.61551363     | 0.02842950  |           |        |
| Corrected Total       | 100      | 15.52718006    |             |           |        |
|                       | R-Square | Coeff Var      | Root MSE    | y Mean    |        |
|                       | 0.831553 | -6.6691E17     | 0.168610    | -0.000000 |        |

The following statements, which use the PLM procedure to compute predictions based on the GLM fit at the true zeros of the polynomial, also confirm that PROC GLM is not able to correctly fit a polynomial of this degree, as shown in [Output 66.3.5](#).

```
proc plm restore=GStore noprint;
 score data=Zeros out=GZeros pred=GPred;
run;

data Zeros;
 merge OZeros GZeros;
run;

proc print noobs;
run;
```

**Output 66.3.5** Predicted Zeros for Ninth-Degree Polynomial

| Polynomial Data |             |          |
|-----------------|-------------|----------|
| x               | OPred       | GPred    |

## Overview: PHREG Procedure

The analysis of survival data requires special techniques because the data are almost always incomplete and familiar parametric assumptions might be unjustifiable. Investigators follow subjects until they reach a prespecified endpoint (for example, death). However, subjects sometimes withdraw from a study, or the study is completed before the endpoint is reached. In these cases, the survival times (also known as failure times) are *censored*; subjects survived to a certain time beyond which their status is unknown. The uncensored survival times are sometimes referred to as *event* times. Methods of survival analysis must account for both censored and uncensored data.

Many types of models have been used for survival data. Two of the more popular types of models are the accelerated failure time model (Kalbfleisch and Prentice 1980) and the Cox proportional hazards model (Cox 1972). Each has its own assumptions about the underlying distribution of the survival times. Two closely related functions often used to describe the distribution of survival times are the survivor function and the hazard function. See the section “[Failure Time Distribution](#)” on page 5608 for definitions. The accelerated failure time model assumes a parametric form for the effects of the explanatory variables and usually assumes a parametric form for the underlying survivor function. The Cox proportional hazards model also assumes a parametric form for the effects of the explanatory variables, but it allows an unspecified form for the underlying survivor function.

The PHREG procedure performs regression analysis of survival data based on the Cox proportional hazards model. Cox’s semiparametric model is widely used in the analysis of survival data to explain the effect of explanatory variables on hazard rates.

The survival time of each member of a population is assumed to follow its own hazard function,  $\lambda_i(t)$ , expressed as

$$\lambda_i(t) = \lambda(t; \mathbf{Z}_i) = \lambda_0(t) \exp(\mathbf{Z}_i' \boldsymbol{\beta})$$

where  $\lambda_0(t)$  is an arbitrary and unspecified baseline hazard function,  $\mathbf{Z}_i$  is the vector of explanatory variables for the  $i$ th individual, and  $\boldsymbol{\beta}$  is the vector of unknown regression parameters that is associated with the explanatory variables. The vector  $\boldsymbol{\beta}$  is assumed to be the same for all individuals. The survivor function can be expressed as

$$S(t; \mathbf{Z}_i) = [S_0(t)]^{\exp(\mathbf{Z}_i' \boldsymbol{\beta})}$$

where  $S_0(t) = \exp(-\int_0^t \lambda_0(u) du)$  is the baseline survivor function. To estimate  $\boldsymbol{\beta}$ , Cox (1972, 1975) introduced the partial likelihood function, which eliminates the unknown baseline hazard  $\lambda_0(t)$  and accounts for censored survival times.

The partial likelihood of Cox also allows time-dependent explanatory variables. An explanatory variable is time-dependent if its value for any given individual can change over time. Time-dependent variables have many useful applications in survival analysis. You can use a time-dependent variable to model the effect of subjects changing treatment groups. Or you can include time-dependent variables such as blood pressure or blood chemistry measures that vary with time during the course of a study. You can also use time-dependent variables to test the validity of the proportional hazards model.

An alternative way to fit models with time-dependent explanatory variables is to use the counting process style of input. The counting process formulation enables PROC PHREG to fit a superset of the Cox model,

known as the multiplicative hazards model. This extension also includes recurrent events data and left-truncation of failure times. The theory of these models is based on the counting process pioneered by Andersen and Gill (1982), and the model is often referred to as the Andersen-Gill model.

Multivariate failure-time data arise when each study subject can potentially experience several events (for example, multiple infections after surgery) or when there exists some natural or artificial clustering of subjects (for example, a litter of mice) that induces dependence among the failure times of the same cluster. Data in the former situation are referred to as multiple events data, which include recurrent events data as a special case; data in the latter situation are referred to as clustered data. You can use PROC PHREG to carry out various methods of analyzing these data.

The population under study can consist of a number of subpopulations, each of which has its own baseline hazard function. PROC PHREG performs a stratified analysis to adjust for such subpopulation differences. Under the stratified model, the hazard function for the  $j$ th individual in the  $i$ th stratum is expressed as

$$\lambda_{ij}(t) = \lambda_{i0}(t) \exp(\mathbf{Z}'_{ij}\boldsymbol{\beta})$$

where  $\lambda_{i0}(t)$  is the baseline hazard function for the  $i$ th stratum and  $\mathbf{Z}_{ij}$  is the vector of explanatory variables for the individual. The regression coefficients are assumed to be the same for all individuals across all strata.

Ties in the failure times can arise when the time scale is genuinely discrete or when survival times that are generated from the continuous-time model are grouped into coarser units. The PHREG procedure includes four methods of handling ties. The *discrete* logistic model is available for discrete time-scale data. The other three methods apply to continuous time-scale data. The *exact* method computes the exact conditional probability under the model that the set of observed tied event times occurs before all the censored times with the same value or before larger values. *Breslow* and *Efron* methods provide approximations to the exact method.

Variable selection is a typical exploratory exercise in multiple regression when the investigator is interested in identifying important prognostic factors from a large number of candidate variables. The PHREG procedure provides four selection methods: forward selection, backward elimination, stepwise selection, and best subset selection. The best subset selection method is based on the likelihood score statistic. This method identifies a specified number of best models that contain one, two, or three variables and so on, up to the single model that contains all of the explanatory variables.

The PHREG procedure also enables you to do the following: include an offset variable in the model; weight the observations in the input data; test linear hypotheses about the regression parameters; perform conditional logistic regression analysis for matched case-control studies; output survivor function estimates, residuals, and regression diagnostics; and estimate and plot the survivor function for a new set of covariates.

PROC PHREG can also be used to fit the multinomial logit choice model to discrete choice data. See [http://support.sas.com/resources/papers/tnote/tnote\\_marketresearch.html](http://support.sas.com/resources/papers/tnote/tnote_marketresearch.html) for more information about discrete choice modeling and the multinomial logit model. Look for the “Discrete Choice” report.

The PHREG procedure uses ODS Graphics to create graphs as part of its output. For example, the ASSESS statement uses a graphical method that uses ODS Graphics to check the adequacy of the model. See Chapter 21, “Statistical Graphics Using ODS,” for general information about ODS Graphics.

For both the BASELINE and OUTPUT statements, the default method of estimating a survivor function has changed to the Breslow (1972) estimator—that is, METHOD=CH. The option NOMEAN that was available

in the BASELINE statement prior to SAS/STAT 9.2 has become obsolete—that is, requested statistics at the sample average values of the covariates are no longer computed and added to the OUT= data set. However, if the COVARIATES= data set is not specified, the requested statistics are computed and output for the covariate set that consists of the reference levels for the CLASS variables and sample averages for the continuous variable. In addition to the requested statistics, the OUT= data set also contains all variables in the COVARIATES= data set.

The remaining sections of this chapter contain information about how to use PROC PHREG, information about the underlying statistical methodology, and some sample applications of the procedure. The section “Getting Started: PHREG Procedure” on page 5543 introduces PROC PHREG with two examples. The section “Syntax: PHREG Procedure” on page 5553 describes the syntax of the procedure. The section “Details: PHREG Procedure” on page 5608 summarizes the statistical techniques used in PROC PHREG. The section “Examples: PHREG Procedure” on page 5678 includes eight additional examples of useful applications. Experienced SAS/STAT software users might decide to proceed to the “Syntax” section, while other users might choose to read both the “Getting Started” and “Examples” sections before proceeding to “Syntax” and “Details.”

---

## Getting Started: PHREG Procedure

This section uses the two-sample vaginal cancer mortality data from Kalbfleisch and Prentice (1980, p. 2) in two examples to illustrate some of the basic features of PROC PHREG. The first example carries out a classical Cox regression analysis and the second example performs a Bayesian analysis of the Cox model.

Two groups of rats received different pretreatment regimes and then were exposed to a carcinogen. Investigators recorded the survival times of the rats from exposure to mortality from vaginal cancer. Four rats died of other causes, so their survival times are censored. Interest lies in whether the survival curves differ between the two groups.

The following DATA step creates the data set Rats, which contains the variable Days (the survival time in days), the variable Status (the censoring indicator variable: 0 if censored and 1 if not censored), and the variable Group (the pretreatment group indicator).

```
data Rats;
 label Days = 'Days from Exposure to Death';
 input Days Status Group @@;
 datalines;
143 1 0 164 1 0 188 1 0 188 1 0
190 1 0 192 1 0 206 1 0 209 1 0
213 1 0 216 1 0 220 1 0 227 1 0
230 1 0 234 1 0 246 1 0 265 1 0
304 1 0 216 0 0 244 0 0 142 1 1
156 1 1 163 1 1 198 1 1 205 1 1
232 1 1 232 1 1 233 1 1 233 1 1
233 1 1 233 1 1 239 1 1 240 1 1
261 1 1 280 1 1 280 1 1 296 1 1
296 1 1 323 1 1 204 0 1 344 0 1
;
```

By using ODS Graphics, PROC PHREG allows you to plot the survival curve for Group=0 and the survival curve for Group=1, but first you must save these two covariate values in a SAS data set as in the following DATA step:

```
data Regimes;
 Group=0;
 output;
 Group=1;
 output;
run;
```

---

## Classical Method of Maximum Likelihood

PROC PHREG fits the Cox model by maximizing the partial likelihood and computes the baseline survivor function by using the Breslow (1972) estimate. The following statements produce [Figure 67.1](#) and [Figure 67.2](#):

```
ods graphics on;
proc phreg data=Rats plot(overlay)=survival;
 model Days*Status(0)=Group;
 baseline covariates=regimes out=_null_;
run;
ods graphics off;
```

In the MODEL statement, the response variable, Days, is crossed with the censoring variable, Status, with the value that indicates censoring is enclosed in parentheses. The values of Days are considered censored if the value of Status is 0; otherwise, they are considered event times.

Graphs are produced when ODS Graphics is enabled. The survival curves for the two observations in the data set Regime, specified in the COVARIATES= option in the BASELINE statement, are requested through the PLOTS= option with the OVERLAY option for overlaying both survival curves in the same plot.

[Figure 67.2](#) shows a typical printed output of a classical analysis. Since Group takes only two values, the null hypothesis for no difference between the two groups is identical to the null hypothesis that the regression coefficient for Group is 0. All three tests in the “Testing Global Null Hypothesis: BETA=0” table (see the section “Testing the Global Null Hypothesis” on page 5625) suggest that the survival curves for the two pretreatment groups might not be the same. In this model, the hazard ratio (or risk ratio) for Group, defined as the exponentiation of the regression coefficient for Group, is the ratio of the hazard functions between the two groups. The estimate is 0.551, implying that the hazard function for Group=1 is smaller than that for Group=0. In other words, rats in Group=1 lived longer than those in Group=0. This conclusion is also revealed in the plot of the survivor functions in [Figure 67.2](#).

**Figure 67.1** Comparison of Two Survival Curves

**Figure 67.2** Survivorship for the Two Pretreatment Regimes

In this example, the comparison of two survival curves is put in the form of a proportional hazards model. This approach is essentially the same as the log-rank (Mantel-Haenszel) test. In fact, if there are no ties in the survival times, the likelihood score test in the Cox regression analysis is identical to the log-rank test. The advantage of the Cox regression approach is the ability to adjust for the other variables by including them in the model. For example, the present model could be expanded by including a variable that contains the initial body weights of the rats.

Next, consider a simple test of the validity of the proportional hazards assumption. The proportional hazards model for comparing the two pretreatment groups is given by the following:

$$\lambda(t) = \begin{cases} \lambda_0(t) & \text{if GROUP} = 0 \\ \lambda_0(t)e^{\beta_1} & \text{if GROUP} = 1 \end{cases}$$

The ratio of hazards is  $e^{\beta_1}$ , which does not depend on time. If the hazard ratio changes with time, the proportional hazards model assumption is invalid. Simple forms of departure from the proportional hazards model can be investigated with the following time-dependent explanatory variable  $x = x(t)$ :

$$x(t) = \begin{cases} 0 & \text{if GROUP} = 0 \\ \log(t) - 5.4 & \text{if GROUP} = 1 \end{cases}$$

Here,  $\log(t)$  is used instead of  $t$  to avoid numerical instability in the computation. The constant, 5.4, is the average of the logs of the survival times and is included to improve interpretability. The hazard ratio in the two groups then becomes  $e^{\beta_1 - 5.4\beta_2 t^{\beta_2}}$ , where  $\beta_2$  is the regression parameter for the time-dependent variable  $x$ . The term  $e^{\beta_1}$  represents the hazard ratio at the geometric mean of the survival times. A nonzero value of  $\beta_2$  would imply an increasing ( $\beta_2 > 0$ ) or decreasing ( $\beta_2 < 0$ ) trend in the hazard ratio with time.

The following statements implement this simple test of the proportional hazards assumption. The MODEL statement includes the time-dependent explanatory variable X, which is defined subsequently by the programming statement. At each event time, subjects in the risk set (those alive just before the event time) have their X values changed accordingly.

```
proc phreg data=Rats;
 model Days*Status(0)=Group X;
 X=Group*(log(Days) - 5.4);
run;
```

The analysis of the parameter estimates is displayed in [Figure 67.3](#). The Wald chi-square statistic for testing the null hypothesis that  $\beta_2 = 0$  is 0.0158. The statistic is not statistically significant when compared to a chi-square distribution with one degree of freedom ( $p = 0.8999$ ). Thus, you can conclude that there is no evidence of an increasing or decreasing trend over time in the hazard ratio.

**Figure 67.3** A Simple Test of Trend in the Hazard Ratio

## Bayesian Analysis

PROC PHREG uses the partial likelihood of the Cox model as the likelihood and generates a chain of posterior distribution samples by the Gibbs Sampler. Summary statistics, convergence diagnostics, and diagnostic plots are provided for each parameter. The following statements generate [Figure 67.4](#)–[Figure 67.10](#):

```
ods graphics on;
proc phreg data=Rats;
 model Days*Status(0)=Group;
 bayes seed=1 outpost=Post;
run;
ods graphics off;
```

The BAYES statement invokes the Bayesian analysis. The SEED= option is specified to maintain reproducibility; the OUTPOST= option saves the posterior distribution samples in a SAS data set for post-

processing; no other options are specified in the BAYES statement. By default, a uniform prior distribution is assumed on the regression coefficient Group. The uniform prior is a flat prior on the real line with a distribution that reflects ignorance of the location of the parameter, placing equal probability on all possible values the regression coefficient can take. Using the uniform prior in the following example, you would expect the Bayesian estimates to resemble the classical results of maximizing the likelihood. If you can elicit an informative prior on the regression coefficients, you should use the COEFFPRIOR= option to specify it.

You should make sure that the posterior distribution samples have achieved convergence before using them for Bayesian inference. PROC PHREG produces three convergence diagnostics by default. If ODS Graphics is enabled before calling PROC PHREG as in the preceding program, diagnostics plots are also displayed.

The results of this analysis are shown in the following figures.

The “Model Information” table in Figure 67.4 summarizes information about the model you fit and the size of the simulation.

**Figure 67.4** Model Information

| The PHREG Procedure |           |                             |
|---------------------|-----------|-----------------------------|
| Bayesian Analysis   |           |                             |
| Model Information   |           |                             |
| Data Set            | WORK.RATS |                             |
| Dependent Variable  | Days      | Days from Exposure to Death |
| Censoring Variable  | Status    |                             |
| Censoring Value(s)  | 0         |                             |
| Model               | Cox       |                             |
| Ties Handling       | BRESLOW   |                             |
| Sampling Algorithm  | ARMS      |                             |
| Burn-In Size        | 2000      |                             |
| MC Sample Size      | 10000     |                             |
| Thinning            | 1         |                             |

PROC PHREG first fits the Cox model by maximizing the partial likelihood. The only parameter in the model is the regression coefficient of Group. The maximum likelihood estimate (MLE) of the parameter and its 95% confidence interval are shown in Figure 67.5.

**Figure 67.5** Classical Parameter Estimates

| Maximum Likelihood Estimates |    |          |                |                       |        |
|------------------------------|----|----------|----------------|-----------------------|--------|
| Parameter                    | DF | Estimate | Standard Error | 95% Confidence Limits |        |
| Group                        | 1  | -0.5959  | 0.3484         | -1.2788               | 0.0870 |

Since no prior is specified for the regression coefficient, the default uniform prior is used. This information is displayed in the “Uniform Prior for Regression Coefficients” table in Figure 67.6.

**Figure 67.6** Coefficient Prior

| Uniform Prior for Regression Coefficients |          |
|-------------------------------------------|----------|
| Parameter                                 | Prior    |
| Group                                     | Constant |

The “Fit Statistics” table in [Figure 67.7](#) lists information about the fitted model. The table displays the DIC (deviance information criterion) and pD (effective number of parameters). See the section “Fit Statistics” on page 5662 for details.

**Figure 67.7** Fit Statistics

| Fit Statistics                      |         |
|-------------------------------------|---------|
| DIC (smaller is better)             | 203.444 |
| pD (Effective Number of Parameters) | 1.003   |

Summary statistics of the posterior samples are displayed in the “Posterior Summaries” table and “Posterior Intervals” table as shown in [Figure 67.8](#). Note that the mean and standard deviation of the posterior samples are comparable to the MLE and its standard error, respectively, due to the use of the uniform prior.

**Figure 67.8** Summary Statistics

| The PHREG Procedure |       |                     |                    |              |         |         |

| Bayesian Analysis   |       |                     |                    |              |         |         |
| Posterior Summaries |       |                     |                    |              |         |         |
| Parameter           | N     | Mean                | Standard Deviation | Percentiles  |         |         |
|                     |       |                     |                    | 25%          | 50%     | 75%     |
| Group               | 10000 | -0.5998             | 0.3511             | -0.8326      | -0.5957 | -0.3670 |
| Posterior Intervals |       |                     |                    |              |         |         |
| Parameter           | Alpha | Equal-Tail Interval |                    | HPD Interval |         |         |
| Group               | 0.050 | -1.3042             | 0.0721             | -1.2984      | 0.0756  |         |

PROC PHREG provides diagnostics to assess the convergence of the generated Markov chain. [Figure 67.9](#) shows three of these diagnostics: the lag1, lag5, lag10, and lag50 autocorrelations; the Geweke diagnostic; and the effective sample size. There is no indication that the Markov chain has not reached convergence. See the section “Statistical Diagnostic Tests” on page 144 for information about interpreting these diagnostics.

**Figure 67.9** Convergence Diagnostics

| The PHREG Procedure        |         |                      |            |        |
|----------------------------|---------|----------------------|------------|--------|
| Bayesian Analysis          |         |                      |            |        |
| Posterior Autocorrelations |         |                      |            |        |
| Parameter                  | Lag 1   | Lag 5                | Lag 10     | Lag 50 |
| Group                      | -0.0079 | 0.0091               | -0.0161    | 0.0101 |
| Geweke Diagnostics         |         |                      |            |        |
| Parameter                  | z       | Pr >  z              |            |        |
| Group                      | 0.0149  | 0.9881               |            |        |
| Effective Sample Sizes     |         |                      |            |        |
| Parameter                  | ESS     | Autocorrelation Time | Efficiency |        |
| Group                      | 10000.0 | 1.0000               | 1.0000     |        |

You can also assess the convergence of the generated Markov chain by examining the trace plot, the autocorrelation function plot, and the posterior density plot. [Figure 67.10](#) displays a panel of these three plots for the parameter Group. This graphical display is automatically produced when ODS Graphics is enabled. Note that the trace of the samples centers on  $-0.6$  with only small fluctuations, the autocorrelations are quite small, and the posterior density appears bell-shaped—all exemplifying the behavior of a converged Markov chain.

Figure 67.10 Diagnostic Plots

The proportional hazards model for comparing the two pretreatment groups is

$$\lambda(t) = \begin{cases} \lambda_0(t) & \text{if Group}=0 \\ \lambda_0(t)e^\beta & \text{if Group}=1 \end{cases}$$

The probability that the hazard of Group=0 is greater than that of Group=1 is

$$\Pr(\lambda_0(t) > \lambda_0(t)e^\beta) = \Pr(\beta < 0)$$

This probability can be enumerated from the posterior distribution samples by computing the fraction of samples with a coefficient less than 0. The following DATA step and PROC MEANS perform this calculation:

```
data New;
 set Post;
 Indicator=(Group < 0);
 label Indicator='Group < 0';
run;
proc means data=New(keep=Indicator) n mean;
run;
```

**Figure 67.11** Prob(Hazard(Group=0) > Hazard(Group=1))

| The MEANS Procedure                     |           |
|-----------------------------------------|-----------|
| Analysis Variable : Indicator Group < 0 |           |
| N                                       | Mean      |
| 10000                                   | 0.9581000 |

The PROC MEANS results are displayed in [Figure 67.11](#). There is a 95.8% chance that the hazard rate of Group=0 is greater than that of Group=1. The result is consistent with the fact that the average survival time of Group=0 is less than that of Group=1.

## Syntax: PHREG Procedure

The following statements are available in the PHREG procedure. Items within < > are optional.

```

PROC PHREG < options > ;
 ASSESS keyword < / options > ;
 BASELINE < OUT=SAS-data-set > < COVARIATES=SAS-data-set >
 < keyword=name ... keyword=name > < / options > ;
 BAYES < options > ;
 BY variables ;
 CLASS variable < (options) > < ... variable < (options) > > < / options > ;
 CONTRAST < 'label' > effect values < , ... , effect values > < / options > ;
 FREQ variable ;
 EFFECT name = effect-type (variables < / options >) ;
 ESTIMATE < 'label' > estimate-specification < / options > ;
 HAZARDRATIO < 'label' > variable < / options > ;
 ID variables ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 MODEL response < * censor(list) > = < effects > < / options > ;
 OUTPUT < OUT=SAS-data-set > < keyword=name ... keyword=name > < / options > ;
 Programming statements ;
 RANDOM variable < / options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 STRATA variable < (list) > < ... variable < (list) > > < / option > ;
 < label: > TEST equation < , ... , equation > < / options > ;
 WEIGHT variable < / option > ;

```

The PROC PHREG and MODEL statements are required. The CLASS statement, if present, must precede the MODEL statement, and the ASSESS or CONTRAST statement, if present, must come after the MODEL statement. The BAYES statement, that invokes a Bayesian analysis, is not compatible with the ASSESS, CONTRAST, ID, OUTPUT, and TEST statements, as well as a number of options in the PROC PHREG and MODEL statements. See the section “[Specifics for Bayesian Analysis](#)” on page 5653 for details.

The rest of this section provides detailed syntax information for each statement, beginning with the PROC PHREG statement. The remaining statements are covered in alphabetical order.

## PROC PHREG Statement

**PROC PHREG** < options > ;

The PROC PHREG statement invokes the PHREG procedure. Table 67.1 summarizes the options available in the PROC PHREG statement.

**Table 67.1** PROC PHREG Statement Options

| Option      | Description                                                                                                |
|-------------|------------------------------------------------------------------------------------------------------------|
| ALPHA=      | Specifies the level of significance                                                                        |
| ATRISK      | Displays a table that contains the number of units and the corresponding number of events in the risk sets |
| COVM        | Uses the model-based covariance matrix in the analysis                                                     |
| COVOUT      | Adds the estimated covariance matrix to the OUTEST= data set                                               |
| COVSANDWICH | Requests the robust sandwich estimate for the covariance matrix                                            |
| DATA=       | Names the SAS data set to be analyzed                                                                      |
| INEST=      | Names the SAS data set that contains initial estimates                                                     |
| MULTIPASS   | Recompiles the risk sets                                                                                   |
| NAMELEN=    | Specifies the length of effect names                                                                       |
| NOPRINT     | Suppresses all displayed output                                                                            |
| NOSUMMARY   | Suppresses the summary display observation frequencies                                                     |
| OUTEST=     | Creates an output SAS data set containing estimates of the regression coefficients                         |
| PLOTS       | Controls the plots produced through ODS Graphics                                                           |
| SIMPLE      | Displays simple descriptive statistics                                                                     |

You can specify the following *options* in the PROC PHREG statement.

### ALPHA=*number*

specifies the level of significance  $\alpha$  for  $100(1 - \alpha)\%$  confidence intervals. The value *number* must be between 0 and 1; the default value is 0.05, which results in 95% intervals. This value is used as the default confidence level for limits computed by the BASELINE, BAYES, CONTRAST, HAZARDRATIO, and MODEL statements. You can override this default by specifying the ALPHA= option in the separate statements.

### ATRISK

displays a table that contains the number of units at risk at each event time and the corresponding number of events in the risk sets. For example, the following risk set information is displayed if the ATRISK option is specified in the example in the section “Getting Started: PHREG Procedure” on page 5543.

| Risk Set Information |         |       |
|----------------------|---------|-------|
| Number of Units      |         |       |
| Days                 | At Risk | Event |
| 142                  | 40      | 1     |
| 143                  | 39      | 1     |
| 156                  | 38      | 1     |
| ⋮                    | ⋮       | ⋮     |
| 296                  | 5       | 2     |
| 304                  | 3       | 1     |
| 323                  | 2       | 1     |

**COVOUT**

adds the estimated covariance matrix of the parameter estimates to the OUTEST= data set. The COVOUT option has no effect unless the OUTEST= option is specified.

**COVM**

requests that the model-based covariance matrix (which is the inverse of the observed information matrix) be used in the analysis if the COVS option is also specified. The COVM option has no effect if the COVS option is not specified.

**COVSANDWICH <(AGGREGATE)>****COVS <(AGGREGATE)>**

requests the robust sandwich estimate of Lin and Wei (1989) for the covariance matrix. When this option is specified, this robust sandwich estimate is used in the Wald tests for testing the global null hypothesis, null hypotheses of individual parameters, and the hypotheses in the CONTRAST and TEST statements. In addition, a modified score test is computed in the testing of the global null hypothesis, and the parameter estimates table has an additional StdErrRatio column, which contains the ratios of the robust estimate of the standard error relative to the corresponding model-based estimate. Optionally, you can specify the keyword AGGREGATE enclosed in parentheses after the COVSANDWICH (or COVS) option, which requests a summing up of the score residuals for each distinct ID pattern in the computation of the robust sandwich covariance estimate. This AGGREGATE option has no effect if the ID statement is not specified.

**DATA=SAS-data-set**

names the SAS data set that contains the data to be analyzed. If you omit the DATA= option, the procedure uses the most recently created SAS data set.

**INEST=SAS-data-set**

names the SAS data set that contains initial estimates for all the parameters in the model. BY-group processing is allowed in setting up the INEST= data set. See the section “[INEST= Input Data Set](#)” on page 5665 for more information.

**MULTIPASS**

requests that, for each Newton-Raphson iteration, PROC PHREG recompile the risk sets corresponding to the event times for the (start,stop) style of response and recomputes the values of the time-dependent variables defined by the programming statements for each observation in the risk sets. If the MULTIPASS option is not specified, PROC PHREG computes all risk sets and all the variable values and saves them in a utility file. The MULTIPASS option decreases required disk space at the

expense of increased execution time; however, for very large data, it might actually save time since it is time-consuming to write and read large utility files. This option has an effect only when the (start,stop) style of response is used or when there are time-dependent explanatory variables.

**NAMELEN=*n***

specifies the length of effect names in tables and output data sets to be *n* characters, where *n* is a value between 20 and 200. The default length is 20 characters.

**NOPRINT**

suppresses all displayed output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

**NOSUMMARY**

suppresses the summary display of the event and censored observation frequencies.

**OUTEST=*SAS-data-set***

creates an output SAS data set that contains estimates of the regression coefficients. The data set also contains the convergence status and the log likelihood. If you use the COVOUT option, the data set also contains the estimated covariance matrix of the parameter estimators. See the section “**OUTEST= Output Data Set**” on page 5664 for more information.

**PLOTS<(global-plot-options)> = *plot-request*****PLOTS<(global-plot-options)> = (*plot-request* <...<*plot-request*>>)**

controls the baseline functions plots produced through ODS Graphics. Each observation in the COVARIATES= data set in the BASELINE statement represents a set of covariates for which a curve is produced for each *plot-request* and for each stratum. You can use the ROWID= option in the BASELINE statement to specify a variable in the COVARIATES= data set for identifying the curves produced for the covariate sets. If the ROWID= option is not specified, the curves produced are identified by the covariate values if there is only a single covariate or by the observation numbers of the COVARIATES= data set if the model has two or more covariates. If the COVARIATES= data set is not specified, a reference set of covariates consisting of the reference levels for the CLASS variables and the average values for the continuous variables is used. For plotting more than one curve, you can use the OVERLAY= option to group the curves in separate plots. When you specify one *plot-request*, you can omit the parentheses around the plot request. Here are some examples:

```
plots=survival
plots=(survival cumhaz)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc phreg plots(cl)=survival;
 model Time*Status(0)=X1-X5;
 baseline covariates=One;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The *global-plot-options* include the following:

**CL=<EQTAIL | HPD>**

displays the pointwise interval limits for the specified curves. For the classical analysis, CL displays the confidence limits. For the Bayesian analysis, CL=EQTAIL displays the equal-tail credible limits and CL=HPD displays the HPD limits. Specifying just CL in a Bayesian analysis defaults to CL=HPD.

**OVERLAY <=overlay-option>**

specifies how the curves for the various strata and covariate sets are overlaid. If the STRATA statement is not specified, specifying OVERLAY without any option will overlay the curves for all the covariate sets. The available *overlay-options* are as follows:

**BYGROUP**

**GROUP**

overlays, for each stratum, all curves for the covariate sets that have the same **GROUP=** value in the COVARIATES= data set in the same plot.

**INDIVIDUAL**

**IND**

displays, for each stratum, a separate plot for each covariate set.

**BYROW**

**ROW**

displays, for each covariate set, a separate plot containing the curves for all the strata.

**BYSTRATUM**

**STRATUM**

displays, for each stratum, a separate plot containing the curves for all sets of covariates.

The default is OVERLAY=BYGROUP if the **GROUP=** option is specified in the BASELINE statement or if the COVARIATES= data set contains the `_GROUP_` variable; otherwise the default is OVERLAY=INDIVIDUAL.

**TIMERANGE=(<min> <,max>)**

**TIMERANGE=<min> <,max>**

**RANGE=(<min> <,max>)**

**RANGE=<min> <,max>**

specifies the range of values on the time axis to clip the display. The *min* and *max* values are the lower and upper bounds of the range. By default, *min* is 0 and *max* is the largest event time.

The *plot-requests* include the following:

**CUMHAZ**

plots the estimated cumulative hazard function for each set of covariates in the COVARIATES= data set in the BASELINE statement. If the COVARIATES= data set is not specified, the estimated cumulative hazard function is plotted for the reference set of covariates consisting of reference levels for the CLASS variables and average values for the continuous variables.

**MCF**

plots the estimated mean cumulative function for each set of covariates in the COVARIATES= data set in the BASELINE statement. If the COVARIATES= data set is not specified, the estimated mean cumulative function is plotted for the reference set of covariates consisting of reference levels for the CLASS variables and average values for the continuous variables.

**NONE**

suppresses all the plots in the procedure. Specifying this option is equivalent to disabling ODS Graphics for the entire procedure.

**SURVIVAL**

plots the estimated survivor function for each set of covariates in the COVARIATES= data set in the BASELINE statement. If COVARIATES= data set is not specified, the estimated survivor function is plotted for the reference set of covariates consisting of reference levels for the CLASS variables and average values for the continuous variables.

**SIMPLE**

displays simple descriptive statistics (mean, standard deviation, minimum, and maximum) for each explanatory variable in the MODEL statement.

**ASSESS Statement**

**ASSESS** < VAR=(list) > < PH > < / options > ;

The ASSESS statement performs the graphical and numerical methods of Lin, Wei, and Ying (1993) for checking the adequacy of the Cox regression model. The methods are derived from cumulative sums of martingale residuals over follow-up times or covariate values. You can assess the functional form of a covariate or you can check the proportional hazards assumption for each covariate in the Cox model. PROC PHREG uses ODS Graphics for the graphical displays. You must specify at least one of the following options to create an analysis.

**VAR=(variable-list)**

specifies the list of explanatory variables for which their functional forms are assessed. For each variable on the list, the observed cumulative martingale residuals are plotted against the values of the explanatory variable along with 20 (or  $n$  if NPATHS= $n$  is specified) simulated residual patterns.

**PROPORTIONALHAZARDS****PH**

requests the checking of the proportional hazards assumption. For each explanatory variable in the model, the observed score process component is plotted against the follow-up time along with 20 (or  $n$  if NPATHS= $n$  is specified) simulated patterns.

The following options can be specified after a slash (/):

**NPATHS= $n$** 

specifies the number of simulated residual patterns to be displayed in a cumulative martingale residual plot or a score process plot. The default is  $n=20$ .

**CRPANEL**

requests that a plot with four panels, each containing the observed cumulative martingale residuals and two simulated residual patterns, be created.

**RESAMPLE <=n>**

requests that the Kolmogorov-type supremum test be computed on 1,000 simulated patterns or on *n* simulated patterns if *n* is specified.

**SEED=*n***

specifies an integer seed for the random number generator used in creating simulated realizations for plots and for the Kolmogorov-type supremum tests. Specifying a seed enables you to reproduce identical graphs and *p*-values for the model assessments from the same PHREG specification. If the SEED= option is not specified, or if you specify a nonpositive seed, a random seed is derived from the time of day.

**BASELINE Statement**

**BASELINE** <OUT=SAS-data-set> <OUTDIFF=SAS-data-set> <COVARIATES=SAS-data-set>  
<TIMELIST=list> <keyword=name . . . keyword=name> </ options> ;

The BASELINE statement creates a SAS data set (named by the OUT= option) that contains the baseline function estimates at the event times of each stratum for every set of covariates in the COVARIATES= data set. If the COVARIATES= data set is not specified, a reference set of covariates consisting of the reference levels for the CLASS variables and the average values for the continuous variables is used. You can use the DIRADJ option to obtain the direct adjusted survival curve that averages the estimated survival curves for the observations in the COVARIATES= data set. No BASELINE data set is created if the model contains a time-dependent variable defined by means of programming statement.

Table 67.2 summarizes the options available in the BASELINE statement.

**Table 67.2** BASELINE Statement Options

| Option                                | Description                                                                                |
|---------------------------------------|--------------------------------------------------------------------------------------------|
| <b>Data Set and Time List Options</b> |                                                                                            |
| OUT=                                  | Specifies the output BASELINE data set                                                     |
| OUTDIFF=                              | Specifies the output data set that contains differences of direct adjusted survival curves |
| COVARIATES=                           | Specifies the SAS data set that contains the explanatory variables                         |
| TIMELIST=                             | Specifies a list of time points for Bayesian computation of survival estimates.            |
| <b>Keyword Options</b>                |                                                                                            |
| CMF=                                  | Specifies the cumulative mean function estimate                                            |
| CUMHAZ=                               | Specifies the cumulative hazard function estimate                                          |
| LOGLOGS=                              | Specifies the log of the negative log of SURVIVAL                                          |
| LOGSURV=                              | Specifies the log of SURVIVAL                                                              |
| LOWERCMF=                             | Specifies the lower pointwise confidence limit for CMF                                     |
| LOWERCUMHAZ=                          | specifies the lower pointwise confidence limit for CUMHAZ                                  |

Table 67.2 continued

| Options              | Description                                                                                               |
|----------------------|-----------------------------------------------------------------------------------------------------------|
| LOWERHPDCUMHAZ=      | Specifies the lower limit of the HPD interval for CUMHAZ                                                  |
| LOWERHPD=            | Specifies the lower limit of the HPD interval for SURVIVAL                                                |
| LOWER=               | Specifies the lower pointwise confidence limit for SURVIVAL                                               |
| STDCMF=              | Specifies the estimated standard error of CMF                                                             |
| STDCUMHAZ=           | Specifies the estimated standard error of CUMHAZ                                                          |
| STDERR=              | Specifies the standard error of SURVIVAL                                                                  |
| STDXBETA=            | Specifies the estimated standard error of the linear predictor estimator                                  |
| SURVIVAL=            | Specifies the survivor function estimate                                                                  |
| UPPERCMF=            | Specifies the upper pointwise confidence limit for CMF                                                    |
| UPPERCUMHAZ=         | Specifies the upper pointwise confidence limit for CUMHAZ                                                 |
| UPPERHPDCUMHAZ=      | Specifies the upper limit of the HPD interval for CUMHAZ                                                  |
| UPPERHPD=            | Specifies the upper limit of the HPD interval for SURVIVAL                                                |
| UPPER=               | Specifies the upper pointwise confidence limit for SURVIVAL                                               |
| XBETA=               | Specifies the estimate of the linear predictor $\mathbf{x}'\boldsymbol{\beta}$                            |
| <b>Other Options</b> |                                                                                                           |
| ALPHA=               | Specifies the significance level of the confidence interval for the survivor function                     |
| CLTYPE=              | Specifies the method used to compute the confidence limits                                                |
| DIRADJ               | Computes direct adjusted survival curves                                                                  |
| GROUP=               | Names a variable whose values are used to identify or group the survival curves                           |
| METHOD=              | Specifies the method used to compute the survivor function estimates                                      |
| ROWID=               | Names the variable in the COVARIATES= data set for identifying the baseline functions curves in the plots |

The following options are available in the BASELINE statement.

**OUT=SAS-data-set**

names the output BASELINE data set. If you omit the OUT= option, the data set is created and given a default name by using the DATA*n* convention. See the section “OUT= Output Data Set in the BASELINE Statement” on page 5665 for more information.

**OUTDIFF=SAS-data-set**

names the output data set that contains all pairwise differences of direct adjusted probabilities between groups if the GROUP= variable is specified, or between strata if the GROUP= variable is not specified. It is required that the DIRADJ option be specified to use the OUTDIFF= option.

**COVARIATES=SAS-data-set**

names the SAS data set that contains the sets of explanatory variable values for which the quantities of interest are estimated. All variables in the COVARIATES= data set are copied to the OUT= data set. Thus, any variable in the COVARIATES= data set can be used to identify the covariate sets in the OUT= data set.

**TIMELIST=*list***

specifies a list of time points at which the survival function estimates and cumulative hazard function estimates are computed. The following specifications are equivalent:

```
timelist=5,20 to 50 by 10
timelist=5 20 30 40 50
```

If the TIMELIST= option is not specified, the default is to carry out the prediction at all event times and at time 0. This option can be used only for the Bayesian analysis.

**keyword=*name***

specifies the statistics to be included in the OUT= data set and assigns names to the variables that contain these statistics. Specify a *keyword* for each desired statistic, an equal sign, and the name of the variable for the statistic. Not all *keywords* listed in Table 67.3 (and discussed in the text that follows) are appropriate for both the classical analysis and the Bayesian analysis; and the table summarizes the choices for each analysis.

**Table 67.3** Summary of the Keyword Choices

| <b>Keyword</b>                    | <b>Classical</b> | <b>Bayesian</b> |
|-----------------------------------|------------------|-----------------|
| <b>Survivor Function</b>          |                  |                 |
| SURVIVAL=                         | X                | X               |
| STDERR=                           | X                | X               |
| LOWER=                            | X                | X               |
| UPPER=                            | X                | X               |
| LOWERHPD=                         |                  | X               |
| UPPERHPD=                         |                  | X               |
| <b>Cumulative Hazard Function</b> |                  |                 |
| CUMHAZ=                           | X                | X               |
| STDCUMHAZ=                        | X                | X               |
| LOWERCUMHAZ=                      | X                | X               |
| UPPERCUMHAZ=                      | X                | X               |
| LOWERHPDCUMHAZ=                   |                  | X               |
| UPPERHPDCUMHAZ=                   |                  | X               |
| <b>Cumulative Mean Function</b>   |                  |                 |
| CMF=                              | X                |                 |
| STDCMF=                           | X                |                 |
| LOWERCMF=                         | X                |                 |
| UPPERCMF=                         | X                |                 |
| <b>Others</b>                     |                  |                 |
| XBETA=                            | X                | X               |
| STDXBETA=                         | X                | X               |
| LOGSURV=                          | X                |                 |
| LOGLOGS=                          | X                |                 |

The available *keywords* are as follows.

**CMF=****MCF=**

specifies the cumulative mean function estimate for recurrent events data. Specifying `CMF=_ALL_` is equivalent to specifying `CMF=CMF`, `STDCMF=StdErrCMF`, `LOWERCMF=LowerCMF`, and `UPPERCMF=UpperCMF`. Nelson (2002) refers to the mean function estimate as MCF (mean cumulative function).

**CUMHAZ=**

specifies the cumulative hazard function estimate. Specifying `CUMHAZ=_ALL_` is equivalent to specifying `CUMHAZ=CumHaz`, `STDCUMHAZ=StdErrCumHaz`, `LOWERCUMHAZ=LowerCumHaz`, and `UPPERCUMHAZ=UpperCumHaz`. For a Bayesian analysis, `CUMHAZ=_ALL_` also includes `LOWERHPDCUMHAZ=LowerHPDCumHaz` and `UpperHPDCUMHAZ=UpperHPDCumHaz`.

**LOGLOGS=**

specifies the log of the negative log of `SURVIVAL`.

**LOGSURV=**

specifies the log of `SURVIVAL`.

**LOWER=****L=**

specifies the lower pointwise confidence limit for the survivor function. For a Bayesian analysis, this is the lower limit of the equal-tail credible interval for the survivor function. The confidence level is determined by the `ALPHA=` option.

**LOWERCMF=****LOWERMCF=**

specifies the lower pointwise confidence limit for the cumulative mean function. The confidence level is determined by the `ALPHA=` option.

**LOWERHPD=**

specifies the lower limit of the HPD interval for the survivor function. The confidence level is determined by the `ALPHA=` option.

**LOWERHPDCUMHAZ=**

specifies the lower limit of the HPD interval for the cumulative hazard function. The confidence level is determined by the `ALPHA=` option.

**LOWERCUMHAZ=**

specifies the lower pointwise confidence limit for the cumulative hazard function. For a Bayesian analysis, this is the lower limit of the equal-tail credible interval for the cumulative hazard function. The confidence level is determined by the `ALPHA=` option.

**STDERR=**

specifies the standard error of the survivor function estimator. For a Bayesian analysis, this is the standard deviation of the posterior distribution of the survivor function.

**STDCMF=**

**STDMCF=**

specifies the estimated standard error of the cumulative mean function estimator.

**STDCUMHAZ=**

specifies the estimated standard error of the cumulative hazard function estimator. For a Bayesian analysis, this is the standard deviation of the posterior distribution of the cumulative hazard function.

**STDXBETA=**

specifies the estimated standard error of the linear predictor estimator. For a Bayesian analysis, this is the standard deviation of the posterior distribution of the linear predictor.

**SURVIVAL=**

specifies the survivor function ( $S(t) = [S_0(t)]^{\exp(\beta'x)}$ ) estimate. Specifying SURVIVAL=\_ALL\_ is equivalent to specifying SURVIVAL=Survival, STDERR=StdErrSurvival, LOWER=LowerSurvival, and UPPER=UpperSurvival; and for a Bayesian analysis, SURVIVAL=\_ALL\_ also specifies LOWERHPD= LowerHPDSurvival and UPPERHPD=UpperHPDSurvival.

**UPPER=**

**U=**

specifies the upper pointwise confidence limit for the survivor function. For a Bayesian analysis, this is the upper limit of the equal-tail credible interval for the survivor function. The confidence level is determined by the ALPHA= option.

**UPPERCMF=**

**UPPERMCF=**

specifies the upper pointwise confidence limit for the cumulative mean function. The confidence level is determined by the ALPHA= option.

**UPPERCUMHAZ=**

specifies the upper pointwise confidence limit for the cumulative hazard function. For a Bayesian analysis, this is the upper limit of the equal-tail credible interval for the cumulative hazard function. The confidence level is determined by the ALPHA= option.

**UPPERHPD=**

specifies the upper limit of the equal-tail credible interval for the survivor function. The confidence level is determined by the ALPHA= option.

**UPPERHPDCUMHAZ=**

specifies the upper limit of the equal-tail credible interval for the cumulative hazard function. The confidence level is determined by the ALPHA= option.

**XBETA=**

specifies the estimate of the linear predictor  $x'\beta$ .

The following options can appear in the BASELINE statement after a slash (/). The METHOD= and CLTYPE= options apply only to the estimate of the survivor function in the classical analysis. For the Bayesian analysis, the survivor function is estimated by the Breslow (1972) method.

**ALPHA=***value*

specifies the significance level of the confidence interval for the survivor function. The value must be between 0 and 1. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified.

**CLTYPE=***method*

specifies the method used to compute the confidence limits for  $S(t, \mathbf{z})$ , the survivor function for a subject with a fixed covariate vector  $\mathbf{z}$  at event time  $t$ . The CLTYPE= option can take the following values:

**LOG**

specifies that the confidence limits for  $\log(S(t, \mathbf{z}))$  be computed using the normal theory approximation. The confidence limits for  $S(t, \mathbf{z})$  are obtained by back-transforming the confidence limits for  $\log(S(t, \mathbf{z}))$ . The default is CLTYPE=LOG.

**LOGLOG**

specifies that the confidence limits for the  $\log(-\log(S(t, \mathbf{z})))$  be computed using normal theory approximation. The confidence limits for  $S(t, \mathbf{z})$  are obtained by back-transforming the confidence limits for  $\log(-\log(S(t, \mathbf{z})))$ .

**NORMAL**

<LINEAR> specifies that the confidence limits for  $S(t, \mathbf{z})$  be computed directly using normal theory approximation.

**DIRADJ**

computes direct adjusted survival curves (Makuch 1982; Gail and Byar 1986; Zhang et al. 2007) by averaging the estimated survival curves for the observations in the COVARIATES= data set. See the section “Direct Adjusted Survival Curves” on page 5646 and Example 67.8 for the computation and specific details. If the COVARIATES= data set is not specified, the input data set specified in the DATA= option in the PROC PHREG statement is used instead. If you also specify the GROUP= option, PROC PHREG computes an adjusted survival curve for each value of the GROUP= variable.

**GROUP=***variable*

names a variable whose values identify or group the estimated survival curves. The behavior of this option depends on whether you also specify the DIRADJ option:

- If you also specify the DIRADJ option, *variable* must be a CLASS variable in the model. A direct adjusted survival curve is computed for each value of *variable* in the input data. The *variable* does not have to be a variable in the COVARIATES= data set. Each direct adjusted survival curve is the average of the survival curves of all individuals in the COVARIATES= data set with their value of *variable* set to a specific value.
- If you do not specify the DIRADJ option, *variable* is required to be a numeric variable in the COVARIATES= data set. Survival curves for the observations with the same value of the *variable* are overlaid in the same plot.

**METHOD=***method*

specifies the method used to compute the survivor function estimates. See the section “Survivor Function Estimators” on page 5643 for details. You can specify the following *methods*:

**BRESLOW****CH****EMP**

specifies that the Breslow (1972) estimator be used to compute the survivor function—that is, that the survivor function be estimated by exponentiating the negative empirical cumulative hazard function.

**FH**

specifies that the Fleming-Harrington (FH) estimates be computed. The FH estimator is a tie-breaking modification of the Breslow estimator. If there are no tied event times, this estimator is the same as the Breslow estimator.

**PL**

specifies that the product-limit estimates of the survivor function be computed. This estimator is not available if you use the model syntax that allows two time variables for counting process style of input; in such a case the Breslow estimator (METHOD=BRESLOW) is used instead.

The default is METHOD=BRESLOW.

**ROWID=***variable*

**ID=***variable*

**ROW=***variable*

names a variable in the COVARIATES= data set for identifying the baseline function curves in the plots. This option has no effect if the PLOTS= option in the PROC PHREG statement is not specified. Values of this variable are used to label the curves for the corresponding rows in the COVARIATES= data set. You can specify ROWID=\_OBS\_ to use the observation numbers in the COVARIATES= data set for identification.

For recurrent events data, both CMF= and CUMHAZ= statistics are the Nelson estimators, but their standard error are not the same. Confidence limits for the cumulative mean function and cumulative hazard function are based on the log transform.

---

## BAYES Statement

**BAYES** < *options* > ;

The BAYES statement requests a Bayesian analysis of the regression model by using Gibbs sampling. The Bayesian posterior samples (also known as the chain) for the regression parameters can be output to a SAS data set. Table 67.4 summarizes the options available in the BAYES statement.

**Table 67.4** BAYES Statement Options

| Option                     | Description                                      |
|----------------------------|--------------------------------------------------|
| <b>Monte Carlo Options</b> |                                                  |
| INITIAL=                   | Specifies initial values of the chain            |
| NBI=                       | Specifies the number of burn-in iterations       |
| NMC=                       | Specifies the number of iterations after burn-in |
| SAMPLING=                  | Specifies the sampling algorithm                 |

Table 67.4 continued

| Option                                                    | Description                                                   |
|-----------------------------------------------------------|---------------------------------------------------------------|
| SEED=                                                     | Specifies the random number generator seed                    |
| THINNING=                                                 | Controls the thinning of the Markov chain                     |
| <b>Model and Prior Options</b>                            |                                                               |
| COEFFPRIOR=                                               | Specifies the prior of the regression coefficients            |
| DISPERSIONPRIOR=                                          | Specifies the prior of the dispersion parameter for frailties |
| PIECEWISE=                                                | Specifies details of the piecewise exponential model          |
| <b>Summaries and Diagnostics of the Posterior Samples</b> |                                                               |
| DIAGNOSTICS=                                              | Displays convergence diagnostics                              |
| PLOTS=                                                    | Displays diagnostic plots                                     |
| STATISTICS=                                               | Displays summary statistics                                   |
| <b>Posterior Samples</b>                                  |                                                               |
| OUTPOST=                                                  | Names a SAS data set for the posterior samples                |

The following list describes these options and their suboptions.

**COEFFPRIOR=UNIFORM | NORMAL** <(normal-option)> | **ZELLNER** <(zellner-option)>

**CPRIOR=UNIFORM | NORMAL** <(normal-option)> | **ZELLNER** <(zellner-option)>

**COEFF=UNIFORM | NORMAL** <(normal-option)> | **ZELLNER** <(zellner-option)>

specifies the prior distribution for the regression coefficients. The default is COEFFPRIOR=UNIFORM.

The following prior distributions are available:

#### UNIFORM

specifies a flat prior—that is, the prior that is proportional to a constant ( $p(\beta_1, \dots, \beta_k) \propto 1$  for all  $-\infty < \beta_i < \infty$ ).

**NORMAL**<(normal-option)>

specifies a normal distribution. The *normal-options* include the following:

**INPUT=SAS-data-set**

specifies a SAS data set that contains the mean and covariance information of the normal prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain a variable to represent each regression coefficient. If the data set also contains the `_NAME_` variable, values of this variable are used to identify the covariances for the `_TYPE_='COV'` observations; otherwise, the `_TYPE_='COV'` observations are assumed to be in the same order as the explanatory variables in the MODEL statement. PROC PHREG reads the mean vector from the observation with `_TYPE_='MEAN'` and the covariance matrix from observations with `_TYPE_='COV'`. For an independent normal prior, the variances can be specified with `_TYPE_='VAR'`; alternatively, the precisions (inverse of the variances) can be specified with `_TYPE_='PRECISION'`.

**RELVAR** <=c>

specifies a normal prior  $N(\mathbf{0}, c\mathbf{J})$ , where  $\mathbf{J}$  is a diagonal matrix with diagonal elements equal to the variances of the corresponding ML estimator. By default,  $c=1E6$ .

**VAR=c**

specifies the normal prior  $N(\mathbf{0}, c\mathbf{I})$ , where  $\mathbf{I}$  is the identity matrix.

If you do not specify a *normal-option*, the normal prior  $N(\mathbf{0}, 10^6\mathbf{I})$ , where  $\mathbf{I}$  is the identity matrix, is used. See the section “Normal Prior” on page 5658 for details.

**ZELLNER< (zellner-option) >**

specifies the Zellner g-prior for the regression coefficients. The g-prior is a normal prior distribution with mean zero and covariance matrix equal to  $(g\mathbf{X}'\mathbf{X})^{-1}$ , where  $\mathbf{X}$  is the design matrix and  $g$  can be a constant or a parameter with a gamma prior. The *zellner-options* include the following:

**G=number**

specifies a constant *number* for  $g$ .

**GAMMA < (SHAPE=a ISCALE=b) >**

specifies that  $g$  has a gamma prior distribution  $G(a, b)$  with density  $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$ .  
By default,  $a=b=1E-4$ .

If you do not specify a *zellner-option*, the default is ZELLNER( $g=1E-6$ ).

**DISPERSIONPRIOR=GAMMA< (gamma-options) > | IGAMMA< (igamma-options) > | IMPROPER****DPRIOR=GAMMA< (gamma-options) > | IGAMMA< (igamma-options) > | IMPROPER**

specifies the prior distribution of the dispersion parameter. For gamma frailty, the dispersion parameter is the variance of the gamma frailty; for lognormal frailty, the dispersion parameter is the variance of the normal random component. The default is DISPERSIONPRIOR=IMPROPER.

You can specify the following values for this options:

**GAMMA< (gamma-options) >**

specifies the gamma prior. A gamma prior  $G(a, b)$  with hyperparameters  $a$  and  $b$  has density  $f(\theta) = \frac{b^a \theta^{a-1} e^{-b\theta}}{\Gamma(a)}$ , where  $a$  is the shape parameter and  $b$  is the inverse-scale parameter. You can use the following *gamma-options* enclosed in parentheses to specify the hyperparameters:

**SHAPE=a****ISCALE=b**

results in a  $G(a, b)$  prior when both *gamma-options* are specified.

**SHAPE=c**

results in a  $G(c, c)$  prior when specified alone.

**ISCALE=c**

results in a  $G(c, c)$  prior when specify alone.

The default is SHAPE=1E-4 and ISCALE=1E-4.

**IGAMMA< (igamma-options) >**

specifies the inverse-gamma prior. An inverse-gamma prior  $IG(a, b)$  with hyperparameters  $a$  and  $b$  has a density  $f(\theta) = \frac{b^a \theta^{-(a+1)} e^{-\frac{b}{\theta}}}{\Gamma(a)}$ , where  $a$  is the shape parameter and  $b$  is the scale parameter. You can use the following *igamma-options* enclosed in parentheses to specify the hyperparameters:

**SHAPE=*a*****SCALE=*b***

results in a  $IG(a, b)$  prior when both *igamma-options* are specified.

**SHAPE=*c***

results in a  $IG(c, c)$  prior when specified alone.

**SCALE=*c***

results in a  $IG(c, c)$  prior when specified alone.

The default is SHAPE=2.001 AND SCALE=0.01.

**IMPROPER**

specifies the improper prior, which has a density  $f(\theta)$  proportional to  $\theta^{-1}$ .

**DIAGNOSTICS=ALL | NONE | *keyword* | (*keyword-list*)****DIAG=ALL | NONE | *keyword* | (*keyword-list*)**

controls the number of diagnostics produced. You can request all the diagnostics in the following list by specifying DIAGNOSTICS=ALL. If you do not want any of these diagnostics, you specify DIAGNOSTICS=NONE. If you want some but not all of the diagnostics, or if you want to change certain settings of these diagnostics, you specify a subset of the following keywords. The default is DIAGNOSTICS=(AUTOCORR GEWEKE ESS).

**AUTOCORR <(LAGS= *numeric-list*)>**

computes the autocorrelations of lags given by LAGS= list for each parameter. Elements in the list are truncated to integers and repeated values are removed. If the LAGS= option is not specified, autocorrelations of lags 1, 5, 10, and 50 are computed for each variable. See the section “[Autocorrelations](#)” on page 152 for details.

**ESS**

computes the effective sample size of Kass et al. (1998), the correlation time, and the efficiency of the chain for each parameter. See the section “[Effective Sample Size](#)” on page 152 for details.

**MCSE****MCERROR**

computes the Monte Carlo standard error for each parameter. The Monte Carlo standard error, which measures the simulation accuracy, is the standard error of the posterior mean estimate and is calculated as the posterior standard deviation divided by the square root of the effective sample size. See the section “[Standard Error of the Mean Estimate](#)” on page 153 for details.

**HEIDELBERGER <(heidel-options)>**

computes the Heidelberg and Welch tests for each parameter. See the section “[Heidelberg and Welch Diagnostics](#)” on page 148 for details. The tests consist of a stationary test and a halfwidth test. The former tests the null hypothesis that the sample values form a stationary process. If the stationarity test is passed, a halfwidth test is then carried out. Optionally, you can specify one or more of the following *heidel-options*:

**SALPHA=***value*

specifies the  $\alpha$  level ( $0 < \alpha < 1$ ) for the stationarity test. The default is the value of the **ALPHA=** option in the PROC PHREG statement, or 0.05 if that option is not specified.

**HALPHA=***value*

specifies the  $\alpha$  level ( $0 < \alpha < 1$ ) for the halfwidth test. The default is the value of the **ALPHA=** option in the PROC PHREG statement, or 0.05 if that option is not specified.

**EPS=***value*

specifies a small positive number  $\epsilon$  such that if the halfwidth is less than  $\epsilon$  times the sample mean of the retaining samples, the halfwidth test is passed.

**GELMAN** <*gelman-options*>

computes the Gelman and Rubin convergence diagnostics. See the section “[Gelman and Rubin Diagnostics](#)” on page 145 for details. You can specify one or more of the following *gelman-options*:

**NCHAIN=***number***N=***number*

specifies the number of parallel chains used to compute the diagnostic and has to be 2 or larger. The default is NCHAIN=3. The NCHAIN= option is ignored when the INITIAL= option is specified in the BAYES statement, and in such a case, the number of parallel chains is determined by the number of valid observations in the INITIAL= data set.

**ALPHA=***value*

specifies the significance level for the upper bound. The default is the value of the **ALPHA=** option in the PROC PHREG statement, or 0.05 if that option is not specified (resulting in a 97.5% bound).

**GEWEKE** <*geweke-options*>

computes the Geweke diagnostics. See the section “[Geweke Diagnostics](#)” on page 146 for details. The diagnostic is essentially a two-sample *t*-test between the first  $f_1$  portion and the last  $f_2$  portion of the chain. The default is  $f_1=0.1$  and  $f_2=0.5$ , but you can choose other fractions by using the following *geweke-options*:

**FRAC1=***value*

specifies the early  $f_1$  fraction of the Markov chain.

**FRAC2=***value*

specifies the latter  $f_2$  fraction of the Markov chain.

**RAFTERY** <*raftery-options*>

computes the Raftery and Lewis diagnostics. See the section “[Raftery and Lewis Diagnostics](#)” on page 149 for details. The diagnostic evaluates the accuracy of the estimated quantile ( $\hat{\theta}_Q$  for a given  $Q \in (0, 1)$ ) of a chain.  $\hat{\theta}_Q$  can achieve any degree of accuracy when the chain is allowed to run for a long time. A stopping criterion is when the estimated probability  $\hat{P}_Q = \Pr(\theta \leq \hat{\theta}_Q)$  reaches within  $\pm R$  of the value  $Q$  with probability  $S$ ; that is,  $\Pr(Q - R \leq \hat{P}_Q \leq Q + R) = S$ . The following *raftery-options* enable you to specify  $Q$ ,  $R$ ,  $S$ , and a precision level  $\epsilon$  for a stationary test.

**QUANTILE=***value***Q=***value*

specifies the order (a value between 0 and 1) of the quantile of interest. The default is 0.025.

**ACCURACY=***value***R=***value*

specifies a small positive number as the margin of error for measuring the accuracy of estimation of the quantile. The default is 0.005.

**PROBABILITY=***value***S=***value*

specifies the probability of attaining the accuracy of the estimation of the quantile. The default is 0.95.

**EPSILON=***value***EPS=***value*

specifies the tolerance level (a small positive number) for the test. The default is 0.001.

**INITIAL=***SAS-data-set*

specifies the SAS data set that contains the initial values of the Markov chains. The INITIAL= data set must contain a variable for each parameter in the model. You can specify multiple rows as the initial values of the parallel chains for the Gelman-Rubin statistics, but posterior summary statistics, diagnostics, and plots are computed only for the first chain.

**NBI=***number*

specifies the number of burn-in iterations before the chains are saved. The default is 2000.

**NMC=***number*

specifies the number of iterations after the burn-in. The default is 10000.

**OUTPOST=***SAS-data-set***OUT=***SAS-data-set*names the SAS data set that contains the posterior samples. See the section “[OUTPOST= Output Data Set in the BAYES Statement](#)” on page 5665 for more information. Alternatively, you can output the posterior samples into a data set, as shown in the following example in which the data set is named PostSamp.

```
ODS OUTPUT PosteriorSample = PostSamp;
```

**PIECEWISE** <=*keyword* <(< **NINTERVAL=***number* > < **INTERVALS=**(*numeric-list*) > < **PRIOR=***option* >)>>specifies that the piecewise constant baseline hazard model be used in the Bayesian analysis. You can specify one of the following two *keywords*:**HAZARD**

models the baseline hazard parameters in the original scale. The hazard parameters are named Lambda1, Lambda2, . . . , and so on.

**LOGHAZARD**

models the baseline hazard parameters in the log scale. The log-hazard parameters are named Alpha1, Alpha2, . . . , and so on.

Specifying PIECEWISE by itself is the same as specifying PIECEWISE=LOGHAZARD.

You can choose one of the following two options to specify the partition of the time axis into intervals of constant baseline hazards:

**NINTERVAL=***number*

**N=***number*

specifies the number of intervals with constant baseline hazard rates. PROC PHREG partitions the time axis into the given number of intervals with approximately equal number of events in each interval.

**INTERVALS=***(numeric-list)*

**INTERVAL=***(numeric-list)*

specifies the list of numbers that partition the time axis into disjoint intervals with constant baseline hazard in each interval. For example, INTERVALS=(100, 150, 200, 250, 300) specifies a model with a constant hazard in the intervals [0,100), [100,150), [150,200), [200,250), [250,300), and [300,∞). Each interval must contain at least one event; otherwise, the posterior distribution can be improper, and inferences cannot be derived from an improper posterior distribution.

If neither **NINTERVAL=** nor **INTERVAL=** is specified, the default is **NINTERVAL=8**.

To specify the prior for the baseline hazards  $(\lambda_1, \dots, \lambda_J)$  in the original scale, you specify the following:

**PRIOR = IMPROPER | UNIFORM | GAMMA***<(gamma-option)>* | **ARGAMMA***<(arggamma-option)>*

The default is **PRIOR=IMPROPER**. The available prior options include the following:

**IMPROPER**

specifies the noninformative and improper prior  $p(\lambda_1, \dots, \lambda_J) \propto \prod_i \lambda_i^{-1}$  for all  $\lambda_i > 0$ .

**UNIFORM**

specifies a uniform prior on the real line; that is,  $p(\lambda_i) \propto 1$  for all  $\lambda_i > 0$ .

**GAMMA** *<(gamma-option)>*

specifies an independent gamma prior  $G(a, b)$  with density  $f(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}$ , which can be followed by one of the following *gamma-options* enclosed in parentheses. The hyperparameters  $a$  and  $b$  are the shape and inverse-scale parameters of the gamma distribution, respectively. See the section “[Independent Gamma Prior](#)” on page 5657 for details. The default is  $G(10^{-4}, 10^{-4})$  for each  $\lambda_j$ , setting the prior mean to 1 with variance 1E4. This prior is proper and reasonably noninformative.

**INPUT=SAS-data-set**

specifies a data set containing the hyperparameters of the independent gamma prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain the variables named Lambda1, Lambda2, . . . , and so forth, to represent

the hazard parameters. The observation with `_TYPE_='SHAPE'` identifies the shape parameters, and the observation with `_TYPE_='ISCALE'` identifies the inverse-scale parameters.

**RELSHAPE=<c>**

specifies independent  $G(c\hat{\lambda}_j, c)$  distribution, where  $\hat{\lambda}_j$ 's are the MLEs of the hazard rates. This prior has mean  $\hat{\lambda}_j$  and variance  $\frac{\hat{\lambda}_j}{c}$ . By default,  $c=1E-4$ .

**SHAPE=a and ISCALE=b**

together specify the  $G(a, b)$  prior.

**SHAPE=c****ISCALE=c**

specifies the  $G(c, c)$  prior.

**ARGAMMA <(argamma-option)>**

specifies an autoregressive gamma prior of order 1, which can be followed by one of the following *argamma-options*. See the section “AR1 Prior” on page 5657 for details.

**INPUT=SAS-data-set**

specifies a data set containing the hyperparameters of the correlated gamma prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain the variables named `Lambda1`, `Lambda2`, `...`, and so forth, to represent the hazard parameters. The observation with `_TYPE_='SHAPE'` identifies the shape parameters, and the observation with `_TYPE_='ISCALE'` identifies the *relative* inverse-scale parameters; that is, if  $a_j$  and  $b_j$  are, respectively, the SHAPE and ISCALE values for  $\lambda_j$ ,  $1 \leq j \leq J$ , then  $\lambda_1 \sim G(a_1, b_1)$ , and  $\lambda_j \sim G(a_j, b_j/\lambda_{j-1})$  for  $2 \leq j \leq J$ .

**SHAPE=a and SCALE=b**

together specify that  $\lambda_1 \sim G(a, b)$  and  $\lambda_j \sim G(a, b/\lambda_{j-1})$  for  $2 \leq j \leq J$ .

**SHAPE=c****ISCALE=c**

specifies that  $\lambda_1 \sim G(c, c)$  and  $\lambda_j \sim G(c, c/\lambda_{j-1})$  for  $2 \leq j \leq J$ .

To specify the prior for  $\alpha_1, \dots, \alpha_J$ , the hazard parameters in the log scale, you specifying the following:

**PRIOR=UNIFORM | NORMAL<(normal-option)>**

specifies the prior for the loghazard parameters. The default is `PRIOR=UNIFORM`. The available `PRIOR=` options are as follows:

**UNIFORM**

specifies the uniform prior on the real line; that is,  $\alpha_i \propto 1$  for all  $-\infty < \alpha_i < \infty$ .

**NORMAL<(normal-option)>**

specifies a normal prior distribution on the log-hazard parameters. The *normal-options* include the following. If you do not specify a *normal-option*, the normal prior  $N(\mathbf{0}, 10^6\mathbf{I})$ , where  $\mathbf{I}$  is the identity matrix, is used.

**INPUT=SAS-data-set**

specifies a SAS data set containing the mean and covariance information of the normal prior. The data set must contain the `_TYPE_` variable to identify the observation type, and it must contain variables named `Alpha1`, `Alpha2`, ..., and so forth, to represent the log-hazard parameters. If the data set also contains the `_NAME_` variable, the value of this variable will be used to identify the covariances for the `_TYPE_='COV'` observations; otherwise, the `_TYPE_='COV'` observations are assumed to be in the same order as the explanatory variables in the MODEL statement. PROC PHREG reads the mean vector from the observation with `_TYPE_='MEAN'` and the covariance matrix from observations with `_TYPE_='COV'`. See the section “Normal Prior” on page 5658 for details. For an independent normal prior, the variances can be specified with `_TYPE_='VAR'`; alternatively, the precisions (inverse of the variances) can be specified with `_TYPE_='PRECISION'`.

If you have a joint normal prior for the log-hazard parameters and the regression coefficients, specify the same data set containing the mean and covariance information of the multivariate normal distribution in both the `COEFFPRIOR=NORMAL(INPUT=)` and the `PIECEWISE=LOGHAZARD(PRIOR=NORMAL(INPUT=))` options. See the section “Joint Multivariate Normal Prior for Log-Hazards and Regression Coefficients” on page 5658 for details.

**RELVAR <c>**

specifies the normal prior  $N(\mathbf{0}, \mathbf{cJ})$ , where  $\mathbf{J}$  is a diagonal matrix with diagonal elements equal to the variances of the corresponding ML estimator. By default,  $\mathbf{c}=1E6$ .

**VAR=c**

specifies the normal prior  $N(\mathbf{0}, \mathbf{cI})$ , where  $\mathbf{I}$  is the identity matrix.

**PLOTS <(global-plot-options)> = plot-request****PLOTS <(global-plot-options)> = (plot-requests)**

controls the diagnostic plots produced through ODS Graphics. Three types of plots can be requested: trace plots, autocorrelation function plots, and kernel density plots. By default, the plots are displayed in panels unless the global plot option `UNPACK` is specified. If you specify more than one type of plots, the plots are displayed by parameters unless the global plot option `GROUPBY=TYPE` is specified. When you specify only one plot request, you can omit the parentheses around the plot request. For example:

```
plots=none
plots(unpack)=trace
plots=(trace autocorr)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc phreg;
 model y=x;
 bayes plots=trace;
run;
ods graphics off;
```

If ODS Graphics is enabled but you do not specify the PLOTS= option in the BAYES statement, then PROC PHREG produces, for each parameter, a panel that contains the trace plot, the autocorrelation function plot, and the density plot. This is equivalent to specifying `plots=(trace autocorr density)`.

The *global-plot-options* include the following:

**FRINGE**

creates a fringe plot on the X axis of the density plot.

**GROUPBY = PARAMETER | TYPE**

specifies how the plots are to be grouped when there is more than one type of plots. The choices are as follows:

**TYPE**

specifies that the plots be grouped by type.

**PARAMETER**

specifies that the plots be grouped by parameter.

GROUPBY=PARAMETER is the default.

**SMOOTH**

displays a fitted penalized B-spline curve each trace plot.

**UNPACKPANEL**

**UNPACK**

specifies that all paneled plots be unpacked, meaning that each plot in a panel is displayed separately.

The *plot-requests* include the following:

**ALL**

specifies all types of plots. PLOTS=ALL is equivalent to specifying PLOTS=(TRACE AUTOCORR DENSITY).

**AUTOCORR**

displays the autocorrelation function plots for the parameters.

**DENSITY**

displays the kernel density plots for the parameters.

**NONE**

suppresses all diagnostic plots.

**TRACE**

displays the trace plots for the parameters. See the section “[Visual Analysis via Trace Plots](#)” on page 139 for details.

Consider a model with four parameters, X1–X4. Displays for various specification are depicted as follows.

1. PLOTS=(TRACE AUTOCORR) displays the trace and autocorrelation plots for each parameter side by side with two parameters per panel:

---

|           |           |              |
|-----------|-----------|--------------|
| Display 1 | Trace(X1) | Autocorr(X1) |
|           | Trace(X2) | Autocorr(X2) |

|           |           |              |
|-----------|-----------|--------------|
| Display 2 | Trace(X3) | Autocorr(X3) |
|           | Trace(X4) | Autocorr(X4) |

---

2. PLOTS(GROUPBY=TYPE)=(TRACE AUTOCORR) displays all the paneled trace plots, followed by panels of autocorrelation plots:

---

|           |           |
|-----------|-----------|
| Display 1 | Trace(X1) |
|           | Trace(X2) |

|           |           |
|-----------|-----------|
| Display 2 | Trace(X3) |
|           | Trace(X4) |

|           |              |              |
|-----------|--------------|--------------|
| Display 3 | Autocorr(X1) | Autocorr(X2) |
|           | Autocorr(X3) | Autocorr(X4) |

---

3. PLOTS(UNPACK)=(TRACE AUTOCORR) displays a separate trace plot and a separate correlation plot, parameter by parameter:

---

|           |           |
|-----------|-----------|
| Display 1 | Trace(X1) |
|-----------|-----------|

|           |              |
|-----------|--------------|
| Display 2 | Autocorr(X1) |
|-----------|--------------|

|           |           |
|-----------|-----------|
| Display 3 | Trace(X2) |
|-----------|-----------|

|           |              |
|-----------|--------------|
| Display 4 | Autocorr(X2) |
|-----------|--------------|

|           |           |
|-----------|-----------|
| Display 5 | Trace(X3) |
|-----------|-----------|

|           |              |
|-----------|--------------|
| Display 6 | Autocorr(X3) |
|-----------|--------------|

|           |           |
|-----------|-----------|
| Display 7 | Trace(X4) |
|-----------|-----------|

|           |              |
|-----------|--------------|
| Display 8 | Autocorr(X4) |
|-----------|--------------|

---

4. PLOTS(UNPACK GROUPBY=TYPE) = (TRACE AUTOCORR) displays all the separate trace plots followed by the separate autocorrelation plots:

---

|           |              |
|-----------|--------------|
| Display 1 | Trace(X1)    |
| Display 2 | Trace(X2)    |
| Display 3 | Trace(X3)    |
| Display 4 | Trace(X4)    |
| Display 5 | Autocorr(X1) |
| Display 6 | Autocorr(X2) |
| Display 7 | Autocorr(X3) |
| Display 8 | Autocorr(X4) |

---

**SAMPLING=keyword**

specifies the sampling algorithm used in the Markov chain Monte Carlo (MCMC) simulations. Two sampling algorithms are available:

**ARMS****GIBBS**

requests the use of the adaptive rejection Metropolis sampling (ARMS) algorithm to draw the Gibbs samples. ALGORITHM=ARMS is the default.

**RWM**

requests the use of the random walk Metropolis (RWM) algorithm to draw the samples.

For details about the MCMC sampling algorithms, see the section “[Markov Chain Monte Carlo Method](#)” on page 133 in Chapter 7, “[Introduction to Bayesian Analysis Procedures](#).”

**SEED=number**

specifies an integer seed ranging from 1 to  $2^{31}-1$  for the random number generator in the simulation. Specifying a seed enables you to reproduce identical Markov chains for the same specification. If the SEED= option is not specified, or if you specify a nonpositive seed, a random seed is derived from the time of day.

**STATISTICS <(global-options)> = ALL | NONE | keyword | (keyword-list)****STATS <(global-statoptions)> = ALL | NONE | keyword | (keyword-list)**

controls the number of posterior statistics produced. Specifying STATISTICS=ALL is equivalent to specifying STATISTICS=(SUMMARY INTERVAL COV CORR). If you do not want any posterior statistics, you specify STATISTICS=NONE. The default is STATISTICS=(SUMMARY INTERVAL). See the section “[Summary Statistics](#)” on page 153 for details. The *global-options* include the following:

**ALPHA=***numeric-list*

controls the probabilities of the credible intervals. The ALPHA= values must be between 0 and 1. Each ALPHA= value produces a pair of 100(1–ALPHA)% equal-tail and HPD intervals for each parameters. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified (yielding the 95% credible intervals for each parameter).

**PERCENT=***numeric-list*

requests the percentile points of the posterior samples. The PERCENT= values must be between 0 and 100. The default is PERCENT= 25, 50, 75, which yield the 25th, 50th, and 75th percentile points for each parameter.

You can specify the following values for a *keyword* or as part of a *keyword-list*. To specify a list, place parentheses around multiple keywords that are separated by spaces.

**CORR**

produces the posterior correlation matrix.

**COV**

produces the posterior covariance matrix.

**SUMMARY**

produces the means, standard deviations, and percentile points for the posterior samples. The default is to produce the 25th, 50th, and 75th percentile points, but you can use the global PERCENT= option to request specific percentile points.

**INTERVAL**

produces equal-tail credible intervals and HPD intervals. The default is to produce the 95% equal-tail credible intervals and 95% HPD intervals, but you can use the global ALPHA= option to request intervals of any probabilities.

**THINNING=***number***THIN=***number*

controls the thinning of the Markov chain. Only one in every  $k$  samples is used when THINNING= $k$ , and if NBI= $n_0$  and NMC= $n$ , the number of samples kept is

$$\left[ \frac{n_0 + n}{k} \right] - \left[ \frac{n_0}{k} \right]$$

where  $[a]$  represents the integer part of the number  $a$ . The default is THINNING=1.

**BY Statement****BY variables ;**

You can specify a BY statement with PROC PHREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the PHREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* < (*options*) > ... < *variable* < (*options*) > > < / *global-options* > ;

The CLASS statement names the classification variables to be used as explanatory variables in the analysis.

The CLASS statement must precede the MODEL statement. Most options can be specified either as individual variable *options* or as *global-options*. You can specify *options* for each variable by enclosing the options in parentheses after the variable name. You can also specify *global-options* for the CLASS statement by placing them after a slash (/). *Global-options* are applied to all the variables specified in the CLASS statement. If you specify more than one CLASS statement, the *global-options* specified in any one CLASS statement apply to all CLASS statements. However, individual CLASS variable *options* override the *global-options*. You can specify the following values for either an *option* or a *global-option*:

### CPREFIX=*n*

specifies that, at most, the first *n* characters of a CLASS variable name be used in creating names for the corresponding design variables. The default is  $32 - \min(32, \max(2, f))$ , where *f* is the formatted length of the CLASS variable.

### DESCENDING

#### DESC

reverses the sort order of the classification variable. If both the DESCENDING and ORDER= options are specified, PROC PHREG orders the categories according to the ORDER= option and then reverses that order.

### LPREFIX=*n*

specifies that, at most, the first *n* characters of a CLASS variable label be used in creating labels for the corresponding design variables. The default is  $256 - \min(256, \max(2, f))$ , where *f* is the formatted length of the CLASS variable.

### MISSING

treats missing values ('.', '.\_', '.A', ..., '.Z' for numeric variables and blanks for character variables) as valid values for the CLASS variable.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of classification variables. This ordering determines which parameters in the model correspond to each level in the data, so the ORDER= option can be useful when you use the CONTRAST statement. By default, ORDER=FORMATTED. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent. When ORDER=FORMATTED is in effect for numeric variables for which you have supplied no explicit format, the levels are ordered by their internal values.

The following table shows how PROC PHREG interprets values of the ORDER= option.

| Value of ORDER= | Levels Sorted By                                                                                                                         |
|-----------------|------------------------------------------------------------------------------------------------------------------------------------------|
| DATA            | Order of appearance in the input data set                                                                                                |
| FORMATTED       | External formatted values, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) values |
| FREQ            | Descending frequency count; levels with more observations come earlier in the order                                                      |
| INTERNAL        | Unformatted value                                                                                                                        |

For more information about sort order, see the chapter on the SORT procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PARAM=keyword**

specifies the parameterization method for the classification variable or variables. You can specify any of the *keywords* shown in the following table; the default is PARAM=REF. Design matrix columns are created from CLASS variables according to the corresponding coding schemes:

| Value of PARAM=           | Coding                                                                                              |
|---------------------------|-----------------------------------------------------------------------------------------------------|
| EFFECT                    | Effect coding                                                                                       |
| GLM                       | Less-than-full-rank reference cell coding (this <i>keyword</i> can be used only in a global option) |
| ORDINAL<br>THERMOMETER    | Cumulative parameterization for an ordinal CLASS variable                                           |
| POLYNOMIAL<br>POLY        | Polynomial coding                                                                                   |
| REFERENCE<br>REF          | Reference cell coding                                                                               |
| ORTHEFFECT                | Orthogonalizes PARAM=EFFECT coding                                                                  |
| ORTHORDINAL<br>ORTHOTHERM | Orthogonalizes PARAM=ORDINAL coding                                                                 |
| ORTHPOLY                  | Orthogonalizes PARAM=POLYNOMIAL coding                                                              |
| ORTHREF                   | Orthogonalizes PARAM=REFERENCE coding                                                               |

All parameterizations are full rank, except for the GLM parameterization. The **REF=** option in the CLASS statement determines the reference level for EFFECT and REFERENCE coding and for their orthogonal parameterizations. It also indirectly determines the reference level for a singular GLM parameterization through the order of levels.

If **PARAM=ORTHPOLY** or **PARAM=POLY** and the classification variable is numeric, then the **ORDER=** option in the CLASS statement is ignored, and the internal unformatted values are used. See the section “[Other Parameterizations](#)” on page 387 of Chapter 19, “[Shared Concepts and Topics](#),” for further details.

**REF=** *'level' | keyword*

specifies the reference level for **PARAM=EFFECT**, **PARAM=REFERENCE**, and their orthogonalizations. For **PARAM=GLM**, the **REF=** option specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the linear estimates with a singular parameterization.

For an individual variable **REF=** option (but not for a global **REF=** option), you can specify the *level* of the variable to use as the reference level. Specify the formatted value of the variable if a format is assigned. For a global or individual variable **REF=** option, you can use one of the following *keywords*. The default is **REF=LAST**.

**FIRST**     designates the first ordered level as reference.

**LAST**      designates the last ordered level as reference.

**TRUNCATE**<=*n*>

specifies the length *n* of CLASS variable values to use in determining CLASS variable levels. The default is to use the full formatted length of the CLASS variable. If you specify **TRUNCATE** without the length *n*, the first 16 characters of the formatted values are used. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases before SAS 9. The **TRUNCATE** option is available only as a global option.

## Class Variable Naming Convention

Parameter names for a CLASS predictor variable are constructed by concatenating the CLASS variable name with the CLASS levels. However, for the POLYNOMIAL and orthogonal parameterizations, parameter names are formed by concatenating the CLASS variable name and keywords that reflect the parameterization. See the section “[Other Parameterizations](#)” on page 387 in Chapter 19, “[Shared Concepts and Topics](#),” for examples and further details.

## Class Variable Parameterization with Unbalanced Designs

PROC PHREG initially parameterizes the CLASS variables by looking at the levels of the variables across the complete data set. If you have an *unbalanced* replication of levels across variables or BY groups, then the design matrix and the parameter interpretation might be different from what you expect. For instance, suppose you have a model with one CLASS variable A with three levels (1, 2, and 3), and another CLASS variable B with two levels (1 and 2). If the third level of A occurs only with the first level of B, if you use the EFFECT parameterization, and if your model contains the effect A(B) and an intercept, then the design for A within the second level of B is not a differential effect. In particular, the design looks like the following:

|   |   | Design Matrix |    |        |    |
|---|---|---------------|----|--------|----|
|   |   | A(B=1)        |    | A(B=2) |    |
| B | A | A1            | A2 | A1     | A2 |
| 1 | 1 | 1             | 0  | 0      | 0  |
| 1 | 2 | 0             | 1  | 0      | 0  |
| 1 | 3 | -1            | -1 | 0      | 0  |
| 2 | 1 | 0             | 0  | 1      | 0  |
| 2 | 2 | 0             | 0  | 0      | 1  |

PROC PHREG detects linear dependency among the last two design variables and sets the parameter for A2(B=2) to zero, resulting in an interpretation of these parameters as if they were reference- or dummy-coded. The REFERENCE or GLM parameterization might be more appropriate for such problems.

## CONTRAST Statement

**CONTRAST** *'label'* *row-description* <, ... *row-description*> </ *options*> ;

The CONTRAST statement provides a mechanism for obtaining customized hypothesis tests. It is similar to the CONTRAST statement in PROC GLM and PROC CATMOD, depending on the coding schemes used with any categorical variables involved.

The CONTRAST statement enables you to specify a matrix,  $\mathbf{L}$ , for testing the hypothesis  $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ . You must be familiar with the details of the model parameterization that PROC PHREG uses (for more information, see the PARAM= option in the section “CLASS Statement” on page 5578). Optionally, the CONTRAST statement enables you to estimate each row,  $\mathbf{L}'_i\boldsymbol{\beta}$ , of  $\mathbf{L}\boldsymbol{\beta}$  and test the hypothesis  $\mathbf{L}'_i\boldsymbol{\beta} = 0$ . Computed statistics are based on the asymptotic chi-square distribution of the Wald statistic.

There is no limit to the number of CONTRAST statements that you can specify, but they must appear after the MODEL statement.

The syntax of a *row-description* is:

*effect values* <, ... , *effect values*>

The following parameters are specified in the CONTRAST statement:

- label* identifies the contrast on the output. A label is required for every contrast specified, and it must be enclosed in quotes.
- effect* identifies an effect that appears in the MODEL statement. You do not need to include all effects that are included in the MODEL statement.
- values* are constants that are elements of the  $\mathbf{L}$  matrix associated with the effect. To correctly specify your contrast, it is crucial to know the ordering of parameters within each effect and the variable levels associated with any parameter. The “Class Level Information” table shows the ordering of levels within variables. The E option, described later in this section, enables you to verify the proper correspondence of *values* to parameters.

The rows of  $\mathbf{L}$  are specified in order and are separated by commas. Multiple degree-of-freedom hypotheses can be tested by specifying multiple *row-descriptions*. For any of the full-rank parameterizations, if an effect

is not specified in the CONTRAST statement, all of its coefficients in the **L** matrix are set to 0. If too many values are specified for an effect, the extra ones are ignored. If too few values are specified, the remaining ones are set to 0.

When you use effect coding (by specifying PARAM=EFFECT in the CLASS statement), all parameters are directly estimable (involve no other parameters). For example, suppose an effect coded CLASS variable **A** has four levels. Then there are three parameters ( $\alpha_1, \alpha_2, \alpha_3$ ) representing the first three levels, and the fourth parameter is represented by

$$-\alpha_1 - \alpha_2 - \alpha_3$$

To test the first versus the fourth level of **A**, you would test

$$\alpha_1 = -\alpha_1 - \alpha_2 - \alpha_3$$

or, equivalently,

$$2\alpha_1 + \alpha_2 + \alpha_3 = 0$$

which, in the form  $\mathbf{L}\boldsymbol{\beta} = 0$ , is

$$\begin{bmatrix} 2 & 1 & 1 \end{bmatrix} \begin{bmatrix} \alpha_1 \\ \alpha_2 \\ \alpha_3 \end{bmatrix} = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1 vs. 4' A 2 1 1;
```

To contrast the third level with the average of the first two levels, you would test

$$\frac{\alpha_1 + \alpha_2}{2} = \alpha_3$$

or, equivalently,

$$\alpha_1 + \alpha_2 - 2\alpha_3 = 0$$

Therefore, you would use the following CONTRAST statement:

```
contrast '1&2 vs. 3' A 1 1 -2;
```

Other CONTRAST statements involving classification variables with PARAM=EFFECT are constructed similarly. For example:

```
contrast '1 vs. 2' A 1 -1 0;
contrast '1&2 vs. 4' A 3 3 2;
contrast '1&2 vs. 3&4' A 2 2 0;
contrast 'Main Effect' A 1 0 0,
A 0 1 0,
A 0 0 1;
```

When you use the less-than-full-rank parameterization (by specifying PARAM=GLM in the CLASS statement), each row is checked for estimability. If PROC PHREG finds a contrast to be nonestimable, it displays missing values in corresponding rows in the results. PROC PHREG handles missing level combinations of categorical variables in the same manner as PROC GLM. Parameters corresponding to missing level combinations are not included in the model. This convention can affect the way in which you specify the **L** matrix in your CONTRAST statement. If the elements of **L** are not specified for an effect that contains a specified effect, then the elements of the specified effect are distributed over the levels of the higher-order effect just as the GLM procedure does for its CONTRAST and ESTIMATE statements. For example, suppose that the model contains effects A and B and their interaction A\*B. If you specify a CONTRAST statement involving A alone, the **L** matrix contains nonzero terms for both A and A\*B, since A\*B contains A.

The Cox model contains no explicit intercept parameter, so it is not valid to specify one in the CONTRAST statement. As a consequence, you can test or estimate only homogeneous linear combinations (those with zero-intercept coefficients, such as contrasts that represent group differences) for the GLM parameterization.

The degrees of freedom are the number of linearly independent constraints implied by the CONTRAST statement—that is, the rank of **L**.

You can specify the following *options* after a slash (/).

**ALPHA=** *p*

specifies the level of significance *p* for the  $100(1 - p)\%$  confidence interval for each contrast when the ESTIMATE option is specified. The value *p* must be between 0 and 1. By default, *p* is equal to the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified.

**E**

requests that the **L** matrix be displayed.

**ESTIMATE=***keyword*

requests that each individual contrast (that is, each row,  $l'_i\beta$ , of **L** $\beta$ ) or exponentiated contrast ( $e^{l'_i\beta}$ ) be estimated and tested. PROC PHREG displays the point estimate, its standard error, a Wald confidence interval, and a Wald chi-square test for each contrast. The significance level of the confidence interval is controlled by the ALPHA= option. You can estimate the contrast or the exponentiated contrast ( $e^{l'_i\beta}$ ), or both, by specifying one of the following *keywords*:

|      |                                                                               |
|------|-------------------------------------------------------------------------------|
| PARM | specifies that the contrast itself be estimated.                              |
| EXP  | specifies that the exponentiated contrast be estimated.                       |
| BOTH | specifies that both the contrast and the exponentiated contrast be estimated. |

**SINGULAR=***number*

tunes the estimability check. This option is ignored when the full-rank parameterization is used. If **v** is a vector, define ABS(**v**) to be the largest absolute value of the elements of **v**. For a row vector  $l'$  of the contrast matrix **L**, define *c* to be equal to ABS( $l'$ ) if ABS( $l'$ ) is greater than 0; otherwise, *c* equals 1. If  $\text{ABS}(l' - l'\mathbf{T})$  is greater than  $c * \text{number}$ , then  $l'$  is declared nonestimable. The **T** matrix is the Hermite form matrix  $\mathbf{I}_0^{-1}\mathbf{I}_0$ , where  $\mathbf{I}_0^{-1}$  represents a generalized inverse of the information matrix  $\mathbf{I}_0$  of the null model. The value for *number* must be between 0 and 1; the default value is 1E-4.

**TEST**< (*keywords*)>

requests a Type 3 test for each contrast. The default is to use the Wald statistic, but you can request other statistics by specifying one or more of the following *keywords*:

**ALL**

requests the likelihood ratio tests, the score tests, and the Wald tests. Specifying TEST(ALL) is equivalent to specifying TEST=(LR SCORE WALD).

**NONE**

suppresses the Type 3 analysis. Even if the TEST option is not specified, PROC PHREG displays the Wald test results for each model effect if a CLASS variable is involved in a MODEL effect. The NONE option can be used to suppress such display.

**LR**

requests the likelihood ratio tests. This request is not honored if the COVS option is also specified.

**SCORE**

requests the score tests. This request is not honored if the COVS option is also specified.

**WALD**

requests the Wald tests.

\*

## EFFECT Statement

**EFFECT** *name*=*effect-type* (*variables* < / *options*>);

The EFFECT statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects that are formed from continuous or classification variables, as discussed in the section “GLM Parameterization of Classification Variables and Effects” on page 383 in Chapter 19, “Shared Concepts and Topics.”

You can specify the following *effect-types*:

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>COLLECTION</b>        | is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.       |
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                           |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                             |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 67.5 summarizes the *options* available in the EFFECT statement.

