Missing data are allowed in the response variables; the MODEL statement augments missing data automatically. (In releases before SAS/STAT 12.1, observations with missing values were discarded prior to analysis and PROC MCMC did not attempt to model these values.) In each iteration, PROC MCMC samples missing values from their posterior distributions and incorporates them as part of the simulation. PROC MCMC creates one variable for each missing response value. There are two ways to create the missing value variable names; see the [NAMESUFFIX=](#) option for the naming convention of the variables.

## Distributions in MODEL Statement

Standard distributions that the MODEL statement supports are listed in the [Table 55.2](#) (univariate) and [Table 55.3](#) (multivariate). See the section “[Standard Distributions](#)” on page 4476 for density specifications. You can also specify all distributions except the multinomial distribution in the [PRIOR](#) and [HYPERPRIOR](#) statements. The [RANDOM](#) statement supports only a subset of the distributions (see [Table 55.4](#)).

PROC MCMC allows some distributions to be parameterized in multiple ways. For example, you can specify a normal distribution with a variance, standard deviation, or precision parameter. For distributions that have different parameterizations, you must specify an option to clearly name the ambiguous parameter. For example, in the normal distribution, you must indicate whether the second argument represents variance, standard deviation, or precision.

All univariate distributions, with the exception of binary and uniform, can have the optional LOWER= and UPPER= arguments, which specify a truncated density. See the section “[Truncation and Censoring](#)” on page 4494 for more details. Truncation is not supported for multivariate distributions.

**Table 55.2** Univariate Distributions

| Distribution Name                                                                 | Definition                                                                                                                 |
|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>beta</b> ( $\langle \mathbf{a} = \alpha, \langle \mathbf{b} = \beta \rangle$ ) | Beta distribution with shape parameters $\alpha$ and $\beta$                                                               |
| <b>binary</b> ( $\langle \mathbf{prob p} = p \rangle$ )                           | Binary (Bernoulli) distribution with probability of success $p$ . You can use the alias <b>bern</b> for this distribution. |
| <b>binomial</b> ( $\langle \mathbf{n} = n, \langle \mathbf{prob p} = p \rangle$ ) | Binomial distribution with count $n$ and probability of success $p$                                                        |

Table 55.2 (continued)

| Distribution Name                                                                                                      | Definition                                                                                                                                                                                                                                                                         |
|------------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>cauchy</b> (<location loc = > $\theta$ , <scale s = > $\lambda$ )                                                   | Cauchy distribution with location $\theta$ and scale $\lambda$                                                                                                                                                                                                                     |
| <b>chisq</b> (<df=> $\nu$ )                                                                                            | $\chi^2$ distribution with $\nu$ degrees of freedom                                                                                                                                                                                                                                |
| <b>dgeneral</b> (//)                                                                                                   | General log-likelihood function that you construct using SAS programming statements for single or multiple discrete parameters. Also see the function <b>general</b> . The name <b>dlogden</b> is an alias for this function.                                                      |
| <b>expchisq</b> (<df=> $\nu$ )                                                                                         | Log transformation of a $\chi^2$ distribution with $\nu$ degrees of freedom: $\theta \sim \mathbf{chisq}(\nu) \Leftrightarrow \log(\theta) \sim \mathbf{expchisq}(\nu)$ . You can use the alias <b>echisq</b> for this distribution.                                               |
| <b>expexpon</b> (scale s= $\lambda$ )<br><b>expexpon</b> (iscale is= $\lambda$ )                                       | Log transformation of an exponential distribution with scale or inverse-scale parameter $\lambda$ : $\theta \sim \mathbf{expon}(\lambda) \Leftrightarrow \log(\theta) \sim \mathbf{expexpon}(\lambda)$ . You can use the alias <b>eexpon</b> for this distribution.                |
| <b>expGamma</b> (<shape sp=> $a$ , scale s= $\lambda$ )<br><b>expGamma</b> (<shape sp=> $a$ , iscale is= $\lambda$ )   | Log transformation of a gamma distribution with shape $a$ and scale or inverse-scale $\lambda$ : $\theta \sim \mathbf{gamma}(a, \lambda) \Leftrightarrow \log(\theta) \sim \mathbf{expgamma}(a, \lambda)$ . You can use the alias <b>egamma</b> for this distribution.             |
| <b>expichisq</b> (<df=> $\nu$ )                                                                                        | Log transformation of an inverse $\chi^2$ distribution with $\nu$ degrees of freedom: $\theta \sim \mathbf{ichisq}(\nu) \Leftrightarrow \log(\theta) \sim \mathbf{expichisq}(\nu)$ . You can use the alias <b>eichisq</b> for this distribution.                                   |
| <b>expiGamma</b> (<shape sp=> $a$ , scale s= $\lambda$ )<br><b>expiGamma</b> (<shape sp=> $a$ , iscale is= $\lambda$ ) | Log transformation of an inverse-gamma distribution with shape $a$ and scale or inverse-scale $\lambda$ : $\theta \sim \mathbf{igamma}(a, \lambda) \Leftrightarrow \log(\theta) \sim \mathbf{expigamma}(a, \lambda)$ . You can use the alias <b>eigamma</b> for this distribution. |
| <b>expsichisq</b> (<df=> $\nu$ , <scale s=> $s$ )                                                                      | Log transformation of a scaled inverse $\chi^2$ distribution with $\nu$ degrees of freedom and scale parameter $s$ : $\theta \sim \mathbf{sichisq}(\nu) \Leftrightarrow \log(\theta) \sim \mathbf{expsichisq}(\nu)$ . You can use the alias <b>esichisq</b> for this distribution. |
| <b>expon</b> (scale s= $\lambda$ )<br><b>expon</b> (iscale is= $\lambda$ )                                             | Exponential distribution with scale or inverse-scale parameter $\lambda$                                                                                                                                                                                                           |
| <b>gamma</b> (<shape sp=> $a$ , scale s= $\lambda$ )<br><b>gamma</b> (<shape sp=> $a$ , iscale is= $\lambda$ )         | Gamma distribution with shape $a$ and scale or inverse-scale $\lambda$                                                                                                                                                                                                             |

Table 55.2 (continued)

| Distribution Name                                                                                                                                                                                                                                                                     | Definition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

The covariance matrix $\Sigma$ is a multiple of the scale and a matrix with a first-order autoregressive structure. When <b>rho=0</b> , this distribution becomes a multivariate normal distribution