**Table 67.5** EFFECT Statement Options

| Option                             | Description                                                                                                                                           |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Collection Effects Options</b>  |                                                                                                                                                       |
| DETAILS                            | Displays the constituents of the collection effect                                                                                                    |
| <b>Lag Effects Options</b>         |                                                                                                                                                       |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                         |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                             |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                            |
| PERIOD=                            | Names the variable that defines the period                                                                                                            |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                             |
| <b>Multimember Effects Options</b> |                                                                                                                                                       |
| NOEFFECT                           | Specifies that observations with all missing levels for the multi-member variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                             |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                       |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                                |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                              |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                               |
| <b>Spline Effects Options</b>      |                                                                                                                                                       |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                               |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                     |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                               |

For more information about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “EFFECT Statement” on page 393 in Chapter 19, “Shared Concepts and Topics.”

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 < , <'label'> estimate-specification <(divisor=n)> > < , ... >
 </ options > ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $\mathbf{L}\boldsymbol{\beta}$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 67.6 summarizes *options* available in the ESTIMATE statement. If the BAYES statement is specified, the ADJUST=, STEPDOWN, TESTVALUE, LOWER, UPPER, and JOINT options are ignored. The PLOTS= option is not available for the maximum likelihood analysis. It is available only for the Bayesian analysis.

**Table 67.6** ESTIMATE Statement Options

| Option                                                     | Description                                                                    |
|------------------------------------------------------------|--------------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                                |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                          |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects      |
| SINGULAR=                                                  | Tunes the estimability checking difference                                     |
| <b>Degrees of Freedom and <i>p</i>-values</b>              |                                                                                |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates          |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                               |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                     |
| STEPDOWN                                                   | Adjusts multiplicity-corrected <i>p</i> -values further in a step-down fashion |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                           |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                     |
| <b>Statistical Output</b>                                  |                                                                                |
| CL                                                         | Constructs confidence limits                                                   |
| CORR                                                       | Displays the correlation matrix of estimates                                   |
| COV                                                        | Displays the covariance matrix of estimates                                    |
| E                                                          | Prints the $\mathbf{L}$ matrix                                                 |
| JOINT                                                      | Produces a joint <i>F</i> or chi-square test for the estimable functions       |
| PLOTS=                                                     | Requests ODS statistical graphics if the analysis is sampling-based            |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers              |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 of Chapter 19, “Shared Concepts and Topics.”

---

## FREQ Statement

**FREQ** *variable* </ option > ;

The FREQ statement identifies the *variable* (in the input data set) that contains the frequency of occurrence of each observation. PROC PHREG treats each observation as if it appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. If not an integer, the frequency value is truncated to an integer. If the frequency value is missing, the observation is not used in the estimation of the regression parameters.

The following option can be specified in the FREQ statement after a slash (/):

**NOTRUNCATE**

**NOTRUNC**

specifies that frequency values are not truncated to integers.

---

## HAZARDRATIO Statement

**HAZARDRATIO** < 'label' > *variable* </ options > ;

The HAZARDRATIO statement enables you to request hazard ratios for any variable in the model at customized settings. For example, if the model contains the interaction of a CLASS variable A and a continuous variable X, the following specification displays a table of hazard ratios comparing the hazards of each pair of levels of A at X=3:

```
hazardratio A / at (X=3) diff=ALL;
```

The HAZARDRATIO statement identifies the variable whose hazard ratios are to be evaluated. If the variable is a continuous variable, the hazard ratio compares the hazards for a given change (by default, a increase of 1 unit) in the variable. For a CLASS variable, a hazard ratio compares the hazards of two levels of the variable. More than one HAZARDRATIO statement can be specified, and an optional label (specified as a quoted string) helps identify the output.

Table 67.7 summarizes the options available in the HAZARDRATIO statement.

**Table 67.7** HAZARDRATIO Statement Options

| Option      | Description                                                           |
|-------------|-----------------------------------------------------------------------|
| ALPHA=      | Specifies the alpha level                                             |
| AT          | Specifies the variables that interact with the variable of interest   |
| CL=         | Specifies confidence limits                                           |
| DIFF=       | Specifies which differences to consider                               |
| E           | Displays the log-hazard ratio                                         |
| PLCONV=     | Controls the convergence criterion                                    |
| PLMAXIT=    | Specifies the maximum number of iterations to achieve the convergence |
| PLSINGULAR= | Specifies the tolerance for testing the singularity                   |
| UNITS=      | Specifies the units of change                                         |

Options for the HAZARDRATIO statement are as follows.

**ALPHA=number**

specifies the alpha level of the interval estimates for the hazard ratios. The value must be between 0 and 1. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified.

**AT (variable=ALL | REF | list <... variable=ALL | REF | list > )**

specifies the variables that interact with the variable of interest and the corresponding values of the interacting variables. If the interacting variable is continuous and a numeric list is specified after the equal sign, hazard ratios are computed for each value in the list. If the interacting variable is a CLASS variable, you can specify, after the equal sign, a list of quoted strings corresponding to various levels of the CLASS variable, or you can specify the keyword ALL or REF. Hazard ratios are computed at each value of the list if the list is specified, or at each level of the interacting variable if ALL is specified, or at the reference level of the interacting variable if REF is specified.

If this option is not specified, PROC PHREG finds all the variables that interact with the variable of interest. If an interacting variable is a CLASS variable, *variable= ALL* is the default; if the interacting variable is continuous, *variable=m* is the default, where *m* is the average of all the sampled values of the continuous variable.

Suppose the model contains two interactions: an interaction A\*B of CLASS variables A and B, and another interaction A\*X of A with a continuous variable X. If 3.5 is the average of the sampled values of X, the following two HAZARDRATIO statements are equivalent:

```
hazardratio A;
hazardratio A / at (B=ALL X=3.5);
```

**CL=WALD | PL | BOTH**

specifies whether to create the Wald or profile-likelihood confidence limits, or both for the classical analysis. By default, Wald confidence limits are produced. This option is not applicable to a Bayesian analysis.

**DIFF=ALL | REF**

specifies which differences to consider for the level comparisons of a CLASS variable. The default is DIFF=ALL. This option is ignored in the estimation of hazard ratios for a continuous variable. DIFF=ALL requests all differences, and DIFF=REF requests comparisons between the reference level and all other levels of the CLASS variable.

**E**

displays the vector **h** of linear coefficients such that  $\mathbf{h}'\boldsymbol{\beta}$  is the log-hazard ratio, with  $\boldsymbol{\beta}$  being the vector of regression coefficients.

**PLCONV=value**

controls the convergence criterion for the profile-likelihood confidence limits. The quantity *value* must be a positive number, with a default value of 1E-4. The PLCONV= option has no effect if profile-likelihood confidence intervals (CL=PL) are not requested.

**PLMAXIT=*n***

specifies the maximum number of iterations to achieve the convergence of the profile-likelihood confidence limits. By default, PLMAXITER=25. If convergence is not attained in *n* iterations, the corresponding profile-likelihood confidence limit for the hazard ratio is set to missing. The PLMAXITER= option has no effect if profile-likelihood confidence intervals (CL=PL) are not requested.

**PLSINGULAR=*value***

specifies the tolerance for testing the singularity of the Hessian matrix in the computation of the profile-likelihood confidence limits. The test requires that a pivot for sweeping this matrix be at least this number times a norm of the matrix. Values of the PLSINGULAR= option must be numeric. By default, *value* is the machine epsilon times 1E7, which is approximately 1E-9. The PLSINGULAR= option has no effect if profile-likelihood confidence intervals (CL=PL) are not requested.

**UNITS=*value***

specifies the units of change in the continuous explanatory variable for which the customized hazard ratio is estimated. The default is UNITS=1. This option is ignored in the computation of the hazard ratios for a CLASS variable.

---

## ID Statement

**ID** *variables* ;

The ID statement specifies additional variables for identifying observations in the input data. These variables are placed in the OUT= data set created by the OUTPUT statement. In the computation of the COVSANDWICH estimate, you can aggregate over distinct values of these ID variables.

Only variables in the input data set can be included in the ID statement.

---

## LSMEANS Statement

**LSMEANS** < *model-effects* > < / *options* > ;

The LSMEANS statement compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 67.8 summarizes the options available in the LSMEANS statement. If the BAYES statement is specified, the ADJUST=, STEPDOWN, and LINES options are ignored. The PLOTS= option is not available for the maximum likelihood analysis. It is available only for the Bayesian analysis.

**Table 67.8** LSMEANS Statement Options

| Option                                              | Description                                                                                 |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                             |
| AT                                                  | Modifies the covariate value in computing LS-means                                          |
| BYLEVEL                                             | Computes separate margins                                                                   |
| DIFF                                                | Requests differences of LS-means                                                            |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| SINGULAR=                                           | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                             |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences            |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                            |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion                      |
| <b>Statistical Output</b>                           |                                                                                             |
| CL                                                  | Constructs confidence limits for means and mean differences                                 |
| CORR                                                | Displays the correlation matrix of LS-means                                                 |
| COV                                                 | Displays the covariance matrix of LS-means                                                  |
| E                                                   | Prints the L matrix                                                                         |
| LINES                                               | Produces a “Lines” display for pairwise LS-means differences                                |
| MEANS                                               | Prints the LS-means                                                                         |
| PLOTS=                                              | Requests graphs of means and mean comparisons                                               |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                           |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 of Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect < 'label' > values < divisor=n >
 < , < 'label' > values < divisor=n > > < , ... >
 < / options > ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 67.9 summarizes the options available in the LSMESTIMATE statement. If the BAYES statement is specified, the ADJUST=, STEPDOWN, TESTVALUE, LOWER, UPPER, and JOINT options are ignored. The PLOTS= option is not available for the maximum likelihood analysis. It is available only for the Bayesian analysis.

**Table 67.9** LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                    |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |
| <b>Statistical Output</b>                           |                                                                                     |
| CL                                                  | Constructs confidence limits for means and mean differences                         |
| CORR                                                | Displays the correlation matrix of LS-means                                         |
| COV                                                 | Displays the covariance matrix of LS-means                                          |
| E                                                   | Prints the <b>L</b> matrix                                                          |
| ELSM                                                | Prints the <b>K</b> matrix                                                          |
| JOINT                                               | Produces a joint $F$ or chi-square test for the LS-means and LS-means differences   |
| PLOTS=                                              | Requests graphs of means and mean comparisons                                       |
| SEED=                                               | Specifies the seed for computations that depend on random numbers                   |

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” on page 470 of Chapter 19, “Shared Concepts and Topics.”

## MODEL Statement

**MODEL** *response* < \* *censor (list)* > = *effects* < / *options* > ;

**MODEL** (*t1*, *t2*) < \* *censor (list)* > = *effects* < / *options* > ;

The MODEL statement identifies the variables to be used as the failure time variables, the optional censoring variable, and the explanatory effects, including covariates, main effects, interactions, nested effects; see the section “Specification of Effects” on page 3324 of Chapter 42, “The GLM Procedure,” for more information. A note of caution: specifying the effect T\*A in the MODEL statement, where T is the time variable and A is

a CLASS variable, does not make the effect time-dependent. See the section “Time and CLASS Variables Usage” on page 5609 for more information.

Two forms of MODEL syntax can be specified; the first form allows one time variable, and the second form allows two time variables for the counting process style of input (see the section “Counting Process Style of Input” on page 5615 for more information).

In the first MODEL statement, the name of the failure time variable precedes the equal sign. This name can optionally be followed by an asterisk, the name of the censoring variable, and a list of censoring values (separated by blanks or commas if there is more than one) enclosed in parentheses. If the censoring variable takes on one of these values, the corresponding failure time is considered to be censored. Following the equal sign are the explanatory effects (sometimes called independent variables or covariates) for the model.

Instead of a single failure-time variable, the second MODEL statement identifies a pair of failure-time variables. Their names are enclosed in parentheses, and they signify the endpoints of a semiclosed interval  $(t1, t2]$  during which the subject is at risk. If the censoring variable takes on one of the censoring values, the time  $t2$  is considered to be censored.

The censoring variable must be numeric and the failure-time variables must contain nonnegative values. Any observation with a negative failure time is excluded from the analysis, as is any observation with a missing value for any of the variables listed in the MODEL statement. Failure-time variables with a SAS date format are not recommended because the dates might be translated into negative numbers and consequently the corresponding observation would be discarded.

Table 67.10 summarizes the *options* available in the MODEL statement. These *options* can be specified after a slash (/). Four convergence criteria are allowed for the maximum likelihood optimization: ABSFCONV=, FCONV=, GCONV=, and XCONV=. If you specify more than one convergence criterion, the optimization is terminated as soon as one of the criteria is satisfied. If none of the criteria is specified, the default is GCONV=1E-8.

**Table 67.10** MODEL Statement Options

| Option                             | Description                                                                                                                                        |
|------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Model Specification Options</b> |                                                                                                                                                    |
| NOFIT                              | Suppresses model fitting                                                                                                                           |
| OFFSET=                            | Specifies offset variable                                                                                                                          |
| SELECTION=                         | Specifies effect selection method                                                                                                                  |
| <b>Effect Selection Options</b>    |                                                                                                                                                    |
| BEST=                              | Controls the number of models displayed for SCORE selection                                                                                        |
| DETAILS                            | Requests detailed results at each step                                                                                                             |
| HIERARCHY=                         | Specifies whether and how hierarchy is maintained and whether a single effect or multiple effects are allowed to enter or leave the model per step |
| INCLUDE=                           | Specifies number of effects included in every model                                                                                                |
| MAXSTEP=                           | Specifies maximum number of steps for STEPWISE selection                                                                                           |
| SEQUENTIAL                         | Adds or deletes effects in sequential order                                                                                                        |
| SLENTRY=                           | Specifies significance level for entering effects                                                                                                  |
| SLSTAY=                            | Specifies significance level for removing effects                                                                                                  |

Table 67.10 *continued*

| Option                                         | Description                                                                                                           |
|------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------|
| START=                                         | Specifies number of variables in first model                                                                          |
| STOP=                                          | Specifies number of variables in final model                                                                          |
| STOPRES                                        | Adds or deletes variables by residual chi-square criterion                                                            |
| <b>Maximum Likelihood Optimization Options</b> |                                                                                                                       |
| ABSFCONV=                                      | Specifies absolute function convergence criterion                                                                     |
| FCONV=                                         | Specifies relative function convergence criterion                                                                     |
| FIRTH                                          | Specifies Firth's penalized likelihood method                                                                         |
| GCONV=                                         | Specifies relative gradient convergence criterion                                                                     |
| XCONV=                                         | Specifies relative parameter convergence criterion                                                                    |
| MAXITER=                                       | Specifies maximum number of iterations                                                                                |
| RIDGEINIT=                                     | Specifies the initial ridging value                                                                                   |
| RIDGING=                                       | Specifies the technique to improve the log likelihood function when its value is worse than that of the previous step |
| SINGULAR=                                      | Specifies tolerance for testing singularity                                                                           |
| <b>Confidence Interval Options</b>             |                                                                                                                       |
| ALPHA=                                         | Specifies $\alpha$ for the $100(1 - \alpha)\%$ confidence intervals                                                   |
| PLCONV=                                        | Specifies profile-likelihood convergence criterion                                                                    |
| RISKLIMITS=                                    | Computes confidence intervals for hazard ratios                                                                       |
| <b>Display Options</b>                         |                                                                                                                       |
| CORRB                                          | Displays correlation matrix                                                                                           |
| COVB                                           | Displays covariance matrix                                                                                            |
| ITPRINT                                        | Displays iteration history                                                                                            |
| NODUMMYPRINT                                   | Suppresses "Class Level Information" table                                                                            |
| TYPE1                                          | Displays Type 1 analysis                                                                                              |
| TYPE3                                          | Displays Type 3 analysis                                                                                              |
| <b>Miscellaneous Options</b>                   |                                                                                                                       |
| ENTRYTIME=                                     | Specifies the delayed entry time variable                                                                             |
| TIES=                                          | Specifies the method of handling ties in failure times                                                                |

**ALPHA=value**

sets the significance level used for the confidence limits for the hazard ratios. The quantity *value* must be between 0 and 1. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified. This option has no effect unless the RISKLIMITS option is specified.

**ABSFCONV=value****CONVERGELIKE=value**

specifies the absolute function convergence criterion. Termination requires a small change in the objective function (log partial likelihood function) in subsequent iterations,

$$|l_k - l_{k-1}| < \text{value}$$

where  $l_k$  is the value of the objective function at iteration  $k$ .

**BEST=*n***

is used exclusively with the SCORE model selection method. The BEST=*n* option specifies that *n* models with the highest-score chi-square statistics are to be displayed for each model size. If the option is omitted and there are no more than 10 explanatory variables, then all possible models are listed for each model size. If the option is omitted and there are more than 10 explanatory variables, then the number of models selected for each model size is, at most, equal to the number of explanatory variables listed in the MODEL statement.

See [Example 67.2](#) for an illustration of the SCORE selection method and the BEST= option.

**CORRB**

displays the estimated correlation matrix of the parameter estimates.

**COVB**

displays the estimated covariance matrix of the parameter estimates.

**DETAILS**

produces a detailed display at each step of the model-building process. It produces an “Analysis of Variables Not in the Model” table before displaying the variable selected for entry for FORWARD or STEPWISE selection. For each model fitted, it produces the “Analysis of Maximum Likelihood Estimates” table.

See [Example 67.1](#) for a discussion of these tables.

**ENTRYTIME=*variable*****ENTRY=*variable***

specifies the name of the variable that represents the left-truncation time. This option has no effect when the counting process style of input is specified. See the section “[Left-Truncation of Failure Times](#)” on page 5617 for more information.

**FCONV=*value***

specifies the relative function convergence criterion. Termination requires a small relative change in the objective function (log partial likelihood function) in subsequent iterations,

$$\frac{|l_k - l_{k-1}|}{|l_{k-1}| + 1\text{E} - 6} < \textit{value}$$

where  $l_k$  is the value of the objective function at iteration  $k$ .

**FIRTH**

performs Firth’s penalized maximum likelihood estimation to reduce bias in the parameter estimates (Heinze and Schemper 2001; Firth 1993). This method is useful when the likelihood is monotone—that is, the likelihood converges to finite value while at least one estimate diverges to infinity.

**GCONV=*value***

specifies the relative gradient convergence criterion. Termination requires that the normalized prediction function reduction is small,

$$\frac{\mathbf{g}_k \mathbf{H}_k^{-1} \mathbf{g}_k}{|l_k| + 1\text{E} - 6} < \textit{value}$$

where  $l_k$  is the log partial likelihood,  $\mathbf{g}_k$  is the gradient vector (first partial derivatives of the log partial likelihood), and  $\mathbf{H}_k$  is the negative Hessian matrix (second partial derivatives of the log partial likelihood), all at iteration  $k$ .

**HIERARCHY=***keyword*

**HIER=***keyword*

specifies whether and how the model hierarchy requirement is applied and whether a single effect or multiple effects are allowed to enter or leave the model in one step. You can specify that only CLASS variable effects, or both CLASS and continuous variable effects, be subject to the hierarchy requirement. The HIERARCHY= option is ignored unless you also specify the FORWARD, BACKWARD, or STEPWISE selection method.

Model hierarchy refers to the requirement that, for any term to be in the model, all effects contained in the term must be present in the model. For example, in order for the interaction A\*B to enter the model, the main effects A and B must be in the model. Likewise, neither effect A nor B can leave the model while the interaction A\*B is in the model.

You can specify any of the following *keywords* in the HIERARCHY= option:

**NONE**

indicates that the model hierarchy is not maintained. Any single effect can enter or leave the model at any given step of the selection process.

**SINGLE**

indicates that only one effect can enter or leave the model at one time, subject to the model hierarchy requirement. For example, suppose that you specify the main effects A and B and the interaction of A\*B in the model. In the first step of the selection process, either A or B can enter the model. In the second step, the other main effect can enter the model. The interaction effect can enter the model only when both main effects have already been entered. Also, before A or B can be removed from the model, the A\*B interaction must first be removed. All effects (CLASS and continuous variables) are subject to the hierarchy requirement.

**SINGLECLASS**

is the same as HIERARCHY=SINGLE except that only CLASS effects are subject to the hierarchy requirement.

**MULTIPLE**

indicates that more than one effect can enter or leave the model at one time, subject to the model hierarchy requirement. In a forward selection step, a single main effect can enter the model, or an interaction can enter the model together with all the effects that are contained in the interaction. In a backward elimination step, an interaction itself, or the interaction together with all the effects that the interaction contains, can be removed. All effects (CLASS and continuous variable) are subject to the hierarchy requirement.

**MULTIPLECLASS**

is the same as HIERARCHY=MULTIPLE except that only CLASS effects are subject to the hierarchy requirement.

The default value is HIERARCHY=SINGLE, which means that model hierarchy is to be maintained for all effects (that is, both CLASS and continuous variable effects) and that only a single effect can enter or leave the model at each step.

**INCLUDE=*n***

includes the first *n* effects in the MODEL statement in every model. By default, INCLUDE=0. The INCLUDE= option has no effect when SELECTION=NONE.

**ITPRINT**

displays the iteration history, including the last evaluation of the gradient vector.

**MAXITER=*n***

specifies the maximum number of iterations allowed. The default value for *n* is 25. If convergence is not attained in *n* iterations, the displayed output and all data sets created by PROC PHREG contain results that are based on the last maximum likelihood iteration.

**MAXSTEP=*n***

specifies the maximum number of times the explanatory variables can move in and out of the model before the STEPWISE model-building process ends. The default value for *n* is twice the number of explanatory variables in the MODEL statement. The option has no effect for other model selection methods.

**NODUMMYPRINT****NODESIGNPRINT****NODP**

suppresses the “Class Level Information” table, which shows how the design matrix columns for the CLASS variables are coded.

**NOFIT**

performs the global score test, which tests the joint significance of all the explanatory variables in the MODEL statement. No parameters are estimated. If the NOFIT option is specified along with other MODEL statement options, NOFIT takes precedence, and all other options are ignored except the TIES= option.

**OFFSET=*name***

specifies the name of an offset variable, which is an explanatory variable with a regression coefficient fixed as one. This option can be used to incorporate risk weights for the likelihood function.

**PLCONV=*value***

controls the convergence criterion for confidence intervals based on the profile-likelihood function. The quantity *value* must be a positive number, with a default value of 1E-4. The PLCONV= option has no effect if profile-likelihood based confidence intervals are not requested.

**RIDGING=*keyword***

specifies the technique to improve the log likelihood when its value is worse than that of the previous step. The available *keywords* are as follows:

**ABSOLUTE**

specifies that the diagonal elements of the negative (expected) Hessian be inflated by adding the ridge value.

**RELATIVE**

specifies that the diagonal elements be inflated by the factor equal to 1 plus the ridge value.

**NONE**

specifies the crude line-search method of taking half a step be used instead of ridging.

The default is RIDGING=RELATIVE.

**RIDGEINIT=***value*

specifies the initial ridge value. The maximum ridge value is 2000 times the maximum of 1 and the initial ridge value. The initial ridge value is raised to 1E-4 if it is less than 1E-4. By default, RIDGEINIT=1E-4. This option has no effect for RIDGING=ABSOLUTE.

**RISKLIMITS**< =*keyword* >**RL**< =*keyword* >

produces confidence intervals for hazard ratios of main effects not involved in interactions or nestings. Computation of these confidence intervals is based on the profile likelihood or based on individual Wald tests. The confidence coefficient can be specified with the ALPHA= option. You can specify one of the following keywords:

**PL**

requests profile-likelihood confidence limits.

**WALD**

requests confidence limits based on the Wald tests.

**BOTH**

request both profile-likelihood and Wald confidence limits.

Classification main effects that use parameterizations other than REF, EFFECT, or GLM are ignored. If you need to compute hazard ratios for an effect involved in interactions or nestings, or using some other parameterization, then you should specify a HAZARDRATIO statement for that effect.

**SELECTION**=*method*

specifies the method used to select the model. The *methods* available are as follows:

**BACKWARD****B**

requests backward elimination.

**FORWARD****F**

requests forward selection.

**NONE****N**

fits the complete model specified in the MODEL statement. This is the default value.

**SCORE**

requests best subset selection. It identifies a specified number of models with the highest-score chi-square statistic for all possible model sizes ranging from one explanatory variable to the total number of explanatory variables listed in the MODEL statement. This option is not allowed if an explanatory effect in the MODEL statement contains a CLASS variable.

**STEPWISE****S**

requests stepwise selection.

For more information, see the section “[Effect Selection Methods](#)” on page 5648.

**SEQUENTIAL**

forces variables to be added to the model in the order specified in the MODEL statement or to be eliminated from the model in the reverse order of that specified in the MODEL statement.

**SINGULAR=value**

specifies the singularity criterion for determining linear dependencies in the set of explanatory variables. The default value is 1E-12.

**SLENTRY=value****SLE=value**

specifies the significance level (a value between 0 and 1) for entering an explanatory variable into the model in the FORWARD or STEPWISE method. For all variables not in the model, the one with the smallest  $p$ -value is entered if the  $p$ -value is less than or equal to the specified significance level. The default value is 0.05.

**SLSTAY=value****SLS=value**

specifies the significance level (a value between 0 and 1) for removing an explanatory variable from the model in the BACKWARD or STEPWISE method. For all variables in the model, the one with the largest  $p$ -value is removed if the  $p$ -value exceeds the specified significance level. The default value is 0.05.

**START=n**

begins the FORWARD, BACKWARD, or STEPWISE selection process with the first  $n$  effects listed in the MODEL statement. The value of  $n$  ranges from 0 to  $s$ , where  $s$  is the total number of effects in the MODEL statement. The default value of  $n$  is  $s$  for the BACKWARD method and 0 for the FORWARD and STEPWISE methods. Note that  $START=n$  specifies only that the first  $n$  effects appear in the first model, while  $INCLUDE=n$  requires that the first  $n$  effects be included in every model. For the SCORE method,  $START=n$  specifies that the smallest models contain  $n$  effects, where  $n$  ranges from 1 to  $s$ ; the default value is 1. The  $START=$  option has no effect when  $SELECTION=NONE$ .

**STOP=n**

specifies the maximum (FORWARD method) or minimum (BACKWARD method) number of effects to be included in the final model. The effect selection process is stopped when  $n$  effects are found. The value of  $n$  ranges from 0 to  $s$ , where  $s$  is the total number of effects in the MODEL statement. The default value of  $n$  is  $s$  for the FORWARD method and 0 for the BACKWARD method. For the SCORE method,  $STOP=n$  specifies that the smallest models contain  $n$  effects, where  $n$  ranges from 1 to  $s$ ; the default value of  $n$  is  $s$ . The  $STOP=$  option has no effect when  $SELECTION=NONE$  or  $STEPWISE$ .

**STOPRES****SR**

specifies that the addition and deletion of variables be based on the result of the likelihood score test for testing the joint significance of variables not in the model. This score chi-square statistic is referred to as the residual chi-square. In the FORWARD method, the STOPRES option enters the explanatory variables into the model one at a time until the residual chi-square becomes insignificant (that is, until the  $p$ -value of the residual chi-square exceeds the SLENTY= value). In the BACKWARD method, the STOPRES option removes variables from the model one at a time until the residual chi-square becomes significant (that is, until the  $p$ -value of the residual chi-square becomes less than the SLSTAY= value). The STOPRES option has no effect for the STEPWISE method.

**TYPE1**

requests that a Type 1 (sequential) analysis of likelihood ratio test be performed. This consists of sequentially fitting models, beginning with the null model and continuing up to the model specified in the MODEL statement. The likelihood ratio statistic for each successive pair of models is computed and displayed in a table.

**TYPE3** <(keywords)>

requests a Type 3 test for each effect that is specified in the MODEL statement. The default is to use the Wald statistic, but you can request other statistics by specifying one or more of the following keywords:

**ALL**

requests the likelihood ratio tests, the score tests, and the Wald tests. Specifying TYPE3(ALL) is equivalent to specifying TYPE3=(LR SCORE WALD).

**NONE**

suppresses the Type 3 analysis. Even if the TYPE3 option is not specified, PROC PHREG displays the Wald test results for each model effect if a CLASS variable is involved in a MODEL effect. The NONE option can be used to suppress such display.

**LR**

requests the likelihood ratio tests. This request is not honored if the COVS option is also specified.

**SCORE**

requests the score tests. This request is not honored if the COVS option is also specified.

**WALD**

requests the Wald tests.

**TIES=method**

specifies how to handle ties in the failure time. The following *methods* are available:

**BRESLOW**

uses the approximate likelihood of Breslow (1974). This is the default value.

**DISCRETE**

replaces the proportional hazards model by the discrete logistic model

$$\frac{\lambda(t; \mathbf{z})}{1 - \lambda(t; \mathbf{z})} = \frac{\lambda_0(t)}{1 - \lambda_0(t)} \exp(\mathbf{z}'\boldsymbol{\beta})$$

where  $\lambda_0(t)$  and  $h(t; \mathbf{z})$  are discrete hazard functions.

**EFRON**

uses the approximate likelihood of Efron (1977).

**EXACT**

computes the exact conditional probability under the proportional hazards assumption that all tied event times occur before censored times of the same value or before larger values. This is equivalent to summing all terms of the marginal likelihood for  $\beta$  that are consistent with the observed data (Kalbfleisch and Prentice 1980; DeLong, Guirguis, and So 1994).

The EXACT method can take a considerable amount of computer resources. If ties are not extensive, the EFRON and BRESLOW methods provide satisfactory approximations to the EXACT method for the continuous time-scale model. In general, Efron's approximation gives results that are much closer to the EXACT method results than Breslow's approximation does. If the time scale is genuinely discrete, you should use the DISCRETE method. The DISCRETE method is also required in the analysis of case-control studies when there is more than one case in a matched set. If there are no ties, all four methods result in the same likelihood and yield identical estimates. The default, TIES=BRESLOW, is the most efficient method when there are no ties.

**XCONV=value**

**CONVEREPARM=value**

specifies the relative parameter convergence criterion. Termination requires a small relative parameter change in subsequent iterations,

$$\max_i |\delta_k^{(i)}| < value$$

where

$$\delta_k^{(i)} = \begin{cases} \theta_k^{(i)} - \theta_{k-1}^{(i)} & |\theta_{k-1}^{(i)}| < .01 \\ \frac{\theta_k^{(i)} - \theta_{k-1}^{(i)}}{\theta_{k-1}^{(i)}} & \text{otherwise} \end{cases}$$

where  $\theta_k^{(i)}$  is the estimate of the  $i$ th parameter at iteration  $k$ .

**OUTPUT Statement**

**OUTPUT < OUT=SAS-data-set > < keyword=name ... keyword=name > < / options > ;**

The OUTPUT statement creates a new SAS data set containing statistics calculated for each observation. These can include the estimated linear predictor ( $\mathbf{z}'_j \hat{\beta}$ ) and its standard error, survival distribution estimates, residuals, and influence statistics. In addition, this data set includes the time variable, the explanatory variables listed in the MODEL statement, the censoring variable (if specified), and the BY, STRATA, FREQ, and ID variables (if specified).

For observations with missing values in the time variable or any explanatory variables, the output statistics are set to missing. However, for observations with missing values only in the censoring variable or the FREQ variable, survival estimates are still computed. Therefore, by adding observations with missing values in the FREQ variable or the censoring variable, you can compute the survivor function estimates for new observations or for settings of explanatory variables not present in the data without affecting the model fit.

No OUTPUT data set is created if the model contains a time-dependent variable defined by means of programming statements.

The following list explains specifications in the OUTPUT statement.

**OUT=SAS-data-set**

names the output data set. If you omit the OUT= option, the OUTPUT data set is created and given a default name by using the DATA $n$  convention. See the section “OUT= Output Data Set in the OUTPUT Statement” on page 5665 for more information.

**keyword=name**

specifies the statistics included in the OUTPUT data set and names the new variables that contain the statistics. Specify a keyword for each desired statistic (see the following list of keywords), an equal sign, and either a variable or a list of variables to contain the statistic. The keywords that accept a list of variables are DFBETA, RESSCH, RESSCO, and WTRESSCH. For these keywords, you can specify as many names in *name* as the number of explanatory variables specified in the MODEL statement. If you specify  $k$  names and  $k$  is less than the total number of explanatory variables, only the changes for the first  $k$  parameter estimates are output. The keywords and the corresponding statistics are as follows:

**ATRISK**

specifies the number of subjects at risk at the observation time  $\tau_j$  (or at the right endpoint of the at-risk interval when a counting process MODEL specification is used).

**DFBETA**

specifies the approximate changes in the parameter estimates ( $\hat{\beta} - \hat{\beta}_{(j)}$ ) when the  $j$ th observation is omitted. These variables are a weighted transform of the score residual variables and are useful in assessing local influence and in computing robust variance estimates.

**LD**

specifies the approximate likelihood displacement when the observation is left out. This diagnostic can be used to assess the impact of each observation on the overall fit of the model.

**LMAX**

specifies the relative influence of observations on the overall fit of the model. This diagnostic is useful in assessing the sensitivity of the fit of the model to each observation.

**LOGLOGS**

specifies the log of the negative log of SURVIVAL.

**LOGSURV**

specifies the log of SURVIVAL.

**RESDEV**

specifies the deviance residual  $\hat{D}_j$ . This is a transform of the martingale residual to achieve a more symmetric distribution.

**RESMART**

specifies the martingale residual  $\hat{M}_j$ . The residual at the observation time  $\tau_j$  can be interpreted as the difference over  $[0, \tau_j]$  in the observed number of events minus the expected number of events given by the model.

**RESSCH**

specifies the Schoenfeld residuals. These residuals are useful in assessing the proportional hazards assumption.

**RESSCO**

specifies the score residuals. These residuals are a decomposition of the first partial derivative of the log likelihood. They can be used to assess the leverage exerted by each subject in the parameter estimation. They are also useful in constructing robust sandwich variance estimators.

**STDXBETA**

specifies the standard error of the **XBETA** predictor,  $\sqrt{\mathbf{z}'_j \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \mathbf{z}_j}$ .

**SURVIVAL**

specifies the survivor function estimate  $\hat{S}_j = [\hat{S}_0(\tau_j)]^{\exp(\mathbf{z}'_j \hat{\boldsymbol{\beta}})}$ , where  $\tau_j$  is the observation time.

**WTRESSCH**

specifies the weighted Schoenfeld residuals. These residuals are useful in investigating the nature of nonproportionality if the proportional hazard assumption does not hold.

**XBETA**

specifies the estimate of the linear predictor,  $\mathbf{z}'_j \hat{\boldsymbol{\beta}}$ .

The following *options* can appear in the OUTPUT statement after a slash (/) as follows:

**ORDER=value**

specifies the order of the observations in the OUTPUT data set. The following *values* are available:

- DATA** requests that the output observations be sorted the same as the input data set.
- SORTED** requests that the output observations be sorted by strata and descending order of the time variable within each stratum.

The default is ORDER=DATA.

**METHOD=method**

specifies the method used to compute the survivor function estimates. See the section “Survivor Function Estimators” on page 5643 for details. The following *methods* are available:

**BRESLOW****CH****EMP**

specifies that the empirical cumulative hazard function estimate of the survivor function be computed; that is, the survivor function is estimated by exponentiating the negative empirical cumulative hazard function.

**FH**

specifies that the Fleming-Harrington (FH) estimates be computed. The FH estimator is a tie-breaking modification of the Breslow estimator. If there are no tied event times, this estimator is the same as the Breslow estimator.

**PL**

specifies that the product-limit estimates of the survivor function be computed. This estimator is not available if you use the model syntax that allows two time variables for the counting process style of input; in such a case, the Breslow estimator (METHOD=BRESLOW) is used instead.

The default is METHOD=BRESLOW.

---

## Programming Statements

Programming statements are used to create or modify the values of the explanatory variables in the MODEL statement. They are especially useful in fitting models with time-dependent explanatory variables. Programming statements can also be used to create explanatory variables that are not time dependent. For example, you can create indicator variables from a categorical variable and incorporate them into the model. PROC PHREG programming statements cannot be used to create or modify the values of the response variable, the censoring variable, the frequency variable, or the strata variables.

The following DATA step statements are available in PROC PHREG:

```

ABORT;
ARRAY arrayname < [dimensions] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
 < , expression < TO expression > < BY expression > > ...
 < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
 ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length) = expression;
WHEN (expression) program-statement;
 OTHERWISE program-statement;

```

By default, the PUT statement in PROC PHREG writes results to the Output window instead of the Log window. If you want the results of the PUT statements to go to the Log window, add the following statement before the PUT statements:

```
FILE LOG;
```

DATA step functions are also available. Use these programming statements the same way you use them in the DATA step. For detailed information, see *SAS Statements: Reference*.

Consider the following example of using programming statements in PROC PHREG. Suppose blood pressure is measured at multiple times during the course of a study investigating the effect of blood pressure on some survival time. By treating the blood pressure as a time-dependent explanatory variable, you are able to use the value of the most recent blood pressure at each specific point of time in the modeling process rather than using the initial blood pressure or the final blood pressure. The values of the following variables are recorded for each patient, if they are available. Otherwise, the variables contain missing values.

|        |                                                     |
|--------|-----------------------------------------------------|
| Time   | survival time                                       |
| Censor | censoring indicator (with 0 as the censoring value) |
| BP0    | blood pressure on entry to the study                |
| T1     | time 1                                              |
| BP1    | blood pressure at T1                                |
| T2     | time 2                                              |
| BP2    | blood pressure at T2                                |

The following programming statements create a variable BP. At each time T, the value of BP is the blood pressure reading for that time, if available. Otherwise, it is the last blood pressure reading.

```
proc phreg;
 model Time*Censor(0)=BP;
 BP = BP0;
 if Time>=T1 and T1^=. then BP=BP1;
 if Time>=T2 and T2^=. then BP=BP2;
run;
```

For other illustrations of using programming statements, see the section “Classical Method of Maximum Likelihood” on page 5544 and Example 67.6.

---

## RANDOM Statement

**RANDOM** *variable* </ options > ;

The RANDOM statement enables you to fit a shared frailty model for clustered data (see the section “The Frailty Model” on page 5618 for details). The *variable* that represents the clusters must be a CLASS variable (declared in the CLASS statement).

The following *options* can be specified in the RANDOM statement:

### **ABSPCONV=***r*

specifies an absolute variance estimate convergence criterion for the doubly iterative estimation process. The PHREG procedure applies this criterion to the variance parameter estimate of the random effects. Suppose  $\hat{\theta}^{(j)}$  denotes the estimate of the variance parameter at the *j*th optimization. By default, PROC PHREG examines the relative change in the variance estimate between optimizations (see the PCONV= option). The purpose of the ABSPCONV= criterion is to stop the doubly iterative process when the absolute change  $|\hat{\theta}^{(j)} - \hat{\theta}^{(j-1)}|$  is less than the tolerance criterion *r*. This convergence criterion does not affect the convergence criteria applied within any individual optimization. In order to change the convergence behavior within an individual optimization, you can use the

ABSCONV=, ABSFCONV=, ABSGCONV=, ABSXCONV=, FCONV=, or GCONV= option in the NLOPTIONS statement.

**ALPHA=value**

specifies the  $\alpha$  level of the confidence limits for the random effects. The default is the value of the ALPHA= option in the PROC PHREG statement, or 0.05 if that option is not specified. This option is ignored if the SOLUTION option is not also specified.

**DIST=GAMMA | LOGNORMAL**

specifies the distribution of the shared frailty. DIST=GAMMA specifies a gamma frailty model. DIST=LOGNORMAL specifies a lognormal frailty model; that is, the log-frailty random variable has a normal distribution with mean zero. The default is DIST=LOGNORMAL.

**METHOD=REML | ML**

specifies the estimation method for the variance parameter of the normal random effects. METHOD=REML performs the residual maximum likelihood; METHOD=ML performs maximum likelihood. This option is ignored for the gamma frailty model. The default is METHOD=REML.

**NOCLPRINT**

suppresses the display of the “Class Level Information for Random Effects” table.

**PCONV=r**

specifies the variance estimate convergence criterion for the doubly iterative estimation process. The PHREG procedure applies this criterion to the variance estimate of the random effects. Suppose  $\hat{\theta}^{(j)}$  denotes the estimate of variance at the  $j$ th optimization. The procedure terminates the doubly iterative process if the relative change

$$2 \times \frac{|\hat{\theta}^{(j)} - \hat{\theta}^{(j-1)}|}{|\hat{\theta}^{(j)}| + |\hat{\theta}^{(j-1)}|}$$

is less than  $r$ . To check an absolute convergence criterion in addition, you can specify the ABSPCONV= option in the RANDOM statement. The default value for  $r$  is 1E-4. This convergence criterion does not affect the convergence criteria applied within any individual optimization. In order to change the convergence behavior within an individual optimization, you can use the ABSCONV=, ABSFCONV=, ABSGCONV=, ABSXCONV=, FCONV=, or GCONV= option in the NLOPTIONS statement.

**SOLUTION < (number-list) >**

displays statistical measures of the random-effect parameters. The behavior of this option depends on whether you also specify the BAYES statement:

- When you do not specify a BAYES statement, this option displays point estimates and confidence intervals for the random components and for the frailties.
- When you also specify a BAYES statement, this option displays the summary statistics and diagnostics of the random-effect parameters. Optionally, you can specify a *number-list* of indices of the random-effect parameters for which the summary statistics and diagnostics are to be displayed. For example, to display the summary statistics and diagnostics for the second to the fifth random-effect parameters, specify

**SOLUTION(2 to 5)**

If you specify SOLUTION without a list, summary statistics and diagnostics are displayed for each random-effect parameter.

**INITIALVARIANCE**=*value*

**INITIAL**=*value*

specifies an initial value of the dispersion parameter. For the lognormal frailty model, the dispersion parameter represents the variance of the normal random effect; for the gamma frailty model, it represents the variance of the gamma frailty. The default is INITIAL=1.

## STRATA Statement

**STRATA** *variable* <(list)> <... *variable* <(list)>> </option> ;

The proportional hazards assumption might not be realistic for all data. If so, it might still be reasonable to perform a stratified analysis. The STRATA statement names the variables that determine the stratification. Strata are formed according to the nonmissing values of the STRATA variables unless the MISSING option is specified. In the STRATA statement, *variable* is a variable with values that are used to determine the strata levels, and *list* is an optional list of values for a numeric variable. Multiple variables can appear in the STRATA statement.

The values for *variable* can be formatted or unformatted. If the variable is a character variable, or if the variable is numeric and no list appears, then the strata are defined by the unique values of the variable. If the variable is numeric and is followed by a list, then the levels for that variable correspond to the intervals defined by the list. The corresponding strata are formed by the combination of levels and unique values. The list can include numeric values separated by commas or blanks, *value* to *value* by *value* range specifications, or combinations of these.

For example, the specification

```
strata age (5, 10 to 40 by 10) sex;
```

indicates that the levels for *age* are to be less than 5, 5 to 10, 10 to 20, 20 to 30, 30 to 40, and greater than 40. (Note that observations with exactly the cutpoint value fall into the interval preceding the cutpoint.) Thus, with the *sex* variable, this STRATA statement specifies 12 strata altogether.

The following option can be specified in the STRATA statement after a slash (/):

### MISSING

allows missing values (‘.’ for numeric variables and blanks for character variables) as valid STRATA variable values. Otherwise, observations with missing STRATA variable values are deleted from the analysis.

## SLICE Statement

**SLICE** *model-effect* </options> ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

---

## STORE Statement

**STORE** <OUT=>*item-store-name* </ LABEL='label'> ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

---

## TEST Statement

<label:> **TEST** *equation* <, ..., *equation*> </ options> ;

The TEST statement tests linear hypotheses about the regression coefficients. PROC PHREG performs a Wald test for the joint hypothesis specified in a single TEST statement. Each equation specifies a linear hypothesis; multiple equations (rows of the joint hypothesis) are separated by commas. The *label*, which must be a valid SAS name, is used to identify the resulting output and should always be included. You can submit multiple TEST statements.

The form of an equation is as follows:

*term* < ± *term* ... > <= < ± *term* < ± *term* ... >>>

where *term* is a variable or a constant or a constant times a variable. The variable is any explanatory variable in the MODEL statement. When no equal sign appears, the expression is set to 0. The following program illustrates possible uses of the TEST statement:

```
proc phreg;
 model time= A1 A2 A3 A4;
 Test1: test A1, A2;
 Test2: test A1=0,A2=0;
 Test3: test A1=A2=A3;
 Test4: test A1=A2,A2=A3;
run;
```

Note that the first and second TEST statements are equivalent, as are the third and fourth TEST statements.

The following *options* can be specified in the TEST statement after a slash (/):

### AVERAGE

enables you to assess the average effect of the variables in the given TEST statement. An overall estimate of the treatment effect is computed as a weighted average of the treatment coefficients as illustrated in the following statement:

```
TREATMENT: test trt1, trt2, trt3, trt4 / average;
```

Let  $\beta_1, \beta_2, \beta_3,$  and  $\beta_4$  be corresponding parameters for trt1, trt2, trt3, and trt4, respectively. Let  $\hat{\beta} = (\hat{\beta}_1, \hat{\beta}_2, \hat{\beta}_3, \hat{\beta}_4)'$  be the estimated coefficient vector and let  $\hat{V}(\hat{\beta})$  be the corresponding variance estimate. Assuming  $\beta_1 = \beta_2 = \beta_3 = \beta_4$ , let  $\bar{\beta}$  be the average treatment effect. The effect is

estimated by  $\mathbf{c}'\hat{\boldsymbol{\beta}}$ , where  $\mathbf{c} = [\mathbf{1}'_4 \hat{\mathbf{V}}^{-1}(\hat{\boldsymbol{\beta}}) \mathbf{1}_4]^{-1} \hat{\mathbf{V}}^{-1}(\hat{\boldsymbol{\beta}}) \mathbf{1}_4$  and  $\mathbf{1}_4 = (1, 1, 1, 1)'$ . A test of the null hypothesis  $H_0 : \bar{\beta} = 0$  is also included, which is more sensitive than the multivariate test for testing the null hypothesis  $H_0 : \beta_1 = \beta_2 = \beta_3 = \beta_4 = 0$ .

**E**

specifies that the linear coefficients and constants be printed. When the AVERAGE option is specified along with the E option, the optimal weights of the average effect are also printed in the same tables as the coefficients.

**PRINT**

displays intermediate calculations. This includes  $\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}'$  bordered by  $(\mathbf{L}\hat{\boldsymbol{\beta}} - \mathbf{c})$ , and  $[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1}$  bordered by  $[\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1}(\mathbf{L}\hat{\boldsymbol{\beta}} - \mathbf{c})$ , where  $\mathbf{L}$  is a matrix of linear coefficients and  $\mathbf{c}$  is a vector of constants.

See the section “Using the TEST Statement to Test Linear Hypotheses” on page 5628 for details.

## WEIGHT Statement

**WEIGHT** *variable* </option> ;

The *variable* in the WEIGHT statement identifies the variable in the input data set that contains the case weights. When the WEIGHT statement appears, each observation in the input data set is weighted by the value of the WEIGHT variable. The WEIGHT values can be nonintegral and are not truncated. Observations with negative, zero, or missing values for the WEIGHT variable are not used in the model fitting. When the WEIGHT statement is not specified, each observation is assigned a weight of 1. The WEIGHT statement is available for TIES=BRESLOW and TIES=EFRON only.

The following *option* can be specified in the WEIGHT statement after a slash (/):

**NORMALIZE****NORM**

causes the weights specified by the WEIGHT *variable* to be normalized so that they add up the actual sample size. With this option, the estimated covariance matrix of the parameter estimators is invariant to the scale of the WEIGHT variable.

## Details: PHREG Procedure

### Failure Time Distribution

Let  $T$  be a nonnegative random variable representing the failure time of an individual from a homogeneous population. The survival distribution function (also known as the survivor function) of  $T$  is written as

$$S(t) = \Pr(T \geq t)$$

A mathematically equivalent way of specifying the distribution of  $T$  is through its hazard function. The hazard function  $\lambda(t)$  specifies the instantaneous failure rate at  $t$ . If  $T$  is a continuous random variable,  $\lambda(t)$  is expressed as

$$\lambda(t) = \lim_{\Delta t \rightarrow 0^+} \frac{\Pr(t \leq T < t + \Delta t \mid T \geq t)}{\Delta t} = \frac{f(t)}{S(t)}$$

where  $f(t)$  is the probability density function of  $T$ . If  $T$  is discrete with masses at  $x_1 < x_2 < \dots$ , then survivor function is given by

$$S(t) = \sum_{x_j \leq t} \Pr(T = x_j) = \sum_j \Pr(T = j) \delta(t - x_j)$$

where  $\delta(u)=0$  if  $u < 0$  and  $\delta(u)=1$  otherwise. The discrete hazards are given by

$$\lambda_j = \Pr(T = x_j \mid T \geq x_j) = \frac{\Pr(T = x_j)}{S(x_j)} \quad j = 1, 2, \dots$$

---

## Time and CLASS Variables Usage

The following DATA step creates an artificial data set, `Test`, to be used in this section. There are four variables in `Test`: the variable `T` contains the failure times; the variable `Status` is the censoring indicator variable with the value 1 for an uncensored failure time and the value 0 for a censored time; the variable `A` is a categorical variable with values 1, 2, and 3 representing three different categories; and the variable `MirrorT` is an exact copy of `T`.

```
data Test;
 input T Status A @@;
 MirrorT = T;
 datalines;
23 1 1 7 0 1
23 1 1 10 1 1
20 0 1 13 0 1
24 1 1 10 1 1
18 1 2 6 1 2
18 0 2 6 1 2
13 0 2 13 1 2
 9 0 2 15 1 2
 8 1 3 6 1 3
12 0 3 4 1 3
11 1 3 8 1 1
 6 1 3 7 1 3
 7 1 3 12 1 3
 9 1 2 15 1 2
 3 1 2 14 0 3
 6 1 1 13 1 2
;
```

### Time Variable on the Right Side of the MODEL Statement

When the time variable is explicitly used in an explanatory effect in the MODEL statement, the effect is *not* time-dependent. In the following specification, T is the time variable, but T does not play the role of the time variable in the explanatory effect T\*A:

```
proc phreg data=Test;
 class A;
 model T*Status(0)=T*A;
run;
```

The parameter estimates of this model are shown in Figure 67.12.

**Figure 67.12** T\*A Effect

| The PHREG Procedure                      |     |                    |                |            |            |              |         |  |
|------------------------------------------|-----|--------------------|----------------|------------|------------|--------------|---------|--|
| Analysis of Maximum Likelihood Estimates |     |                    |                |            |            |              |         |  |
| Parameter                                | DF  | Parameter Estimate | Standard Error | Chi-Square | Pr > ChiSq | Hazard Ratio | Label   |  |
| T*A                                      | 1 1 | -0.16549           | 0.05042        | 10.7734    | 0.0010     | .            | A 1 * T |  |
| T*A                                      | 2 1 | -0.11852           | 0.04181        | 8.0344     | 0.0046     | .            | A 2 * T |  |

To verify that the effect T\*A in the MODEL statement is not time-dependent, T is replaced by MirrorT, which is an exact copy of T, as in the following statements:

```
proc phreg data=Test;
 class A;
 model T*Status(0)=A*MirrorT;
run;
```

The results of fitting this model (Figure 67.13) are identical to those of the previous model (Figure 67.12), except for the parameter names and labels. The effect A\*MirrorT is not time-dependent, so neither is A\*T.

Figure 67.13 T\*A Effect

| The PHREG Procedure                      |    |                    |                |            |            |

| MirrorT*A 2                              | 1  | -0.11852           | 0.04181        | 8.0344     | 0.0046     |

| Analysis of Maximum Likelihood Estimates |              |               |
|------------------------------------------|--------------|---------------|
| Parameter                                | Hazard Ratio | Label         |
| MirrorT*A 1                              | .            | A 1 * MirrorT |
| MirrorT*A 2                              | .            | A 2 * MirrorT |

## CLASS Variables and Programming Statements

In PROC PHREG, the levels of CLASS variables are determined by the CLASS statement and the input data and are not affected by user-supplied programming statements. Consider the following statements, which produce the results in Figure 67.14. Variable A is declared as a CLASS variable in the CLASS statement. By default, the reference parameterization is used with A=3 as the reference level. Two regression coefficients are estimated for the two dummy variables of A.

```
proc phreg data=Test;
 class A;
 model T*Status(0)=A;
run;
```

Figure 67.14 shows the dummy variables of A and the regression coefficients estimates.

Figure 67.14 Design Variable and Regression Coefficient Estimates

| The PHREG Procedure     |       |                  |   |
|-------------------------|-------|------------------|---|
| Class Level Information |       |                  |   |
| Class                   | Value | Design Variables |   |
| A                       | 1     | 1                | 0 |
|                         | 2     | 0                | 1 |
|                         | 3     | 0                | 0 |

Figure 67.14 continued

| Analysis of Maximum Likelihood Estimates |    |                    |                |            |            |              |           |
|------------------------------------------|----|--------------------|----------------|------------|------------|--------------|-----------|
| Parameter                                | DF | Parameter Estimate | Standard Error | Chi-Square | Pr > ChiSq | Hazard Ratio | Label     |
| A                                        | 1  | 1                  | -1.40925       | 0.64802    | 4.7293     | 0.0297       | 0.244 A 1 |
| A                                        | 2  | 1                  | -0.65705       | 0.51764    | 1.6112     | 0.2043       | 0.518 A 2 |

Now consider the programming statement that attempts to change the value of the CLASS variable A as in the following specification:

```
proc phreg data=Test;
 class A;
 model T*Status(0)=A;
 if A=3 then A=2;
run;
```

Results of this analysis are shown in Figure 67.15 and are identical to those in Figure 67.14. The `if A=3 then A=2` programming statement has no effects on the design variables for A, which have already been determined.

| The PHREG Procedure                      |       |                    |                |            |            |              |           |
|------------------------------------------|-------|--------------------|----------------|------------|------------|--------------|-----------|
| Class Level Information                  |       |                    |                |            |            |              |           |
| Class                                    | Value | Design Variables   |                |            |            |              |           |
| A                                        | 1     | 1                  | 0              |            |            |              |           |
|                                          | 2     | 0                  | 1              |            |            |              |           |
|                                          | 3     | 0                  | 0              |            |            |              |           |
| Analysis of Maximum Likelihood Estimates |       |                    |                |            |            |              |           |
| Parameter                                | DF    | Parameter Estimate | Standard Error | Chi-Square | Pr > ChiSq | Hazard Ratio | Label     |
| A                                        | 1     | 1                  | -1.40925       | 0.64802    | 4.7293     | 0.0297       | 0.244 A 1 |
| A                                        | 2     | 1                  | -0.65705       | 0.51764    | 1.6112     | 0.2043       | 0.518 A 2 |

Additionally any variable used in a programming statement that has already been declared in the CLASS statement is *not* treated as a collection of the corresponding design variables. Consider the following statements:

```

proc phreg data=Test;
 class A;
 model T*Status(0)=A X;
 X=T*A;
run;

```

The CLASS variable A generates two design variables as explanatory variables. The variable X created by the `X=T*A` programming statement is a single time-dependent covariate whose values are evaluated using the exact values of A given in the data, not the dummy-coded values that represent the levels of A. In data set Test, A assumes the values of 1, 2, and 3, and these are the exact values that are used in producing X. If A were a character variable with values ‘Bird’, ‘Cat’, and ‘Dog’, the programming statement `X=T*A` would have produced an error in the attempt to multiply a number with a character value.

**Figure 67.16** Single Time-Dependent Variable X\*A

| The PHREG Procedure                      |    |                    |                |            |            |              |       |     |
|------------------------------------------|----|--------------------|----------------|------------|------------|--------------|-------|-----|
| Analysis of Maximum Likelihood Estimates |    |                    |                |            |            |              |       |     |
| Parameter                                | DF | Parameter Estimate | Standard Error | Chi-Square | Pr > ChiSq | Hazard Ratio | Label |     |
| A                                        | 1  | 1                  | 0.15798        | 1.69338    | 0.0087     | 0.9257       | 1.171 | A 1 |
| A                                        | 2  | 1                  | 0.00898        | 0.87573    | 0.0001     | 0.9918       | 1.009 | A 2 |
| X                                        |    | 1                  | 0.09268        | 0.09535    | 0.9448     | 0.3311       | 1.097 |     |

To generalize the simple test of proportional hazard assumption for the design variables of A (as in the section the “[Classical Method of Maximum Likelihood](#)” on page 5544), you specify the following statements, which are not the same as in the preceding program or as in the specification in the section “[Time Variable on the Right Side of the MODEL Statement](#)” on page 5610:

```

proc phreg data=Test;
 class A;
 model T*Status(0)=A X1 X2;
 X1= T*(A=1);
 X2= T*(A=2);
run;

```

The Boolean parenthetical expressions (A=1) and (A=2) resolve to a value of 1 or 0, depending on whether the expression is true or false, respectively.

Results of this test are shown in [Figure 67.17](#).

**Figure 67.17** Simple Test of Proportional Hazards Assumption

| The PHREG Procedure                      |    |                    |                |            |            |              |       |     |

In general, when your model contains a categorical explanatory variable that is time-dependent, it might be necessary to use hardcoded dummy variables to represent the categories of the categorical variable. Alternatively, you might consider using the counting-process style of input where you break up the covariate history of an individual into a number of records with nonoverlapping start and stop times and declare the categorical time-dependent variable in the CLASS statement.

## Partial Likelihood Function for the Cox Model

Let  $\mathbf{Z}_l(t)$  denote the vector explanatory variables for the  $l$ th individual at time  $t$ . Let  $t_1 < t_2 < \dots < t_k$  denote the  $k$  distinct, ordered event times. Let  $d_i$  denote the multiplicity of failures at  $t_i$ ; that is,  $d_i$  is the size of the set  $\mathcal{D}_i$  of individuals that fail at  $t_i$ . Let  $w_l$  be the weight associated with the  $l$ th individual. Using this notation, the likelihood functions used in PROC PHREG to estimate  $\boldsymbol{\beta}$  are described in the following sections.

### Continuous Time Scale

Let  $\mathcal{R}_i$  denote the risk set just before the  $i$ th ordered event time  $t_i$ . Let  $\mathcal{R}_i^*$  denote the set of individuals whose event or censored times exceed  $t_i$  or whose censored times are equal to  $t_i$ .

#### Exact Likelihood

$$L_1(\boldsymbol{\beta}) = \prod_{i=1}^k \left\{ \int_0^{\infty} \prod_{j \in \mathcal{D}_i} \left[ 1 - \exp \left( - \frac{e^{\boldsymbol{\beta}' \mathbf{Z}_j(t_i)}}{\sum_{l \in \mathcal{R}_i^*} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} t} \right) \right] \exp(-t) dt \right\}$$

#### Breslow Likelihood

$$L_2(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j(t_i)}}{\left[ \sum_{l \in \mathcal{R}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right]^{d_i}}$$

Incorporating weights, the Breslow likelihood becomes

$$L_2(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} w_j \mathbf{Z}_j(t_i)}}{\left[ \sum_{l \in \mathcal{R}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right]^{\sum_{j \in \mathcal{D}_i} w_j}}$$

### Efron Likelihood

$$L_3(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j(t_i)}}{\prod_{j=1}^{d_i} \left( \sum_{l \in \mathcal{R}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} - \frac{j-1}{d_i} \sum_{l \in \mathcal{D}_i} e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right)}$$

Incorporating weights, the Efron likelihood becomes

$$L_3(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} w_j \mathbf{Z}_j(t_i)}}{\left[ \prod_{j=1}^{d_i} \left( \sum_{l \in \mathcal{R}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} - \frac{j-1}{d_i} \sum_{l \in \mathcal{D}_i} w_l e^{\boldsymbol{\beta}' \mathbf{Z}_l(t_i)} \right) \right]^{\frac{1}{d_i} \sum_{j \in \mathcal{D}_i} w_j}}$$

## Discrete Time Scale

Let  $\mathcal{Q}_i$  denote the set of all subsets of  $d_i$  individuals from the risk set  $\mathcal{R}_i$ . For each  $\mathbf{q} \in \mathcal{Q}_i$ ,  $\mathbf{q}$  is a  $d_i$ -tuple  $(q_1, q_2, \dots, q_{d_i})$  of individuals who might have failed at  $t_i$ .

### Discrete Logistic Likelihood

$$L_4(\boldsymbol{\beta}) = \prod_{i=1}^k \frac{e^{\boldsymbol{\beta}' \sum_{j \in \mathcal{D}_i} \mathbf{Z}_j(t_i)}}{\sum_{\mathbf{q} \in \mathcal{Q}_i} e^{\boldsymbol{\beta}' \sum_{l=1}^{d_i} \mathbf{Z}_{q_l}(t_i)}}$$

The computation of  $L_4(\boldsymbol{\beta})$  and its derivatives is based on an adaptation of the recurrence algorithm of Gail, Lubin, and Rubinstein (1981) to the logarithmic scale. When there are no ties on the event times (that is,  $d_i \equiv 1$ ), all four likelihood functions  $L_1(\boldsymbol{\beta})$ ,  $L_2(\boldsymbol{\beta})$ ,  $L_3(\boldsymbol{\beta})$ , and  $L_4(\boldsymbol{\beta})$  reduce to the same expression. In a stratified analysis, the partial likelihood is the product of the partial likelihood functions for the individual strata.

---

## Counting Process Style of Input

In the counting process formulation, data for each subject are identified by a triple  $\{N, Y, \mathbf{Z}\}$  of counting, at-risk, and covariate processes. Here,  $N(t)$  indicates the number of events that the subject experiences over the time interval  $(0, t]$ ;  $Y(t)$  indicates whether the subject is at risk at time  $t$  (one if at risk and zero otherwise);

and  $\mathbf{Z}(t)$  is a vector of explanatory variables for the subject at time  $t$ . The sample path of  $N$  is a step function with jumps of size +1 at the event times, and  $N(0) = 0$ . Unless  $\mathbf{Z}(t)$  changes continuously with time, the data for each subject can be represented by multiple observations, each identifying a semiclosed time interval  $(t_1, t_2]$ , the values of the explanatory variables over that interval, and the event status at  $t_2$ . The subject remains at risk during the interval  $(t_1, t_2]$ , and an event might occur at  $t_2$ . Values of the explanatory variables for the subject remain unchanged in the interval. This style of data input was originated by Therneau (1994).

For example, a patient has a tumor recurrence at weeks 3, 10, and 15 and is followed up to week 23. Consider three fixed explanatory variables Trt (treatment), Number (initial tumor number), and Size (initial tumor size), and one time-dependent covariate Z that represents a hormone level. The value of Z might change during the follow-up period. The data for this patient are represented by the following four observations:

| T1 | T2 | Status | Trt | Number | Size | Z    |
|----|----|--------|-----|--------|------|------|
| 0  | 3  | 1      | 1   | 1      | 3    | 12.3 |
| 3  | 10 | 1      | 1   | 1      | 3    | 14.7 |
| 10 | 15 | 1      | 1   | 1      | 3    | 13.8 |
| 15 | 23 | 0      | 1   | 1      | 3    | 15.5 |

Here (T1,T2] contains the at-risk intervals. The variable Event indicates whether a recurrence has occurred at T2; a value of 1 indicates a tumor recurrence, and a value of 0 indicates nonrecurrence. The following statements fit a multiplicative hazards model with baseline covariates Trt, Number, and Size, and a time-varying covariate Z.

```
proc phreg;
 model (T1,T2) * Status(0) = Trt Z1 Z2 Z3;
run;
```

Another useful application of the counting process formulation is delayed entry of subjects into the risk set. For example, in studying the mortality of workers exposed to a carcinogen, the survival time is chosen to be the worker's age at death by malignant neoplasm. Any worker joining the workplace at a later age than a given event failure time is not included in the corresponding risk set. The variables of a worker consist of Entry (age at which the worker entered the workplace), Age (age at death or age censored), Status (an indicator of whether the observation time is censored, with the value 0 identifying a censored time), and X1 and X2 (explanatory variables thought to be related to survival). The specification for such an application is as follows:

```
proc phreg;
 model (Entry, Age) * Status(0) = X1 X2;
run;
```

Alternatively, you can use a time-dependent variable to control the risk set, as illustrated in the following specification:

```
proc phreg;
 model Age * Status(0) = X1 X2;
 if Age < Entry then X1= .;
run;
```

Here, X1 becomes a time-dependent variable. At a given death time  $t$ , the value of X1 is reevaluated for each subject with  $\text{Age} \geq t$ ; subjects with  $\text{Entry} > t$  are given a missing value in X1 and are subsequently removed

from the risk set. Computationally, this approach is not as efficient as the one that uses the counting process formulation.

---

## Left-Truncation of Failure Times

Left-truncation occurs when individuals are not observed at the natural time origin of the phenomenon under study but come under observation at some known later time (called the left-truncation time). The risk set just prior to an event time does not include individuals whose left-truncation times exceed the given event time. Thus, any contribution to the likelihood must be conditional on the truncation limit having been exceeded.

You use the `ENTRY=` option to specify the variable that represents the left-truncation time. Suppose `T1` and `T2` represent the left-truncation time and the survival time, respectively. To account for left-truncation, you specify the following statements:

```
proc phreg;
 model T2*Dead(0)=X1-X10/entry=T1;
 title 'The ENTRY= option is Specified';
run;
```

Equivalently, you can use the counting process style of input for left-truncation:

```
proc phreg;
 model (T1, T2)*Dead(0)=X1-X10;
 title 'Counting Process Style of Input';
run;
```

Since the product-limit estimator of the survivor function is not available for the counting process style of input, you cannot use PROC PHREG to obtain the product-limit estimate of the survivor function if you have data with left-truncation times. In the preceding PROC PHREG calls, if you also specify `METHOD=PL` in a `BASELINE` statement or an `OUTPUT` statement, it is defaulted to `METHOD=BRESLOW`.

---

## The Multiplicative Hazards Model

Consider a set of  $n$  subjects such that the counting process  $N_i \equiv \{N_i(t), t \geq 0\}$  for the  $i$ th subject represents the number of observed events experienced over time  $t$ . The sample paths of the process  $N_i$  are step functions with jumps of size  $+1$ , with  $N_i(0) = 0$ . Let  $\boldsymbol{\beta}$  denote the vector of unknown regression coefficients. The multiplicative hazards function  $\Lambda(t, \mathbf{Z}_i(t))$  for  $N_i$  is given by

$$Y_i(t)d\Lambda(t, \mathbf{Z}_i(t)) = Y_i(t) \exp(\boldsymbol{\beta}'\mathbf{Z}_i(t))d\Lambda_0(t)$$

where

- $Y_i(t)$  indicates whether the  $i$ th subject is at risk at time  $t$  (specifically,  $Y_i(t) = 1$  if at risk and  $Y_i(t) = 0$  otherwise)
- $\mathbf{Z}_i(t)$  is the vector of explanatory variables for the  $i$ th subject at time  $t$
- $\Lambda_0(t)$  is an unspecified baseline hazard function

See Fleming and Harrington (1991) and Andersen et al. (1992). The Cox model is a special case of this multiplicative hazards model, where  $Y_i(t) = 1$  until the first event or censoring, and  $Y_i(t) = 0$  thereafter.

The partial likelihood for  $n$  independent triplets  $(N_i, Y_i, \mathbf{Z}_i), i = 1, \dots, n$ , has the form

$$\mathcal{L}(\boldsymbol{\beta}) = \prod_{i=1}^n \prod_{t \geq 0} \left\{ \frac{Y_i(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_i(t))}{\sum_{j=1}^n Y_j(t) \exp(\boldsymbol{\beta}' \mathbf{Z}_j(t))} \right\}^{\Delta N_i(t)}$$

where  $\Delta N_i(t) = 1$  if  $N_i(t) - N_i(t-) = 1$ , and  $\Delta N_i(t) = 0$  otherwise.

## The Frailty Model

You can use the frailty model to model correlations between failures of the same cluster. The hazard rate for the  $j$ th individual in the  $i$ th cluster is

$$\lambda_{ij}(t) = \lambda_0(t) e^{\boldsymbol{\beta}' \mathbf{Z}_{ij}(t) + \gamma_i}$$

where  $\lambda_0(t)$  is an arbitrary baseline hazard rate,  $\mathbf{Z}_{ij}$  is the vector of (fixed-effect) covariates,  $\boldsymbol{\beta}$  is the vector of regression coefficients, and  $\gamma_i$  is the random effect for cluster  $i$ .

Frailties are the exponential transformations of the random components, and the frailty model can be written as

$$\lambda_{ij}(t) = \lambda_0(t) e^{\gamma_i} e^{\boldsymbol{\beta}' \mathbf{Z}_{ij}(t)}$$

The random components  $\gamma_1, \dots, \gamma_s$  (alternatively, the frailties  $e^{\gamma_1}, \dots, e^{\gamma_s}$ ) are assumed to be independent and identically distributed. Modeling is based on the random effects rather than on the frailties.

Two frailty distributions are available in PROC PHREG: gamma and lognormal. Use the DIST= option in the RANDOM statement to choose the distribution. Let  $\theta$  be an unknown parameter. The frailty distributions are listed in Table 67.11.

**Table 67.11** Frailty Distributions

| Frailty Option | Distribution                                                         | Density $f(\boldsymbol{\gamma}_i)$                                                                                                                    | Mean and Variance                                |
|----------------|----------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------|
| DIST=GAMMA     | $e^{\gamma_i} \sim G\left(\frac{1}{\theta}, \frac{1}{\theta}\right)$ | $\frac{\exp(\frac{\gamma_i}{\theta}) \exp\left(-\frac{\exp(\gamma_i)}{\theta}\right)}{\theta^{\frac{1}{\theta}} \Gamma\left(\frac{1}{\theta}\right)}$ | $E(e^{\gamma_i})=1 \quad V(e^{\gamma_i})=\theta$ |
| DIST=LOGNORMAL | $\gamma_i \sim N(0, \theta)$                                         | $\frac{1}{\sqrt{(2\pi\theta)}} \exp\left(-\frac{\gamma_i^2}{2\theta}\right)$                                                                          | $E(\gamma_i)=0 \quad V(\gamma_i)=\theta$         |

The unknown parameter  $\theta$  is a dispersion parameter. Each frailty distribution has a central tendency of 1 (the gamma frailty has a mean of 1, and the lognormal frailty has a median of 1). Thus, you can infer that individuals in cluster  $i$  with frailty  $e^{\gamma_i} > 1$  (or  $e^{\gamma_i} < 1$ ) tend to fail at a faster (or slower) rate than they fail under an independence model.

PROC PHREG estimates the regression coefficients  $\boldsymbol{\beta}$ , the random effects  $\gamma_1, \dots, \gamma_s$ , and the dispersion parameter  $\theta$ . The RANDOM statement in PROC PHREG enables you to fit a shared frailty model by a

penalized partial likelihood approach. If you also specify the BAYES statement, PROC PHREG performs a Bayesian analysis of the shared frailty model.

If the RANDOM statement is specified, any ASSESS, BASELINE, and OUTPUT statements are ignored. Also ignored are the COVS options in the PROC PHREG statement and the following options in the MODEL statement: BEST=, DETAILS, HIERARCHY=, INCLUDE=, NOFIT, PLCONV=, SELECTION=, SEQUENTIAL, SLENTY=, SLSTAY=, TYPE1, and TYPE3(ALL, LR, SCORE). Profile likelihood confidence intervals for the hazard ratios are not available for the frailty model analysis.

---

## Hazard Ratios

Consider a dichotomous risk factor variable  $X$  that takes the value 1 if the risk factor is present and 0 if the risk factor is absent. The log-hazard function is given by

$$\log[\lambda(t|X)] = \log[\lambda_0(t)] + \beta_1 X$$

where  $\lambda_0(t)$  is the baseline hazard function.

The hazard ratio  $\psi$  is defined as the ratio of the hazard for those with the risk factor ( $X = 1$ ) to the hazard without the risk factor ( $X = 0$ ). The log of the hazard ratio is given by

$$\log(\psi) \equiv \log[\psi(X = 1, X = 0)] = \log[\lambda(t|X = 1)] - \log[\lambda(t|X = 0)] = \beta_1$$

In general, the hazard ratio can be computed by exponentiating the difference of the log-hazard between any two population profiles. This is the approach taken by the HAZARDRATIO statement, so the computations are available regardless of parameterization, interactions, and nestings. However, as shown in the preceding equation for  $\log(\psi)$ , hazard ratios of main effects can be computed as functions of the parameter estimates, and the remainder of this section is concerned with this methodology.

The parameter,  $\beta_1$ , associated with  $X$  represents the change in the log-hazard from  $X = 0$  to  $X = 1$ . So the hazard ratio is obtained by simply exponentiating the value of the parameter associated with the risk factor. The hazard ratio indicates how the hazard change as you change  $X$  from 0 to 1. For instance,  $\psi = 2$  means that the hazard when  $X = 1$  is twice the hazard when  $X = 0$ .

Suppose the values of the dichotomous risk factor are coded as constants  $a$  and  $b$  instead of 0 and 1. The hazard when  $X = a$  becomes  $\lambda(t) \exp(a\beta_1)$ , and the hazard when  $X = b$  becomes  $\lambda(t) \exp(b\beta_1)$ . The hazard ratio corresponding to an increase in  $X$  from  $a$  to  $b$  is

$$\psi = \exp[(b - a)\beta_1] = [\exp(\beta_1)]^{b-a} \equiv [\exp(\beta_1)]^c$$

Note that for any  $a$  and  $b$  such that  $c = b - a = 1$ ,  $\psi = \exp(\beta_1)$ . So the hazard ratio can be interpreted as the change in the hazard for any increase of one unit in the corresponding risk factor. However, the change in hazard for some amount other than one unit is often of greater interest. For example, a change of one pound in body weight might be too small to be considered important, while a change of 10 pounds might be more meaningful. The hazard ratio for a change in  $X$  from  $a$  to  $b$  is estimated by raising the hazard ratio estimate for a unit change in  $X$  to the power of  $c = b - a$  as shown previously.

For a polytomous risk factor, the computation of hazard ratios depends on how the risk factor is parameterized. For illustration, suppose that Cell is a risk factor with four categories: Adeno, Large, Small, and Squamous.

For the effect parameterization scheme (PARAM=EFFECT) with Squamous as the reference group, the design variables for Cell are as follows:

| Cell     | Design Variables |       |       |
|----------|------------------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ |
| Adeno    | 1                | 0     | 0     |
| Large    | 0                | 1     | 0     |
| Small    | 0                | 0     | 1     |
| Squamous | -1               | -1    | -1    |

The log-hazard for Adeno is

$$\begin{aligned}\log[\lambda(t|\text{Adeno})] &= \log[\lambda_0(t)] + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) \\ &= \lambda_0(t) + \beta_1\end{aligned}$$

The log-hazard for Squamous is

$$\begin{aligned}\log[\lambda(t|\text{Squamous})] &= \log[\lambda_0(t)] + \beta_1(X_1 = -1) + \beta_2(X_2 = -1) + \beta_3(X_3 = -1) \\ &= \log[\lambda_0(t)] - \beta_1 - \beta_2 - \beta_3\end{aligned}$$

Therefore, the log-hazard ratio of Adeno versus Squamous

$$\begin{aligned}\log[\psi(\text{Adeno, Squamous})] &= \log[\lambda(t|\text{Adeno})] - \log[\lambda(t|\text{Squamous})] \\ &= 2\beta_1 + \beta_2 + \beta_3\end{aligned}$$

For the reference cell parameterization scheme (**PARAM=REF**) with Squamous as the reference cell, the design variables for Cell are as follows:

| Cell     | Design Variables |       |       |
|----------|------------------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ |
| Adeno    | 1                | 0     | 0     |
| Large    | 0                | 1     | 0     |
| Small    | 0                | 0     | 1     |
| Squamous | 0                | 0     | 0     |

The log-hazard ratio of Adeno versus Squamous is given by

$$\begin{aligned}\log(\psi(\text{Adeno, Squamous})) &= \log[\lambda(t|\text{Adeno})] - \log[\lambda(t|\text{Squamous})] \\ &= (\log[\lambda_0(t)] + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) - \\ &\quad (\log[\lambda_0(t)] + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0)) \\ &= \beta_1\end{aligned}$$

For the GLM parameterization scheme (PARAM=GLM), the design variables are as follows:

| Cell     | Design Variables |       |       |       |
|----------|------------------|-------|-------|-------|
|          | $X_1$            | $X_2$ | $X_3$ | $X_4$ |
| Adeno    | 1                | 0     | 0     | 0     |
| Large    | 0                | 1     | 0     | 0     |
| Small    | 0                | 0     | 1     | 0     |
| Squamous | 0                | 0     | 0     | 1     |

The log-hazard ratio of Adeno versus Squamous is

$$\begin{aligned}
 & \log(\psi(\text{Adeno}, \text{Squamous})) \\
 &= \log[\lambda(t|\text{Adeno})] - \log[\lambda(t|\text{Squamous})] \\
 &= \log[\lambda_0(t) + \beta_1(X_1 = 1) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 0)] - \\
 & \quad (\log(\lambda_0(t)) + \beta_1(X_1 = 0) + \beta_2(X_2 = 0) + \beta_3(X_3 = 0) + \beta_4(X_4 = 1)) \\
 &= \beta_1 - \beta_4
 \end{aligned}$$

Consider Cell as the only risk factor in the Cox regression in [Example 67.3](#). The computation of hazard ratio of Adeno versus Squamous for various parameterization schemes is tabulated in [Table 67.12](#).

**Table 67.12** Hazard Ratio Comparing Adeno to Squamous

| PARAM= | Parameter Estimates |                 |                 |                 | Hazard Ratio Estimates                            |
|--------|---------------------|-----------------|-----------------|-----------------|---------------------------------------------------|
|        | $\hat{\beta}_1$     | $\hat{\beta}_2$ | $\hat{\beta}_3$ | $\hat{\beta}_4$ |                                                   |
| EFFECT | 0.5772              | -0.2115         | 0.2454          |                 | $\exp(2 \times 0.5772 - 0.2115 + 0.2454) = 3.281$ |
| REF    | 1.8830              | 0.3996          | 0.8565          |                 | $\exp(1.8830) = 3.281$                            |
| GLM    | 1.8830              | 0.3996          | 0.8565          | 0.0000          | $\exp(1.8830) = 3.281$                            |

The fact that the log-hazard ratio ( $\log(\psi)$ ) is a linear function of the parameters enables the **HAZARDRATIO** statement to compute the hazard ratio of the main effect even in the presence of interactions and nest effects. The section “[Hazard Ratios](#)” on page 5619 details the estimation of the hazard ratios in a classical analysis.

To customize hazard ratios for specific units of change for a continuous risk factor, you can use the **UNITS=** option in a **HAZARDRATIO** statement to specify a list of relevant units for each explanatory variable in the model. Estimates of these customized hazard ratios are given in a separate table. Let  $(L_j, U_j)$  be a confidence interval for  $\log(\psi)$ . The corresponding lower and upper confidence limits for the customized hazard ratio  $\exp(c\beta_j)$  are  $\exp(cL_j)$  and  $\exp(cU_j)$ , respectively (for  $c > 0$ ), or  $\exp(cU_j)$  and  $\exp(cL_j)$ , respectively (for  $c < 0$ ).

## Proportional Rates/Means Models for Recurrent Events

Let  $N(t)$  be the number of events experienced by a subject over the time interval  $(0, t]$ . Let  $dN(t)$  be the increment of the counting process  $N$  over  $[t, t + dt)$ . The rate function is given by

$$d\mu_{\mathbf{Z}}(t) = E[dN(t)|Z(t)] = e^{\beta' \mathbf{Z}(t)} d\mu_0(t)$$

where  $\mu_0(\cdot)$  is an unknown continuous function. If the  $\mathbf{Z}$  are time independent, the rate model is reduced to the mean model

$$\mu_{\mathbf{Z}}(t) = e^{\boldsymbol{\beta}'\mathbf{Z}} \mu_0(t)$$

The partial likelihood for  $n$  independent triplets  $(N_i, Y_i, \mathbf{Z}_i)$ ,  $i = 1, \dots, n$ , of counting, at-risk, and covariate processes is the same as that of the multiplicative hazards model. However, a robust sandwich estimate is used for the covariance matrix of the parameter estimator instead of the model-based estimate.

Let  $T_{ki}$  be the  $k$ th event time of the  $i$ th subject. Let  $C_i$  be the censoring time of the  $i$ th subject. The at-risk indicator and the failure indicator are, respectively,

$$Y_i(t) = I(C_i \geq t) \text{ and } \Delta_{ki} = I(T_{ki} \leq C_i)$$

Denote

$$S^{(0)}(\boldsymbol{\beta}, t) = \sum_{i=1}^n Y_i(t) e^{\boldsymbol{\beta}'\mathbf{Z}_i(t)} \text{ and } \bar{\mathbf{Z}}(\boldsymbol{\beta}, t) = \frac{\sum_{i=1}^n Y_i(t) e^{\boldsymbol{\beta}'\mathbf{Z}_i(t)} \mathbf{Z}_i(t)}{S^{(0)}(\boldsymbol{\beta}, t)}$$

Let  $\hat{\boldsymbol{\beta}}$  be the maximum likelihood estimate of  $\boldsymbol{\beta}$ , and let  $\mathcal{I}(\hat{\boldsymbol{\beta}})$  be the observed information matrix. The robust sandwich covariance matrix estimate is given by

$$\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \sum_{i=1}^n \left[ W_i(\hat{\boldsymbol{\beta}}) W_i'(\hat{\boldsymbol{\beta}}) \right] \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$$

where

$$W_i(\boldsymbol{\beta}) = \sum_k \Delta_{ki} \left\{ Z_i(T_{ki}) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, T_{ki}) \right\} - \sum_{i=1}^n \sum_l \frac{\Delta_{lj} Y_i(T_{lj}) e^{\boldsymbol{\beta}'\mathbf{Z}_i(T_{lj})}}{S^{(0)}(\boldsymbol{\beta}, T_{lj})} \left\{ Z_i(T_{lj}) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, T_{lj}) \right\}$$

For a given realization of the covariates  $\boldsymbol{\xi}$ , the Nelson estimator is used to predict the mean function

$$\hat{\mu}_{\boldsymbol{\xi}}(t) = e^{\hat{\boldsymbol{\beta}}'\boldsymbol{\xi}} \sum_{i=1}^n \sum_k \frac{I(T_{ki} \leq t) \Delta_{ki}}{S^{(0)}(\hat{\boldsymbol{\beta}}, T_{ki})}$$

with standard error estimate given by

$$\hat{\sigma}^2(\hat{\mu}_{\boldsymbol{\xi}}(t)) = \sum_{i=1}^n \left( \frac{1}{n} \hat{\Psi}_i(t, \boldsymbol{\xi}) \right)^2$$

where

$$\begin{aligned} \frac{1}{n} \hat{\Psi}_i(t, \boldsymbol{\xi}) &= e^{\hat{\boldsymbol{\beta}}'\boldsymbol{\xi}} \left\{ \sum_k \frac{I(T_{ki} \leq t) \Delta_{ik}}{S^{(0)}(\hat{\boldsymbol{\beta}}, T_{ki})} - \sum_{j=1}^n \sum_k \frac{Y_i(T_{kj}) e^{\hat{\boldsymbol{\beta}}'\mathbf{Z}_i(T_{kj})} I(T_{kj} \leq t) \Delta_{kj}}{[S^{(0)}(\hat{\boldsymbol{\beta}}, T_{kj})]^2} \right. \\ &\quad \left[ \sum_{i=1}^n \sum_k \frac{I(T_{ki} \leq t) \Delta_{ik} [\bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, T_{ki}) - \boldsymbol{\xi}]}{S^{(0)}(\hat{\boldsymbol{\beta}}, T_{ki})} \right] \\ &\quad \left. \times \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \int_0^{\tau} [\mathbf{Z}_i(u) - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, u)] d\hat{M}_i(u) \right\} \end{aligned}$$

Since the cumulative mean function is always nonnegative, the log transform is used to compute confidence intervals. The  $100(1 - \alpha)\%$  pointwise confidence limits for  $\mu_{\xi}(t)$  are

$$\hat{\mu}_{\xi}(t) e^{\pm z_{\alpha/2} \frac{\hat{\sigma}(\hat{\mu}_{\xi}(t))}{\hat{\mu}_{\xi}(t)}}$$

where  $z_{\alpha/2}$  is the upper  $100\alpha/2$  percentage point of the standard normal distribution.

## Newton-Raphson Method

Let  $L(\boldsymbol{\beta})$  be one of the likelihood functions described in the previous subsections. Let  $l(\boldsymbol{\beta}) = \log L(\boldsymbol{\beta})$ . Finding  $\boldsymbol{\beta}$  such that  $L(\boldsymbol{\beta})$  is maximized is equivalent to finding the solution  $\hat{\boldsymbol{\beta}}$  to the likelihood equations

$$\frac{\partial l(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} = 0$$

With  $\hat{\boldsymbol{\beta}}^0 = \mathbf{0}$  as the initial solution, the iterative scheme is expressed as

$$\hat{\boldsymbol{\beta}}^{j+1} = \hat{\boldsymbol{\beta}}^j - \left[ \frac{\partial^2 l(\hat{\boldsymbol{\beta}}^j)}{\partial \boldsymbol{\beta}^2} \right]^{-1} \frac{\partial l(\hat{\boldsymbol{\beta}}^j)}{\partial \boldsymbol{\beta}}$$

The term after the minus sign is the Newton-Raphson step. If the likelihood function evaluated at  $\hat{\boldsymbol{\beta}}^{j+1}$  is less than that evaluated at  $\hat{\boldsymbol{\beta}}^j$ , then  $\hat{\boldsymbol{\beta}}^{j+1}$  is recomputed using half the step size. The iterative scheme continues until convergence is obtained—that is, until  $\hat{\boldsymbol{\beta}}_{j+1}$  is sufficiently close to  $\hat{\boldsymbol{\beta}}^j$ . Then the maximum likelihood estimate of  $\boldsymbol{\beta}$  is  $\hat{\boldsymbol{\beta}} = \hat{\boldsymbol{\beta}}_{j+1}$ .

The model-based variance estimate of  $\hat{\boldsymbol{\beta}}$  is obtained by inverting the information matrix  $\mathcal{I}(\hat{\boldsymbol{\beta}})$

$$\hat{\mathbf{V}}_m(\hat{\boldsymbol{\beta}}) = \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) = - \left[ \frac{\partial^2 l(\hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} \right]^{-1}$$

## Firth's Modification for Maximum Likelihood Estimation

In fitting a Cox model, the phenomenon of monotone likelihood is observed if the likelihood converges to a finite value while at least one parameter diverges (Heinze and Schemper 2001).

Let  $\mathbf{x}_l(t)$  denote the vector explanatory variables for the  $l$ th individual at time  $t$ . Let  $t_1 < t_2 < \dots < t_m$  denote the  $k$  distinct, ordered event times. Let  $d_j$  denote the multiplicity of failures at  $t_j$ ; that is,  $d_j$  is the size of the set  $\mathcal{D}_j$  of individuals that fail at  $t_j$ . Let  $\mathcal{R}_j$  denote the risk set just before  $t_j$ . Let  $\boldsymbol{\beta} = (\beta_1, \dots, \beta_k)'$  be the vector of regression parameters. The Breslow log partial likelihood is given by

$$l(\boldsymbol{\beta}) = \log L(\boldsymbol{\beta}) = \sum_{j=1}^m \left\{ \boldsymbol{\beta}' \sum_{l \in \mathcal{D}_j} \mathbf{x}_l(t_j) - d_j \log \sum_{h \in \mathcal{R}_j} e^{\boldsymbol{\beta}' \mathbf{x}_h(t_j)} \right\}$$

Denote

$$\mathbf{S}_j^{(a)}(\boldsymbol{\beta}) = \sum_{h \in \mathcal{R}_j} e^{\boldsymbol{\beta}' \mathbf{x}_h(t_j)} [\mathbf{x}_h(t_j)]^{\otimes a} \quad a = 0, 1, 2$$

Then the score function is given by

$$\begin{aligned} \mathbf{U}(\boldsymbol{\beta}) &\equiv (U(\beta_1), \dots, U(\beta_k))' \\ &= \frac{\partial l(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}} \\ &= \sum_{j=1}^m \left\{ \sum_{l \in \mathcal{D}_j} \mathbf{x}_l(t_j) - d_j \frac{\mathbf{S}_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right\} \end{aligned}$$

and the Fisher information matrix is given by

$$\begin{aligned} \mathcal{I}(\boldsymbol{\beta}) &= -\frac{\partial^2 l(\boldsymbol{\beta})}{\partial \boldsymbol{\beta}^2} \\ &= \sum_{j=1}^m d_j \left\{ \frac{\mathbf{S}_j^{(2)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \left[ \frac{\mathbf{S}_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right] \left[ \frac{\mathbf{S}_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right]' \right\} \end{aligned}$$

Heinze (1999); Heinze and Schemper (2001) applied the idea of Firth (1993) by maximizing the penalized partial likelihood

$$l^*(\boldsymbol{\beta}) = l(\boldsymbol{\beta}) + 0.5 \log(|\mathcal{I}(\boldsymbol{\beta})|)$$

The score function  $\mathbf{U}(\boldsymbol{\beta})$  is replaced by the modified score function by  $\mathbf{U}^*(\boldsymbol{\beta}) \equiv (U^*(\beta_1), \dots, U^*(\beta_k))'$ , where

$$U^*(\beta_r) = U(\beta_r) + 0.5 \text{tr} \left\{ \mathcal{I}^{-1}(\boldsymbol{\beta}) \frac{\partial \mathcal{I}(\boldsymbol{\beta})}{\partial \beta_r} \right\} \quad r = 1, \dots, k$$

The Firth estimate is obtained iteratively as

$$\boldsymbol{\beta}^{(s+1)} = \boldsymbol{\beta}^{(s)} + \mathcal{I}^{-1}(\boldsymbol{\beta}^{(s)}) \mathbf{U}^*(\boldsymbol{\beta}^{(s)})$$

The covariance matrix  $\hat{\mathbf{V}}$  is computed as  $\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$ , where  $\hat{\boldsymbol{\beta}}$  is the maximum penalized partial likelihood estimate.

### Explicit formulae for $\frac{\partial \mathcal{I}(\boldsymbol{\beta})}{\partial \beta_r}$ , $r = 1, \dots, k$

Denote

$$\begin{aligned} \mathbf{x}_h(t) &= (x_{h1}(t), \dots, x_{hk}(t))' \\ \mathbf{Q}_{jr}^{(a)}(\boldsymbol{\beta}) &= \sum_{h \in \mathcal{R}_j} e^{\boldsymbol{\beta}' \mathbf{x}_h(t_j)} x_{hr}(t_j) [\mathbf{x}_h(t_j)]^{\otimes a} \quad a = 0, 1, 2; r = 1, \dots, k \end{aligned}$$

Then

$$\frac{\partial \mathcal{I}(\boldsymbol{\beta})}{\partial \beta_r} = \sum_{j=1}^m d_j \left\{ \left[ \frac{\mathbf{Q}_{jr}^{(2)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \frac{\mathbf{Q}_{jr}^{(0)}(\boldsymbol{\beta}) S_j^{(2)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta}) S_j^{(0)}(\boldsymbol{\beta})} \right] - \left[ \frac{\mathbf{Q}_{jr}^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \frac{\mathbf{Q}_{jr}^{(0)}(\boldsymbol{\beta}) S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta}) S_j^{(0)}(\boldsymbol{\beta})} \right] \left[ \frac{S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right]' - \left[ \frac{S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} \right] \left[ \frac{\mathbf{Q}_{jr}^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta})} - \frac{\mathbf{Q}_{jr}^{(0)}(\boldsymbol{\beta}) S_j^{(1)}(\boldsymbol{\beta})}{S_j^{(0)}(\boldsymbol{\beta}) S_j^{(0)}(\boldsymbol{\beta})} \right]' \right\} \quad r = 1, \dots, k$$

---

## Robust Sandwich Variance Estimate

For the  $i$ th subject,  $i = 1, \dots, n$ , let  $X_i$ ,  $w_i$ , and  $\mathbf{Z}_i(t)$  be the observed time, weight, and the covariate vector at time  $t$ , respectively. Let  $\Delta_i$  be the event indicator and let  $Y_i(t) = I(X_i \geq t)$ . Let

$$S^{(r)}(\boldsymbol{\beta}, t) = \sum_{j=1}^n w_j Y_j(t) e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \mathbf{Z}_j^{\otimes r}(t), \quad r = 0, 1$$

Let  $\bar{\mathbf{Z}}(\boldsymbol{\beta}, t) = \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)}$ . The score residual for the  $i$ th subject is

$$\mathbf{L}_i(\boldsymbol{\beta}) = \Delta_i \left\{ \mathbf{Z}_i(X_i) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, X_i) \right\} - \sum_{j=1}^n \Delta_j \frac{w_j Y_j(X_j) e^{\boldsymbol{\beta}' \mathbf{Z}_j(X_j)}}{S^{(0)}(\boldsymbol{\beta}, X_j)} \left\{ \mathbf{Z}_j(X_j) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, X_j) \right\}$$

For TIES=EFRON, the computation of the score residuals is modified to comply with the Efron partial likelihood. See the section “Residuals” on page 5639 for more information.

The robust sandwich variance estimate of  $\hat{\boldsymbol{\beta}}$  derived by Binder (1992), who incorporated weights into the analysis, is

$$\hat{\mathbf{V}}_s(\hat{\boldsymbol{\beta}}) = \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \left[ \sum_{j=1}^n (w_j \mathbf{L}_j(\hat{\boldsymbol{\beta}}))^{\otimes 2} \right] \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})$$

where  $\mathcal{I}(\hat{\boldsymbol{\beta}})$  is the observed information matrix, and  $\mathbf{a}^{\otimes 2} = \mathbf{a}\mathbf{a}'$ . Note that when  $w_i \equiv 1$ ,

$$\hat{\mathbf{V}}_s(\hat{\boldsymbol{\beta}}) = \mathbf{D}'\mathbf{D}$$

where  $\mathbf{D}$  is the matrix of DFBETA residuals. This robust variance estimate was proposed by Lin and Wei (1989) and Reid and Crèpeau (1985).

## Testing the Global Null Hypothesis

The following statistics can be used to test the global null hypothesis  $H_0: \boldsymbol{\beta} = \mathbf{0}$ . Under mild assumptions, each statistic has an asymptotic chi-square distribution with  $p$  degrees of freedom given the null hypothesis. The value  $p$  is the dimension of  $\boldsymbol{\beta}$ . For clustered data, the likelihood ratio test, the score test, and the Wald test assume independence of observations within a cluster, while the robust Wald test and the robust score test do not need such an assumption.

**Likelihood Ratio Test**

$$\chi_{LR}^2 = 2 \left[ l(\hat{\boldsymbol{\beta}}) - l(\mathbf{0}) \right]$$

**Score Test**

$$\chi_S^2 = \left[ \frac{\partial l(\mathbf{0})}{\partial \boldsymbol{\beta}} \right]' \left[ -\frac{\partial^2 l(\mathbf{0})}{\partial \boldsymbol{\beta}^2} \right]^{-1} \left[ \frac{\partial l(\mathbf{0})}{\partial \boldsymbol{\beta}} \right]$$

**Wald's Test**

$$\chi_W^2 = \hat{\boldsymbol{\beta}}' \left[ -\frac{\partial^2 l(\hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} \right] \hat{\boldsymbol{\beta}}$$

**Robust Score Test**

$$\chi_{RS}^2 = \left[ \sum_i \mathbf{L}_i^0 \right]' \left[ \sum_i \mathbf{L}_i^0 \mathbf{L}_i^{0'} \right]^{-1} \left[ \sum_i \mathbf{L}_i^0 \right]$$

where  $\mathbf{L}_i^0$  is the score residual of the  $i$ th subject at  $\boldsymbol{\beta} = \mathbf{0}$ ; that is,  $\mathbf{L}_i^0 = \mathbf{L}_i(\mathbf{0}, \infty)$ , where the score process  $\mathbf{L}_i(\boldsymbol{\beta}, t)$  is defined in the section “Residuals” on page 5639.

**Robust Wald's Test**

$$\chi_{RW}^2 = \hat{\boldsymbol{\beta}}' [\hat{\mathbf{V}}_s(\hat{\boldsymbol{\beta}})]^{-1} \hat{\boldsymbol{\beta}}$$

where  $\hat{\mathbf{V}}_s(\hat{\boldsymbol{\beta}})$  is the sandwich variance estimate (see the section “Robust Sandwich Variance Estimate” on page 5625 for details).

**Type 3 Tests**

The following statistics can be used to test the null hypothesis  $H_{0L}: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ , where  $\mathbf{L}$  is a matrix of known coefficients. Under mild assumptions, each of the following statistics has an asymptotic chi-square distribution with  $p$  degrees of freedom, where  $p$  is the rank of  $\mathbf{L}$ . Let  $\tilde{\boldsymbol{\beta}}_L$  be the maximum likelihood of  $\boldsymbol{\beta}$  under the null hypothesis  $H_{0L}$ ; that is,

$$l(\tilde{\boldsymbol{\beta}}_L) = \max_{\mathbf{L}\boldsymbol{\beta}=\mathbf{0}} l(\boldsymbol{\beta})$$

**Likelihood Ratio Statistic**

$$\chi_{LR}^2 = 2 \left[ l(\hat{\boldsymbol{\beta}}) - l(\tilde{\boldsymbol{\beta}}_L) \right]$$

### Score Statistic

$$\chi_S^2 = \left[ \frac{\partial l(\tilde{\boldsymbol{\beta}}_L)}{\partial \boldsymbol{\beta}} \right]' \left[ -\frac{\partial^2 l(\tilde{\boldsymbol{\beta}}_L)}{\partial \boldsymbol{\beta}^2} \right]^{-1} \left[ \frac{\partial l(\tilde{\boldsymbol{\beta}}_L)}{\partial \boldsymbol{\beta}} \right]$$

### Wald's Statistic

$$\chi_W^2 = (\mathbf{L}\hat{\boldsymbol{\beta}})' [\mathbf{L}\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})\mathbf{L}']^{-1} (\mathbf{L}\hat{\boldsymbol{\beta}})$$

where  $\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$  is the estimated covariance matrix, which can be the model-based covariance matrix  $\left[ -\frac{\partial^2 l(\hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} \right]^{-1}$  or the sandwich covariance matrix  $V_S(\hat{\boldsymbol{\beta}})$  (see the section “Robust Sandwich Variance Estimate” on page 5625 for details).

---

## Confidence Limits for a Hazard Ratio

Let  $\mathbf{e}_j$  be the  $j$ th unit vector—that is, the  $j$ th entry of the vector is 1 and all other entries are 0. The hazard ratio for the explanatory variable with regression coefficient  $\beta_j = \mathbf{e}_j' \boldsymbol{\beta}$  is defined as  $\exp(\beta_j)$ . In general, a log-hazard ratio can be written as  $\mathbf{h}' \boldsymbol{\beta}$ , a linear combination of the regression coefficients, and the hazard ratio  $\exp(\mathbf{h}' \boldsymbol{\beta})$  is obtained by replacing  $\mathbf{e}_j$  with  $\mathbf{h}$ .

### Point Estimate

The hazard ratio  $\exp(\mathbf{e}_j' \boldsymbol{\beta})$  is estimated by  $\exp(\mathbf{e}_j' \hat{\boldsymbol{\beta}})$ , where  $\hat{\boldsymbol{\beta}}$  is the maximum likelihood estimate of the  $\boldsymbol{\beta}$ .

### Wald's Confidence Limits

The  $100(1 - \alpha)\%$  confidence limits for the hazard ratio are calculated as

$$\exp \left( \mathbf{e}_j' \hat{\boldsymbol{\beta}} \pm z_{\alpha/2} \sqrt{\mathbf{e}_j' \hat{\mathbf{V}}(\hat{\boldsymbol{\beta}}) \mathbf{e}_j} \right)$$

where  $\hat{\mathbf{V}}(\hat{\boldsymbol{\beta}})$  is estimated covariance matrix, and  $z_{\alpha/2}$  is the  $100(1 - \alpha/2)$  percentile point of the standard normal distribution.

### Profile-Likelihood Confidence Limits

The construction of the profile-likelihood-based confidence interval is derived from the asymptotic  $\chi^2$  distribution of the generalized likelihood ratio test of Venzon and Moolgavkar (1988). Suppose that the parameter vector is  $\boldsymbol{\beta} = (\beta_1, \dots, \beta_k)'$  and you want to compute a confidence interval for  $\beta_j$ . The profile-likelihood function for  $\beta_j = \gamma$  is defined as

$$l_j^*(\gamma) = \max_{\boldsymbol{\beta} \in \mathcal{B}_j(\gamma)} l(\boldsymbol{\beta})$$

where  $\mathcal{B}_j(\gamma)$  is the set of all  $\boldsymbol{\beta}$  with the  $j$ th element fixed at  $\gamma$ , and  $l(\boldsymbol{\beta})$  is the log-likelihood function for  $\boldsymbol{\beta}$ . If  $l_{\max} = l(\hat{\boldsymbol{\beta}})$  is the log likelihood evaluated at the maximum likelihood estimate  $\hat{\boldsymbol{\beta}}$ , then  $2(l_{\max} - l_j^*(\beta_j))$

has a limiting chi-square distribution with one degree of freedom if  $\beta_j$  is the true parameter value. Let  $l_0 = l_{\max} - 0.5\chi_1^2(1 - \alpha)$ , where  $\chi_1^2(1 - \alpha)$  is the  $100(1 - \alpha)$  percentile of the chi-square distribution with one degree of freedom. A  $100(1 - \alpha)\%$  confidence interval for  $\beta_j$  is

$$\{\gamma : l_j^*(\gamma) \geq l_0\}$$

The endpoints of the confidence interval are found by solving numerically for values of  $\beta_j$  that satisfy equality in the preceding relation. To obtain an iterative algorithm for computing the confidence limits, the log-likelihood function in a neighborhood of  $\beta$  is approximated by the quadratic function

$$\tilde{l}(\beta + \delta) = l(\beta) + \delta' \mathbf{g} + \frac{1}{2} \delta' \mathbf{V} \delta$$

where  $\mathbf{g} = \mathbf{g}(\beta)$  is the gradient vector and  $\mathbf{V} = \mathbf{V}(\beta)$  is the Hessian matrix. The increment  $\delta$  for the next iteration is obtained by solving the likelihood equations

$$\frac{d}{d\delta} \{\tilde{l}(\beta + \delta) + \lambda(\mathbf{e}'_j \delta - \gamma)\} = \mathbf{0}$$

where  $\lambda$  is the Lagrange multiplier,  $\mathbf{e}_j$  is the  $j$ th unit vector, and  $\gamma$  is an unknown constant. The solution is

$$\delta = -\mathbf{V}^{-1}(\mathbf{g} + \lambda \mathbf{e}_j)$$

By substituting this  $\delta$  into the equation  $\tilde{l}(\beta + \delta) = l_0$ , you can estimate  $\lambda$  as

$$\lambda = \pm \left( \frac{2(l_0 - l(\beta) + \frac{1}{2} \mathbf{g}' \mathbf{V}^{-1} \mathbf{g})}{\mathbf{e}'_j \mathbf{V}^{-1} \mathbf{e}_j} \right)^{\frac{1}{2}}$$

The upper confidence limit for  $\beta_j$  is computed by starting at the maximum likelihood estimate of  $\beta$  and iterating with positive values of  $\lambda$  until convergence is attained. The process is repeated for the lower confidence limit, using negative values of  $\lambda$ .

Convergence is controlled by value  $\epsilon$  specified with the PLCONV= option in the MODEL statement (the default value of  $\epsilon$  is  $1\text{E-}4$ ). Convergence is declared on the current iteration if the following two conditions are satisfied:

$$|l(\beta) - l_0| \leq \epsilon$$

and

$$(\mathbf{g} + \lambda \mathbf{e}_j)' \mathbf{V}^{-1} (\mathbf{g} + \lambda \mathbf{e}_j) \leq \epsilon$$

The profile-likelihood confidence limits for the hazard ratio  $\exp(\mathbf{e}'_j \beta)$  are obtained by exponentiating these confidence limits.

## Using the TEST Statement to Test Linear Hypotheses

Linear hypotheses for  $\beta$  are expressed in matrix form as

$$H_0: \mathbf{L}\beta = \mathbf{c}$$

where  $\mathbf{L}$  is a matrix of coefficients for the linear hypotheses, and  $\mathbf{c}$  is a vector of constants. The Wald chi-square statistic for testing  $H_0$  is computed as

$$\chi_W^2 = (\mathbf{L}\hat{\beta} - \mathbf{c})' [\mathbf{L}\hat{\mathbf{V}}(\hat{\beta})\mathbf{L}']^{-1} (\mathbf{L}\hat{\beta} - \mathbf{c})$$

where  $\hat{\mathbf{V}}(\hat{\beta})$  is the estimated covariance matrix. Under  $H_0$ ,  $\chi_W^2$  has an asymptotic chi-square distribution with  $r$  degrees of freedom, where  $r$  is the rank of  $\mathbf{L}$ .

### Optimal Weights for the AVERAGE option in the TEST Statement

Let  $\beta_0 = (\beta_{i_1}, \dots, \beta_{i_s})'$ , where  $\{\beta_{i_1}, \dots, \beta_{i_s}\}$  is a subset of  $s$  regression coefficients. For any vector  $\mathbf{e} = (e_1, \dots, e_s)'$  of length  $s$ ,

$$\mathbf{e}'\hat{\beta}_0 \sim N(\mathbf{e}'\beta_0, \mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e})$$

To find  $\mathbf{e}$  such that  $\mathbf{e}'\hat{\beta}_0$  has the minimum variance, it is necessary to minimize  $\mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e}$  subject to  $\sum_{i=1}^s e_i = 1$ . Let  $\mathbf{1}_s$  be a vector of 1's of length  $s$ . The expression to be minimized is

$$\mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e} - \lambda(\mathbf{e}'\mathbf{1}_s - 1)$$

where  $\lambda$  is the Lagrange multiplier. Differentiating with respect to  $\mathbf{e}$  and  $\lambda$ , respectively, yields

$$\begin{aligned} \hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e} - \lambda\mathbf{1}_s &= \mathbf{0} \\ \mathbf{e}'\mathbf{1}_s - 1 &= 0 \end{aligned}$$

Solving these equations gives

$$\mathbf{e} = [\mathbf{1}'_s \hat{\mathbf{V}}^{-1}(\hat{\beta}_0) \mathbf{1}_s]^{-1} \hat{\mathbf{V}}^{-1}(\hat{\beta}_0) \mathbf{1}_s$$

This provides a one degree-of-freedom test for testing the null hypothesis  $H_0 : \beta_{i_1} = \dots = \beta_{i_s} = 0$  with normal test statistic

$$Z = \frac{\mathbf{e}'\hat{\beta}_0}{\sqrt{\mathbf{e}'\hat{\mathbf{V}}(\hat{\beta}_0)\mathbf{e}}}$$

This test is more sensitive than the multivariate test specified by the TEST statement

**Multivariate: test X1, ..., Xs;**

where X1, ..., Xs are the variables with regression coefficients  $\beta_{i_1}, \dots, \beta_{i_s}$ , respectively.

## Analysis of Multivariate Failure Time Data

Multivariate failure time data arise when each study subject can potentially experience several events (for instance, multiple infections after surgery) or when there exists some natural or artificial clustering of subjects (for instance, a litter of mice) that induces dependence among the failure times of the same cluster. Data in the former situation are referred to as multiple events data, and data in the latter situation are referred to as clustered data. The multiple events data can be further classified into ordered and unordered data. For ordered data, there is a natural ordering of the multiple failures within a subject, which includes recurrent events data as a special case. For unordered data, the multiple event times result from several concurrent failure processes.

Multiple events data can be analyzed by the Wei, Lin, and Weissfeld (1989), or WLW, method based on the marginal Cox models. For the special case of recurrent events data, you can fit the intensity model (Andersen and Gill 1982), the proportional rates/means model (Pepe and Cai 1993; Lawless and Nadeau 1995; Lin et al. 2000), or the stratified models for total time and gap time proposed by Prentice, Williams,

and Peterson (1981), or PWP. For clustered data, you can carry out the analysis of Lee, Wei, and Amato (1992) based on the marginal Cox model. To use PROC PHREG to perform these analyses correctly and effectively, you have to array your data in a specific way to produce the correct risk sets.

All examples described in this section can be found in the program *phrmult.sas* in the SAS/STAT sample library. Furthermore, the “Examples” section in this chapter contains two examples to illustrate the methods of analyzing recurrent events data and clustered data.

### Marginal Cox Models for Multiple Events Data

Suppose there are  $n$  subjects and each subject can experience up to  $K$  potential events. Let  $\mathbf{Z}_{ki}(\cdot)$  be the covariate process associated with the  $k$ th event for the  $i$ th subject. The marginal Cox models are given by

$$\lambda_k(t; \mathbf{Z}_{ki}) = \lambda_{k0} e^{\boldsymbol{\beta}'_k \mathbf{Z}_{ki}(t)}, k = 1, \dots, K; i = 1, \dots, n$$

where  $\lambda_{k0}(t)$  is the (event-specific) baseline hazard function for the  $k$ th event and  $\boldsymbol{\beta}_k$  is the (event-specific) column vector of regression coefficients for the  $k$ th event. WLW estimates  $\boldsymbol{\beta}_1, \dots, \boldsymbol{\beta}_K$  by the maximum partial likelihood estimates  $\hat{\boldsymbol{\beta}}_1, \dots, \hat{\boldsymbol{\beta}}_K$ , respectively, and uses a robust sandwich covariance matrix estimate for  $(\hat{\boldsymbol{\beta}}'_1, \dots, \hat{\boldsymbol{\beta}}'_K)'$  to account for the dependence of the multiple failure times.

By using a properly prepared input data set, you can estimate the regression parameters for all the marginal Cox models and compute the robust sandwich covariance estimates in one PROC PHREG invocation. For convenience of discussion, suppose each subject can potentially experience  $K = 3$  events and there are two explanatory variables Z1 and Z2. The event-specific parameters to be estimated are  $\boldsymbol{\beta}_1 = (\beta_{11}, \beta_{21})'$  for the first marginal model,  $\boldsymbol{\beta}_2 = (\beta_{12}, \beta_{22})'$  for the second marginal model, and  $\boldsymbol{\beta}_3 = (\beta_{13}, \beta_{23})'$  for the third marginal model. Inference of these parameters is based on the robust sandwich covariance matrix estimate of the parameter estimators. It is necessary that each row of the input data set represent the data for a potential event of a subject. The input data set should contain the following:

- an ID variable for identifying the subject so that all observations of the same subject have the same ID value
- an Enum variable to index the multiple events. For example, Enum=1 for the first event, Enum=2 for the second event, and so on.
- a Time variable to represent the observed time from some time origin for the event. For recurrence events data, it is the time from the study entry to each recurrence.
- a Status variable to indicate whether the Time value is a censored or uncensored time. For example, Status=1 indicates an uncensored time and Status=0 indicates a censored time.
- independent variables (Z1 and Z2)

The WLW analysis can be carried out by specifying the following:

```
proc phreg covs(aggregate);
 model Time*Status(0)=Z11 Z12 Z13 Z21 Z22 Z23;
 strata Enum;
 id ID;
 Z11= Z1 * (Enum=1);
 Z12= Z1 * (Enum=2);
```

```

Z13= Z1 * (Enum=3);
Z21= Z2 * (Enum=1);
Z22= Z2 * (Enum=2);
Z23= Z2 * (Enum=3);
run;

```

The variable Enum is specified in the STRATA statement so that there is one marginal Cox model for each distinct value of Enum. The variables Z11, Z12, Z13, Z21, Z22, and Z23 in the MODEL statement are event-specific variables derived from the independent variables Z1 and Z2 by the given programming statements. In particular, the variables Z11, Z12, and Z13 are event-specific variables for the explanatory variable Z1; the variables Z21, Z22, and Z23 are event-specific variables for the explanatory variable Z2. For  $j = 1, 2$ , and  $k = 1, 2, 3$ , variable Zjk contains the same values as the explanatory variable Zj for the rows that correspond to  $k$ th marginal model and the value 0 for all other rows; as such,  $\beta_{jk}$  is the regression coefficient for Zjk. You can avoid using the programming statements in PROC PHREG if you create these event-specific variables in the input data set by using the same programming statements in a DATA step.

The option COVS(AGGREGATE) is specified in the PROC PHREG statement to obtain the robust sandwich estimate of the covariance matrix, and the score residuals used in computing the middle part of the sandwich estimate are aggregated over identical ID values. You can also include TEST statements in the PROC PHREG code to test various linear hypotheses of the regression parameters based on the robust sandwich covariance matrix estimate.

Consider the AIDS study data in Wei, Lin, and Weissfeld (1989) from a randomized clinical trial to assess the antiretroviral capacity of ribavirin over time in AIDS patients. Blood samples were collected at weeks 4, 8, and 12 from each patient in three treatment groups (placebo, low dose of ribavirin, and high dose). For each serum sample, the failure time is the number of days before virus positivity was detected. If the sample was contaminated or it took a longer period of time than was achievable in the laboratory, the sample was censored. For example:

- Patient #1 in the placebo group has uncensored times 9, 6, and 7 days (that is, it took 9 days to detect viral positivity in the first blood sample, 6 days for the second blood sample, and 7 days for the third blood sample).
- Patient #14 in the low-dose group of ribavirin has uncensored times of 16 and 17 days for the first and second sample, respectively, and a censored time of 21 days for the third blood sample.
- Patient #28 in the high-dose group has an uncensored time of 21 days for the first sample, no measurement for the second blood sample, and a censored time of 25 days for the third sample.

For a full-rank parameterization, two design variables are sufficient to represent three treatment groups. Based on the reference coding with placebo as the reference, the values of the two dummy explanatory variables Z1 and Z2 representing the treatments are as follows:

| Treatment Group     | Z1 | Z2 |
|---------------------|----|----|
| Placebo             | 0  | 0  |
| Low dose ribavirin  | 1  | 0  |
| High dose ribavirin | 0  | 1  |

The bulk of the task in using PROC PHREG to perform the WLW analysis lies in the preparation of the input data set. As discussed earlier, the input data set should contain the ID, Enum, Time, and Status variables,

and event-specific independent variables Z11, Z12, Z13, Z21, Z22, and Z23. Data for the three patients described earlier are arrayed as follows:

| ID | Time | Status | Enum | Z1 | Z2 |
|----|------|--------|------|----|----|
| 1  | 9    | 1      | 1    | 0  | 0  |
| 1  | 6    | 1      | 2    | 0  | 0  |
| 1  | 7    | 1      | 3    | 0  | 0  |
| 14 | 16   | 1      | 1    | 1  | 0  |
| 14 | 17   | 1      | 2    | 1  | 0  |
| 14 | 21   | 0      | 3    | 1  | 0  |
| 28 | 21   | 1      | 1    | 0  | 1  |
| 28 | 25   | 0      | 3    | 0  | 1  |

The first three rows are data for Patient #1 with event times at 9, 6, and 7 days, one row for each event. The next three rows are data for Patient #14, who has an uncensored time of 16 days for the first serum sample, an uncensored time of 17 days for the second sample, and a censored time of 21 days for the third sample. The last two rows are data for Patient #28 of the high-dose group (Z1=0 and Z2=1). Since the patient did not have a second serum sample, there are only two rows of data.

To perform the WLW analysis, you specify the following statements:

```
proc phreg covs(aggregate);
 model Time*Status(0)=Z11 Z12 Z13 Z21 Z22 Z23;
 strata Enum;
 id ID;
 Z11= Z1 * (Enum=1);
 Z12= Z1 * (Enum=2);
 Z13= Z1 * (Enum=3);
 Z21= Z2 * (Enum=1);
 Z22= Z2 * (Enum=2);
 Z23= Z2 * (Enum=3);
 EqualLowDose: test Z11=Z12, Z12=Z23;
 AverageLow: test Z11,Z12,Z13 / e average;
run;
```

Two linear hypotheses are tested using the TEST statements. The specification

```
EqualLowDose: test Z11=Z12, Z12=Z13;
```

tests the null hypothesis  $\beta_{11} = \beta_{12} = \beta_{13}$  of identical low-dose effects across three marginal models. The specification

```
AverageLow: test Z11,Z12,Z13 / e average;
```

tests the null hypothesis of no low-dose effects (that is,  $\beta_{11} = \beta_{12} = \beta_{13} = 0$ ). The AVERAGE option computes the optimal weights for estimating the average low-dose effect  $\beta_1^* = \beta_{11} = \beta_{12} = \beta_{13}$  and performs a 1 DF test for testing the null hypothesis that  $\beta_1^* = 0$ . The E option displays the coefficients for the linear hypotheses, including the optimal weights.

## Marginal Cox Models for Clustered Data

Suppose there are  $n$  clusters with  $K_i$  members in the  $i$ th cluster,  $i = 1, \dots, n$ . Let  $\mathbf{Z}_{ki}(\cdot)$  be the covariate process associated with the  $k$ th member of the  $i$ th cluster. The marginal Cox model is given by

$$\lambda(t; \mathbf{Z}_{ki}) = \lambda_0(t) e^{\boldsymbol{\beta}' \mathbf{Z}_{ki}(t)} \quad k = 1, \dots, K_i; i = 1, \dots, n$$

where  $\lambda_0(t)$  is an arbitrary baseline hazard function and  $\boldsymbol{\beta}$  is the vector of regression coefficients. Lee, Wei, and Amato (1992) estimate  $\boldsymbol{\beta}$  by the maximum partial likelihood estimate  $\hat{\boldsymbol{\beta}}$  under the independent working assumption, and use a robust sandwich covariance estimate to account for the intracluster dependence.

To use PROC PHREG to analyze the clustered data, each member of a cluster is represented by an observation in the input data set. The input data set to PROC PHREG should contain the following:

- an ID variable to identify the cluster so that members of the same cluster have the same ID value
- a Time variable to represent the observed survival time of a member of a cluster
- a Status variable to indicate whether the Time value is an uncensored or censored time. For example, Status=1 indicates an uncensored time and Status=0 indicates a censored time.
- the explanatory variables thought to be related to the failure time

Consider a tumor study in which one of three female rats of the same litter was randomly subjected to a drug treatment. The failure time is the time from randomization to the detection of tumor. If a rat died before the tumor was detected, the failure time was censored. For example:

- In litter #1, the drug-treated rat has an uncensored time of 101 days, one untreated rat has a censored time of 49 days, and the other untreated rat has a failure time of 104 days.
- In litter #3, the drug-treated rat has a censored time of 104 days, one untreated rat has a censored time of 102 days, and the other untreated rat has a censored time of 104 days.

In this example, a litter is a cluster and the rats of the same litter are members of the cluster. Let Trt be a 0-1 variable representing the treatment a rat received, with value 1 for drug treatment and 0 otherwise. Data for the two litters of rats described earlier contribute six observations to the input data set:

| Litter | Time | Status | Trt |
|--------|------|--------|-----|
| 1      | 101  | 1      | 1   |
| 1      | 49   | 0      | 0   |
| 1      | 104  | 1      | 0   |
| 3      | 104  | 0      | 1   |
| 3      | 102  | 0      | 0   |
| 3      | 104  | 0      | 0   |

The analysis of Lee, Wei, and Amato (1992) can be performed by PROC PHREG as follows:

```
proc phreg covs(aggregate);
 model Time*Status(0)=Treatment;
 id Litter;
run;
```

## Intensity and Rate/Mean Models for Recurrent Events Data

Suppose each subject experiences recurrences of the same phenomenon. Let  $N(t)$  be the number of events a subject experiences over the interval  $[0, t]$  and let  $\mathbf{Z}(\cdot)$  be the covariate process of the subject.

The intensity model (Andersen and Gill 1982) is given by

$$\lambda_{\mathbf{Z}}(t)dt = E\{dN(t)|\mathcal{F}_{t-}\} = \lambda_0(t)e^{\boldsymbol{\beta}'\mathbf{Z}(t)}dt$$

where  $\mathcal{F}_t$  represents all the information of the processes  $N$  and  $\mathbf{Z}$  up to time  $t$ ,  $\lambda_0(t)$  is an arbitrary baseline intensity function, and  $\boldsymbol{\beta}$  is the vector of regression coefficients. This model consists of two components: (1) all the influence of the prior events on future recurrences, if there is any, is mediated through the time-dependent covariates, and (2) the covariates have multiplicative effects on the instantaneous rate of the counting process. If the covariates are time invariant, the risk of recurrences is unaffected by the past events.

The proportional rates and means models (Pepe and Cai 1993; Lawless and Nadeau 1995; Lin et al. 2000) assume that the covariates have multiplicative effects on the mean and rate functions of the counting process. The rate function is given by

$$d\mu_{\mathbf{Z}}(t) = E\{dN(t)|\mathbf{Z}(t)\} = e^{\boldsymbol{\beta}'\mathbf{Z}(t)}d\mu_0(t)$$

where  $\mu_0(t)$  is an unknown continuous function and  $\boldsymbol{\beta}$  is the vector of regression parameters. If  $\mathbf{Z}$  is time invariant, the mean function is given by

$$\mu_{\mathbf{Z}}(t) = E\{N(t)|\mathbf{Z}\} = e^{\boldsymbol{\beta}'\mathbf{Z}}\mu_0(t)$$

For both the intensity and the proportional rates/means models, estimates of the regression coefficients are obtained by solving the partial likelihood score function. However, the covariance matrix estimate for the intensity model is computed as the inverse of the observed information matrix, while that for the proportional rates/means model is given by a sandwich estimate. For a given pattern of fixed covariates, the Nelson estimate for the cumulative intensity function is the same for the cumulative mean function, but their standard errors are not the same.

To fit the intensity or rate/mean model by using PROC PHREG, the counting process style of input is needed. A subject with  $K$  events contributes  $K + 1$  observations to the input data set. The  $k$ th observation of the subject identifies the time interval from the  $(k - 1)$  event or time 0 (if  $k = 1$ ) to the  $k$ th event,  $k = 1, \dots, K$ . The  $(K + 1)$  observation represents the time interval from the  $K$ th event to time of censorship. The input data set should contain the following variables:

- a TStart variable to represent the  $(k - 1)$  recurrence time or the value 0 if  $k = 1$
- a TStop variable to represent the  $k$ th recurrence time or the follow-up time if  $k = K + 1$

- a `Status` variable indicating whether the `TStop` time is a recurrence time or a censored time; for example, `Status=1` for a recurrence time and `Status=0` for censored time
- explanatory variables thought to be related to the recurrence times

If the rate/mean model is used, the input data should also contain an `ID` variable for identifying the subjects.

Consider the chronic granulomatous disease (CGD) data listed in Fleming and Harrington (1991). The disease is a rare disorder characterized by recurrent pyrogenic infections. The study is a placebo-controlled randomized clinical trial conducted by the International CGD Cooperative Study to assess the effect of gamma interferon to reduce the rate of infection. For each study patient the times of recurrent infections along with a number of prognostic factors were collected. For example:

- Patient #17404, age 38, in the gamma interferon group had a follow-up time of 293 without any infection.
- Patient #204001, age 12, in the placebo group had an infection at 219 days, a recurrent infection at 373 days, and was followed up to 414 days.

Let `Trt` be the variable representing the treatment status with value 1 for gamma interferon and value 2 for placebo. Let `Age` be a covariate representing the age of the CGD patient. Data for the two CGD patients described earlier are given in the following table.

| <code>ID</code> | <code>TStart</code> | <code>TStop</code> | <code>Status</code> | <code>Trt</code> | <code>Age</code> |
|-----------------|---------------------|--------------------|---------------------|------------------|------------------|
| 174054          | 0                   | 293                | 0                   | 1                | 38               |
| 204001          | 0                   | 219                | 1                   | 2                | 12               |
| 204001          | 219                 | 373                | 1                   | 2                | 12               |
| 204001          | 373                 | 414                | 0                   | 2                | 12               |

Since Patient #174054 had no infection through the end of the follow-up period (293 days), there is only one observation representing the period from time 0 to the end of the follow-up. Data for Patient #204001 are broken into three observations, since there are two infections. The first observation represents the period from time 0 to the first infection, the second observation represents the period from the first infection to the second infection, and the third time period represents the period from the second infection to the end of the follow-up.

The following specification fits the intensity model:

```
proc phreg;
 model (TStart, TStop)*Status(0)=Trt Age;
run;
```

You can predict the cumulative intensity function for a given pattern of fixed covariates by specifying the `CUMHAZ=` option in the `BASELINE` statement. Suppose you are interested in two fixed patterns, one for patients of age 30 in the gamma interferon group and the other for patients of age 1 in the placebo group. You first create the SAS data set as follows:

```

data Pattern;
 Trt=1; Age=30;
 output;
 Trt=2; Age=1;
 output;
run;

```

You then include the following BASELINE statement in the PROC PHREG specification. The CUMHAZ=\_all\_ option produces the cumulative hazard function estimates, the standard error estimates, and the lower and upper pointwise confidence limits.

```
baseline covariates=Pattern out=out1 cumhaz=_all_;
```

The following specification of PROC PHREG fits the mean model and predicts the cumulative mean function for the two patterns of covariates in the Pattern data set:

```

proc phreg covs(aggregate);
 model (Tstart,Tstop)*Status(0)=Trt Age;
 baseline covariates=Pattern out=out2 cmf=_all_;
 id ID;
run;

```

The COV(AGGREGATE) option, along with the ID statement, computes the robust sandwich covariance matrix estimate. The CMF=\_ALL\_ option adds the cumulative mean function estimates, the standard error estimates, and the lower and upper pointwise confidence limits to the OUT=Out2 data set.

## PWP Models for Recurrent Events Data

Let  $N(t)$  be the number of events a subject experiences by time  $t$ . Let  $\mathbf{Z}(t)$  be the covariate vectors of the subject at time  $t$ . For a subject who has  $K$  events before censorship takes place, let  $t_0 = 0$ , let  $t_k$  be the  $k$ th recurrence time,  $k = 1, \dots, K$ , and let  $t_{K+1}$  be the censored time. Prentice, Williams, and Peterson (1981) consider two time scales, a total time from the beginning of the study and a gap time from immediately preceding failure. The PWP models are stratified Cox-type models that allow the shape of the hazard function to depend on the number of preceding events and possibly on other characteristics of  $\{N(t)$  and  $\mathbf{Z}(t)\}$ . The total time and gap time models are given, respectively, as follows:

$$\begin{aligned} \lambda(t|\mathcal{F}_{t-}) &= \lambda_{0k}(t)e^{\beta_k' \mathbf{Z}(t)}, & t_{k-1} < t \leq t_k \\ \lambda(t|\mathcal{F}_{t-}) &= \lambda_{0k}(t - t_{k-1})e^{\beta_k' \mathbf{Z}(t)}, & t_{k-1} < t \leq t_k \end{aligned}$$

where  $\lambda_{0k}$  is an arbitrary baseline intensity functions, and  $\beta_k$  is a vector of stratum-specific regression coefficients. Here, a subject moves to the  $k$ th stratum immediately after his  $(k - 1)$  recurrence time and remains there until the  $k$ th recurrence occurs or until censorship takes place. For instance, a subject who experiences only one event moves from the first stratum to the second stratum after the event occurs and remains in the second stratum until the end of the follow-up.

You can use PROC PHREG to carry out the analyses of the PWP models, but you have to prepare the input data set to provide the correct risk sets. The input data set for analyzing the total time is the same as the AG model with an additional variable to represent the stratum that the subject is in. A subject with  $K$  events contributes  $K + 1$  observations to the input data set, one for each stratum that the subject moves to. The input data should contain the following variables:

- a TStart variable to represent the  $(k - 1)$  recurrence time or the value 0 if  $k = 1$
- a TStop variable to represent the  $k$ th recurrence time or the time of censorship if  $k = K + 1$
- a Status variable with value 1 if the Time value is a recurrence time and value 0 if the Time value is a censored time
- an Enum variable representing the index of the stratum that the subject is in. For a subject who has only one event at  $t_1$  and is followed to time  $t_c$ , Enum=1 for the first observation (where Time= $t_1$  and Status=1) and Enum=2 for the second observation (where Time= $t_c$  and Status=0).
- explanatory variables thought to be related to the recurrence times

To analyze gap times, the input data set should also include a GapTime variable that is equal to (TStop – TStart).

Consider the data of two subjects in CGD data described in the previous section:

- Patients #174054, age 38, in the gamma interferon group had a follow-up time of 293 without any infection.
- Patient #204001, age 12, in the placebo group had an infection at 219 days, a recurrent infection at 373 days, and a follow-up time of 414 days.

To illustrate, suppose all subjects have at most two observed events. The data for the two subjects in the input data set are as follows:

| ID     | TStart | TStop | Gaptime | Status | Enum | Trt | Age |
|--------|--------|-------|---------|--------|------|-----|-----|
| 174054 | 0      | 293   | 293     | 0      | 1    | 1   | 38  |
| 204001 | 0      | 219   | 219     | 1      | 1    | 2   | 12  |
| 204001 | 219    | 373   | 154     | 1      | 2    | 2   | 12  |
| 204001 | 373    | 414   | 41      | 0      | 3    | 2   | 12  |

Subject #174054 contributes only one observation to the input data, since there is no observed event. Subject #204001 contributes three observations, since there are two observed events.

To fit the total time model of PWP with stratum-specific slopes, either you can create the stratum-specific explanatory variables (Trt1, Trt2, and Trt3 for Trt, and Age1, Age2, and Age3 for Age) in a DATA step, or you can specify them in PROC PHREG by using programming statements as follows:

```
proc phreg;
 model (TStart,TStop)*Status(0)=Trt1 Trt2 Trt3 Age1 Age2 Age3;
 strata Enum;
 Trt1= Trt * (Enum=1);
 Trt2= Trt * (Enum=2);
 Trt3= Trt * (Enum=3);
 Age1= Age * (Enum=1);
 Age2= Age * (Enum=2);
 Age3= Age * (Enum=3);
run;
```

To fit the total time model of PWP with the common regression coefficients, you specify the following:

```
proc phreg;
 model (TStart, TStop)*Status(0)=Trt Age;
 strata Enum;
run;
```

To fit the gap time model of PWP with stratum-specific regression coefficients, you specify the following:

```
proc phreg;
 model Gaptime*Status(0)=Trt1 Trt2 Trt3 Age1 Age2 Age3;
 strata Enum;
 Trt1= Trt * (Enum=1);
 Trt2= Trt * (Enum=2);
 Trt3= Trt * (Enum=3);
 Age1= Age * (Enum=1);
 Age2= Age * (Enum=2);
 Age3= Age * (Enum=3);
run;
```

To fit the gap time model of PWP with common regression coefficients, you specify the following:

```
proc phreg;
 model Gaptime*Status(0)=Trt Age;
 strata Enum;
run;
```

---

## Model Fit Statistics

Suppose the model contains  $p$  regression parameters. Let  $\Delta_j$  and  $f_j$  be the event indicator and the frequency, respectively, of the  $j$ th observation. The three criteria displayed by the PHREG procedure are calculated as follows:

- $-2$  Log Likelihood:

$$-2 \text{ Log L} = -2 \log(L_n(\hat{\beta}))$$

where  $L_n(\cdot)$  is a partial likelihood function for the corresponding TIES= option as described in the section “[Partial Likelihood Function for the Cox Model](#)” on page 5614, and  $\hat{\beta}$  is the maximum likelihood estimate of the regression parameter vector.

- Akaike’s Information Criterion:

$$\text{AIC} = -2 \text{ Log L} + 2p$$

- Schwarz Bayesian (Information) Criterion:

$$\text{SBC} = -2 \text{ Log L} + p \log\left(\sum_j f_j \Delta_j\right)$$

The  $-2$  Log Likelihood statistic has a chi-square distribution under the null hypothesis (that all the explanatory effects in the model are zero) and the procedure produces a  $p$ -value for this statistic. The AIC and SBC statistics give two different ways of adjusting the  $-2$  Log Likelihood statistic for the number of terms in the model and the number of observations used. These statistics should be used when comparing different models for the same data (for example, when you use the METHOD=STEPWISE option in the MODEL statement); lower values of the statistic indicate a more desirable model.

## Residuals

This section describes the computation of residuals (RESMART=, RESDEV=, RESSCH=, and RESSCO=) in the OUTPUT statement.

First, consider TIES=BRESLOW. Let

$$\begin{aligned} S^{(0)}(\boldsymbol{\beta}, t) &= \sum_i Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \\ S^{(1)}(\boldsymbol{\beta}, t) &= \sum_i Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \mathbf{Z}_i(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\ d\Lambda_0(\boldsymbol{\beta}, t) &= \sum_i \frac{dN_i(t)}{S^{(0)}(\boldsymbol{\beta}, t)} \\ dM_i(\boldsymbol{\beta}, t) &= dN_i(t) - Y_i(t) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} d\Lambda_0(\boldsymbol{\beta}, t) \end{aligned}$$

The martingale residual at  $t$  is defined as

$$\hat{M}_i(t) = \int_0^t dM_i(\hat{\boldsymbol{\beta}}, s) = N_i(t) - \int_0^t Y_i(s) e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_i(s)} d\Lambda_0(\hat{\boldsymbol{\beta}}, s)$$

Here  $\hat{M}_i(t)$  estimates the difference over  $(0, t]$  between the observed number of events for the  $i$ th subject and a conditional expected number of events. The quantity  $\hat{M}_i \equiv \hat{M}_i(\infty)$  is referred to as the martingale residual for the  $i$ th subject. When the counting process MODEL specification is used, the RESMART= variable contains the component  $(\hat{M}_i(t_2) - \hat{M}_i(t_1))$  instead of the martingale residual at  $t_2$ . The martingale residual for a subject can be obtained by summing up these component residuals within the subject. For the Cox model with no time-dependent explanatory variables, the martingale residual for the  $i$ th subject with observation time  $t_i$  and event status  $\Delta_i$  is

$$\hat{M}_i = \Delta_i - e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_i} \int_0^{t_i} d\Lambda_0(\hat{\boldsymbol{\beta}}, s)$$

The deviance residuals  $D_i$  are a transform of the martingale residuals:

$$D_i = \text{sign}(\hat{M}_i) \sqrt{2 \left[ -\hat{M}_i - N_i(\infty) \log \left( \frac{N_i(\infty) - \hat{M}_i}{N_i(\infty)} \right) \right]}$$

The square root shrinks large negative martingale residuals, while the logarithmic transformation expands martingale residuals that are close to unity. As such, the deviance residuals are more symmetrically distributed around zero than the martingale residuals. For the Cox model, the deviance residual reduces to the form

$$D_i = \text{sign}(\hat{M}_i) \sqrt{2[-\hat{M}_i - \Delta_i \log(\Delta_i - \hat{M}_i)]}$$

When the counting process MODEL specification is used, values of the RESDEV= variable are set to missing because the deviance residuals can be calculated only on a per-subject basis.

The Schoenfeld (1982) residual vector is calculated on a per-event-time basis. At the  $j$ th event time  $t_{ij}$  of the  $i$ th subject, the Schoenfeld residual

$$\hat{U}_i(t_{ij}) = \mathbf{Z}_i(t_{ij}) - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t_{ij})$$

is the difference between the  $i$ th subject covariate vector at  $t_{ij}$  and the average of the covariate vectors over the risk set at  $t_{ij}$ . Under the proportional hazards assumption, the Schoenfeld residuals have the sample path of a random walk; therefore, they are useful in assessing time trend or lack of proportionality. Harrell (1986) proposed a  $z$ -transform of the Pearson correlation between these residuals and the rank order of the failure time as a test statistic for nonproportional hazards. Therneau, Grambsch, and Fleming (1990) considered a Kolmogorov-type test based on the cumulative sum of the residuals.

The score process for the  $i$ th subject at time  $t$  is

$$\mathbf{L}_i(\boldsymbol{\beta}, t) = \int_0^t [\mathbf{Z}_i(s) - \bar{\mathbf{Z}}(\boldsymbol{\beta}, s)] dM_i(\boldsymbol{\beta}, s)$$

The vector  $\hat{\mathbf{L}}_i \equiv \mathbf{L}_i(\hat{\boldsymbol{\beta}}, \infty)$  is the score residual for the  $i$ th subject. When the counting process MODEL specification is used, the RESSCO= variables contain the components of  $(\mathbf{L}_i(\hat{\boldsymbol{\beta}}, t_2) - \mathbf{L}_i(\hat{\boldsymbol{\beta}}, t_1))$  instead of the score process at  $t_2$ . The score residual for a subject can be obtained by summing up these component residuals within the subject.

The score residuals are a decomposition of the first partial derivative of the log likelihood. They are useful in assessing the influence of each subject on individual parameter estimates. They also play an important role in the computation of the robust sandwich variance estimators of Lin and Wei (1989) and Wei, Lin, and Weissfeld (1989).

For TIES=EFRON, the preceding computation is modified to comply with the Efron partial likelihood. For a given time  $t$ , let  $\Delta_i(t)=1$  if the  $t$  is an event time of the  $i$ th subject and 0 otherwise. Let  $d(t) = \sum_i \Delta_i(t)$ , which is the number of subjects that have an event at  $t$ . For  $1 \leq k \leq d(t)$ , let

$$\begin{aligned} S^{(0)}(\boldsymbol{\beta}, k, t) &= \sum_i Y_i(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_i(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \\ S^{(1)}(\boldsymbol{\beta}, k, t) &= \sum_i Y_i(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_i(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} \mathbf{Z}_i(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, k, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, k, t)}{S^{(0)}(\boldsymbol{\beta}, k, t)} \\ d\Lambda_0(\boldsymbol{\beta}, k, t) &= \sum_i \frac{dN_i(t)}{S^{(0)}(\boldsymbol{\beta}, k, t)} \\ dM_i(\boldsymbol{\beta}, k, t) &= dN_i(t) - Y_i(t) \left( 1 - \Delta_i(t) \frac{k-1}{d(t)} \right) e^{\boldsymbol{\beta}' \mathbf{Z}_i(t)} d\Lambda_0(\boldsymbol{\beta}, k, t) \end{aligned}$$

The martingale residual at  $t$  for the  $i$ th subject is defined as

$$\hat{M}_i(t) = \int_0^t \frac{1}{d(s)} \sum_{k=1}^{d(s)} dM_i(\hat{\beta}, k, s) = N_i(t) - \int_0^t \frac{1}{d(s)} \sum_{k=1}^{d(s)} Y_i(s) \left( 1 - \Delta_i(s) \frac{k-1}{d(s)} \right) e^{\hat{\beta}' \mathbf{Z}_i(s)} d\Lambda_0(\hat{\beta}, k, s)$$

Deviance residuals are computed by using the same transform on the corresponding martingale residuals as in TIES=BRESLOW.

The Schoenfeld residual vector for the  $i$ th subject at event time  $t_{ij}$  is

$$\hat{U}_i(t_{ij}) = \mathbf{Z}_i(t_{ij}) - \frac{1}{d(t_{ij})} \sum_{k=1}^{d(t_{ij})} \bar{\mathbf{Z}}(\hat{\beta}, k, t_{ij})$$

The score process for the  $i$ th subject at time  $t$  is given by

$$\mathbf{L}_i(\beta, t) = \int_0^t \frac{1}{d(s)} \sum_{k=1}^{d(s)} \left( \mathbf{Z}_i(s) - \bar{\mathbf{Z}}(\beta, k, s) \right) dM_i(\beta, k, s)$$

For TIES=DISCRETE or TIES=EXACT, it is difficult to come up with modifications that are consistent with the corresponding partial likelihood. Residuals for these TIES= methods are computed by using the same formulae as in TIES=BRESLOW.

## Diagnostics Based on Weighted Residuals

The vector of weighted Schoenfeld residuals,  $\mathbf{r}_i$ , is computed as

$$\mathbf{r}_i = n_e \mathcal{I}^{-1}(\hat{\beta}) \hat{U}_i(t_i)$$

where  $n_e$  is the total number of events and  $\hat{U}_i(t_i)$  is the vector of Schoenfeld residuals at the event time  $t_i$ . The components of  $\mathbf{r}_i$  are output to the WTRESSCH= variables.

The weighted Schoenfeld residuals are useful in assessing the proportional hazards assumption. The idea is that most of the common alternatives to the proportional hazards can be cast in terms of a time-varying coefficient model

$$\lambda(t, \mathbf{Z}) = \lambda_0(t) \exp(\beta_1(t)Z_1 + \beta_2(t)Z_2 + \dots)$$

where  $\lambda(t, \mathbf{Z})$  and  $\lambda_0(t)$  are hazard rates. Let  $\hat{\beta}_j$  and  $r_{ij}$  be the  $j$ th component of  $\hat{\beta}$  and  $\mathbf{r}_i$ , respectively. Grambsch and Therneau (1994) suggest using a smoothed plot of  $(\hat{\beta}_j + r_{ij})$  versus  $t_i$  to discover the functional form of the time-varying coefficient  $\beta_j(t)$ . A zero slope indicates that the coefficient is not varying with time.

The weighted score residuals are used more often than their unscaled counterparts in assessing local influence. Let  $\hat{\beta}_{(i)}$  be the estimate of  $\beta$  when the  $i$ th subject is left out, and let  $\delta \hat{\beta}_i = \hat{\beta} - \hat{\beta}_{(i)}$ . The  $j$ th component of  $\delta \hat{\beta}_i$  can be used to assess any untoward effect of the  $i$ th subject on  $\hat{\beta}_j$ . The exact computation of  $\delta \hat{\beta}_i$

involves refitting the model each time a subject is omitted. Cain and Lange (1984) derived the following approximation of  $\Delta_i$  as weighted score residuals:

$$\delta \hat{\beta}_i = \mathcal{I}^{-1}(\hat{\beta}) \hat{\mathbf{L}}_i$$

Here,  $\hat{\mathbf{L}}_i$  is the vector of the score residuals for the  $i$ th subject. Values of  $\delta \hat{\beta}_i$  are output to the DFBETA= variables. Again, when the counting process MODEL specification is used, the DFBETA= variables contain the component  $\mathcal{I}^{-1}(\hat{\beta})(\mathbf{L}_i(\hat{\beta}, t_2) - \mathbf{L}_i(\hat{\beta}, t_1))$ , where the score process  $\mathbf{L}_i(\beta, t)$  is defined in the section “Residuals” on page 5639. The vector  $\delta \hat{\beta}_i$  for the  $i$ th subject can be obtained by summing these components within the subject.

Note that these DFBETA statistics are a transform of the score residuals. In computing the robust sandwich variance estimators of Lin and Wei (1989) and Wei, Lin, and Weissfeld (1989), it is more convenient to use the DFBETA statistics than the score residuals (see Example 67.10).

## Influence of Observations on Overall Fit of the Model

The LD statistic approximates the likelihood displacement, which is the amount by which minus twice the log likelihood ( $-2 \log L(\hat{\beta})$ ), under a fitted model, changes when each subject in turn is left out. When the  $i$ th subject is omitted, the likelihood displacement is

$$2 \log L(\hat{\beta}) - 2 \log L(\hat{\beta}_{(i)})$$

where  $\hat{\beta}_{(i)}$  is the vector of parameter estimates obtained by fitting the model without the  $i$ th subject. Instead of refitting the model without the  $i$ th subject, Pettitt and Bin Daud (1989) propose that the likelihood displacement for the  $i$ th subject be approximated by

$$\text{LD}_i = \hat{\mathbf{L}}_i' \mathcal{I}^{-1}(\hat{\beta}) \hat{\mathbf{L}}_i$$

where  $\hat{\mathbf{L}}_i$  is the score residual vector of the  $i$ th subject. This approximation is output to the LD= variable.

The LMAX statistic is another global influence statistic. This statistic is based on the symmetric matrix

$$\mathbf{B} = \mathbf{L} \mathcal{I}^{-1}(\hat{\beta}) \mathbf{L}'$$

where  $\mathbf{L}$  is the matrix with rows that are the score residual vectors  $\hat{\mathbf{L}}_i$ . The elements of the eigenvector associated with the largest eigenvalue of the matrix  $\mathbf{B}$ , standardized to unit length, give a measure of the sensitivity of the fit of the model to each observation in the data. The influence of the  $i$ th subject on the global fit of the model is proportional to the magnitude of  $\zeta_i$ , where  $\zeta_i$  is the  $i$ th element of the vector  $\boldsymbol{\zeta}$  that satisfies

$$\mathbf{B} \boldsymbol{\zeta} = \lambda_{\max} \boldsymbol{\zeta} \quad \text{and} \quad \boldsymbol{\zeta}' \boldsymbol{\zeta} = 1$$

with  $\lambda_{\max}$  being the largest eigenvalue of  $\mathbf{B}$ . The sign of  $\zeta_i$  is irrelevant, and its absolute value is output to the LMAX= variable.

When the counting process MODEL specification is used, the LD= and LMAX= variables are set to missing, because these two global influence statistics can be calculated on a per-subject basis only.

## Survivor Function Estimators

Three estimators of the survivor function are available: the Breslow (1972) estimator, which is based on the empirical cumulative hazard function, the Fleming and Harrington (1984) estimator, which is a tie-breaking modification of the Breslow estimator, and the product-limit estimator (Kalbfleisch and Prentice 1980, pp. 84–86).

Let  $\{t_1 < \dots < t_k\}$  be the distinct uncensored times of the survival data.

### Breslow Estimator

To select this estimator, specify the METHOD=BRESLOW option in the BASELINE statement or OUTPUT statement. For the  $j$ th subject, let  $\{(X_j, \Delta_j, \mathbf{Z}_j(\cdot))\}$  represent the failure time, the event indicator, and the vector of covariate values, respectively. For  $t \geq 0$ , let

$$\begin{aligned} Y_j(t) &= I(X_j \geq t) \\ \Delta_j(t) &= \begin{cases} 1 & X_j = t \text{ \& } \Delta_j = 1 \\ 0 & \text{otherwise} \end{cases} \\ d(t) &= \sum_j \Delta_j(t) \end{aligned}$$

Note that  $d(t)$  is the number of subjects that have an event at  $t$ . Let

$$\begin{aligned} S^{(0)}(\boldsymbol{\beta}, t) &= \sum_j Y_j(t) e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \\ S^{(1)}(\boldsymbol{\beta}, t) &= \sum_j Y_j(t) e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \mathbf{Z}_j(t) \\ \bar{\mathbf{Z}}(\boldsymbol{\beta}, t) &= \frac{S^{(1)}(\boldsymbol{\beta}, t)}{S^{(0)}(\boldsymbol{\beta}, t)} \end{aligned}$$

For a given realization of the explanatory variables  $\boldsymbol{\xi}$ , the cumulative hazard function estimator at  $\boldsymbol{\xi}$  is

$$\hat{\Lambda}_B(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \frac{d(t_i)}{S^{(0)}(\hat{\boldsymbol{\beta}}, t_i)}$$

with variance estimated by

$$\hat{\sigma}^2(\hat{\Lambda}_B(t, \boldsymbol{\xi})) = e^{2\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\boldsymbol{\beta}}, t_i)]^2} + H(t, \boldsymbol{\xi})' [\mathcal{I}(\hat{\boldsymbol{\beta}})]^{-1} H(t, \boldsymbol{\xi})$$

where

$$H(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \frac{d(t_i)}{S^{(0)}(\hat{\boldsymbol{\beta}}, t_i)} \left( \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t_i) - \boldsymbol{\xi} \right)$$

For the marginal model, the variance estimator computation follows Spiekerman and Lin (1998).

The Breslow estimate of the survivor function for  $\mathbf{Z} = \boldsymbol{\xi}$  is

$$\hat{S}_B(t, \boldsymbol{\xi}) = \exp(-\hat{\Lambda}_B(t, \boldsymbol{\xi}))$$

By the delta method, the standard error of  $\hat{S}_B(t, \boldsymbol{\xi})$  is approximated by

$$\hat{\sigma}(\hat{S}_B(t, \boldsymbol{\xi})) = \hat{S}_B(t, \boldsymbol{\xi}) \hat{\sigma}(\hat{\Lambda}_B(t, \boldsymbol{\xi}))$$

### Fleming-Harrington Estimator

To select this estimator, specify the METHOD=FH option in the BASELINE statement or OUTPUT statement. With  $Y_j(t)$  and  $d(t)$  as defined in the section “Breslow Estimator” on page 5643 and for  $1 \leq k \leq d(t)$ , let

$$\begin{aligned} S_E^{(0)}(\boldsymbol{\beta}, k, t) &= \sum_j Y_j(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_j(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \\ S_E^{(1)}(\boldsymbol{\beta}, k, t) &= \sum_j Y_j(t) \left\{ 1 - \frac{k-1}{d(t)} \Delta_j(t) \right\} e^{\boldsymbol{\beta}' \mathbf{Z}_j(t)} \mathbf{Z}_j(t) \\ \bar{\mathbf{Z}}_E \boldsymbol{\beta}, k, t &= \frac{S_E^{(1)}(\boldsymbol{\beta}, k, t)}{S_E^{(0)}(\boldsymbol{\beta}, k, t)} \end{aligned}$$

For a given realization of the explanatory variables, the Fleming-Harrington adjustment of the cumulative hazard function is

$$\hat{\Lambda}_F(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \left\{ \sum_{k=1}^{d(t_i)} \frac{1}{S_E^{(0)}(\hat{\boldsymbol{\beta}}, k, t_i)} \right\}$$

with variance estimated by

$$\hat{\sigma}^2(\hat{\Lambda}_F(t, \boldsymbol{\xi})) = e^{2\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \sum_{t_i \leq t} \left\{ \sum_{k=1}^{d(t_i)} \frac{1}{[S_E^{(0)}(\hat{\boldsymbol{\beta}}, k, t_i)]^2} \right\} + H_E(t, \boldsymbol{\xi})' [\mathcal{I}(\hat{\boldsymbol{\beta}})]^{-1} H_E(t, \boldsymbol{\xi})$$

where

$$H_E(t, \boldsymbol{\xi}) = e^{\hat{\boldsymbol{\beta}}' \boldsymbol{\xi}} \left\{ \left[ \sum_{t_i \leq t} \sum_{k=1}^{d(t_i)} \frac{1}{S_E^{(0)}(\hat{\boldsymbol{\beta}}, k, t_i)} \bar{\mathbf{Z}}_E(\hat{\boldsymbol{\beta}}, k, t_i) \right] - \hat{\Lambda}_F(t, \mathbf{0}) \boldsymbol{\xi} \right\}$$

The Fleming-Harrington estimate of the survivor function for  $\mathbf{Z} = \boldsymbol{\xi}$  is

$$\hat{S}_F(t, \boldsymbol{\xi}) = \exp(-\hat{\Lambda}_F(t, \boldsymbol{\xi}))$$

By the delta method, the standard error of  $\hat{S}_F(t, \boldsymbol{\xi})$  is approximated by

$$\hat{\sigma}(\hat{S}_F(t, \boldsymbol{\xi})) = \hat{S}_F(t, \boldsymbol{\xi}) \hat{\sigma}(\hat{\Lambda}_F(t, \boldsymbol{\xi}))$$

## Product-Limit Estimator

To select this estimator, specify the METHOD=PL option in the BASELINE statement or OUTPUT statement. Let  $\mathcal{D}_i$  denote the set of individuals that fail at  $t_i$ . Let  $\mathcal{C}_i$  denote the set of individuals that are censored in the half-open interval  $[t_i, t_{i+1})$ , where  $t_0 = 0$  and  $t_{k+1} = \infty$ . Let  $\gamma_l$  denote the censoring times in  $[t_i, t_{i+1})$ , where  $l$  ranges over  $\mathcal{C}_i$ .

The likelihood function for all individuals is given by

$$\mathcal{L} = \prod_{i=0}^k \left\{ \prod_{l \in \mathcal{D}_i} \left( [S_0(t_i)]^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} - [S_0(t_i + 0)]^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} \right) \prod_{l \in \mathcal{C}_i} [S_0(\gamma_l + 0)]^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} \right\}$$

where  $\mathcal{D}_0$  is empty. The likelihood  $\mathcal{L}$  is maximized by taking  $S_0(t) = S_0(t_i + 0)$  for  $t_i < t \leq t_{i+1}$  and allowing the probability mass to fall only on the observed event times  $t_1, \dots, t_k$ . By considering a discrete model with hazard contribution  $1 - \alpha_i$  at  $t_i$ , you take  $S_0(t_i) = S_0(t_{i-1} + 0) = \prod_{j=0}^{i-1} \alpha_j$ , where  $\alpha_0 = 1$ . Substitution into the likelihood function produces

$$\mathcal{L} = \prod_{i=0}^k \left\{ \prod_{j \in \mathcal{D}_i} \left( 1 - \alpha_i^{\exp(\mathbf{Z}'_j \boldsymbol{\beta})} \right) \prod_{l \in \mathcal{R}_i - \mathcal{D}_i} \alpha_i^{\exp(\mathbf{Z}'_l \boldsymbol{\beta})} \right\}$$

If you replace  $\boldsymbol{\beta}$  with  $\hat{\boldsymbol{\beta}}$  estimated from the partial likelihood function and then maximize with respect to  $\alpha_1, \dots, \alpha_k$ , the maximum likelihood estimate  $\hat{\alpha}_i$  of  $\alpha_i$  becomes a solution of

$$\sum_{j \in \mathcal{D}_i} \frac{\exp(\mathbf{Z}'_j \hat{\boldsymbol{\beta}})}{1 - \hat{\alpha}_i^{\exp(\mathbf{Z}'_j \hat{\boldsymbol{\beta}})}} = \sum_{l \in \mathcal{R}_i} \exp(\mathbf{Z}'_l \hat{\boldsymbol{\beta}})$$

When only a single failure occurs at  $t_i$ ,  $\hat{\alpha}_i$  can be found explicitly. Otherwise, an iterative solution is obtained by the Newton method.

The baseline survival function is estimated by

$$\hat{S}_0(t) = \hat{S}_0(t_{i-1} + 0) = \prod_{j=0}^{i-1} \hat{\alpha}_j, t_{i-1} < t \leq t_i$$

For a given realization of the explanatory variables  $\boldsymbol{\xi}$ , the product-limit estimate of the survival function at  $\mathbf{Z} = \boldsymbol{\xi}$  is

$$\hat{S}_P(t, \boldsymbol{\xi}) = [\hat{S}_0(t)]^{\exp(\boldsymbol{\beta}' \boldsymbol{\xi})}$$

Approximating the variance of  $-\log(\hat{S}_P(t, \boldsymbol{\xi}))$  by the variance estimate of the Breslow estimator of the cumulative hazard function, the variance of the product-limit estimator at  $\mathbf{Z} = \boldsymbol{\xi}$  is given by

$$\hat{\sigma}(\hat{S}_P(t, \boldsymbol{\xi})) = \hat{S}_P(t, \boldsymbol{\xi}) \hat{\sigma}(\hat{\Lambda}_B(t, \boldsymbol{\xi}))$$

### Direct Adjusted Survival Curves

Consider the Breslow estimator of the survival function. For  $j = 1, \dots, n$ , let  $\xi_j$  represent the covariate set of the  $j$ th patient. The direct adjusted survival curve averages the estimated survival curves for each patient:

$$\bar{S}(t) = \frac{1}{n} \sum_{j=1}^n \hat{S}(t, \xi_j)$$

The variance of  $\bar{S}(t)$  can be estimated by

$$\hat{\sigma}^2(\bar{S}(t)) = \frac{1}{n^2} \left( V^{(1)}(t) + V^{(2)}(t) \right)$$

where

$$V^{(1)}(t) = \left( \sum_{j=1}^n e^{\hat{\beta}' \xi_j} \hat{S}(t, \xi_j) \right)^2 \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\beta}, t_i)]^2}$$

$$V^{(2)}(t) = \left( \sum_{j=1}^n \hat{S}(t, \xi_j) H(t, \xi_j) \right)' \left[ \mathcal{I}(\hat{\beta}) \right]^{-1} \left( \sum_{j=1}^n \hat{S}(t, \xi_j) H(t, \xi_j) \right)$$

### Comparison of Direct Adjusted Probabilities of Two Strata

For a stratified Cox model, let  $k$  index the strata. For the  $j$ th patient, let  $\hat{S}_k(t, \xi_j)$  and  $H_k(t, \xi_j)$  be the estimated survival function and the  $\mathbf{H}$  vector for the  $k$ th stratum. The direct adjusted survival curve for the  $k$ th stratum is

$$\bar{S}_k(t) = \frac{1}{n} \sum_{j=1}^n \hat{S}_k(t, \xi_j)$$

The variance of  $\bar{S}_1(t) - \bar{S}_2(t)$  can be estimated by

$$\hat{\sigma}^2(\bar{S}_1(t) - \bar{S}_2(t)) = \frac{1}{n^2} \left( U_1^{(1)}(t) + U_2^{(1)} + U_{12}^{(2)}(t) \right)$$

where

$$U_k^{(1)}(t) = \left( \sum_{j=1}^n e^{\hat{\beta}' \xi_j} \hat{S}_k(t, \xi_j) \right)^2 \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\beta}, t_i)]^2} \quad k = 1, 2$$

$$U_{12}^{(2)}(t) = \left\{ \sum_{j=1}^n \left[ \hat{S}_1(t, \xi_j) H_1(t, \xi_j) - \hat{S}_2(t, \xi_j) H_2(t, \xi_j) \right] \right\}' \mathcal{I}^{-1}(\hat{\beta}) \left\{ \sum_{j=1}^n \left[ \hat{S}_1(t, \xi_j) H_2(t, \xi_j) - \hat{S}_2(t, \xi_j) H_1(t, \xi_j) \right] \right\}$$

### Comparison of Direct Adjusted Survival Probabilities of Two Treatments

For  $j = 1, \dots, n$ , let  $\xi_{jk}$  represent the covariate set of the  $j$ th patient with the  $k$ th treatment,  $k = 1, 2$ . The direct adjusted survival curve for the  $k$ th treatment is

$$\bar{S}_k(t) = \frac{1}{n} \sum_{i=j}^n \hat{S}(t, \xi_{jk})$$

The variance of  $\bar{S}_1(t) - \bar{S}_2(t)$  can be estimated by

$$\hat{\sigma}^2(\bar{S}_1(t) - \bar{S}_2(t)) = \frac{1}{n^2} \left( V_{12}^{(1)}(t) + V_{12}^{(2)}(t) \right)$$

where

$$V_{12}^{(1)}(t) = \left\{ \sum_{j=1}^n \left[ e^{\beta' \xi_{1j}} \hat{S}(t, \xi_{1j}) - e^{\beta' \xi_{2j}} \hat{S}(t, \xi_{2j}) \right] \right\}^2 \sum_{t_i \leq t} \frac{d(t_i)}{[S^{(0)}(\hat{\beta}, t_i)]^2}$$

$$V_{12}^{(2)}(t) = \left\{ \sum_{j=1}^n \left[ \hat{S}(t, \xi_{1j}) H(t, \xi_{1j}) - \hat{S}(t, \xi_{2j}) H(t, \xi_{2j}) \right] \right\}' \mathcal{I}^{-1}(\hat{\beta})$$

$$\left\{ \sum_{j=1}^n \left[ \hat{S}(t, \xi_{1j}) H(t, \xi_{1j}) - \hat{S}(t, \xi_{2j}) H(t, \xi_{2j}) \right] \right\}$$

### Confidence Intervals for the Survivor Function

When the computation of confidence limits for the survivor function  $S(t)$  is based on the asymptotic normality of the survival estimator  $\hat{S}(t)$ —which can be the Breslow estimator  $\hat{S}_B(t)$ , the Fleming-Harrington estimator  $\hat{S}_F(t)$ , or the product-limit estimator  $\hat{S}_P(t)$ —the approximate confidence interval might include impossible values outside the range  $[0, 1]$  at extreme values of  $t$ . This problem can be avoided by applying the asymptotic normality to a transformation of  $S(t)$  for which the range is unrestricted. In addition, certain transformed confidence intervals for  $S(t)$  perform better than the usual linear confidence intervals (Borgan and Liestøl 1990). The CLTYPE= option in the BASELINE statement enables you to choose one of the following transformations: the log-log function, the log function, and the linear function.

Let  $g$  be the transformation that is being applied to the survivor function  $S(t)$ . By the delta method, the standard error of  $g(\hat{S}(t))$  is estimated by

$$\tau(t) = \hat{\sigma} \left[ g(\hat{S}(t)) \right] = g'(\hat{S}(t)) \hat{\sigma}[\hat{S}(t)]$$

where  $g'$  is the first derivative of the function  $g$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$g^{-1} \left\{ g[\hat{S}(t)] \pm z_{\frac{\alpha}{2}} g'[\hat{S}(t)] \hat{\sigma}[\hat{S}(t)] \right\}$$

where  $g^{-1}$  is the inverse function of  $g$ . The choices for the transformation  $g$  are as follows:

- CLTYPE=NORMAL specifies linear transformation, which is the same as having no transformation in which  $g$  is the identity. The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\hat{S}(t) - z_{\frac{\alpha}{2}} \hat{\sigma} \left[ \hat{S}(t) \right] \leq S(t) \leq \hat{S}(t) + z_{\frac{\alpha}{2}} \hat{\sigma} \left[ \hat{S}(t) \right]$$

- CLTYPE=LOG specifies log transformation. The estimated variance of  $\log(\hat{S}(t))$  is  $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2(\hat{S}(t))}{\hat{S}^2(t)}$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\hat{S}(t) \exp\left(-z_{\frac{\alpha}{2}} \hat{\tau}(t)\right) \leq S(t) \leq \hat{S}(t) \exp\left(z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)$$

- CLTYPE=LOGLOG specifies log-log transformation. The estimated variance of  $\log(-\log(\hat{S}(t)))$  is  $\hat{\tau}^2(t) = \frac{\hat{\sigma}^2[\hat{S}(t)]}{[\hat{S}(t) \log(\hat{S}(t))]^2}$ . The  $100(1-\alpha)\%$  confidence interval for  $S(t)$  is given by

$$\left[ \hat{S}(t) \right]^{\exp\left(z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)} \leq S(t) \leq \left[ \hat{S}(t) \right]^{\exp\left(-z_{\frac{\alpha}{2}} \hat{\tau}(t)\right)}$$

---

## Effect Selection Methods

Five effect selection methods are available. The simplest method (and the default) is SELECTION=NONE, for which PROC PHREG fits the complete model as specified in the MODEL statement. The other four methods are FORWARD for forward selection, BACKWARD for backward elimination, STEPWISE for stepwise selection, and SCORE for best subsets selection. These methods are specified with the SELECTION= option in the MODEL statement and are based on the score test or Wald test as described in the section “Type 3 Tests” on page 5626.

When SELECTION=FORWARD, PROC PHREG first estimates parameters for effects that are forced into the model. These are the first  $n$  effects in the MODEL statement, where  $n$  is the number specified by the START= or INCLUDE= option in the MODEL statement ( $n$  is zero by default). Next, the procedure computes the score statistic for each effect that is not in the model. Each score statistic is the chi-square statistic of the score test for testing the null hypothesis that the corresponding effect that is not in the model is null. If the largest of these statistics is significant at the SLSENTRY= level, the effect with the largest score statistic is added to the model. After an effect is entered in the model, it is never removed from the model. The process is repeated until none of the remaining effects meet the specified level for entry or until the STOP= value is reached.

When SELECTION=BACKWARD, parameters for the complete model as specified in the MODEL statement are estimated unless the START= option is specified. In that case, only the parameters for the first  $n$  effects in the MODEL statement are estimated, where  $n$  is the number specified by the START= option. Next, the procedure computes the Wald statistic of each effect in the model. Each Wald’s statistic is the chi-square statistic of the Wald test for testing the null hypothesis that the corresponding effect is null. If the smallest of these statistics is not significant at the SLSTAY= level, the effect with the smallest Wald statistic is removed. After an effect is removed from the model, it remains excluded. The process is repeated until no other variable in the model meets the specified level for removal or until the STOP= value is reached.

The SELECTION=STEPWISE option is similar to the SELECTION=FORWARD option except that effects already in the model do not necessarily remain. Effects are entered into and removed from the model in such

a way that each forward selection step can be followed by one or more backward elimination steps. The stepwise selection process terminates if no further effect can be added to the model or if the effect just entered into the model is the only effect that is removed in the subsequent backward elimination.

For SELECTION=SCORE, PROC PHREG uses the branch-and-bound algorithm of Furnival and Wilson (1974) to find a specified number of models with the highest score (chi-square) statistic for all possible model sizes, from 1, 2, or 3 variables, and so on, up to the single model that contains all of the explanatory variables. The number of models displayed for each model size is controlled by the BEST= option. You can use the START= option to impose a minimum model size, and you can use the STOP= option to impose a maximum model size. For instance, with BEST=3, START=2, and STOP=5, the SCORE selection method displays the best three models (that is, the three models with the highest score chi-squares) that contain 2, 3, 4, and 5 variables. One of the limitations of the branch-and-bound algorithm is that it works only when each explanatory effect contains exactly one parameter—the SELECTION=SCORE option is not allowed when an explanatory effect in the MODEL statement contains a CLASS variable.

The SEQUENTIAL and STOPRES options can alter the default criteria for adding variables to or removing variables from the model when they are used with the FORWARD, BACKWARD, or STEPWISE selection method.

---

## Assessment of the Proportional Hazards Model

The proportional hazards model specifies that the hazard function for the failure time  $T$  associated with a  $p \times 1$  column covariate vector  $\mathbf{Z}$  takes the form

$$\lambda(t; \mathbf{Z}) = \lambda_0(t)e^{\boldsymbol{\beta}'\mathbf{Z}}$$

where  $\lambda_0(\cdot)$  is an unspecified baseline hazard function and  $\boldsymbol{\beta}$  is a  $p \times 1$  column vector of regression parameters. Lin, Wei, and Ying (1993) present graphical and numerical methods for model assessment based on the cumulative sums of martingale residuals and their transforms over certain coordinates (such as covariate values or follow-up times). The distributions of these stochastic processes under the assumed model can be approximated by the distributions of certain zero-mean Gaussian processes whose realizations can be generated by simulation. Each observed residual pattern can then be compared, both graphically and numerically, with a number of realizations from the null distribution. Such comparisons enable you to assess objectively whether the observed residual pattern reflects anything beyond random fluctuation. These procedures are useful in determining appropriate functional forms of covariates and assessing the proportional hazards assumption. You use the ASSESS statement to carry out these model-checking procedures.

For a sample of  $n$  subjects, let  $(X_i, \Delta_i, \mathbf{Z}_i)$  be the data of the  $i$ th subject; that is,  $X_i$  represents the observed failure time,  $\Delta_i$  has a value of 1 if  $X_i$  is an uncensored time and 0 otherwise, and  $\mathbf{Z}_i = (Z_{1i}, \dots, Z_{pi})'$  is a  $p$ -vector of covariates. Let  $N_i(t) = \Delta_i I(X_i \leq t)$  and  $Y_i(t) = I(X_i \geq t)$ . Let

$$S^{(0)}(\boldsymbol{\beta}, t) = \sum_{i=1}^n Y_i(t)e^{\boldsymbol{\beta}'\mathbf{Z}_i} \quad \text{and} \quad \mathbf{Z}(\boldsymbol{\beta}, t) = \frac{\sum_{i=1}^n Y_i(t)e^{\boldsymbol{\beta}'\mathbf{Z}_i} \mathbf{Z}_i}{S^{(0)}(\boldsymbol{\beta}, t)}$$

Let  $\hat{\boldsymbol{\beta}}$  be the maximum partial likelihood estimate of  $\boldsymbol{\beta}$ , and let  $\mathcal{I}(\hat{\boldsymbol{\beta}})$  be the observed information matrix.

The martingale residuals are defined as

$$\hat{M}_i(t) = N_i(t) - \int_0^t Y_i(u)e^{\hat{\boldsymbol{\beta}}'\mathbf{Z}_i} d\hat{\Lambda}_0(u), \quad i = 1, \dots, n$$

where  $\hat{\Lambda}_0(t) = \int_0^t \frac{\sum_{i=1}^n dN_i(u)}{S^{(0)}(\hat{\beta}, u)}$ .

The empirical score process  $\mathbf{U}(\hat{\beta}, t) = (U_1(\hat{\beta}, t), \dots, U_p(\hat{\beta}, t))'$  is a transform of the martingale residuals:

$$\mathbf{U}(\hat{\beta}, t) = \sum_{i=1}^n \mathbf{Z}_i \hat{M}_i(t)$$

### Checking the Functional Form of a Covariate

To check the functional form of the  $j$ th covariate, consider the partial-sum process of  $\hat{M}_i = \hat{M}_i(\infty)$ :

$$W_j(z) = \sum_{i=1}^n I(Z_{ji} \leq z) \hat{M}_i$$

Under that null hypothesis that the model holds,  $W_j(z)$  can be approximated by the zero-mean Gaussian process

$$\begin{aligned} \hat{W}_j(z) &= \sum_{l=1}^n \Delta_l \left\{ I(Z_{jl} \leq z) - \frac{\sum_{i=1}^n Y_i(X_l) e^{\hat{\beta}' \mathbf{Z}_i} I(Z_{ij} \leq z)}{S^{(0)}(\hat{\beta}, X_l)} \right\} G_l - \\ &\quad \sum_{k=1}^n \int_0^\infty Y_k(s) e^{\hat{\beta}' \mathbf{Z}_k} I(Z_{jk} \leq z) [\mathbf{Z}_k - \bar{\mathbf{Z}}(\hat{\beta}, s)]' d\hat{\Lambda}_0(s) \\ &\quad \times \mathcal{I}^{-1}(\hat{\beta}) \sum_{l=1}^n \Delta_l [\mathbf{Z}_l - \bar{\mathbf{Z}}(\hat{\beta}, X_l)] G_l \end{aligned}$$

where  $(G_1, \dots, G_n)$  are independent standard normal variables that are independent of  $(X_i, \Delta_i, \mathbf{Z}_i)$ ,  $i = 1, \dots, n$ .

You can assess the functional form of the  $j$ th covariate by plotting a small number of realizations (the default is 20) of  $\hat{W}_j(z)$  on the same graph as the observed  $W_j(z)$  and visually comparing them to see how typical the observed pattern of  $W_j(z)$  is of the null distribution samples. You can supplement the graphical inspection method with a Kolmogorov-type supremum test. Let  $s_j$  be the observed value of  $S_j = \sup_z |W_j(z)|$  and let  $\hat{S}_j = \sup_z |\hat{W}_j(z)|$ . The  $p$ -value  $\Pr(S_j \geq s_j)$  is approximated by  $\Pr(\hat{S}_j \geq s_j)$ , which in turn is approximated by generating a large number of realizations (1000 is the default) of  $\hat{W}_j(\cdot)$ .

### Checking the Proportional Hazards Assumption

Consider the standardized empirical score process for the  $j$ th component of  $\mathbf{Z}$

$$U_j^*(t) = [\mathcal{I}^{-1}(\hat{\beta})_{jj}]^{\frac{1}{2}} U_j(\hat{\beta}, t),$$

Under the null hypothesis that the model holds,  $U_j^*(t)$  can be approximated by

$$\begin{aligned} \hat{U}_j^*(t) &= [\mathcal{I}^{-1}(\hat{\boldsymbol{\beta}})_{jj}]^{\frac{1}{2}} \left\{ \sum_{l=1}^n I(X_l \leq t) \Delta_l [Z_{jl} - \bar{Z}_j(\hat{\boldsymbol{\beta}}, t)] G_l - \right. \\ &\quad \sum_{k=1}^n \int_0^t Y_k(s) e^{\hat{\boldsymbol{\beta}}' \mathbf{Z}_k} Z_{jk} [\mathbf{Z}_k - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, s)]' d\hat{\Lambda}_0(s) \\ &\quad \left. \times \mathcal{I}^{-1}(\hat{\boldsymbol{\beta}}) \sum_{l=1}^n \Delta_l [\mathbf{Z}_l - \bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, X_l)] G_l \right\} \end{aligned}$$

where  $\bar{Z}_j(\hat{\boldsymbol{\beta}}, t)$  is the  $j$ th component of  $\bar{\mathbf{Z}}(\hat{\boldsymbol{\beta}}, t)$ , and  $(G_1, \dots, G_n)$  are independent standard normal variables that are independent of  $(X_i, \Delta_i, \mathbf{Z}_i, (i = 1, \dots, n))$ .

You can assess the proportional hazards assumption for the  $j$ th covariate by plotting a few realizations of  $\hat{U}_j^*(t)$  on the same graph as the observed  $U_j^*(t)$  and visually comparing them to see how typical the observed pattern of  $U_j^*(t)$  is of the null distribution samples. Again you can supplement the graphical inspection method with a Kolmogorov-type supremum test. Let  $s_j^*$  be the observed value of  $S_j^* = \sup_t |U_j^*(t)|$  and let  $\hat{S}_j^* = \sup_t |\hat{U}_j^*(t)|$ . The  $p$ -value  $\Pr[S_j^* \geq s_j^*]$  is approximated by  $\Pr[\hat{S}_j^* \geq s_j^*]$ , which in turn is approximated by generating a large number of realizations (1000 is the default) of  $\hat{U}_j^*(\cdot)$ .

## The Penalized Partial Likelihood Approach for Fitting Frailty Models

Let  $\boldsymbol{\gamma} = (\gamma_1, \dots, \gamma_s)'$  be the vector of random components for the  $s$  clusters.

### Gamma Frailty Model

Assume each  $e^{\gamma_i}$  has an independent and identically distributed gamma distribution with mean 1 and a common unknown variance  $\theta$ ; that is,  $e^{\gamma_i}$  is iid  $G(\frac{1}{\theta}, \frac{1}{\theta})$ . The penalty function is

$$-\frac{1}{\theta} \sum_{i=1}^s (\gamma_i - e^{\gamma_i})$$

plus a function of  $\theta$ . The penalized partial log likelihood is given by

$$l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta) = l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma}) + \frac{1}{\theta} \sum_{i=1}^s (\gamma_i - e^{\gamma_i})$$

where  $l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})$  is the log of any of the partial likelihoods in the sections “Partial Likelihood Function for the Cox Model” on page 5614 and “The Multiplicative Hazards Model” on page 5617.

The profile marginal log-likelihood of this shared frailty model (Therneau and Grambsch 2000, pp. 257–258) is

$$l_m(\theta) = l_p(\hat{\boldsymbol{\beta}}(\theta), \hat{\boldsymbol{\gamma}}(\theta), \theta) + \sum_{i=1}^s \left\{ \theta^{-1} - (\theta^{-1} + d_i) \log[\theta^{-1} + d_i] + \theta^{-1} \log(\theta^{-1}) + \log \left[ \frac{\Gamma(\theta^{-1} + d_i)}{\Gamma(\theta^{-1})} \right] \right\}$$

where  $d_i$  is the number of events in the  $i$ th cluster.

The maximization of this approximate likelihood is a doubly iterative process that alternates between the following two steps:

- For a provisional value of  $\theta$ , the best linear unbiased predictors (BLUP) of  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  are computed by maximizing the penalized partial log-likelihood  $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$ . The marginal likelihood is evaluated. This constitutes the inner loop.
- A new value of  $\theta$  is obtained by the golden section search based on the marginal likelihood of all the previous iterations. This constitutes the outer loop.

The outer loop is iterated until the bracketing interval of  $\theta$  is small.

### Lognormal Frailty Model

With each  $\gamma_i$  having a zero-mean normal distribution and a common variance  $\theta$ , the penalty function is

$$\frac{1}{2\theta} \boldsymbol{\gamma}' \boldsymbol{\gamma}$$

plus a function of  $\theta$ . The penalized partial log likelihood is given by

$$l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta) = l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma}) - \frac{1}{2\theta} \boldsymbol{\gamma}' \boldsymbol{\gamma}$$

where  $l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})$  is the log of any of the partial likelihoods in the sections “[Partial Likelihood Function for the Cox Model](#)” on page 5614 and “[The Multiplicative Hazards Model](#)” on page 5617.

For a given  $\theta$ , let  $\mathbf{H}$  be the negative Hessian of the penalized partial log likelihood  $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$ ; that is,

$$\mathbf{H} = \mathbf{H}(\boldsymbol{\beta}, \boldsymbol{\gamma}) = \begin{bmatrix} \mathbf{H}_{11} & \mathbf{H}_{12} \\ \mathbf{H}_{21} & \mathbf{H}_{22} \end{bmatrix}$$

where  $\mathbf{H}_{11} = -\frac{\partial^2 l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)}{\partial \boldsymbol{\beta}^2}$ ,  $\mathbf{H}_{12} = \mathbf{H}'_{21} = -\frac{\partial^2 l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)}{\partial \boldsymbol{\beta} \partial \boldsymbol{\gamma}}$ , and  $\mathbf{H}_{22} = -\frac{\partial^2 l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)}{\partial \boldsymbol{\gamma}^2}$ .

The marginal log likelihood of this shared frailty model is

$$l_m(\boldsymbol{\beta}, \theta) = -\frac{1}{2} \log(\theta^s) + \log \left[ \int e^{l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)} d\boldsymbol{\gamma} \right]$$

Using a Laplace approximation to the integral as in Breslow and Clayton (1993), an approximate marginal log likelihood (Ripatti and Palmgren 2000; Therneau and Grambsch 2000) is given by

$$l_m(\boldsymbol{\beta}, \theta) \approx -\frac{1}{2} \log(\theta^s) - \frac{1}{2} \log(|\mathbf{H}_{22}(\boldsymbol{\beta}, \tilde{\boldsymbol{\gamma}}, \theta)|) - l_p(\boldsymbol{\beta}, \tilde{\boldsymbol{\gamma}}, \theta)$$

The maximization of this approximate likelihood is a doubly iterative process that alternates between the following two steps:

- For a provisional value of  $\theta$ , PROC PHREG computes the best linear unbiased predictors (BLUP) of  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  by maximizing the penalized partial log likelihood  $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$ . This constitutes the inner loop.

- For  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$  fixed at the BLUP values, PROC PHREG estimates  $\theta$  by maximizing the approximate marginal likelihood  $l_m(\boldsymbol{\beta}, \theta)$ . This constitutes the outer loop.

The outer loop is iterated until the difference between two successive estimates of  $\theta$  is small.

The ML estimate of  $\theta$  is

$$\hat{\theta} = \frac{\hat{\boldsymbol{\gamma}}' \hat{\boldsymbol{\gamma}} + \text{trace}(\mathbf{H}_{22}^{-1})}{s}$$

The variance for  $\hat{\theta}$  is

$$\text{var}(\hat{\theta}) = 2\hat{\theta} \left[ s + \frac{1}{\hat{\theta}^2} \text{trace}(\mathbf{H}_{22}^{-1} \mathbf{H}_{22}^{-1}) - \frac{2}{\hat{\theta}} \text{trace}(\mathbf{H}_{22}^{-1}) \right]^{-1}$$

The REML estimation of  $\theta$  is obtained by replacing  $(\mathbf{H}_{22})^{-1}$  by  $(\mathbf{H}^{-1})_{22}$ .

The inverse of the final  $\mathbf{H}$  matrix is used as the variance estimate of  $(\hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\gamma}})'$ .

The final BLUP estimates of the random components  $\gamma_1, \dots, \gamma_s$  can be displayed by using the SOLUTION option in the RANDOM statement. Also displayed are estimates of the lognormal frailties, which are the exponentiated estimates of the BLUP estimates.

### Wald-Type Tests for Penalized Models

Let  $\mathbf{I}$  be the negative Hessian of the partial log likelihood  $l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})$ :

$$\mathbf{I} = \begin{bmatrix} \mathbf{I}_{11} & \mathbf{I}_{12} \\ \mathbf{I}_{21} & \mathbf{I}_{22} \end{bmatrix}$$

where  $\mathbf{I}_{11} = -\frac{\partial^2 l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})}{\partial \boldsymbol{\beta}^2}$ ,  $\mathbf{I}_{12} = \mathbf{I}_{21}' = -\frac{\partial^2 l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})}{\partial \boldsymbol{\beta} \partial \boldsymbol{\gamma}}$ , and  $\mathbf{I}_{22} = -\frac{\partial^2 l_{\text{partial}}(\boldsymbol{\beta}, \boldsymbol{\gamma})}{\partial \boldsymbol{\gamma}^2}$ . Write  $\boldsymbol{\tau}' = (\boldsymbol{\beta}', \boldsymbol{\gamma}')'$ . The Wald-type chi-square statistic for testing  $H_0 : \mathbf{C}\boldsymbol{\tau} = \mathbf{0}$  is

$$(\mathbf{C}\hat{\boldsymbol{\tau}})'(\mathbf{C}\mathbf{H}^{-1}\mathbf{C}')^{-1}(\mathbf{C}\hat{\boldsymbol{\tau}})$$

Let  $\mathbf{H}$  be the negative Hessian of the penalized partial log likelihood  $l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta)$  at the ML estimate  $\theta$ ; that is,  $\mathbf{H} = \frac{\partial^2}{\partial \boldsymbol{\beta} \partial \boldsymbol{\gamma}} l_p(\boldsymbol{\beta}, \boldsymbol{\gamma}, \hat{\theta})$ . Let  $\mathbf{V} = \mathbf{H}^{-1} \mathbf{I} \mathbf{H}^{-1}$ . Gray (1992) recommends the following generalized degrees of freedom for the Wald test:

$$\text{DF} = \text{trace}[(\mathbf{C}\mathbf{H}^{-1}\mathbf{C}')^{-1} \mathbf{C}\mathbf{V}\mathbf{C}']$$

See Therneau and Grambsch (2000, Section 5.8) for a discussion of this Wald-type test.

PROC PHREG uses the label "Adjusted DF" to represent this generalized degrees of freedom in the output.

---

## Specifics for Bayesian Analysis

To request a Bayesian analysis, you specify the new BAYES statement in addition to the PROC PHREG statement and the MODEL statement. You include a CLASS statement if you have effects that involve categorical variables. The FREQ or WEIGHT statement can be included if you have a frequency or weight

variable, respectively, in the input data. The STRATA statement can be used to carry out a stratified analysis for the Cox model, but it is not allowed in the piecewise constant baseline hazard model. Programming statements can be used to create time-dependent covariates for the Cox model, but they are not allowed in the piecewise constant baseline hazard model. However, you can use the counting process style of input to accommodate time-dependent covariates that are not continuously changing with time for the piecewise constant baseline hazard model and the Cox model as well. The HAZARDRATIO statement enables you to request a hazard ratio analysis based on the posterior samples. The ASSESS, CONTRAST, ID, OUTPUT, and TEST statements, if specified, are ignored. Also ignored are the COVM and COVS options in the PROC PHREG statement and the following options in the MODEL statement: BEST=, CORRB, COVB, DETAILS, HIERARCHY=, INCLUDE=, MAXSTEP=, NOFIT, PLCONV=, SELECTION=, SEQUENTIAL, SLENTY=, and SLSTAY=.

## Piecewise Constant Baseline Hazard Model

### Single Failure Time Variable

Let  $\{(t_i, \mathbf{x}_i, \delta_i), i = 1, 2, \dots, n\}$  be the observed data. Let  $a_0 = 0 < a_1 < \dots < a_{J-1} < a_J = \infty$  be a partition of the time axis.

**Hazards in Original Scale** The hazard function for subject  $i$  is

$$h(t|\mathbf{x}_i; \boldsymbol{\theta}) = h_0(t) \exp(\boldsymbol{\beta}'\mathbf{x}_i)$$

where

$$h_0(t) = \lambda_j \text{ if } a_{j-1} \leq t < a_j, j = 1, \dots, J$$

The baseline cumulative hazard function is

$$H_0(t) = \sum_{j=1}^J \lambda_j \Delta_j(t)$$

where

$$\Delta_j(t) = \begin{cases} 0 & t < a_{j-1} \\ t - a_{j-1} & a_{j-1} \leq t < a_j \\ a_j - a_{j-1} & t \geq a_j \end{cases}$$

The log likelihood is given by

$$\begin{aligned} l(\boldsymbol{\lambda}, \boldsymbol{\beta}) &= \sum_{i=1}^n \delta_i \left[ \sum_{j=1}^J I(a_{j-1} \leq t_i < a_j) \log \lambda_j + \boldsymbol{\beta}'\mathbf{x}_i \right] - \sum_{i=1}^n \left[ \sum_{j=1}^J \Delta_j(t_i) \lambda_j \right] \exp(\boldsymbol{\beta}'\mathbf{x}_i) \\ &= \sum_{j=1}^J d_j \log \lambda_j + \sum_{i=1}^n \delta_i \boldsymbol{\beta}'\mathbf{x}_i - \sum_{j=1}^J \lambda_j \left[ \sum_{i=1}^n \Delta_j(t_i) \exp(\boldsymbol{\beta}'\mathbf{x}_i) \right] \end{aligned}$$

where  $d_j = \sum_{i=1}^n \delta_i I(a_{j-1} \leq t_i < a_j)$ .

Note that for  $1 \leq j \leq J$ , the full conditional for  $\lambda_j$  is log-concave only when  $d_j > 0$ , but the full conditionals for the  $\beta$ 's are always log-concave.

For a given  $\beta$ ,  $\frac{\partial l}{\partial \lambda} = 0$  gives

$$\tilde{\lambda}_j(\beta) = \frac{d_j}{\sum_{i=1}^n \Delta_j(t_i) \exp(\beta' \mathbf{x}_i)}, \quad j = 1, \dots, J$$

Substituting these values into  $l(\lambda, \beta)$  gives the profile log likelihood for  $\beta$

$$l_p(\beta) = \sum_{i=1}^n \delta_i \beta' \mathbf{x}_i - \sum_{j=1}^J d_j \log \left[ \sum_{l=1}^n \Delta_j(t_l) \exp(\beta' \mathbf{x}_l) \right] + c$$

where  $c = \sum_j (d_j \log d_j - d_j)$ . Since the constant  $c$  does not depend on  $\beta$ , it can be discarded from  $l_p(\beta)$  in the optimization.

The MLE  $\hat{\beta}$  of  $\beta$  is obtained by maximizing

$$l_p(\beta) = \sum_{i=1}^n \delta_i \beta' \mathbf{x}_i - \sum_{j=1}^J d_j \log \left[ \sum_{l=1}^n \Delta_j(t_l) \exp(\beta' \mathbf{x}_l) \right]$$

with respect to  $\beta$ , and the MLE  $\hat{\lambda}$  of  $\lambda$  is given by

$$\hat{\lambda} = \tilde{\lambda}(\hat{\beta})$$

For  $j = 1, \dots, J$ , let

$$\begin{aligned} \mathbf{S}_j^{(r)}(\beta) &= \sum_{l=1}^n \Delta_j(t_l) e^{\beta' \mathbf{x}_l} \mathbf{x}_l^{\otimes r}, \quad r = 0, 1, 2 \\ \mathbf{E}_j(\beta) &= \frac{\mathbf{S}_j^{(1)}(\beta)}{S_j^{(0)}(\beta)} \end{aligned}$$

The partial derivatives of  $l_p(\beta)$  are

$$\begin{aligned} \frac{\partial l_p(\beta)}{\partial \beta} &= \sum_{i=1}^n \delta_i \mathbf{x}_i - \sum_{j=1}^J d_j \mathbf{E}_j(\beta) \\ -\frac{\partial^2 l_p(\beta)}{\partial \beta^2} &= \sum_{j=1}^J d_j \left\{ \frac{\mathbf{S}_j^{(2)}(\beta)}{S_j^{(0)}(\beta)} - \left[ \mathbf{E}_j(\beta) \right] \left[ \mathbf{E}_j(\beta) \right]' \right\} \end{aligned}$$

The asymptotic covariance matrix for  $(\hat{\lambda}, \hat{\beta})$  is obtained as the inverse of the information matrix given by

$$\begin{aligned} -\frac{\partial^2 l(\hat{\lambda}, \hat{\beta})}{\partial \lambda^2} &= \mathcal{D} \left( \frac{d_1}{\hat{\lambda}_1^2}, \dots, \frac{d_J}{\hat{\lambda}_J^2} \right) \\ -\frac{\partial^2 l(\hat{\lambda}, \hat{\beta})}{\partial \beta^2} &= \sum_{j=1}^J \hat{\lambda}_j \mathbf{S}_j^{(2)}(\hat{\beta}) \\ -\frac{\partial^2 l(\hat{\lambda}, \hat{\beta})}{\partial \lambda \partial \beta} &= (\mathbf{S}_1^{(1)}(\hat{\beta}), \dots, \mathbf{S}_J^{(1)}(\hat{\beta})) \end{aligned}$$

See Example 6.5.1 in Lawless (2003) for details.

**Hazards in Log Scale** By letting

$$\alpha_j = \log(\lambda_j), \quad j = 1, \dots, J$$

you can build a prior correlation among the  $\lambda_j$ 's by using a correlated prior  $\boldsymbol{\alpha} \sim N(\boldsymbol{\alpha}_0, \Sigma_\alpha)$ , where  $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_J)'$ .

The log likelihood is given by

$$l(\boldsymbol{\alpha}, \boldsymbol{\beta}) = \sum_{j=1}^J d_j \alpha_j + \sum_{i=1}^n \delta_i \boldsymbol{\beta}' \mathbf{x}_i - \sum_{j=1}^J e^{\alpha_j} S_j^{(0)}(\boldsymbol{\beta})$$

Then the MLE of  $\lambda_j$  is given by

$$e^{\hat{\alpha}_j} = \hat{\lambda}_j = \frac{d_j}{S_j^0(\hat{\boldsymbol{\beta}})}$$

Note that the full conditionals for  $\alpha$ 's and  $\beta$ 's are always log-concave.

The asymptotic covariance matrix for  $(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})$  is obtained as the inverse of the information matrix formed by

$$\begin{aligned} -\frac{\partial^2 l(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\alpha}^2} &= \mathcal{D}\left(e^{\hat{\alpha}_1} S_1^0(\hat{\boldsymbol{\beta}}), \dots, e^{\hat{\alpha}_J} S_J^0(\hat{\boldsymbol{\beta}})\right) \\ -\frac{\partial^2 l(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\beta}^2} &= \sum_{j=1}^J e^{\hat{\alpha}_j} \mathbf{S}_j^{(2)}(\hat{\boldsymbol{\beta}}) \\ -\frac{\partial^2 l(\hat{\boldsymbol{\alpha}}, \hat{\boldsymbol{\beta}})}{\partial \boldsymbol{\alpha} \partial \boldsymbol{\beta}} &= (e^{\hat{\alpha}_1} \mathbf{S}_1^{(1)}(\hat{\boldsymbol{\beta}}), \dots, e^{\hat{\alpha}_J} \mathbf{S}_J^{(1)}(\hat{\boldsymbol{\beta}})) \end{aligned}$$

### Counting Process Style of Input

Let  $\{(s_i, t_i], \mathbf{x}_i, \delta_i\}, i = 1, 2, \dots, n\}$  be the observed data. Let  $a_0 = 0 < a_1 < \dots < a_k$  be a partition of the time axis, where  $a_k > t_i$  for all  $i = 1, 2, \dots, n$ .

Replacing  $\Delta_j(t_i)$  with

$$\Delta_j((s_i, t_i]) = \begin{cases} 0 & t_i < a_{j-1} \vee s_i > a_j \\ t_i - \max(s_i, a_{j-1}) & a_{j-1} \leq t_i < a_j \\ a_j - \max(s_i, a_{j-1}) & t_i \geq a_j \end{cases}$$

the formulation for the single failure time variable applies.

### Priors for Model Parameters

For a Cox model, the model parameters are the regression coefficients. For a piecewise exponential model, the model parameters consist of the regression coefficients and the hazards or log-hazards. The priors for the hazards and the priors for the regression coefficients are assumed to be independent, while you can have a joint multivariate normal prior for the log-hazards and the regression coefficients.

**Hazard Parameters**

Let  $\lambda_1, \dots, \lambda_J$  be the constant baseline hazards.

**Improper Prior** The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) = \prod_{j=1}^J \frac{1}{\lambda_j}, \forall \lambda_j > 0$$

This prior is improper (nonintegrable), but the posterior distribution is proper as long as there is at least one event time in each of the constant hazard intervals.

**Uniform Prior** The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) \propto 1, \forall \lambda_j > 0$$

This prior is improper (nonintegrable), but the posteriors are proper as long as there is at least one event time in each of the constant hazard intervals.

**Gamma Prior** The gamma distribution  $G(a, b)$  has a PDF

$$f_{a,b}(t) = \frac{b(bt)^{a-1}e^{-bt}}{\Gamma(a)}, t > 0$$

where  $a$  is the shape parameter and  $b^{-1}$  is the scale parameter. The mean is  $\frac{a}{b}$  and the variance is  $\frac{a}{b^2}$ .

**Independent Gamma Prior** Suppose for  $j = 1, \dots, J$ ,  $\lambda_j$  has an independent  $G(a_j, b_j)$  prior. The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) \propto \prod_{j=1}^J \left\{ \lambda_j^{a_j-1} e^{-b_j \lambda_j} \right\}, \forall \lambda_j > 0$$

**AR1 Prior**  $\lambda_1, \dots, \lambda_J$  are correlated as follows:

$$\begin{aligned} \lambda_1 &\sim G(a_1, b_1) \\ \lambda_2 &\sim G\left(a_2, \frac{b_2}{\lambda_1}\right) \\ \dots &\dots \\ \lambda_J &\sim G\left(a_J, \frac{b_J}{\lambda_{J-1}}\right) \end{aligned}$$

The joint prior density is given by

$$p(\lambda_1, \dots, \lambda_J) \propto \lambda_1^{a_1-1} e^{-b_1 \lambda_1} \prod_{j=2}^J \left( \frac{b_j}{\lambda_{j-1}} \right)^{a_j} \lambda_j^{a_j-1} e^{-\frac{b_j}{\lambda_{j-1}} \lambda_j}$$

**Log-Hazard Parameters**

Write  $\boldsymbol{\alpha} = (\alpha_1, \dots, \alpha_J)' \equiv (\log \lambda_1, \dots, \log \lambda_J)'$ .

**Uniform Prior** The joint prior density is given by

$$p(\alpha_1 \dots \alpha_J) \propto 1, \forall -\infty < \alpha_i < \infty$$

Note that the uniform prior for the log-hazards is the same as the improper prior for the hazards.

**Normal Prior** Assume  $\boldsymbol{\alpha}$  has a multivariate normal prior with mean vector  $\boldsymbol{\alpha}_0$  and covariance matrix  $\boldsymbol{\Psi}_0$ . The joint prior density is given by

$$p(\boldsymbol{\alpha}) \propto e^{-\frac{1}{2}(\boldsymbol{\alpha}-\boldsymbol{\alpha}_0)'\boldsymbol{\Psi}_0^{-1}(\boldsymbol{\alpha}-\boldsymbol{\alpha}_0)}$$

**Regression Coefficients**

Let  $\boldsymbol{\beta} = (\beta_1, \dots, \beta_k)'$  be the vector of regression coefficients.

**Uniform Prior** The joint prior density is given by

$$p(\beta_1, \dots, \beta_k) \propto 1, \forall -\infty < \beta_i < \infty$$

This prior is improper, but the posterior distributions for  $\boldsymbol{\beta}$  are proper.

**Normal Prior** Assume  $\boldsymbol{\beta}$  has a multivariate normal prior with mean vector  $\boldsymbol{\beta}_0$  and covariance matrix  $\boldsymbol{\Sigma}_0$ . The joint prior density is given by

$$p(\boldsymbol{\beta}) \propto e^{-\frac{1}{2}(\boldsymbol{\beta}-\boldsymbol{\beta}_0)'\boldsymbol{\Sigma}_0^{-1}(\boldsymbol{\beta}-\boldsymbol{\beta}_0)}$$

**Joint Multivariate Normal Prior for Log-Hazards and Regression Coefficients** Assume  $(\boldsymbol{\alpha}', \boldsymbol{\beta}')$  has a multivariate normal prior with mean vector  $(\boldsymbol{\alpha}'_0, \boldsymbol{\beta}'_0)'$  and covariance matrix  $\boldsymbol{\Phi}_0$ . The joint prior density is given by

$$p(\boldsymbol{\alpha}, \boldsymbol{\beta}) \propto e^{-\frac{1}{2}[(\boldsymbol{\alpha}-\boldsymbol{\alpha}_0)', (\boldsymbol{\beta}-\boldsymbol{\beta}_0)']\boldsymbol{\Phi}_0^{-1}[(\boldsymbol{\alpha}-\boldsymbol{\alpha}_0)', (\boldsymbol{\beta}-\boldsymbol{\beta}_0)']}$$

**Zellner's g-Prior** Assume  $\boldsymbol{\beta}$  has a multivariate normal prior with mean vector  $\mathbf{0}$  and covariance matrix  $(g\mathbf{X}'\mathbf{X})^{-1}$ , where  $\mathbf{X}$  is the design matrix and  $g$  is either a constant or it follows a gamma prior with density  $f(\tau) = \frac{b(b\tau)^{a-1}e^{-b\tau}}{\Gamma(a)}$  where  $a$  and  $b$  are the SHAPE= and ISCALE= parameters. Let  $k$  be the rank of  $\mathbf{X}$ . The joint prior density with  $g$  being a constant  $c$  is given by

$$p(\boldsymbol{\beta}) \propto c^{\frac{k}{2}} e^{-\frac{1}{2}\boldsymbol{\beta}'(c\mathbf{X}'\mathbf{X})^{-1}\boldsymbol{\beta}}$$

The joint prior density with  $g$  having a gamma prior is given by

$$p(\boldsymbol{\beta}, \tau) \propto \tau^{\frac{k}{2}} e^{-\frac{1}{2}\boldsymbol{\beta}'(\tau\mathbf{X}'\mathbf{X})^{-1}\boldsymbol{\beta}} \frac{b(b\tau)^{a-1}e^{-b\tau}}{\Gamma(a)}$$

**Dispersion Parameter for Frailty Model**

**Improper Prior** The density is

$$p(\theta) = \frac{1}{\theta}$$

**Inverse Gamma Prior** The inverse gamma distribution  $IG(a, b)$  has a density

$$p(\theta|a, b) = \frac{b^a \theta^{-(a+1)} e^{-\frac{b}{\theta}}}{\Gamma(a)}$$

where  $a$  and  $b$  are the SHAPE= and SCALE= parameters.

**Gamma Prior** The gamma distribution  $G(a, b)$  has a density

$$p(\theta|a, b) = \frac{b^a \theta^{a-1} e^{-b\theta}}{\Gamma(a)}$$

where  $a$  and  $b$  are the SHAPE= and ISCALE= parameters.

**Posterior Distribution**

Denote the observed data by  $D$ .

**Cox Model**

$$\pi(\boldsymbol{\beta}|D) \propto \underbrace{L(D|\boldsymbol{\beta})}_{\text{partial likelihood}} \overbrace{p(\boldsymbol{\beta})}^{\text{prior}}$$

**Frailty Model**

Based on the framework of Sargent (1998),

$$\pi(\boldsymbol{\beta}, \boldsymbol{\gamma}, \theta|D) \propto \underbrace{L(D|\boldsymbol{\beta}, \boldsymbol{\gamma})}_{\text{partial likelihood}} \overbrace{g(\boldsymbol{\gamma}|\theta)}^{\text{random effects}} \underbrace{p(\boldsymbol{\beta})p(\theta)}_{\text{priors}}$$

where the joint density of the random effects  $\boldsymbol{\gamma} = (\gamma_1, \dots, \gamma_s)'$  is given by

$$g(\boldsymbol{\gamma}|\theta) \propto \begin{cases} \prod_i \exp\left(\frac{\gamma_i}{\theta}\right) \exp\left(-\exp\left(\frac{\gamma_i}{\theta}\right)\right) & \text{gamma frailty} \\ \prod_i \exp\left(-\frac{\gamma_i^2}{2\theta}\right) & \text{lognormal frailty} \end{cases}$$

**Piecewise Exponential Model****Hazard Parameters**

$$\pi(\boldsymbol{\lambda}, \boldsymbol{\beta} | D) \propto L_H(D | \boldsymbol{\lambda}, \boldsymbol{\beta}) p(\boldsymbol{\lambda}) p(\boldsymbol{\beta})$$

where  $L_H(D | \boldsymbol{\lambda}, \boldsymbol{\beta})$  is the likelihood function with hazards  $\boldsymbol{\lambda}$  and regression coefficients  $\boldsymbol{\beta}$  as parameters.

**Log-Hazard Parameters**

$$\pi(\boldsymbol{\alpha}, \boldsymbol{\beta} | D) \propto \begin{cases} L_{LH}(D | \boldsymbol{\alpha}, \boldsymbol{\beta}) p(\boldsymbol{\alpha}, \boldsymbol{\beta}) & \text{if } (\boldsymbol{\alpha}', \boldsymbol{\beta}')' \sim \text{MVN} \\ L_{LH}(D | \boldsymbol{\alpha}, \boldsymbol{\beta}) p(\boldsymbol{\alpha}) p(\boldsymbol{\beta}) & \text{otherwise} \end{cases}$$

where  $L_{LH}(D | \boldsymbol{\alpha}, \boldsymbol{\beta})$  is the likelihood function with log-hazards  $\boldsymbol{\alpha}$  and regression coefficients  $\boldsymbol{\beta}$  as parameters.

**Sampling from the Posterior Distribution**

For the Gibbs sampler, PROC PHREG uses the ARMS (adaptive rejection Metropolis sampling) algorithm of Gilks, Best, and Tan (1995) to sample from the full conditionals. This is the default sampling scheme. Alternatively, you can request the random walk Metropolis (RWM) algorithm to sample an entire parameter vector from the posterior distribution. For a general discussion of these algorithms, see section “[Markov Chain Monte Carlo Method](#)” on page 133.

You can output these posterior samples into a SAS data set by using the OUTPOST= option in the BAYES statement, or you can use the following SAS statement to output the posterior samples into the SAS data set Post:

```
ods output PosteriorSample=Post;
```

The output data set also includes the variables LogLike and LogPost, which represent the log of the likelihood and the log of the posterior log density, respectively.

Let  $\boldsymbol{\theta} = (\theta_1, \dots, \theta_k)'$  be the parameter vector. For the Cox model, the  $\theta_i$ 's are the regression coefficients  $\beta_i$ 's, and for the piecewise constant baseline hazard model, the  $\theta_i$ 's consist of the baseline hazards  $\lambda_i$ 's (or log baseline hazards  $\alpha_i$ 's) and the regression coefficients  $\beta_j$ 's. Let  $L(D | \boldsymbol{\theta})$  be the likelihood function, where  $D$  is the observed data. Note that for the Cox model, the likelihood contains the infinite-dimensional baseline hazard function, and the gamma process is perhaps the most commonly used prior process (Ibrahim, Chen, and Sinha 2001). However, Sinha, Ibrahim, and Chen (2003) justify using the partial likelihood as the likelihood function for the Bayesian analysis. Let  $p(\boldsymbol{\theta})$  be the prior distribution. The posterior  $f\pi(\boldsymbol{\theta} | D)$  is proportional to the joint distribution  $L(D | \boldsymbol{\theta}) p(\boldsymbol{\theta})$ .

**Gibbs Sampler**

The full conditional distribution of  $\theta_i$  is proportional to the joint distribution; that is,

$$\pi(\theta_i | \theta_j, i \neq j, D) \propto L(D | \boldsymbol{\theta}) p(\boldsymbol{\theta})$$

For example, the one-dimensional conditional distribution of  $\theta_1$ , given  $\theta_j = \theta_j^*, 2 \leq j \leq k$ , is computed as

$$\pi(\theta_1 | \theta_j = \theta_j^*, 2 \leq j \leq k, D) = L(D | \boldsymbol{\theta} = (\theta_1, \theta_2^*, \dots, \theta_k^*)') p(\boldsymbol{\theta} = (\theta_1, \theta_2^*, \dots, \theta_k^*)')$$

Suppose you have a set of arbitrary starting values  $\{\theta_1^{(0)}, \dots, \theta_k^{(0)}\}$ . Using the ARMS algorithm, an iteration of the Gibbs sampler consists of the following:

- draw  $\theta_1^{(1)}$  from  $\pi(\theta_1|\theta_2^{(0)}, \dots, \theta_k^{(0)}, D)$
- draw  $\theta_2^{(1)}$  from  $\pi(\theta_2|\theta_1^{(1)}, \theta_3^{(0)}, \dots, \theta_k^{(0)}, D)$
- $\vdots$
- draw  $\theta_k^{(1)}$  from  $\pi(\theta_k|\theta_1^{(1)}, \dots, \theta_{k-1}^{(1)}, D)$

After one iteration, you have  $\{\theta_1^{(1)}, \dots, \theta_k^{(1)}\}$ . After  $n$  iterations, you have  $\{\theta_1^{(n)}, \dots, \theta_k^{(n)}\}$ . Cumulatively, a chain of  $n$  samples is obtained.

### Random Walk Metropolis Algorithm

PROC PHREG uses a multivariate normal proposal distribution  $q(\cdot|\theta)$  centered at  $\theta$ . With an initial parameter vector  $\theta^{(0)}$ , a new sample  $\theta^{(1)}$  is obtained as follows:

- sample  $\theta^*$  from  $q(\cdot|\theta^{(0)})$
- calculate the quantity  $r = \min \left\{ \frac{\pi(\theta^*|D)}{\pi(\theta^{(0)}|D)}, 1 \right\}$
- sample  $u$  from the uniform distribution  $U(0, 1)$
- set  $\theta^{(1)} = \theta^*$  if  $u < r$ ; otherwise set  $\theta^{(1)} = \theta^{(0)}$

With  $\theta^{(1)}$  taking the role of  $\theta^{(0)}$ , the previous steps are repeated to generate the next sample  $\theta^{(2)}$ . After  $n$  iterations, a chain of  $n$  samples  $\{\theta^{(1)}, \dots, \theta^{(n)}\}$  is obtained.

### Starting Values of the Markov Chains

When the BAYES statement is specified, PROC PHREG generates one Markov chain that contains the approximate posterior samples of the model parameters. Additional chains are produced when the Gelman-Rubin diagnostics are requested. Starting values (initial values) can be specified in the INITIAL= data set in the BAYES statement. If the INITIAL= option is not specified, PROC PHREG picks its own initial values for the chains based on the maximum likelihood estimates of  $\theta$  and the prior information of  $\theta$ .

Denote  $[x]$  as the integral value of  $x$ .

### Constant Baseline Hazards $\lambda_i$ 's

For the first chain that the summary statistics and diagnostics are based on, the initial values are

$$\lambda_i^{(0)} = \hat{\lambda}_i$$

For subsequent chains, the starting values are picked in two different ways according to the total number of chains specified. If the total number of chains specified is less than or equal to 10, initial values of the  $r$ th chain ( $2 \leq r \leq 10$ ) are given by

$$\lambda_i^{(0)} = \hat{\lambda}_i e^{\pm \left( \left[ \frac{r}{2} \right] + 2 \right) \hat{s}(\hat{\lambda}_i)}$$

with the plus sign for odd  $r$  and minus sign for even  $r$ . If the total number of chains is greater than 10, initial values are picked at random over a wide range of values. Let  $u_i$  be a uniform random number between 0 and 1; the initial value for  $\lambda_i$  is given by

$$\lambda_i^{(0)} = \hat{\lambda}_i e^{16(u_i - 0.5)\hat{s}(\hat{\lambda}_i)}$$

### Regression Coefficients and Log-Hazard Parameters $\theta_i$ 's

The  $\theta_i$ 's are the regression coefficients  $\beta_i$ 's, and in the piecewise exponential model, include the log-hazard parameters  $\alpha_i$ 's. For the first chain that the summary statistics and regression diagnostics are based on, the initial values are

$$\theta_i^{(0)} = \hat{\theta}_i$$

If the number of chains requested is less than or equal to 10, initial values for the  $r$ th chain ( $2 \leq r \leq 10$ ) are given by

$$\theta_i^{(0)} = \hat{\theta}_i \pm \left(2 + \left\lceil \frac{r}{2} \right\rceil\right) \hat{s}(\hat{\theta}_i)$$

with the plus sign for odd  $r$  and minus sign for even  $r$ . When there are more than 10 chains, the initial value for the  $\theta_i$  is picked at random over the range  $(\hat{\theta}_i - 8\hat{s}(\hat{\theta}_i), \hat{\theta}_i + 8\hat{s}(\hat{\theta}_i))$ ; that is,

$$\theta_i^{(0)} = \hat{\theta}_i + 16(u_i - 0.5)\hat{s}(\hat{\theta}_i)$$

where  $u_i$  is a uniform random number between 0 and 1.

### Fit Statistics

Denote the observed data by  $D$ . Let  $\boldsymbol{\theta}$  be the vector of parameters of length  $k$ . Let  $L(D|\boldsymbol{\theta})$  be the likelihood. The deviance information criterion (DIC) proposed in Spiegelhalter et al. (2002) is a Bayesian model assessment tool. Let  $\text{Dev}(\boldsymbol{\theta}) = -2 \log L(D|\boldsymbol{\theta})$ . Let  $\overline{\text{Dev}(\boldsymbol{\theta})}$  and  $\bar{\boldsymbol{\theta}}$  be the corresponding posterior means of  $\text{Dev}(\boldsymbol{\theta})$  and  $\boldsymbol{\theta}$ , respectively. The deviance information criterion is computed as

$$\text{DIC} = 2\overline{\text{Dev}(\boldsymbol{\theta})} - \text{Dev}(\bar{\boldsymbol{\theta}})$$

Also computed is

$$pD = \overline{\text{Dev}(\boldsymbol{\theta})} - \text{Dev}(\bar{\boldsymbol{\theta}})$$

where  $pD$  is interpreted as the effective number of parameters.

Note that  $\text{Dev}(\boldsymbol{\theta})$  defined here does not have the standardizing term as in the section “Deviance Information Criterion (DIC)” on page 155. Nevertheless, the DIC calculated here is still useful for variable selection.

### Posterior Distribution for Quantities of Interest

Let  $\boldsymbol{\theta} = (\theta_1, \dots, \theta_k)'$  be the parameter vector. For the Cox model, the  $\theta_i$ 's are the regression coefficients  $\beta_i$ 's; for the piecewise constant baseline hazard model, the  $\theta_i$ 's consist of the baseline hazards  $\lambda_i$ 's (or log baseline hazards  $\alpha_i$ 's) and the regression coefficients  $\beta_j$ 's. Let  $\mathcal{S} = \{\boldsymbol{\theta}^{(r)}, r = 1, \dots, N\}$  be the chain that represents the posterior distribution for  $\boldsymbol{\theta}$ .

Consider a quantity of interest  $\tau$  that can be expressed as a function  $f(\boldsymbol{\theta})$  of the parameter vector  $\boldsymbol{\theta}$ . You can construct the posterior distribution of  $\tau$  by evaluating the function  $f(\boldsymbol{\theta}^{(r)})$  for each  $\boldsymbol{\theta}^{(r)}$  in  $\mathcal{S}$ . The posterior chain for  $\tau$  is  $\{f(\boldsymbol{\theta}^{(r)}), r = 1, \dots, N\}$ . Summary statistics such as mean, standard deviation, percentiles, and credible intervals are used to describe the posterior distribution of  $\tau$ .

### Hazard Ratio

As shown in the section “Hazard Ratios” on page 5619, a log-hazard ratio is a linear combination of the regression coefficients. Let  $\mathbf{h}$  be the vector of linear coefficients. The posterior sample for this hazard ratio is the set  $\{\exp(\mathbf{h}'\boldsymbol{\beta}^{(r)}), r = 1, \dots, N\}$ .

### Survival Distribution

Let  $\mathbf{x}$  be a covariate vector of interest.

**Cox Model** Let  $\{(t_i, \mathbf{z}_i, \delta_i), i = 1, 2, \dots, n\}$  be the observed data. Define

$$Y_i(t) = \begin{cases} 1 & t < t_i \\ 0 & \text{otherwise} \end{cases}$$

Consider the  $r$ th draw  $\boldsymbol{\beta}^{(r)}$  of  $\mathcal{S}$ . The baseline cumulative hazard function at time  $t$  is given by

$$H_0(t|\boldsymbol{\beta}^{(r)}) = \sum_{i:t_i \leq t} \frac{\delta_i}{\sum_{l=1}^n Y_l(t_i) \exp(\mathbf{z}_l' \boldsymbol{\beta}^{(r)})}$$

For the given covariate vector  $\mathbf{x}$ , the cumulative hazard function at time  $t$  is

$$H(t; \mathbf{x}|\boldsymbol{\beta}^{(r)}) = H_0(t|\boldsymbol{\beta}^{(r)}) \exp(\mathbf{x}' \boldsymbol{\beta}^{(r)})$$

and the survival function at time  $t$  is

$$S(t; \mathbf{x}|\boldsymbol{\beta}^{(r)}) = \exp[-H^{(r)}(t; \mathbf{x}|\boldsymbol{\beta}^{(r)})]$$

**Piecewise Exponential Model** Let  $0 = a_0 < a_1 < \dots < a_J < \infty$  be a partition of the time axis. Consider the  $r$ th draw  $\boldsymbol{\theta}^{(r)}$  in  $\mathcal{S}$ , where  $\boldsymbol{\theta}^{(r)}$  consists of  $\boldsymbol{\lambda}^{(r)} = (\lambda_1^{(r)}, \dots, \lambda_J^{(r)})'$  and  $\boldsymbol{\beta}^{(r)}$ . The baseline cumulative hazard function at time  $t$  is

$$H_0(t|\boldsymbol{\lambda}^{(r)}) = \sum_{j=1}^J \lambda_j^{(r)} \Delta_j(t)$$

where

$$\Delta_j(t) = \begin{cases} 0 & t < a_{j-1} \\ t - a_{j-1} & a_{j-1} \leq t < a_j \\ a_j - a_{j-1} & t \geq a_j \end{cases}$$

For the given covariate vector  $\mathbf{x}$ , the cumulative hazard function at time  $t$  is

$$H(t; \mathbf{x}|\boldsymbol{\lambda}^{(r)}, \boldsymbol{\beta}^{(r)}) = H_0(t|\boldsymbol{\lambda}^{(r)}) \exp(\mathbf{x}' \boldsymbol{\beta}^{(r)})$$

and the survival function at time  $t$  is

$$S(t; \mathbf{x}|\boldsymbol{\lambda}^{(r)}, \boldsymbol{\beta}^{(r)}) = \exp[-H(t; \mathbf{x}|\boldsymbol{\lambda}^{(r)}, \boldsymbol{\beta}^{(r)})]$$

---

## Computational Resources

Let  $n$  be the number of observations in a BY group. Let  $p$  be the number of explanatory variables. The minimum working space (in bytes) needed to process the BY group is

$$\max\{12n, 24p^2 + 160p\}$$

Extra memory is needed for certain TIES= options. Let  $k$  be the maximum multiplicity of tied times. The TIES=DISCRETE option requires extra memory (in bytes) of

$$4k(p^2 + 4p)$$

The TIES=EXACT option requires extra memory (in bytes) of

$$24(k^2 + 5k)$$

If sufficient space is available, the input data are also kept in memory. Otherwise, the input data are reread from the utility file for each evaluation of the likelihood function and its derivatives, with the resulting execution time substantially increased.

---

## Input and Output Data Sets

### OUTEST= Output Data Set

The OUTEST= data set contains one observation for each BY group containing the maximum likelihood estimates of the regression coefficients. If you also use the COVOUT option in the PROC PHREG statement, there are additional observations containing the rows of the estimated covariance matrix. If you specify SELECTION=FORWARD, BACKWARD, or STEPWISE, only the estimates of the parameters and covariance matrix for the final model are output to the OUTEST= data set.

#### *Variables in the OUTEST= Data Set*

The OUTEST= data set contains the following variables:

- any BY variables specified
- `_TIES_`, a character variable of length 8 with four possible values: BRESLOW, DISCRETE, EFRON, and EXACT. These are the four values of the TIES= option in the MODEL statement.
- `_TYPE_`, a character variable of length 8 with two possible values: PARMS for parameter estimates or COV for covariance estimates. If both the COVM and COVS options are specified in the PROC PHREG statement along with the COVOUT option, `_TYPE_='COVM'` for the model-based covariance estimates and `_TYPE_='COVS'` for the robust sandwich covariance estimates.
- `_STATUS_`, a character variable indicating whether the estimates have converged
- `_NAME_`, a character variable containing the name of the TIME variable for the row of parameter estimates and the name of each explanatory variable to label the rows of covariance estimates

- one variable for each regression coefficient and one variable for the offset variable if the **OFFSET=** option is specified. If an explanatory variable is not included in the final model in a variable selection process, the corresponding parameter estimates and covariances are set to missing.
- **\_LNLIKE\_**, a numeric variable containing the last computed value of the log likelihood

### **Parameter Names in the **OUTEST=** Data Set**

For continuous explanatory variables, the names of the parameters are the same as the corresponding variables. For CLASS variables, the parameter names are obtained by concatenating the corresponding CLASS variable name with the CLASS category; see the **PARAM=** option in the **CLASS** statement for more details. For interaction and nested effects, the parameter names are created by concatenating the names of each component effect.

### **INEST= Input Data Set**

You can specify starting values for the maximum likelihood iterative algorithm in the **INEST=** data set. The **INEST=** data set has the same structure as the **OUTEST=** data set but is not required to have all the variables or observations that appear in the **OUTEST=** data set.

The **INEST=** data set must contain variables that represent the regression coefficients of the model. If BY processing is used, the **INEST=** data set should also include the BY variables, and there must be one observation for each BY group. If the **INEST=** data set also contains the **\_TYPE\_** variable, only observations with **\_TYPE\_** value 'PARMS' are used as starting values.

### **OUT= Output Data Set in the **OUTPUT** Statement**

The **OUT=** data set in the **OUTPUT** statement contains all the variables in the input data set, along with statistics you request by specifying *keyword=name* options. The new variables contain a variety of diagnostics that are calculated for each observation in the input data set.

### **OUT= Output Data Set in the **BASELINE** Statement**

The **OUT=** data set in the **BASELINE** statement contains all the variables in the **COVARIATES=** data set, along with statistics you request by specifying *keyword=name* options. For unstratified input data, there are  $1 + n$  observations in the **OUT=** data set for each observation in the **COVARIATES=** data set, where  $n$  is the number of distinct event times in the input data. For input data that are stratified into  $k$  strata, with  $n_i$  distinct events in the  $i$ th stratum,  $i = 1, \dots, k$ , there are  $1+n_i$  observations for the  $i$ th stratum in the **OUT=** data set for each observation in the **COVARIATES=** data set.

### **OUTDIFF= Output Data Set in the **BASELINE** Statement**

The **OUTDIFF=** data set contains the differences of the direct adjusted survival probabilities between two treatments or two strata and their standard errors.

### **OUTPOST= Output Data Set in the **BAYES** Statement**

The **OUTPOST=** data set contains the generated posterior samples. There are  $3+n$  variables, where  $n$  is the number of model parameters. The variable **Iteration** represents the iteration number, the variable **LogLike** contains the log-likelihood values, and the variable **LogPost** contains the log-posterior-density values. The other  $n$  variables represent the draws of the Markov chain for the model parameters.

---

## Displayed Output

If you use the NOPRINT option in the PROC PHREG statement, the procedure does not display any output. Otherwise, PROC PHREG displays results of the analysis in a collection of tables. The tables are listed separately for the maximum likelihood analysis and for the Bayesian analysis.

### Maximum Likelihood Analysis Displayed Output

#### ***Model Information***

The “Model Information” table displays the two-level name of the input data set, the name and label of the failure time variable, the name and label of the censoring variable and the values indicating censored times, the model (either the Cox model or the piecewise constant baseline hazard model), the name and label of the OFFSET variable, the name and label of the FREQ variable, the name and label of the WEIGHT variable, and the method of handling ties in the failure time for the Cox model. The ODS name of the “Model Information” table is ModelInfo.

#### ***Number of Observations***

The “Number of Observations” table displays the number of observations read and used in the analysis. The ODS name of the “Number of Observations” is NObs.

#### ***Class Level Information***

The “Class Level Information” table is displayed when there are CLASS variables in the model. The table lists the categories of every CLASS variable that is used in the model and the corresponding design variable values. The ODS name of the “Class Level Information” table is ClassLevelInfo.

#### ***Class Level Information for Random Effects***

The “Class Level Information for Random Effects” table is displayed when the RANDOM statement is specified. The table lists the categories of the classification variable specified in the RANDOM statement. The ODS name of the “Class Level Information for Random Effects” table is ClassLevelInfoR.

#### ***Summary of the Number of Event and Censored Values***

The “Summary of the Number of Event and Censored Values” table displays, for each stratum, the breakdown of the number of events and censored values. The ODS name of the “Summary of the Number of Event and Censored Values” table is CensoredSummary.

#### ***Risk Sets Information***

The “Risk Sets Information” table is displayed if you specify the ATRISK option in the PROC PHREG statement. The table displays, for each event time, the number of units at-risk and the number of units that experience the event. The ODS name of the “Risk Sets Information” table is RiskSetInfo.

#### ***Descriptive Statistics for Continuous Explanatory Variables***

The “Simple Statistics for Continuous Explanatory Variables” table is displayed when you specify the SIMPLE option in the PROC PHREG statement. The table contains, for each stratum, the mean, standard deviation, and minimum and maximum for each continuous explanatory variable in the MODEL statement. For ODS purposes, the name of the “Descriptive Statistics for Continuous Explanatory Variables” table is “SimpleStatistics.”

**Frequency Distribution of CLASS Variables**

The “Frequency Distribution of CLASS Variables” table is displayed if you specify the SIMPLE option in the PROC PHREG statement and there are CLASS variables in the model. The table lists the frequency of the levels of the CLASS variables. The ODS name of the “Frequency Distribution of CLASS Variables” table is ClassLevelFreq.

**Maximum Likelihood Iteration History**

The “Maximum Likelihood Iteration History” table is displayed if you specify the ITPRINT option in the MODEL statement. The table contains the iteration number, ridge value or step size, log likelihood, and parameter estimates at each iteration. The ODS name of the “Maximum Likelihood Iteration History” table is IterHistory.

**Gradient of Last Iteration**

The “Gradient of Last Iteration” table is displayed if you specify the ITPRINT option in the MODEL statement. The ODS name of the “Gradient of Last Iteration” table is LastGradient.

**Convergence Status**

The “Convergence Status” table displays the convergence status of the Newton-Raphson maximization. The ODS name of the “Convergence Status” table is ConvergenceStatus.

**Model Fit Statistics**

The “Model Fit Statistics” table displays the values of  $-2 \log$  likelihood for the null model and the fitted model, the AIC, and SBC. The ODS name of the “Model Fit Statistics” table is FitStatistics.

**Covariance Parameter Estimates**

The “Covariance Parameter Estimates” table displays the estimate of the variance parameter of the random effect and the standard error estimate of the variance parameter estimator. The ODS name of the “Covariance Parameter Estimates” table is CovParms.

**Testing Global Null Hypothesis: BETA=0**

The “Testing Global Null Hypothesis: BETA=0” table displays results of the likelihood ratio test, the score test, and the Wald test for testing the hypothesis that all parameters are zero. For the frailty model, the score test is not displayed and an adjusted degrees of freedom is used (see the section “Wald-Type Tests for Penalized Models” on page 5653 for more information.) For ODS purpose, the name of the “Testing Global Null Hypothesis: BETA=0” table is “GlobalTests.”

**Likelihood Ratio Statistics for Type 1 Analysis**

The “Likelihood Ratio Statistics for Type 1 Analysis” table is displayed if the TYPE1 option is specified in the MODEL statement. The table displays the degrees of freedom, the likelihood ratio chi-square statistic, and the  $p$ -value for each effect in the model. The ODS name of “Likelihood Ratio Statistics for Type 1 Analysis” is Type1.

**Type 3 Tests**

The “Type 3 Tests” table is displayed if the model contains a CLASS variable or if the TYPE3 option is specified in the MODEL statement. The table displays, for each specified statistic, the Type 3 chi-square, the degrees of freedom, and the  $p$ -value for each effect in the model. For the frailty model, the table also

displays the adjusted Wald-type test results (see the section “Wald-Type Tests for Penalized Models” on page 5653 for details.) The ODS name of “Type 3 Tests” is Type3.

### ***Analysis of Maximum Likelihood Estimates***

The “Analysis of Maximum Likelihood Estimates” table displays the maximum likelihood estimate of the parameter; the estimated standard error, computed as the square root of the corresponding diagonal element of the estimated covariance matrix; the ratio of the robust standard error estimate to the model-based standard error estimate if you specify the COVS option in the PROC PHREG statement; the Wald Chi-Square statistic, computed as the square of the parameter estimate divided by its standard error estimate; the degrees of freedom of the Wald chi-square statistic, which has a value of 1 unless the corresponding parameter is redundant or infinite, in which case the value is 0; the  $p$ -value of the Wald chi-square statistic with respect to a chi-square distribution with one degree of freedom; the hazard ratio estimate; and the confidence limits for the hazard ratio if you specified the RISKLIMITS option in the MODEL statement. The ODS name of the “Analysis of Maximum Likelihood Estimates” table is ParameterEstimates.

### ***Solution for Random Effects***

The “Solution for Random Effects” table displays the BLUP estimates of the random effects, the estimated standard errors, the confidence intervals for the random effects, the exponentiated values of the BLUP estimates, and confidence intervals for the exponentiated random effects. The ODS name of the “Solution for Random Effects” table is SolutionR.

### ***Regression Models Selected by Score Criterion***

The “Regression Models Selected by Score Criterion” table is displayed if you specify SELECTION=SCORE in the MODEL statement. The table contains the number of explanatory variables in each model, the score chi-square statistic, and the names of the variables included in the model. The ODS name of the “Regression Models Selected by Score Criterion” table is BestSubsets.

### ***Analysis of Effects Eligible for Entry***

The “Analysis of Effects Eligible for Entry” table is displayed if you use the FORWARD or STEPWISE selection method and you specify the DETAILS option in the MODEL statement. The table contains the score chi-square statistic for testing the significance of each variable not in the model (after adjusting for the variables already in the model), and the  $p$ -value of the chi-square statistic with respect to a chi-square distribution with one degree of freedom. This table is produced before a variable is selected for entry in a forward selection step. The ODS name of the “Analysis of Effects Eligible for Entry” table is EffectsToEntry.

### ***Analysis of Effects Eligible for Removal***

The “Analysis of Effects Eligible for Removal” table is displayed if you use the BACKWARD or STEPWISE selection method and you specify the DETAILS option in the MODEL statement. The table contains the Wald chi-square statistic for testing the significance of each candidate effect for removal, the degrees of freedom of the Wald chi-square, and the corresponding  $p$ -value. This table is produced before an effect is selected for removal. The ODS name of the “Analysis of Effects Eligible for Removal” table is EffectsToRemoval.

### ***Summary of Backward Elimination***

The “Summary of Backward Elimination” table is displayed if you specify the SELECTION=BACKWARD option in the MODEL statement. The table contains the step number, the effects removed at each step, the

corresponding chi-square statistic, the degrees of freedom, and the  $p$ -value. For ODS purpose, the name of the “Summary of Backward Elimination” table is “ModelBuildingSummary.”

### **Summary of Forward Selection**

The “Summary of Forward Selection” table is displayed if you specify the SELECTION=FORWARD option in the MODEL statement. The table contains the step number, the effects entered at each step, the corresponding chi-square statistic, the degrees of freedom, and the  $p$ -value. For ODS purpose, the name of the “Summary of Forward Selection” table is “ModelBuildingSummary.”

### **Summary of Stepwise Selection**

The “Summary of Stepwise Selection” table is displayed if you specify SELECTION=STEPWISE is specified in the MODEL statement. The table contains the step number, the effects entered or removed at each step, the corresponding chi-square statistic, the degrees of freedom, and the corresponding  $p$ -value. For ODS purpose, the name of the “Summary of Stepwise Selection” table is “ModelBuildingSummary.”

### **Covariance Matrix**

The “Covariance Matrix” table is displayed if you specify the COVB option in the MODEL statement. The table contains the estimated covariance matrix for the parameter estimates. For ODS purposes, the name of the “Covariance Matrix” table is “CovB.”

### **Correlation Matrix**

The “Correlation Matrix” table is displayed if you specify the COVB option in the MODEL statement. The table contains the estimated correlation matrix for the parameter estimates. For ODS purposes, the name of the “Correlation Matrix” table is “CorrB.”

### **Hazard Ratios for *label***

The “Hazard Ratios for *label*” table is displayed if you specify the HAZARDRATIO statement. The table displays the estimate and confidence limits for each hazard ratio. The ODS name of the “Hazard Ratios for *label*” table is HazardRatios.

### **Coefficients of Contrast *label***

The “Coefficients of Contrast *label*” table is displayed if you specify the E option in the CONTRAST statement. The table displays the parameter names and the corresponding coefficients of each row of contrast *label*. The ODS name of the “Coefficients of Contrast *label*” table is ContrastCoeff.

### **Contrast Test Results**

The “Contrast Test Results” table is displayed if you specify the CONTRAST statement. The table displays the degrees of freedom, test statistics, and the  $p$ -values for testing each contrast. The ODS name of the “Contrast Test Results” table is ContrastTest.

### **Contrast Estimation and Testing Results by Row**

The “Contrast Estimation and Testing Results by Row” table is displayed if you specify the ESTIMATE option in the CONTRAST statement. The table displays, for each row, the estimate of the linear function of the coefficients, its standard error, and the confidence limits for the linear function. The ODS name of the “Contrast Estimation and Testing Results by Row” table is ContrastEstimate.

**Linear Coefficients for *label***

The “Linear Coefficients *label*” table is displayed if you specify the E option in the TEST statement with *label* being the TEST statement label. The table contains the coefficients and constants of the linear hypothesis. For ODS purposes, the name of the “Linear Coefficients for *label*” table is “TestCoeff.”

**L[cov(b)]L' and Lb-c**

The “L[cov(b)]L' and Lb-c” table is displayed if you specified the PRINT option in a TEST statement with *label* being the TEST statement label. The table displays the intermediate calculations of the Wald test. The ODS name of the “L[cov(b)]L' and Lb-c” table is TestPrint1.

**Ginv(L[cov(b)]L') and Ginv(L[cov(b)]L')(Lb-c)**

The “Ginv(L[cov(b)]L') and Ginv(L[cov(b)]L')(Lb-c)” table is displayed if you specified the PRINT option in a TEST statement with *label* being the TEST statement label. The table displays the intermediate calculations of the Wald test. The ODS name of the “Ginv(L[cov(b)]L') and Ginv(L[cov(b)]L')(Lb-c)” table is TestPrint2.

***label* Test Results**

The “*label* Test Results” table is displayed if you specify a TEST statement with *label* being the TEST statement label. The table contains the Wald chi-square statistic, the degrees of freedom, and the *p*-value. The ODS name of “*label* Test Results” table is TestStmts.

**Average Effect for *label***

The “Average Effect for *label*” table is displayed if the AVERAGE option is specified in a TEST statement with *label* being the TEST statement label. The table contains the weighted average of the parameter estimates for the variables in the TEST statement, the estimated standard error, the z-score, and the *p*-value. The ODS name of the “Average Effect for *label*” is TestAverage.

**Reference Set of Covariates for Plotting**

The “Reference Set of Covariates for Plotting” table is displayed if the PLOTS= option is requested without specifying the COVARIATES= data set in the BASELINE statement. The tables contains the values of the covariates for the reference set, where the reference levels are used for the CLASS variables and the sample averages for the continuous variables.

**Bayesian Analysis Displayed Output****Model Information**

The “Model Information” table displays the two-level name of the input data set, the name and label of the failure time variable, the name and label of the censoring variable and the values indicating censored times, the model (either the Cox model or the piecewise constant baseline hazard model), the name and label of the OFFSET variable, the name and label of the FREQ variable, the name and label of the WEIGHT variable, the method of handling ties in the failure time, the number of burn-in iterations, the number of iterations after the burn-in, and the number of thinning iterations. The ODS name of the “Model Information” table is ModelInfo.

**Number of Observations**

The “Number of Observations” table displays the number of observations read and used in the analysis. The ODS name of the “Number of Observations” is NObs.

### ***Summary of the Number of Event and Censored Values***

The “Summary of the Number of Event and Censored Values” table displays, for each stratum, the breakdown of the number of events and censored values. This table is not produced if the NONSUMMARY option is specified in the PROC PHREG statement. The ODS name of the “Summary of the Number of Event and Censored Values” table is CensoredSummary.

### ***Descriptive Statistics for Continuous Explanatory Variables***

The “Simple Statistics for Continuous Explanatory Variables” table is displayed when you specify the SIMPLE option in the PROC PHREG statement. The table contains, for each stratum, the mean, standard deviation, and minimum and maximum for each continuous explanatory variable in the MODEL statement. For ODS purposes, the name of the “Descriptive Statistics for Continuous Explanatory Variables” table is “SimpleStatistics.”

### ***Class Level Information***

The “Class Level Information” table is displayed if there are CLASS variables in the model. The table lists the categories of every CLASS variable in the model and the corresponding design variable values. The ODS name of the “Class Level Information” table is ClassLevelInfo.

### ***Frequency Distribution of CLASS Variables***

The “Frequency Distribution of CLASS Variables” table is displayed if you specify the SIMPLE option in the PROC PHREG statement and there are CLASS variables in the model. The table lists the frequency of the levels of the CLASS variables. The ODS name of the “Frequency Distribution of CLASS Variables” table is ClassLevelFreq.

### ***Regression Parameter Information***

The “Regression Parameter Information” table displays the names of the parameters and the corresponding level information of effects containing the CLASS variables. The ODS name of the “Regression Parameter Information” table is ParmInfo.

### ***Constant Baseline Hazard Time Intervals***

The “Constant Baseline Hazard Time Intervals” table displays the intervals of constant baseline hazard and the corresponding numbers of failure times and event times. This table is produced only if you specify the PIECEWISE option in the BAYES statement. The ODS name of the “Constant Baseline Hazard Time Intervals” table is Interval.

### ***Maximum Likelihood Estimates***

The “Maximum Likelihood Estimates” table displays, for each parameter, the maximum likelihood estimate, the estimated standard error, and the 95% confidence limits. The ODS name of the “Maximum Likelihood Estimates” table is ParameterEstimates.

### ***Hazard Prior***

The “Hazard Prior” table is displayed if you specify the PIECEWISE=HAZARD option in the BAYES statement. It describes the prior distribution of the hazard parameters. The ODS name of the “Hazard Prior” table is HazardPrior.

**Log-Hazard Prior**

The “Log-Hazard Prior” table is displayed if you specify the `PIECEWISE=LOGHAZARD` option in the `BAYES` statement. It describes the prior distribution of the log-hazard parameters. The ODS name of the “Log-Hazard Prior” table is `HazardPrior`.

**Coefficient Prior**

The “Coefficient Prior” table displays the prior distribution of the regression coefficients. The ODS name of the “Coefficient Prior” table is `CoeffPrior`.

**Initial Values**

The “Initial Values” table is displayed if you specify the `INITIAL` option in the `BAYES` statement. The table contains the initial values of the parameters for the Gibbs sampling. The ODS name of the “Initial Values” table is `InitialValues`.

**Fit Statistics**

The “Fit Statistics” table displays the DIC and pD statistics for each parameter. The ODS name of the “Fit Statistics” table is `FitStatistics`.

**Posterior Summaries**

The “Posterior Summaries” table displays the size of the posterior sample, the mean, the standard error, and the percentiles for each model parameter. The ODS name of the “Posterior Summaries” table is `PostSummaries`.

**Posterior Intervals**

The “Posterior Intervals” table displays the equal-tail interval and the HPD interval for each model parameter. The ODS name of the “Posterior Intervals” table is `PostIntervals`.

**Posterior Covariance Matrix**

The “Posterior Covariance Matrix” table is produced if you include `COV` in the `SUMMARY=` option in the `BAYES` statement. This table displays the sample covariance of the posterior samples. The ODS name of the “Posterior Covariance Matrix” table is `Cov`.

**Posterior Correlation Matrix**

The “Posterior Correlation Matrix” table is displayed if you include `CORR` in the `SUMMARY=` option in the `BAYES` statement. The table contains the sample correlation of the posterior samples. The ODS name of the “Posterior Correlation Matrix” table is `Corr`.

**Posterior Autocorrelations**

The “Posterior Autocorrelations” table displays the lag 1, lag 5, lag 10, and lag 50 autocorrelations for each parameter. The ODS name of the “Posterior Autocorrelations” table is `AutoCorr`.

**Gelman-Rubin Diagnostics**

The “Gelman-Rubin Diagnostics” table is produced if you include `GELMAN` in the `DIAGNOSTIC=` option in the `BAYES` statement. This table displays the estimate of the potential scale reduction factor and its 97.5% upper confidence limit for each parameter. The ODS name of the “Gelman-Rubin Diagnostics” table is `Gelman`.

**Geweke Diagnostics**

The “Geweke Diagnostics” table displays the Geweke statistic and its  $p$ -value for each parameter. The ODS name of the “Geweke Diagnostics” table is Geweke.

**Raftery-Lewis Diagnostics**

The “Raftery-Lewis Diagnostics” tables is produced if you include RAFTERY in the DIAGNOSTIC= option in the BAYES statement. This table displays the Raftery and Lewis diagnostics for each variable. For ODS purposes, the name of the “Raftery-Diagnostics” table is “Raftery.”

**Heidelberger-Welch Diagnostics**

The “Heidelberger-Welch Diagnostics” table is displayed if you include HEIDELBERGER in the DIAGNOSTIC= option in the BAYES statement. This table describes the results of a stationary test and a halfwidth test for each parameter. The ODS name of the “Heidelberger-Welch Diagnostics” table is Heidelberg.

**Effective Sample Sizes**

The “Effective Sample Sizes” table displays, for each parameter, the effective sample size, the correlation time, and the efficiency. The ODS name of the “Effective Sample Sizes” table is ESS.

**Hazard Ratios for label**

The “Hazard Ratios for *label*” table is displayed if you specify the HAZARDRATIO statement. The table displays the posterior summary for each hazard ratio. The summary includes the mean, standard error, quartiles, and equal-tailed and HPD intervals. The ODS name of the “Hazard Ratios for *label*” table is HazardRatios.

**Reference Set of Covariates for Plotting**

The “Reference Set of Covariates for Plotting” table is displayed if the PLOTS= option is requested without specifying the COVARIATES= data set in the BASELINE statement. The table contains the values of the covariates for the reference set, where the reference levels are used for the CLASS variables and the sample averages for the continuous variables.

---

## ODS Table Names

PROC PHREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed separately in Table 67.13 for the maximum likelihood analysis and in Table 67.14 for the Bayesian analysis. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Each of the EFFECT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements creates ODS tables, which are not listed in Table 67.13 and Table 67.14. For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

**Table 67.13** ODS Tables for a Maximum Likelihood Analysis Produced by PROC PHREG

| ODS Table Name | Description           | Statement / Option      |
|----------------|-----------------------|-------------------------|
| BestSubsets    | Best subset selection | MODEL / SELECTION=SCORE |

Table 67.13 continued

| ODS Table Name             | Description                                                  | Statement / Option      |
|----------------------------|--------------------------------------------------------------|-------------------------|
| CensoredSummary            | Summary of event and censored observations                   | Default                 |
| ClassLevelFreq             | Frequency distribution of CLASS variables                    | CLASS, PROC / SIMPLE    |
| ClassLevelInfo             | CLASS variable levels and design variables                   | CLASS                   |
| ClassLevelInfoR            | Class levels for random effects                              | RANDOM                  |
| ContrastCoeff              | L matrix for contrasts                                       | CONTRAST / E            |
| ContrastEstimate           | Individual contrast estimates                                | CONTRAST / ESTIMATE=    |
| ContrastTest               | Wald test for contrasts                                      | CONTRAST                |
| ConvergenceStatus          | Convergence status                                           | Default                 |
| CorrB                      | Estimated correlation matrix of parameter estimators         | MODEL / CORRB           |
| CovB                       | Estimated covariance matrix of parameter estimators          | MODEL / COVB            |
| CovParms                   | Variance estimates of the random effects                     | RANDOM                  |
| EffectsToEnter             | Analysis of effects for entry                                | MODEL / SELECTION=FIS   |
| EffectsToRemove            | Analysis of effects for removal                              | MODEL / SELECTION=BIS   |
| FitStatistics              | Model fit statistics                                         | Default                 |
| FunctionalFormSupTest      | Supremum test for functional form                            | ASSESS / VAR=           |
| GlobalScore                | Global chi-square test                                       | MODEL / NOFIT           |
| GlobalTests                | Tests of the global null hypothesis                          | Default                 |
| HazardRatios               | Hazard ratios and confidence limits                          | HAZARDRATIO             |
| IterHistory                | Iteration history                                            | MODEL / ITPRINT         |
| LastGradient               | Last evaluation of gradient                                  | MODEL / ITPRINT         |
| ModelBuildingSummary       | Summary of model building                                    | MODEL / SELECTION=BIFIS |
| ModelInfo                  | Model information                                            | Default                 |
| NObs                       | Number of observations                                       | Default                 |
| ParameterEstimates         | Maximum likelihood estimates of model parameters             | Default                 |
| ProportionalHazardsSupTest | Supremum test for proportional hazards assumption            | ASSESS / PH             |
| ResidualChiSq              | Residual chi-square                                          | MODEL / SELECTION=FIB   |
| ReferenceSet               | Reference set of covariates for plotting                     | PROC / PLOTS=           |
| RiskSetInfo                | Risk set information                                         | PROC / ATRISK           |
| SimpleStatistics           | Summary statistics of input continuous explanatory variables | PROC / SIMPLE           |
| SolutionR                  | Solutions for random effects                                 | RANDOM / SOLUTION       |
| TestAverage                | Average effect for test                                      | TEST / AVERAGE          |
| TestCoeff                  | Coefficients for linear hypotheses                           | TEST / E                |
| TestPrint1                 | $L[\text{cov}(\mathbf{b})]L'$ and $L\mathbf{b}-\mathbf{c}$   | TEST / PRINT            |

**Table 67.13** *continued*

| ODS Table Name | Description                                                                                                                                                             | Statement / Option    |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------|
| TestPrint2     | $G_{\text{inv}}(\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}')$ and<br>$G_{\text{inv}}(\mathbf{L}[\text{cov}(\mathbf{b})]\mathbf{L}')(\mathbf{L}\mathbf{b}-\mathbf{c})$ | TEST / PRINT          |
| TestStmtns     | Linear hypotheses testing results                                                                                                                                       | TEST                  |
| Type1          | Type 1 likelihood ratio tests                                                                                                                                           | MODEL / TYPE1         |
| Type3          | Type 3 chi-square tests                                                                                                                                                 | MODEL / TYPE3   CLASS |

**Table 67.14** ODS Table for a Bayesian Analysis Produced by PROC PHREG

| ODS Table Name     | Description                                       | Statement / Option                  |
|--------------------|---------------------------------------------------|-------------------------------------|
| AutoCorr           | Autocorrelations of the posterior samples         | BAYES                               |
| CensoredSummary    | Numbers of the event and censored observations    | PROC                                |
| ClassLevelFreq     | Frequency distribution of CLASS variables         | CLASS, PROC / SIMPLE                |
| ClassLevelInfo     | CLASS variable levels and design variables        | CLASS                               |
| CoeffPrior         | Prior distribution of the regression coefficients | BAYES                               |
| Corr               | Posterior correlation matrix                      | BAYES / SUMMARY=CORR                |
| Cov                | Posterior covariance Matrix                       | BAYES / SUMMARY=COV                 |
| ESS                | Effective sample sizes                            | BAYES / DIAGNOSTICS=ESS             |
| FitStatistics      | Fit statistics                                    | BAYES                               |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC PHREG generates are listed separately in [Table 67.15](#) for the maximum likelihood analysis and in [Table 67.16](#) for the Bayesian analysis. When the ODS Graphics are in effect in a Bayesian analysis, each of the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots associated with their analyses. For information of these plots, see the corresponding sections of Chapter 19, “[Shared Concepts and Topics.](#)”

**Table 67.15** Graphs for a Maximum Likelihood Analysis Produced by PROC PHREG

| ODS Graph Name      | Plot Description                              | Statement / Option     |
|---------------------|-----------------------------------------------|------------------------|
| CumhazPlot          | Cumulative hazard function plot               | PROC / PLOTS=CUMHAZ    |
| CumulativeResiduals | Cumulative martingale residual plot           | ASSESS / VAR=          |
| CumResidPanel       | Panel plot of cumulative martingale residuals | ASSESS / VAR=, CRPANEL |
| MCFPlot             | Mean cumulative function plot                 | PROC / PLOTS=MCF       |
| ScoreProcess        | Standardized score process plot               | ASSESS / PH            |
| SurvivalPlot        | Survivor function plot                        | PROC / PLOTS=SURVIVAL  |

**Table 67.16** Graphs for a Bayesian Analysis Produced by PROC PHREG

| ODS Graph Name | Plot Description                                   | Statement / Option                     |

| TDPanel        | Trace and density panel                            | BAYES / PLOTS=(TRACE DENSITY)          |
| TracePanel     | Trace panel                                        | BAYES / PLOTS=TRACE                    |
| TracePlot      | Trace plot                                         | BAYES / PLOTS(UNPACK)=TRACE            |

## Examples: PHREG Procedure

This section contains 14 examples of PROC PHREG applications. The first 12 examples use the classical method of maximum likelihood, while the last two examples illustrate the Bayesian methodology.

### Example 67.1: Stepwise Regression

Krall, Uthoff, and Harley (1975) analyzed data from a study on multiple myeloma in which researchers treated 65 patients with alkylating agents. Of those patients, 48 died during the study and 17 survived. The following DATA step creates the data set Myeloma. The variable Time represents the survival time in months from diagnosis. The variable VStatus consists of two values, 0 and 1, indicating whether the patient was alive or dead, respectively, at the end of the study. If the value of VStatus is 0, the corresponding value of Time is censored. The variables thought to be related to survival are LogBUN (log(BUN) at diagnosis), HGB (hemoglobin at diagnosis), Platelet (platelets at diagnosis: 0=abnormal, 1=normal), Age (age at diagnosis, in years), LogWBC (log(WBC) at diagnosis), Frac (fractures at diagnosis: 0=none, 1=present), LogPBM (log percentage of plasma cells in bone marrow), Protein (proteinuria at diagnosis), and SCalc (serum calcium at diagnosis). Interest lies in identifying important prognostic factors from these nine explanatory variables.

```

The stepwise selection process consists of a series of alternating forward selection and backward elimination steps. The former adds variables to the model, while the latter removes variables from the model.

The following statements use PROC PHREG to produce a stepwise regression analysis. Stepwise selection is requested by specifying the SELECTION=STEPWISE option in the MODEL statement. The option SLENTRY=0.25 specifies that a variable has to be significant at the 0.25 level before it can be entered into the model, while the option SLSTAY=0.15 specifies that a variable in the model has to be significant at the 0.15 level for it to remain in the model. The DETAILS option requests detailed results for the variable selection process.

```

proc phreg data=Myeloma;
 model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC
 Frac LogPBM Protein SCalc
 / selection=stepwise slentry=0.25
 slstay=0.15 details;
run;

```

Results of the stepwise regression analysis are displayed in [Output 67.1.1](#) through [Output 67.1.7](#).

Individual score tests are used to determine which of the nine explanatory variables is first selected into the model. In this case, the score test for each variable is the global score test for the model containing that variable as the only explanatory variable. [Output 67.1.1](#) displays the chi-square statistics and the corresponding  $p$ -values. The variable LogBUN has the largest chi-square value (8.5164), and it is significant ( $p = 0.0035$ ) at the SLENTY=0.25 level. The variable LogBUN is thus entered into the model.

**Output 67.1.1** Individual Score Test Results for All Variables

 Testing Global Null Hypothesis: BETA=0

 Test Chi-Square DF Pr > ChiSq
Likelihood Ratio 7.7572 1 0.0053
Score 8.5164 1 0.0035
Wald 8.3392 1 0.0039

 Analysis of Maximum Likelihood Estimates

 Parameter DF Parameter Estimate Standard Error Chi-Square Pr > ChiSq Hazard Ratio
LogBUN 1 1.74595 0.60460 8.3392 0.0039 5.731

```

The next step consists of selecting another variable to add to the model. Output 67.1.3 displays the chi-square statistics and  $p$ -values of individual score tests (adjusted for LogBUN) for the remaining eight variables. The score chi-square for a given variable is the value of the likelihood score test for testing the

significance of the variable in the presence of LogBUN. The variable HGB is selected because it has the highest chi-square value (4.3468), and it is significant ( $p = 0.0371$ ) at the SLENTRY=0.25 level.

### Output 67.1.3 Score Tests Adjusted for the Variable LogBUN

Output 67.1.5 shows Step 3 of the selection process, in which the variable SCalc is added, resulting in the model with LogBUN, HGB, and SCalc as the explanatory variables. Note that SCalc has the smallest Wald chi-square statistic, and it is not significant ( $p = 0.1782$ ) at the SLSTAY=0.15 level.

**Output 67.1.5** Third Model in the Stepwise Regression

| Step 3. Effect SCalc is entered. The model contains the following effects: |     |                    |    |                 |  |  |
|----------------------------------------------------------------------------|-----|--------------------|----|-----------------|--|--|
| LogBUN                                                                     | HGB | SCalc              |    |                 |  |  |
| Convergence Status                                                         |     |                    |    |                 |  |  |
| Convergence criterion (GCONV=1E-8) satisfied.                              |     |                    |    |                 |  |  |

**Output 67.1.6** *continued*

**NOTE:** Model building terminates because the effect to be entered is the effect that was removed in the last step.

The procedure also displays a summary table of the steps in the stepwise selection process, as shown in Output 67.1.7.

**Output 67.1.7** Model Selection Summary

| Summary of Stepwise Selection |         |         |    |        |            |            |            |
|-------------------------------|---------|---------|----|--------|------------|------------|------------|
| Step                          | Effect  |         | DF | Number |            | Wald       |            |
|                               | Entered | Removed |    | In     | Chi-Square | Chi-Square | Pr > ChiSq |
| 1                             | LogBUN  |         | 1  | 1      | 8.5164     |            | 0.0035     |
| 2                             | HGB     |         | 1  | 2      | 4.3468     |            | 0.0371     |
| 3                             | SCalc   |         | 1  | 3      | 1.8225     |            | 0.1770     |
| 4                             |         | SCalc   | 1  | 2      |            | 1.8127     | 0.1782     |

The stepwise selection process results in a model with two explanatory variables, LogBUN and HGB.

---

## Example 67.2: Best Subset Selection

An alternative to stepwise selection of variables is best subset selection. This method uses the branch-and-bound algorithm of Furnival and Wilson (1974) to find a specified number of best models containing one, two, or three variables, and so on, up to the single model containing all of the explanatory variables. The criterion used to determine the “best” subset is based on the global score chi-square statistic. For two models A and B, each having the same number of explanatory variables, model A is considered to be better than model B if the global score chi-square statistic for A exceeds that for B.

In the following statements, best subset selection analysis is requested by specifying the SELECTION=SCORE option in the MODEL statement. The BEST=3 option requests the procedure to identify only the three best models for each size. In other words, PROC PHREG will list the three models having the highest score statistics of all the models possible for a given number of covariates.

```
proc phreg data=Myeloma;
 model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC
 Frac LogPBM Protein SCalc
 / selection=score best=3;
run;
```

Output 67.2.1 displays the results of this analysis. The number of explanatory variables in the model is given in the first column, and the names of the variables are listed on the right. The models are listed in descending order of their score chi-square values within each model size. For example, among all models containing two explanatory variables, the model that contains the variables LogBUN and HGB has the largest score value (12.7252), the model that contains the variables LogBUN and Platelet has the second-largest score

value (11.1842), and the model that contains the variables LogBUN and SCalc has the third-largest score value (9.9962).

### Output 67.2.1 Best Variable Combinations

| The PHREG Procedure                           |                  |                                                          |  |

### Example 67.3: Modeling with Categorical Predictors

Consider the data for the Veterans Administration lung cancer trial presented in Appendix 1 of Kalbfleisch and Prentice (1980). In this trial, males with advanced inoperable lung cancer were randomized to a standard therapy and a test chemotherapy. The primary endpoint for the therapy comparison was time to death in days, represented by the variable Time. Negative values of Time are censored values. The data include information about a number of explanatory variables: Therapy (type of therapy: standard or test), Cell (type

of tumor cell: adeno, large, small, or squamous), Prior (prior therapy: 0=no, 10=yes), Age (age, in years), Duration (months from diagnosis to randomization), and Kps (Karnofsky performance scale). A censoring indicator variable, Censor, is created from the data, with the value 1 indicating a censored time and the value 0 indicating an event time. The following DATA step saves the data in the data set VALung.

```
proc format;
 value yesno 0='no' 10='yes';
run;

data VALung;
 drop check m;
 retain Therapy Cell;
 infile cards column=column;

The following statements use the PHREG procedure to fit the Cox proportional hazards model to these data. The variables `Prior`, `Cell`, and `Therapy`, which are categorical variables, are declared in the `CLASS` statement. By default, PROC PHREG parameterizes the `CLASS` variables by using the reference coding with the last category as the reference category. However, you can explicitly specify the reference category of your choice. Here, `Prior=no` is chosen as the reference category for prior therapy, `Cell=large` is chosen as the reference category for type of tumor cell, and `Therapy=standard` is chosen as the reference category for the type of therapy. In the `MODEL` statement, the term `Prior|Therapy` is just another way of specifying the main effects `Prior`, `Therapy`, and the `Prior*Therapy` interaction.

```

proc phreg data=VALung;
 class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
 model Time*Status(0) = Kps Duration Age Cell Prior|Therapy;
run;

```

Coding of the `CLASS` variables is displayed in [Output 67.3.1](#). There is one dummy variable for `Prior` and one for `Therapy`, since both variables are binary. The dummy variable has a value of 0 for the reference category (`Prior=no`, `Therapy=standard`). The variable `Cell` has four categories and is represented by three dummy variables. Note that the reference category, `Cell=large`, has a value of 0 for all three dummy variables.

**Output 67.3.1** Reference Coding of CLASS Variables

| The PHREG Procedure     |          |                  |   |   |
|-------------------------|----------|------------------|---|---|
| Class Level Information |          |                  |   |   |
| Class                   | Value    | Design Variables |   |   |
| Prior                   | no       | 0                |   |   |
|                         | yes      | 1                |   |   |
| Cell                    | adeno    | 1                | 0 | 0 |
|                         | large    | 0                | 0 | 0 |
|                         | small    | 0                | 1 | 0 |
|                         | squamous | 0                | 0 | 1 |
| Therapy                 | standard | 0                |   |   |
|                         | test     | 1                |   |   |

The test results of individual model effects are shown in [Output 67.3.2](#). There is a strong prognostic effect of Kps on patient's survivorship ( $p < 0.0001$ ), and the survival times for patients of different Cell types differ significantly ( $p = 0.0003$ ). The Prior\*Therapy interaction is marginally significant ( $p = 0.0416$ )—that is, prior therapy might play a role in whether one treatment is more effective than the other.

**Output 67.3.2** Wald Tests of Individual Effects

| Type 3 Tests  |    |                    |            |
|---------------|----|--------------------|------------|
| Effect        | DF | Wald<br>Chi-Square | Pr > ChiSq |

| Duration      | 1  | 0.1159             | 0.7335     |
| Age           | 1  | 1.9772             | 0.1597     |
| Cell          | 3  | 18.5339            | 0.0003     |
| Prior         | 1  | 2.5296             | 0.1117     |
| Therapy       | 1  | 5.2349             | 0.0221     |
| Prior*Therapy | 1  | 4.1528             | 0.0416     |

In the Cox proportional hazards model, the effects of the covariates are to act multiplicatively on the hazard of the survival time, and therefore it is a little easier to interpret the corresponding hazard ratios than the regression parameters. For a parameter that corresponds to a continuous variable, the hazard ratio is the ratio of hazard rates for an increase of one unit of the variable. From [Output 67.3.3](#), the hazard ratio estimate for Kps is 0.968, meaning that an increase of 10 units in Karnofsky performance scale will shrink the hazard rate by  $1 - (0.968)^{10} = 28\%$ . For a CLASS variable parameter, the hazard ratio presented in the [Output 67.3.3](#) is the ratio of the hazard rates between the given category and the reference category. The hazard rate of

Cell=adeno is 219% that of Cell=large, the hazard rate of Cell=small is 62% that of Cell=large, and the hazard rate of Cell=squamous is only 66% that of Cell=large. Hazard ratios for Prior and Therapy are missing since the model contains the Prior\*Therapy interaction. You can use the HAZARDRATIO statement to obtain the hazard ratios for a main effect in the presence of interaction as shown later in this example.

The following PROC PHREG statements illustrate the use of the backward elimination process to identify the effects that affect the survivorship of the lung cancer patients. The option **SELECTION=BACKWARD** is specified to carry out the backward elimination. The option **SLSTAY=0.1** specifies the significant level for retaining the effects in the model.

```
proc phreg data=VALung;
 class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
 model Time*Status(0) = Kps Duration Age Cell Prior|Therapy
 / selection=backward slstay=0.1;
run;
```

Results of the backward elimination process are summarized in **Output 67.3.4**. The effect Duration was eliminated first and was followed by Age.

**Output 67.3.4** Effects Eliminated from the Model

**Output 67.3.5** shows the Type 3 analysis of effects and the maximum likelihood estimates of the regression coefficients of the model. Without controlling for Age and Duration, KPS and Cell remain significant, but the Prior\*Therapy interaction is less prominent than before ( $p = 0.0871$ ) though still significant at 0.1 level.

**Output 67.3.5** Type 3 Effects and Parameter Estimates for the Selected Model

Finally, the following statements refit the previous model and computes hazard ratios at settings beyond those displayed in the “Analysis of Maximum Likelihood Estimates” table. You can use either the HAZARDRATIO statement or the CONTRAST statement to obtain hazard ratios. Using the CONTRAST statement to compute hazard ratios for CLASS variables can be a daunting task unless you are familiar with the parameterization schemes (see the section “Parameterization of Model Effects” on page 383 of Chapter 19, “Shared Concepts and Topics,” for details), but you have control over which specific hazard ratios you want to compute. HAZARDRATIO statements, on the other hand, are designed specifically to provide hazard ratios. They are easy to use and you can also request both the Wald confidence limits and the profile-likelihood confidence limits; the latter is not available for the CONTRAST statements. Three HAZARDRATIO statements are specified; each has the CL=BOTH option to request both the Wald confidence limits and the profile-likelihood limits. The first HAZARDRATIO statement, labeled ‘H1’, estimates the hazard ratio for an increase of 10 units in the KPS; the UNITS= option specifies the number of units increase. The second HAZARDRATIO statement, labeled ‘H2’ computes the hazard ratios for comparing any pairs of tumor Cell

types. The third HAZARDRATIO statement, labeled 'H3', compares the test therapy with the standard therapy. The DIFF=REF option specifies that each nonreference category is compared to the reference category. The purpose of using DIFF=REF here is to ensure that the hazard ratio is comparing the test therapy to the standard therapy instead of the other way around. Three CONTRAST statements, labeled 'C1', 'C2', and 'C3', parallel to the HAZARDRATIO statements 'H1', 'H2', and 'H3', respectively, are specified. The ESTIMATE=EXP option specifies that the linear predictors be estimated in the exponential scale, which are precisely the hazard ratios.

```
proc phreg data=VALung;
 class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
 model Time*Status(0) = Kps Cell Prior|Therapy;
 hazardratio 'H1' Kps / units=10 cl=both;
 hazardratio 'H2' Cell / cl=both;
 hazardratio 'H3' Therapy / diff=ref cl=both;
 contrast 'C1' Kps 10 / estimate=exp;
 contrast 'C2' cell 1 0 0, /* adeno vs large */
 cell 1 -1 0, /* adeno vs small */
 cell 1 0 -1, /* adeno vs squamous */
 cell 0 -1 0, /* large vs small */
 cell 0 0 -1, /* large vs Squamous */
 cell 0 1 -1 /* small vs squamous */
 / estimate=exp;
 contrast 'C3' Prior 0 Therapy 1 Prior*Therapy 0,
 Prior 0 Therapy 1 Prior*Therapy 1 / estimate=exp;
run;
```

Output 67.3.6 displays the results of the three HAZARDRATIO statements in separate tables. Results of the three CONTRAST statements are shown in one table in Output 67.3.7. However, point estimates and the Wald confidence limits for the hazard ratio agree in between the two outputs.

**Output 67.3.6** Results from HAZARDRATIO Statements

**Example 67.4: Firth's Correction for Monotone Likelihood**

In fitting the Cox regression model by maximizing the partial likelihood, the estimate of an explanatory variable X will be infinite if the value of X at each uncensored failure time is the largest of all the values of X in the risk set at that time (Tsiatis 1981; Bryson and Johnson 1981). You can exploit this information to artificially create a data set that has the condition of monotone likelihood for the Cox regression. The following DATA step modifies the Myeloma data in Example 67.1 to create a new explanatory variable, Contrived, which has the value 1 if the observed time is less than or equal to 65 and has the value 0 otherwise. The phenomenon of monotone likelihood will be demonstrated in the new data set Myeloma2.

```
data Myeloma2;
 set Myeloma;
 Contrived= (Time <= 65);
run;
```

For illustration purposes, consider a Cox model with three explanatory variables, one of which is the variable Contrived. The following statements invoke PROC PHREG to perform the Cox regression. The IPRINT option is specified in the MODEL statement to print the iteration history of the optimization.

```
proc phreg data=Myeloma2;
 model Time*Vstatus(0)=LOGbun HGB Contrived / itprint;
run;
```

The symptom of monotony is demonstrated in [Output 67.4.1](#). The log likelihood converges to the value of  $-136.56$  while the coefficient for `Contrived` diverges. Although the Newton-Raphson optimization process did not fail, it is obvious that convergence is questionable. A close examination of the standard errors in the “Analysis of Maximum Likelihood Estimates” table reveals a very large value for the coefficient of `Contrived`. This is very typical of a diverged estimate.

**Output 67.4.1** Monotone Likelihood Behavior Displayed

Next, the Firth correction was applied as shown in the following statements. Also, the profile-likelihood confidence limits for the hazard ratios are requested by using the `RISKLIMITS=PL` option.

```
proc phreg data=Myeloma2;
 model Time*Vstatus(0)=LogBUN HGB Contrived /
 firth risklimits=pl itprint;
run;
```

PROC PHREG uses the penalized likelihood maximum to obtain a finite estimate for the coefficient of Contrived (Output 67.4.2). The much preferred profile-likelihood confidence limits, as shown in (Heinze and Schemper 2001), are also displayed.

**Example 67.5: Conditional Logistic Regression for m:n Matching**

Conditional logistic regression is used to investigate the relationship between an outcome and a set of prognostic factors in matched case-control studies. The outcome is whether the subject is a case or a control. If there is only one case and one control, the matching is 1:1. The m:n matching refers to the situation in which there is a varying number of cases and controls in the matched sets. You can perform conditional logistic regression with the PHREG procedure by using the discrete logistic model and forming a stratum for each matched set. In addition, you need to create dummy survival times so that all the cases in a matched set have the same event time value, and the corresponding controls are censored at later times.

Consider the following set of low infant birth-weight data extracted from Appendix 1 of Hosmer and Lemeshow (1989). These data represent 189 women, of whom 59 had low-birth-weight babies and 130

had normal-weight babies. Under investigation are the following risk factors: weight in pounds at the last menstrual period (LWT), presence of hypertension (HT), smoking status during pregnancy (Smoke), and presence of uterine irritability (UI). For HT, Smoke, and UI, a value of 1 indicates a “yes” and a value of 0 indicates a “no.” The woman’s age (Age) is used as the matching variable. The SAS data set LBW contains a subset of the data corresponding to women between the ages of 16 and 32.

```

The variable Low is used to determine whether the subject is a case (Low=1, low-birth-weight baby) or a control (Low=0, normal-weight baby). The dummy time variable Time takes the value 1 for cases and 2 for controls.

The following statements produce a conditional logistic regression analysis of the data. The variable Time is the response, and Low is the censoring variable. Note that the data set is created so that all the cases have the same event time and the controls have later censored times. The matching variable Age is used in the STRATA statement so that each unique age value defines a stratum. The variables LWT, Smoke, HT, and UI are specified as explanatory variables. The TIES=DISCRETE option requests the discrete logistic model.

```
proc phreg data=LBW;
 model Time*Low(0)= LWT Smoke HT UI / ties=discrete;
 strata Age;
run;
```

The procedure displays a summary of the number of event and censored observations for each stratum. These are the number of cases and controls for each matched set shown in [Output 67.5.1](#).

**Output 67.5.1** Summary of Number of Case and Controls

Results of the conditional logistic regression analysis are shown in [Output 67.5.2](#). Based on the Wald test for individual variables, the variables LWT, Smoke, and HT are statistically significant while UI is marginal.

The hazard ratios, computed by exponentiating the parameter estimates, are useful in interpreting the results of the analysis. If the hazard ratio of a prognostic factor is larger than 1, an increment in the factor increases the hazard rate. If the hazard ratio is less than 1, an increment in the factor decreases the hazard rate. Results indicate that women were more likely to have low-birth-weight babies if they were underweight in the last menstrual cycle, were hypertensive, smoked during pregnancy, or suffered uterine irritability.

For matched case-control studies with one case per matched set (1:n matching), the likelihood function for the conditional logistic regression reduces to that of the Cox model for the continuous time scale. For this situation, you can use the default TIES=BRESLOW.

---

**Example 67.6: Model Using Time-Dependent Explanatory Variables**

Time-dependent variables can be used to model the effects of subjects transferring from one treatment group to another. One example of the need for such strategies is the Stanford heart transplant program. Patients are accepted if physicians judge them suitable for heart transplant. Then, when a donor becomes available, physicians choose transplant recipients according to various medical criteria. A patient’s status can be changed during the study from waiting for a transplant to being a transplant recipient. Transplant status can be defined by the time-dependent covariate function  $z = z(t)$  as

$$z(t) = \begin{cases} 0 & \text{if the patient has not received the transplant at time } t \\ 1 & \text{if the patient has received the transplant at time } t \end{cases}$$

The Stanford heart transplant data that appear in Crowley and Hu (1977) consist of 103 patients, 69 of whom received transplants. The data are saved in a SAS data set called Heart in the following DATA step. For each patient in the program, there is a birth date (Bir\_Date), a date of acceptance (Acc\_Date), and a date last seen (Ter\_Date). The survival time (Time) in days is defined as  $\text{Time} = \text{Ter\_Date} - \text{Acc\_Date}$ . The survival time is said to be uncensored (Status=1) or censored (Status=0), depending on whether Ter\_Date is the date of death or the closing date of the study. The age, in years, at acceptance into the program is  $\text{Acc\_Age} = (\text{Acc\_Date} - \text{Bir\_Date}) / 365$ . Previous open-heart surgery for each patient is indicated by the variable PrevSurg. For each transplant recipient, there is a date of transplant (Xpl\_Date) and three measures (NMismatch, Antigen, Mismatch) of tissue-type mismatching. The waiting period (WaitTime) in days for a transplant recipient is calculated as  $\text{WaitTime} = \text{Xpl\_Date} - \text{Acc\_Date}$ , and the age (in years) at transplant is  $\text{Xpl\_Age} = (\text{Xpl\_Date} - \text{Bir\_Date}) / 365$ . For those who do not receive heart transplants, the WaitTime, Xpl\_Age, NMismatch, Antigen, and Mismatch variables contain missing values.

The input data contain dates that have a two-digit year representation. The SAS option YEARCUTOFF=1900 is specified to ensure that a two-digit year xx is year 19xx.

```

Crowley and Hu (1977) have presented a number of analyses to assess the effects of various explanatory variables on the survival of patients. This example fits two of the models that they have considered.

The first model consists of two explanatory variables—the transplant status and the age at acceptance. The transplant status (XStatus) is a time-dependent variable defined by the programming statements between the MODEL statement and the RUN statement. The XStatus variable takes the value 1 or 0 at time  $t$  (measured from the date of acceptance), depending on whether or not the patient has received a transplant at that time. Note that the value of XStatus changes for subjects in each risk set (subjects still alive just before each distinct event time); therefore, the variable cannot be created in the DATA step. The variable

Acc\_Age, which is not time dependent, accounts for the possibility that pretransplant risks vary with age. The following statements fit this model:

```
proc phreg data= Heart;
 model Time*Status(0)= XStatus Acc_Age;
 if (WaitTime = . or Time < WaitTime) then XStatus=0.;
 else XStatus= 1.0;
run;
```

Results of this analysis are shown in [Output 67.6.1](#). Transplantation appears to be associated with a slight decrease in risk, although the effect is not significant ( $p = 0.8261$ ). The age at acceptance as a pretransplant risk factor adds significantly to the model ( $p = 0.0289$ ). The risk increases significantly with age at acceptance.

The second model consists of three explanatory variables—the transplant status, the transplant age, and the mismatch score. Four transplant recipients who were not typed have no Mismatch values; they are excluded from the analysis by the use of a WHERE clause. The transplant age (XAge) and the mismatch score (XScore) are also time dependent and are defined in a fashion similar to that of XStatus. While the patient is waiting for a transplant, XAge and XScore have a value of 0. After the patient has migrated to the recipient population, XAge takes on the value of Xpl\_Age (transplant age for the recipient), and XScore takes on the value of Mismatch (a measure of the degree of dissimilarity between donor and recipient). The following statements fit this model:

```
proc phreg data= Heart;
 model Time*Status(0)= XStatus XAge XScore;
 where NotTyped ^= 'y';
 if (WaitTime = . or Time < WaitTime) then do;
 XStatus=0.;
 XAge=0.;
 XScore= 0.;
 end;
 else do;
 XStatus= 1.0;
 XAge= Xpl_Age;
 XScore= Mismatch;
 end;
run;
```

Results of the analysis are shown in [Output 67.6.2](#). Note that only 99 patients are included in this analysis, instead of 103 patients as in the previous analysis, since four transplant recipients who were not typed are excluded. The variable XAge is statistically significant ( $p = 0.0143$ ), with a hazard ratio exceeding 1. Therefore, patients who had a transplant at younger ages lived longer than those who received a transplant later in their lives. The variable XScore has only minimal effect on the survival ( $p = 0.1121$ ).

## Example 67.7: Time-Dependent Repeated Measurements of a Covariate

Repeated determinations can be made during the course of a study of variables thought to be related to survival. Consider an experiment to study the dosing effect of a tumor-promoting agent. Forty-five rodents initially exposed to a carcinogen were randomly assigned to three dose groups. After the first death of an animal, the rodents were examined every week for the number of papillomas. Investigators were interested in determining the effects of dose on the carcinoma incidence after adjusting for the number of papillomas.

The input data set TUMOR consists of the following 19 variables:

- ID (subject identification)
- Time (survival time of the subject)
- Dead (censoring status where 1=dead and 0=censored)
- Dose (dose of the tumor-promoting agent)
- P1–P15 (number of papillomas at the 15 times that animals died. These 15 death times are weeks 27, 34, 37, 41, 43, 45, 46, 47, 49, 50, 51, 53, 65, 67, and 71. For instance, subject 1 died at week 47; it had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. For an animal that died before week 71, the number of papillomas is missing for those times beyond its death.)

The following SAS statements create the data set TUMOR:

```
data Tumor;
 infile datalines missover;
 input ID Time Dead Dose P1-P15;

The number of papillomas (NPap) for each animal in the study was measured repeatedly over time. One way of handling time-dependent repeated measurements in the PHREG procedure is to use programming statements to capture the appropriate covariate values of the subjects in each risk set. In this example, NPap is a time-dependent explanatory variable with values that are calculated by means of the programming statements shown in the following SAS statements:

```

proc phreg data=Tumor;
 model Time*Dead(0)=Dose NPap;
 array pp{*} P1-P14;
 array tt{*} t1-t15;
 t1=27; t2=34; t3=37; t4=41; t5=43;
 t6=45; t7=46; t8=47; t9=49; t10=50;
 t11=51; t12=53; t13=65; t14=67; t15=71;
 if Time < tt[1] then NPap=0;
 else if time >= tt[15] then NPap=P15;
 else do i=1 to dim(pp);
 if tt[i] <= Time < tt[i+1] then NPap= pp[i];
 end;
run;

```

At each death time, the NPap value of each subject in the risk set is recalculated to reflect the actual number of papillomas at the given death time. For instance, subject one in the data set Tumor was in the risk sets at weeks 27 and 34; at week 27, the animal had no papilloma, while at week 34, it had five papillomas. Results of the analysis are shown in [Output 67.7.1](#). After the number of papillomas is adjusted for, the dose effect of the tumor-promoting agent is not statistically significant.

## Output 67.7.1 Cox Regression Analysis on the Survival of Rodents

Another way to handle time-dependent repeated measurements in the PHREG procedure is to use the counting process style of input. Multiple records are created for each subject, one record for each distinct pattern of the time-dependent measurements. Each record contains a T1 value and a T2 value representing the time interval (T1,T2] during which the values of the explanatory variables remain unchanged. Each record also contains the censoring status at T2.

One advantage of using the counting process formulation is that you can easily obtain various residuals and influence statistics that are not available when programming statements are used to compute the values of the time-dependent variables. On the other hand, creating multiple records for the counting process formulation requires extra effort in data manipulation.

Consider a counting process style of input data set named Tumor1. It contains multiple observations for each subject in the data set Tumor. In addition to variables ID, Time, Dead, and Dose, four new variables are generated:

- T1 (left endpoint of the risk interval)
- T2 (right endpoint of the risk interval)
- NPap (number of papillomas in the time interval (T1,T2])
- Status (censoring status at T2)

For example, five observations are generated for the rodent that died at week 47 and that had no papilloma at week 27, five papillomas at week 34, six at week 37, eight at week 41, and 10 at weeks 43, 45, 46, and 47. The values of T1, T2, NPap, and Status for these five observations are (0,27,0,0), (27,34,5,0), (34,37,6,0), (37,41,8,0), and (41,47,10,1). Note that the variables ID, Time, and Dead are not needed for the estimation of the regression parameters, but they are useful for plotting the residuals.

The following SAS statements create the data set Tumor1:

```
data Tumor1(keep=ID Time Dead Dose T1 T2 NPap Status);
 array pp{*} P1-P14;
 array qq{*} P2-P15;
 array tt{1:15} _temporary_
 (27 34 37 41 43 45 46 47 49 50 51 53 65 67 71);
 set Tumor;
 T1 = 0;
 T2 = 0;
 Status = 0;
 if (Time = tt[1]) then do;
 T2 = tt[1];
 NPap = p1;
 Status = Dead;
 output;
 end;
 else do _i_=1 to dim(pp);
 if (tt[_i_] = Time) then do;
 T2= Time;
 NPap = pp[_i_];
 Status = Dead;
 output;
 end;
 end;
```

```

 else if (tt[_i_] < Time) then do;
 if (pp[_i_] ^= qq[_i_]) then do;
 if qq[_i_] = . then T2= Time;
 else T2= tt[_i_];
 NPap= pp[_i_];
 Status= 0;
 output;
 T1 = T2;
 end;
 end;
 end;
end;
if (Time >= tt[15]) then do;
 T2 = Time;
 NPap = P15;
 Status = Dead;
 output;
end;
run;

```

In the following SAS statements, the counting process MODEL specification is used. The DFBETA statistics are output to a SAS data set named Out1. Note that Out1 contains multiple observations for each subject—that is, one observation for each risk interval (T1,T2).

```

proc phreg data=Tumor1;
 model (T1,T2)*Status(0)=Dose NPap;
 output out=Out1 resmart=Mart dfbeta=db1-db2;
 id ID Time Dead;
run;

```

The output from PROC PHREG (not shown) is identical to [Output 67.7.1](#) except for the “Summary of the Number of Event and Censored Values” table. The number of event observations remains unchanged between the two specifications of PROC PHREG, but the number of censored observations differs due to the splitting of each subject’s data into multiple observations for the counting process style of input.

Next, the MEANS procedure sums up the component statistics for each subject and outputs the results to a SAS data set named Out2:

```

proc means data=Out1 noprint;
 by ID Time Dead;
 var Mart db1-db2;
 output out=Out2 sum=Mart db_Dose db_NPap;
run;

```

Finally, DFBETA statistics are plotted against subject ID for easy identification of influential points:

```

title 'DfBetas for Dose';
proc sgplot data=Out2;
 yaxis label="DfBeta" grid;
 refline 0 / axis=y;
 scatter y=db_Dose x=ID;
run;
title 'DfBetas for NPap';
proc sgplot data=Out2;
 yaxis label="DfBeta" grid;
 refline 0 / axis=y;
 scatter y=db_NPap x=ID;
run;

```

The plots of the DFBETA statistics are shown in [Output 67.7.2](#) and [Output 67.7.3](#). Subject 30 appears to have a large influence on both the Dose and NPap coefficients. Subjects 31 and 35 have considerable influences on the DOSE coefficient, while subjects 22 and 44 have rather large influences on the NPap coefficient.

**Output 67.7.2** Plot of DFBETA Statistic for DOSE versus Subject Number

**Output 67.7.3** Plot of DFBETA Statistic for NPAP versus Subject Number

### Example 67.8: Survival Curves

You might want to use your regression analysis results to predict the survivorship of subjects of specific covariate values. The `COVARIATES=` data set in the `BASELINE` statement enables you to specify the sets of covariate values for the prediction. On the other hand, you might want to summarize the survival experience of an average patient for a given population. The `DIRADJ` option in the `BASELINE` statement computes the direct adjusted survival curve that averages the estimated survival curves for patients whose covariates are represented in the `COVARIATES=` data set. By using the `PLOTS=` option in the `PROC PHREG` statement, you can use ODS Graphics to display the predicted survival curves. You can elect to output the predicted survival curves in a SAS data set by optionally specifying the `OUT=` option in the `BASELINE` statement. This example illustrates how to obtain the covariate-specific survival curves and the direct adjusted survival curve by using the Myeloma data set in [Example 67.1](#), where variables `LogBUN` and `HGB` were identified as the most important prognostic factors.

Suppose you want to compute the predicted survival curves for two sets of covariate values: (LogBUN=1.0, HGB=10) and (LogBUN=1.8, HGB=12). These values are saved in the data set `Inrisks` in the following DATA step. Also created in this data set is the variable `Id`, whose values will be used in identifying the covariate sets in the survival plot.

```
data Inrisks;
 length Id $20;
 input LogBUN HGB Id $12-31;
 datalines;
1.00 10.0 logBUN=1.0 HGB=10
1.80 12.0 logBUN=1.8 HGB=12
;
```

The following statements plot the survival functions in [Output 67.8.1](#) and save the survival estimates in the data set `Pred1`:

```
ods graphics on;
proc phreg data=Myeloma plots(overlay)=survival;
 model Time*VStatus(0)=LogBUN HGB;
 baseline covariates=Inrisks out=Pred1 survival=_all_/rowid=Id;
run;
```

The `COVARIATES=` option in the `BASELINE` statement specifies the data set that contains the set of covariates of interest. The `PLOTS=` option in the `PROC PHREG` statement creates the survival plot. The `OVERLAY` suboption overlays the two curves in the same plot. If the `OVERLAY` suboption is not specified, each curve is displayed in a separate plot. The `ROWID=` option in the `BASELINE` statement specifies that the values of the variable `Id` in the `COVARIATES=` data set be used to identify the curves in the plot. The `SURVIVAL=_ALL_` option in the `BASELINE` statement requests that the estimated survivor function, standard error, and lower and upper confidence limits for the survivor function be output into the SAS data set that is specified in the `OUT=` option.

The survival Plot ([Output 67.8.1](#)) contains two curves, one for each of row of covariates in the data set `Inrisks`.

**Output 67.8.1** Estimated Survivor Function Plot

The following statements print out the observations in the data set `Pred1` for the realization `LogBUN=1.00` and `HGB=10.0`:

```
proc print data=Pred1(where=(logBUN=1 and HGB=10));
run;
```

As shown in [Output 67.8.2](#), 32 observations represent the survivor function for the realization `LogBUN=1.00` and `HGB=10.0`. The first observation has survival time 0 and survivor function estimate 1.0. Each of the remaining 31 observations represents a distinct event time in the input data set `Myeloma`. These observations are presented in ascending order of the event times. Note that all the variables in the `COVARIATES=InRisks` data set are included in the `OUT=Pred1` data set. Likewise, you can print out the observations that represent the survivor function for the realization `LogBUN=1.80` and `HGB=12.0`.

**Output 67.8.2** Survivor Function Estimates for LogBUN=1.0 and HGB=10.0

Next, the DIRADJ option in the BASELINE statement is used to request a survival curve that represents the survival experience of an average patient in the population in which the COVARIATES= data set is sampled. When the DIRADJ option is specified, PROC PHREG computes the direct adjusted survival function by averaging the predicted survival functions for the rows in the COVARIATES= data set. The following statements plot the direct adjusted survival function in [Output 67.8.3](#).

```
proc phreg data=Myeloma plots=survival;
 model Time*VStatus(0)=LogBUN HGB;
 baseline covariates=Myeloma survival=_all_/diradj;
run;
```

When the DIRADJ option is specified in the BASELINE statement, the default COVARIATES= data set is the input data set. For clarity, the COVARIATES=MYELOMA is specified in the BASELINE statement in the preceding PROC PHREG call.

**Output 67.8.3** Average Survival Function for the Myeloma Data

If neither the COVARIATES= data set nor the DIRADJ option is specified in the BASELINE statement, PROC PHREG computes a predicted survival curve based on  $\bar{\mathbf{Z}}$ , the average values of the covariate vectors in the input data (Neuberger et al. 1986). This curve represents the survival experience of a patient with an average prognostic index  $\beta'\bar{\mathbf{Z}}$  equal to the average prognostic index of all patients. This approach has a couple of drawbacks: it is possible that no patient could ever have such an average index, and it does not account for the variability in the prognostic factor from patient to patient.

The DIRADJ option is particularly useful if the model contains a categorical explanatory variable that represents different treatments of interest. By specifying this categorical variable in the GROUP= option, you obtain a direct adjusted survival curve for each category of the variable. In addition, you can use the OUTDIFF= option to save all pairwise differences of these direct adjusted survival probabilities in a data set. For illustration, consider a model that also includes the categorical variable Frac, which has a value 0 if a patient did not have a fracture at diagnosis and 1 otherwise, as an explanatory variable. The following statements plot the adjusted survival curves in [Output 67.8.4](#) and save the differences of the direct adjusted survival probabilities in the data set Diff1:

```

proc phreg data=Myeloma plots(overlay)=survival;
 class Frac;
 model Time*VStatus(0)=LogBUN HGB Frac;
 baseline covariates=Myeloma outdiff=Diff1 survival=_all_/diradj group=Frac;
run;

```

Because the CLASS variable Frac is specified as the GROUP= variable, a separate direct adjusted survival curve is computed for each value of the variable Frac. Each direct adjusted survival curve is the average of the predicted survival curves for all the patients in the entire Myeloma data set with their Frac value set to a specific constant. For example, the direct adjusted survival curve for Frac=0 (no fracture at diagnosis) is computed as follows:

1. The value of the variable Frac is set to 0 for all observations in the Myeloma data set.
2. The survival curve for each observation in the modified data set is computed.
3. All the survival curves computed in step 2 are averaged.

**Output 67.8.4** Average Survival by Fracture Status

Output 67.8.4 shows that patients without fracture at diagnosis have better survival than those with fractures. Differences in the survival probabilities and their standard errors are displayed in Output 67.8.5.

```
proc print data=Diff1;
run;
ods graphics off;
```

**Output 67.8.5** Differences in the Survival between Fracture and Nonfracture

| Obs | Frac | Frac2 | Time  | Surv<br>Diff | StdErr  |

## Example 67.9: Analysis of Residuals

Residuals are used to investigate the lack of fit of a model to a given subject. You can obtain martingale and deviance residuals for the Cox proportional hazards regression analysis by requesting that they be included in the OUTPUT data set. You can plot these statistics and look for outliers.

Consider the stepwise regression analysis performed in [Example 67.1](#). The final model included variables LogBUN and HGB. You can generate residual statistics for this analysis by refitting the model containing those variables and including an OUTPUT statement as in the following invocation of PROC PHREG. The keywords XBETA, RESMART, and RESDEV identify new variables that contain the linear predictor scores  $z_j'\hat{\beta}$ , martingale residuals, and deviance residuals. These variables are xb, mart, and dev, respectively.

```
proc phreg data=Myeloma noprint;
 model Time*Vstatus(0)=LogBUN HGB;
 output out=Outp xbeta=Xb resmart=Mart resdev=Dev;
run;
```

The following statements plot the residuals against the linear predictor scores:

```
title "Myeloma Study";
proc sgplot data=Outp;
 yaxis grid;
 refline 0 / axis=y;
 scatter y=Mart x=Xb;
run;
proc sgplot data=Outp;
 yaxis grid;
 refline 0 / axis=y;
 scatter y=Dev x=Xb;
run;
```

The resulting plots are shown in [Output 67.9.1](#) and [Output 67.9.2](#). The martingale residuals are skewed because of the single event setting of the Cox model. The martingale residual plot shows an isolation point (with linear predictor score 1.09 and martingale residual  $-3.37$ ), but this observation is no longer distinguishable in the deviance residual plot. In conclusion, there is no indication of a lack of fit of the model to individual observations.

**Output 67.9.1** Martingale Residual Plot

Output 67.9.2 Deviance Residual Plot

## Example 67.10: Analysis of Recurrent Events Data

Recurrent events data consist of times to a number of repeated events for each sample unit—for example, times of recurrent episodes of a disease in patients. Various ways of analyzing recurrent events data are described in the section “[Analysis of Multivariate Failure Time Data](#)” on page 5629. The bladder cancer data listed in Wei, Lin, and Weissfeld (1989) are used here to illustrate these methods.

The data consist of 86 patients with superficial bladder tumors, which were removed when the patients entered the study. Of these patients, 48 were randomized into the placebo group, and 38 were randomized into the group receiving thiotepa. Many patients had multiple recurrences of tumors during the study, and new tumors were removed at each visit. The data set contains the first four recurrences of the tumor for each patient, and each recurrence time was measured from the patient’s entry time into the study.

The data consist of the following eight variables:

- Trt, treatment group (1=placebo and 2=thiotepa)
- Time, follow-up time
- Number, number of initial tumors
- Size, initial tumor size
- T1, T2, T3, and T4, times of the four potential recurrences of the bladder tumor. A patient with only two recurrences has missing values in T3 and T4.

In the data set Bladder, four observations are created for each patient, one for each of the four potential tumor recurrences. In addition to values of Trt, Number, and Size for the patient, each observation contains the following variables:

- ID, patient’s identification (which is the sequence number of the subject)
- Visit, visit number (with value  $k$  for the  $k$ th potential tumor recurrence)
- TStart, time of the  $(k - 1)$  recurrence for Visit= $k$ , or the entry time 0 if VISIT=1, or the follow-up time if the  $(k - 1)$  recurrence does not occur
- TStop, time of the  $k$ th recurrence if Visit= $k$  or follow-up time if the  $k$ th recurrence does not occur
- Status, event status of TStop (1=recurrence and 0=censored)

For instance, a patient with only one recurrence time at month 6 who was followed until month 10 will have values for Visit, TStart, TStop, and Status of (1,0,6,1), (2,6,10,0), (3,10,10,0), and (4,10,10,0), respectively. The last two observations are redundant for the intensity model and the proportional means model, but they are important for the analysis of the marginal Cox models. If the follow-up time is beyond the time of the fourth tumor recurrence, it is tempting to create a fifth observation with the time of the fourth tumor recurrence as the TStart value, the follow-up time as the TStop value, and a Status value of 0. However, Therneau and Grambsch (2000, Section 8.5) have warned against incorporating such observations into the analysis.

The following SAS statements create the data set Bladder:

```

data Bladder;
 keep ID TStart TStop Status Trt Number Size Visit;
 retain ID TStart 0;
 array tt T1-T4;
 infile datalines missover;
 input Trt Time Number Size T1-T4;
 ID + 1;
 TStart=0;
 do over tt;
 Visit=_i_;
 if tt = . then do;
 TStop=Time;
 Status=0;
 end;
 else do;
 TStop=tt;
 Status=1;
 end;
 output;
 TStart=TStop;
end;
if (TStart < Time) then delete;
datalines;

First, consider fitting the intensity model (Andersen and Gill 1982) and the proportional means model (Lin et al. 2000). The counting process style of input is used in the PROC PHREG specification. For the proportional means model, inference is based on the robust sandwich covariance estimate, which is requested by the COVS(AGGREGATE) option in the PROC PHREG statement. The COVM option is specified for the analysis of the intensity model to use the model-based covariance estimate. Note that some of the observations in the data set `Bladder` have a degenerated interval of risk. The presence of these observations does not affect the results of the analysis since none of these observations are included in any of the risk sets. However, the procedure will run more efficiently without these observations; consequently, in the following SAS statements, the WHERE clause is used to eliminate these redundant observations:

```

title 'Intensity Model and Proportional Means Model';
proc phreg data=Bladder covm covs(aggregate);
 model (TStart, TStop) * Status(0) = Trt Number Size;
 id id;
 where TStart < TStop;
run;

```

Results of fitting the intensity model and the proportional means model are shown in [Output 67.10.1](#) and [Output 67.10.2](#), respectively. The robust sandwich standard error estimate for `Trt` is larger than its model-based counterpart, rendering the effect of thiotepa less significant in the proportional means model ( $p = 0.0747$ ) than in the intensity model ( $p = 0.0215$ ).

Next, consider the conditional models of Prentice, Williams, and Peterson (1981). In the PWP models, the risk set for the  $(k + 1)$  recurrence is restricted to those patients who have experienced the first  $k$  recurrences. For example, a patient who experienced only one recurrence is an event observation for the first recurrence; this patient is a censored observation for the second recurrence and should not be included in the risk set for the third or fourth recurrence. The following DATA step eliminates those observations that should not be in the risk sets, forming a new input data set (named Bladder2) for fitting the PWP models. The variable Gaptime, representing the gap times between successive recurrences, is also created.

```
data Bladder2(drop=LastStatus);
 retain LastStatus;
 set Bladder;
 by ID;
 if first.id then LastStatus=1;
 if (Status=0 and LastStatus=0) then delete;
 LastStatus=Status;
 Gaptime=Tstop-Tstart;
run;
```

The following statements fit the PWP total time model. The variables Trt1, Trt2, Trt3, and Trt4 are visit-specific variables for Trt; the variables Number1, Number2, Number3, and Number4 are visit-specific variables for Number; and the variables Size1, Size2, Size3, and Size4 are visit-specific variables for Size.

```
title 'PWP Total Time Model with Noncommon Effects';
proc phreg data=Bladder2;
 model (Tstart,Tstop) * Status(0) = Trt1-Trt4 Number1-Number4
 Size1-Size4;

 Trt1= Trt * (Visit=1);
 Trt2= Trt * (Visit=2);
 Trt3= Trt * (Visit=3);
 Trt4= Trt * (Visit=4);
 Number1= Number * (Visit=1);
 Number2= Number * (Visit=2);
 Number3= Number * (Visit=3);
 Number4= Number * (Visit=4);
 Size1= Size * (Visit=1);
 Size2= Size * (Visit=2);
 Size3= Size * (Visit=3);
 Size4= Size * (Visit=4);
 strata Visit;
run;
```

Results of the analysis of the PWP total time model are shown in [Output 67.10.3](#). There is no significant treatment effect on the total time in any of the four tumor recurrences.

The following statements fit the PWP gap-time model:

```

title 'PWP Gap-Time Model with Noncommon Effects';
proc phreg data=Bladder2;
 model Gaptime * Status(0) = Trt1-Trt4 Number1-Number4
 Size1-Size4;

 Trt1= Trt * (Visit=1);
 Trt2= Trt * (Visit=2);
 Trt3= Trt * (Visit=3);
 Trt4= Trt * (Visit=4);
 Number1= Number * (Visit=1);
 Number2= Number * (Visit=2);
 Number3= Number * (Visit=3);
 Number4= Number * (Visit=4);

```

```

Size1= Size * (Visit=1);
Size2= Size * (Visit=2);
Size3= Size * (Visit=3);
Size4= Size * (Visit=4);
strata Visit;
run;

```

Results of the analysis of the PWP gap-time model are shown in [Output 67.10.4](#). Note that the regression coefficients for the first tumor recurrence are the same as those of the total time model, since the total time and the gap time are the same for the first recurrence. There is no significant treatment effect on the gap times for any of the four tumor recurrences.

**Output 67.10.4** Analysis of the PWP Gap-Time Model with Noncommon Effects

You can fit the PWP total time model with common effects by using the following SAS statements. However, the analysis is not shown here.

```

title2 'PWP Total Time Model with Common Effects';
proc phreg data=Bladder2;
 model (tstart,tstop) * status(0) = Trt Number Size;
 strata Visit;
run;

```

You can fit the PWP gap-time model with common effects by using the following statements. Again, the analysis is not shown here.

```

title2 'PWP Gap Time Model with Common Effects';
proc phreg data=Bladder2;
 model Gaptime * Status(0) = Trt Number Size;
 strata Visit;
run;

```

Recurrent events data are a special case of multiple events data in which the recurrence times are regarded as multivariate failure times and the marginal approach of Wei, Lin, and Weissfeld (1989) can be used. WLW fits a Cox model to each of the component times and makes statistical inference of the regression parameters based on a robust sandwich covariance matrix estimate. No specific correlation structure is imposed on the multivariate failure times. For the  $k$ th marginal model, let  $\beta_k$  denote the row vector of regression parameters, let  $\hat{\beta}_k$  denote the maximum likelihood estimate of  $\beta_k$ , let  $\hat{A}_k$  denote the covariance matrix obtained by inverting the observed information matrix, and let  $R_k$  denote the matrix of score residuals. WLW showed that the joint distribution of  $(\hat{\beta}_1, \dots, \hat{\beta}_4)'$  can be approximated by a multivariate normal distribution with mean vector  $(\beta_1, \dots, \beta_4)'$  and robust covariance matrix

$$\begin{pmatrix} \mathbf{V}_{11} & \mathbf{V}_{12} & \mathbf{V}_{13} & \mathbf{V}_{14} \\ \mathbf{V}_{21} & \mathbf{V}_{22} & \mathbf{V}_{23} & \mathbf{V}_{24} \\ \mathbf{V}_{31} & \mathbf{V}_{32} & \mathbf{V}_{33} & \mathbf{V}_{34} \\ \mathbf{V}_{41} & \mathbf{V}_{42} & \mathbf{V}_{43} & \mathbf{V}_{44} \end{pmatrix}$$

with the submatrix  $V_{ij}$  given by

$$V_{ij} = \hat{A}_i (\mathbf{R}'_i \mathbf{R}_j) \hat{A}_j$$

In this example, there are four marginal proportional hazards models, one for each potential recurrence time. Instead of fitting one model at a time, you can fit all four marginal models in one analysis by using the STRATA statement and model-specific covariates as in the following statements. Using Visit as the STRATA variable on the input data set Bladder, PROC PHREG simultaneously fits all four marginal models, one for each Visit value. The COVS(AGGREGATE) option is specified to compute the robust sandwich variance estimate by summing up the score residuals for each distinct pattern of ID value. The TEST statement TREATMENT is used to perform the global test of no treatment effect for each tumor recurrence, the AVERAGE option is specified to estimate the parameter for the common treatment effect, and the E option displays the optimal weights for the common treatment effect.

```

title 'Wei-Lin-Weissfeld Model';
proc phreg data=Bladder covs(aggregate);
 model TStop*Status(0)=Trt1-Trt4 Number1-Number4 Size1-Size4;

run;

```

Out of the 86 patients, 47 patients have only one tumor recurrence, 29 patients have two recurrences, 22 patients have three recurrences, and 14 patients have four recurrences (Output 67.10.5). Parameter estimates for the four marginal models are shown in Output 67.10.6. The 4 DF Wald test (Output 67.10.7) indicates a lack of evidence of a treatment effect in any of the four recurrences ( $p = 0.4105$ ). The optimal weights for estimating the parameter of the common treatment effect are 0.67684, 0.25723,  $-0.07547$ , and 0.14140 for Trt1, Trt2, Trt3, and Trt4, respectively, which gives a parameter estimate of  $-0.5489$  with a standard error estimate of 0.2853. A more sensitive test for a treatment effect is the 1 DF test based on this common parameter; however, there is still insufficient evidence for such effect at the 0.05 level ( $p = 0.0543$ ).

**Example 67.11: Analysis of Clustered Data**

When experimental units are naturally or artificially clustered, failure times of experimental units within a cluster are correlated. Two approaches can be taken to adjust for the intracluster correlation. In the marginal Cox model approach, Lee, Wei, and Amato (1992) estimate the regression parameters in the Cox model by the maximum partial likelihood estimates under an independent working assumption and use a robust sandwich covariance matrix estimate to account for the intracluster dependence. Lin (1994) illustrates this methodology by using a subset of data from the Diabetic Retinopathy Study (DRS). An alternative approach to account for the within-cluster correlation is to use a shared frailty model where cluster effects are incorporated into the model as independent and identically distributed random variables.

The following DATA step creates the data set Blind that represents 197 diabetic patients who have a high risk of experiencing blindness in both eyes as defined by DRS criteria. One eye of each patient is treated with laser photocoagulation. The hypothesis of interest is whether the laser treatment delays the occurrence of blindness. Since juvenile and adult diabetes have very different courses, it is also desirable to examine how the age of onset of diabetes might affect the time of blindness. Since there are no biological differences between the left eye and the right eye, it is natural to assume a common baseline hazard function for the failure times of the left and right eyes.

Each patient is a cluster that contributes two observations to the input data set, one for each eye. The following variables are in the input data set Blind:

- ID, patient's identification
- Time, time to blindness
- Status, blindness indicator (0:censored and 1:blind)
- Treat, treatment received (Laser or Others)
- Type, type of diabetes (Juvenile: onset at age  $\leq 20$  or Adult: onset at age  $> 20$ )

```
proc format;
 value type 0='Juvenile' 1='Adult';
 value Rx 1='Laser' 0='Others';
run;

As a preliminary analysis, PROC FREQ is used to summarize the number of eyes that developed blindness.

```
proc freq data=Blind;
 table Treat*Status;
run;
```

By the end of the study, 54 eyes treated with laser photocoagulation and 101 eyes treated by other means have developed blindness (Output 67.11.1).

**Output 67.11.1** Distribution of Blindness

The following statements use PROC PHREG to carry out the analysis of Lee, Wei, and Amato (1992). The explanatory variables in this Cox model are Treat, Type, and the Treat  $\times$  Type interaction. The COVS(AGGREGATE) option is specified to compute the robust sandwich covariance matrix estimate. The ID statement identifies the variable that represents the clusters. The HAZARDRATIO statement requests hazard ratios for the treatments be displayed.

```
proc phreg data=Blind covs(aggregate);
 class Treat Type;
 model Time*Status(0)=Treat|Type;
 id ID;
 hazardratio 'Marginal Model Analysis' Treat;
run;
```

Results of the marginal model analysis are displayed in [Output 67.11.2](#). The robust standard error estimates are smaller than the model-based counterparts, since the ratio of the robust standard error estimate relative to the model-based estimate is less than 1 for each parameter. Laser photocoagulation appears to be effective ( $p = 0.0217$ ) in delaying the occurrence of blindness, although there is also a significant interaction effect between treatment and type of diabetes ( $p = 0.0053$ ).

**Output 67.11.2** Inference Based the Marginal Model

| Treat*Type                               | Laser Adult | 0.0053     | .            | Treat Laser * Type Adult |  |  |

Hazard ratio estimates of the laser treatment relative to nonlaser treatment are displayed in [Output 67.11.3](#). For both types of diabetes, the 95% confidence interval for the hazard ratio lies below 1. This indicates that laser-photocoagulation treatment is more effective in delaying blindness regardless of the type of diabetes. However, the effect is more prominent for adult-onset diabetes than for juvenile-onset diabetes since the hazard ratio estimates for the former are less than those of the latter.

**Output 67.11.3** Hazard Ratio Estimates for Marginal Model

| Marginal Model Analysis: Hazard Ratios for Treat |                |                                   |       |

| Description                                      | Point Estimate | 95% Wald Robust Confidence Limits |       |
| Treat Laser vs Others At Type=Adult              | 0.281          | 0.175                             | 0.451 |
| Treat Laser vs Others At Type=Juvenile           | 0.654          | 0.455                             | 0.940 |

Next, you analyze the same data by using a shared frailty model. The following statements use PROC PHREG to fit a shared frailty model to the Blind data set. The RANDOM statement identifies the variable ID as the variable that represents the clusters. You must declare the cluster variable as a classification variable in the CLASS statement.

```
proc phreg data=Blind;
 class ID Treat Type;
 model Time*Status(0)=Treat|Type;
 random ID;
 hazardratio 'Frailty Model Analysis' Treat;
run;
```

Selected results of this analysis are displayed in [Output 67.11.4](#) to [Output 67.11.6](#).

The “Random Class Level Information” table in [Output 67.11.4](#) displays the 197 ID values of the patients. You can suppress the display of this table by using the NOCLPRINT option in the RANDOM statement.

#### Output 67.11.4 Unique Cluster Identification Values

The “Covariance Parameter Estimates” table in [Output 67.11.5](#) displays the estimate and asymptotic estimated standard error of the common variance parameter of the normal random effects.

#### Output 67.11.5 Variance Estimate of the Normal Random Effects

| Covariance Parameter Estimates |                  |                   |
|--------------------------------|------------------|-------------------|
| Cov<br>Parm                    | REML<br>Estimate | Standard<br>Error |
| ID                             | 0.8308           | 0.2145            |

[Output 67.11.6](#) displays the Wald tests for both the fixed effects and the random effects. The random effects are statistically significant ( $p = 0.0042$ ). Results of testing the fixed effects are very similar to those based on the robust variance estimates. Laser photocoagulation appears to be effective ( $p = 0.0252$ ) in delaying the occurrence of blindness, although there is also a significant treatment by diabetes type interaction effect ( $p = 0.0071$ ).

| Treat*Type                               | Laser Adult | Adult | .               | Treat Laser * Type Adult |  |  |

Estimates of hazard ratios of the laser treatment relative to nonlaser treatment are displayed in [Output 67.11.7](#). These estimates closely resemble those computed in analysis based on the marginal Cox model in [Output 67.11.3](#), which leads to the same conclusion that laser photocoagulation is effective in delaying blindness for both types of diabetes, and more effective for the adult-onset diabetes than for juvenile-onset diabetes.

## Example 67.12: Model Assessment Using Cumulative Sums of Martingale Residuals

The Mayo liver disease example of Lin, Wei, and Ying (1993) is reproduced here to illustrate the checking of the functional form of a covariate and the assessment of the proportional hazards assumption. The data represent 418 patients with primary biliary cirrhosis (PBC), among whom 161 had died as of the date of data listing. A subset of the variables is saved in the SAS data set Liver. The data set contains the following variables:

- Time, follow-up time, in years
- Status, event indicator with value 1 for death time and value 0 for censored time
- Age, age in years from birth to study registration
- Albumin, serum albumin level, in gm/dl
- Bilirubin, serum bilirubin level, in mg/dl
- Edema, edema presence
- Prottime, prothrombin time, in seconds

The following statements create the data set Liver:

```
data Liver;
 input Time Status Age Albumin Bilirubin Edema Prottime @@;
 label Time="Follow-up Time in Years";
 Time= Time / 365.25;

```

Consider fitting a Cox model for the survival time of the PCB patients with the covariates Bilirubin,  $\log(\text{Prottime})$ ,  $\log(\text{Albumin})$ , Age, and Edema. The log transform, which is often applied to blood chemistry measurements, is deliberately not employed for Bilirubin. It is of interest to assess the functional form of the variable Bilirubin in the Cox model. The specifications are as follows:

```
ods graphics on;
proc phreg data=Liver;
 model Time*Status(0)=Bilirubin logProttime logAlbumin Age Edema;
 logProttime=log(Prottime);
 logAlbumin=log(Albumin);
 assess var=(Bilirubin) / resample seed=7548;
run;
```

The ASSESS statement creates a plot of the cumulative martingale residuals against the values of the covariate Bilirubin, which is specified in the VAR= option. The RESAMPLE option computes the  $p$ -value of a Kolmogorov-type supremum test based on a sample of 1,000 simulated residual patterns.

Parameter estimates of the model fit are shown in [Output 67.12.1](#). The plot in [Output 67.12.2](#) displays the observed cumulative martingale residual process for Bilirubin together with 20 simulated realizations from the null distribution. When ODS Graphics is enabled, this graphical display is requested by specifying the ASSESS statement. It is obvious that the observed process is atypical compared to the simulated realizations. Also, none of the 1,000 simulated realizations has an absolute maximum exceeding that of the observed cumulative martingale residual process. Both the graphical and numerical results indicate that a transform is deemed necessary for Bilirubin in the model.

**Output 67.12.3** Typical Cumulative Residual Plot Patterns

**Table 67.17** Model Misspecifications

| Plot | Data              | Fitted Model |
|------|-------------------|--------------|
| (a)  | $\log(X)$         | $X$          |
| (b)  | $\{X, X^2\}$      | $X$          |
| (c)  | $\{X, X^2, X^3\}$ | $\{X, X^2\}$ |
| (d)  | $I(X > 5)$        | $X$          |

The curve of observed cumulative martingale residuals in [Output 67.12.2](#) most resembles the behavior of the curve in plot (a) of [Output 67.12.3](#), indicating that  $\log(\text{Bilirubin})$  might be a more appropriate term in the model than Bilirubin.

Next, the analysis of the natural history of the PBC is repeated with  $\log(\text{Bilirubin})$  replacing Bilirubin, and the functional form of  $\log(\text{Bilirubin})$  is assessed. Also assessed is the proportional hazards assumption for the Cox model. The analysis is carried out by the following statements:

```

proc phreg data=Liver;
 model Time*Status(0)=logBilirubin logProttime logAlbumin Age Edema;
 logBilirubin=log(Bilirubin);
 logProttime=log(Prottime);
 logAlbumin=log(Albumin);
 assess var=(logBilirubin) ph / crpanel resample seed=19;
run;
ods graphics off;

```

The SEED= option specifies a integer seed for generating random numbers. The CRPANEL option in the ASSESS statement requests a panel of four plots. Each plot displays the observed cumulative martingale residual process along with two simulated realizations. The PH option checks the proportional hazards assumption of the model by plotting the observed standardized score process with 20 simulated realizations for each covariate in the model.

Output 67.12.4 displays the parameter estimates of the fitted model. The cumulative martingale residual plots in Output 67.12.5 and Output 67.12.6 show that the observed martingale residual process is more typical of the simulated realizations. The  $p$ -value for the Kolmogorov-type supremum test based on 1,000 simulations is 0.052, indicating that the log transform is a much improved functional form for Bilirubin.

**Output 67.12.4** Model with log(Bilirubin) as a Covariate

## Example 67.13: Bayesian Analysis of the Cox Model

This example illustrates the use of an informative prior. Hazard ratios, which are transformations of the regression parameters, are useful for interpreting survival models. This example also demonstrates the use of the HAZARDRATIO statement to obtain customized hazard ratios.

Consider the VALung data set in [Example 67.3](#). In this example, the Cox model is used for the Bayesian analysis. The parameters are the coefficients of the continuous explanatory variables (Kps, Duration, and Age) and the coefficients of the design variables for the categorical explanatory variables (Prior, Cell, and Therapy). You use the CLASS statement in PROC PHREG to specify the categorical variables and their reference levels. Using the default reference parameterization, the design variables for the categorical variables are Prioryes (for Prior with Prior='no' as reference), Celladeno, Cellsmall, Cellsquamous (for Cell with Cell='large' as reference), and Therapytest (for Therapy='standard' as reference).

Consider the explanatory variable Kps. The Karnofsky performance scale index enables patients to be classified according to their functional impairment. The scale can range from 0 to 100—0 for dead, and 100 for a normal, healthy person with no evidence of disease. Recall that a flat prior was used for the regression coefficient in the example in the section “[Bayesian Analysis](#)” on page 5547. A flat prior on the Kps coefficient implies that the coefficient is as likely to be 0.1 as it is to be  $-100000$ . A coefficient of  $-5$  means that a decrease of 20 points in the scale increases the hazard by  $e^{-20 \times -5} (=2.68 \times 10^{43})$ -fold, which is a rather unreasonable and unrealistic expectation for the effect of the Karnofsky index, much less than the value of  $-100000$ . Suppose you have a more realistic expectation: the effect is somewhat small and is more likely to be negative than positive, and a decrease of 20 points in the Karnofsky index will change the hazard from 0.9-fold (some minor positive effect) to 4-fold (a large negative effect). You can convert this opinion to a more informative prior on the Kps coefficient  $\beta_1$ . Mathematically,

$$0.9 < e^{-20\beta_1} < 4$$

which is equivalent to

$$-0.0693 < \beta_1 < 0.0053$$

This becomes the plausible range that you believe the Kps coefficient can take. Now you can find a normal distribution that best approximates this belief by placing the majority of the prior distribution mass within this range. Assuming this interval is  $\mu \pm 2\sigma$ , where  $\mu$  and  $\sigma$  are the mean and standard deviation of the normal prior, respectively, the hyperparameters  $\mu$  and  $\sigma$  are computed as follows:

$$\begin{aligned}\mu &= \frac{-0.0693 + 0.0053}{2} = -0.032 \\ \sigma &= \frac{0.0053 - (-0.0693)}{4} = 0.0186\end{aligned}$$

Note that a normal prior distribution with mean  $-0.0320$  and standard deviation  $0.0186$  indicates that you believe, before looking at the data, that a decrease of 20 points in the Karnofsky index will probably change the hazard rate by 0.9-fold to 4-fold. This does not rule out the possibility that the Kps coefficient can take a more extreme value such as  $-5$ , but the probability of having such extreme values is very small.

Assume the prior distributions are independent for all the parameters. For the coefficient of Kps, you use a normal prior distribution with mean  $-0.0320$  and variance  $0.0186^2 (=0.00035)$ . For other parameters, you resort to using a normal prior distribution with mean 0 and variance 1E6, which is fairly noninformative. Means and variances of these independent normal distributions are saved in the data set Prior as follows:

```

In the following BAYES statement, COEFFPRIOR=NORMAL(INPUT=Prior) specifies the normal prior distribution for the regression coefficients with details contained in the data set Prior. Summary statistics of the posterior distribution are produced by default. Autocorrelations and effective sample size are requested as convergence diagnostics as well as the trace plots for visual analysis. For comparisons of hazards, three HAZARDRATIO statements are specified—one for the variable Therapy, one for the variable Age, and one for the variable Cell.

```

ods graphics on;
proc phreg data=VALung;
class Prior(ref='no') Cell(ref='large') Therapy(ref='standard');
model Time*Status(0) = Kps Duration Age Prior Cell Therapy;
bayes seed=1 coeffprior=normal(input=Prior) diagnostic=(autocorr ess)
 plots=trace;
hazardratio 'Hazard Ratio Statement 1' Therapy;
hazardratio 'Hazard Ratio Statement 2' Age / unit=10;
hazardratio 'Hazard Ratio Statement 3' Cell;
run;
ods graphics off;

```

This analysis generates a posterior chain of 10,000 iterations after 2,000 iterations of burn-in, as depicted in Output 67.13.1.

Output 67.13.10 continued

The first HAZARDRATIO statement compares the hazards between the standard therapy and the test therapy. Summaries of the posterior distribution of the corresponding hazard ratio are shown in Output 67.13.11. There is a 95% chance that the hazard ratio of standard therapy versus test therapy lies between 0.5 and 1.1.

Output 67.13.11 Hazard Ratio for Treatment

| Hazard Ratio Statement 1: Hazard Ratios for Therapy |           |        |                         |        |                  |        |

## Example 67.14: Bayesian Analysis of Piecewise Exponential Model

This example illustrates using a piecewise exponential model in a Bayesian analysis. Consider the Rats data set in the section “Getting Started: PHREG Procedure” on page 5543. In the following statements, PROC PHREG is used to carry out a Bayesian analysis for the piecewise exponential model. In the BAYES statement, the option `PIECEWISE` stipulates a piecewise exponential model, and `PIECEWISE=HAZARD` requests that the constant hazards be modeled in the original scale. By default, eight intervals of constant hazards are used, and the intervals are chosen such that each has roughly the same number of events.

```
data Rats;
 label Days = 'Days from Exposure to Death';
 input Days Status Group @@;
 datalines;
143 1 0 164 1 0 188 1 0 188 1 0
190 1 0 192 1 0 206 1 0 209 1 0
213 1 0 216 1 0 220 1 0 227 1 0
230 1 0 234 1 0 246 1 0 265 1 0
304 1 0 216 0 0 244 0 0 142 1 1
156 1 1 163 1 1 198 1 1 205 1 1
232 1 1 232 1 1 233 1 1 233 1 1
233 1 1 233 1 1 239 1 1 240 1 1
261 1 1 280 1 1 280 1 1 296 1 1
296 1 1 323 1 1 204 0 1 344 0 1
;

proc phreg data=Rats;
 model Days*Status(0)=Group;
 bayes seed=1 piecewise=hazard;
run;
```

The “Model Information” table in [Output 67.14.1](#) shows that the piecewise exponential model is being used.

**Output 67.14.1** Model Information

| The PHREG Procedure |                       |                             |
|---------------------|-----------------------|-----------------------------|
| Bayesian Analysis   |                       |                             |
| Model Information   |                       |                             |
| Data Set            | WORK.RATS             |                             |
| Dependent Variable  | Days                  | Days from Exposure to Death |
| Censoring Variable  | Status                |                             |
| Censoring Value(s)  | 0                     |                             |
| Model               | Piecewise Exponential |                             |
| Sampling Algorithm  | ARMS                  |                             |
| Burn-In Size        | 2000                  |                             |
| MC Sample Size      | 10000                 |                             |
| Thinning            | 1                     |                             |

By default the time axis is partitioned into eight intervals of constant hazard. [Output 67.14.2](#) details the number of events and observations in each interval. Note that the constant hazard parameters are named  $\text{Lambda1}, \dots, \text{Lambda8}$ . You can supply your own partition by using the `INTERVALS=` suboption within the `PIECEWISE=HAZARD` option.

**Output 67.14.2** Interval Partition

| Constant Hazard Time Intervals |        |   |       |                  |  |
|--------------------------------|--------|---|-------|------------------|--|
| Interval                       |        | N | Event | Hazard           |  |
| [Lower,                        | Upper) |   |       | Parameter        |  |
| 0                              | 176    | 5 | 5     | $\text{Lambda1}$ |  |
| 176                            | 201.5  | 5 | 5     | $\text{Lambda2}$ |  |
| 201.5                          | 218    | 7 | 5     | $\text{Lambda3}$ |  |
| 218                            | 232.5  | 5 | 5     | $\text{Lambda4}$ |  |
| 232.5                          | 233.5  | 4 | 4     | $\text{Lambda5}$ |  |
| 233.5                          | 253.5  | 5 | 4     | $\text{Lambda6}$ |  |
| 253.5                          | 288    | 4 | 4     | $\text{Lambda7}$ |  |
| 288                            | Infty  | 5 | 4     | $\text{Lambda8}$ |  |

The model parameters consist of the eight hazard parameters  $\text{Lambda1}, \dots, \text{Lambda8}$ , and the regression coefficient `Group`. The maximum likelihood estimates are displayed in [Output 67.14.3](#). Again, these estimates are used as the starting values for simulation of the posterior distribution.

**Output 67.14.3** Maximum Likelihood Estimates

| Maximum Likelihood Estimates |    |          |                |                       |         |
|------------------------------|----|----------|----------------|-----------------------|---------|
| Parameter                    | DF | Estimate | Standard Error | 95% Confidence Limits |         |
| $\text{Lambda1}$             | 1  | 0.000953 | 0.000443       | 0.000084              | 0.00182 |
| $\text{Lambda2}$             | 1  | 0.00794  | 0.00371        | 0.000672              | 0.0152  |
| $\text{Lambda3}$             | 1  | 0.0156   | 0.00734        | 0.00120               | 0.0300  |
| $\text{Lambda4}$             | 1  | 0.0236   | 0.0115         | 0.00112               | 0.0461  |
| $\text{Lambda5}$             | 1  | 0.3669   | 0.1959         | -0.0172               | 0.7509  |
| $\text{Lambda6}$             | 1  | 0.0276   | 0.0148         | -0.00143              | 0.0566  |
| $\text{Lambda7}$             | 1  | 0.0262   | 0.0146         | -0.00233              | 0.0548  |
| $\text{Lambda8}$             | 1  | 0.0545   | 0.0310         | -0.00626              | 0.1152  |
| <code>Group</code>           | 1  | -0.6223  | 0.3468         | -1.3020               | 0.0573  |

Without using the `PRIOR=` suboption within the `PIECEWISE=HAZARD` option to specify the prior of the hazard parameters, the default is to use the noninformative and improper prior displayed in [Output 67.14.4](#).

**Output 67.14.4** Hazard Prior

| Improper Prior for Hazards |             |
|----------------------------|-------------|
| Parameter                  | Prior       |
| Lambda1                    | 1 / Lambda1 |
| Lambda2                    | 1 / Lambda2 |
| Lambda3                    | 1 / Lambda3 |
| Lambda4                    | 1 / Lambda4 |
| Lambda5                    | 1 / Lambda5 |
| Lambda6                    | 1 / Lambda6 |
| Lambda7                    | 1 / Lambda7 |
| Lambda8                    | 1 / Lambda8 |

The noninformative uniform prior is used for the regression coefficient Group (Output 67.14.5), as in the section “Bayesian Analysis” on page 5547.

**Output 67.14.5** Coefficient Prior

| Uniform Prior for Regression Coefficients |          |
|-------------------------------------------|----------|
| Parameter                                 | Prior    |
| Group                                     | Constant |

Summary statistics for all model parameters are shown in Output 67.14.6 and Output 67.14.7.

**Output 67.14.6** Summary Statistics

| The PHREG Procedure |       |          |                       |             |          |         |
|---------------------|-------|----------|-----------------------|-------------|----------|---------|
| Bayesian Analysis   |       |          |                       |             |          |         |
| Posterior Summaries |       |          |                       |             |          |         |
| Parameter           | N     | Mean     | Standard<br>Deviation | Percentiles |          |         |

### Overview: PLAN Procedure

The PLAN procedure constructs designs and randomizes plans for factorial experiments, especially nested and crossed experiments and randomized block designs. PROC PLAN can also be used for generating lists of permutations and combinations of numbers. The PLAN procedure can construct the following types of experimental designs:

- full factorial designs, with and without randomization
- certain balanced and partially balanced incomplete block designs
- generalized cyclic incomplete block designs
- Latin square designs

For other kinds of experimental designs, especially fractional factorial, response surface, and orthogonal array designs, see the FACTEX and OPTTEX procedures and the ADX Interface in SAS/QC software.

PROC PLAN generates designs by first generating a selection of the levels for the first factor. Then, for the second factor, PROC PLAN generates a selection of its levels for each level of the first factor. In general, for a given factor, the PLAN procedure generates a selection of its levels for all combinations of levels for the factors that precede it.

The selection can be done in five different ways:

- randomized selection, for which the levels are returned in a random order
- ordered selection, for which the levels are returned in a standard order every time a selection is generated
- cyclic selection, for which the levels returned are computed by cyclically permuting the levels of the previous selection
- permuted selection, for which the levels are a permutation of the integers  $1, \dots, n$
- combination selection, for which the  $m$  levels are selected as a combination of the integers  $1, \dots, n$  taken  $m$  at a time

The randomized selection method can be used to generate randomized plans. Also, by appropriate use of cyclic selection, any of the designs in the very wide class of generalized cyclic block designs (Jarrett and Hall 1978) can be generated.

There is no limit to the depth to which the different factors can be nested, and any number of randomized plans can be generated.

You can also declare a list of factors to be selected simultaneously with the lowest (that is, the most nested) factor. The levels of the factors in this list can be seen as constituting the treatment to be applied to the cells of the design. For this reason, factors in this list are called *treatments*. With this list, you can generate and randomize plans in one run of PROC PLAN.

## Getting Started: PLAN Procedure

### Three Replications with Four Factors

Suppose you want to determine if the order in which four drugs are given affects the response of a subject. If you have only three subjects to test, you can use the following statements to design the experiment.

```
proc plan seed=27371;
 factors Replicate=3 ordered Drug=4;
run;
```

These statements produce a design with three replicates of the four levels of the factor Drug arranged in random order. The three levels of Replicate are arranged in order, as shown in [Figure 68.1](#).

**Figure 68.1** Three Replications and Four Factors

| The PLAN Procedure |           |          |         |
|--------------------|-----------|----------|---------|
| Factor             | Select    | Levels   | Order   |
| Replicate          | 3         | 3        | Ordered |
| Drug               | 4         | 4        | Random  |
|                    | Replicate | --Drug-- |         |
|                    | 1         | 3 2 4 1  |         |
|                    | 2         | 1 2 4 3  |         |
|                    | 3         | 4 1 2 3  |         |

You might also want to apply one of four different treatments to each cell of this plan (for example, applying different amounts of each drug). The following additional statements create the output shown in [Figure 68.2](#):

```
factors Replicate=3 ordered Drug=4;
treatments Treatment=4;
run;
```

**Figure 68.2** Using the TREATMENTS Statement

| The PLAN Procedure |        |        |         |
|--------------------|--------|--------|---------|
| Plot Factors       |        |        |         |
| Factor             | Select | Levels | Order   |
| Replicate          | 3      | 3      | Ordered |
| Drug               | 4      | 4      | Random  |
| Treatment Factors  |        |        |         |
| Factor             | Select | Levels | Order   |
| Treatment          | 4      | 4      | Random  |

Figure 68.2 continued

| Replicate | --Drug-- | --Treatment-- |   |   |   |
|-----------|----------|---------------|---|---|---|
| 1         | 3 1 2 4  | 2             | 1 | 3 | 4 |
| 2         | 4 3 2 1  | 4             | 1 | 2 | 3 |
| 3         | 3 2 4 1  | 1             | 4 | 2 | 3 |

## Randomly Assigning Subjects to Treatments

You can use the PLAN procedure to design a completely randomized design. Suppose you have 12 experimental units, and you want to assign one of two treatments to each unit. Use a DATA step to store the unrandomized design in a SAS data set, and then call PROC PLAN to randomize it by specifying one factor with the default type of RANDOM, having 12 levels. The following statements produce Figure 68.3 and Figure 68.4:

```

title 'Completely Randomized Design';
/* The unrandomized design */

data Unrandomized;
 do Unit=1 to 12;
 if (Unit <= 6) then Treatment=1;
 else Treatment=2;
 output;
 end;
run;

/* Randomize the design */

proc plan seed=27371;
 factors Unit=12;
 output data=Unrandomized out=Randomized;
run;

proc sort data=Randomized;
 by Unit;
run;
proc print;
run;

```

Figure 68.3 shows that the 12 levels of the unit factor have been randomly reordered and then lists the new ordering.

**Figure 68.3** A Completely Randomized Design for Two Treatments

| Completely Randomized Design |        |        |        |
|------------------------------|--------|--------|--------|
| The PLAN Procedure           |        |        |        |
| Factor                       | Select | Levels | Order  |
| Unit                         | 12     | 12     | Random |
| -----Unit-----               |        |        |        |
| 8                            | 5      | 1      | 4      |
| 6                            | 2      | 12     | 7      |
| 3                            | 9      | 10     | 11     |

After the data set is sorted by the unit variable, the randomized design is displayed (Figure 68.4).

**Figure 68.4** A Completely Randomized Design for Two Treatments

| Completely Randomized Design |      |           |
|------------------------------|------|-----------|
| Obs                          | Unit | Treatment |
| 1                            | 1    | 1         |
| 2                            | 2    | 1         |
| 3                            | 3    | 2         |
| 4                            | 4    | 1         |
| 5                            | 5    | 1         |
| 6                            | 6    | 1         |
| 7                            | 7    | 2         |
| 8                            | 8    | 1         |
| 9                            | 9    | 2         |
| 10                           | 10   | 2         |
| 11                           | 11   | 2         |
| 12                           | 12   | 2         |

You can also generate the plan by using a **TREATMENTS** statement instead of a DATA step. The following statements generate the same plan.

```
proc plan seed=27371;
 factors Unit=12;
 treatments Treatment=12 cyclic (1 1 1 1 1 1 2 2 2 2 2 2);
 output out=Randomized;
run;
```

## Syntax: PLAN Procedure

The following statements are available in the PLAN procedure:

```
PROC PLAN < options > ;
 FACTORS factor-selections < / NOPRINT > ;
 OUTPUT OUT=SAS-data-set < factor-value-settings > ;
 TREATMENTS factor-selections ;
```

To use PROC PLAN, you need to specify the PROC PLAN statement and at least one FACTORS statement before the first RUN statement. The TREATMENTS statement, OUTPUT statement, and additional FACTORS statements can appear either before the first RUN statement or after it.

The rest of this section gives detailed syntax information for each of the statements, beginning with the PROC PLAN statement. The remaining statements are described in alphabetical order.

You can use PROC PLAN interactively by specifying multiple groups of statements, separated by RUN statements. For details, see the section “Using PROC PLAN Interactively” on page 5782.

## PROC PLAN Statement

```
PROC PLAN < options > ;
```

The PROC PLAN statement invokes the PLAN procedure. Optionally, you can also specify a random number seed or a default method for selecting levels of factors. By default, the procedure uses a random number seed generated from reading the time of day from the computer’s clock and randomly selects levels of factors. These defaults can be modified with the SEED= and ORDERED options, respectively. Unlike many SAS/STAT procedures, the PLAN procedure does not have a DATA= option in the PROC PLAN statement; in this procedure, both the input and output data sets are specified in the OUTPUT statement.

Table 68.1 summarizes the options available in the PROC PLAN statement.

**Table 68.1** PROC PLAN Statement Options

| Option  | Description                                                                   |
|---------|-------------------------------------------------------------------------------|
| ORDERED | Selects the levels of the factor as the integers 1, 2, . . . , $m$ , in order |
| SEED=   | Specifies an integer used to start the pseudo-random number generator         |

You can specify the following options in the PROC PLAN statement:

### ORDERED

selects the levels of the factor as the integers 1, 2, . . . ,  $m$ , in order. For more detail, see “*Selection-Types*” on page 5777 and “*Specifying Factor Structures*” on page 5784.

### SEED=*number*

specifies an integer used to start the pseudo-random number generator for selecting factor levels randomly. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

## FACTORS Statement

**FACTORS** *factor-selections* </ **NOPRINT** > ;

The FACTORS statement specifies the factors of the plan and generates the plan. Taken together, the *factor-selections* specify the plan to be generated; more than one *factor-selection* request can be used in a FACTORS statement. The form of a *factor-selection* is

*name* = *m* < **OF** *n* > < *selection-type* > ;

where

- name* is a valid SAS name. This gives the name of a factor in the design.
- m* is a positive integer that gives the number of values to be selected. If *n* is specified, the value of *m* must be less than or equal to *n*.
- n* is a positive integer that gives the number of values to be selected from.
- selection-type* specifies one of five methods for selecting *m* values. Possible values are COMB, CYCLIC, ORDERED, PERM, and RANDOM. The CYCLIC *selection-type* has additional optional specifications that enable you to specify an initial block of numbers to be cyclically permuted and an increment used to permute the numbers. By default, the *selection-type* is RANDOM, unless you use the ORDERED option in the PROC PLAN statement. In this case, the default *selection-type* is ORDERED. For details, see the following section, “[Selection-Types](#)”; for examples, see the section “[Syntax Examples](#)” on page 5778.

The following option can appear in the FACTORS statement after the slash:

### **NOPRINT**

suppresses the display of the plan. This is particularly useful when you require only an output data set. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

### **Selection-Types**

PROC PLAN interprets *selection-type* as follows:

- RANDOM** selects the *m* levels of the factor randomly without replacement from the integers 1, 2, . . . , *n*. Or, if *n* is not specified, RANDOM selects levels by randomly ordering the integers 1, 2, . . . , *m*.
- ORDERED** selects the levels of the factor as the integers 1, 2, . . . , *m*, in that order.
- PERM** selects the *m* levels of the factor as a permutation of the integers 1, . . . , *m* according to an algorithm that cycles through all *m*! permutations. The permutations are produced in a sorted standard order; see [Example 68.6](#).
- COMB** selects the *m* levels of the factor as a combination of the integers 1, . . . , *n* taken *m* at a time, according to an algorithm that cycles through all  $n!/(m!(n - m)!)$  combinations. The combinations are produced in a sorted standard order; see [Example 68.6](#).

**CYCLIC** *<(initial-block)>* *<increment>* selects the levels of the factor by cyclically permuting the integers 1, 2, . . . , *n*. Wrapping occurs at *m* if *n* is not specified, and at *n* if *n* is specified. Additional optional specifications are as follows.

With the *selection-type* CYCLIC, you can optionally specify an *initial-block* and an *increment*. The *Argument* *initial-block* must be specified within parentheses, and it specifies the block of numbers to permute. The first permutation is the block you specify, the second is the block permuted by 1 (or by the *increment* you specify), and so on. By default, the *initial-block* is the integers 1, 2, . . . , *m*. If you specify an *initial-block*, it must have *m* values. Values specified in the *initial-block* do not have to be given in increasing order.

The *increment* specifies the increment by which to permute the block of numbers. By default, the *increment* is 1.

## Syntax Examples

This section gives some simple syntax examples. For more complex examples and details on how to generate various designs, see “[Specifying Factor Structures](#)” on page 5784. The examples in this section assume that you use the default random selection method and do not use the **ORDERED** option in the **PROC PLAN** statement.

The following specification generates a random permutation of the numbers 1, 2, 3, 4, and 5.

```
factors A=5;
```

The following specification generates a random permutation of five of the integers from 1 to 8, selected without replacement.

```
factors A=5 of 8;
```

Adding the **ORDERED** *selection-type* to the two previous specifications generates an ordered list of the integers 1 to 5. The following specification cyclically permutes the integers 1, 2, 3, and 4.

```
factors A=4 cyclic;
```

Since this simple request generates only one permutation of the numbers, the procedure generates an ordered list of the integers 1 to 4. The following specification cyclically permutes the integers 5 to 8.

```
factors A=4 of 8 cyclic (5 6 7 8);
```

In this case, since only one permutation is performed, the procedure generates an ordered list of the integers 5 to 8. The following specification produces an ordered list for A, with values 1 and 2.

```
factors A=2 ordered B=4 of 8 cyclic (5 6 7 8) 2;
```

The associated factor levels for B are 5, 6, 7, 8 for level 1 of A, and 7, 8, 1, 2 for level 2 of A.

## Handling More Than One Factor-Selection

For cases with more than one *factor-selection* in the same **FACTORS** statement, **PROC PLAN** constructs the design as follows:

1. **PROC PLAN** first generates levels for the first *factor-selection*. These levels are permutations of integers (1, 2, and so on) appropriate for the selection type chosen. If you do not specify a selection

type, PROC PLAN uses the default (RANDOM); if you specify the **ORDERED** option in the **PROC PLAN** statement, the procedure uses **ORDERED** as the default selection type.

2. For every integer generated for the first *factor-selection*, levels are generated for the second *factor-selection*. These levels are generated according to the specifications following the second equal sign.
3. This process is repeated until levels for all *factor-selections* have been generated.

The following statements give an example of generating a design with two random factors:

```
proc plan;
 factors One=4 Two=3;
run;
```

The procedure first generates a random permutation of the integers 1 to 4 and then, for each of these, generates a random permutation of the integers 1 to 3. You can think of factor Two as being nested within factor One, where the levels of factor One are to be randomly assigned to 4 units.

As another example, six random permutations of the numbers 1, 2, 3 can be generated by specifying the following statements:

```
proc plan;
 factors a=6 ordered b=3;
run;
```

---

## OUTPUT Statement

**OUTPUT** **OUT=SAS-data-set** < **DATA=SAS-data-set** > < *factor-value-settings* > ;

The OUTPUT statement applies only to the last plan generated. If you use PROC PLAN interactively, the OUTPUT statement for a given plan must be immediately preceded by the **FACTORS** statement (and the **TREATMENTS** statement, if appropriate) for the plan.

See “Output Data Sets” on page 5783 for more information about how output data sets are constructed.

You can specify the following options in the OUTPUT statement:

**OUT=SAS-data-set**

**DATA=SAS-data-set**

You can use the OUTPUT statement both to output the last plan generated and to use the last plan generated to randomize another SAS data set.

When you specify only the OUT= option in the OUTPUT statement, PROC PLAN saves the last plan generated to the specified data set. The output data set contains one variable for each factor in the plan and one observation for each cell in the plan. The value of a variable in a given observation is the level of the corresponding factor for that cell. The OUT= option is required.

When you specify both the DATA= and OUT= options in the OUTPUT statement, then PROC PLAN uses the last plan generated to randomize the input data set (DATA=), saving the results to the output data set (OUT=). The output data set has the same form as the input data set but has modified values for the variables that correspond to factors (see the section “Output Data Sets” on page 5783 for details). Values for variables not corresponding to factors are transferred without change.

*factor-value-settings*

specify the values input or output for the factors in the design. The form for *factor-value-settings* is different when only an `OUT=` data set is specified and when both `OUT=` and `DATA=` data sets are specified.

Both forms are discussed in the following section.

**Factor-Value-Settings with Only an `OUT=` Data Set**

When you specify only an `OUT=` data set, the form for each *factor-value-setting* specification is one of the following:

```
factor-name < NVALS=list-of-n-numbers > < ORDERED | RANDOM > ;
```

or

```
factor-name < CVALS=list-of-n-strings > < ORDERED | RANDOM > ;
```

where

- factor-name* is a factor in the last **FACTORS** statement preceding the **OUTPUT** statement.
- NVALS=** lists *n* numeric values for the factor. By default, the procedure uses `NVALS=(1 2 3 ... n)`.
- CVALS=** lists *n* character strings for the factor. Each string can have up to 40 characters, and each string must be enclosed in quotes. **CAUTION:** When you use the `CVALS=` option, the variable created in the output data set has a length equal to the length of the longest string given as a value; shorter strings are padded with trailing blanks. For example, the values output for the first level of a two-level factor with the following two different specifications are not the same.

```
CVALS=('String 1' "String 2")
```

```
CVALS=('String 1' "A longer string")
```

The value output with the second specification is 'String 1' followed by seven blanks. In order to match two such values (for example, when merging two plans), you must use the `TRIM` function in the **DATA** step (see *SAS Functions and CALL Routines: Reference*).

- ORDERED | RANDOM** specifies how values (those given with the `NVALS=` or `CVALS=` option, or the default values) are associated with the levels of a factor (the integers 1, 2, ..., *n*). The default association type is **ORDERED**, for which the first value specified is output for a factor level setting of 1, the second value specified is output for a level of 2, and so on. You can also specify an association type of **RANDOM**, for which the levels are associated with the values in a random order. Specifying **RANDOM** is useful for randomizing crossed experiments (see the section "[Randomizing Designs](#)" on page 5786).

The following statements give an example of using the **OUTPUT** statement with only an `OUT=` data set and with both the `NVALS=` and `CVALS=` specifications.

```
proc plan;
 factors a=6 ordered b=3;
 output out=design a nvals=(10 to 60 by 10)
 b cvals=('HSX' 'SB2' 'DNY');
run;
```

The DESIGN data set contains two variables, a and b. The values of the variable a are 10 when factor a equals 1, 20 when factor a equals 2, and so on. Values of the variable b are ‘HSX’ when factor b equals 1, ‘SB2’ when factor b equals 2, and ‘DNY’ when factor b equals 3.

### Factor-Value-Settings with OUT= and DATA= Data Sets

If you specify an input data set with **DATA=**, then PROC PLAN assumes that each factor in the last plan generated corresponds to a variable in the input set. If the variable name is different from the name of the factor to which it corresponds, the two can be associated in the values specification by

*input-variable-name = factor-name ;*

Then, the **NVALS=** or **CVALS=** specification can be used. The values given by **NVALS=** or **CVALS=** specify the input values as well as the output values for the corresponding variable.

Since the procedure assumes that the collection of input factor values constitutes a plan position description (see the section “**Output Data Sets**” on page 5783), the values must correspond to integers less than or equal to *m*, the number of values selected for the associated factor. If any input values do not correspond, then the collection does not define a plan position, and the corresponding observation is output without changing the values of any of the factor variables.

The following statements demonstrate the use of *factor-value-settings*. The input SAS data set a contains variables Block and Plot, which are renamed Day and Hour, respectively.

```
proc plan;
 factors Day=7 Hour=6;
 output data=a out=b
 Block = Day cvals=('Mon' 'Tue' 'Wed' 'Thu'
 'Fri' 'Sat' 'Sun')
 Plot = Hour;
run;
```

For another example of using both a **DATA=** and **OUT=** data set, see the section “**Randomly Assigning Subjects to Treatments**” on page 5774.

---

## TREATMENTS Statement

**TREATMENTS** *factor-selections ;*

The TREATMENTS statement specifies the treatments of the plan to generate, but it does not generate a plan. If you supply several **FACTORS** and TREATMENTS statements before the first RUN statement, the procedure uses only the last TREATMENTS specification and applies it to the plans that are generated by each of the **FACTORS** statements. The TREATMENTS statement must follow a **FACTORS** statement. The TREATMENTS statement has the same syntax as the **FACTORS** statement. The individual *factor-selections* also have the same form as in the **FACTORS** statement:

```
name = m <OF n> <selection-type> ;
```

The procedure generates each treatment simultaneously with the lowest (that is, the most nested) factor in the last **FACTORS** statement. The  $m$  value for each treatment must be at least as large as the  $m$  for the most nested factor.

The following statements use both a **FACTORS** and a **TREATMENTS** statement. First the **FACTORS** statement sets up the rows and columns of a  $3 \times 3$  square (factors  $r$  and  $c$ ). Then, the **TREATMENTS** statement augments the square with two cyclic treatments. The resulting design is a  $3 \times 3$  Graeco-Latin square, a type of design useful in main-effects factorial experiments.

```
proc plan;
 factors r=3 ordered c=3 ordered;
 treatments a=3 cyclic
 b=3 cyclic 2;
run;
```

The resulting Graeco-Latin square design is shown in [Figure 68.5](#). Notice how the values of  $r$  and  $c$  are ordered (1, 2, 3) as requested.

**Figure 68.5** A  $3 \times 3$  Graeco-Latin Square

| The PLAN Procedure |       |       |       |     |
|--------------------|-------|-------|-------|-----|
| r                  | --c-- | --a-- | --b-- |     |
| 1                  | 1 2 3 | 1 2 3 | 1     | 2 3 |
| 2                  | 1 2 3 | 2 3 1 | 3     | 1 2 |
| 3                  | 1 2 3 | 3 1 2 | 2     | 3 1 |

---

## Details: PLAN Procedure

---

### Using PROC PLAN Interactively

After specifying a design with a **FACTORS** statement and running PROC PLAN with a **RUN** statement, you can generate additional plans and output data sets without invoking PROC PLAN again.

In PROC PLAN, all statements can be used interactively. You can execute statements singly or in groups by following the single statement or group of statements with a **RUN** statement.

If you use PROC PLAN interactively, you can end the procedure with a **DATA** step, another PROC step, an **ENDSAS** statement, or a **QUIT** statement. The syntax of the **QUIT** statement is

```
quit;
```

When you use PROC PLAN interactively, additional **RUN** statements do not end the procedure but tell PROC PLAN to execute additional statements.

## Output Data Sets

To understand how PROC PLAN creates output data sets, you need to look at how the procedure represents a plan. A plan is a list of values for all the factors, the values being chosen according to the *factor-selection* requests you specify. For example, consider the plan produced by the following statements:

```
proc plan seed=12345;
 factors a=3 b=2;
run;
```

The plan as displayed by PROC PLAN is shown in Figure 68.6.

**Figure 68.6** A Simple Plan

| The PLAN Procedure |        |        |        |   |
|--------------------|--------|--------|--------|---|
| Factor             | Select | Levels | Order  |   |
| a                  | 3      | 3      | Random |   |
| b                  | 2      | 2      | Random |   |
|                    |        | a      | -b-    |   |
|                    |        | 2      | 2      | 1 |
|                    |        | 1      | 1      | 2 |
|                    |        | 3      | 2      | 1 |

The first cell of the plan has a=2 and b=2, the second has a=2 and b=1, the third has a=1 and b=1, and so on. If you output the plan to a data set with the OUTPUT statement, by default the output data set contains a numeric variable with that factor's name; the values of this numeric variable are the numbers of the successive levels selected for the factor in the plan. For example, the following statements produce Figure 68.7.

```
proc plan seed=12345;
 factors a=3 b=2;
 output out=out;
run;
proc print data=out;
run;
```

**Figure 68.7** Output Data Set from Simple Plan

| Obs | a | b |
|-----|---|---|
| 1   | 2 | 2 |
| 2   | 2 | 1 |
| 3   | 1 | 1 |
| 4   | 1 | 2 |
| 5   | 3 | 2 |
| 6   | 3 | 1 |

Alternatively, you can specify the values that are output for a factor with the `CVALS=` or `NVALS=` option. Also, you can specify that the internal values be associated with the output values in random order with the `RANDOM` option. See the section “[OUTPUT Statement](#)” on page 5779.

If you also specify an input data set (`DATA=`), each factor is associated with a variable in the `DATA=` data set. This occurs either implicitly by the factor and variable having the same name or explicitly as described in the specifications for the `OUTPUT` statement. In this case, the values of the variables corresponding to the factors are first read and then interpreted as describing the position of a cell in the plan. Then the respective values taken by the factors at that position are assigned to the variables in the `OUT=` data set. For example, consider the data set defined by the following statements.

```
data in;
 input a b;
 datalines;
1 1
2 1
3 1
;
```

Suppose you specify this data set as an input data set for the `OUTPUT` statement.

```
proc plan seed=12345;
 factors a=3 b=2;
 output out=out data=in;
run;
proc print data=out;
run;
```

PROC PLAN interprets the first observation as referring to the cell in the first row and column of the plan, since `a=1` and `b=1`; likewise, the second observation is interpreted as the cell in the second row and first column, and the third observation as the cell in the third row and first column. In the output data set, `a` and `b` have the values they have in the plan at these positions, as shown in [Figure 68.8](#).

**Figure 68.8** Output Form of Input Data Set from Simple Plan

| Obs | a | b |
|-----|---|---|
| 1   | 2 | 2 |
| 2   | 1 | 1 |
| 3   | 3 | 2 |

When the factors are random, this has the effect of randomizing the input data set in the same manner as the plan produced (see the sections “[Randomizing Designs](#)” on page 5786 and “[Randomly Assigning Subjects to Treatments](#)” on page 5774).

---

## Specifying Factor Structures

By appropriately combining features of the PLAN procedure, you can construct an extensive set of designs. The basic tools are the *factor-selections*, which are used in the `FACTORS` and `TREATMENTS` statements.

Table 68.2 summarizes how the procedure interprets various *factor-selections* (assuming that the **ORDERED** option is not specified in the **PROC PLAN** statement).

**Table 68.2** *Factor-Selection Interpretation*

| <b>Form of Request</b>                                                              | <b>Interpretation</b>                                                                                                                                 | <b>Example</b>                                     | <b>Results</b>                                                                                                                                                                                      |
|-------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>name=m</i>                                                                       | produce a random permutation of the integers $1, 2, \dots, m$                                                                                         | <b>t=15</b>                                        | lists a random ordering of the numbers $1, 2, \dots, 15$                                                                                                                                            |
| <i>name=m</i><br>cyclic                                                             | cyclically permute the integers $1, 2, \dots, m$                                                                                                      | <b>t=5 cyclic</b>                                  | selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,1; then 3,4,5,1,2; and so on.                                                                                                   |
| <i>name=m</i> of <i>n</i>                                                           | choose a random sample of <i>m</i> integers (without replacement) from the set of integers $1, 2, \dots, n$                                           | <b>t=5 of 15</b>                                   | lists a random selection of 5 numbers from 1 to 15. First, the procedure selects 5 numbers and then arranges them in random order.                                                                  |
| <i>name=m</i> of <i>n</i><br>ordered                                                | has the same effect as <i>name=m</i> ordered                                                                                                          | <b>t=5 of 15<br/>ordered</b>                       | lists the integers 1 to 5 in increasing order (same as t=5 ordered)                                                                                                                                 |
| <i>name=m</i> of <i>n</i><br>cyclic                                                 | permute <i>m</i> of the <i>n</i> integers                                                                                                             | <b>t=5 of 30<br/>cyclic</b>                        | selects the integers 1 to 5. On the next iteration, selects 2,3,4,5,6; then 3,4,5,6,7; and so on. The 30th iteration produces 30,1,2,3,4; the 31st iteration produces 1,2,3,4,5; and so on.         |
| <i>name=m</i><br>perm                                                               | produce a list of all permutations of <i>m</i> integers                                                                                               | <b>t=5 perm</b>                                    | lists the integers 1,2,3,4,5 on the first iteration; on the second lists 1,2,3,5,4; on the 119th iteration lists 5,4,3,1,2; and on the last (120th) lists 5,4,3,2,1.                                |
| <i>name=m</i> of <i>n</i><br>comb                                                   | choose combinations of <i>m</i> integers from <i>n</i> integers                                                                                       | <b>t=3 of 5<br/>comb</b>                           | lists all combinations of 5 choose 3 integers. The first iteration is 1,2,3; the second is 1,2,4; the third is 1,2,5; and so on until the last iteration 3,4,5.                                     |
| <i>name=m</i> of <i>n</i><br>cyclic<br>( <i>initial-block</i> )                     | permute <i>m</i> of the <i>n</i> integers, starting with the values specified in the <i>initial-block</i>                                             | <b>t=4 of 30<br/>cyclic<br/>(2 10 15 18)</b>       | selects the integers 2,10,15,18. On the next iteration, selects 3,11,16,19; then 4,12,17,20; and so on. The thirteenth iteration is 14,22,27,30; the fourteenth iteration is 15,23,28,1; and so on. |
| <i>name=m</i> of <i>n</i><br>cyclic<br>( <i>initial-block</i> )<br><i>increment</i> | permute <i>m</i> of the <i>n</i> integers. Start with the values specified in the <i>initial-block</i> , then add the <i>increment</i> to each value. | <b>t=4 of 30<br/>cyclic<br/>(2 10 15 18)<br/>2</b> | selects the integers 2,10,15,18. On the next iteration, selects 4,12,17,20; then 6,14,19,22; and so on. The wrap occurs at the eighth iteration. The eighth iteration is 16,24,29,2; and so on.     |

In Table 68.2, in order for more than one iteration to appear in the plan, another *name=j* factor selection (with  $j > 1$ ) must precede the example factor selection. For example, the following statements produce six of the iterations described in the last entry of Table 68.2.

```
proc plan;
 factors c=6 ordered t=4 of 30 cyclic (2 10 15 18) 2;
run;
```

The following statements create a randomized complete block design and output the design to a data set.

```
proc plan ordered;
 factors blocks=3 cell=5;
 treatments t=5 random;
 output out=rcdb;
run;
```

---

## Randomizing Designs

In many situations, proper randomization is crucial for the validity of any conclusions to be drawn from an experiment. Randomization is used both to neutralize the effect of any unknown systematic biases that might be involved in the design and to provide a basis for the assumptions underlying the analysis.

You can use PROC PLAN to randomize an already existing design: one produced by a previous call to PROC PLAN, perhaps, or a more specialized design taken from a standard reference such as Cochran and Cox (1957). The method is to specify the appropriate block structure in the **FACTORS** statement and then to specify the data set where the design is stored with the **DATA=** option in the **OUTPUT** statement. For an illustration of this method, see the section “Randomly Assigning Subjects to Treatments” on page 5774).

Two sorts of randomization are provided for, corresponding to the **RANDOM** factor selection and association types in the **FACTORS** and **OUTPUT** statements, respectively. Designs in which factors are completely nested (for example, block designs) should be randomized by specifying that the selection type of each factor is **RANDOM** in the **FACTORS** statement, which is the default (see Example 68.3). On the other hand, if the factors are crossed (for example, row-and-column designs), they should be randomized by one random reassignment of their values for the whole design. To do this, specify that the association type of each factor is **RANDOM** in the **OUTPUT** statement (see Example 68.4).

---

## Displayed Output

The PLAN procedure displays the following output:

- the  $m$  value for each factor, which is the number of values to be selected
- the  $n$  value for each factor, which is the number of values to be selected from
- the selection type for each factor, as specified in the **FACTORS** statement
- the initial block and increment number for cyclic factors
- the *factor-value-selections* making up each plan

In addition, notes are written to the log that give the starting and ending values of the random number seed for each call to PROC PLAN.

---

## ODS Table Names

PROC PLAN assigns a name to each table it creates. You can use these names to reference the table in the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 68.3** ODS Tables Produced by PROC PLAN

| ODS Table Name | Description                  | Statements                |
|----------------|------------------------------|---------------------------|
| FInfo          | General factor information   | FACTORS and no TREATMENTS |
| PFInfo         | Plot factor information      | FACTORS and TREATMENTS    |
| Plan           | Computed plan                | default                   |
| TFInfo         | Treatment factor information | FACTORS and TREATMENTS    |

---

## Examples: PLAN Procedure

---

### Example 68.1: A Split-Plot Design

This plan is appropriate for a split-plot design with main plots forming a randomized complete block design. In this example, there are three blocks, four main plots per block, and two subplots per main plot. First, three random permutations (one for each of the blocks) of the integers 1, 2, 3, and 4 are produced. The four integers correspond to the four levels of the main plot factor *a*; the permutation determines how the levels of *a* are assigned to the main plots within a block. For each of these 12 numbers (four numbers per block for three blocks), a random permutation of the integers 1 and 2 is produced. Each two-integer permutation determines the assignment of the two levels of the subplot factor *b* within a main plot. The following statements produce Output 68.1.1:

```
title 'Split Plot Design';
proc plan seed=37277;
 factors Block=3 ordered a=4 b=2;
run;
```

**Output 68.1.1** A Split-Plot Design

| Split Plot Design  |        |        |         |
|--------------------|--------|--------|---------|
| The PLAN Procedure |        |        |         |
| Factor             | Select | Levels | Order   |
| Block              | 3      | 3      | Ordered |
| a                  | 4      | 4      | Random  |
| b                  | 2      | 2      | Random  |

| Block | a | -b- |
|-------|---|-----|
| 1     | 4 | 2 1 |
|       | 3 | 2 1 |
|       | 1 | 2 1 |
|       | 2 | 2 1 |
| 2     | 4 | 1 2 |
|       | 3 | 1 2 |
|       | 1 | 2 1 |
|       | 2 | 1 2 |
| 3     | 4 | 2 1 |
|       | 2 | 2 1 |
|       | 3 | 2 1 |
|       | 1 | 2 1 |

**Example 68.2: A Hierarchical Design**

In this example, three plants are nested within four pots, which are nested within three houses. The **FACTORS** statement requests a random permutation of the numbers 1, 2, and 3 to choose Houses randomly. The second step requests a random permutation of the numbers 1, 2, 3, and 4 for each of those first three numbers to randomly assign Pots to Houses. Finally, the **FACTORS** statement requests a random permutation of 1, 2, and 3 for each of the 12 integers in the second set of permutations. This last step randomly assigns Plants to Pots. The following statements produce **Output 68.2.1**:

```

title 'Hierarchical Design';
proc plan seed=17431;
 factors Houses=3 Pots=4 Plants=3 / noprint;
 output out=nested;
run;

proc print data=nested;
run;

```

**Output 68.2.1** A Hierarchical Design

| Hierarchical Design |        |      |        |
|---------------------|--------|------|--------|
| Obs                 | Houses | Pots | Plants |
| 1                   | 1      | 3    | 2      |
| 2                   | 1      | 3    | 3      |
| 3                   | 1      | 3    | 1      |
| 4                   | 1      | 1    | 3      |
| 5                   | 1      | 1    | 1      |
| 6                   | 1      | 1    | 2      |
| 7                   | 1      | 2    | 2      |
| 8                   | 1      | 2    | 3      |
| 9                   | 1      | 2    | 1      |
| 10                  | 1      | 4    | 3      |
| 11                  | 1      | 4    | 2      |
| 12                  | 1      | 4    | 1      |
| 13                  | 2      | 4    | 1      |
| 14                  | 2      | 4    | 3      |
| 15                  | 2      | 4    | 2      |
| 16                  | 2      | 2    | 2      |
| 17                  | 2      | 2    | 1      |
| 18                  | 2      | 2    | 3      |
| 19                  | 2      | 3    | 2      |
| 20                  | 2      | 3    | 3      |
| 21                  | 2      | 3    | 1      |
| 22                  | 2      | 1    | 2      |
| 23                  | 2      | 1    | 3      |
| 24                  | 2      | 1    | 1      |
| 25                  | 3      | 4    | 1      |
| 26                  | 3      | 4    | 3      |
| 27                  | 3      | 4    | 2      |
| 28                  | 3      | 1    | 3      |
| 29                  | 3      | 1    | 2      |
| 30                  | 3      | 1    | 1      |

**Example 68.3: An Incomplete Block Design**

Jarrett and Hall (1978) give an example of a generalized cyclic design with good efficiency characteristics. The design consists of two replicates of 52 treatments in 13 blocks of size 8. The following statements use the PLAN procedure to generate this design in an appropriately randomized form and store it in a SAS data set GCBD. Then the design is sorted and transposed to display in randomized order. The following statements produce Output 68.3.1 and Output 68.3.2:

```

title 'Generalized Cyclic Block Design';
proc plan seed=33373;
 factors Block=13 Plot=8;
 treatments Treatment=8 of 52 cyclic (1 2 3 4 32 43 46 49) 4;
 output out=GCBD;
quit;
proc sort data=GCBD out=GCBD;
 by Block Plot;
run;
proc transpose data= GCBD(rename=(Plot=_NAME_))
 out =tGCBD(drop=_NAME_);
 by Block;
 var Treatment;
run;
proc print data=tGCBD noobs;
run;

```

Output 68.3.1 A Generalized Cyclic Block Design

| Generalized Cyclic Block Design |                 |                         |                     |                           |

**Example 68.4: A Latin Square Design**

All of the preceding examples involve designs with completely nested block structures, for which PROC PLAN was especially designed. However, by appropriate coordination of its facilities, PROC PLAN can accommodate a much wider class of designs. A Latin square design is based on experimental units that have a row-and-column block structure. The following statements use the **CYCLIC** option in the **TREATMENTS** statement to generate a simple  $4 \times 4$  Latin square. The **RANDOM** option in the **OUTPUT** statement randomizes the generated Latin square by randomly permuting the row, column, and treatment values independently. This example also uses *factor-value-settings* in the **OUTPUT** statement.

```

title 'Latin Square Design';
proc plan seed=37430;
 factors Row=4 ordered Col=4 ordered / noprint;
 treatments Tmt=4 cyclic;
 output out=LatinSquare
 Row cvals=('Day 1' 'Day 2' 'Day 3' 'Day 4') random
 Col cvals=('Lab 1' 'Lab 2' 'Lab 3' 'Lab 4') random
 Tmt nvals=(0 100 250 450) random;
quit;

proc sort data=LatinSquare out=LatinSquare;
 by Row Col;
run;
proc transpose data= LatinSquare(rename=(Col=_NAME_))
 out =tLatinSquare(drop=_NAME_);
 by Row;
 var Tmt;
run;
proc print data=tLatinSquare noobs;
run;

```

The preceding statements produce [Output 68.4.1](#).

**Output 68.4.1** A Randomized Latin Square Design

| Latin Square Design |       |       |       |       |
|---------------------|-------|-------|-------|-------|
| Row                 | Lab_1 | Lab_2 | Lab_3 | Lab_4 |
| Day 1               | 0     | 250   | 100   | 450   |
| Day 2               | 250   | 450   | 0     | 100   |
| Day 3               | 100   | 0     | 450   | 250   |
| Day 4               | 450   | 100   | 250   | 0     |

You can use the PLAN procedure to randomize Latin squares from any transformation sets. See Kempthorne (1952) for definitions of transformation sets. In particular, the following DATA step and PROC PLAN statements demonstrate how to randomize a Latin square from the second transformation set defined in Kempthorne (1952). The following DATA step creates a  $4 \times 4$  Latin square from the transformation set 2:

```
data Unrandomized;
 do Row = 1 to 4;
 do Col = 1 to 4;
 input Tmt @@;
 output;
 end;
 end;
 datalines;
1 2 3 4
2 1 4 3
3 4 1 2
4 3 2 1
;
```

The following PROC PLAN statements permute the rows and columns and randomly assign treatment levels.

```
proc plan;
 factors Row = 4;
 output data= Unrandomized out=Randomized1;
run;
 factors Col = 4;
 output data= Randomized1 out=Randomized2;
run;
 factors Tmt = 4;
 output data= Randomized2 out=Randomized3;
run;

proc sort data=Randomized3;
 by Row Col;
run;
proc transpose data= Randomized3 out =tLatinSquare2(drop=_NAME_);
 by Row;
 var Tmt;
run;
proc print data=tLatinSquare2 noobs;
run;
```

**Output 68.4.2** A Randomized Latin Square from a Different Transformation Set

```

**Example 68.5: A Generalized Cyclic Incomplete Block Design**

The following statements depict how to create an appropriately randomized generalized cyclic incomplete block design for  $v$  treatments (given by the value of  $t$ ) in  $b$  blocks (given by the value of  $b$ ) of size  $k$  (with values of  $p$  indexing the cells within a block) with initial block  $(e_1 e_2 \dots e_k)$  and increment number  $i$ .

```

factors b=b p=k ;
treatments t=k of v cyclic (e1 e2 ... ek) i ;

```

For example, the specification

```
proc plan seed=37430;
 factors b=10 p=4;
 treatments t=4 of 30 cyclic (1 3 4 26) 2;
run;
```

generates the generalized cyclic incomplete block design given in Example 1 of Jarrett and Hall (1978), which is given by the rows and columns of the plan associated with the treatment factor *t* in [Output 68.5.1](#).

**Output 68.5.1** A Generalized Cyclic Incomplete Block Design

| The PLAN Procedure |        |         |             |                           |

## Example 68.6: Permutations and Combinations

Occasionally, you might need to generate all possible permutations of  $n$  things, or all possible combinations of  $n$  things taken  $m$  at a time.

For example, suppose you are planning an experiment in cognitive psychology where you want to present four successive stimuli to each subject. You want to observe each permutation of the four stimuli. The following statements use PROC PLAN to create a data set containing all possible permutations of four numbers in random order.

```

title 'All Permutations of 1,2,3,4';
proc plan seed=60359;
 factors Subject = 24
 Order = 4 ordered;
 treatments Stimulus = 4 perm;
 output out=Psych;
run;

proc sort data=Psych out=Psych;
 by Subject Order;
run;

proc transpose data= Psych(rename=(Order=_NAME_))
 out =tPsych(drop=_NAME_);
 by Subject;
 var Stimulus;
run;

proc print data=tPsych noobs;
run;

```

The variable Subject is set at 24 levels because there are  $4! = 24$  total permutations to be listed. If Subject > 24, the list repeats. [Output 68.6.1](#) displays the PROC PLAN output. Note that the variable Subject is listed in random order.

**Output 68.6.1** List of Permutations

| All Permutations of 1,2,3,4 |        |        |         |
|-----------------------------|--------|--------|---------|
| The PLAN Procedure          |        |        |         |
| Plot Factors                |        |        |         |
| Factor                      | Select | Levels | Order   |
| Subject                     | 24     | 24     | Random  |
| Order                       | 4      | 4      | Ordered |
| Treatment Factors           |        |        |         |
| Factor                      | Select | Levels | Order   |
| Stimulus                    | 4      | 4      | Perm    |

**Output 68.6.1** *continued*

| Subject | -Order- | -Stimulus- |
|---------|---------|------------|
| 4       | 1 2 3 4 | 1 2 3 4    |

The output data set Psych contains 96 observations of the 3 variables (Subject, Order, and Stimulus). Sorting the output data set by Subject and by Order within Subject results in all possible permutations of Stimulus in random order. PROC TABULATE displays these permutations in [Output 68.6.2](#).

**Output 68.6.2** Randomized Permutations

| All Permutations of 1,2,3,4 |    |    |    |    |

| 11                          | 4  | 2  | 3  | 1  |
| 12                          | 3  | 2  | 1  | 4  |
| 13                          | 3  | 1  | 2  | 4  |
| 14                          | 2  | 1  | 4  | 3  |
| 15                          | 1  | 2  | 4  | 3  |
| 16                          | 3  | 1  | 4  | 2  |
| 17                          | 1  | 4  | 3  | 2  |
| 18                          | 3  | 2  | 4  | 1  |
| 19                          | 2  | 1  | 3  | 4  |
| 20                          | 4  | 3  | 2  | 1  |
| 21                          | 3  | 4  | 1  | 2  |
| 22                          | 4  | 1  | 2  | 3  |
| 23                          | 2  | 3  | 4  | 1  |
| 24                          | 1  | 3  | 2  | 4  |

As another example, suppose you have six alternative treatments, any four of which can occur together in a block (in no particular order). The following statements use PROC PLAN to create a data set containing all possible combinations of six numbers taken four at a time. In this case, you use ODS to create the data set.

```

title 'All Combinations of (6 Choose 4) Integers';
proc plan;
 factors Block=15 ordered
 Treat= 4 of 6 comb;
 ods output Plan=Combinations;
run;

proc print data=Combinations noobs;
run;

```

The variable Block has 15 levels since there are a total of  $6!/(4!2!) = 15$  combinations of four integers chosen from six integers. The data set formed by ODS from the displayed plan has one row for each block, with the four values of Treat corresponding to four different variables, as shown in [Output 68.6.3](#) and [Output 68.6.4](#).

## Example 68.7: Crossover Designs

In *crossover* experiments, the same experimental units or subjects are given multiple treatments in sequence, and the model for the response at any one period includes an effect for the treatment applied in the previous period. A good design for a crossover experiment is therefore one that balances how often each treatment is preceded by each other treatment. Cox (1992) gives the following example of a balanced crossover experiment for paper production. In this experiment, the subjects are production runs of the mill, with the treatments being six different concentrations of pulp used in sequence. The following statements construct this design in a standard form:

```
proc plan;
 factors Run=6 ordered Period=6 ordered;
 treatments Treatment=6 cyclic (1 2 6 3 5 4);
run;
```

Output 68.7.1 shows the results of the preceding statements.

**Output 68.7.1** Crossover Design for Six Treatments

| The PLAN Procedure |        |             |         |                           |
|--------------------|--------|-------------|---------|---------------------------|
| Plot Factors       |        |             |         |                           |
| Factor             | Select | Levels      | Order   |                           |
| Run                | 6      | 6           | Ordered |                           |
| Period             | 6      | 6           | Ordered |                           |
| Treatment Factors  |        |             |         |                           |
| Factor             | Select | Levels      | Order   | Initial Block / Increment |
| Treatment          | 6      | 6           | Cyclic  | (1 2 6 3 5 4) / 1         |
|                    | Run    | ---Period-- |         | -Treatment-               |
|                    | 1      | 1 2 3 4 5 6 |         | 1 2 6 3 5 4               |
|                    | 2      | 1 2 3 4 5 6 |         | 2 3 1 4 6 5               |
|                    | 3      | 1 2 3 4 5 6 |         | 3 4 2 5 1 6               |
|                    | 4      | 1 2 3 4 5 6 |         | 4 5 3 6 2 1               |
|                    | 5      | 1 2 3 4 5 6 |         | 5 6 4 1 3 2               |
|                    | 6      | 1 2 3 4 5 6 |         | 6 1 5 2 4 3               |

The construction method for this example is due to Williams (1949). The initial block for the treatment variable Treatment is defined as follows for  $n = 6$ :

$$(1 \quad 2 \quad n \quad 3 \quad n - 1 \quad \dots \quad n/2 \quad n/2 + 2 \quad n/2)$$

This general form serves to generate a balanced crossover design for  $n$  treatments and  $n$  subjects in  $n$  periods when  $n$  is even. When  $n$  is odd,  $2n$  subjects are required, with the following initial blocks, respectively for odd and even  $n$ :

$$\begin{pmatrix} 1 & 2 & n & 3 & n-1 & \dots & n/2+1 & n/2 \\ n/2 & n/2+1 & \dots & n-1 & 3 & n & 2 & 1 \end{pmatrix}$$

In order to randomize Williams' crossover designs, the following statements randomly permute the subjects and treatments:

```
proc plan seed=136149876;
 factors Run=6 ordered Period=6 ordered / noprint;
 treatments Treatment=6 cyclic (1 2 6 3 5 4);
 output out=RandomizedDesign
 Run random
 Treatment random
 ;
run;

/*
/ Relabel Period to obtain the same design as in Cox (1992) .
/-----*/
data RandomizedDesign;
 set RandomizedDesign;
 Period = mod(Period+2,6)+1;
run;

proc sort data=RandomizedDesign;
 by Run Period;
run;

proc transpose data=RandomizedDesign out=tDesign(drop=_name_);
 by notsorted Run;
 var Treatment;
run;

data tDesign;
 set tDesign;
 rename COL1-COL6 = Period_1-Period_6;
run;

proc print data=tDesign noobs;
run;
```

In the preceding statements, Run and Treatment are randomized by using the **RANDOM** option in the **OUTPUT** statement, and new labels for Period are obtained in a subsequent **DATA** step. This Period relabeling is not necessary and might not be valid for Williams' designs in general; it is used in this example only to match results with those of Cox (1992). The **SORT** and **TRANSPOSE** steps then prepare the design to be printed in a standard form, shown in [Output 68.7.2](#).

**Output 68.7.2** Randomized Crossover Design

| Run | Period_1 | Period_2 | Period_3 | Period_4 | Period_5 | Period_6 |
|-----|----------|----------|----------|----------|----------|----------|
| 1   | 3        | 6        | 2        | 5        | 4        | 1        |
| 2   | 5        | 3        | 4        | 6        | 1        | 2        |
| 3   | 1        | 4        | 5        | 2        | 6        | 3        |
| 4   | 2        | 1        | 6        | 4        | 3        | 5        |
| 5   | 6        | 5        | 1        | 3        | 2        | 4        |
| 6   | 4        | 2        | 3        | 1        | 5        | 6        |

The analysis of a crossover experiment requires for each observation a *carryover* variable whose values are the treatment in the preceding period. The following statements add such a variable to the randomized design constructed previously:

```
proc sort data=RandomizedDesign;
 by Run Period;
run;
data RandomizedDesign;
 set RandomizedDesign;
 by Run period;
 LagTreatment = lag(Treatment);
 if (first.Run) then LagTreatment = .;
run;

proc transpose data=RandomizedDesign out=tDesign(drop=_name_);
 by notsorted Run;
 var LagTreatment;
run;
data tDesign;
 set tDesign;
 rename COL1-COL6 = Period_1-Period_6;
run;
proc print data=tDesign noobs;
run;
```

Output 68.7.3 displays the values of the carryover variable for each run and period.

**Output 68.7.3** Lag Treatment Effect in Crossover Design

| Run | Period_1 | Period_2 | Period_3 | Period_4 | Period_5 | Period_6 |
|-----|----------|----------|----------|----------|----------|----------|
| 1   | .        | 3        | 6        | 2        | 5        | 4        |
| 2   | .        | 5        | 3        | 4        | 6        | 1        |
| 3   | .        | 1        | 4        | 5        | 2        | 6        |
| 4   | .        | 2        | 1        | 6        | 4        | 3        |
| 5   | .        | 6        | 5        | 1        | 3        | 2        |
| 6   | .        | 4        | 2        | 3        | 1        | 5        |

Of course, the carryover variable has no effect in the first period, which is why it is coded with a missing value in this case.

The experimental LAG effect in the EFFECT statement in PROC ORTHOREG provides a convenient mechanism for incorporating the carryover effect into the analysis. The following statements first add the observed data to the design to create the Mills data set. Then PROC ORTHOREG is invoked, and the carryover effect is defined as a lag effect with the relevant period and subject information specified. ODS is used to trim down the results to show only the parts that are usually of interest in crossover analysis. For more information about the EFFECTS statement in PROC ORTHOREG, see the section “EFFECT Statement” on page 5517.

The Type I analysis of variance indicates that all effects are significant—in particular, both the direct and the carryover effects of the treatment. In the presence of carryover effects, the LS-means need to be defined

with some care. The LS-means for treatments computed using balanced margins for the carryover effect are inestimable; so the OBSMARGINS option is specified in the LSMEANS statement in order to use the observed margins instead. The observed margins take the absence of a carryover effect in the first period into account. Note that the LS-means themselves of the carryover effect are inestimable, but their differences are estimable. The LS-means of the direct effect of the treatment and the ANOM differences for the LS-means of their carryover effect match the “adjusted direct effects” and “adjusted residual effects,” respectively, of Cox (1992).

## Overview: PLM Procedure

The PLM procedure performs postfitting statistical analyses for the contents of a SAS item store that was previously created with the STORE statement in some other SAS/STAT procedure. An item store is a special SAS-defined binary file format used to store and restore information with a hierarchical structure.

The statements available in the PLM procedure are designed to reveal the contents of the source item store via the Output Delivery System (ODS) and to perform postfitting tasks such as the following:

- testing hypotheses
- computing confidence intervals
- producing prediction plots
- scoring a new data set

The use of item stores and PROC PLM enables you to separate common postprocessing tasks, such as testing for treatment differences and predicting new observations under a fitted model, from the process of model building and fitting. A numerically expensive model fitting technique can be applied once to produce a source item store. The PLM procedure can then be called multiple times and the results of the fitted model analyzed without incurring the model fitting expenditure again.

The PLM procedure offers the most advanced postprocessing techniques available in SAS/STAT software. These techniques include step-down multiplicity adjustments for  $p$ -values,  $F$  tests with order restrictions, analysis of means (ANOM), and sampling-based linear inference based on Bayes posterior estimates.

The following procedures support the STORE statement for the generation of item stores that can be processed with the PLM procedure: GENMOD, GLIMMIX, GLM, GLMSELECT, LIFEREG, LOGISTIC, MIXED, ORTHOREG, PHREG, PROBIT, SURVEYLOGISTIC, SURVEYPHREG, and SURVEYREG. The RELIABILITY procedure in SAS/QC software also supports the STORE statement. For details about the STORE statement, see the section “STORE Statement” on page 501 of Chapter 19, “Shared Concepts and Topics.”

---

## Basic Features

The PLM procedure, unlike most SAS/STAT procedures, does not operate primarily on an input data set. Instead, the procedure requires you to specify an item store with the RESTORE= option in the PROC PLM statement. The item store contains the necessary information and context about the statistical model that was fit when the store was created. SAS data sets are used only to provide input information in some circumstances. For example, when scoring a data set or when computing least squares means with specially defined population margins. In other words, instead of reading raw data and fitting a model, the PLM procedure reads the results of a model having been fit.

In order to interact with the item store and to reveal its contents, the PLM procedure supports the SHOW statement which converts item store information into standard ODS tables for viewing and further processing.

The PLM procedure is sensitive to the contents of the item store. For example, if a BAYES statement was in effect when the item store was created, the posterior parameter estimates are saved to the item store so that the PLM procedure can perform postprocessing tasks by taking the posterior distribution of estimable functions into account. As another example, for item stores that are generated by a mixed model procedure using the Satterthwaite or Kenward-Roger (Kenward and Roger 1997) degrees-of-freedom method, these methods continue to be available when the item store contents are processed with the PLM procedure.

Because the PLM procedure does not read data and does not fit a model, the processing time of this procedure is usually considerably less than the processing time of the procedure that generates the item store.

## PROC PLM Contrasted with Other SAS Procedures

In contrast to other analytic procedures in SAS/STAT software, the PLM procedure does not use an input data set. Instead, it retrieves information from an item store.

Some of the statements in the PLM procedure are also available as postprocessing statements in other procedures. Table 69.1 lists SAS/STAT procedures that support the same postprocessing statements as PROC PLM does.

**Table 69.1** SAS/STAT Procedures with Postprocessing Statements Similar to PROC PLM

|                | EFFECTPLOT | ESTIMATE | LSMEANS | LSMESTIMATE | SLICE | TEST |

| SURVEYREG      |            | ✓        | ✓       | ✓           | ✓     | ✓    |

Table entries marked with ✓ indicate procedures that support statements with the same functionality as in PROC PLM. Those entries marked with ✓\* indicate procedures that support statements with same names but different syntaxes from PROC PLM. You can find the most comprehensive set of features for these statements in the PLM procedure. For example, the LSMEANS statement is available in all of the listed procedures. For example, the ESTIMATE statement available in the GENMOD, GLIMMIX, GLM and MIXED procedures does not support all options that PROC PLM supports, such as multiple rows and multiplicity adjustments.

The WHERE statement in other procedures enables you to conditionally select a subset of the observations from the input data set so that the procedure processes only the observations that meet the specified conditions. Since the PLM procedure does not use an input data set, the WHERE statement in the PLM procedure has different functionality. If the item store contains information about BY groups—that is, a BY statement

was in effect when the item store was created—you can use the **WHERE** statement to select specific BY groups for the analysis. You can also use the **FILTER** statement in the PLM procedure to filter results from the ODS output and output data sets.

## Getting Started: PLM Procedure

The following DATA step creates a data set from a randomized block experiment with a factorial treatment structure of factors A and B:

```
data BlockDesign;
 input block a b y @@;
 datalines;
 1 1 1 56 1 1 2 41
 1 2 1 50 1 2 2 36
 1 3 1 39 1 3 2 35

 ;
```

The GLM procedure is used in the following statements to fit the model and to create a source item store for the PLM procedure:

```
proc glm data=BlockDesign;
 class block a b;
 model y = block a b a*b / solution;
 store sasuser.BlockAnalysis / label='PLM: Getting Started';
run;
```

The CLASS statement identifies the variables Block, A, and B as classification variables. The MODEL statement specifies the response variable and the model effects. The block effect models the design effect, and the a, b, and a\*b effects model the factorial treatment structure. The STORE statement requests that the context and results of this analysis be saved to an item store named sasuser.BlockAnalysis. Because the SASUSER library is specified as the library name of the item store, the store will be available after the SAS session completes. The optional label in the STORE statement identifies the store in subsequent analyses with the PLM procedure.

Note that having BlockDesign as the name of the output store would not create a conflict with the input data set name, because data sets and item stores are saved as files of different types.

Figure 69.1 displays the results from the GLM procedure. The “Class Level Information” table shows the number of levels and their values for the three classification variables. The “Parameter Estimates” table shows the estimates and their standard errors along with *t* tests.

**Figure 69.1** Class Variable Information, Fit Statistics, and Parameter Estimates

The following statements invoke the PLM procedure and use `sasuser.BlockAnalysis` as the source item store:

```
proc plm restore=sasuser.BlockAnalysis;
run;
```

These statements produce [Figure 69.2](#). The “Store Information” table displays information that is gleaned from the source item store. For example, the store was created by the GLM procedure at the indicated time and date, and the input data set for the analysis was `WORK.BLOCKDESIGN`. The label used earlier in the `STORE` statement of the GLM procedure also appears as a descriptor in [Figure 69.2](#).

Figure 69.2 Default Information

| The PLM Procedure       |                         |
|-------------------------|-------------------------|
| Store Information       |                         |
| Item Store              | SASUSER.BLOCKANALYSIS   |
| Label                   | PLM: Getting Started    |
| Data Set Created From   | WORK.BLOCKDESIGN        |
| Created By              | PROC GLM                |
| Date Created            | 13JUN12:12:33:28        |
| Response Variable       | y                       |
| Class Variables         | block a b               |
| Model Effects           | Intercept block a b a*b |
| Class Level Information |                         |
| Class                   | Levels Values           |
| block                   | 4 1 2 3 4               |
| a                       | 3 1 2 3                 |
| b                       | 2 1 2                   |

The “Store Information” table also echoes partial information about the variables and model effects that are used in the analysis. The “Class Level Information” table is produced by the PLM procedure by default whenever the model contains effects that depend on CLASS variables.

The following statements request a display of the fit statistics and the parameter estimates from the source item store and a test of the treatment main effects and their interactions:

```
proc plm restore=sasuser.BlockAnalysis;
 show fit parms;
 test a b a*b;
run;
```

The statements produce Figure 69.3. Notice that the estimates and standard errors in the “Parameter Estimates” table agree with the results displayed earlier by the GLM procedure, except for small differences in formatting.

Figure 69.3 Fit Statistics, Parameter Estimates, and Tests of Effects

| The PLM Procedure |          |
|-------------------|----------|

| b                               | 1      | 15     | 8.38    | 0.0111 |
| a*b                             | 2      | 15     | 1.74    | 0.2097 |

Since the main effects, but not the interaction are significant in this experiment, the subsequent analysis focuses on the main effects, in particular on the effect of variable A.

The following statements request the least squares means of the A effect along with their pairwise differences:

```
proc plm restore=sasuser.BlockAnalysis seed=3;
 lsmeans a / diff;
 lsmestimate a -1 1,
 1 1 -2 / uppertailed ftest;
run;
```

The **LSMESTIMATE** statement tests two linear combinations of the A least squares means: equality of the first two levels and whether the sum of the first two level effects equals twice the effect of the third level. The **FTEST** option in the **LSMESTIMATE** statement requests a joint *F* test for this two-row contrast. The **UPPERTAILED** option requests that the *F* test also be carried out under one-sided order restrictions. Since *F* tests under order restrictions (chi-bar-square statistic) require a simulation-based approach for the calculation of *p*-values, the random number stream is initialized with a seed value through the **SEED=** option in the **PROC PLM** statement.

The results of the **LSMEANS** and the **LSMESTIMATE** statement are shown in Figure 69.4.

Figure 69.4 LS-Means Related Inference for A Effect

| a                                        | 2      | 15       | 7.54           | 0.0054 | 15.07           | 0.0001        |        |

The least squares means for the three levels of variable A are 32.875, 34.125, and 25.75. The differences between the third level and the first and second levels are statistically significant at the 5% level ( $p$ -values of 0.0079 and 0.0026, respectively). There is no significant difference between the first two levels. The first row of the “Least Squares Means Estimates” table also displays the difference between the first two levels of factor A. Although the (absolute value of the) estimate and its standard error are identical to those in the “Differences of a Least Squares Means” table, the  $p$ -values do not agree because one-sided tests were requested in the LSMESTIMATE statement.

The “F Test” table in Figure 69.4 shows the two degree-of-freedom test for the linear combinations of the LS-means. The  $F$  value of 7.54 with  $p$ -value of 0.0054 represents the usual (two-sided)  $F$  test. Under the one-sided right-tailed order restriction imposed by the UPPERTAILED option, the ChiBarSq value of 15.07 represents the observed value of the chi-bar-square statistic of Silvapulle and Sen (2004). The associated  $p$ -value of 0.0001 was obtained by simulation.

Now suppose that you are interested in analyzing the relationship of the interaction cell means. (Typically this would not be the case in this example since the  $a*b$  interaction is not significant; see [Figure 69.3](#).) The `SLICE` statement in the following PROC PLM run produces an  $F$  test of equality and all pair-wise differences of the interaction means for the subset (partition) where variable B is at level '1'. With ODS Graphics enabled, the pairwise differences are displayed in a diffogram.

```
ods graphics on;
proc plm restore=sasuser.BlockAnalysis;
 slice a*b / sliceby(b='1') diff;
run;
ods graphics off;
```

The results are shown in [Figure 69.5](#). Since variable A has three levels, the test of equality of the A means at level '1' of B is a two-degree comparison. This comparison is statistically significant ( $p$ -value equals 0.0040). You can conclude that the three levels of A are not the same for the first level of B.

**Figure 69.5** Results from Analyzing an Interaction Partition

| b 1                                           | 2 | 3         | 12.0000   | 3.2914            | 15 | 3.65    | 0.0024  |

The table of “Simple Differences” was produced by the `DIFF` option in the `SLICE` statement. As is the case with the marginal comparisons in [Figure 69.4](#), there are significant differences against the third level of A if variable B is held fixed at '1'.

[Figure 69.6](#) shows the diffogram that displays the three pairwise least squares mean differences and their significance. Each line segment corresponds to a comparison. It centers at the least squares means in the pair with its length corresponding to the projected width of a confidence interval for the difference. If the variable B is held fixed at '1', both the first two levels are significantly different from the third level, but the difference between the first and the second level is not significant.

**Figure 69.6** LS-Means Difference Diffogram

## Syntax: PLM Procedure

The following statements are available in the PLM procedure:

```

PROC PLM RESTORE=item-store-specification < options > ;
 CODE < options > ;
 EFFECTPLOT < plot-type < (plot-definition-options) > > < / options > ;
 ESTIMATE < 'label' > estimate-specification < (divisor=n) >
 < , ... < 'label' > estimate-specification < (divisor=n) > > < / options > ;
 FILTER expression ;
 LSMEANS < model-effects > < / options > ;
 LSMESTIMATE model-effect < 'label' > values < divisor=n >
 < , ... < 'label' > values < divisor=n > > < / options > ;
 SCORE DATA=SAS-data-set < OUT=SAS-data-set >
 < keyword<=name> > ...
 < keyword<=name> > < / options > ;
 SHOW options ;
 SLICE model-effect < / options > ;
 TEST < model-effects > < / options > ;
 WHERE expression ;

```

With the exception of the **PROC PLM** statement and the **FILTER** statement, any statement can appear multiple times and in any order. The default order in which the statements are processed by the PLM procedure depends on the specification in the item store and can be modified with the **STMTORDER=** option in the **PROC PLM** statement.

In contrast to many other SAS/STAT modeling procedures, the PLM procedure does not have common modeling statements such as the **CLASS** and **MODEL** statements. This is because the information about classification variables and model effects is contained in the source item store that is passed to the procedure in the **PROC PLM** statement. All subsequent statements are checked for consistency with the stored model. For example, the statement

```
lsmeans c / diff;
```

is detected as not valid unless one of the following conditions was true at the time when the source store was created:

- The effect C was used in the model.
- C was specified in the **CLASS** statement.
- The **CLASS** variables in the model had a GLM parameterization.

The **FILTER**, **SCORE**, **SHOW**, and **WHERE** statements are described in full after the **PROC PLM** statement in alphabetical order. The **CODE**, **EFFECTPLOT**, **ESTIMATE**, **LSMEANS**, **LSMESTIMATE**, **SLICE**, and **TEST** statements are also used by many other procedures. Summary descriptions of functionality and syntax for these statements are also given after the **PROC PLM** statement in alphabetical order, but full documentation about them is available in Chapter 19, “Shared Concepts and Topics.”

## PROC PLM Statement

**PROC PLM RESTORE=***item-store-specification* < options > ;

The PROC PLM statement invokes the PLM procedure. The **RESTORE=** option with *item-store-specification* is required. Table 69.2 summarizes the options available in the PROC PLM statement.

**Table 69.2** PROC PLM Statement Options

| Option                        | Description                                                                                    |
|-------------------------------|------------------------------------------------------------------------------------------------|
| <b>Basic Options</b>          |                                                                                                |
| <b>RESTORE=</b>               | Specifies the source item store for processing                                                 |
| <b>SEED=</b>                  | Specifies the random number seed                                                               |
| <b>STMTORDER=</b>             | Affects the order in which statements are grouped during processing                            |
| <b>FORMAT=</b>                | Specifies how the PLM procedure handles user-defined formats                                   |
| <b>WHEREFORMAT</b>            | Specifies the constants (literals) in terms of the formatted values of the BY variables        |
| <b>Computational Options</b>  |                                                                                                |
| <b>ALPHA=</b>                 | Specifies the nominal significance level                                                       |
| <b>DDFMETHOD=</b>             | Specifies the method for determining denominator degrees of freedom                            |
| <b>PERCENTILES=</b>           | Supplies a list of percentiles for the construction of HPD intervals                           |
| <b>Displayed Output</b>       |                                                                                                |
| <b>MAXLEN=</b>                | Determines the maximum length of informational strings                                         |
| <b>NOCLPRINT</b>              | Suppresses the display of the “Class Level Information” table                                  |
| <b>NOINFO</b>                 | Suppresses the display of the “Store Information” table                                        |
| <b>NOPRINT</b>                | Suppresses tabular and graphical output                                                        |
| <b>PLOT</b>                   | Controls the plots produced through ODS Graphics                                               |
| <b>Singularity Tolerances</b> |                                                                                                |
| <b>ESTEPS=</b>                | Specifies the tolerance value used in determining the estimability of linear functions         |
| <b>SINGCHOL=</b>              | Tunes the singularity criterion in Cholesky decompositions                                     |
| <b>SINGRES=</b>               | Sets the tolerance for which the residual variance or scale parameter is considered to be zero |
| <b>SINGULAR=</b>              | Tunes the general singularity criterion                                                        |
| <b>ZETA=</b>                  | Tunes the sensitivity in forming Type III functions                                            |

You can specify the following *options*:

### **ALPHA=** $\alpha$

specifies the nominal significance level for multiplicity corrections and for the construction of confidence intervals. The value of  $\alpha$  must be between 0 and 1. The default is the value specified in the source item store, or 0.05 if the item store does not provide a value. The confidence level based on  $\alpha$  is  $1 - \alpha$ .

**DDFMETHOD=RESIDUAL | RES | ERROR****DDFMETHOD=NONE****DDFMETHOD=KENROG | KR | KENWARDROGER****DDFMETHOD=SATTERTH | SAT | SATTERTHWAITE**

specifies the method for determining denominator degrees of freedom for tests and confidence intervals. The default degree-of-freedom method is determined by the contents of the item store. You can override the default to some extent with the DDFMETHOD= option.

If you choose DDFMETHOD=NONE, then infinite denominator degrees of freedom are assumed for tests and confidence intervals. This essentially produces  $z$  tests and intervals instead of  $t$  tests and intervals and chi-square tests instead of  $F$  tests.

The KENWARDROGER and SATTERTHWAITE methods require that the source item store contain information about these methods. This information is currently available for item stores that were created with the MIXED or GLIMMIX procedures when the appropriate DDFM= option was in effect.

**ESTEPS= $\epsilon$** 

specifies the tolerance value used in determining the estimability of linear functions. The default value is determined by the contents of the source item store; it is usually 1E-4.

**FORMAT=NOLOAD | RELOAD**

specifies how the PLM procedure handles user-defined formats, which are not permanent. When the item store is created, user-defined formats are stored. When the PLM procedure opens an item store, it uses this option as follows. If FORMAT=RELOAD (the default), the stored formats are loaded again from the item store and formats that already exist in your SAS session are replaced by the reloaded formats. If FORMAT=NOLOAD, stored formats are not loaded from the item store and existing formats are not replaced.

With FORMAT=NOLOAD, you prevent the PLM procedure from reloading the format from the item store. As a consequence, PLM statements might fail if a format was present at the item store creation and is not available in your SAS session. Also, if you modify the format that was used in the item store creation and use FORMAT=NOLOAD, you might obtain unexpected results because levels of classification variables are remapped.

The “Class Level Information” table always displays the formatted values of classification variables that were used in fitting the model, regardless of the FORMAT= option. For more details about using formats with the PLM procedure, see “[User-Defined Formats and the PLM Procedure](#)” on page 5834.

**MAXLEN= $n$** 

determines the maximum length of informational strings in the “Store Information” table. This table displays, for example, lists of classification or BY variables and lists of model effects. The value of  $n$  determines the truncation length for these strings. The minimum and maximum values for  $n$  are 20 and 256, respectively. The default is  $n = 100$ .

**NOCLPRINT<= $number$ >**

suppresses the display of the “Class Level Information” table if you do not specify  $number$ . If you specify  $number$ , only levels with totals that are less than  $number$  are listed in the table. The PLM procedure produces the “Class Level Information” table by default when the model contains effects that depend on classification variables.

**NOINFO**

suppresses the display of the “Store Information” table.

**NOPRINT**

suppresses the generation of tabular and graphical output. When the NOPRINT option is in effect, ODS tables are also not produced.

**PERCENTILES=***value-list***PERCENTILE=***value-list*

supplies a list of percentiles for the construction of highest posterior density (HPD) intervals when the PLM procedure performs a sampling-based analysis (for example, when processing an item store that contains posterior parameter estimates from a Bayesian analysis). The default set of percentiles depends on the contents of the source item store; it is typically PERCENTILES=25, 50, 75. The entries in *value-list* must be strictly between 0 and 100.

**PLOTS** <(*global-plot-option*)> <=*specific-plot-options*>

controls the plots produced through ODS Graphics. ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc plm plots=all;
 lsmeans a/diff;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

**Global Plot Option**

The following *global-plot-option* applies to all plots produced by PROC PLM.

**UNPACKPANEL****UNPACK**

suppresses paneling. (By default, multiple plots can appear in some output panels.) Specify UNPACK to display each plot separately.

**Specific Plot Options**

You can specify the following *specific-plot-options*:

**ALL**

requests that all the appropriate plots be produced.

**NONE**

suppresses all plots.

**SEED=number**

specifies the random number seed for analyses that depend on a random number stream. You can also specify the random number seed through some PLM statements (for example, through the SEED= options in the ESTIMATE, LSMEANS, and LSMESTIMATE statements). However, note that there is only a single random number stream per procedure run. Specifying the SEED= option in the PROC PLM statement initializes the stream for all subsequent statements. If you do not specify a random number seed, the source item store might supply one for you. If a seed is in effect when the PLM procedure opens the source store, the “Store Information” table displays its value.

If the random number seed is less than or equal to zero, the seed is generated from reading the time of day from the computer clock and a log message indicates the chosen seed value.

**SINGCHOL=number**

tunes the singularity criterion in Cholesky decompositions. The default value depends on the contents of the source item store. The default value is typically 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**SINGRES=number**

sets the tolerance for which the residual variance or scale parameter is considered to be zero. The default value depends on the contents of the source item store. The default value is typically 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**SINGULAR=number**

tunes the general singularity criterion applied by the PLM procedure in divisions and inversions. The default value used by the PLM procedure depends on the contents of the item store. The default value is typically 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**RESTORE=item-store-specification**

specifies the source item store for processing. This option is required because, in contrast to SAS data sets, there is no default item store. An *item-store-specification* consists of a one- or two-level name as with SAS data sets. As with data sets, the default library association of an item store is with the WORK library, and any stores created in this library are deleted when the SAS session concludes.

**STMTORDER=SYNTAX | GROUP****STMT=SYNTAX | GROUP**

affects the order in which statements are grouped during processing. The default behavior depends on the contents of the source item store and can be modified with the STMTORDER= option. If STMTORDER=SYNTAX is in effect, the statements are processed in the order in which they appear. Note that this precludes the hierarchical grouping of ODS objects. If STMTORDER=GROUP is in effect, the statements are processed in groups and in the following order: **SHOW**, **TEST**, **LSMEANS**, **SLICE**, **LSMESTIMATE**, **ESTIMATE**, **SCORE**, **EFFECTPLOT**, and **CODE**.

**WHEREFORMAT**

specifies that the constants (literals) specified in **WHERE** expressions for group selection are in terms of the formatted values of the BY variables. By default, WHERE expressions are specified in terms of the unformatted (raw) values of the BY variables, as in the SAS DATA step.

**ZETA=number**

tunes the sensitivity in forming Type III functions. Any element in the estimable function basis with an absolute value less than *number* is set to 0. The default depends on the contents of the source item store; it usually is 1E-8.

---

## CODE Statement

**CODE** < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 69.3 summarizes the *options* available in the CODE statement.

**Table 69.3** CODE Statement Options

| Option    | Description                                                                  |
|-----------|------------------------------------------------------------------------------|
| CATALOG=  | Names the catalog entry where the generated code is saved                    |
| DUMMIES   | Retains the dummy variables in the data set                                  |
| ERROR     | Computes the error function                                                  |
| FILE=     | Names the file where the generated code is saved                             |
| FORMAT=   | Specifies the numeric format for the regression coefficients                 |
| GROUP=    | Specifies the group identifier for array names and statement labels          |
| IMPUTE    | Imputes predicted values for observations with missing or invalid covariates |
| LINESIZE= | Specifies the line size of the generated code                                |
| LOOKUP=   | Specifies the algorithm for looking up CLASS levels                          |
| RESIDUAL  | Computes residuals                                                           |

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

---

## EFFECTPLOT Statement

**EFFECTPLOT** < plot-type < (plot-definition-options) > > < / options > ;

The EFFECTPLOT statement produces a display of the fitted model and provides options for changing and enhancing the displays. Table 69.4 describes the available *plot-types* and their *plot-definition-options*.

**Table 69.4** *Plot-Types and Plot-Definition-Options*

| <b>Plot-Type and Description</b>                                                                                                                                                                                                             | <b>Plot-Definition-Options</b>                                                                                                       |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| <p><b>BOX</b></p> <p>Displays a box plot of continuous response data at each level of a CLASS effect, with predicted values superimposed and connected by a line. This is an alternative to the <b>INTERACTION</b> <i>plot-type</i>.</p>     | <p><b>PLOTBY=</b> variable or CLASS effect<br/> <b>X=</b> CLASS variable or effect</p>                                               |
| <p><b>CONTOUR</b></p> <p>Displays a contour plot of predicted values against two continuous covariates.</p>                                                                                                                                  | <p><b>PLOTBY=</b> variable or CLASS effect<br/> <b>X=</b> continuous variable<br/> <b>Y=</b> continuous variable</p>                 |
| <p><b>FIT</b></p> <p>Displays a curve of predicted values versus a continuous variable.</p>                                                                                                                                                  | <p><b>PLOTBY=</b> variable or CLASS effect<br/> <b>X=</b> continuous variable</p>                                                    |
| <p><b>INTERACTION</b></p> <p>Displays a plot of predicted values (possibly with error bars) versus the levels of a CLASS effect. The predicted values are connected with lines and can be grouped by the levels of another CLASS effect.</p> | <p><b>PLOTBY=</b> variable or CLASS effect<br/> <b>SLICEBY=</b> variable or CLASS effect<br/> <b>X=</b> CLASS variable or effect</p> |
| <p><b>SLICEFIT</b></p> <p>Displays a curve of predicted values versus a continuous variable grouped by the levels of a CLASS effect.</p>                                                                                                     | <p><b>PLOTBY=</b> variable or CLASS effect<br/> <b>SLICEBY=</b> variable or CLASS effect<br/> <b>X=</b> continuous variable</p>      |

For full details about the syntax and options of the EFFECTPLOT statement, see the section “EFFECTPLOT Statement” on page 411 in Chapter 19, “Shared Concepts and Topics.”

---

## ESTIMATE Statement

```
ESTIMATE <'label'> estimate-specification <(divisor=n)>
 < , ... <'label'> estimate-specification <(divisor=n)> >
 </ options > ;
```

The ESTIMATE statement provides a mechanism for obtaining custom hypothesis tests. Estimates are formed as linear estimable functions of the form  $L\beta$ . You can perform hypothesis tests for the estimable functions, construct confidence limits, and obtain specific nonlinear transformations.

Table 69.5 summarizes the options available in the ESTIMATE statement.

**Table 69.5** ESTIMATE Statement Options

| Option                                                     | Description                                                                     |
|------------------------------------------------------------|---------------------------------------------------------------------------------|
| <b>Construction and Computation of Estimable Functions</b> |                                                                                 |
| DIVISOR=                                                   | Specifies a list of values to divide the coefficients                           |
| NOFILL                                                     | Suppresses the automatic fill-in of coefficients for higher-order effects       |
| SINGULAR=                                                  | Tunes the estimability checking difference                                      |
| <b>Degrees of Freedom and <math>p</math>-values</b>        |                                                                                 |
| ADJUST=                                                    | Determines the method for multiple comparison adjustment of estimates           |
| ALPHA= $\alpha$                                            | Determines the confidence level ( $1 - \alpha$ )                                |
| LOWER                                                      | Performs one-sided, lower-tailed inference                                      |
| STEPDOWN                                                   | Adjusts multiplicity-corrected $p$ -values further in a step-down fashion       |
| TESTVALUE=                                                 | Specifies values under the null hypothesis for tests                            |
| UPPER                                                      | Performs one-sided, upper-tailed inference                                      |
| <b>Statistical Output</b>                                  |                                                                                 |
| CL                                                         | Constructs confidence limits                                                    |
| CORR                                                       | Displays the correlation matrix of estimates                                    |
| COV                                                        | Displays the covariance matrix of estimates                                     |
| E                                                          | Prints the L matrix                                                             |
| JOINT                                                      | Produces a joint $F$ or chi-square test for the estimable functions             |
| PLOTS=                                                     | Requests ODS statistical graphics if the analysis is sampling-based             |
| SEED=                                                      | Specifies the seed for computations that depend on random numbers               |
| <b>Generalized Linear Modeling</b>                         |                                                                                 |
| CATEGORY=                                                  | Specifies how to construct estimable functions with multinomial data            |
| EXP                                                        | Exponentiates and displays estimates                                            |
| ILINK                                                      | Computes and displays estimates and standard errors on the inverse linked scale |

For details about the syntax of the ESTIMATE statement, see the section “ESTIMATE Statement” on page 437 in Chapter 19, “Shared Concepts and Topics.”

## FILTER Statement

**FILTER** *expression* ;

The FILTER statement enables you to filter the results of the PLM procedure, specifically the contents of ODS tables and the output data sets. There can be at most one FILTER statement per PROC PLM run, and the filter is applied to all BY groups and to all queries generated through WHERE expressions.

A filter *expression* follows the same pattern as a *where-expression* in the **WHERE** statement. The expressions consist of operands and operators. For more information about specifying *where-expressions*, see the **WHERE** statement for the PLM procedure and *SAS Language Reference: Concepts*.

Valid keywords for the formation of operands in the FILTER statement are shown in Table 69.6.

**Table 69.6** Keywords for Filtering Results

| Keyword    | Description                                                                                                  |
|------------|--------------------------------------------------------------------------------------------------------------|
| Prob       | Regular (unadjusted) $p$ -values from $t$ , $F$ , or chi-square tests                                        |
| ProbChi    | Regular (unadjusted) $p$ -values from chi-square tests                                                       |
| ProbF      | Regular (unadjusted) $p$ -values from $F$ tests                                                              |
| ProbT      | Regular (unadjusted) $p$ -values from $t$ tests                                                              |
| AdjP       | Adjusted $p$ -values                                                                                         |
| Estimate   | Results displayed in “Estimates” column of ODS tables                                                        |
| Pred       | Predicted values in <b>SCORE</b> output data sets                                                            |
| Resid      | Residuals in <b>SCORE</b> output data sets.                                                                  |
| Std        | Standard errors in ODS tables and in <b>SCORE</b> results                                                    |
| Mu         | Results displayed in the “Mean” column of ODS tables (this column is typically produced by the ILINK option) |
| tValue     | The value of the usual $t$ statistic                                                                         |
| FValue     | The value of the usual $F$ statistic                                                                         |
| Chisq      | The value of the chi-square statistic                                                                        |
| testStat   | The value of the test statistic (a generic keyword for the ‘tValue’, ‘FValue’, and ‘Chisq’ tokens)           |
| Lower      | The lower confidence limit displayed in ODS tables                                                           |
| Upper      | The upper confidence limit displayed in ODS tables                                                           |
| AdjLower   | The adjusted lower confidence limit displayed in ODS tables                                                  |
| AdjUpper   | The adjusted upper confidence limit displayed in ODS tables                                                  |
| LowerMu    | The lower confidence limit for the mean displayed in ODS tables                                              |
| UpperMu    | The upper confidence limit for the mean displayed in ODS tables                                              |
| AdjLowerMu | The adjusted lower confidence limit for the mean displayed in ODS tables                                     |
| AdjUpperMu | The adjusted upper confidence limit for the mean displayed in ODS tables                                     |

When you write filtering expressions, be advised that filtering variables that are not used in the results are typically set to missing values. For example, the following statements select all results (filter nothing) because no adjusted  $p$ -values are computed:

```
proc plm restore=MyStore;
 lsmeans a / diff;
 filter adjp < 0.05;
run;
```

If the adjusted  $p$ -values are set to missing values, the condition `adjp < 0.05` is true in each case (missing values always compare smaller than the smallest nonmissing value).

See “Example 69.6: Comparing Multiple B-Splines” on page 5853 for an example of using the `FILTER` statement.

Filtering results has no effect on the item store contents that are displayed with the `SHOW` statement. However, BY-group selection with the `WHERE` statement can limit the amount of information that is displayed by the `SHOW` statements.

---

## LSMEANS Statement

**LSMEANS** < model-effects > < / options > ;

The LSMEANS statement computes and compares least squares means (LS-means) of fixed effects. LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs.

Table 69.7 summarizes the options available in the LSMEANS statement.

**Table 69.7** LSMEANS Statement Options

| Option                                              | Description                                                                                 |
|-----------------------------------------------------|---------------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                             |
| <code>AT</code>                                     | Modifies the covariate value in computing LS-means                                          |
| <code>BYLEVEL</code>                                | Computes separate margins                                                                   |
| <code>DIFF</code>                                   | Requests differences of LS-means                                                            |
| <code>OM=</code>                                    | Specifies the weighting scheme for LS-means computation as determined by the input data set |
| <code>SINGULAR=</code>                              | Tunes estimability checking                                                                 |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                             |
| <code>ADJUST=</code>                                | Determines the method for multiple-comparison adjustment of LS-means differences            |
| <code>ALPHA=<math>\alpha</math></code>              | Determines the confidence level $(1 - \alpha)$                                              |
| <code>STEPDOWN</code>                               | Adjusts multiple-comparison $p$ -values further in a step-down fashion                      |
| <b>Statistical Output</b>                           |                                                                                             |
| <code>CL</code>                                     | Constructs confidence limits for means and mean differences                                 |
| <code>CORR</code>                                   | Displays the correlation matrix of LS-means                                                 |
| <code>COV</code>                                    | Displays the covariance matrix of LS-means                                                  |
| <code>E</code>                                      | Prints the <b>L</b> matrix                                                                  |
| <code>LINES</code>                                  | Produces a “Lines” display for pairwise LS-means differences                                |
| <code>MEANS</code>                                  | Prints the LS-means                                                                         |
| <code>PLOTS=</code>                                 | Requests graphs of means and mean comparisons                                               |
| <code>SEED=</code>                                  | Specifies the seed for computations that depend on random numbers                           |

---

Table 69.7 *continued*

| Option                             | Description                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Generalized Linear Modeling</b> |                                                                                                                   |
| EXP                                | Exponentiates and displays estimates of LS-means or LS-means differences                                          |
| ILINK                              | Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale |
| ODDSRATIO                          | Reports (simple) differences of least squares means in terms of odds ratios if permitted by the link function     |

For details about the syntax of the LSMEANS statement, see the section “LSMEANS Statement” on page 453 in Chapter 19, “Shared Concepts and Topics.”

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </options> ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 69.8 summarizes the options available in the LSMESTIMATE statement.

Table 69.8 LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level $(1 - \alpha)$                                      |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |

Table 69.8 *continued*

| Option                             | Description                                                                                                       |
|------------------------------------|-------------------------------------------------------------------------------------------------------------------|
| <b>Statistical Output</b>          |                                                                                                                   |
| CL                                 | Constructs confidence limits for means and mean differences                                                       |
| CORR                               | Displays the correlation matrix of LS-means                                                                       |
| COV                                | Displays the covariance matrix of LS-means                                                                        |
| E                                  | Prints the <b>L</b> matrix                                                                                        |
| ELSM                               | Prints the <b>K</b> matrix                                                                                        |
| JOINT                              | Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences                            |
| PLOTS=                             | Requests graphs of means and mean comparisons                                                                     |
| SEED=                              | Specifies the seed for computations that depend on random numbers                                                 |
| <b>Generalized Linear Modeling</b> |                                                                                                                   |
| CATEGORY=                          | Specifies how to construct estimable functions with multinomial data                                              |
| EXP                                | Exponentiates and displays LS-means estimates                                                                     |
| ILINK                              | Computes and displays estimates and standard errors of LS-means (but not differences) on the inverse linked scale |

For details about the syntax of the LSMESTIMATE statement, see the section “[LSMESTIMATE Statement](#)” on page 470 in Chapter 19, “[Shared Concepts and Topics](#).”

## SCORE Statement

```
SCORE DATA=SAS-data-set < OUT=SAS-data-set >
 < keyword< =name> > ...
 < keyword< =name> > < / options > ;
```

The SCORE statement applies the contents of the source item store to compute predicted values and other observation-wise statistics for a SAS data set.

You can specify the following syntax elements in the SCORE statement before the option slash (/):

### **DATA=SAS-data-set**

specifies the input data set for scoring. This option is required, and the data set is examined for congruity with the previously fitted (and stored) model. For example, all necessary variables to form a row of the **X** matrix must be present in the input data set and must be of the correct type and format. The following variables do not have to be present in the input data set:

- the response variable
- the *events* and *trials* variables used in the *events/trials* syntax for binomial data
- variables used in WEIGHT or FREQ statements

**OUT=SAS-data-set**

specifies the name of the output data set. If you do not specify an output data set with the OUT= option, the PLM procedure uses the DATA*n* convention to name the output data set.

**keyword<=name>**

specifies a statistic to be included in the OUT= data set and optionally assigns the statistic the variable name *name*. Table 69.9 lists the keywords and the default names assigned by the PLM procedure if you do not specify a *name*.

**Table 69.9** Keywords for Output Statistics

| Keyword   | Description                                     | Expression                                        | Name      |
|-----------|-------------------------------------------------|---------------------------------------------------|-----------|
| PREDICTED | Linear predictor                                | $\hat{\eta} = \mathbf{x}\hat{\boldsymbol{\beta}}$ | Predicted |
| STDERR    | Standard deviation of linear predictor          | $\sqrt{\text{Var}(\hat{\eta})}$                   | StdErr    |
| RESIDUAL  | Residual                                        | $y - g^{-1}(\hat{\eta})$                          | Resid     |
| LCLM      | Lower confidence limit for the linear predictor |                                                   | LCLM      |
| UCLM      | Upper confidence limit for the linear predictor |                                                   | UCLM      |
| LCL       | Lower prediction limit for the linear predictor |                                                   | LCL       |
| UCL       | Upper prediction limit for the linear predictor |                                                   | UCL       |

Prediction limits (LCL, UCL) are available only for statistical models that allow such limits, typically regression-type models for normally distributed data with an identity link function.

You can specify the following options in the SCORE statement after a slash (/):

**ALPHA=number**

determines the coverage probability for two-sided confidence and prediction intervals. The coverage probability is computed as  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**DF=number**

specifies the degrees of freedom to use in the construction of prediction and confidence limits.

**ILINK**

requests that predicted values be inversely linked to produce predictions on the data scale. By default, predictions are produced on the linear scale where covariate effects are additive.

**NOUNIQUE**

requests that names not be made unique in the case of naming conflicts. By default, the PLM procedure avoids naming conflicts by assigning a unique name to each output variable. If you specify the NOUNIQUE option, variables with conflicting names are not renamed. In that case, the first variable added to the output data set takes precedence.

**NOVAR**

requests that variables from the input data set not be added to the output data set.

**OBSCAT**

requests that statistics in models for multinomial data be written to the output data set only for the response level that corresponds to the observed level of the observation.

**SAMPLE**

requests that the sample of parameter estimates in the item store be used to form scoring statistics. This option is useful when the item store contains the results of a Bayesian analysis and a posterior sample of parameter estimates. The predicted value is then computed as the average predicted value across the posterior estimates, and the standard error measures the standard deviation of these estimates. For example, let  $\widehat{\beta}_1, \dots, \widehat{\beta}_k$  denote the  $k$  posterior sample estimates of  $\beta$ , and let  $\mathbf{x}_i$  denote the  $x$ -vector for the  $i$ th observation in the scoring data set. If the **SAMPLE** option is in effect, the output statistics for the predicted value, the standard error, and the residual of the  $i$ th observation are computed as

$$\begin{aligned}\eta_{ij} &= \mathbf{x}_i \widehat{\beta}_j \\ \text{PRED}_i &= \bar{\eta}_i = \frac{1}{k} \sum_{j=1}^k \eta_{ij} \\ \text{STDERR}_i &= \left( \frac{1}{k-1} \sum_{j=1}^k (\eta_{ij} - \bar{\eta}_i)^2 \right)^{1/2} \\ \text{RESIDUAL}_i &= y_i - g^{-1}(\bar{\eta}_i)\end{aligned}$$

where  $g^{-1}(\cdot)$  denotes the inverse link function.

If, in addition, the **ILINK** option is in effect, the calculations are as follows:

$$\begin{aligned}\eta_{ij} &= \mathbf{x}_i \widehat{\beta}_j \\ \text{PRED}_i &= \frac{1}{k} \sum_{j=1}^k g^{-1}(\eta_{ij}) \\ \text{STDERR}_i &= \left( \frac{1}{k-1} \sum_{j=1}^k (g^{-1}(\eta_{ij}) - \text{PRED}_i)^2 \right)^{1/2} \\ \text{RESIDUAL}_i &= y_i - \text{PRED}_i\end{aligned}$$

The LCL and UCL statistics are not available with the **SAMPLE** option. When the LCLM and UCLM statistics are requested, the **SAMPLE** option yields the lower  $100 \times \alpha/2\%$  and upper  $100 \times (1 - \alpha/2)\%$  percentiles of the predicted values under the sample (posterior) distribution. When you request residuals with the **SAMPLE** option, the calculation depends on whether the **ILINK** option is specified.

## SHOW Statement

**SHOW** *options* ;

The SHOW statement uses the Output Delivery System to display contents of the item store. This statement is useful for verifying that the contents of the item store apply to the analysis and for generating ODS tables. Table 69.10 summarizes the options available in the SHOW statement.

**Table 69.10** SHOW Statement Options

| Option      | Description                                                                                     |
|-------------|-------------------------------------------------------------------------------------------------|
| ALL         | Displays all applicable contents                                                                |
| BYVAR       | Displays information about the BY variables                                                     |
| CLASSLEVELS | Displays the “Class Level Information” table                                                    |
| CORRELATION | Produces the correlation matrix of the parameter estimates                                      |
| COVARIANCE  | Produces the covariance matrix of the parameter estimates                                       |
| EFFECTS     | Displays information about the constructed effects                                              |
| FITSTATS    | Displays the fit statistics                                                                     |
| HESSIAN     | Displays the Hessian matrix                                                                     |
| HERMITE     | Generates the Hermite matrix $\mathbf{H} = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\mathbf{X})$ |
| PARAMETERS  | Displays the parameter estimates                                                                |
| PROGRAM     | Displays the SAS program that generated the item store                                          |
| XPX         | Displays the crossproduct matrix $\mathbf{X}'\mathbf{X}$                                        |
| XPXI        | Displays the generalized inverse of the crossproduct matrix $\mathbf{X}'\mathbf{X}$             |

You can specify the following options after the SHOW statement:

**ALL | \_ALL\_**

displays all applicable contents.

**BYVAR | BY**

displays information about the BY variables in the source item store. If a BY statement was present when the item store was created, the PLM procedure performs the analysis separately for each BY group.

**CLASSLEVELS | CLASS**

displays the “Class Level Information” table. This table is produced by the PLM procedure by default if the model contains effects that depend on classification variables.

**CORRELATION | CORR | CORRB**

produces the correlation matrix of the parameter estimates. If the source item store contains a posterior sample of parameter estimates, the computed matrix is the correlation matrix of the sample covariance matrix.

**COVARIANCE | COV | COVB**

produces the covariance matrix of the parameter estimates. If the source item store contains a posterior sample of parameter estimates, the PLM procedure computes the empirical sample covariance matrix from the posterior estimates. You can convert this matrix into a sample correlation matrix with the CORRELATION option in the SHOW statement.

**EFFECTS**

displays information about the constructed effects in the model. Constructed effects are those that were created with the EFFECT statement in the procedure run that generated the source item store.

**FITSTATS | FIT**

displays the fit statistics from the item store.

**HESSIAN | HESS**

displays the Hessian matrix.

**HERMITE | HERM**

generates the Hermite matrix  $\mathbf{H} = (\mathbf{X}'\mathbf{X})^{-1}(\mathbf{X}'\mathbf{X})$ . The PLM procedure chooses a reflexive,  $g_2$ -inverse for the generalized inverse of the crossproduct matrix  $\mathbf{X}'\mathbf{X}$ . See “Important Linear Algebra Concepts” on page 44 of Chapter 3, “Introduction to Statistical Modeling with SAS/STAT Software,” for information about generalized inverses and the sweep operator.

**PARAMETERS<=n>****PARMS<=n>**

displays the parameter estimates. The structure of the display depends on whether a posterior sample of parameter estimates is available in the source item store. If such a sample is present, up to the first 20 parameter vectors are shown in wide format. You can modify this number with the  $n$  argument.

If no posterior sample is present, the single vector of parameter estimates is shown in narrow format. If the store contains information about the covariance matrix of the parameter estimates, then standard errors are added.

**PROGRAM<(WIDTH=n)>****PROG<(WIDTH=n)>**

displays the SAS program that generated the item store, provided that this was stored at store generation time. The program does not include comments, titles, or some other global statements. The optional width parameter  $n$  determines the display width of the source code.

**XPX | CROSSPRODUCT**

displays the crossproduct matrix  $\mathbf{X}'\mathbf{X}$ .

**XPXI**

displays the generalized inverse of the crossproduct matrix  $\mathbf{X}'\mathbf{X}$ . The PLM procedure obtains a reflexive  $g_2$ -inverse by sweeping. See “Important Linear Algebra Concepts” on page 44 of Chapter 3, “Introduction to Statistical Modeling with SAS/STAT Software,” for information about generalized inverses and the sweep operator.

**SLICE Statement**

**SLICE** *model-effect* </options> ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

---

## TEST Statement

**TEST** < *model-effects* > < / *options* > ;

The TEST statement enables you to perform  $F$  tests for model effects that test Type I, Type II, or Type III hypotheses. See Chapter 15, “The Four Types of Estimable Functions,” for details about the construction of Type I, II, and III estimable functions.

Table 69.11 summarizes the options available in the TEST statement.

**Table 69.11** TEST Statement Options

| Option    | Description                                                |
|-----------|------------------------------------------------------------|
| CHISQ     | Requests chi-square tests                                  |
| DDF=      | Specifies denominator degrees of freedom for fixed effects |
| E         | Requests Type I, Type II, and Type III coefficients        |
| E1        | Requests Type I coefficients                               |
| E2        | Requests Type II coefficients                              |
| E3        | Requests Type III coefficients                             |
| HTYPE=    | Indicates the type of hypothesis test to perform           |
| INTERCEPT | Adds a row that corresponds to the overall intercept       |

For details about the syntax of the TEST statement, see the section “TEST Statement” on page 502 in Chapter 19, “Shared Concepts and Topics.”

---

## WHERE Statement

**WHERE** *expression* ;

You can use the WHERE statement in the PLM procedure when the item store contains BY-variable information and you want to apply the PROC PLM statements to only a subset of the BY groups.

A WHERE expression is a type of SAS expression that defines a condition. In the DATA step and in procedures that use SAS data sets as the input source, the WHERE expression is used to select observations for inclusion in the DATA step or in the analysis. In the PLM procedure, which does not accept a SAS data set but rather takes an item store that was created by a qualifying SAS/STAT procedure, the WHERE statement is also used to specify conditions. The conditional selection does not apply to observations in PROC PLM, however. Instead, you use the WHERE statement in the PLM procedure to select a subset of BY groups from the item store to which to apply the PROC PLM statements.

The general syntax of the WHERE statement is

**WHERE** *operand* < *operator operand* > < **AND** | **OR** *operand* < *operator operand* > . . . > ;

where

*operand* is something to be operated on. The operand can be the name of a BY variable in the item store, a SAS function, a constant, or a predefined name to identify columns in result tables.

*operator* is a symbol that requests a comparison, logical operation, or arithmetic calculation. All SAS expression operators are valid for a WHERE expression.

For more details about how to specify general WHERE expressions, see *SAS Language Reference: Concepts*. Notice that the **FILTER** statement accepts similar expressions that are specified in terms of predefined keywords. Expressions in the WHERE statement of the PLM procedure are written in terms of BY variables.

There is no limit to the number of WHERE statements in the PLM procedure. When you specify multiple WHERE statements, the statements are *not* cumulative. Each WHERE statement is executed separately. You can think of each selection WHERE statement as one analytic query to the item store: the WHERE statement defines the query, and the PLM procedure is the querying engine. For example, suppose that the item store contains results for the numeric BY variables A and B. The following statements define two separate queries of the item store:

```
WHERE a = 4;
WHERE (b < 3) and (a > 4);
```

The PLM procedure first applies the requested analysis to all BY groups where a equals 4 (irrespective of the value of variable b). The analysis is then repeated for all BY groups where b is less than 3 and a is greater than 4.

Group selection with WHERE statements is possible only if the item store contains BY variables. You can use the **BYVAR** option in the **SHOW** statement to display the BY variables in the item store.

Note that WHERE expressions in the SAS DATA step and in many procedures are specified in terms of the unformatted values of data set variables, even if a format was applied to the variable. If you specify the **WHEREFORMAT** option in the **PROC PLM** statement, the PLM procedure evaluates WHERE expressions for BY variables in terms of the formatted values. For example, assume that the following format was applied to the variable tx when the item store was created:

```
proc format;
 value bf 1 = 'Control'
 2 = 'Treated';
run;
```

Then the following two PROC PLM runs are equivalent:

```
proc plm restore=MyStore;
 show parms;
 where b = 2;
run;

proc plm restore=MyStore whereformat;
 show parms;
 where b = 'Treated';
run;
```

---

## Details: PLM Procedure

---

### BY Processing and the PLM Procedure

When a BY statement is in effect for the analysis that creates an item store, the information about BY variables and BY-group-specific modeling results are transferred to the item store. In this case, the PLM procedure automatically assumes a processing mode for the item store that is akin to BY processing, with the PLM statements being applied in turn for each of the BY groups. Also, you can then obtain a table of BY groups with the **BYVAR** option in the **SHOW** statement. The “Source Information” table also displays the variable names of the BY variables if BY groups are present. The **WHERE** statement can be used to restrict the analysis to specific BY groups that meet the conditions of the **WHERE** expression.

See [Example 69.4](#) for an example that uses BY-group-specific information in the source item store.

As with procedures that operate on input data sets, the BY variable information is added automatically to any output data sets and ODS tables produced by the PLM procedure.

When you score a data set with the **SCORE** statement and the item store contains BY variables, three situations can arise:

- None of the BY variables are present in the scoring data set. In this situation the results of the BY groups in the item store are applied in turn to the entire scoring data set. For example, if the scoring data set contains 50 observations and no BY-variable information, the number of observations in the output data set of the **SCORE** statement equals 50 times the number of BY groups.
- The scoring data set contains only a part of the BY variables, or the variables have different type or format. The PLM procedure does not process such an incompatible scoring data set.
- All BY variables are in the scoring data set in the same type and format as when the item store was created. The BY-group-specific results are applied to each observation in the scoring data set. The scoring data set does not have to be sorted or grouped by the BY variables. However, it is computationally more efficient if the scoring data set is arranged by groups of the BY variables.

---

### Analysis Based on Posterior Estimates

If an item store is saved from a Bayesian analysis (by PROC GENMOD or PROC PHREG or PROC LIFEREG), then PROC PLM can perform sampling-based inference based on Bayes posterior estimates that are saved in the item store. For example, the following statements request a Bayesian analysis and save the results to an item store named `sasuser.gmd`. For the Bayesian analysis, the random number generator seed is set to 1. By default, a noninformative distribution is set as the prior distribution for the regression coefficients and the posterior sample size is 10,000.

```
proc genmod data=gs;
 class a b;
 model y = a b;
 bayes seed=1;
 store sasuser.gmd / label='Bayesian Analysis';
run;
```

When the PLM procedure opens the item store `sasuser.gmd`, it detects that the results were saved from a Bayesian analysis. The posterior sample of regression coefficient estimates are then loaded to perform statistical inference tasks.

The majority of postprocessing tasks involve inference based on an estimable linear function  $\mathbf{L}\widehat{\boldsymbol{\beta}}$ , which often requires its mean and variance. When the standard frequentist analyses are performed, the mean and variance have explicit forms because the parameter estimate  $\widehat{\boldsymbol{\beta}}$  is analytically tractable. However, explicit forms are not usually available when Bayesian models are fitted. Instead, empirical means and variance-covariance matrices for the estimable function are constructed from the posterior sample.

Let  $\widehat{\boldsymbol{\beta}}_i, i = 1, \dots, N_p$  denote the  $N_p$  vectors of posterior sample estimates of  $\boldsymbol{\beta}$  saved in `sasuser.gmd`. Use these vectors to construct the posterior sample of estimable functions  $\mathbf{L}\widehat{\boldsymbol{\beta}}_i$ . The posterior mean of the estimable function is thus

$$\overline{\mathbf{L}\widehat{\boldsymbol{\beta}}} = \frac{1}{N_p} \sum_{i=1}^{N_p} \mathbf{L}\widehat{\boldsymbol{\beta}}_i$$

and the posterior variance of the estimable function is

$$\mathbf{V}(\mathbf{L}\widehat{\boldsymbol{\beta}}) = \frac{1}{N_p - 1} \sum_{i=1}^{N_p} (\mathbf{L}\widehat{\boldsymbol{\beta}}_i - \overline{\mathbf{L}\widehat{\boldsymbol{\beta}}})^2$$

Sometimes statistical inference on a transformation of  $\mathbf{L}\widehat{\boldsymbol{\beta}}$  is requested. For example, the EXP option for the ESTIMATE and LSMESTIMATE statements requests analysis based on  $\exp(\mathbf{L}\widehat{\boldsymbol{\beta}})$ , exponentiation of the estimable function. If this type of analysis is requested, the posterior sample of transformed estimable functions is constructed by transforming each of the estimable function evaluated at the posterior sample:  $f(\mathbf{L}\widehat{\boldsymbol{\beta}}_i), i = 1, \dots, N_p$ . The posterior mean and variance for  $f(\mathbf{L}\widehat{\boldsymbol{\beta}})$  are then computed from the constructed sample to make the inference:

$$\overline{f(\mathbf{L}\widehat{\boldsymbol{\beta}})} = \frac{1}{N_p} \sum_{i=1}^{N_p} f(\mathbf{L}\widehat{\boldsymbol{\beta}}_i)$$

$$\mathbf{V}(f(\mathbf{L}\widehat{\boldsymbol{\beta}})) = \frac{1}{N_p - 1} \sum_{i=1}^{N_p} (f(\mathbf{L}\widehat{\boldsymbol{\beta}}_i) - \overline{f(\mathbf{L}\widehat{\boldsymbol{\beta}})})^2$$

After obtaining the posterior mean and variance, the PLM procedure proceeds to perform statistical inference based on them.

---

## User-Defined Formats and the PLM Procedure

The PLM procedure does not support a FORMAT statement because it operates without an input data set, and also because changing the format properties of variables could alter the interpretation of parameter estimates, thus creating a dissonance with variable properties in effect when the item store was created. Instead, user-defined formats that are applied to classification variables when the item store is created are saved to the store and are by default reloaded by the PLM procedure. When the PLM procedure loads a format, notes are issued to the log.

You can change the load behavior for formats with the `FORMAT=` option in the `PROC PLM` statement.

User-defined formats do not need to be supplied in a new SAS session. However, when a user-defined format with the same name as a stored format exists and the default `FORMAT=RELOAD` option is in effect, the format definition loaded from the item store replaces the format currently in effect.

In the following statements, the format `AFORM` is created and applied to the variable `a` in the `PROC GLM` step. This format definition is transferred to the item store `sasuser.glm` through the `STORE` statement.

```
proc format;
 value aform 1='One' 2='Two' 3='Three';
run;
proc glm data=sp;
 format a aform.;
 class block a b;
 model y = block a b x;
 store sasuser.glm;
 weight x;
run;
```

The following statements replace the format definition of the `AFORM` format. The `PLM` step then reloads the `AFORM` format (from the item store) and thereby restores its original state.

```
proc format;
 value aform 1='Un' 2='Deux' 3='Trois';
run;
proc plm restore=sasuser.glm;
 show class;
 score data=sp out=plmout lcl lclm ucl uclm;
run;
```

The following notes, issued by the `PLM` procedure, inform you that the procedure loaded the format, the format already existed, and the existing format was replaced:

```
NOTE: The format AFORM was loaded from item store SASUSER.GLM.
NOTE: Format AFORM is already on the library.
NOTE: Format AFORM has been output.
```

After the `PROC PLM` run, the definition that is in effect for the format `AFORM` corresponds to the following SAS statements:

```
proc format;
 value aform 1='One' 2='Two' 3='Three';
run;
```

---

## ODS Table Names

`PROC PLM` assigns a name to each table it creates. You can use these names to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 69.12. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Each of the EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements also creates tables, which are not listed in Table 69.12. For information about these tables, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

**Table 69.12** ODS Tables Produced by PROC PLM

| Table Name         | Description                                                      | Required Option                                             |
|--------------------|------------------------------------------------------------------|-------------------------------------------------------------|
| ByVarInfo          | Information about BY variables in source item store (if present) | SHOW BYVAR                                                  |
| ClassLevels        | Level information from the CLASS statement                       | Default output when model effects depend on CLASS variables |
| Corr               | Correlation matrix of parameter estimates                        | SHOW CORR                                                   |
| Cov                | Covariance matrix of parameter estimates                         | SHOW COV                                                    |
| FitStatistics      | Fit statistics                                                   | SHOW FIT                                                    |
| Hessian            | Hessian matrix                                                   | SHOW HESSIAN                                                |
| Hermite            | Hermite matrix                                                   | SHOW HERMITE                                                |
| ParameterEstimates | Parameter estimates                                              | SHOW PARMS                                                  |
| ParameterSample    | Sampled (posterior) parameter estimates                          | SHOW PARMS                                                  |
| Program            | Originating source code                                          | SHOW PROGRAM                                                |
| StoreInfo          | Information about source item store                              | Default                                                     |

| XpXI               | $(\mathbf{X}'\mathbf{X})^{-1}$ matrix                            | SHOW XPXI                                                   |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, then each of the EFFECTPLOT, ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements can produce plots associated with their analyses. For information about these plots, see the corresponding sections of Chapter 19, “Shared Concepts and Topics.”

---

## Examples: PLM Procedure

---

### Example 69.1: Scoring with PROC PLM

Logistic regression with model selection is often used to extract useful information and build interpretable models for classification problems with many variables. This example demonstrates how you can use PROC LOGISTIC to build a spline model on a simulated data set and how you can later use the fitted model to classify new observations.

The following DATA step creates a data set named SimuData, which contains 5,000 observations and 100 continuous variables:

```
%let nObs = 5000;
%let nVars = 100;
data SimuData;
 array x{&nVars};
 do obsNum=1 to &nObs;
 do j=1 to &nVars;
 x{j}=ranuni(1);
 end;

 linp = 10 + 11*x1 - 10*sqrt(x2) + 2/x3 - 8*exp(x4) + 7*x5*x5
 - 6*x6**1.5 + 5*log(x7) - 4*sin(3.14*x8) + 3*x9 - 2*x10;
 TrueProb = 1/(1+exp(-linp));

 if ranuni(1) < TrueProb then y=1;
 else y=0;

 output;
 end;
run;
```

The response is binary based on the inversely transformed logit values. The true logit is a function of only 10 of the 100 variables, including nonlinear transformations of seven variables, as follows:

$$\text{logit}(p) = 10 + 11x_1 - 10\sqrt{x_2} + \frac{2}{x_3} - 8 \exp(x_4) + 7x_5^2 - 6x_6^{1.5} + 5 \log(x_7) - 4 \sin(3.14x_8) + 3x_9 - 2x_{10}$$

Now suppose the true model is not known. With some exploratory data analysis, you determine that the dependency of the logit on some variables is nonlinear. Therefore, you decide to use splines to model this nonlinear dependence. Also, you want to use stepwise regression to remove unimportant variable transformations. The following statements perform the task:

```
proc logistic data=SimuData;
 effect splines = spline(x1-x&nVars/separate);
 model y = splines/selection=stepwise;
 store sasuser.SimuModel;
run;
```

By default, PROC LOGISTIC models the probability that  $y = 0$ . The EFFECT statement requests an effect named splines constructed by all predictors in the data. The SEPARATE option specifies that the spline

basis for each variable be treated as a separate set so that model selection applies to each individual set. The `SELECTION=STEPWISE` specifies the stepwise regression as the model selection technique. The `STORE` statement requests that the fitted model be saved to an item store `sasuser.SimuModel`. See “[Example 69.2: Working with Item Stores](#)” on page 5838 for an example with more details about working with item stores.

The spline effect for each predictor produces seven columns in the design matrix, making stepwise regression computationally intensive. For example, a typical Pentium 4 workstation takes around ten minutes to run the preceding statements. Real data sets for classification can be much larger. See examples at UCI Machine Learning Repository (Asuncion and Newman 2007). If new observations about which you want to make predictions are available at model fitting time, you can add the `SCORE` statement in the `LOGISTIC` procedure. Consider the case in which observations to predict become available after fitting the model. With `PROC PLM`, you do not have to repeat the computationally intensive model-fitting processes multiple times. You can use the `SCORE` statement in the `PLM` procedure to score new observations based on the item store `sasuser.SimuModel` that was created during the initial model building. For example, to compute the probability of  $y = 0$  for one new observation with all predictor values equal to 0.15 in the data set `test`, you can use the following statements:

```
data test;
 array x{&nVars};
 do j=1 to &nVars;
 x{j}=0.15;
 end;
 drop j;
 output;
run;

proc plm restore=sasuser.SimuModel;
 score data=test out=testout predicted / ilink;
run;
```

The `ILINK` option in the `SCORE` statement requests that predicted values be inversely transformed to the response scale. In this case, it is the predicted probability of  $y = 0$ . [Output 69.1.1](#) shows the predicted probability for the new observation.

**Output 69.1.1** Predicted Probability for One New Observation

| Obs | Predicted |
|-----|-----------|
| 1   | 0.56649   |

---

## Example 69.2: Working with Item Stores

This example demonstrates how procedures save statistical analysis context and results into item stores and how you can use `PROC PLM` to make post hoc inference based on saved item stores. The data are taken from McCullagh and Nelder (1989) and concern the effects on taste of various cheese additives. Four cheese additives were tested, and 52 response ratings for each additive were obtained. The response was measured on a scale of nine categories that range from strong dislike (1) to excellent taste (9). The following program

saves the data in the data set Cheese. The variable *y* contains the taste rating, the variable *Additive* contains cheese additive types, and the variable *freq* contains the frequencies with which each additive received each rating.

```
data Cheese;
 do Additive = 1 to 4;
 do y = 1 to 9;
 input freq @@;
 output;
 end;
 end;
 label y='Taste Rating';
 datalines;
0 0 1 7 8 8 19 8 1
6 9 12 11 7 6 1 0 0
1 1 6 8 23 7 5 1 0
0 0 0 1 3 7 14 16 11
;
```

The response *y* is a categorical variable that contains nine ordered levels. You can use PROC LOGISTIC to fit an ordinal model to investigate the effects of the cheese additive types on taste ratings. Suppose you also want to save the ordinal model into an item store so that you can make statistical inference later. You can use the following statements to perform the tasks:

```
proc logistic data=cheese;
 freq freq;
 class additive y / param=glm;
 model y=additive;
 store sasuser.cheese;
 title 'Ordinal Model on Cheese Additives';
run;
```

By default, PROC LOGISTIC uses the cumulative logit model for the ordered categorical response. The STORE statement saves the fitted model to a SAS item store named *sasuser.cheese*. The name is a two-level SAS name of the form *libname.membername*. If *libname* is not specified in the STORE statement, the fitted results are saved in *work.membername* and the item store is deleted after the current SAS session ends. With this example, the fitted model is saved to an item store named *sasuser.cheese* in the *Sasuser* library. It is not deleted after the current SAS session ends. You can use PROC PLM to restore the results later.

The following statements use PROC PLM to load the saved model context and results by specifying RESTORE= with the target item store *sasuser.cheese*. Then they use two SHOW statements to display separate information saved in the item store. The first SHOW statement with the PROGRAM option displays the program that was used to generate the item store *sasuser.cheese*. The second SHOW statement with the PARMS option displays parameter estimates and associated statistics of the fitted ordinal model.

```
proc plm restore=sasuser.cheese;
 show program;
 show parms;
run;
```

Output 69.2.1 displays the program that generated the item store *sasuser.cheese*. Except for the title information, it matches the original program.

**Output 69.2.1** Program Information from sasuser.cheese

```

Ordinal Model on Cheese Additives

The PLM Procedure

SAS Program Information

proc logistic data=cheese;
 freq freq;
 class additive y / param=glm;
 model y=additive;
 store sasuser.cheese;
run;

```

Output 69.2.2 displays estimates of the intercept terms and covariates and associated statistics. The intercept terms correspond to eight cumulative logits defined on taste ratings; that is, the  $i$ th intercept for  $i$ th logit is

$$\log\left(\frac{\sum_{j \leq i} p_j}{1 - \sum_{j \leq i} p_j}\right)$$

**Output 69.2.2** Parameter Estimates of the Ordinal Model

| Parameter Estimates |              |          |                |
|---------------------|--------------|----------|----------------|
| Parameter           | Taste Rating | Estimate | Standard Error |
| Intercept           | 1            | -7.0801  | 0.5624         |
| Intercept           | 2            | -6.0249  | 0.4755         |
| Intercept           | 3            | -4.9254  | 0.4272         |
| Intercept           | 4            | -3.8568  | 0.3902         |
| Intercept           | 5            | -2.5205  | 0.3431         |
| Intercept           | 6            | -1.5685  | 0.3086         |
| Intercept           | 7            | -0.06688 | 0.2658         |
| Intercept           | 8            | 1.4930   | 0.3310         |
| Additive 1          |              | 1.6128   | 0.3778         |
| Additive 2          |              | 4.9645   | 0.4741         |
| Additive 3          |              | 3.3227   | 0.4251         |
| Additive 4          |              | 0        | .              |

You can perform various statistical inference tasks from a saved item store, as long as the task is applicable under the model context. For example, you can perform group comparisons between different cheese additive types. See the next example for details.

---

### Example 69.3: Group Comparisons in an Ordinal Model

This example continues the study of the effects on taste of various cheese additives. You have finished fitting an ordinal logistic model and saved it to an item store named `sasuser.cheese` in the previous example. Suppose you want to make comparisons between any pair of cheese additives. You can conduct the analysis by using the ESTIMATE statement and constructing an appropriate L matrix, or by using the LSMEANS statement to compute least squares means differences. For an ordinal logistic model with the cumulative logit link, the least squares means are predicted population margins of the cumulative logits. The following statements compute and display differences between least squares means of cheese additive:

```
ods graphics on;
proc plm restore=sasuser.cheese;
 lsmeans additive / cl diff oddsratio plot=diff;
run;
ods graphics off;
```

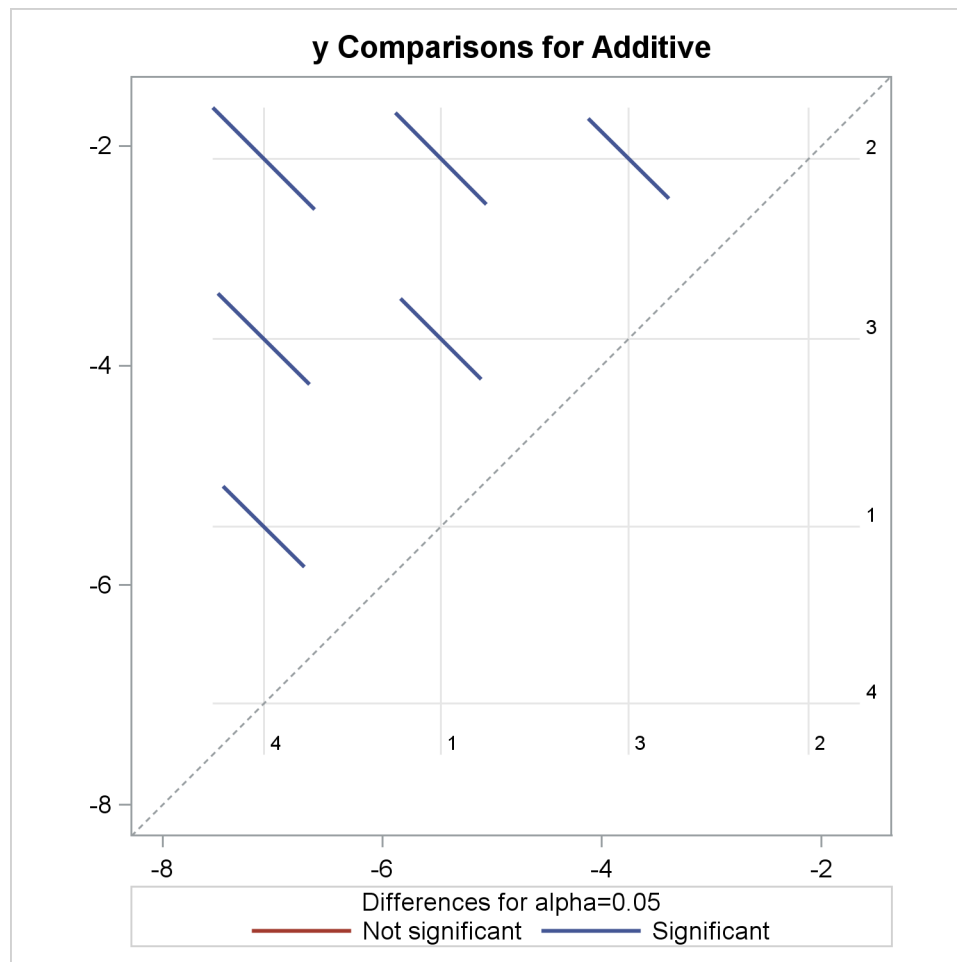

The LSMEANS statement contains four options. The DIFF option requests least squares means differences for cheese additives. Since the fitted model is an ordinal logistic model with the cumulative logit link, the least squares means differences represent log cumulative odds ratios. The ODDSRATIO option requests exponentiation of the LS-means differences which produces cumulative odds ratios. The CL option constructs confidence limits for the LS-means differences. When ODS Graphics is enabled, the PLOTS=DIFF option requests a display of all pairwise least squares means differences and their significance.

Output 69.3.1 displays the LS-means differences. The reported log odds ratios indicate the relative difference among the cheese additives. A negative log odds ratio indicates that the first category (displayed in the Additive column) having a lower taste rating is less likely than the second category (displayed in the \_Additive column) having a lower taste rating. For example, the log odds ratio between cheese additive 1 and 2 is  $-3.3517$  and the corresponding odds ratio is  $0.035$ . This means the odds of cheese additive 1 receiving a poor rating is  $0.035$  times the odds of cheese additive 2 receiving a poor rating. In addition to the highly significant  $p$ -value ( $< 0.0001$ ), the confidence limits for both the log odds ratio and the odds ratio indicate that you can reject the null hypothesis that the odds of cheese additive 1 having a lower taste rating is the same as that of cheese additive 2 having a lower rating. Similarly, the odds of cheese additive 2 having a lower rating is  $143.241$  (with 95% confidence limits  $(56.558, 362.777)$ ) times the odds of cheese additive 4 having a lower rating. With the same logic, you can conclude that the preference order for the four cheese types from the most favorable to the least favorable is: 4, 1, 3 and 2.

**Output 69.3.1** LS-Means Differences of Additive

| Ordinal Model on Cheese Additives           |           |          |                |            |                                       |                                       |

Output 69.3.2 displays the DiffPlot. This shows that all pairs of LS-means differences, equivalent to log odds ratios in this case, are significant at the level of  $\alpha = 0.05$ . This means that the preference between any pair of the four cheese additive types are statistically significantly different.

**Output 69.3.2** LS-Means Plot of Pairwise Differences

## Example 69.4: Posterior Inference for Binomial Data

This example demonstrates how you can use PROC PLM to perform posterior inference from a Bayesian analysis. The data for this example are taken from Weisberg (1985) and concern the effect of small electrical currents on farm animals. The ultimate goal of the experiment was to understand the effects of high-voltage power lines on livestock and to better protect farm animals. Seven cows and six shock intensities were used in two experiments. In one experiment, each cow was given 30 electrical shocks with five at each shock intensity in random order. The number of shock responses was recorded for each cow at each shock level. The experiment was then repeated to investigate whether the response diminished due to fatigue of cows, or due to learning. So each cow received a total of 60 shocks. For the following analysis, the cow difference is ignored. The following DATA step lists the data where the variable `current` represents the shock level, the variable `response` represents the number of shock responses, the variable `trial` represents the total number of trials at each shock level, and the variable `experiment` represents the experiment number (1 for the initial experiment and 2 for the repeated one):

```

data cow;
 input current response trial experiment;
 datalines;
0 0 35 1
0 0 35 2
1 6 35 1
1 3 35 2
2 13 35 1
2 8 35 2
3 26 35 1
3 21 35 2
4 33 35 1
4 27 35 2
5 34 35 1
5 29 35 2
;

```

Suppose you are interested in modeling the distribution of the shock response based on the level of the current and the experiment number. You can use the GENMOD procedure to fit a frequentist logistic model for the data. However, if you have some prior information about parameter estimates, you can fit a Bayesian logistic regression model to take this prior information into account. In this case, suppose you believe the logit of response has a positive association with the shock level but you are uncertain about the ranges of other regression coefficients. To incorporate this prior information in the regression model, you can use the following statements:

```

data prior;
 input _type_$ current;
 datalines;
mean 100
var 50
;

proc genmod data=cow;
 class experiment;
 bayes coeffprior=normal(input=prior) seed=1;
 model response/trial = current|experiment / dist=binomial;
 store cowgmd;
 title 'Bayesian Logistic Model on Cow';
run;

```

The DATA step creates a data set prior that specifies the prior distribution for the variable current, which in this case is a normal distribution with mean 100 and variance 50. This reflects a rough belief in a positive coefficient in a moderate range for current. The prior distribution parameters are not specified for experiment and the interaction between experiment and current, and so PROC GENMOD assigns a default prior for them, which is a normal distribution with mean 0 and variance 1E6.

The BAYES statement in PROC GENMOD specifies that the regression coefficients follow a normal distribution with mean and variance specified in the input data set named prior. It also specifies 1 as the seed for the random number generator in the simulation of the posterior sample. The MODEL statement requests a logistic regression model with a logit link. The STORE statement requests that the fitted results be saved into an item store named cowgmd.

The convergence diagnostics in the output of PROC GENMOD indicate that the Markov chain has converged. [Output 69.4.1](#) displays summaries on the posterior sample of the regression coefficients. The posterior mean for the intercept is  $-3.5857$  with a 95% HPD interval  $(-4.5226, -2.6303)$ . The posterior mean of the coefficient for current is  $1.1893$  with a 95% HPD interval  $(0.8950, 1.4946)$ , which indicates a positive association between the logit of response and the shock level. Further investigation about whether shock reaction was different between two experiment is warranted.

**Output 69.4.1** Posterior Summaries on the Bayesian Logistic Model

Bayesian model fitting typically involves a large amount of simulation. Using the item store and PROC PLM, you do not need to refit the model to perform further posterior inference. Suppose you want to determine whether the shock reaction for the current level is different between the two experiments. You can use PROC PLM with the ESTIMATE statement in the following statements:

```
proc plm restore=cowgmd;
 estimate
 'Diff at current 0' experiment 1 -1 current*experiment [1, 0 1] [-1, 0 2],
 'Diff at current 1' experiment 1 -1 current*experiment [1, 1 1] [-1, 1 2],
 'Diff at current 2' experiment 1 -1 current*experiment [1, 2 1] [-1, 2 2],
 'Diff at current 3' experiment 1 -1 current*experiment [1, 3 1] [-1, 3 2],
 'Diff at current 4' experiment 1 -1 current*experiment [1, 4 1] [-1, 4 2],
 'Diff at current 5' experiment 1 -1 current*experiment [1, 5 1] [-1, 5 2]
 / exp cl;
run;
```

Each line in the ESTIMATE statement compares the fits between the two groups at each current level. The nonpositional syntax is used for the interaction effect current\*experiment. For example, the first line requests coefficient 1 for the interaction effect at current level 0 for the initial experiment, and coefficient

-1 for the effect at current level 0 for the repeated experiment. The two terms are then added to derive the difference. For more details about the nonpositional syntax, see “Positional and Nonpositional Syntax for Coefficients in Linear Functions” on page 448 of Chapter 19, “Shared Concepts and Topics.”

The EXP option exponentiates log odds ratios to produce odds ratios. The CL option requests that confidence limits be constructed for both log odds ratios and odds ratios. Output 69.4.2 lists the posterior sample estimates for differences between experiments at different current levels.

**Output 69.4.2** Comparisons between Experiments at Different Current Levels

The sample statistics are constructed from the posterior sample saved in the item store `cowgmd`. From the output, the odds of a cow showing shock reaction at level 0 in the initial experiment is 1.2811 (with a 95% HPD interval (0.07387, 3.1001)) times the odds in the repeated experiment. The HPD interval for the odds ratio is constructed based on the mean and variance of the sample of the exponentiated log odds ratios, instead of based on the exponentiated mean and variance of the posterior sample of log odds ratios. The HPD interval suggests that there is not much evidence that the cows responded differently at current level 0 between the two experiments. Similar conclusions can be drawn for current level 1, 2, and 5. However, there is strong evidence that cows responded differently at current level 3 and 4 between the two experiments. The possible explanation is that, if the current level is so small that cows could hardly feel it or the current level is so strong that cows could hardly bear it, cows would respond consistently in the two experiment. If the current level is moderate, cows might get used to it and their response diminished in the repeated experiment.

You can visualize the distribution of the posterior sample of log odds ratios by specifying the `PLOTS=` option in the `ESTIMATE` statement. In the following statements, ODS Graphics is enabled by the `ODS GRAPHICS ON` statement, the `PLOTS=BOXPLOT` option requests a box plot of posterior distribution of log odds ratios. The suboption `ORIENT=HORIZONTAL` specifies a horizontal orientation of the boxes.

```
ods graphics on;
proc plm restore=cowgmd;
 estimate
 'Diff at current 0' experiment 1 -1 current*experiment [1, 0 1] [-1, 0 2],
 'Diff at current 1' experiment 1 -1 current*experiment [1, 1 1] [-1, 1 2],
 'Diff at current 2' experiment 1 -1 current*experiment [1, 2 1] [-1, 2 2],
 'Diff at current 3' experiment 1 -1 current*experiment [1, 3 1] [-1, 3 2],
 'Diff at current 4' experiment 1 -1 current*experiment [1, 4 1] [-1, 4 2],
 'Diff at current 5' experiment 1 -1 current*experiment [1, 5 1] [-1, 5 2]
 / plots=boxplot(orient=horizontal);
run;
ods graphics off;
```

Output 69.4.3 displays the box plot of the posterior sample of log odds ratios. The two boxes for differences at current level 3 and 4 show that the corresponding log odds ratios are significantly larger than the reference value  $x = 0$ . This indicate that there is obvious evidence that the probability of cow response is larger in the initial experiment than in the repeated one at the two current levels. The other four boxes show that the corresponding log odds ratios are not significantly different from 0, which suggests that there is no obvious reaction difference at current level 0, 1, 2, and 5 between the two experiments.

**Output 69.4.3** Box Plot of Difference between Two Experiments

### Example 69.5: BY-Group Processing

This example uses a data set on a study of the analgesic effects of treatments on elderly patients with neuralgia. The purpose of this example is to show how PROC PLM behaves under different situations when BY-group processing is present. Two test treatments and a placebo are compared to test whether the patient reported pain or not. For each patient, the information of age, gender, and the duration of complaint before the treatment began were recorded. The following DATA step creates the data set named Neuralgia:

```

Data Neuralgia;
 input Treatment $ Sex $ Age Duration Pain $ @@;
 datalines;
P F 68 1 No B M 74 16 No P F 67 30 No
P M 66 26 Yes B F 67 28 No B F 77 16 No
A F 71 12 No B F 72 50 No B F 76 9 Yes
A M 71 17 Yes A F 63 27 No A F 69 18 Yes
B F 66 12 No A M 62 42 No P F 64 1 Yes
A F 64 17 No P M 74 4 No A F 72 25 No
P M 70 1 Yes B M 66 19 No B M 59 29 No
A F 64 30 No A M 70 28 No A M 69 1 No

```

```

B F 78 1 No P M 83 1 Yes B F 69 42 No
B M 75 30 Yes P M 77 29 Yes P F 79 20 Yes
A M 70 12 No A F 69 12 No B F 65 14 No
B M 70 1 No B M 67 23 No A M 76 25 Yes
P M 78 12 Yes B M 77 1 Yes B F 69 24 No
P M 66 4 Yes P F 65 29 No P M 60 26 Yes
A M 78 15 Yes B M 75 21 Yes A F 67 11 No
P F 72 27 No P F 70 13 Yes A M 75 6 Yes
B F 65 7 No P F 68 27 Yes P M 68 11 Yes
P M 67 17 Yes B M 70 22 No A M 65 15 No
P F 67 1 Yes A M 67 10 No P F 72 11 Yes
A F 74 1 No B M 80 21 Yes A F 69 3 No
;

```

The data set contains five variables. Treatment is a classification variable that has three levels: A and B represent the two test treatments, and P represents the placebo treatment. Sex is a classification variable that indicates each patient's gender. Age is a continuous variable that indicates the age in years of each patient when a treatment began. Duration is a continuous variable that indicates the duration of complaint in months. The last variable Pain is the response variable with two levels: 'Yes' if pain was reported, 'No' if no pain was reported.

Suppose there is some preliminary belief that the dependency of pain on the explanatory variables is different for male and female patients, leading to separate models between genders. You believe there might be redundant information for predicting the probability of Pain. Thus, you want to perform model selection to eliminate unnecessary effects. You can use the following statements:

```

proc sort data=Neuralgia;
 by sex;
run;

proc logistic data=Neuralgia;
 class Treatment / param=glm;
 model pain = Treatment Age Duration / selection=backward;
 by sex;
 store painmodel;
 title 'Logistic Model on Neuralgia';
run;

```

PROC SORT is called to sort the data by variable Sex. The LOGISTIC procedure is then called to fit the probability of no pain. Three variables are specified for the full model: Treatment, Age, and Duration. Backward elimination is used as the model selection method. The BY statement fits separate models for male and female patients. Finally, the STORE statement specifies that the fitted results be saved to an item store named painmodel.

Output 69.5.1 lists parameter estimates from the two models after backward elimination is performed. From the model for female patients, Treatment is the only factor that affects the probability of no pain, and Treatment A and B have the same positive effect in predicting the probability of no pain. From the model for male patients, both Treatment and Age are included in the selected model. Treatment A and B have different positive effects, while Age has a negative effect in predicting the probability of no pain.

**Output 69.5.1** Parameter Estimates for Male and Female Patients

| Logistic Model on Neuralgia              |    |          |                |                 |            |

| Treatment P                              | 0  | 0        | .              | .               | .          |
| ----- Sex=M -----                        |    |          |                |                 |            |
| Analysis of Maximum Likelihood Estimates |    |          |                |                 |            |
| Parameter                                | DF | Estimate | Standard Error | Wald Chi-Square | Pr > ChiSq |
| Intercept                                | 1  | 20.6178  | 9.1638         | 5.0621          | 0.0245     |
| Treatment A                              | 1  | 3.9982   | 1.7333         | 5.3208          | 0.0211     |
| Treatment B                              | 1  | 4.5556   | 1.9252         | 5.5993          | 0.0180     |
| Treatment P                              | 0  | 0        | .              | .               | .          |
| Age                                      | 1  | -0.3416  | 0.1408         | 5.8869          | 0.0153     |

Now the fitted models are saved to the item store `painmodel`. Suppose you want to use it to score several new observations. The following DATA steps create three data sets for scoring:

```
data score1;
 input Treatment $ Sex $ Age;
 datalines;
A F 20
B F 30
P F 40
A M 20
B M 30
P M 40
;

data score2;
 set score1(drop=sex);
run;

data score3;
 set score2(drop=Age);
run;
```

The first score data set `score1` contains six observations and all the variables that are specified in the full model. The second score data set `score2` is a duplicate of `score1` except that `Sex` is dropped. The third score data set `score3` is a duplicate of `score2` except that `Age` is dropped. You can use the following statements to score the three data sets:

```
proc plm restore=painmodel;
 score data=score1 out=score1out predicted;
 score data=score2 out=score2out predicted;
 score data=score3 out=score3out predicted;
run;
```

Output 69.5.2 lists the store information that PROC PLM reads from the item store `painmodel`. The “Model Effects” entry lists all three variables that are specified in the full model before the BY-group processing.

**Output 69.5.2** Item Store Information for `painmodel`

| Logistic Model on Neuralgia |                                  |
|-----------------------------|----------------------------------|
| The PLM Procedure           |                                  |
| Store Information           |                                  |
| Item Store                  | WORK.PAINMODEL                   |
| Data Set Created From       | WORK.NEURALGIA                   |
| Created By                  | PROC LOGISTIC                    |
| Date Created                | 13JUN12:12:38:48                 |
| By Variable                 | Sex                              |
| Response Variable           | Pain                             |
| Link Function               | Logit                            |
| Distribution                | Binary                           |
| Class Variables             | Treatment Pain                   |
| Model Effects               | Intercept Treatment Age Duration |

With the three SCORE statements, three data sets are thus produced: `score1out`, `score2out`, and `score3out`. They contain the linear predictors in addition to all original variables. The data set `score1out` contains the values shown in Output 69.5.3.

**Output 69.5.3** Values of Data Set `score1out`

| Logistic Model on Neuralgia |           |     |     |           |
|-----------------------------|-----------|-----|-----|-----------|
| Obs                         | Treatment | Sex | Age | Predicted |
| 1                           | A         | F   | 20  | 2.1972    |
| 2                           | B         | F   | 30  | 2.1972    |
| 3                           | P         | F   | 40  | -0.4055   |
| 4                           | A         | M   | 20  | 17.7850   |
| 5                           | B         | M   | 30  | 14.9269   |
| 6                           | P         | M   | 40  | 6.9557    |

Linear predictors are computed for all six observations. Because the BY variable Sex is available in score1, PROC PLM uses separate models to score observations of male and female patients. So an observation with the same Treatment and Age has different linear predictors for different genders.

The data set score2out contains the values shown in [Output 69.5.4](#).

**Output 69.5.4** Values of Data Set score2out

| Logistic Model on Neuralgia |     |           |     |           |
|-----------------------------|-----|-----------|-----|-----------|
| Obs                         | Sex | Treatment | Age | Predicted |
| 1                           | F   | A         | 20  | 2.1972    |
| 2                           | F   | B         | 30  | 2.1972    |
| 3                           | F   | P         | 40  | -0.4055   |
| 4                           | F   | A         | 20  | 2.1972    |
| 5                           | F   | B         | 30  | 2.1972    |
| 6                           | F   | P         | 40  | -0.4055   |
| 7                           | M   | A         | 20  | 17.7850   |
| 8                           | M   | B         | 30  | 14.9269   |
| 9                           | M   | P         | 40  | 6.9557    |
| 10                          | M   | A         | 20  | 17.7850   |
| 11                          | M   | B         | 30  | 14.9269   |
| 12                          | M   | P         | 40  | 6.9557    |

The second score data set score2 does not contain the BY variable Sex. PROC PLM continues to score the full data set two times. Each time the scoring is based on the fitted model for each corresponding BY-group. In the output data set, Sex is added at the first column as the BY-group indicator. The first six entries correspond to the model for female patients, and the next six entries correspond to the model for male patients. Age is not included in the first model, and Treatment A and B have the same parameter estimates, so observations 1, 2, 4, and 5 have the same linear predicted value.

The data set score3out contains the values shown in [Output 69.5.5](#).

**Output 69.5.5** Values of Data Set score3out

| Logistic Model on Neuralgia |     |           |           |
|-----------------------------|-----|-----------|-----------|

| 11                          | M   | B         | .         |
| 12                          | M   | P         | .         |

The third score data set `score3` does not contain the BY variable `Sex`. PROC PLM scores the full data twice with separate models. Furthermore, it does not contain the variable `Age`, which is a selected variable for predicting the probability of no pain for male patients. Thus, PROC PLM computes linear predictor values for `score3` by using the first model for female patients, and sets the linear predictor to missing when using the second model for male patients to score the data set.

## Example 69.6: Comparing Multiple B-Splines

This example conducts an analysis similar to Example 15 in Chapter 41.33, “Examples: GLIMMIX Procedure.” It uses simulated data to perform multiple comparisons among predicted values in a model with group-specific trends that are modeled through regression splines. The estimable functions are formed using nonpositional syntax with constructed effects. Consider the data in the following DATA step. Each of the 100 observations for the continuous response variable `y` is associated with one of two groups.

```
data spline;
 input group y @@;
 x = _n_;
 datalines;
1 -.020 1 0.199 2 -1.36 1 -.026
2 -.397 1 0.065 2 -.861 1 0.251

;
```

The following statements fit a model with separate trends for the two groups; the trends are modeled as B-splines.

```

proc orthoreg data=spline;
 class group;
 effect spl = spline(x);
 model y = group spl*group / noint;
 store ortho_spline;
 title 'B-splines Comparisons';
run;

```

Results from this analysis are shown in [Output 69.6.1](#). The “Parameter Estimates” table shows the estimates for the spline coefficients in the two groups.

By default, the ORTHOREG procedure constructs B-splines with seven knots. Since B-spline coefficients satisfy a sum-to-one constraint and since the model contains group-specific intercepts, the last spline coefficient for each group is redundant and is set to 0.

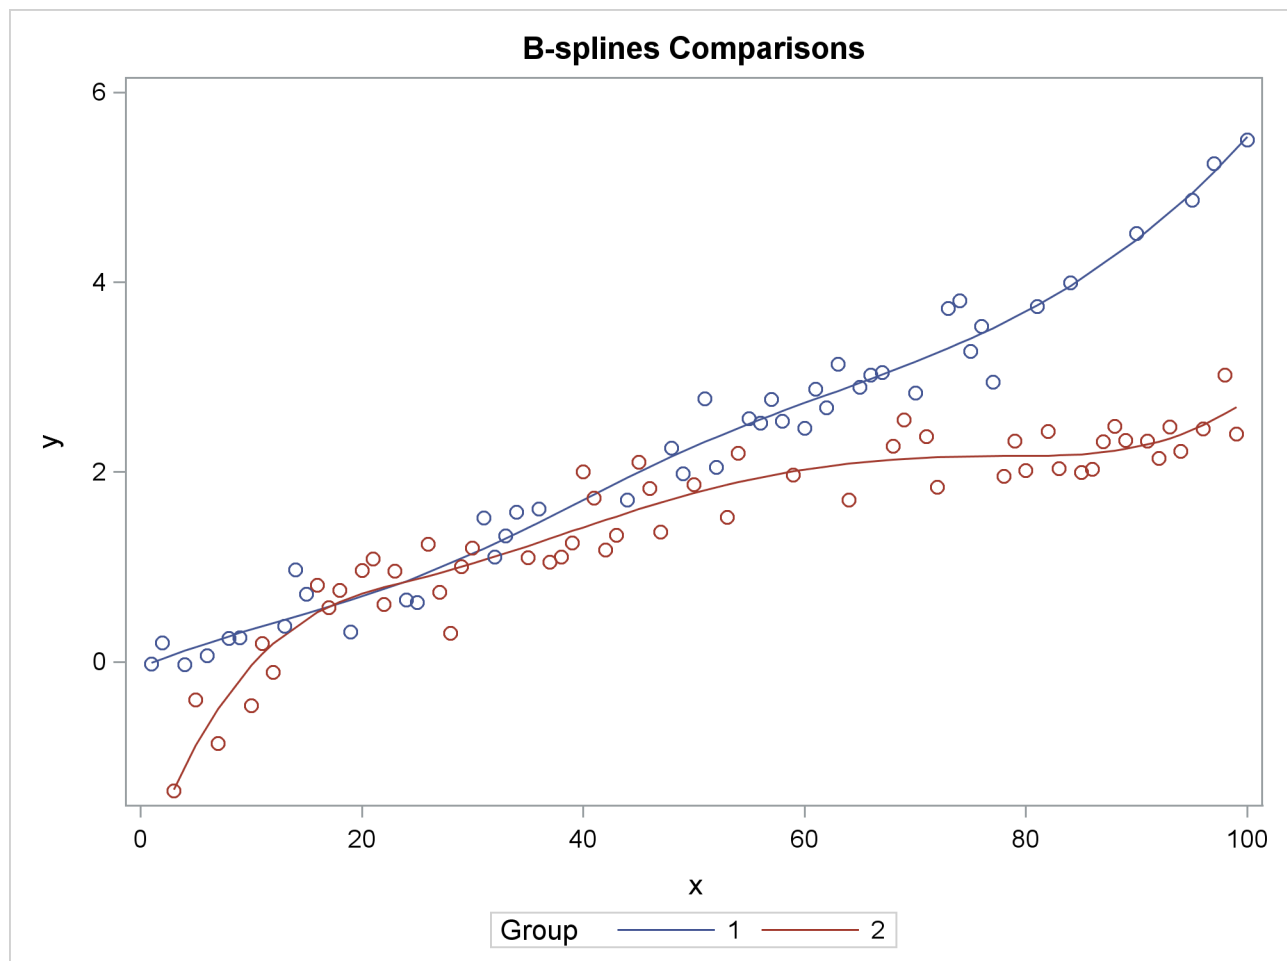

The following statements make a prediction for the input data set by using the SCORE statement with PROC PLM and graph the observed and predicted values in the two groups:

```
proc plm restore=ortho_spline;
 score data=spline out=ortho_pred predicted=p;
run;

proc sgplot data=ortho_pred;
 series y=p x=x / group=group name="fit";
 scatter y=y x=x / group=group;
 keylegend "fit" / title="Group";
run;
```

The prediction plot in [Output 69.6.2](#) suggests that there is some separation of the group trends for small values of  $x$  and for values that exceed about  $x = 40$ .

**Output 69.6.2** Observed Data and Predicted Values by Group

In order to determine the range on which the trends separate significantly, the PLM procedure is executed in the following statements with an [ESTIMATE](#) statement that applies group comparisons at a number of values for the spline variable  $x$ :

```

%macro GroupDiff;
 %do x=0 %to 75 %by 5;
 "Diff at x=&x" group 1 -1 group*spl [1,1 &x] [-1,2 &x],
 %end;
 'Diff at x=80' group 1 -1 group*spl [1,1 80] [-1,2 80]
%mend;

proc plm restore=ortho_spline;
 show effects;
 estimate %GroupDiff / adjust=simulate seed=1 stepdown;
run;

```

For example, the following ESTIMATE statement compares the trends between the two groups at  $x = 25$ :

```
estimate 'Diff at x=25' group 1 -1 group*spl [1,1 25] [-1,2 25];
```

The nonpositional syntax is used for the `group*spl` effect. For example, the specification `[-1, 2 25]` requests that the spline be computed at  $x = 25$  for the second level of variable `group`. The resulting coefficients are added to the  $L$  vector for the estimate after being multiplied with  $-1$ .

Because comparisons are made at a large number of values for  $x$ , a multiplicity correction is in order to adjust the  $p$ -values to reflect familywise error control. Simulated  $p$ -values with step-down adjustment are used here.

Output 69.6.3 displays the “Store Information” for the item store and information about the spline effect (the result of the `SHOW` statement).

Notice that the “Store Information” in [Output 69.6.3](#) displays the classification variables (from the CLASS statement in PROC ORTHOREG), the constructed effects (from the EFFECT statement in PROC ORTHOREG), and the model effects (from the MODEL statement in PROC ORTHOREG). [Output 69.6.4](#) shows that at the 5% significance level the trends are significantly different for  $x \leq 10$  and for  $x \geq 40$ . Between those values you cannot reject the hypothesis of trend congruity.

To see this effect more clearly, you can filter the results by adding the a filtering statement to the previous PROC PLM step:

```
proc plm restore=ortho_spline;
 estimate %GroupDiff / adjust=simulate seed=1 stepdown;
 filter adjp > 0.05;
run;
```

This produces [Output 69.6.5](#), which displays the subset of the results in [Output 69.6.4](#) that meets the condition in the `FILTER` expression.

**Output 69.6.5** Filtered Estimate Results

## Example 69.7: Linear Inference with Arbitrary Estimates

Suppose that you have calculated a vector of parameter estimates of dimension  $(p \times 1)$  and its associated variance-covariance matrix by some statistical method. You might want to use these results to perform linear inference, or to score a data set and calculate predicted values and their standard errors.

The following DATA steps create two SAS data sets. The first, called `parms`, contains six estimates that represent two uncorrelated groups. The data set `cov` contains the covariance matrix of the estimates. The lack of correlation between the two sets of three parameters is evident in the block-diagonal structure of the covariance matrix.

```

data parms;
 length name $6;
 input Name$ Value;
 datalines;
alpha1 -3.5671
beta1 0.4421
gamma1 -2.6230
alpha2 -3.0111
beta2 0.3977
gamma2 -2.4442
;

data cov;
 input Parm row col1-col6;
 datalines;
1 1 0.007462 -0.005222 0.010234 0.000000 0.000000 0.000000
1 2 -0.005222 0.048197 -0.010590 0.000000 0.000000 0.000000
1 3 0.010234 -0.010590 0.215999 0.000000 0.000000 0.000000
1 4 0.000000 0.000000 0.000000 0.031261 -0.009096 0.015785
1 5 0.000000 0.000000 0.000000 -0.009096 0.039487 -0.019996
1 6 0.000000 0.000000 0.000000 0.015785 -0.019996 0.126172
;

```

Suppose that you are interested in testing whether the parameters are homogeneous across groups—that is, whether  $\alpha_1 = \alpha_2$ ,  $\beta_1 = \beta_2$ ,  $\gamma_1 = \gamma_2$ . You are interested in testing the hypothesis jointly and separately with multiplicity adjustment.

To use the PLM procedure, you first need to create an item store that contains the necessary information as if the preceding parameter vector and covariance matrix were the result of a statistical modeling procedure. The following statements use the GLIMMIX procedure to create such an item store, by fitting a saturated linear model with the data set that contains the parameter estimates serving as the input data set:

```

proc glimmix data=parms order=data;
 class Name;
 model Value = Name / noint ddfm=none s;
 random _residual_ / type=lin(1) ldata=cov v;
 parms (1) / noiter;
 store ArtificialModel;
 title 'Linear Inference';
run;

```

The RANDOM statement is used to form the covariance structure for the estimates. The PARMs statement prevents iterative updates of the covariance parameters. The resulting marginal covariance matrix of the “data” is thus identical to the covariance matrix in the data set cov. The ORDER=DATA option in the PROC GLIMMIX statement is used to arrange the levels of the classification variable Name in the order in which they appear in the data set so that the order of the parameters matches that of the covariance matrix.

The results of this analysis are shown in [Output 69.7.1](#). Note that the parameter estimates are identical to the values passed in the input data set and their standard errors equal the square root of the diagonal elements of the cov data set.

| name                        | beta1  | 0.4421   | 0.2195         | Infty | 2.01    | 0.0440  |
| name                        | gamma1 | -2.6230  | 0.4648         | Infty | -5.64   | <.0001  |
| name                        | alpha2 | -3.0111  | 0.1768         | Infty | -17.03  | <.0001  |
| name                        | beta2  | 0.3977   | 0.1987         | Infty | 2.00    | 0.0454  |
| name                        | gamma2 | -2.4442  | 0.3552         | Infty | -6.88   | <.0001  |

There are other ways to fit a saturated model with the GLIMMIX procedure. For example, you can use the TYPE=UN covariance structure in the RANDOM statement with a properly prepared input data set for the PDATA= option in the PARMS statement. See Example 17 in Chapter 41.33, “Examples: GLIMMIX Procedure,” for details.

Once the item store exists, you can apply the linear inference capabilities of the PLM procedure. For example, the ESTIMATE statement in the following statements test the hypothesis of parameter homogeneity across groups:

```
proc plm restore=ArtificialModel;
 estimate
 'alpha1 = alpha2' Name 1 0 0 -1 0 0,
 'beta1 = beta2 ' Name 0 1 0 0 -1 0,
 'gamma1 = gamma2' Name 0 0 1 0 0 -1 /
 adjust=bon stepdown ftest(label='Homogeneity');
run;
```

| Label                             | Num DF   | Den DF         | F Value | Pr > F  |         |        |
| Homogeneity                       | 3        | Infty          | 2.79    | 0.0389  |         |        |

The  $F$  test in [Output 69.7.2](#) shows that the joint test of homogeneity is rejected. The individual tests with familywise control of the Type I error show that the overall difference is due to a significant change in the  $\alpha$  parameters. The hypothesis of homogeneity across the two groups cannot be rejected for the  $\beta$  and  $\gamma$  parameters.

## Overview: PLS Procedure

The PLS procedure fits models by using any one of a number of linear predictive methods, including *partial least squares* (PLS). Ordinary least squares regression, as implemented in SAS/STAT procedures such as PROC GLM and PROC REG, has the single goal of minimizing sample response prediction error, seeking linear functions of the predictors that explain as much variation in each response as possible. The techniques implemented in the PLS procedure have the additional goal of accounting for variation in the predictors, under the assumption that directions in the predictor space that are well sampled should provide better prediction for *new* observations when the predictors are highly correlated. All of the techniques implemented in the PLS procedure work by extracting successive linear combinations of the predictors, called *factors* (also called *components*, *latent vectors*, or *latent variables*), which optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, the method of partial least squares balances the two objectives, seeking factors that explain both response and predictor variation.

Note that the name “partial least squares” also applies to a more general statistical method that is *not* implemented in this procedure. The partial least squares method was originally developed in the 1960s by the econometrician Herman Wold (1966) for modeling “paths” of causal relation between any number of “blocks” of variables. However, the PLS procedure fits only *predictive* partial least squares models, with one “block” of predictors and one “block” of responses. If you are interested in fitting more general path models, you should consider using the CALIS procedure.

---

## Basic Features

The techniques implemented by the PLS procedure are as follows:

- principal components regression, which extracts factors to explain as much predictor sample variation as possible
- reduced rank regression, which extracts factors to explain as much response variation as possible. This technique, also known as (maximum) redundancy analysis, differs from multivariate linear regression only when there are multiple responses.
- partial least squares regression, which balances the two objectives of explaining response variation and explaining predictor variation. Two different formulations for partial least squares are available: the original predictive method of Wold (1966) and the SIMPLS method of de Jong (1993).

The number of factors to extract depends on the data. Basing the model on more extracted factors improves the model fit to the observed data, but extracting too many factors can cause *overfitting*—that is, tailoring the model too much to the current data, to the detriment of future predictions. The PLS procedure enables you to choose the number of extracted factors by *cross validation*—that is, fitting the model to part of the data, minimizing the prediction error for the unfitted part, and iterating with different portions of the data in the roles of fitted and unfitted. Various methods of cross validation are available, including one-at-a-time validation and splitting the data into blocks. The PLS procedure also offers test set validation, where the model is fit to the entire primary input data set and the fit is evaluated over a distinct test data set.

You can use the general linear modeling approach of the GLM procedure to specify a model for your design, allowing for general polynomial effects as well as classification or ANOVA effects. You can save the model fit by the PLS procedure in a data set and apply it to new data by using the SCORE procedure.

The PLS procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the statistical graphics available with the PLS procedure, see the PLOTS options in the PROC PLS statements and the section “ODS Graphics” on page 5891.

## Getting Started: PLS Procedure

### Spectrometric Calibration

The example in this section illustrates basic features of the PLS procedure. The data are reported in Umetrics (1995); the original source is Lindberg, Persson, and Wold (1983). Suppose that you are researching pollution in the Baltic Sea, and you would like to use the spectra of samples of seawater to determine the amounts of three compounds present in samples from the Baltic Sea: lignin sulfonate (ls: pulp industry pollution), humic acids (ha: natural forest products), and optical whitener from detergent (dt). Spectrometric calibration is a type of problem in which partial least squares can be very effective. The predictors are the spectra emission intensities at different frequencies in sample spectrum, and the responses are the amounts of various chemicals in the sample.

For the purposes of calibrating the model, samples with known compositions are used. The calibration data consist of 16 samples of known concentrations of ls, ha, and dt, with spectra based on 27 frequencies (or, equivalently, wavelengths). The following statements create a SAS data set named Sample for these data.

```

data Sample;

## Fitting a PLS Model

To isolate a few underlying spectral factors that provide a good predictive model, you can fit a PLS model to the 16 samples by using the following SAS statements:

```

proc pls data=sample;
 model ls ha dt = v1-v27;
run;

```

By default, the PLS procedure extracts at most 15 factors. The procedure lists the amount of variation accounted for by each of these factors, both individual and cumulative; this listing is shown in [Figure 70.1](#).

**Figure 70.1** PLS Variation Summary

| The PLS Procedure                                                   |               |          |                     |          |
|---------------------------------------------------------------------|---------------|----------|---------------------|----------|
| Percent Variation Accounted for<br>by Partial Least Squares Factors |               |          |                     |          |
| Number of<br>Extracted<br>Factors                                   | Model Effects |          | Dependent Variables |          |
|                                                                     | Current       | Total    | Current             | Total    |
| 1                                                                   | 97.4607       | 97.4607  | 41.9155             | 41.9155  |
| 2                                                                   | 2.1830        | 99.6436  | 24.2435             | 66.1590  |
| 3                                                                   | 0.1781        | 99.8217  | 24.5339             | 90.6929  |
| 4                                                                   | 0.1197        | 99.9414  | 3.7898              | 94.4827  |
| 5                                                                   | 0.0415        | 99.9829  | 1.0045              | 95.4873  |
| 6                                                                   | 0.0106        | 99.9935  | 2.2808              | 97.7681  |
| 7                                                                   | 0.0017        | 99.9952  | 1.1693              | 98.9374  |
| 8                                                                   | 0.0010        | 99.9961  | 0.5041              | 99.4415  |
| 9                                                                   | 0.0014        | 99.9975  | 0.1229              | 99.5645  |
| 10                                                                  | 0.0010        | 99.9985  | 0.1103              | 99.6747  |
| 11                                                                  | 0.0003        | 99.9988  | 0.1523              | 99.8270  |
| 12                                                                  | 0.0003        | 99.9991  | 0.1291              | 99.9561  |
| 13                                                                  | 0.0002        | 99.9994  | 0.0312              | 99.9873  |
| 14                                                                  | 0.0004        | 99.9998  | 0.0065              | 99.9938  |
| 15                                                                  | 0.0002        | 100.0000 | 0.0062              | 100.0000 |

Note that all of the variation in both the predictors and the responses is accounted for by only 15 factors; this is because there are only 16 sample observations. More important, almost all of the variation is accounted for with even fewer factors—one or two for the predictors and three to eight for the responses.

### Selecting the Number of Factors by Cross Validation

A PLS model is not complete until you choose the number of factors. You can choose the number of factors by using cross validation, in which the data set is divided into two or more groups. You fit the model to all groups except one, and then you check the capability of the model to predict responses for the group omitted. Repeating this for each group, you then can measure the overall capability of a given form of the model. The predicted residual sum of squares (PRESS) statistic is based on the residuals generated by this process.

To select the number of extracted factors by cross validation, you specify the **CV=** option with an argument that says which cross validation method to use. For example, a common method is split-sample validation, in which the different groups are composed of every  $n$ th observation beginning with the first, every  $n$ th observation beginning with the second, and so on. You can use the **CV=SPLIT** option to specify split-sample validation with  $n = 7$  by default, as in the following SAS statements:

```
proc pls data=sample cv=split;
 model ls ha dt = v1-v27;
run;
```

The resulting output is shown in [Figure 70.2](#) and [Figure 70.3](#).

**Figure 70.2** Split-Sample Validated PRESS Statistics for Number of Factors

| The PLS Procedure                                           |                       |        |

| 4                                 | 0.1197                                                              | 99.9414 | 3.7898              | 94.4827 |
| 5                                 | 0.0415                                                              | 99.9829 | 1.0045              | 95.4873 |
| 6                                 | 0.0106                                                              | 99.9935 | 2.2808              | 97.7681 |

The absolute minimum PRESS is achieved with six extracted factors. Notice, however, that this is not much smaller than the PRESS for three factors. By using the **CVTEST** option, you can perform a statistical model comparison suggested by van der Voet (1994) to test whether this difference is significant, as shown in the following SAS statements:

```
proc pls data=sample cv=split cvtest (seed=12345);
 model ls ha dt = v1-v27;
run;
```

The model comparison test is based on a rerandomization of the data. By default, the seed for this randomization is based on the system clock, but it is specified here. The resulting output is shown in Figure 70.4 and Figure 70.5.

**Figure 70.4** Testing Split-Sample Validation for Number of Factors

| The PLS Procedure                                           |                       |          |                |  |
|-------------------------------------------------------------|-----------------------|----------|----------------|--|

| 15                                                          | 0.531049              | 7.538298 | 0.0030         |  |
| Minimum root mean PRESS                                     |                       |          | 0.4750         |  |
| Minimizing number of factors                                |                       |          | 6              |  |
| Smallest number of factors with p > 0.1                     |                       |          | 3              |  |

**Figure 70.5** PLS Variation Summary for Tested Split-Sample Validated Model

| Percent Variation Accounted for<br>by Partial Least Squares Factors |               |         |                     |         |
|---------------------------------------------------------------------|---------------|---------|---------------------|---------|
| Number of<br>Extracted<br>Factors                                   | Model Effects |         | Dependent Variables |         |
|                                                                     | Current       | Total   | Current             | Total   |
| 1                                                                   | 97.4607       | 97.4607 | 41.9155             | 41.9155 |
| 2                                                                   | 2.1830        | 99.6436 | 24.2435             | 66.1590 |
| 3                                                                   | 0.1781        | 99.8217 | 24.5339             | 90.6929 |

The  $p$ -value of 0.1430 in comparing the cross validated residuals from models with 6 and 3 factors indicates that the difference between the two models is insignificant; therefore, the model with fewer factors is preferred. The variation summary shows that over 99% of the predictor variation and over 90% of the response variation are accounted for by the three factors.

## Predicting New Observations

Now that you have chosen a three-factor PLS model for predicting pollutant concentrations based on sample spectra, suppose that you have two new samples. The following SAS statements create a data set containing the spectra for the new samples:

```
data newobs;
 input obsnam $ v1-v27 @@;
 datalines;
EM17 3933 4518 5637 6006 5721 5187 4641 4149 3789
 3579 3447 3381 3327 3234 3078 2832 2571 2274
 2040 1818 1629 1470 1350 1245 1134 1050 987
EM25 2904 2997 3255 3150 2922 2778 2700 2646 2571
 2487 2370 2250 2127 2052 1713 1419 1200 984
 795 648 525 426 351 291 240 204 162
;
```

You can apply the PLS model to these samples to estimate pollutant concentration. To do so, append the new samples to the original 16, and specify that the predicted values for all 18 be output to a data set, as shown in the following statements:

```
data all;
 set sample newobs;
run;

proc pls data=all nfac=3;
 model ls ha dt = v1-v27;
 output out=pred p=p_ls p_ha p_dt;
run;

proc print data=pred;
 where (obsnam in ('EM17','EM25'));
 var obsnam p_ls p_ha p_dt;
run;
```

The new observations are not used in calculating the PLS model, since they have no response values. Their predicted concentrations are shown in [Figure 70.6](#).

**Figure 70.6** Predicted Concentrations for New Observations

| Obs | obsnam | p_ls     | p_ha    | p_dt    |
|-----|--------|----------|---------|---------|
| 17  | EM17   | 2.54261  | 0.31877 | 81.4174 |
| 18  | EM25   | -0.24716 | 1.37892 | 46.3212 |

Finally, if ODS Graphics is enabled, PLS also displays by default a plot of the amount of variation accounted for by each factor, as well as a correlations loading plot that summarizes the first two dimensions of the PLS model. The following statements, which are the same as the previous split-sample validation analysis but with ODS Graphics enabled, additionally produce [Figure 70.7](#) and [Figure 70.8](#):

```
ods graphics on;

proc pls data=sample cv=split cvtest(seed=12345);
 model ls ha dt = v1-v27;
run;

ods graphics off;
```

**Figure 70.7** Split-Sample Cross Validation Plot

Figure 70.8 Correlation Loadings Plot

The cross validation plot in [Figure 70.7](#) gives a visual representation of the selection of the optimum number of factors discussed previously. The correlation loadings plot is a compact summary of many features of the PLS model. For example, it shows that the first factor is highly positively correlated with all spectral values, indicating that it is approximately an average of them all; the second factor is positively correlated with the lowest frequencies and negatively correlated with the highest, indicating that it is approximately a contrast between the two ends of the spectrum. The observations, represented by their number in the data set on this plot, are generally spaced well apart, indicating that the data give good information about these first two factors. For more details on the interpretation of the correlation loadings plot, see the section “[ODS Graphics](#)” on page 5891 and [Example 70.1](#).

## Syntax: PLS Procedure

The following statements are available in the PLS procedure. Items within the angle brackets are optional.

```
PROC PLS < options > ;
 BY variables ;
 CLASS variables < / option > ;
 EFFECT name=effect-type (variables < / options >) ;
 ID variables ;
 MODEL dependent-variables = effects < / options > ;
 OUTPUT OUT=SAS-data-set < options > ;
```

To analyze a data set, you must use the **PROC PLS** and **MODEL** statements. You can use the other statements as needed. **CLASS** and **EFFECT** statements, if present, must precede the **MODEL** statement.

## PROC PLS Statement

```
PROC PLS < options > ;
```

The PROC PLS statement invokes the PLS procedure. Optionally, you can also indicate the analysis data and method in the PROC PLS statement. [Table 70.1](#) summarizes the options available in the PROC PLS statement.

**Table 70.1** PROC PLS Statement Options

| Option     | Description                                                                                 |
|------------|---------------------------------------------------------------------------------------------|
| CENSCALE   | Displays the centering and scaling information                                              |
| CV=ONE     | Specifies the cross validation method to be used                                            |
| CVTEST     | Specifies that van der Voet's (1994) randomization-based model comparison test be performed |
| DATA=      | Names the SAS data set                                                                      |
| DETAILS    | Displays the details of the fitted model                                                    |
| METHOD=PLS | Specifies the general factor extraction method to be used                                   |
| MISSING=   | Specifies how observations with missing values are to be handled in computing the fit       |
| NFAC=      | Specifies the number of factors to extract                                                  |
| NOCENTER   | Suppresses centering of the responses and predictors before fitting                         |
| NOCVSTDIZE | Suppresses re-centering and rescaling of the responses and predictors when cross-validating |
| NOPRINT    | Suppresses the normal display of results                                                    |
| NOSCALE    | Suppresses scaling of the responses and predictors before fitting                           |
| PLOTS      | Controls the plots produced through ODS Graphics                                            |
| VARSCALE   | Specifies that continuous model variables be centered and scaled                            |
| VARSS      | Displays the amount of variation accounted for in each response and predictor               |

The following options are available.

**CENSCALE**

lists the centering and scaling information for each response and predictor.

**CV=ONE**

**CV=SPLIT** <(*n*)>

**CV=BLOCK** <(*n*)>

**CV=RANDOM** <(*cv-random-opts*)>

**CV=TESTSET**(*SAS-data-set*)

specifies the cross validation method to be used. By default, no cross validation is performed. The method **CV=ONE** requests one-at-a-time cross validation, **CV=SPLIT** requests that every *n*th observation be excluded, **CV=BLOCK** requests that *n* blocks of consecutive observations be excluded, **CV=RANDOM** requests that observations be excluded at random, and **CV=TESTSET**(*SAS-data-set*) specifies a test set of observations to be used for validation (formally, this is called “test set validation” rather than “cross validation”). You can, optionally, specify *n* for **CV=SPLIT** and **CV=BLOCK**; the default is *n* = 7. You can also specify the following optional *cv-random-options* in parentheses after the **CV=RANDOM** option:

**NITER**=*n*

specifies the number of random subsets to exclude. The default value is 10.

**NTEST**=*n*

specifies the number of observations in each random subset chosen for exclusion. The default value is one-tenth of the total number of observations.

**SEED**=*n*

specifies an integer used to start the pseudo-random number generator for selecting the random test set. If you do not specify a seed, or specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer’s clock.

**CVTEST** <(*cvtest-options*)>

specifies that van der Voet’s (1994) randomization-based model comparison test be performed to test models with different numbers of extracted factors against the model that minimizes the predicted residual sum of squares; see the section “[Cross Validation](#)” on page 5887 for more information. You can also specify the following *cv-test-options* in parentheses after the **CVTEST** option:

**PVAL**=*n*

specifies the cutoff probability for declaring an insignificant difference. The default value is 0.10.

**STAT**=*test-statistic*

specifies the test statistic for the model comparison. You can specify either T2, for Hotelling’s  $T^2$  statistic, or PRESS, for the predicted residual sum of squares. The default value is T2.

**NSAMP**=*n*

specifies the number of randomizations to perform. The default value is 1000.

**SEED=*n***

specifies the seed value for randomization generation (the clock time is used by default).

**DATA=*SAS-data-set***

names the SAS data set to be used by PROC PLS. The default is the most recently created data set.

**DETAILS**

lists the details of the fitted model for each successive factor. The details listed are different for different extraction methods; see the section “[Displayed Output](#)” on page 5890 for more information.

**METHOD=PLS < ( *PLS-options* )>****METHOD=SIMPLS****METHOD=PCR****METHOD=RRR**

specifies the general factor extraction method to be used. The value PLS requests partial least squares, SIMPLS requests the SIMPLS method of de Jong (1993), PCR requests principal components regression, and RRR requests reduced rank regression. The default is METHOD=PLS. You can also specify the following optional *PLS-options* in parentheses after METHOD=PLS:

**ALGORITHM=NIPALS | SVD | EIG | RLGW**

names the specific algorithm used to compute extracted PLS factors. NIPALS requests the usual iterative NIPALS algorithm, SVD bases the extraction on the singular value decomposition of  $\mathbf{X}'\mathbf{Y}$ , EIG bases the extraction on the eigenvalue decomposition of  $\mathbf{Y}'\mathbf{X}\mathbf{X}'\mathbf{Y}$ , and RLGW is an iterative approach that is efficient when there are many predictors. ALGORITHM=SVD is the most accurate but least efficient approach; the default is ALGORITHM=NIPALS.

**MAXITER=*n***

specifies the maximum number of iterations for the NIPALS and RLGW algorithms. The default value is 200.

**EPSILON=*n***

specifies the convergence criterion for the NIPALS and RLGW algorithms. The default value is  $10^{-12}$ .

**MISSING=NONE****MISSING=AVG****MISSING=EM < ( *EM-options* )>**

specifies how observations with missing values are to be handled in computing the fit. The default is MISSING=NONE, for which observations with any missing variables (dependent or independent) are excluded from the analysis. MISSING=AVG specifies that the fit be computed by filling in missing values with the average of the nonmissing values for the corresponding variable. If you specify MISSING=EM, then the procedure first computes the model with MISSING=AVG and then fills in missing values by their predicted values based on that model and computes the model again. For both methods of imputation, the imputed values contribute to the centering and scaling values, and the difference between the imputed values and their final predictions contributes to the percentage of variation explained. You can also specify the following optional *EM-options* in parentheses after MISSING=EM:

**MAXITER=*n***

specifies the maximum number of iterations for the imputation/fit loop. The default value is 1. If you specify a large value of MAXITER=, then the loop will iterate until it converges (as controlled by the EPSILON= option).

**EPSILON=*n***

specifies the convergence criterion for the imputation/fit loop. The default value is  $10^{-8}$ . This option is effective only if you specify a large value for the MAXITER= option.

**NFAC=*n***

specifies the number of factors to extract. The default is  $\min\{15, p, N\}$ , where  $p$  is the number of predictors (the number of dependent variables for METHOD=RRR) and  $N$  is the number of runs (observations). This is probably more than you need for most applications. Extracting too many factors can lead to an overfit model, one that matches the training data too well, sacrificing predictive ability. Thus, if you use the default NFAC= specification, you should also either use the CV= option to select the appropriate number of factors for the final model or consider the analysis to be preliminary and examine the results to determine the appropriate number of factors for a subsequent analysis.

**NOCENTER**

suppresses centering of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the section “Centering and Scaling” on page 5889 for more information.

**NOCVSTDIZE**

suppresses re-centering and rescaling of the responses and predictors before each model is fit in the cross validation. See the section “Centering and Scaling” on page 5889 for more information.

**NOPRINT**

suppresses the normal display of results. This is useful when you want only the output statistics saved in a data set. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System” for more information.

**NOSCALE**

suppresses scaling of the responses and predictors before fitting. This is useful if the analysis variables are already centered and scaled. See the section “Centering and Scaling” on page 5889 for more information.

**PLOTS** <(global-plot-options)> <= plot-request <(options)>>

**PLOTS** <(global-plot-options)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses from around the plot request. For example:

```
plots=none
plots=cvplot
plots=(diagnostics cvplot)
plots(unpack)=diagnostics
plots(unpack)=(diagnostics corrload(trace=off))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc pls data=pentaTrain;
 model log_RAI = S1-S5 L1-L5 P1-P5;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

If ODS Graphics is enabled but you do not specify the PLOTS= option, then PROC PLS produces by default a plot of the R-square analysis and a correlation loading plot summarizing the first two factors.

The global plot options include the following:

#### **FLIP**

interchanges the X-axis and Y-axis dimensions for the score, weight, and loading plots.

#### **ONLY**

suppresses the default plots. Only plots specifically requested are displayed.

#### **UNPACKPANEL**

##### **UNPACK**

suppresses paneling. By default, multiple plots can appear in some output panels. Specify UNPACKPANEL to get each plot in a separate panel. You can specify PLOTS(UNPACKPANEL) to unpack only the default plots. You can also specify UNPACKPANEL as a suboption for certain specific plots, as discussed in the following.

The plot requests include the following:

#### **ALL**

produces all appropriate plots. You can specify other options with ALL—for example, to request all plots and unpack only the residuals, specify PLOTS=(ALL RESIDUALS(UNPACK)).

#### **CORRLOAD <(TRACE = ON | OFF)>**

produces a correlation loading plot (default). The TRACE= option controls how points corresponding to the X-loadings in the correlation loadings plot are depicted. By default, these points are depicted by the name of the corresponding model effect if there are 20 or fewer of them; otherwise, they are depicted by a connected “trace” through the points. You can use this option to change this behavior.

#### **CVPLOT**

produces a cross validation and R-square analysis. This plot requires the CV= option to be specified, and is displayed by default in this case.

#### **DIAGNOSTICS <(UNPACK)>**

produces a summary panel of the fit for each dependent variable. The summary by default consists of a panel for each dependent variable, with plots depicting the distribution of residuals and predicted values. You can use the UNPACK suboption to specify that the subplots be produced separately.

**DMOD**

produces the DMODX, DMODY, and DMODXY plots.

**DMODX**

produces a plot of the distance of each observation to the X model.

**DMODXY**

produces plots of the distance of each observation to the X and Y models.

**DMODY**

produces a plot of the distance of each observation to the Y model.

**FIT**

produces both the fit diagnostic panel and the ParmProfiles plot.

**NONE**

suppresses the display of graphics.

**PARMPROFILES**

produces profiles of the regression coefficients.

**SCORES <(UNPACK | FLIP)>**

produces the XScores, YScores, XYScores, and DModXY plots. You can use the UNPACK suboption to specify that the subplots for scores be produced separately, and the FLIP option to interchange their default X-axis and Y-axis dimensions.

**RESIDUALS <(UNPACK)>**

plots the residuals for each dependent variable against each independent variable. Residual plots are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately.

**VIP**

produces profiles of variable importance factors.

**WEIGHTS <(UNPACK | FLIP)>**

produces all X and Y loading and weight plots, as well as the VIP plot. You can use the UNPACK suboption to specify that the subplots for weights and loadings be produced separately, and the FLIP option to interchange their default X-axis and Y-axis dimensions.

**XLOADINGPLOT <(UNPACK | FLIP)>**

produces a scatter plot matrix of X-loadings against each other. Loading scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

**XLOADINGPROFILES**

produces profiles of the X-loadings.

**XSCORES <(UNPACK | FLIP)>**

produces a scatter plot matrix of X-scores against each other. Score scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

**XWEIGHTPLOT <(UNPACK | FLIP)>**

produces a scatter plot matrix of X-weights against each other. Weight scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

**XWEIGHTPROFILES**

produces profiles of the X-weights.

**XYScores <(UNPACK)>**

produces a scatter plot matrix of X-scores against Y-scores. Score scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately.

**YScores <(UNPACK | FLIP)>**

produces a scatter plot matrix of Y-scores against each other. Score scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

**YWEIGHTPLOT <(UNPACK | FLIP)>**

produces a scatter plot matrix of Y-weights against each other. Weight scatter plot matrices are by default composed of multiple plots combined into a single panel. You can use the UNPACK suboption to specify that the subplots be produced separately, and the FLIP option to interchange the default X-axis and Y-axis dimensions.

**VARSCALE**

specifies that continuous model variables be centered and scaled prior to centering and scaling the model effects in which they are involved. The rescaling specified by the VARSCALE option is sometimes more appropriate if the model involves crossproducts between model variables; however, the VARSCALE option still might not produce the model you expect. See the section “[Centering and Scaling](#)” on page 5889 for more information.

**VARSS**

lists, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC PLS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the `NOTSORTED` or `DESCENDING` option in the `BY` statement for the PLS procedure. The `NOTSORTED` option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the `BY` variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the `BY` variables by using the `DATASETS` procedure (in Base SAS software).

For more information about `BY`-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the `DATASETS` procedure, see the discussion in the *Base SAS Procedures Guide*.

## CLASS Statement

**CLASS** *variables* </ **TRUNCATE** > ;

The `CLASS` statement names the classification variables to be used in the model. Typical classification variables are `Treatment`, `Sex`, `Race`, `Group`, and `Replication`. If you use the `CLASS` statement, it must appear before the `MODEL` statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the `CLASS` variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the `TRUNCATE` option in the `CLASS` statement.

In any case, you can use formats to group values into levels. See the discussion of the `FORMAT` procedure in the *Base SAS Procedures Guide* and the discussions of the `FORMAT` statement and SAS formats in *SAS Language Reference: Dictionary*.

You can specify the following option in the `CLASS` statement after a slash (/):

### **TRUNCATE**

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of `CLASS` variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

## EFFECT Statement

**EFFECT** *name=effect-type* (*variables*</ *options*>) ;

The `EFFECT` statement enables you to construct special collections of columns for design matrices. These collections are referred to as *constructed effects* to distinguish them from the usual model effects formed from continuous or classification variables, as discussed in the section “[GLM Parameterization of Classification Variables and Effects](#)” on page 383 of Chapter 19, “[Shared Concepts and Topics](#).”

The following *effect-types* are available.

### **COLLECTION**

is a collection effect that defines one or more variables as a single effect with multiple degrees of freedom. The variables in a collection are considered as a unit for estimation and inference.

|                          |                                                                                                                                                                                                           |
|--------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>LAG</b>               | is a classification effect in which the level that is used for a given period corresponds to the level in the preceding period.                                                                           |
| <b>MULTIMEMBER   MM</b>  | is a multimember classification effect whose levels are determined by one or more variables that appear in a CLASS statement.                                                                             |
| <b>POLYNOMIAL   POLY</b> | is a multivariate polynomial effect in the specified numeric variables.                                                                                                                                   |
| <b>SPLINE</b>            | is a regression spline effect whose columns are univariate spline expansions of one or more variables. A spline expansion replaces the original variable with an expanded or larger set of new variables. |

Table 70.2 summarizes the *options* available in the EFFECT statement.

**Table 70.2** EFFECT Statement Options

| Option                             | Description                                                                                                                                          |
|------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>Collection Effects Options</b>  |                                                                                                                                                      |
| DETAILS                            | Displays the constituents of the collection effect                                                                                                   |
| <b>Lag Effects Options</b>         |                                                                                                                                                      |
| DESIGNROLE=                        | Names a variable that controls to which lag design an observation is assigned                                                                        |
| DETAILS                            | Displays the lag design of the lag effect                                                                                                            |
| NLAG=                              | Specifies the number of periods in the lag                                                                                                           |
| PERIOD=                            | Names the variable that defines the period                                                                                                           |
| WITHIN=                            | Names the variable or variables that define the group within which each period is defined                                                            |
| <b>Multimember Effects Options</b> |                                                                                                                                                      |
| NOEFFECT                           | Specifies that observations with all missing levels for the multimember variables should have zero values in the corresponding design matrix columns |
| WEIGHT=                            | Specifies the weight variable for the contributions of each of the classification effects                                                            |
| <b>Polynomial Effects Options</b>  |                                                                                                                                                      |
| DEGREE=                            | Specifies the degree of the polynomial                                                                                                               |
| MDEGREE=                           | Specifies the maximum degree of any variable in a term of the polynomial                                                                             |
| STANDARDIZE=                       | Specifies centering and scaling suboptions for the variables that define the polynomial                                                              |
| <b>Spline Effects Options</b>      |                                                                                                                                                      |
| BASIS=                             | Specifies the type of basis (B-spline basis or truncated power function basis) for the spline expansion                                              |
| DEGREE=                            | Specifies the degree of the spline transformation                                                                                                    |
| KNOTMETHOD=                        | Specifies how to construct the knots for spline effects                                                                                              |

For further details about the syntax of these *effect-types* and how columns of constructed effects are computed, see the section “[EFFECT Statement](#)” on page 393 of Chapter 19, “[Shared Concepts and Topics](#).”

## ID Statement

**ID** *variables* ;

The ID statement names variables whose values are used to label observations in plots. If you do not specify an ID statement, then each observations is labeled in plots by its corresponding observation number.

## MODEL Statement

**MODEL** *response-variables = predictor-effects < / options >* ;

The MODEL statement names the responses and the predictors, which determine the **Y** and **X** matrices of the model, respectively. Usually you simply list the names of the predictor variables as the model effects, but you can also use the effects notation of PROC GLM to specify polynomial effects and interactions; see the section “[Specification of Effects](#)” on page 3324 in Chapter 42, “[The GLM Procedure](#)” for further details. The MODEL statement is required. You can specify only one MODEL statement (in contrast to the REG procedure, for example, which allows several MODEL statements in the same PROC REG run).

You can specify the following options in the MODEL statement after a slash (/).

### INTERCEPT

By default, the responses and predictors are centered; thus, no intercept is required in the model. You can specify the INTERCEPT option to override the default.

### SOLUTION

lists the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

## OUTPUT Statement

**OUTPUT** **OUT=***SAS-data-set keyword=names < . . . keyword=names >* ;

You use the OUTPUT statement to specify a data set to receive quantities that can be computed for every input observation, such as extracted factors and predicted values. The following *keywords* are available:

|           |                                                                           |
|-----------|---------------------------------------------------------------------------|
| PREDICTED | predicted values for responses                                            |
| YRESIDUAL | residuals for responses                                                   |
| XRESIDUAL | residuals for predictors                                                  |
| XSCORE    | extracted factors (X-scores, latent vectors, latent variables, <i>T</i> ) |
| YSCORE    | extracted responses (Y-scores, <i>U</i> )                                 |
| STDY      | standardized (centered and scaled) responses                              |

|         |                                                         |
|---------|---------------------------------------------------------|
| STDY    | standardized (centered and scaled) predictors           |
| H       | approximate leverage                                    |
| PRESS   | approximate predicted residuals                         |
| TSQUARE | scaled sum of squares of score values                   |
| STDXSSE | sum of squares of residuals for standardized predictors |
| STDYSSE | sum of squares of residuals for standardized responses  |

Suppose that there are  $N_x$  predictors and  $N_y$  responses and that the model has  $N_f$  selected factors.

- The keywords XRESIDUAL and STDY define an output variable for each predictor, so  $N_x$  names are required after each one.
- The keywords PREDICTED, YRESIDUAL, STDY, and PRESS define an output variable for each response, so  $N_y$  names are required after each of these keywords.
- The keywords XSCORE and YSCORE specify an output variable for each selected model factor. For these keywords, you provide only one base name, and the variables corresponding to each successive factor are named by appending the factor number to the base name. For example, if  $N_f = 3$ , then a specification of XSCORE=T would produce the variables T1, T2, and T3.
- Finally, the keywords H, TSQUARE, STDXSSE, and STDYSSE each specify a single output variable, so only one name is required after each of these keywords.

---

## Details: PLS Procedure

---

### Regression Methods

All of the predictive methods implemented in PROC PLS work essentially by finding linear combinations of the predictors (factors) to use to predict the responses linearly. The methods differ only in how the factors are derived, as explained in the following sections.

### Partial Least Squares

Partial least squares (PLS) works by extracting one factor at a time. Let  $\mathbf{X} = \mathbf{X}_0$  be the centered and scaled matrix of predictors and let  $\mathbf{Y} = \mathbf{Y}_0$  be the centered and scaled matrix of response values. The PLS method starts with a linear combination  $\mathbf{t} = \mathbf{X}_0\mathbf{w}$  of the predictors, where  $\mathbf{t}$  is called a *score* vector and  $\mathbf{w}$  is its associated *weight* vector. The PLS method predicts both  $\mathbf{X}_0$  and  $\mathbf{Y}_0$  by regression on  $\mathbf{t}$ :

$$\begin{aligned}\hat{\mathbf{X}}_0 &= \mathbf{t}\mathbf{p}', \quad \text{where } \mathbf{p}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{X}_0 \\ \hat{\mathbf{Y}}_0 &= \mathbf{t}\mathbf{c}', \quad \text{where } \mathbf{c}' = (\mathbf{t}'\mathbf{t})^{-1}\mathbf{t}'\mathbf{Y}_0\end{aligned}$$

The vectors  $\mathbf{p}$  and  $\mathbf{c}$  are called the *X-* and *Y-loadings*, respectively.

The specific linear combination  $\mathbf{t} = \mathbf{X}_0\mathbf{w}$  is the one that has maximum covariance  $\mathbf{t}'\mathbf{u}$  with some response linear combination  $\mathbf{u} = \mathbf{Y}_0\mathbf{q}$ . Another characterization is that the X- and Y-weights  $\mathbf{w}$  and  $\mathbf{q}$  are proportional to the first left and right singular vectors of the covariance matrix  $\mathbf{X}'_0\mathbf{Y}_0$  or, equivalently, the first eigenvectors of  $\mathbf{X}'_0\mathbf{Y}_0\mathbf{Y}'_0\mathbf{X}_0$  and  $\mathbf{Y}'_0\mathbf{X}_0\mathbf{X}'_0\mathbf{Y}_0$ , respectively.

This accounts for how the first PLS factor is extracted. The second factor is extracted in the same way by replacing  $\mathbf{X}_0$  and  $\mathbf{Y}_0$  with the X- and Y-residuals from the first factor:

$$\begin{aligned}\mathbf{X}_1 &= \mathbf{X}_0 - \hat{\mathbf{X}}_0 \\ \mathbf{Y}_1 &= \mathbf{Y}_0 - \hat{\mathbf{Y}}_0\end{aligned}$$

These residuals are also called the *deflated* X and Y blocks. The process of extracting a score vector and deflating the data matrices is repeated for as many extracted factors as are wanted.

## SIMPLS

Note that each extracted PLS factor is defined in terms of different X-variables  $\mathbf{X}_i$ . This leads to difficulties in comparing different scores, weights, and so forth. The SIMPLS method of de Jong (1993) overcomes these difficulties by computing each score  $t_i = \mathbf{X}\mathbf{r}_i$  in terms of the original (centered and scaled) predictors  $\mathbf{X}$ . The SIMPLS X-weight vectors  $\mathbf{r}_i$  are similar to the eigenvectors of  $\mathbf{S}\mathbf{S}' = \mathbf{X}'\mathbf{Y}\mathbf{Y}'\mathbf{X}$ , but they satisfy a different orthogonality condition. The  $\mathbf{r}_1$  vector is just the first eigenvector  $\mathbf{e}_1$  (so that the first SIMPLS score is the same as the first PLS score), but whereas the second eigenvector maximizes

$$\mathbf{e}'_1\mathbf{S}\mathbf{S}'\mathbf{e}_2 \text{ subject to } \mathbf{e}'_1\mathbf{e}_2 = 0$$

the second SIMPLS weight  $\mathbf{r}_2$  maximizes

$$\mathbf{r}'_1\mathbf{S}\mathbf{S}'\mathbf{r}_2 \text{ subject to } \mathbf{r}'_1\mathbf{X}'\mathbf{X}\mathbf{r}_2 = \mathbf{t}'_1\mathbf{t}_2 = 0$$

The SIMPLS scores are identical to the PLS scores for one response but slightly different for more than one response; see de Jong (1993) for details. The X- and Y-loadings are defined as in PLS, but since the scores are all defined in terms of  $\mathbf{X}$ , it is easy to compute the overall model coefficients  $\mathbf{B}$ :

$$\begin{aligned}\hat{\mathbf{Y}} &= \sum_i \mathbf{t}_i\mathbf{c}'_i \\ &= \sum_i \mathbf{X}\mathbf{r}_i\mathbf{c}'_i \\ &= \mathbf{X}\mathbf{B}, \text{ where } \mathbf{B} = \mathbf{R}\mathbf{C}'\end{aligned}$$

## Principal Components Regression

Like the SIMPLS method, principal components regression (PCR) defines all the scores in terms of the original (centered and scaled) predictors  $\mathbf{X}$ . However, unlike both the PLS and SIMPLS methods, the PCR method chooses the X-weights/X-scores without regard to the response data. The X-scores are chosen to explain as much variation in  $\mathbf{X}$  as possible; equivalently, the X-weights for the PCR method are the eigenvectors of the predictor covariance matrix  $\mathbf{X}'\mathbf{X}$ . Again, the X- and Y-loadings are defined as in PLS; but, as in SIMPLS, it is easy to compute overall model coefficients for the original (centered and scaled) responses  $\mathbf{Y}$  in terms of the original predictors  $\mathbf{X}$ .

## Reduced Rank Regression

As discussed in the preceding sections, partial least squares depends on selecting factors  $\mathbf{t} = \mathbf{X}\mathbf{w}$  of the predictors and  $\mathbf{u} = \mathbf{Y}\mathbf{q}$  of the responses that have maximum covariance, whereas principal components regression effectively ignores  $\mathbf{u}$  and selects  $\mathbf{t}$  to have maximum variance, subject to orthogonality constraints. In contrast, reduced rank regression selects  $\mathbf{u}$  to account for as much variation in the *predicted* responses as possible, effectively ignoring the predictors for the purposes of factor extraction. In reduced rank regression, the Y-weights  $\mathbf{q}_j$  are the eigenvectors of the covariance matrix  $\hat{\mathbf{Y}}'_{LS}\hat{\mathbf{Y}}_{LS}$  of the responses predicted by ordinary least squares regression; the X-scores are the projections of the Y-scores  $\mathbf{Y}\mathbf{q}_j$  onto the X space.

## Relationships between Methods

When you develop a predictive model, it is important to consider not only the explanatory power of the model for current responses, but also how well sampled the predictive functions are, since this affects how well the model can extrapolate to future observations. All of the techniques implemented in the PLS procedure work by extracting successive factors, or linear combinations of the predictors, that optimally address one or both of these two goals—explaining response variation and explaining predictor variation. In particular, principal components regression selects factors that explain as much predictor variation as possible, reduced rank regression selects factors that explain as much response variation as possible, and partial least squares balances the two objectives, seeking for factors that explain both response and predictor variation.

To see the relationships between these methods, consider how each one extracts a single factor from the following artificial data set consisting of two predictors and one response:

```
data data;
 input x1 x2 y;
 datalines;
 3.37651 2.30716 0.75615

**Figure 70.11** Variation Explained by First Partial Least Squares Regression Factor

| The PLS Procedure                                                   |               |         |                     |         |
|---------------------------------------------------------------------|---------------|---------|---------------------|---------|
| Percent Variation Accounted for<br>by Partial Least Squares Factors |               |         |                     |         |
| Number of<br>Extracted<br>Factors                                   | Model Effects |         | Dependent Variables |         |
|                                                                     | Current       | Total   | Current             | Total   |
| 1                                                                   | 88.5357       | 88.5357 | 26.5304             | 26.5304 |

Notice that, while the first reduced rank regression factor explains *all* of the response variation, it accounts for only about 15% of the predictor variation. In contrast, the first principal components regression factor accounts for most of the predictor variation (93%) but only 9% of the response variation. The first partial least squares factor accounts for only slightly less predictor variation than principal components but about three times as much response variation.

Figure 70.12 illustrates how partial least squares balances the goals of explaining response and predictor variation in this case.

**Figure 70.12** Depiction of First Factors for Three Different Regression Methods

The ellipse shows the general shape of the 11 observations in the predictor space, with the contours of increasing  $y$  overlaid. Also shown are the directions of the first factor for each of the three methods. Notice that, while the predictors vary most in the  $x_1 = x_2$  direction, the response changes most in the orthogonal  $x_1 = -x_2$  direction. This explains why the first principal component accounts for little variation in the response and why the first reduced rank regression factor accounts for little variation in the predictors. The direction of the first partial least squares factor represents a compromise between the other two directions.

---

## Cross Validation

None of the regression methods implemented in the PLS procedure fit the observed data any better than ordinary least squares (OLS) regression; in fact, all of the methods approach OLS as more factors are extracted. The crucial point is that, when there are many predictors, OLS can *overfit* the observed data; biased regression methods with fewer extracted factors can provide better predictability of *future* observations. However, as the preceding observations imply, the quality of the observed data fit cannot be used to choose the number of factors to extract; the number of extracted factors must be chosen on the basis of how well the model fits observations not involved in the modeling procedure itself.

One method of choosing the number of extracted factors is to fit the model to only part of the available data (the *training set*) and to measure how well models with different numbers of extracted factors fit the other part of the data (the *test set*). This is called *test set validation*. However, it is rare that you have enough data to make both parts large enough for pure test set validation to be useful. Alternatively, you can make several different divisions of the observed data into training set and test set. This is called *cross validation*, and there are several different types. In *one-at-a-time* cross validation, the first observation is held out as a single-element test set, with all other observations as the training set; next, the second observation is held out, then the third, and so on. Another method is to hold out successive blocks of observations as test sets—for example, observations 1 through 7, then observations 8 through 14, and so on; this is known as *blocked* validation. A similar method is *split-sample* cross validation, in which successive groups of widely separated observations are held out as the test set—for example, observations {1, 11, 21, ...}, then observations {2, 12, 22, ...}, and so on. Finally, test sets can be selected from the observed data randomly; this is known as *random sample* cross validation.

Which validation you should use depends on your data. Test set validation is preferred when you have enough data to make a division into a sizable training set and test set that represent the predictive population well. You can specify that the number of extracted factors be selected by test set validation by using the `CV=TESTSET(data set)` option, where *data set* is the name of the data set containing the test set. If you do not have enough data for test set validation, you can use one of the cross validation techniques. The most common technique is one-at-a-time validation (which you can specify with the `CV=ONE` option or just the `CV` option), unless the observed data are serially correlated, in which case either blocked or split-sample validation might be more appropriate (`CV=BLOCK` or `CV=SPLIT`); you can specify the number of test sets in blocked or split-sample validation with a number in parentheses after the `CV=` option. Note that `CV=ONE` is the most computationally intensive of the cross validation methods, since it requires a recomputation of the PLS model for every input observation. Also, note that using random subset selection with `CV=RANDOM` might lead two different researchers to produce different PLS models on the same data (unless the same seed is used).

Whichever validation method you use, the number of factors chosen is usually the one that minimizes the predicted residual sum of squares (PRESS); this is the default choice if you specify any of the CV methods with PROC PLS. However, often models with fewer factors have PRESS statistics that are only marginally larger than the absolute minimum. To address this, van der Voet (1994) has proposed a statistical test for comparing the predicted residuals from different models; when you apply van der Voet's test, the number of factors chosen is the fewest with residuals that are insignificantly larger than the residuals of the model with minimum PRESS.

To see how van der Voet's test works, let  $R_{i,jk}$  be the  $j$ th predicted residual for response  $k$  for the model with  $i$  extracted factors; the PRESS statistic is  $\sum_{jk} R_{i,jk}^2$ . Also, let  $i_{\min}$  be the number of factors for which PRESS is minimized. The critical value for van der Voet's test is based on the differences between squared predicted residuals

$$D_{i,jk} = R_{i,jk}^2 - R_{i_{\min},jk}^2$$

One alternative for the critical value is  $C_i = \sum_{jk} D_{i,jk}$ , which is just the difference between the PRESS statistics for  $i$  and  $i_{\min}$  factors; alternatively, van der Voet suggests Hotelling's  $T^2$  statistic  $C_i = \mathbf{d}'_i \mathbf{S}_i^{-1} \mathbf{d}_i$ , where  $\mathbf{d}_i$  is the sum of the vectors  $\mathbf{d}_{i,j} = \{D_{i,j1}, \dots, D_{i,jN_y}\}'$  and  $\mathbf{S}_i$  is the sum of squares and crossproducts matrix

$$\mathbf{S}_i = \sum_j \mathbf{d}_{i,j} \mathbf{d}'_{i,j}$$

Virtually, the significance level for van der Voet's test is obtained by comparing  $C_i$  with the distribution of values that result from randomly exchanging  $R_{i,jk}^2$  and  $R_{i_{\min},jk}^2$ . In practice, a Monte Carlo sample of such values is simulated and the significance level is approximated as the proportion of simulated critical values that are greater than  $C_i$ . If you apply van der Voet's test by specifying the **CVTEST** option, then, by default, the number of extracted factors chosen is the least number with an approximate significance level that is greater than 0.10.

## Centering and Scaling

By default, the predictors and the responses are centered and scaled to have mean 0 and standard deviation 1. Centering the predictors and the responses ensures that the criterion for choosing successive factors is based on how much *variation* they explain, in either the predictors or the responses or both. (See the section “Regression Methods” on page 5883 for more details on how different methods explain variation.) Without centering, both the mean variable value and the variation around that mean are involved in selecting factors. Scaling serves to place all predictors and responses on an equal footing relative to their variation in the data. For example, if Time and Temp are two of the predictors, then scaling says that a change of  $\text{std}(\text{Time})$  in Time is roughly equivalent to a change of  $\text{std}(\text{Temp})$  in Temp.

Usually, both the predictors and responses should be centered and scaled. However, if their values already represent variation around a nominal or target value, then you can use the **NOCENTER** option in the **PROC PLS** statement to suppress centering. Likewise, if the predictors or responses are already all on comparable scales, then you can use the **NOSCALE** option to suppress scaling.

Note that, if the predictors involve crossproduct terms, then, by default, the variables are *not* standardized before standardizing the crossproduct. That is, if the  $i$ th values of two predictors are denoted  $x_i^1$  and  $x_i^2$ , then the default standardized  $i$ th value of the crossproduct is

$$\frac{x_i^1 x_i^2 - \text{mean}_j(x_j^1 x_j^2)}{\text{std}_j(x_j^1 x_j^2)}$$

If you want the crossproduct to be based instead on standardized variables

$$\frac{x_i^1 - m^1}{s^1} \times \frac{x_i^2 - m^2}{s^2}$$

where  $m^k = \text{mean}_j(x_j^k)$  and  $s^k = \text{std}_j(x_j^k)$  for  $k = 1, 2$ , then you should use the **VARSCALE** option in the **PROC PLS** statement. Standardizing the variables separately is usually a good idea, but unless the model also contains all crossproducts nested within each term, the resulting model might not be equivalent to a simple linear model in the same terms. To see this, note that a model involving the crossproduct of two standardized variables

$$\frac{x_i^1 - m^1}{s^1} \times \frac{x_i^2 - m^2}{s^2} = x_i^1 x_i^2 \frac{1}{s^1 s^2} - x_i^1 \frac{m^2}{s^1 s^2} - x_i^2 \frac{m^1}{s^1 s^2} + \frac{m^1 m^2}{s^1 s^2}$$

involves both the crossproduct term and the linear terms for the unstandardized variables.

When cross validation is performed for the number of effects, there is some disagreement among practitioners as to whether each cross validation training set should be retransformed. By default, **PROC PLS** does so, but you can suppress this behavior by specifying the **NOCVSTDIZE** option in the **PROC PLS** statement.

---

## Missing Values

By default, PROC PLS handles missing values very simply. Observations with any missing independent variables (including all classification variables) are excluded from the analysis, and no predictions are computed for such observations. Observations with no missing independent variables but any missing dependent variables are also excluded from the analysis, but predictions are computed.

However, the **MISSING=** option in the **PROC PLS** statement provides more sophisticated ways of modeling in the presence of missing values. If you specify **MISSING=AVG** or **MISSING=EM**, then all observations in the input data set contribute to both the analysis and the **OUTPUT OUT=** data set. With **MISSING=AVG**, the fit is computed by filling in missing values with the average of the nonmissing values for the corresponding variable. With **MISSING=EM**, the procedure first computes the model with **MISSING=AVG**, then fills in missing values with their predicted values based on that model and computes the model again. Alternatively, you can specify **MISSING=EM(MAXITER=*n*)** with a large value of *n* in order to perform this imputation/fit loop until convergence.

---

## Displayed Output

By default, PROC PLS displays just the amount of predictor and response variation accounted for by each factor.

If you perform a cross validation for the number of factors by specifying the **CV** option in the **PROC PLS** statement, then the procedure displays a summary of the cross validation for each number of factors, along with information about the optimal number of factors.

If you specify the **DETAILS** option in the **PROC PLS** statement, then details of the fitted model are displayed for each successive factor. These details for each number of factors include the following:

- the predictor loadings
- the predictor weights
- the response weights
- the coded regression coefficients (for **METHOD=SIMPLS**, **PCR**, or **RRR**)

If you specify the **CENSCALE** option in the **PROC PLS** statement, then centering and scaling information for each response and predictor is displayed.

If you specify the **VARSS** option in the **PROC PLS** statement, the procedure displays, in addition to the average response and predictor sum of squares accounted for by each successive factor, the amount of variation accounted for in each response and predictor.

If you specify the **SOLUTION** option in the **MODEL** statement, then PROC PLS displays the coefficients of the final predictive model for the responses. The coefficients for predicting the centered and scaled responses based on the centered and scaled predictors are displayed, as well as the coefficients for predicting the raw responses based on the raw predictors.

## ODS Table Names

PROC PLS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 70.3. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 70.3** ODS Tables Produced by PROC PLS

| ODS Table Name     | Description                                               | Statement | Option                |
|--------------------|-----------------------------------------------------------|-----------|-----------------------|
| CVResults          | Results of cross validation                               | PROC      | CV                    |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

When ODS Graphics is enabled, by default the PLS procedure produces a plot of the variation accounted for by each extracted factor, as well as a *correlation loading plot* for the first two extracted factors (if the final model has at least two factors). The plot of the variation accounted for can take several forms:

- If the PLS analysis does not include cross validation, then the plot shows the total R square for both model effects and the dependent variables against the number of factors.
- If you specify the **CV=** option to select the number of factors in the final model by cross validation, then the plot shows the R-square analysis discussed previously as well as the root mean PRESS from the cross validation analysis, with the selected number of factors identified by a vertical line.

The correlation loading plot for the first two factors summarizes many aspects of the two most significant dimensions of the model. It consists of overlaid scatter plots of the scores of the first two factors, the loadings of the model effects, and the loadings of the dependent variables. The loadings are scaled so that the amount of variation in the variables that is explained by the model is proportional to the distance from the origin; circles indicating various levels of explained variation are also overlaid on the correlation loading plot. Also, the correlation between the model approximations for any two variables is proportional to the length of the projection of the point corresponding to one variable on a line through the origin passing through the point corresponding to the other variable; the sign of the correlation corresponds to which side of the origin the projected point falls on.

The R square and the first two correlation loadings are plotted by default when ODS Graphics is enabled, but you can produce many other plots for the PROC PLS analysis.

## ODS Graph Names

PROC PLS assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. The names are listed in [Table 70.4](#).

**Table 70.4** Graphs Produced by PROC PLS

| ODS Graph Name         | Plot Description                                                 | Option                         |
|------------------------|------------------------------------------------------------------|--------------------------------|
| CorrLoadPlot           | Correlation loading plot (default)                               | PLOT=CORRLOAD( <i>option</i> ) |
| CVPlot                 | Cross validation and R-square analysis (default, as appropriate) | CV=                            |
| DModXPlot              | Distance of each observation to the X model                      | PLOT=DMODX                     |
| DModXYPlot             | Distance of each observation to the X and Y models               | PLOT=DMODXY                    |
| DModYPlot              | Distance of each observation to the Y model                      | PLOT=DMODY                     |
| DiagnosticsPanel       | Panel of diagnostic plots for the fit                            | PLOT=DIAGNOSTICS               |
| AbsResidualByPredicted | Absolute residual by predicted values                            | PLOT=DIAGNOSTICS(UNPACK)       |
| ObservedByPredicted    | Observed by predicted                                            | PLOT=DIAGNOSTICS(UNPACK)       |
| QQPlot                 | Residual Q-Q plot                                                | PLOT=DIAGNOSTICS(UNPACK)       |
| ResidualByPredicted    | Residual by predicted values                                     | PLOT=DIAGNOSTICS(UNPACK)       |

## Examples: PLS Procedure

---

### Example 70.1: Examining Model Details

This example, from Umetrics (1995), demonstrates different ways to examine a PLS model. The data come from the field of drug discovery. New drugs are developed from chemicals that are biologically active. Testing a compound for biological activity is an expensive procedure, so it is useful to be able to predict biological activity from cheaper chemical measurements. In fact, computational chemistry makes it possible to calculate certain chemical measurements without even making the compound. These measurements include size, lipophilicity, and polarity at various sites on the molecule. The following statements create a data set named `pentaTrain`, which contains these data.

```

data pentaTrain;
 input obsnam $ S1 L1 P1 S2 L2 P2
 S3 L3 P3 S4 L4 P4

```

You would like to study the relationship between these measurements and the activity of the compound, represented by the logarithm of the relative Bradykinin activating activity (log\_RAI). Notice that these data consist of many predictors relative to the number of observations. Partial least squares is especially appropriate in this situation as a useful tool for finding a few underlying predictive factors that account for most of the variation in the response. Typically, the model is fit for part of the data (the “training” or “work” set), and the quality of the fit is judged by how well it predicts the other part of the data (the “test” or “prediction” set). For this example, the first 15 observations serve as the training set and the rest constitute the test set (see Ufkes et al. 1978, 1982).

When you fit a PLS model, you hope to find a few PLS factors that explain most of the variation in both predictors and responses. Factors that explain response variation provide good predictive models for new responses, and factors that explain predictor variation are well represented by the observed values of the predictors. The following statements fit a PLS model with two factors and save predicted values, residuals, and other information for each data point in a data set named outpls.

```
proc pls data=pentaTrain;
 model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

The PLS procedure displays a table, shown in [Output 70.1.1](#), showing how much predictor and response variation is explained by each PLS factor.

**Output 70.1.1** Amount of Training Set Variation Explained

| 13                                                                  | 0.0000        | 100.0000 | 0.0000              | 99.1179 |  |
| 14                                                                  | 0.0000        | 100.0000 | 0.0000              | 99.1179 |  |
| 15                                                                  | 0.0000        | 100.0000 | 0.0000              | 99.1179 |  |

From [Output 70.1.1](#), note that 97% of the response variation is already explained by just two factors, but only 29% of the predictor variation is explained.

The graphics in PROC PLS, available when ODS Graphics is enabled, make it easier to see features of the PLS model.

If ODS Graphics is enabled, then in addition to the tables discussed previously, PROC PLS displays a graphical depiction of the R-square analysis as well as a correlation loadings plot summarizing the model based on the first two PLS factors. The following statements perform the previous analysis with ODS Graphics enabled, producing [Output 70.1.2](#) and [Output 70.1.3](#).

```
ods graphics on;

proc pls data=pentaTrain;
 model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

**Output 70.1.2** Plot of Proportion of Variation Accounted For

**Output 70.1.3** Correlation Loadings Plot

The plot in [Output 70.1.2](#) of the proportion of variation explained (or R square) makes it clear that there is a plateau in the response variation after two factors are included in the model. The correlation loading plot in [Output 70.1.3](#) summarizes many features of this two-factor model, including the following:

- The X-scores are plotted as numbers for each observation. You should look for patterns or clearly grouped observations. If you see a curved pattern, for example, you might want to add a quadratic term. Two or more groupings of observations indicate that it might be better to analyze the groups separately, perhaps by including classification effects in the model. This plot appears to show most of the observations close together, with a few being more spread out with larger positive X-scores for factor 2. There are no clear grouping patterns, but observation 13 stands out.
- The loadings show how much variation in each variable is accounted for by the first two factors, jointly by the distance of the corresponding point from the origin and individually by the distance for the projections of this point onto the horizontal and vertical axes. That the dependent variable is well explained by the model is reflected in the fact that the point for `log_RAI` is near the 100% circle.
- You can also use the projection interpretation to relate variables to each other. For example, projecting other variables' points onto the line that runs through the `log_RAI` point and the origin, you can see that the PLS approximation for the predictor `L3` is highly positively correlated with `log_RAI`, `S3` is

somewhat less correlated but in the negative direction, and several predictors including L1, L5, and S5 have very little correlation with log\_RAI.

Other graphics enable you to explore more of the features of the PLS model. For example, you can examine the X-scores versus the Y-scores to explore how partial least squares chooses successive factors. For a good PLS model, the first few factors show a high correlation between the X- and Y-scores. The correlation usually decreases from one factor to the next. When ODS Graphics is enabled, you can plot the X-scores versus the Y-scores by using the `PLOT=XYSCORES` option, as shown in the following statements.

```
proc pls data=pentaTrain nfac=4 plot=XYScores;
 model log_RAI = S1-S5 L1-L5 P1-P5;
run;
```

The plot of the X-scores versus the Y-scores for the first four factors is shown in [Output 70.1.4](#).

**Output 70.1.4** X-Scores versus Y-Scores

For this example, [Output 70.1.4](#) shows high correlation between X- and Y-scores for the first factor but somewhat lower correlation for the second factor and sharply diminishing correlation after that. This adds strength to the judgment that `NFAC=2` is the right number of factors for these data and this model. Note that observation 13 is again extreme in the first two plots. This run might be overly influential for the PLS analysis; thus, you should check to make sure it is reliable.

As explained earlier, you can draw some inferences about the relationship between individual predictors and the dependent variable from the correlation loading plot. However, the regression coefficient profile and the variable importance plot give a more direct indication of which predictors are most useful for predicting the dependent variable. The regression coefficients represent the importance each predictor has in the prediction of just the response. The variable importance plot, on the other hand, represents the contribution of each predictor in fitting the PLS model for both predictors and response. It is based on the *Variable Importance for Projection* (VIP) statistic of Wold (1994), which summarizes the contribution a variable makes to the model. If a predictor has a relatively small coefficient (in absolute value) *and* a small value of VIP, then it is a prime candidate for deletion. Wold in Umetrics (1995) considers a value less than 0.8 to be “small” for the VIP. The following statements fit a two-factor PLS model and display these two additional plots.

```
proc pls data=pentaTrain nfac=2 plot=(ParmProfiles VIP);
 model log_RAI = S1-S5 L1-L5 P1-P5;
run;

ods graphics off;
```

The additional graphics are shown in [Output 70.1.5](#) and [Output 70.1.6](#).

**Output 70.1.5** Variable Importance Plots

**Output 70.1.6** Regression Parameter Profile

In these two plots, the variables L1, L2, P2, S5, L5, and P5 have small absolute coefficients and small VIP. Looking back at the correlation loadings plot in [Output 70.1.2](#), you can see that these variables tend to be the ones near zero for both PLS factors. You should consider dropping these variables from the model.

## Example 70.2: Examining Outliers

This example is a continuation of [Example 70.1](#).

Standard diagnostics for statistical models focus on the response, allowing you to look for patterns that indicate the model is inadequate or for outliers that do not seem to follow the trend of the rest of the data. However, partial least squares effectively models the predictors as well as the responses, so you should consider the pattern of the fit for both. The DModX and DModY statistics give the distance from each point to the PLS model with respect to the predictors and the responses, respectively, and ODS Graphics enables you to plot these values. No point should be dramatically farther from the model than the rest. If there is a group of points that are all farther from the model than the rest, they might have something in common, in which case they should be analyzed separately.

The following statements fit a reduced model to the data discussed in [Example 70.1](#) and plot a panel of standard diagnostics as well as the distances of the observations to the model.

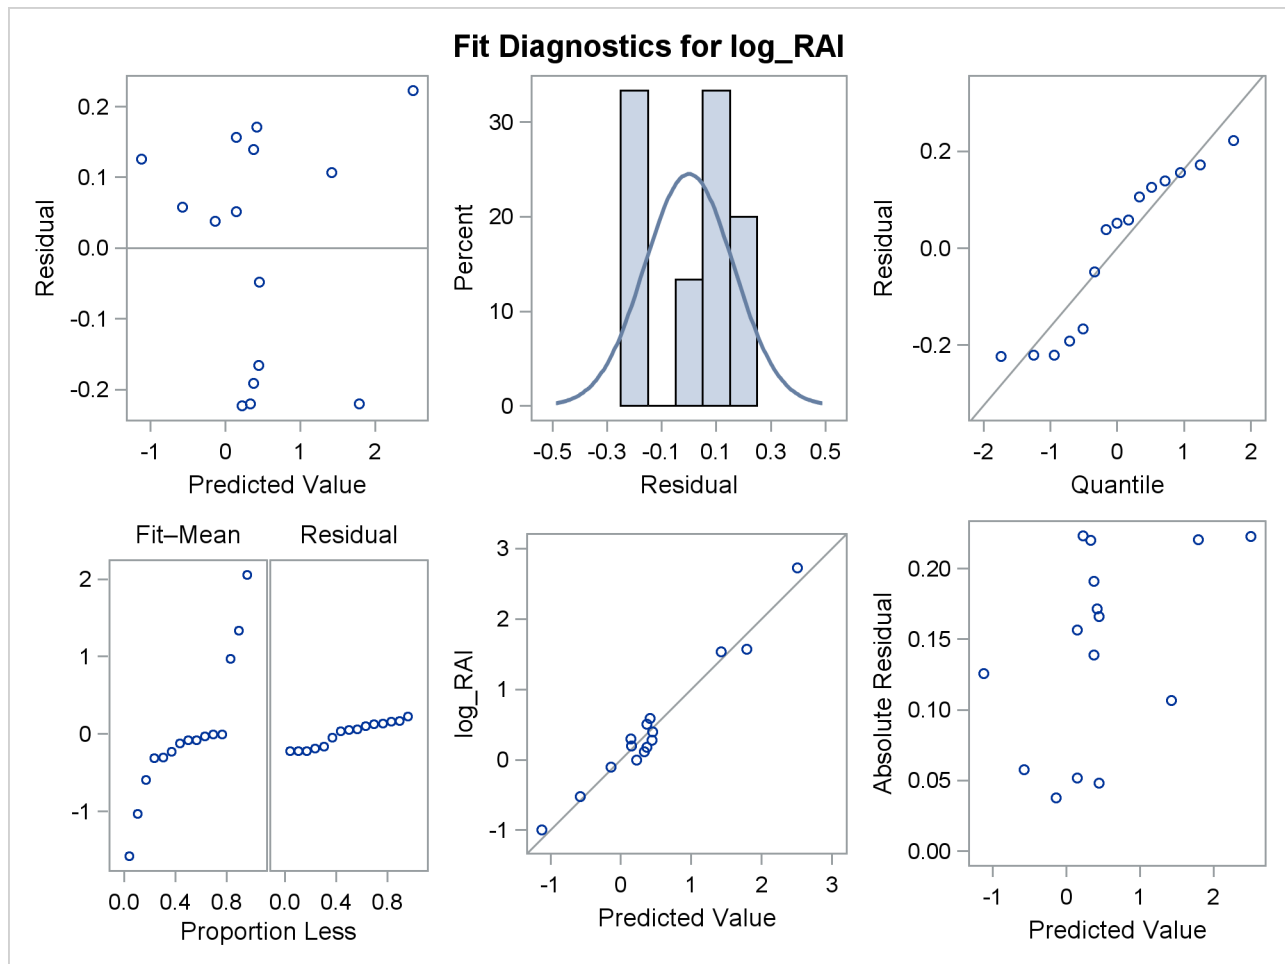

```
ods graphics on;

proc pls data=pentaTrain nfac=2 plot=(diagnostics dmod);
 model log_RAI = S1 P1
 S2
 S3 L3 P3
 S4 L4 ;
run;

ods graphics off;
```

The plots are shown in [Output 70.2.1](#) and [Output 70.2.2](#).

**Output 70.2.1** Model Fit Diagnostics

**Output 70.2.2** Predictor versus Response Distances to the Model

There appear to be no profound outliers in either the predictor space or the response space.

### Example 70.3: Choosing a PLS Model by Test Set Validation

This example demonstrates issues in spectrometric calibration. The data (Umetrics 1995) consist of spectrographic readings on 33 samples containing known concentrations of two amino acids, tyrosine and tryptophan. The spectra are measured at 30 frequencies across the overall range of frequencies. For example, Figure 70.3.1 shows the observed spectra for three samples, one with only tryptophan, one with only tyrosine, and one with a mixture of the two, all at a total concentration of  $10^{-6}$ .

**Output 70.3.1** Spectra for Three Samples of Tyrosine and Tryptophan

Of the 33 samples, 18 are used as a training set and 15 as a test set. The data originally appear in McAvoy et al. (1989).

These data were created in a lab, with the concentrations fixed in order to provide a wide range of applicability for the model. You want to use a linear function of the logarithms of the spectra to predict the logarithms of tyrosine and tryptophan concentration, as well as the logarithm of the total concentration. Actually, because of the possibility of zeros in both the responses and the predictors, slightly different transformations are used. The following statements create SAS data sets containing the training and test data, named `ftrain` and `ftest`, respectively.

```

data ftrain;
 input obsnam $ tot tyr f1-f30 @@;
 try = tot - tyr;
 if (tyr) then tyr_log = log10(tyr); else tyr_log = -8;

The following statements fit a PLS model with 10 factors.

```

proc pls data=ftrain nfac=10;
 model tot_log tyr_log try_log = f1-f30;
run;

```

The table shown in [Output 70.3.2](#) indicates that only three or four factors are required to explain almost all of the variation in both the predictors and the responses.

**Output 70.3.2** Amount of Training Set Variation Explained

In order to choose the optimal number of PLS factors, you can explore how well models based on the training data with different numbers of factors fit the test data. To do so, use the `CV=TESTSET` option, with an argument pointing to the test data set `ftest`. The following statements also employ the ODS Graphics features in PROC PLS to display the cross validation results in a plot.

```

ods graphics on;

proc pls data=ftrain nfac=10 cv=testset(ftest)
 cvtest(stat=press seed=12345);

```

```

model tot_log tyr_log try_log = f1-f30;
run;

```

The tabular results of the test set validation are shown in [Output 70.3.3](#), and the graphical results are shown in [Output 70.3.4](#). They indicate that, although five PLS factors give the minimum predicted residual sum of squares, the residuals for four factors are insignificantly different from those for five. Thus, the smaller model is preferred.

**Output 70.3.4** Test Set Validation Plot

The factor loadings show how the PLS factors are constructed from the centered and scaled predictors. For spectral calibration, it is useful to plot the loadings against the frequency. In many cases, the physical meanings that can be attached to factor loadings help to validate the scientific interpretation of the PLS model. You can use ODS Graphics with PROC PLS to plot the loadings for the four PLS factors against frequency, as shown in the following statements.

```
proc pls data=ftrain nfac=4 plot=XLoadingProfiles;
 model tot_log tyr_log try_log = f1-f30;
run;

ods graphics off;
```

The resulting plot is shown in [Output 70.3.5](#).

**Output 70.3.5** Predictor Loadings across Frequencies

Notice that all four factors handle frequencies below and above about 7 or 8 differently. For example, the first factor is very nearly a simple contrast between the averages of the two sets of frequencies, and the second factor appears to be approximately a weighted sum of only the frequencies in the first set.

### Example 70.4: Partial Least Squares Spline Smoothing

The EFFECT statement makes it easy to construct a wide variety of linear models. In particular, you can use the spline effect to add smoothing terms to a model. A particular benefit of using spline effects in PROC PLS is that, when operating on spline basis functions, the partial least squares algorithm effectively chooses the amount of smoothing automatically, especially if you combine it with cross validation for the selecting the number of factors. This example employs the EFFECT statement to demonstrate partial least squares spline smoothing of agricultural data.

Weibe (1935) presents data from a study of uniformity of wheat yields over a certain rectangular plot of land. The following statements read these wheat yield measurements, indexed by row and column distances, into the SAS data set `Wheat`:

```

data Wheat;
 keep Row Column Yield;
 input Yield @@;
 iRow = int((_N-1)/12);
 iCol = mod(_N-1,12);
 Column = iCol*15 + 1; /* Column distance, in feet */
 Row = iRow* 1 + 1; /* Row distance, in feet */
 Row = 125 - Row + 1; /* Invert rows */
 datalines;
715 595 580 580 615 610 540 515 557 665 560 612
770 710 655 675 700 690 565 585 550 574 511 618

505 500 580 655 470 565 570 555 537 585 589 619
465 430 510 680 460 600 670 615 620 594 616 784
;

```

The following statements use the PLS procedure to smooth these wheat yields using two spline effects, one for rows and another for columns, in addition to their crossproduct. Each spline effect has, by default, seven basis columns; thus their crossproduct has  $49 = 7^2$  columns, for a total of 63 parameters in the full linear model. However, the predictive PLS model does not actually need to have 63 degrees of freedom. Rather, the degree of smoothing is controlled by the number of PLS factors, which in this case is chosen automatically by random subset validation with the CV=RANDOM option.

```

ods graphics on;

proc pls data=Wheat cv=random(seed=1) cvtest(seed=12345)
 plot(only)=contourfit(obs=gradient);
 effect splCol = spline(Column);
 effect splRow = spline(Row);
 model Yield = splCol|splRow;
run;

ods graphics off;

```

These statements produce the output shown in [Output 70.4.1](#) through [Output 70.4.4](#).

**Output 70.4.1** Default Spline Basis: Model and Data Information

| The PLS Procedure              |                                  |
|--------------------------------|----------------------------------|
| Data Set                       | WORK.WHEAT                       |
| Factor Extraction Method       | Partial Least Squares            |
| PLS Algorithm                  | NIPALS                           |
| Number of Response Variables   | 1                                |
| Number of Predictor Parameters | 63                               |
| Missing Value Handling         | Exclude                          |
| Maximum Number of Factors      | 15                               |
| Validation Method              | 10-fold Random Subset Validation |
| Random Subset Seed             | 1                                |
| Validation Testing Criterion   | Prob T**2 > 0.1                  |
| Number of Random Permutations  | 1000                             |
| Random Permutation Seed        | 12345                            |
|                                |                                  |
| Number of Observations Read    | 1500                             |
| Number of Observations Used    | 1500                             |

**Output 70.4.4** Default Spline Basis: Smoothed Yield

The cross validation results in [Output 70.4.2](#) point to a model with eight PLS factors; this is the smallest model whose predicted residual sum of squares (PRESS) is insignificantly different from the model with the absolute minimum PRESS. The variation summary in [Output 70.4.3](#) shows that this model accounts for about 60% of the variation in the Yield values. The OBS=GRADIENT suboption for the PLOT=CONTOURFIT option specifies that the observations in the resulting plot, [Output 70.4.4](#), be colored according to the same scheme as the surface of predicted yield. This coloration enables you to easily tell which observations are above the surface of predicted yield and which are below.

The surface of predicted yield is somewhat smoother than what Weibe (1935) settled on originally, with a predominance of simple, elliptically shaped contours. You can easily specify a potentially more granular model by increasing the number of knots in the spline bases. Even though the more granular model increases the number of predictor parameters, cross validation can still protect you from overfitting the data. The following statements are the same as those shown before, except that the spline effects now have twice as many basis functions:

```
ods graphics on;

proc pls data=Wheat cv=random(seed=1) cvtest(seed=12345)
 plot(only)=contourfit(obs=gradient);
 effect splCol = spline(Column / knotmethod=equal(14));
 effect splRow = spline(Row / knotmethod=equal(14));
 model Yield = splCol|splRow;
run;

ods graphics off;
```

The resulting output is shown in [Output 70.4.5](#) through [Output 70.4.8](#).

**Output 70.4.8** More Granular Spline Basis: Smoothed Yield

Output 70.4.5 shows that the model now has 360 parameters, many more than before. In Output 70.4.6 you can see that with more granular spline effects, fewer PLS factors are required—only two, in fact. However, Output 70.4.7 shows that this model now accounts for over 70% of the variation in the Yield values, and the contours of predicted values in Output 70.4.8 are less inclined to be simple elliptical shapes.

## Overview: POWER Procedure

Power and sample size analysis optimizes the resource usage and design of a study, improving chances of conclusive results with maximum efficiency. The POWER procedure performs prospective power and sample size analyses for a variety of goals, such as the following:

- determining the sample size required to get a significant result with adequate probability (power)
- characterizing the power of a study to detect a meaningful effect
- conducting what-if analyses to assess sensitivity of the power or required sample size to other factors

Here *prospective* indicates that the analysis pertains to planning for a future study. This is in contrast to *retrospective* power analysis for a past study, which is not supported by the procedure.

A variety of statistical analyses are covered:

- *t* tests, equivalence tests, and confidence intervals for means
- tests, equivalence tests, and confidence intervals for binomial proportions
- multiple regression
- tests of correlation and partial correlation
- one-way analysis of variance
- rank tests for comparing two survival curves
- logistic regression with binary response
- Wilcoxon-Mann-Whitney (rank-sum) test

For more complex linear models, see Chapter 44, “[The GLMPOWER Procedure](#).”

Input for PROC POWER includes the components considered in study planning:

- design
- statistical model and test
- significance level (alpha)
- surmised effects and variability
- power
- sample size

You designate one of these components by a missing value in the input, in order to identify it as the result parameter. The procedure calculates this result value over one or more scenarios of input values for all other components. Power and sample size are the most common result values, but for some analyses the result can be something else. For example, you can solve for the sample size of a single group for a two-sample *t* test.

In addition to tabular results, PROC POWER produces graphs. You can produce the most common types of plots easily with default settings and use a variety of options for more customized graphics. For example, you can control the choice of axis variables, axis ranges, number of plotted points, mapping of graphical features (such as color, line style, symbol and panel) to analysis parameters, and legend appearance.

If ODS Graphics is enabled, then PROC POWER uses ODS Graphics to create graphs; otherwise, traditional graphs are produced.

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For specific information about the statistical graphics and options available with the POWER procedure, see the `PLOT` statement and the section “[ODS Graphics](#)” on page 6081.

The POWER procedure is one of several tools available in SAS/STAT software for power and sample size analysis. PROC GLMPOWER supports more complex linear models. The Power and Sample Size application provides a user interface and implements many of the analyses supported in the procedures. See Chapter 44, “[The GLMPOWER Procedure](#),” and Chapter 72, “[The Power and Sample Size Application](#),” for details.

The following sections of this chapter describe how to use PROC POWER and discuss the underlying statistical methodology. The section “[Getting Started: POWER Procedure](#)” on page 5920 introduces PROC POWER with simple examples of power computation for a one-sample  $t$  test and sample size determination for a two-sample  $t$  test. The section “[Syntax: POWER Procedure](#)” on page 5927 describes the syntax of the procedure. The section “[Details: POWER Procedure](#)” on page 6018 summarizes the methods employed by PROC POWER and provides details on several special topics. The section “[Examples: POWER Procedure](#)” on page 6083 illustrates the use of the POWER procedure with several applications.

For an overview of methodology and SAS tools for power and sample size analysis, see Chapter 18, “[Introduction to Power and Sample Size Analysis](#).” For more discussion and examples, see O’Brien and Casteloe (2007); Casteloe (2000); Casteloe and O’Brien (2001); Muller and Benignus (1992); O’Brien and Muller (1993); Lenth (2001).

## Getting Started: POWER Procedure

### Computing Power for a One-Sample $t$ Test

Suppose you want to improve the accuracy of a machine used to print logos on sports jerseys. The logo placement has an inherently high variability, but the horizontal alignment of the machine can be adjusted. The operator agrees to pay for a costly adjustment if you can establish a nonzero mean horizontal displacement in either direction with high confidence. You have 150 jerseys at your disposal to measure, and you want to determine your chances of a significant result (power) by using a one-sample  $t$  test with a two-sided  $\alpha = 0.05$ .

You decide that 8 mm is the smallest displacement worth addressing. Hence, you will assume a true mean of 8 in the power computation. Experience indicates that the standard deviation is about 40.

Use the `ONESAMPLEMEANS` statement in the POWER procedure to compute the power. Indicate power as the result parameter by specifying the `POWER=` option with a missing value (.). Specify your conjectures for the mean and standard deviation by using the `MEAN=` and `STDDEV=` options and for the sample size by using the `NTOTAL=` option. The statements required to perform this analysis are as follows:

```

proc power;
 onesamplemeans
 mean = 8
 ntotal = 150
 stddev = 40
 power = .;
run;

```

Default values for the `TEST=`, `DIST=`, `ALPHA=`, `NULLMEAN=`, and `SIDES=` options specify a two-sided  $t$  test for a mean of 0, assuming a normal distribution with a significance level of  $\alpha = 0.05$ .

Figure 71.1 shows the output.

**Figure 71.1** Sample Size Analysis for One-Sample  $t$  Test

| The POWER Procedure        |        |
|----------------------------|--------|
| One-sample t Test for Mean |        |
| Fixed Scenario Elements    |        |
| Distribution               | Normal |
| Method                     | Exact  |
| Mean                       | 8      |
| Standard Deviation         | 40     |
| Total Sample Size          | 150    |
| Number of Sides            | 2      |
| Null Mean                  | 0      |
| Alpha                      | 0.05   |
| Computed Power             |        |
| Power                      | 0.682  |

The power is about 0.68. In other words, there is about a 2/3 chance that the  $t$  test will produce a significant result demonstrating the machine's average off-center displacement. This probability depends on the assumptions for the mean and standard deviation.

Now, suppose you want to account for some of your uncertainty in conjecturing the true mean and standard deviation by evaluating the power for four scenarios, using reasonable low and high values, 5 and 10 for the mean, and 30 and 50 for the standard deviation. Also, you might be able to measure more than 150 jerseys, and you would like to know under what circumstances you could get by with fewer. You want to plot power for sample sizes between 100 and 200 to visualize how sensitive the power is to changes in sample size for these four scenarios of means and standard deviations. The following statements perform this analysis:

```
ods listing style=htmlbluecml;
ods graphics on;

proc power;
 onesamplemeans
 mean = 5 10
 ntotal = 150
 stddev = 30 50
 power = .;
 plot x=n min=100 max=200;
run;

ods graphics off;
```

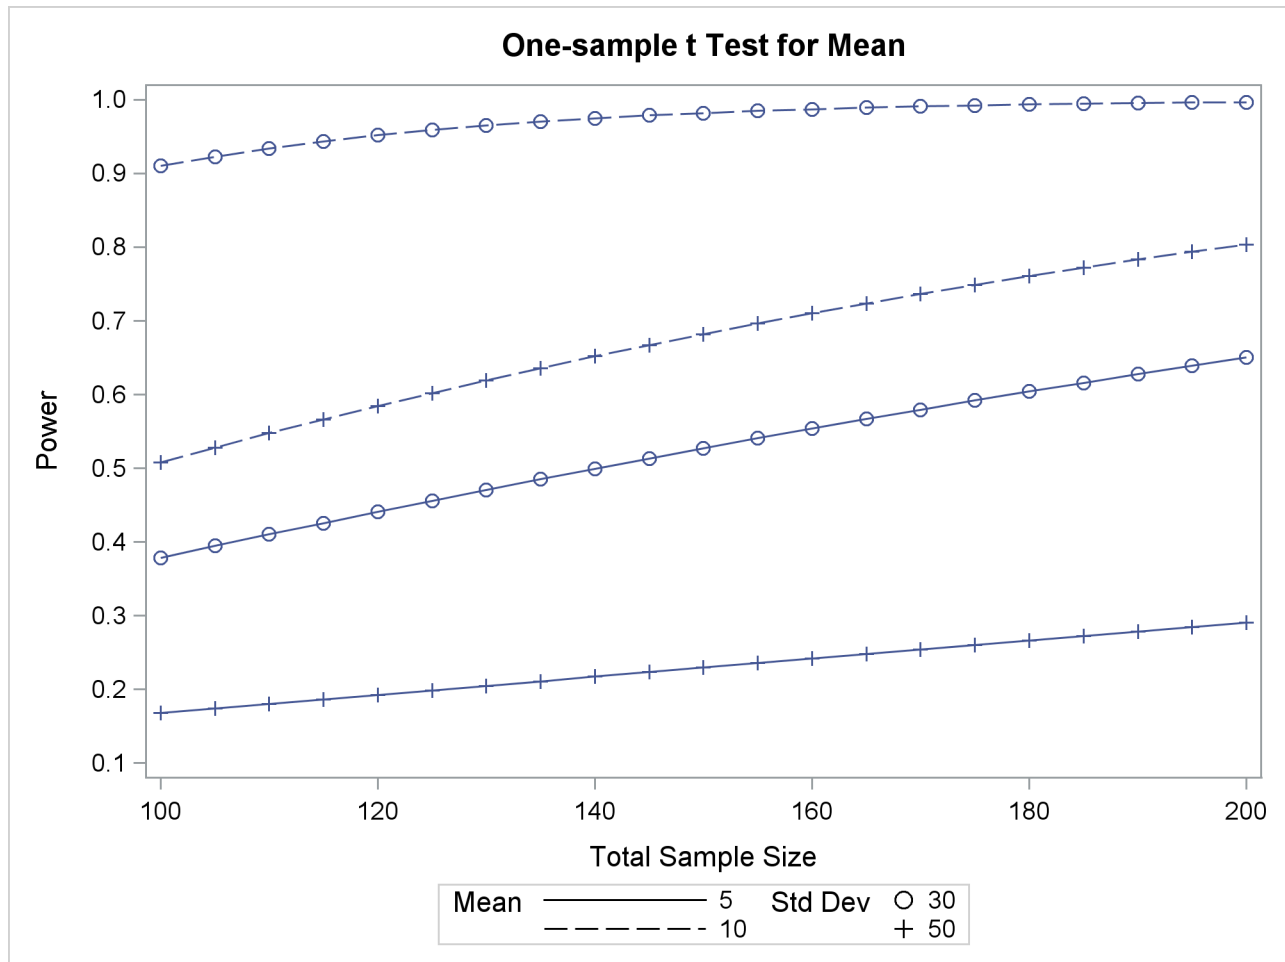

The new mean and standard deviation values are specified by using the **MEAN=** and **STDDEV=** options in the **ONESAMPLEMEANS** statement. The **PLOT** statement with **X=N** produces a plot with sample size on the X axis. (The result parameter, in this case the power, is always plotted on the other axis.) The **MIN=** and **MAX=** options in the **PLOT** statement determine the sample size range. The **ODS GRAPHICS ON** statement enables ODS Graphics. The **ODS LISTING STYLE=HTMLBLUECML** statement specifies the **HTMLBLUECML** style, which is suitable for use with **PROC POWER** because it allows both marker symbols and line styles to vary. See the section “**ODS Styles Suitable for Use with PROC POWER**” on page 6082 for more information.

Figure 71.2 shows the output, and Figure 71.3 shows the plot.

**Figure 71.2** Sample Size Analysis for One-Sample *t* Test with Input Ranges

| The POWER Procedure        |        |         |       |  |

**Figure 71.3** Plot of Power versus Sample Size for One-Sample  $t$  Test with Input Ranges

The power ranges from about 0.23 to 0.98 for a sample size of 150 depending on the mean and standard deviation. In Figure 71.3, the line style identifies the mean, and the plotting symbol identifies the standard deviation. The locations of plotting symbols indicate computed powers; the curves are linear interpolations of these points. The plot suggests sufficient power for a mean of 10 and standard deviation of 30 (for any of the sample sizes) but insufficient power for the other three scenarios.

### Determining Required Sample Size for a Two-Sample $t$ Test

In this example you want to compare two physical therapy treatments designed to increase muscle flexibility. You need to determine the number of patients required to achieve a power of at least 0.9 to detect a group mean difference in a two-sample  $t$  test. You will use  $\alpha = 0.05$  (two-tailed).

The mean flexibility with the standard treatment (as measured on a scale of 1 to 20) is well known to be about 13 and is thought to be between 14 and 15 with the new treatment. You conjecture three alternative scenarios for the means:

1.  $\mu_1 = 13, \mu_2 = 14$
2.  $\mu_1 = 13, \mu_2 = 14.5$
3.  $\mu_1 = 13, \mu_2 = 15$

You conjecture two scenarios for the common group standard deviation:

1.  $\sigma = 1.2$
2.  $\sigma = 1.7$

You also want to try three weighting schemes:

1. equal group sizes (balanced, or 1:1)
2. twice as many patients with the new treatment (1:2)
3. three times as many patients with the new treatment (1:3)

This makes  $3 \times 2 \times 3 = 18$  scenarios in all.

Use the **TWOSAMPLEMEANS** statement in the POWER procedure to determine the sample sizes required to give 90% power for each of these 18 scenarios. Indicate total sample size as the result parameter by specifying the **NTOTAL=** option with a missing value (.). Specify your conjectures for the means by using the **GROUPMEANS=** option. Using the “matched” notation (discussed in the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020), enclose the two group means for each scenario in parentheses. Use the **STDDEV=** option to specify scenarios for the common standard deviation. Specify the weighting schemes by using the **GROUPWEIGHTS=** option. You could again use the matched notation. But for illustrative purposes, specify the scenarios for each group weight separately by using the “crossed” notation, with scenarios for each group weight separated by a vertical bar (|). The statements that perform the analysis are as follows:

```
proc power;
 twosamplemeans
 groupmeans = (13 14) (13 14.5) (13 15)
 stddev = 1.2 1.7
 groupweights = 1 | 1 2 3
 power = 0.9
 ntotal = .;
run;
```

Default values for the **TEST=**, **DIST=**, **NULLDIFF=**, **ALPHA=**, and **SIDES=** options specify a two-sided  $t$  test of group mean difference equal to 0, assuming a normal distribution with a significance level of  $\alpha = 0.05$ . The results are shown in [Figure 71.4](#).

| 6                                            | 13     | 14.0  | 1.7     | 3       | 0.900        | 164     |
| 7                                            | 13     | 14.5  | 1.2     | 1       | 0.910        | 30      |
| 8                                            | 13     | 14.5  | 1.2     | 2       | 0.906        | 33      |
| 9                                            | 13     | 14.5  | 1.2     | 3       | 0.916        | 40      |
| 10                                           | 13     | 14.5  | 1.7     | 1       | 0.900        | 56      |
| 11                                           | 13     | 14.5  | 1.7     | 2       | 0.901        | 63      |
| 12                                           | 13     | 14.5  | 1.7     | 3       | 0.908        | 76      |
| 13                                           | 13     | 15.0  | 1.2     | 1       | 0.913        | 18      |
| 14                                           | 13     | 15.0  | 1.2     | 2       | 0.927        | 21      |
| 15                                           | 13     | 15.0  | 1.2     | 3       | 0.922        | 24      |
| 16                                           | 13     | 15.0  | 1.7     | 1       | 0.914        | 34      |
| 17                                           | 13     | 15.0  | 1.7     | 2       | 0.921        | 39      |
| 18                                           | 13     | 15.0  | 1.7     | 3       | 0.910        | 44      |

The interpretation is that in the best-case scenario (large mean difference of 2, small standard deviation of 1.2, and balanced design), a sample size of  $N = 18$  ( $n_1 = n_2 = 9$ ) patients is sufficient to achieve a power of at least 0.9. In the worst-case scenario (small mean difference of 1, large standard deviation of 1.7, and a 1:3 unbalanced design), a sample size of  $N = 164$  ( $n_1 = 41, n_2 = 123$ ) patients is necessary. The Nominal Power of 0.9 in the “Fixed Scenario Elements” table represents the input target power, and the Actual Power column in the “Computed N Total” table is the power at the sample size (N Total) adjusted to achieve the specified sample weighting exactly.

Note the following characteristics of the analysis, and ways you can modify them if you want:

- The total sample sizes are rounded up to multiples of the weight sums (2 for the 1:1 design, 3 for the 1:2 design, and 4 for the 1:3 design) to ensure that each group size is an integer. To request raw fractional sample size solutions, use the **NFRACTIONAL** option.
- Only the group weight that varies (the one for group 2) is displayed as an output column, while the weight for group 1 appears in the “Fixed Scenario Elements” table. To display the group weights together in output columns, use the matched version of the value list rather than the crossed version.
- If you can specify only differences between group means (instead of their individual values), or if you want to display the mean differences instead of the individual means, use the **MEANDIFF=** option instead of the **GROUPMEANS=** option.

The following statements implement all of these modifications:

```
proc power;
 twosamplemeans
 nfractional
 meandiff = 1 to 2 by 0.5
 stddev = 1.2 1.7
 groupweights = (1 1) (1 2) (1 3)
 power = 0.9
 ntotal = .;
run;
```

Figure 71.5 shows the new results.

| 15                       | 2.0       | 1.2     | 1       | 3       | 22.282926          | 0.910        | 23              |
| 16                       | 2.0       | 1.7     | 1       | 1       | 32.413512          | 0.905        | 33              |
| 17                       | 2.0       | 1.7     | 1       | 2       | 36.195531          | 0.907        | 37              |
| 18                       | 2.0       | 1.7     | 1       | 3       | 42.504535          | 0.903        | 43              |

Note that the Nominal Power of 0.9 applies to the raw computed sample size (Fractional N Total), and the Actual Power column applies to the rounded sample size (Ceiling N Total). Some of the adjusted sample sizes in Figure 71.5 are lower than those in Figure 71.4 because underlying group sample sizes are allowed to be fractional (for example, the first Ceiling N Total of 63 corresponding to equal group sizes of 31.5).

## Syntax: POWER Procedure

The following statements are available in the POWER procedure:

```

PROC POWER < options > ;
 LOGISTIC < options > ;
 MULTREG < options > ;
 ONECORR < options > ;
 ONESAMPLEFREQ < options > ;
 ONESAMPLEMEANS < options > ;
 ONEWAYANOVA < options > ;
 PAIREDFREQ < options > ;
 PAIREDMEANS < options > ;
 PLOT < plot-options > < / graph-options > ;
 TWOSAMPLEFREQ < options > ;
 TWOSAMPLEMEANS < options > ;
 TWOSAMPLESURVIVAL < options > ;
 TWOSAMPLEWILCOXON < options > ;

```

The statements in the POWER procedure consist of the **PROC POWER** statement, a set of *analysis statements* (for requesting specific power and sample size analyses), and the **PLOT** statement (for producing graphs). The **PROC POWER** statement and at least one of the analysis statements are required. The analysis statements are **LOGISTIC**, **MULTREG**, **ONECORR**, **ONESAMPLEFREQ**, **ONESAMPLEMEANS**, **ONEWAYANOVA**, **PAIREFREQ**, **PAIREDMEANS**, **TWOSAMPLEFREQ**, **TWOSAMPLEMEANS**, **TWOSAMPLESURVIVAL**, and **TWOSAMPLEWILCOXON**.

You can use multiple analysis statements and multiple **PLOT** statements. Each analysis statement produces a separate sample size analysis. Each **PLOT** statement refers to the previous analysis statement and generates a separate graph (or set of graphs).

The name of an analysis statement describes the framework of the statistical analysis for which sample size calculations are desired. You use options in the analysis statements to identify the result parameter to compute, to specify the statistical test and computational options, and to provide one or more scenarios for the values of relevant analysis parameters.

Table 71.1 summarizes the basic functions of each statement in PROC POWER. The syntax of each statement in Table 71.1 is described in the following pages.

**Table 71.1** Statements in the POWER Procedure

| Statement                | Description                                                                                        |
|--------------------------|----------------------------------------------------------------------------------------------------|
| <b>PROC POWER</b>        | Invokes the procedure                                                                              |
| <b>LOGISTIC</b>          | Likelihood ratio chi-square test of a single predictor in logistic regression with binary response |
| <b>MULTREG</b>           | Tests of one or more coefficients in multiple linear regression                                    |
| <b>ONECORR</b>           | Fisher's $z$ test and $t$ test of (partial) correlation                                            |
| <b>ONESAMPLEFREQ</b>     | Tests, confidence interval precision, and equivalence tests of a single binomial proportion        |
| <b>ONESAMPLEMEANS</b>    | One-sample $t$ test, confidence interval precision, or equivalence test                            |
| <b>ONEWAYANOVA</b>       | One-way ANOVA including single-degree-of-freedom contrasts                                         |
| <b>PAIREFREQ</b>         | McNemar's test for paired proportions                                                              |
| <b>PAIREDMEANS</b>       | Paired $t$ test, confidence interval precision, or equivalence test                                |
| <b>PLOT</b>              | Displays plots for previous sample size analysis                                                   |
| <b>TWOSAMPLEFREQ</b>     | Chi-square, likelihood ratio, and Fisher's exact tests for two independent proportions             |
| <b>TWOSAMPLEMEANS</b>    | Two-sample $t$ test, confidence interval precision, or equivalence test                            |
| <b>TWOSAMPLESURVIVAL</b> | Log-rank, Gehan, and Tarone-Ware tests for comparing two survival curves                           |
| <b>TWOSAMPLEWILCOXON</b> | Wilcoxon-Mann-Whitney (rank-sum) test for 2 independent groups                                     |

See the section “Summary of Analyses” on page 6018 for a summary of the analyses available and the syntax required for them.

---

## PROC POWER Statement

**PROC POWER** < options > ;

The **PROC POWER** statement invokes the POWER procedure. You can specify the following option.

### **PLOTONLY**

specifies that only graphical results from the **PLOT** statement should be produced.

---

## LOGISTIC Statement

**LOGISTIC** < options > ;

The **LOGISTIC** statement performs power and sample size analyses for the likelihood ratio chi-square test of a single predictor in binary logistic regression, possibly in the presence of one or more covariates that might be correlated with the tested predictor.

## Summary of Options

Table 71.2 summarizes the options available in the **LOGISTIC** statement.

**Table 71.2** LOGISTIC Statement Options

| Option                              | Description                                                                 |
|-------------------------------------|-----------------------------------------------------------------------------|
| <b>Define analysis</b>              |                                                                             |
| <b>TEST=</b>                        | Specifies the statistical analysis                                          |
| <b>Specify analysis information</b> |                                                                             |
| <b>ALPHA=</b>                       | Specifies the significance level                                            |
| <b>COVARIATES=</b>                  | Specifies the distributions of predictor variables                          |
| <b>TESTPREDICTOR=</b>               | Specifies the distribution of the predictor variable being tested           |
| <b>VARDIST=</b>                     | Defines a distribution for a predictor variable                             |
| <b>Specify effects</b>              |                                                                             |
| <b>CORR=</b>                        | Specifies the multiple correlation between the predictor and the covariates |
| <b>COVODDSRATIOS=</b>               | Specifies the odds ratios for the covariates                                |
| <b>COVREGCOEFFS=</b>                | Specifies the regression coefficients for the covariates                    |
| <b>DEFAULTUNIT=</b>                 | Specifies the default change in the predictor variables                     |
| <b>INTERCEPT=</b>                   | Specifies the intercept                                                     |
| <b>RESPONSEPROB=</b>                | Specifies the response probability                                          |
| <b>TESTODDSRATIO=</b>               | Specifies the odds ratio being tested                                       |
| <b>TESTREGCOEFF=</b>                | Specifies the regression coefficient for the predictor variable             |
| <b>UNITS=</b>                       | Specifies the changes in the predictor variables                            |
| <b>Specify sample size</b>          |                                                                             |
| <b>NFRACTIONAL</b>                  | Enables fractional input and output for sample sizes                        |
| <b>NTOTAL=</b>                      | Specifies the sample size                                                   |
| <b>Specify power</b>                |                                                                             |
| <b>POWER=</b>                       | Specifies the desired power of the test                                     |

---

Table 71.2 *continued*

| Option                              | Description                                                            |
|-------------------------------------|------------------------------------------------------------------------|
| <b>Specify computational method</b> |                                                                        |
| DEFAULTNBINS=                       | Specifies the default number of categories for each predictor variable |
| NBINS=                              | Specifies the number of categories for predictor variables             |
| <b>Control ordering in output</b>   |                                                                        |
| OUTPUTORDER=                        | Controls the output order of parameters                                |

Table 71.3 summarizes the valid result parameters in the LOGISTIC statement.

Table 71.3 Summary of Result Parameters in the LOGISTIC Statement

| Analyses   | Solve For            | Syntax              |
|------------|----------------------|---------------------|
| TEST=LRCHI | Power<br>Sample size | POWER=.<br>NTOTAL=. |

## Dictionary of Options

### ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

### CORR=*number-list*

specifies the multiple correlation ( $\rho$ ) between the tested predictor and the covariates. If you also specify the COVARIATES= option, then the sample size is either multiplied (if you are computing power) or divided (if you are computing sample size) by a factor of  $(1 - \rho^2)$ . See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

### COVARIATES=*grouped-name-list*

specifies the distributions of any predictor variables in the model but not being tested, using labels specified with the VARDIST= option. The distributions are assumed to be independent of each other and of the tested predictor. If this option is omitted, then the tested predictor specified by the TEST= option is assumed to be the only predictor in the model. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *grouped-name-list*.

### COVODDSRATIOS=*grouped-number-list*

specifies the odds ratios for the covariates in the full model (including variables in the TESTPREDICTOR= and COVARIATES= options). The ordering of the values corresponds to the ordering in the COVARIATES= option. If the response variable is coded as  $Y = 1$  for success and  $Y = 0$  for failure, then the odds ratio for each covariate  $X$  is the odds of  $Y = 1$  when  $X = a$  divided by the odds of  $Y = 1$  when  $X = b$ , where  $a$  and  $b$  are determined from the DEFAULTUNIT= and UNITS= options. Values must be greater than zero. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *grouped-number-list*.

**COVREGCOEFFS=***grouped-number-list*

specifies the regression coefficients for the covariates in the full model including the test predictor (as specified by the **TESTPREDICTOR=** option). The ordering of the values corresponds to the ordering in the **COVARIATES=** option. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *grouped-number-list*.

**DEFAULTNBINS=***number*

specifies the default number of categories (or “bins”) into which the distribution for each predictor variable is divided in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. Each test predictor or covariate that is absent from the **NBINS=** option derives its bin number from the **DEFAULTNBINS=** option. The default value is **DEFAULTNBINS=10**.

There are two variable distributions for which the number of bins can be overridden internally:

- For an ordinal distribution, the number of ordinal values is always used as the number of bins.
- For a binomial distribution, if the requested number of bins is larger than  $n + 1$ , where  $n$  is the sample size parameter of the binomial distribution, then exactly  $n + 1$  bins are used.

**DEFAULTUNIT=***change-spec*

specifies the default change in the predictor variables assumed for odds ratios specified with the **COVODDSRATIOS=** and **TESTODDSRATIO=** options. Each test predictor or covariate that is absent from the **UNITS=** option derives its change value from the **DEFAULTUNIT=** option. The value must be nonzero. The default value is **DEFAULTUNIT=1**. This option can be used only if at least one of the **COVODDSRATIOS=** and **TESTODDSRATIO=** options is used.

Valid specifications for *change-spec* are as follows:

*number* defines the odds ratio as the ratio of the response variable odds when  $X = a$  to the odds when  $X = a - \textit{number}$  for any constant  $a$ .

$\langle + | - \rangle \textit{SD}$  defines the odds ratio as the ratio of the odds when  $X = a$  to the odds when  $X = a - \sigma$  (or  $X = a + \sigma$ , if  $\textit{SD}$  is preceded by a minus sign (-)) for any constant  $a$ , where  $\sigma$  is the standard deviation of  $X$  (as determined from the **VARDIST=** option).

*multiple*\* $\textit{SD}$  defines the odds ratio as the ratio of the odds when  $X = a$  to the odds when  $X = a - \textit{multiple} * \sigma$  for any constant  $a$ , where  $\sigma$  is the standard deviation of  $X$  (as determined from the **VARDIST=** option).

**PERCENTILES**( $p1, p2$ ) defines the odds ratio as the ratio of the odds when  $X$  is equal to its  $p2 * 100$ th percentile to the odds when  $X$  is equal to its  $p1 * 100$ th percentile (where the percentiles are determined from the distribution specified in the **VARDIST=** option). Values for  $p1$  and  $p2$  must be strictly between 0 and 1.

**INTERCEPT=***number-list*

specifies the intercept in the full model (including variables in the **TESTPREDICTOR=** and **COVARIATES=** options). See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**NBINS=**(*"name" = number <... "name" = number >*)

specifies the number of categories (or “bins”) into which the distribution for each predictor variable (identified by its *name* from the **VARDIST=** option) is divided in internal calculations. Higher values increase computational time and memory requirements but generally lead to more accurate results. Each predictor variable that is absent from the **NBINS=** option derives its bin number from the **DEFAULTNBINS=** option.

There are two variable distributions for which the **NBINS=** value can be overridden internally:

- For an ordinal distribution, the number of ordinal values is always used as the number of bins.
- For a binomial distribution, if the requested number of bins is larger than  $n + 1$ , where  $n$  is the sample size parameter of the binomial distribution, then exactly  $n + 1$  bins are used.

**NFRACTIONAL****NFRAC**

enables fractional input and output for sample sizes. See the section “Sample Size Adjustment Options” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

**NTOTAL=***number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). Values must be at least one. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**OUTPUTORDER=INTERNAL****OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **DEFAULTNBINS=**
- **NBINS=**
- **ALPHA=**
- **RESPONSEPROB=**
- **INTERCEPT=**
- **TESTPREDICTOR=**
- **TESTODDSRATIO=**
- **TESTREGCOEFF=**
- **COVARIATES=**
- **COVODDSRATIOS=**
- **COVREGCOEFFS=**
- **CORR=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **LOGISTIC** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **LOGISTIC** statement.

**POWER=number-list**

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**RESPONSEPROB=number-list**

specifies the response probability in the full model when all predictor variables (including variables in the [TESTPREDICTOR=](#) and [COVARIATES=](#) options) are equal to their means. The log odds of this probability are equal to the intercept in the full model where all predictor are centered at their means. If the response variable is coded as  $Y = 1$  for success and  $Y = 0$  for failure, then this probability is equal to the mean of  $Y$  in the full model when all  $X$ s are equal to their means. Values must be strictly between zero and one. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**TEST=LRCHI**

specifies the likelihood ratio chi-square test of a single model parameter in binary logistic regression. This is the default test option.

**TESTODDSRATIO=number-list**

specifies the odds ratio for the predictor variable being tested in the full model (including variables in the [TESTPREDICTOR=](#) and [COVARIATES=](#) options). If the response variable is coded as  $Y = 1$  for success and  $Y = 0$  for failure, then the odds ratio for the  $X$  being tested is the odds of  $Y = 1$  when  $X = a$  divided by the odds of  $Y = 1$  when  $X = b$ , where  $a$  and  $b$  are determined from the [DEFAULTUNIT=](#) and [UNITS=](#) options. Values must be greater than zero. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**TESTPREDICTOR=name-list**

specifies the distribution of the predictor variable being tested, using labels specified with the [VARDIST=](#) option. This distribution is assumed to be independent of the distributions of the covariates as defined in the [COVARIATES=](#) option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *name-list*.

**TESTREGCOEFF=number-list**

specifies the regression coefficient for the predictor variable being tested in the full model including the covariates specified by the [COVARIATES=](#) option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**UNITS=(“name” = change-spec <... “name” = change-spec >)**

specifies the changes in the predictor variables assumed for odds ratios specified with the [COVODDSRATIOS=](#) and [TESTODDSRATIO=](#) options. Each predictor variable whose *name* (from the [VARDIST=](#) option) is absent from the UNITS option derives its change value from the [DEFAULTUNIT=](#) option. This option can be used only if at least one of the [COVODDSRATIOS=](#) and [TESTODDSRATIO=](#) options is used.

Valid specifications for *change-spec* are as follows:

*number* defines the odds ratio as the ratio of the response variable odds when  $X = a$  to the odds when  $X = a - \textit{number}$  for any constant  $a$ .

**<+|->SD** defines the odds ratio as the ratio of the odds when  $X = a$  to the odds when  $X = a - \sigma$  (or  $X = a + \sigma$ , if SD is preceded by a minus sign (-)) for any constant  $a$ , where  $\sigma$  is the standard deviation of  $X$  (as determined from the **VARDIST=** option).

**multiple\*SD** defines the odds ratio as the ratio of the odds when  $X = a$  to the odds when  $X = a - multiple * \sigma$  for any constant  $a$ , where  $\sigma$  is the standard deviation of  $X$  (as determined from the **VARDIST=** option).

**PERCENTILES( $p1, p2$ )** defines the odds ratio as the ratio of the odds when  $X$  is equal to its  $p2 * 100$ th percentile to the odds when  $X$  is equal to its  $p1 * 100$ th percentile (where the percentiles are determined from the distribution specified in the **VARDIST=** option). Values for  $p1$  and  $p2$  must be strictly between 0 and 1.

Each unit value must be nonzero.

**VARDIST("label")=distribution (parameters)**  
defines a distribution for a predictor variable.

For the **VARDIST=** option,

|                     |                                                                                                                       |
|---------------------|-----------------------------------------------------------------------------------------------------------------------|
| <i>label</i>        | identifies the variable distribution in the output and with the <b>COVARIATES=</b> and <b>TESTPREDICTOR=</b> options. |
| <i>distribution</i> | specifies the distributional form of the variable.                                                                    |
| <i>parameters</i>   | specifies one or more parameters associated with the distribution.                                                    |

Choices for distributional forms and their parameters are as follows:

**ORDINAL ((*values*): (*probabilities*))** is an ordered categorical distribution. The *values* are any numbers separated by spaces. The *probabilities* are numbers between 0 and 1 (inclusive) separated by spaces. Their sum must be exactly 1. The number of *probabilities* must match the number of *values*.

**BETA ( $a, b <, l, r >$ )** is a beta distribution with shape parameters  $a$  and  $b$  and optional location parameters  $l$  and  $r$ . The values of  $a$  and  $b$  must be greater than 0, and  $l$  must be less than  $r$ . The default values for  $l$  and  $r$  are 0 and 1, respectively.

**BINOMIAL ( $p, n$ )** is a binomial distribution with probability of success  $p$  and number of independent Bernoulli trials  $n$ . The value of  $p$  must be greater than 0 and less than 1, and  $n$  must be an integer greater than 0. If  $n = 1$ , then the distribution is binary.

**EXPONENTIAL ( $\lambda$ )** is an exponential distribution with scale  $\lambda$ , which must be greater than 0.

**GAMMA ( $a, \lambda$ )** is a gamma distribution with shape  $a$  and scale  $\lambda$ . The values of  $a$  and  $\lambda$  must be greater than 0.

**LAPLACE ( $\theta, \lambda$ )** is a Laplace distribution with location  $\theta$  and scale  $\lambda$ . The value of  $\lambda$  must be greater than 0.

**LOGISTIC ( $\theta, \lambda$ )** is a logistic distribution with location  $\theta$  and scale  $\lambda$ . The value of  $\lambda$  must be greater than 0.

**LOGNORMAL ( $\theta, \lambda$ )** is a lognormal distribution with location  $\theta$  and scale  $\lambda$ . The value of  $\lambda$  must be greater than 0.

NORMAL ( $\theta, \lambda$ ) is a normal distribution with mean  $\theta$  and standard deviation  $\lambda$ . The value of  $\lambda$  must be greater than 0.

POISSON ( $m$ ) is a Poisson distribution with mean  $m$ . The value of  $m$  must be greater than 0.

UNIFORM ( $l, r$ ) is a uniform distribution on the interval  $[l, r]$ , where  $l < r$ .

## Restrictions on Option Combinations

To specify the intercept in the full model, choose one of the following two parameterizations:

- intercept (using the `INTERCEPT=` options)
- Prob( $Y = 1$ ) when all predictors are equal to their means (using the `RESPONSEPROB=` option)

To specify the effect associated with the predictor variable being tested, choose one of the following two parameterizations:

- odds ratio (using the `TESTODDSRATIO=` options)
- regression coefficient (using the `TESTREGCOEFFS=` option)

To describe the effects of the covariates in the full model, choose one of the following two parameterizations:

- odds ratios (using the `COVODDSRATIOS=` options)
- regression coefficients (using the `COVREGCOEFFS=` options)

## Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the `LOGISTIC` statement.

### Likelihood Ratio Chi-Square Test for One Predictor

You can express effects in terms of response probability and odds ratios, as in the following statements:

```
proc power;
 logistic
 vardist("x1a") = normal(0, 2)
 vardist("x1b") = normal(0, 3)
 vardist("x2") = poisson(7)
 vardist("x3a") = ordinal((-5 0 5) : (.3 .4 .3))
 vardist("x3b") = ordinal((-5 0 5) : (.4 .3 .3))
 testpredictor = "x1a" "x1b"
 covariates = "x2" | "x3a" "x3b"
 responseprob = 0.15
 testoddsratio = 1.75
 covoddsratios = (2.1 1.4)
 ntotal = 100
 power = .;
run;
```

The **VARDIST=** options define the distributions of the predictor variables. The **TESTPREDICTOR=** option specifies two scenarios for the test predictor distribution, Normal(10,2) and Normal(10,3). The **COVARIATES=** option specifies two covariates, the first with a Poisson(7) distribution. The second covariate has an ordinal distribution on the values -5, 0, and 5 with two scenarios for the associated probabilities: (.3, .4, .3) and (.4, .3, .3). The response probability in the full model with all variables equal to zero is specified by the **RESPONSEPROB=** option as 0.15. The odds ratio for a unit decrease in the tested predictor is specified by the **TESTODDSRATIO=** option to be 1.75. Corresponding odds ratios for the two covariates in the full model are specified by the **COVODDSRATIOS=** option to be 2.1 and 1.4. The **POWER=.** option requests a solution for the power at a sample size of 100 as specified by the **NTOTAL=** option.

Default values of the **TEST=** and **ALPHA=** options specify a likelihood ratio test of the first predictor with a significance level of 0.05. The default of **DEFAULTUNIT=1** specifies that all odds ratios are defined in terms of unit changes in predictors. The default of **DEFAULTNBINS=10** specifies that each of the three predictor variables is discretized into a distribution with 10 categories in internal calculations.

You can also express effects in terms of regression coefficients, as in the following statements:

```
proc power;
 logistic
 vardist("x1a") = normal(0, 2)
 vardist("x1b") = normal(0, 3)
 vardist("x2") = poisson(7)
 vardist("x3a") = ordinal((-5 0 5) : (.3 .4 .3))
 vardist("x3b") = ordinal((-5 0 5) : (.4 .3 .3))
 testpredictor = "x1a" "x1b"
 covariates = "x2" | "x3a" "x3b"
 intercept = -6.928162
 testregcoeff = 0.5596158
 covregcoeffs = (0.7419373 0.3364722)
 ntotal = 100
 power = .;
run;
```

The regression coefficients for the tested predictor (**TESTREGCOEFF=0.5596158**) and covariates (**COVREGCOEFFS=(0.7419373 0.3364722)**) are determined by taking the logarithm of the corresponding odds ratios. The intercept in the full model is specified as -6.928162 by the **INTERCEPT=** option. This number is calculated according to the formula at the end of “Analyses in the LOGISTIC Statement” on page 6029, which expresses the intercept in terms of the response probability, regression coefficients, and predictor means:

$$\text{Intercept} = \log\left(\frac{0.15}{1 - 0.15}\right) - (0.5596158(0) + 0.7419373(7) + 0.3364722(0))$$

---

## MULTREG Statement

**MULTREG** <options> ;

The **MULTREG** statement performs power and sample size analyses for Type III *F* tests of sets of predictors in multiple linear regression, assuming either fixed or normally distributed predictors.

## Summary of Options

Table 71.4 summarizes the options available in the MULTREG statement.

**Table 71.4** MULTREG Statement Options

| Option                              | Description                                             |
|-------------------------------------|---------------------------------------------------------|
| <b>Define analysis</b>              |                                                         |
| TEST=                               | Specifies the statistical analysis                      |
| <b>Specify analysis information</b> |                                                         |
| ALPHA=                              | Specifies the significance level                        |
| MODEL=                              | Specifies the assumed distribution of the predictors    |
| NFULLPREDICTORS=                    | Specifies the number of predictors in the full model    |
| NOINT                               | Specifies a no-intercept model                          |
| NREDUCEDPREDICTORS=                 | Specifies the number of predictors in the reduced model |
| NTESTPREDICTORS=                    | Specifies the number of predictors being tested         |
| <b>Specify effects</b>              |                                                         |
| PARTIALCORR=                        | Specifies the partial correlation                       |
| RSQUAREDIFF=                        | Specifies the difference in $R^2$                       |
| RSQUAREFULL=                        | Specifies the $R^2$ of the full model                   |
| RSQUAREREDUCED=                     | Specifies the $R^2$ of the reduced model                |
| <b>Specify sample size</b>          |                                                         |
| NFRACTIONAL                         | Enables fractional input and output for sample sizes    |
| NTOTAL=                             | Specifies the sample size                               |
| <b>Specify power</b>                |                                                         |
| POWER=                              | Specifies the desired power                             |
| <b>Control ordering in output</b>   |                                                         |
| OUTPUTORDER=                        | Controls the order of parameters                        |

Table 71.5 summarizes the valid result parameters in the MULTREG statement.

**Table 71.5** Summary of Result Parameters in the MULTREG Statement

| Analyses   | Solve For   | Syntax   |
|------------|-------------|----------|
| TEST=TYPE3 | Power       | POWER=.  |
|            | Sample size | NTOTAL=. |

## Dictionary of Options

### ALPHA=*number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**MODEL=keyword-list**

specifies the assumed distribution of the tested predictors. **MODEL=FIXED** indicates a fixed predictor distribution. **MODEL=RANDOM** (the default) indicates a joint multivariate normal distribution for the response and tested predictors. You can use the aliases **CONDITIONAL** for **FIXED** and **UNCONDITIONAL** for **RANDOM**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

**FIXED** fixed predictors

**RANDOM** random (multivariate normal) predictors

**NFRACTIONAL****NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

**NFULLPREDICTORS=number-list****NFULLPRED=number-list**

specifies the number of predictors in the full model, not counting the intercept. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NOINT**

specifies a no-intercept model (for both full and reduced models). By default, the intercept is included in the model. If you want to test the intercept, you can specify the **NOINT** option and simply consider the intercept to be one of the predictors being tested. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NREDUCEDPREDICTORS=number-list****NREDUCEDPRED=number-list****NREDPRED=number-list**

specifies the number of predictors in the reduced model, not counting the intercept. This is the same as the difference between values of the **NFULLPREDICTORS=** and **NTESTPREDICTORS=** options. Note that supplying a value of 0 is the same as specifying an *F* test of a Pearson correlation. This option cannot be used at the same time as the **NTESTPREDICTORS=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NTESTPREDICTORS=number-list****NTESTPRED=number-list**

specifies the number of predictors being tested. This is the same as the difference between values of the **NFULLPREDICTORS=** and **NREDUCEDPREDICTORS=** options. Note that supplying identical values for the **NTESTPREDICTORS=** and **NFULLPREDICTORS=** options is the same as specifying an *F* test of a Pearson correlation. This option cannot be used at the same time as the **NREDUCEDPREDICTORS=** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NTOTAL=number-list**

specifies the sample size or requests a solution for the sample size with a missing value (NTOTAL=.). The minimum acceptable value for the sample size depends on the MODEL=, NOINT, NFULLPREDICTORS=, NTESTPREDICTORS=, and NREDUCEDPREDICTORS= options. It ranges from  $p + 1$  to  $p + 3$ , where  $p$  is the value of the NFULLPREDICTORS option. See Table 71.30 for further information about minimum NTOTAL values, and see the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**OUTPUTORDER=INTERNAL****OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. OUTPUTORDER=INTERNAL (the default) arranges the parameters in the output according to the following order of their corresponding options:

- MODEL=
- NFULLPREDICTORS=
- NTESTPREDICTORS=
- NREDUCEDPREDICTORS=
- ALPHA=
- PARTIALCORR=
- RSQUAREFULL=
- RSQUAREREDUCED=
- RSQUAREDIFF=
- NTOTAL=
- POWER=

The OUTPUTORDER=SYNTAX option arranges the parameters in the output in the same order in which their corresponding options are specified in the MULTREG statement. The OUTPUTORDER=REVERSE option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the MULTREG statement.

**PARTIALCORR=number-list****PCORR=number-list**

specifies the partial correlation between the tested predictors and the response, adjusting for any other predictors in the model. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**POWER=number-list**

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**RSQUAREDIFF=number-list****RSQDIFF=number-list**

specifies the difference in  $R^2$  between the full and reduced models. This is equivalent to the proportion of variation explained by the predictors you are testing. It is also equivalent to the squared semipartial correlation of the tested predictors with the response. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**RSQUAREFULL**=*number-list*

**RSQFULL**=*number-list*

specifies the  $R^2$  of the full model, where  $R^2$  is the proportion of variation explained by the model. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**RSQUAREREDUCED**=*number-list*

**RSQREDUCED**=*number-list*

**RSQRED**=*number-list*

specifies the  $R^2$  of the reduced model, where  $R^2$  is the proportion of variation explained by the model. If the reduced model is an empty or intercept-only model (in other words, if **NREDUCEDPREDICTORS**=0 or **NTESTPREDICTORS**=**NFULLPREDICTORS**), then **RSQUAREREDUCED**=0 is assumed. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**TEST**=**TYPE3**

specifies a Type III  $F$  test of a set of predictors adjusting for any other predictors in the model. This is the default test option.

## Restrictions on Option Combinations

To specify the number of predictors, use any two of these three options:

- the number of predictors in the full model (**NFULLPREDICTORS**=)
- the number of predictors in the reduced model (**NREDUCEDPREDICTORS**=)
- the number of predictors being tested (**NTESTPREDICTORS**=)

To specify the effect, choose one of the following parameterizations:

- partial correlation (by using the **PARTIALCORR**= option)
- $R^2$  for the full and reduced models (by using any two of **RSQUAREDIFF**=, **RSQUAREFULL**=, and **RSQUAREREDUCED**=)

## Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **MULTREG** statement.

### **Type III F Test of a Set of Predictors**

You can express effects in terms of partial correlation, as in the following statements. Default values of the **TEST**=, **MODEL**=, and **ALPHA**= options specify a Type III  $F$  test with a significance level of 0.05, assuming normally distributed predictors.

```

proc power;
 multreg
 model = random
 nfullpredictors = 7
 ntestpredictors = 3
 partialcorr = 0.35
 ntotal = 100
 power = .;
run;

```

You can also express effects in terms of  $R^2$ :

```

proc power;
 multreg
 model = fixed
 nfullpredictors = 7
 ntestpredictors = 3
 rsquarefull = 0.9
 rsquarediff = 0.1
 ntotal = .
 power = 0.9;
run;

```

---

## ONECORR Statement

**ONECORR** <options> ;

The **ONECORR** statement performs power and sample size analyses for tests of simple and partial Pearson correlation between two variables. Both Fisher's  $z$  test and the  $t$  test are supported.

### Summary of Options

Table 71.6 summarizes the options available in the **ONECORR** statement.

**Table 71.6** ONECORR Statement Options

| Option                              | Description                                                             |
|-------------------------------------|-------------------------------------------------------------------------|
| <b>Define analysis</b>              |                                                                         |
| <b>DIST=</b>                        | Specifies the underlying distribution assumed for the test statistic    |
| <b>TEST=</b>                        | Specifies the statistical analysis                                      |
| <b>Specify analysis information</b> |                                                                         |
| <b>ALPHA=</b>                       | Specifies the significance level                                        |
| <b>MODEL=</b>                       | Specifies the assumed distribution of the variables                     |
| <b>NPARTIALVARS=</b>                | Specifies the number of variables adjusted for in the correlation       |
| <b>NULLCORR=</b>                    | Specifies the null value of the correlation                             |
| <b>SIDES=</b>                       | Specifies the number of sides and the direction of the statistical test |
| <b>Specify effects</b>              |                                                                         |
| <b>CORR=</b>                        | Specifies the correlation                                               |

Table 71.6 *continued*

| Option                            | Description                                          |
|-----------------------------------|------------------------------------------------------|
| <b>Specify sample size</b>        |                                                      |
| NFRACTIONAL                       | Enables fractional input and output for sample sizes |
| NTOTAL=                           | Specifies the sample size                            |
| <b>Specify power</b>              |                                                      |
| POWER=                            | Specifies the desired power of the test              |
| <b>Control ordering in output</b> |                                                      |
| OUTPUTORDER=                      | Controls the output order of parameters              |

Table 71.7 summarizes the valid result parameters in the `ONECORR` statement.

Table 71.7 Summary of Result Parameters in the `ONECORR` Statement

| Analyses     | Solve For            | Syntax              |
|--------------|----------------------|---------------------|
| TEST=PEARSON | Power<br>Sample size | POWER=.<br>NTOTAL=. |

## Dictionary of Options

### **ALPHA=***number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

### **CORR=***number-list*

specifies the correlation between two variables, possibly adjusting for other variables as determined by the `NPARTIALVARS=` option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

### **DIST=FISHERZ**

### **DIST=T**

specifies the underlying distribution assumed for the test statistic. FISHERZ corresponds to Fisher’s  $z$  normalizing transformation of the correlation coefficient. T corresponds to the  $t$  transformation of the correlation coefficient. Note that `DIST=T` is equivalent to analyses in the `MULTREG` statement with `NTESTPREDICTORS=1`. The default value is FISHERZ.

### **MODEL=***keyword-list*

specifies the assumed distribution of the first variable when `DIST=T`. The second variable is assumed to have a normal distribution. `MODEL=FIXED` indicates a fixed distribution. `MODEL=RANDOM` (the default) indicates a joint bivariate normal distribution with the second variable. You can use the aliases `CONDITIONAL` for `FIXED` and `UNCONDITIONAL` for `RANDOM`. This option can be used only for `DIST=T`. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

FIXED fixed variables

RANDOM random (bivariate normal) variables

## NFRACTIONAL

### NFRAC

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

### NPARTIALVARS=*number-list*

### NPVARS=*number-list*

specifies the number of variables adjusted for in the correlation between the two primary variables. The default value is 0, corresponding to a simple correlation. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

### NTOTAL=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). Values for the sample size must be at least  $p + 3$  when **DIST=T** and **MODEL=CONDITIONAL**, and at least  $p + 4$  when either **DIST=FISHER** or when **DIST=T** and **MODEL=UNCONDITIONAL**, where  $p$  is the value of the **NPARTIALVARS** option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

### NULLCORR=*number-list*

### NULLC=*number-list*

specifies the null value of the correlation. The default value is 0. This option can be used only with the **DIST=FISHERZ** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

## OUTPUTORDER=INTERNAL

## OUTPUTORDER=REVERSE

## OUTPUTORDER=SYNTAX

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **MODEL=**
- **SIDES=**
- **NULL=**
- **ALPHA=**
- **NPARTIALVARS=**
- **CORR=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONECORR** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONECORR** statement.

**POWER=number-list**

specifies the desired power of the test or requests a solution for the power with a missing value (POWER=.). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**SIDES=keyword-list**

specifies the number of sides (or tails) and the direction of the statistical test. Valid keywords are

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

The default value is 2.

**TEST=PEARSON**

specifies a test of the Pearson correlation coefficient between two variables, possibly adjusting for other variables. This is the default test option.

## Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the `ONECORR` statement.

### *Fisher's z Test for Pearson Correlation*

The following statements demonstrate a power computation for Fisher's z test for correlation. Default values of `TEST=PEARSON`, `ALPHA=0.05`, `SIDES=2`, and `NPARTIALVARS=0` are assumed.

```
proc power;
 onecorr dist=fisherz
 nullcorr = 0.15
 corr = 0.35
 ntotal = 180
 power = .;
run;
```

### *t Test for Pearson Correlation*

The following statements demonstrate a sample size computation for the *t* test for correlation. Default values of `TEST=PEARSON`, `MODEL=RANDOM`, `ALPHA=0.05`, and `SIDES=2` are assumed.

```
proc power;
 onecorr dist=t
 npartialvars = 4
 corr = 0.45
 ntotal = .
 power = 0.85;
run;
```

---

## ONESAMPLEFREQ Statement

**ONESAMPLEFREQ** < options > ;

The **ONESAMPLEFREQ** statement performs power and sample size analyses for exact and approximate tests (including equivalence, noninferiority, and superiority) and confidence interval precision for a single binomial proportion.

### Summary of Options

Table 71.8 summarizes the options available in the **ONESAMPLEFREQ** statement.

**Table 71.8** ONESAMPLEFREQ Statement Options

| Option                                         | Description                                                                                                                            |
|------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>Define analysis</b>                         |                                                                                                                                        |
| CI=                                            | Specifies an analysis of precision of a confidence interval                                                                            |
| TEST=                                          | Specifies the statistical analysis                                                                                                     |
| <b>Specify analysis information</b>            |                                                                                                                                        |
| ALPHA=                                         | Specifies the significance level                                                                                                       |
| EQUIVBOUNDS=                                   | Specifies the lower and upper equivalence bounds                                                                                       |
| LOWER=                                         | Specifies the lower equivalence bound                                                                                                  |
| MARGIN=                                        | Specifies the equivalence or noninferiority or superiority margin                                                                      |
| NULLPROPORTION=                                | Specifies the null proportion                                                                                                          |
| SIDES=                                         | Specifies the number of sides and the direction of the statistical test                                                                |
| UPPER=                                         | Specifies the upper equivalence bound                                                                                                  |
| <b>Specify effect</b>                          |                                                                                                                                        |
| HALFWIDTH=                                     | Specifies the desired confidence interval half-width                                                                                   |
| PROPORTION=                                    | Specifies the binomial proportion                                                                                                      |
| <b>Specify variance estimation</b>             |                                                                                                                                        |
| VAREST=                                        | Specifies how the variance is computed                                                                                                 |
| <b>Specify sample size</b>                     |                                                                                                                                        |
| NFRACTIONAL                                    | Enables fractional input and output for sample sizes                                                                                   |
| NTOTAL=                                        | Specifies the sample size                                                                                                              |
| <b>Specify power and related probabilities</b> |                                                                                                                                        |
| POWER=                                         | Specifies the desired power of the test                                                                                                |
| PROBWIDTH=                                     | Specifies the probability of obtaining a confidence interval half-width less than or equal to the value specified by <b>HALFWIDTH=</b> |
| <b>Choose computational method</b>             |                                                                                                                                        |
| METHOD=                                        | Specifies the computational method                                                                                                     |
| <b>Control ordering in output</b>              |                                                                                                                                        |
| OUTPUTORDER=                                   | Controls the output order of parameters                                                                                                |

---

Table 71.9 summarizes the valid result parameters for different analyses in the `ONESAMPLEFREQ` statement.

**Table 71.9** Summary of Result Parameters in the `ONESAMPLEFREQ` Statement

| Analyses                                   | Solve For            | Syntax                                        |
|--------------------------------------------|----------------------|-----------------------------------------------|
| <code>CI=WILSON</code>                     | Prob(width)          | <code>PROBWIDTH=.</code>                      |
| <code>CI=AGRESTICOULL</code>               | Prob(width)          | <code>PROBWIDTH=.</code>                      |
| <code>CI=JEFFREYS</code>                   | Prob(width)          | <code>PROBWIDTH=.</code>                      |
| <code>CI=EXACT</code>                      | Prob(width)          | <code>PROBWIDTH=.</code>                      |
| <code>CI=WALD</code>                       | Prob(width)          | <code>PROBWIDTH=.</code>                      |
| <code>CI=WALD_CORRECT</code>               | Prob(width)          | <code>PROBWIDTH=.</code>                      |
| <code>TEST=ADJZ METHOD=EXACT</code>        | Power                | <code>POWER=.</code>                          |
| <code>TEST=ADJZ METHOD=NORMAL</code>       | Power<br>Sample size | <code>POWER=.</code><br><code>NTOTAL=.</code> |
| <code>TEST=EQUIV_ADJZ METHOD=EXACT</code>  | Power                | <code>POWER=.</code>                          |
| <code>TEST=EQUIV_ADJZ METHOD=NORMAL</code> | Power<br>Sample size | <code>POWER=.</code><br><code>NTOTAL=.</code> |

| <code>TEST=Z METHOD=EXACT</code>           | Power                | <code>POWER=.</code>                          |
| <code>TEST=Z METHOD=NORMAL</code>          | Power<br>Sample size | <code>POWER=.</code><br><code>NTOTAL=.</code> |

## Dictionary of Options

### **ALPHA=***number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. If the `CI=` and `SIDES=1` options are used, then the value must be less than 0.5. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

### **CI**

**CI=AGRESTICOULL** | **AC**

**CI=JEFFREYS**

**CI=EXACT** | **CLOPPERPEARSON** | **CP**

**CI=WALD**

**CI=WALD\_CORRECT**

**CI=WILSON** | **SCORE**

specifies an analysis of precision of a confidence interval for the sample binomial proportion.

The value of the **CI=** option specifies the type of confidence interval. The **CI=AGRESTICOULL** option is a generalization of the “Adjusted Wald / add 2 successes and 2 failures” interval of Agresti and Coull (1998) and is presented in Brown, Cai, and DasGupta (2001). It corresponds to the **TABLES / BINOMIAL (AGRESTICOULL)** option in PROC FREQ. The **CI=JEFFREYS** option specifies the equal-tailed Jeffreys prior Bayesian interval, corresponding to the **TABLES / BINOMIAL (JEFFREYS)** option in PROC FREQ. The **CI=EXACT** option specifies the exact Clopper-Pearson confidence interval based on enumeration, corresponding to the **TABLES / BINOMIAL (EXACT)** option in PROC FREQ. The **CI=WALD** option specifies the confidence interval based on the Wald test (also commonly called the  $z$  test or normal-approximation test), corresponding to the **TABLES / BINOMIAL (WALD)** option in PROC FREQ. The **CI=WALD\_CORRECT** option specifies the confidence interval based on the Wald test with continuity correction, corresponding to the **TABLES / BINOMIAL (CORRECT WALD)** option in PROC FREQ. The **CI=WILSON** option (the default) specifies the confidence interval based on the score statistic, corresponding to the **TABLES / BINOMIAL (WILSON)** option in PROC FREQ.

Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the confidence interval will be at most the value specified by the **HALFWIDTH=** option.

**EQUIVBOUNDS=***grouped-number-list*

specifies the lower and upper equivalence bounds, representing the same information as the combination of the **LOWER=** and **UPPER=** options but grouping them together. The **EQUIVBOUNDS=** option can be used only with equivalence analyses (**TEST=EQUIV\_ADJZ | EQUIV\_EXACT | EQUIV\_Z**). Values must be strictly between 0 and 1. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

**HALFWIDTH=***number-list*

specifies the desired confidence interval half-width. The half-width for a two-sided interval is the length of the confidence interval divided by two. This option can be used only with the **CI=** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**LOWER=***number-list*

specifies the lower equivalence bound for the binomial proportion. The **LOWER=** option can be used only with equivalence analyses (**TEST=EQUIV\_ADJZ | EQUIV\_EXACT | EQUIV\_Z**). Values must be strictly between 0 and 1. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**MARGIN=***number-list*

specifies the equivalence or noninferiority or superiority margin, depending on the analysis.

The **MARGIN=** option can be used with one-sided analyses (**SIDES = 1 | U | L**), in which case it specifies the margin added to the null proportion value in the hypothesis test, resulting in a noninferiority or superiority test (depending on the agreement between the effect and hypothesis directions and the sign of the margin). A test with a null proportion  $p_0$  and a margin  $m$  is the same as a test with null proportion  $p_0 + m$  and no margin.

The **MARGIN=** option can also be used with equivalence analyses (**TEST=EQUIV\_ADJZ | EQUIV\_EXACT | EQUIV\_Z**) when the **NULLPROPORTION=** option is used, in which case it specifies the lower and upper equivalence bounds as  $p_0 - m$  and  $p_0 + m$ , where  $p_0$  is the value of the **NULLPROPORTION=** option and  $m$  is the value of the **MARGIN=** option.

The **MARGIN=** option cannot be used in conjunction with the **SIDES=2** option. (Instead, specify an equivalence analysis by using **TEST=EQUIV\_ADJZ** or **TEST=EQUIV\_EXACT** or **TEST=EQUIV\_Z**). Also, the **MARGIN=** option cannot be used with the **CI=** option.

Values must be strictly between  $-1$  and  $1$ . In addition, the sum of **NULLPROPORTION** and **MARGIN** must be strictly between  $0$  and  $1$  for one-sided analyses, and the derived lower equivalence bound ( $2 * \text{NULLPROPORTION} - \text{MARGIN}$ ) must be strictly between  $0$  and  $1$  for equivalence analyses.

See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

#### **METHOD=EXACT**

#### **METHOD=NORMAL**

specifies the computational method. **METHOD=EXACT** (the default) computes exact results by using the binomial distribution. **METHOD=NORMAL** computes approximate results by using the normal approximation to the binomial distribution.

#### **NFRACTIONAL**

#### **NFRAC**

enables fractional input and output for sample sizes. This option is invalid when the **METHOD=EXACT** option is specified. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRAC-TIONAL** option.

#### **NTOTAL=number-list**

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

#### **NULLPROPORTION=number-list**

#### **NULLP=number-list**

specifies the null proportion. A value of  $0.5$  corresponds to the sign test. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

#### **OUTPUTORDER=INTERNAL**

#### **OUTPUTORDER=REVERSE**

#### **OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLPROPORTION=**
- **ALPHA=**
- **PROPORTION=**
- **NTOTAL=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONESAMPLEFREQ** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONESAMPLEFREQ** statement.

**POWER=number-list**

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**PROBWIDTH=number-list**

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the **HALFWIDTH=** option. A missing value (**PROBWIDTH=.**) requests a solution for this probability. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can be used only with the **CI=** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**PROPORTION=number-list**

**P=number-list**

specifies the binomial proportion—that is, the expected proportion of successes in the hypothetical binomial trial. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**SIDES=keyword-list**

specifies the number of sides (or tails) and the direction of the statistical test. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

If the effect size is zero, then **SIDES=1** is not permitted; instead, specify the direction of the test explicitly in this case with either **SIDES=L** or **SIDES=U**. The default value is 2.

**TEST**

**TEST= ADJZ**

**TEST= EQUIV\_ADJZ**

**TEST= EQUIV\_EXACT**

**TEST= EQUIV\_Z**

**TEST= EXACT**

**TEST= Z**

specifies the statistical analysis. **TEST=ADJZ** specifies a normal-approximate *z* test with continuity adjustment. **TEST=EQUIV\_ADJZ** specifies a normal-approximate two-sided equivalence test based on the *z* statistic with continuity adjustment and a TOST (two one-sided tests) procedure.

**TEST=EQUIV\_EXACT** specifies the exact binomial two-sided equivalence test based on a TOST (two one-sided tests) procedure. **TEST=EQUIV\_Z** specifies a normal-approximate two-sided equivalence test based on the  $z$  statistic without any continuity adjustment, which is the same as the chi-square statistic, and a TOST (two one-sided tests) procedure. **TEST** or **TEST=EXACT** (the default) specifies the exact binomial test. **TEST=Z** specifies a normal-approximate  $z$  test without any continuity adjustment, which is the same as the chi-square test when **SIDES=2**.

**UPPER=number-list**

specifies the upper equivalence bound for the binomial proportion. The **UPPER=** option can be used only with equivalence analyses (**TEST=EQUIV\_ADJZ** | **EQUIV\_EXACT** | **EQUIV\_Z**). Values must be strictly between 0 and 1. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**VAREST=keyword-list**

specifies how the variance is computed in the test statistic for the **TEST=Z**, **TEST=ADJZ**, **TEST=EQUIV\_Z**, and **TEST=EQUIV\_ADJZ** analyses. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *keyword-list*. Valid keywords are as follows:

**NULL** (the default) estimates the variance by using the null proportion(s) (specified by some combination of the **NULLPROPORTION=**, **MARGIN=**, **LOWER=**, and **UPPER=** options). For **TEST=Z** and **TEST=ADJZ**, the null proportion is the value of the **NULLPROPORTION=** option plus the value of the **MARGIN=** option (if it is used). For **TEST=EQUIV\_Z** and **TEST=EQUIV\_ADJZ**, there are two null proportions, corresponding to the lower and upper equivalence bounds, one for each test in the TOST (two one-sided tests) procedure.

**SAMPLE** estimates the variance by using the observed sample proportion.

This option is ignored if the analysis is one other than **TEST=Z**, **TEST=ADJZ**, **TEST=EQUIV\_Z**, or **TEST=EQUIV\_ADJZ**.

## Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the **ONESAMPLEFREQ** statement.

### Exact Test of a Binomial Proportion

The following statements demonstrate a power computation for the exact test of a binomial proportion. Defaults for the **SIDES=** and **ALPHA=** options specify a two-sided test with a 0.05 significance level.

```
proc power;
 onesamplefreq test=exact
 nullproportion = 0.2
 proportion = 0.3
 ntotal = 100
 power = .;
run;
```

**z Test**

The following statements demonstrate a sample size computation for the  $z$  test of a binomial proportion. Defaults for the `SIDES=`, `ALPHA=`, and `VAREST=` options specify a two-sided test with a 0.05 significance level that uses the null variance estimate.

```
proc power;
 onesamplefreq test=z method=normal
 nullproportion = 0.8
 proportion = 0.85
 sides = u
 ntotal = .
 power = .9;
run;
```

**z Test with Continuity Adjustment**

The following statements demonstrate a sample size computation for the  $z$  test of a binomial proportion with a continuity adjustment. Defaults for the `SIDES=`, `ALPHA=`, and `VAREST=` options specify a two-sided test with a 0.05 significance level that uses the null variance estimate.

```
proc power;
 onesamplefreq test=adjz method=normal
 nullproportion = 0.15
 proportion = 0.1
 sides = l
 ntotal = .
 power = .9;
run;
```

**Exact Equivalence Test for a Binomial Proportion**

You can specify equivalence bounds by using the `EQUIVBOUNDS=` option, as in the following statements:

```
proc power;
 onesamplefreq test=equiv_exact
 proportion = 0.35
 equivbounds = (0.2 0.4)
 ntotal = 50
 power = .;
run;
```

You can also specify the combination of `NULLPROPORTION=` and `MARGIN=` options:

```
proc power;
 onesamplefreq test=equiv_exact
 proportion = 0.35
 nullproportion = 0.3
 margin = 0.1
 ntotal = 50
 power = .;
run;
```

Finally, you can specify the combination of LOWER= and UPPER= options:

```
proc power;
 onesamplefreq test=equiv_exact
 proportion = 0.35
 lower = 0.2
 upper = 0.4
 ntotal = 50
 power = .;
run;
```

Note that the three preceding analyses are identical.

### ***Exact Noninferiority Test for a Binomial Proportion***

A noninferiority test corresponds to an upper one-sided test with a negative-valued margin, as demonstrated in the following statements:

```
proc power;
 onesamplefreq test=exact
 sides = U
 proportion = 0.15
 nullproportion = 0.1
 margin = -0.02
 ntotal = 130
 power = .;
run;
```

### ***Exact Superiority Test for a Binomial Proportion***

A superiority test corresponds to an upper one-sided test with a positive-valued margin, as demonstrated in the following statements:

```
proc power;
 onesamplefreq test=exact
 sides = U
 proportion = 0.15
 nullproportion = 0.1
 margin = 0.02
 ntotal = 130
 power = .;
run;
```

### ***Confidence Interval Precision***

The following statements performs a confidence interval precision analysis for the Wilson score-based confidence interval for a binomial proportion. The default value of the ALPHA= option specifies a confidence level of 0.95.

```
proc power;
 onesamplefreq ci=wilson
 halfwidth = 0.1
 proportion = 0.3
 ntotal = 70
 probwidth = .;
run;
```

### Restrictions on Option Combinations

To specify the equivalence bounds for `TEST=EQUIV_ADJZ`, `TEST=EQUIV_EXACT`, and `TEST=EQUIV_Z`, use any of these three option sets:

- lower and upper equivalence bounds, using the `EQUIVBOUNDS=` option
- lower and upper equivalence bounds, using the `LOWER=` and `UPPER=` options
- null proportion (`NULLPROPORTION=`) and margin (`MARGIN=`)

## ONESAMPLEMEANS Statement

**ONESAMPLEMEANS** < options > ;

The `ONESAMPLEMEANS` statement performs power and sample size analyses for *t* tests, equivalence tests, and confidence interval precision involving one sample.

### Summary of Options

Table 71.10 summarizes the options available in the `ONESAMPLEMEANS` statement.

**Table 71.10** ONESAMPLEMEANS Statement Options

| Option                              | Description                                                                |
|-------------------------------------|----------------------------------------------------------------------------|
| <b>Define analysis</b>              |                                                                            |
| <code>CI=</code>                    | Specifies an analysis of precision of the confidence interval for the mean |
| <code>DIST=</code>                  | Specifies the underlying distribution assumed for the test statistic       |
| <code>TEST=</code>                  | Specifies the statistical analysis                                         |
| <b>Specify analysis information</b> |                                                                            |
| <code>ALPHA=</code>                 | Specifies the significance level                                           |
| <code>LOWER=</code>                 | Specifies the lower equivalence bound for the mean                         |
| <code>NULLMEAN=</code>              | Specifies the null mean                                                    |
| <code>SIDES=</code>                 | Specifies the number of sides and the direction of the statistical test    |
| <code>UPPER=</code>                 | Specifies the upper equivalence bound for the mean                         |
| <b>Specify effect</b>               |                                                                            |
| <code>HALFWIDTH=</code>             | Specifies the desired confidence interval half-width                       |
| <code>MEAN=</code>                  | Specifies the mean                                                         |
| <b>Specify variability</b>          |                                                                            |
| <code>CV=</code>                    | Specifies the coefficient of variation                                     |
| <code>STDDEV=</code>                | Specifies the standard deviation                                           |
| <b>Specify sample size</b>          |                                                                            |
| <code>NFRACTIONAL</code>            | Enables fractional input and output for sample sizes                       |
| <code>NTOTAL=</code>                | Specifies the sample size                                                  |

Table 71.10 *continued*

| Option                                         | Description                                                                                                                     |
|------------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| <b>Specify power and related probabilities</b> |                                                                                                                                 |
| POWER=                                         | Specifies the desired power of the test                                                                                         |
| PROBTYPE=                                      | Specifies the type of probability for the PROBWIDTH= option                                                                     |
| PROBWIDTH=                                     | Specifies the probability of obtaining a confidence interval half-width less than or equal to the value specified by HALFWIDTH= |
| <b>Control ordering in output</b>              |                                                                                                                                 |
| OUTPUTORDER=                                   | Controls the output order of parameters                                                                                         |

Table 71.11 summarizes the valid result parameters for different analyses in the ONESAMPLEMEANS statement.

Table 71.11 Summary of Result Parameters in the ONESAMPLEMEANS Statement

| Analyses              | Solve For          | Syntax      |
|-----------------------|--------------------|-------------|
| TEST=T DIST=NORMAL    | Power              | POWER=.     |
|                       | Sample size        | NTOTAL=.    |
|                       | Alpha              | ALPHA=.     |
|                       | Mean               | MEAN=.      |
|                       | Standard Deviation | STDDEV=.    |
| TEST=T DIST=LOGNORMAL | Power              | POWER=.     |
|                       | Sample size        | NTOTAL=.    |
| TEST=EQUIV            | Power              | POWER=.     |
|                       | Sample size        | NTOTAL=.    |
| CI=T                  | Prob(width)        | PROBWIDTH=. |
|                       | Sample size        | NTOTAL=.    |

## Dictionary of Options

### ALPHA=*number-list*

specifies the level of significance of the statistical test or requests a solution for alpha with a missing value (ALPHA=.). The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. If the CI= and SIDES=1 options are used, then the value must be less than 0.5. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

### CI

#### CI=T

specifies an analysis of precision of the confidence interval for the mean. Instead of power, the relevant probability for this analysis is the probability of achieving a desired precision. Specifically, it is the probability that the half-width of the confidence interval will be at most the value specified by the HALFWIDTH= option. If neither the CI= option nor the TEST= option is used, the default is TEST=T.

**CV=number-list**

specifies the coefficient of variation, defined as the ratio of the standard deviation to the mean. You can use this option only with **DIST=LOGNORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**DIST=LOGNORMAL****DIST=NORMAL**

specifies the underlying distribution assumed for the test statistic. **NORMAL** corresponds to the normal distribution, and **LOGNORMAL** corresponds to the lognormal distribution. The default value is **NORMAL**.

**HALFWIDTH=number-list**

specifies the desired confidence interval half-width. The half-width is defined as the distance between the point estimate and a finite endpoint. This option can be used only with the **CI=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**LOWER=number-list**

specifies the lower equivalence bound for the mean. This option can be used only with the **TEST=EQUIV** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**MEAN=number-list**

specifies the mean, in the original scale, or requests a solution for the mean with a missing value (**MEAN=.**). The mean is arithmetic if **DIST=NORMAL** and geometric if **DIST=LOGNORMAL**. This option can be used only with the **TEST=T** and **TEST=EQUIV** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NFRACTIONAL****NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

**NTOTAL=number-list**

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NULLMEAN=number-list****NULLM=number-list**

specifies the null mean, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). The default value is 0 when **DIST=NORMAL** and 1 when **DIST=LOGNORMAL**. This option can be used only with the **TEST=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**OUTPUTORDER=INTERNAL****OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLMEAN=**
- **LOWER=**
- **UPPER=**
- **ALPHA=**
- **MEAN=**
- **HALFWIDTH=**
- **STDDEV=**
- **CV=**
- **NTOTAL=**
- **POWER=**
- **PROBTYPE=**
- **PROBWIDTH=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONESAMPLEMEANS** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONESAMPLEMEANS** statement.

**POWER=number-list**

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. This option can be used only with the **TEST=T** and **TEST=EQUIV** analyses. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**PROBTYPE=keyword-list**

specifies the type of probability for the **PROBWIDTH=** option. A value of **CONDITIONAL** (the default) indicates the conditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH=** option, given that the true mean is captured by the confidence interval. A value of **UNCONDITIONAL** indicates the unconditional probability that the confidence interval half-width is at most the value specified by the **HALFWIDTH=** option. You can use the alias **GIVENVALIDITY** for **CONDITIONAL**. The **PROBTYPE=** option can be used only with the **CI=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*.

**CONDITIONAL** width probability conditional on interval containing the mean

**UNCONDITIONAL** unconditional width probability

**PROBWIDTH=number-list**

specifies the desired probability of obtaining a confidence interval half-width less than or equal to the value specified by the **HALFWIDTH=** option. A missing value (**PROBWIDTH=.**) requests a solution for this probability. The type of probability is controlled with the **PROBTYPE=** option. Values are expressed as probabilities (for example, 0.9) rather than percentages. This option can be used only with the **CI=T** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**SIDES=keyword-list**

specifies the number of sides (or tails) and the direction of the statistical test or confidence interval. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords and their interpretation for the **TEST=** analyses are as follows:

- 1 one-sided with alternative hypothesis in same direction as effect
- 2 two-sided
- U upper one-sided with alternative greater than null value
- L lower one-sided with alternative less than null value

For confidence intervals, **SIDES=U** refers to an interval between the lower confidence limit and infinity, and **SIDES=L** refers to an interval between minus infinity and the upper confidence limit. For both of these cases and **SIDES=1**, the confidence interval computations are equivalent. The **SIDES=** option can be used only with the **TEST=T** and **CI=T** analyses. The default value is 2.

**STDDEV=number-list****STD=number-list**

specifies the standard deviation, or requests a solution for the standard deviation with a missing value (**STDDEV=.**). You can use this option only with **DIST=NORMAL**. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**TEST****TEST=EQUIV****TEST=T**

specifies the statistical analysis. **TEST=EQUIV** specifies an equivalence test of the mean by using a two one-sided tests (TOST) analysis (Schuirmann 1987). **TEST** or **TEST=T** (the default) specifies a *t* test on the mean. If neither the **TEST=** option nor the **CI=** option is used, the default is **TEST=T**.

**UPPER=number-list**

specifies the upper equivalence bound for the mean, in the original scale (whether **DIST=NORMAL** or **DIST=LOGNORMAL**). This option can be used only with the **TEST=EQUIV** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

## Restrictions on Option Combinations

To define the analysis, choose one of the following parameterizations:

- a statistical test (by using the `TEST=` option)
- confidence interval precision (by using the `CI=` option)

## Option Groups for Common Analyses

This section summarizes the syntax for the common analyses supported in the `ONESAMPLEMEANS` statement.

### One-Sample *t* Test

The following statements demonstrate a power computation for the one-sample *t* test. Default values for the `DIST=`, `SIDES=`, `NULLMEAN=`, and `ALPHA=` options specify a two-sided test for zero mean with a normal distribution and a significance level of 0.05.

```
proc power;
 onesamplemeans test=t
 mean = 7
 stddev = 3
 ntotal = 50
 power = .;
run;
```

### One-Sample *t* Test with Lognormal Data

The following statements demonstrate a sample size computation for the one-sample *t* test for lognormal data. Default values for the `SIDES=`, `NULLMEAN=`, and `ALPHA=` options specify a two-sided test for unit mean with a significance level of 0.05.

```
proc power;
 onesamplemeans test=t dist=lognormal
 mean = 7
 cv = 0.8
 ntotal = .
 power = 0.9;
run;
```

### Equivalence Test for Mean of Normal Data

The following statements demonstrate a power computation for the TOST equivalence test for a normal mean. Default values for the `DIST=` and `ALPHA=` options specify a normal distribution and a significance level of 0.05.

```
proc power;
 onesamplemeans test=equiv
 lower = 2
 upper = 7
 mean = 4
 stddev = 3
 ntotal = 100
 power = .;
run;
```

**Equivalence Test for Mean of Lognormal Data**

The following statements demonstrate a sample size computation for the TOST equivalence test for a log-normal mean. The default of `ALPHA=0.05` specifies a significance level of 0.05.

```
proc power;
 onesamplemeans test=equiv dist=lognormal
 lower = 1
 upper = 5
 mean = 3
 cv = 0.6
 ntotal = .
 power = 0.85;
run;
```

**Confidence Interval for Mean**

By default `CI=T` analyzes the conditional probability of obtaining the desired precision, given that the interval contains the true mean, as in the following statements. The defaults of `SIDES=2` and `ALPHA=0.05` specify a two-sided interval with a confidence level of 0.95.

```
proc power;
 onesamplemeans ci = t
 halfwidth = 14
 stddev = 8
 ntotal = 50
 probwidth = .;
run;
```

---

**ONEWAYANOVA Statement**

**ONEWAYANOVA** < options > ;

The **ONEWAYANOVA** statement performs power and sample size analyses for one-degree-of-freedom contrasts and the overall *F* test in one-way analysis of variance.

**Summary of Options**

Table 71.12 summarizes the options available in the **ONEWAYANOVA** statement.

**Table 71.12** ONEWAYANOVA Statement Options

| Option                              | Description                                                             |
|-------------------------------------|-------------------------------------------------------------------------|
| <b>Define analysis</b>              |                                                                         |
| <code>TEST=</code>                  | Specifies the statistical analysis                                      |
| <b>Specify analysis information</b> |                                                                         |
| <code>ALPHA=</code>                 | Specifies the significance level                                        |
| <code>CONTRAST=</code>              | Specifies coefficients for single-degree-of-freedom hypothesis tests    |
| <code>NULLCONTRAST=</code>          | Specifies the null value of the contrast                                |
| <code>SIDES=</code>                 | Specifies the number of sides and the direction of the statistical test |

Table 71.12 continued

| Option                                    | Description                                                 |
|-------------------------------------------|-------------------------------------------------------------|
| <b>Specify effect</b>                     |                                                             |
| GROUPMEANS=                               | Specifies the group means                                   |
| <b>Specify variability</b>                |                                                             |
| STDDEV=                                   | Specifies the error standard deviation                      |
| <b>Specify sample size and allocation</b> |                                                             |
| GROUPNS=                                  | Specifies the group sample sizes                            |
| GROUPWEIGHTS=                             | Specifies the sample size allocation weights for the groups |
| NFRACTIONAL                               | Enables fractional input and output for sample sizes        |
| NPERGROUP=                                | Specifies the common sample size per group                  |
| NTOTAL=                                   | Specifies the sample size                                   |
| <b>Specify power</b>                      |                                                             |
| POWER=                                    | Specifies the desired power of the test                     |
| <b>Control ordering in output</b>         |                                                             |
| OUTPUTORDER=                              | Controls the output order of parameters                     |

Table 71.13 summarizes the valid result parameters for different analyses in the `ONEWAYANOVA` statement.

Table 71.13 Summary of Result Parameters in the `ONEWAYANOVA` Statement

| Analyses      | Solve For   | Syntax                   |
|---------------|-------------|--------------------------|
| TEST=CONTRAST | Power       | POWER=.                  |
|               | Sample size | NTOTAL=.<br>NPERGROUP==. |
| TEST=OVERALL  | Power       | POWER=.                  |
|               | Sample size | NTOTAL=.<br>NPERGROUP==. |

## Dictionary of Options

### **ALPHA=***number-list*

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

### **CONTRAST=** ( *values* ) < ( ... *values* ) >

specifies coefficients for single-degree-of-freedom hypothesis tests. You must provide a coefficient for every mean appearing in the `GROUPMEANS=` option. Specify multiple contrasts either with additional sets of coefficients or with additional `CONTRAST=` options. For example, you can specify two different contrasts of five means by using the following:

```
CONTRAST = (1 -1 0 0 0) (1 0 -1 0 0)
```

**GROUPMEANS**=*grouped-number-list*

**GMEANS**=*grouped-number-list*

specifies the group means. This option is used to implicitly set the number of groups. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

**GROUPNS**=*grouped-number-list*

**GNS**=*grouped-number-list*

specifies the group sample sizes. The number of groups represented must be the same as with the **GROUPMEANS**= option. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

**GROUPWEIGHTS**=*grouped-number-list*

**GWEIGHTS**=*grouped-number-list*

specifies the sample size allocation weights for the groups. This option controls how the total sample size is divided between the groups. Each set of values across all groups represents relative allocation weights. Additionally, if the **NFRACTIONAL** option is not used, the total sample size is restricted to be equal to a multiple of the sum of the group weights (so that the resulting design has an integer sample size for each group while adhering exactly to the group allocation weights). The number of groups represented must be the same as with the **GROUPMEANS**= option. Values must be integers unless the **NFRACTIONAL** option is used. The default value is 1 for each group, amounting to a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

**NFRACTIONAL**

**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option.

**NPERGROUP**=*number-list*

**NPERG**=*number-list*

specifies the common sample size per group or requests a solution for the common sample size per group with a missing value (**NPERGROUP**=.). Use of this option implicitly specifies a balanced design. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NTOTAL**=*number-list*

specifies the sample size or requests a solution for the sample size with a missing value (**NTOTAL**=.). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NULLCONTRAST**=*number-list*

**NULLC**=*number-list*

specifies the null value of the contrast. The default value is 0. This option can be used only with the **TEST=CONTRAST** analysis. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**OUTPUTORDER=INTERNAL****OUTPUTORDER=REVERSE****OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **CONTRAST=**
- **SIDES=**
- **NULLCONTRAST=**
- **ALPHA=**
- **GROUPMEANS=**
- **STDDEV=**
- **GROUPWEIGHTS=**
- **NTOTAL=**
- **NPERGROUP==**
- **GROUPNS=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **ONEWAYANOVA** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **ONEWAYANOVA** statement.

**POWER=number-list**

specifies the desired power of the test or requests a solution for the power with a missing value (**POWER=.**). The power is expressed as a probability, a number between 0 and 1, rather than as a percentage. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**SIDES=keyword-list**

specifies the number of sides (or tails) and the direction of the statistical test. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *keyword-list*. Valid keywords are as follows:

- |   |                                                                   |
|---|-------------------------------------------------------------------|
| 1 | one-sided with alternative hypothesis in same direction as effect |
| 2 | two-sided                                                         |
| U | upper one-sided with alternative greater than null value          |
| L | lower one-sided with alternative less than null value             |

This option can be used only with the **TEST=CONTRAST** analysis. The default value is 2.

**STDDEV=number-list****STD=number-list**

specifies the error standard deviation. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**TEST=CONTRAST****TEST=OVERALL**

specifies the statistical analysis. **TEST=CONTRAST** specifies a one-degree-of-freedom test of a contrast of means. The test is the usual  $F$  test for the two-sided case and the usual  $t$  test for the one-sided case. **TEST=OVERALL** specifies the overall  $F$  test of equality of all means. The default is **TEST=CONTRAST** if the **CONTRAST=** option is used, and **TEST=OVERALL** otherwise.

**Restrictions on Option Combinations**

To specify the sample size and allocation, choose one of the following parameterizations:

- sample size per group in a balanced design (by using the **NPERGROUP==** option)
- total sample size and allocation weights (by using the **NTOTAL=** and **GROUPWEIGHTS=** options)
- individual group sample sizes (by using the **GROUPNS=** option)

**Option Groups for Common Analyses**

This section summarizes the syntax for the common analyses supported in the **ONEWAYANOVA** statement.

**One-Degree-of-Freedom Contrast**

You can use the **NPERGROUP==** option in a balanced design, as in the following statements. Default values for the **SIDES=**, **NULLCONTRAST=**, and **ALPHA=** options specify a two-sided test for a contrast value of 0 with a significance level of 0.05.

```
proc power;
 onewayanova test=contrast
 contrast = (1 0 -1)
 groupmeans = 3 | 7 | 8
 stddev = 4
 npergroup = 50
 power = .;
run;
```

You can also specify an unbalanced design with the **NTOTAL=** and **GROUPWEIGHTS=** options:

```
proc power;
 onewayanova test=contrast
 contrast = (1 0 -1)
 groupmeans = 3 | 7 | 8
 stddev = 4
 groupweights = (1 2 2)
 ntotal = .
 power = 0.9;
run;
```

Another way to specify the sample sizes is with the `GROUPNS=` option:

```
proc power;
 onewayanova test=contrast
 contrast = (1 0 -1)
 groupmeans = 3 | 7 | 8
 stddev = 4
 groupns = (20 40 40)
 power = .;
run;
```

### Overall F Test

The following statements demonstrate a power computation for the overall F test in a one-way ANOVA. The default of `ALPHA=0.05` specifies a significance level of 0.05.

```
proc power;
 onewayanova test=overall
 groupmeans = 3 | 7 | 8
 stddev = 4
 npergroup = 50
 power = .;
run;
```

---

## PAIREDFREQ Statement

`PAIREDFREQ <options>;`

The `PAIREDFREQ` statement performs power and sample size analyses for McNemar's test for paired proportions.

### Summary of Options

Table 71.14 summarizes the options available in the `PAIREDFREQ` statement.

**Table 71.14** PAIREDFREQ Statement Options

| Option                              | Description                                                                                    |
|-------------------------------------|------------------------------------------------------------------------------------------------|
| <b>Define analysis</b>              |                                                                                                |
| <code>DIST=</code>                  | Specifies the underlying distribution assumed for the test statistic                           |
| <code>TEST=</code>                  | Specifies the statistical analysis                                                             |
| <b>Specify analysis information</b> |                                                                                                |
| <code>ALPHA=</code>                 | Specifies the significance level                                                               |
| <code>NULLDISCPRORATIO=</code>      | Specifies the null value of the ratio of discordant proportions                                |
| <code>SIDES=</code>                 | Specifies the number of sides and the direction of the statistical test or confidence interval |
| <b>Specify effects</b>              |                                                                                                |
| <code>CORR=</code>                  | Specifies the correlation $\phi$ between members of a pair                                     |
| <code>DISCPROPDIFF=</code>          | Specifies the discordant proportion difference $p_{01} - p_{10}$                               |
| <code>DISCPROPORTIONS=</code>       | Specifies the two discordant proportions, $p_{10}$ and $p_{01}$                                |

**Table 71.14** *continued*

| Option                             | Description                                                                                                   |
|------------------------------------|---------------------------------------------------------------------------------------------------------------|
| DISCPRORATIO=                      | Specifies the ratio $p_{01}/p_{10}$                                                                           |
| ODDSRATIO=                         | Specifies the odds ratio $[p_{\cdot 1}/(1 - p_{\cdot 1})] / [p_{1 \cdot}/(1 - p_{1 \cdot})]$                  |
| PAIREDPROPORTIONS=                 | Specifies the two paired proportions, $p_{1 \cdot}$ and $p_{\cdot 1}$                                         |
| PROPORTIONDIFF=                    | Specifies the proportion difference $p_{\cdot 1} - p_{1 \cdot}$ .                                             |
| REFPROPORTION=                     | Specifies either the reference first proportion $p_{1 \cdot}$ or the reference discordant proportion $p_{10}$ |
| RELATIVERISK=                      | Specifies the relative risk $p_{\cdot 1}/p_{1 \cdot}$ .                                                       |
| TOTALPROPDISC=                     | Specifies the discordant proportion sum, $p_{10} + p_{01}$                                                    |
| <b>Specify sample size</b>         |                                                                                                               |
| NFRACTIONAL                        | Enables fractional input and output for sample sizes                                                          |
| NPAIRS=                            | Specifies the total number of proportion pairs                                                                |
| <b>Specify power</b>               |                                                                                                               |
| POWER=                             | Specifies the desired power of the test                                                                       |
| <b>Choose computational method</b> |                                                                                                               |
| METHOD=                            | Specifies the computational method                                                                            |
| <b>Control ordering in output</b>  |                                                                                                               |
| OUTPUTORDER=                       | Controls the output order of parameters                                                                       |

Table 71.15 summarizes the valid result parameters in the PAIREFREQ statement.

**Table 71.15** Summary of Result Parameters in the PAIREFREQ Statement

| Analyses                      | Solve For            | Syntax              |
|-------------------------------|----------------------|---------------------|
| TEST=MCNEMAR METHOD=CONNOR    | Power<br>Sample size | POWER=.<br>NPAIRS=. |
| TEST=MCNEMAR METHOD=EXACT     | Power                | POWER=.             |
| TEST=MCNEMAR METHOD=MIETTINEN | Power<br>Sample size | POWER=.<br>NPAIRS=. |

## Dictionary of Options

**ALPHA=number-list**

specifies the level of significance of the statistical test. The default is 0.05, corresponding to the usual  $0.05 \times 100\% = 5\%$  level of significance. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**CORR=number-list**

specifies the correlation  $\phi$  between members of a pair. See the section “Specifying Value Lists in Analysis Statements” on page 6020 for information about specifying the *number-list*.

**DISCPRORPORTIONS**=*grouped-number-list*

**DISCPS**=*grouped-number-list*

specifies the two discordant proportions,  $p_{10}$  and  $p_{01}$ . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

**DISCPRPDIFF**=*number-list*

**DISCPDIFF**=*number-list*

specifies the difference  $p_{01} - p_{10}$  between discordant proportions. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**DISCPRPRATIO**=*number-list*

**DISCPRATIO**=*number-list*

specifies the ratio  $p_{01}/p_{10}$  of discordant proportions. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**DIST=EXACT\_COND**

**DIST=NORMAL**

specifies the underlying distribution assumed for the test statistic. **EXACT\_COND** corresponds to the exact conditional test, based on the exact binomial distribution of the two types of discordant pairs given the total number of discordant pairs. **NORMAL** corresponds to the conditional test based on the normal approximation to the binomial distribution of the two types of discordant pairs given the total number of discordant pairs. The default value is **EXACT\_COND**.

**METHOD=CONNOR**

**METHOD=EXACT**

**METHOD=MIETTINEN**

specifies the computational method. **METHOD=EXACT** (the default) uses the exact binomial distributions of the total number of discordant pairs and the two types of discordant pairs. **METHOD=CONNOR** uses an approximation from Connor (1987), and **METHOD=MIETTINEN** uses an approximation from Miettinen (1968). The **CONNOR** and **MIETTINEN** methods are valid only for **DIST=NORMAL**.

**NFRACTIONAL**

**NFRAC**

enables fractional input and output for sample sizes. See the section “[Sample Size Adjustment Options](#)” on page 6023 for information about the ramifications of the presence (and absence) of the **NFRACTIONAL** option. This option cannot be used with **METHOD=EXACT**.

**NPAIRS**=*number-list*

specifies the total number of proportion pairs (concordant and discordant) or requests a solution for the number of pairs with a missing value (**NPAIRS=.**). See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**NULLDISCPRORATIO=***number-list*

**NULLDISCRATIO=***number-list*

**NULLRATIO=***number-list*

**NULLR=***number-list*

specifies the null value of the ratio of discordant proportions. The default value is 1. See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**ODDSRATIO=***number-list*

**OR=***number-list*

specifies the odds ratio  $[p_{.1}/(1 - p_{.1})] / [p_{1.}/(1 - p_{1.})]$ . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *number-list*.

**OUTPUTORDER=INTERNAL**

**OUTPUTORDER=REVERSE**

**OUTPUTORDER=SYNTAX**

controls how the input and default analysis parameters are ordered in the output. **OUTPUTORDER=INTERNAL** (the default) arranges the parameters in the output according to the following order of their corresponding options:

- **SIDES=**
- **NULLDISCPRORATIO=**
- **ALPHA=**
- **PAIREDPROPORTIONS=**
- **PROPORTIONDIFF=**
- **ODDSRATIO=**
- **RELATIVERISK=**
- **CORR=**
- **DISCPROPORTIONS=**
- **DISCPROPDIFF=**
- **TOTALPROPDISC=**
- **REFPROPORTION=**
- **DISCPRORATIO=**
- **NPAIRS=**
- **POWER=**

The **OUTPUTORDER=SYNTAX** option arranges the parameters in the output in the same order in which their corresponding options are specified in the **PAIREDFREQ** statement. The **OUTPUTORDER=REVERSE** option arranges the parameters in the output in the reverse of the order in which their corresponding options are specified in the **PAIREDFREQ** statement.

**PAIREDPROPORTIONS=***grouped-number-list*

**PPROPORTIONS=***grouped-number-list*

**PAIREDPS=***grouped-number-list*

**PPS=***grouped-number-list*

specifies the two paired proportions,  $p_{1.}$  and  $p_{.1}$ . See the section “[Specifying Value Lists in Analysis Statements](#)” on page 6020 for information about specifying the *grouped-number-list*.

**POWER=***number-list*
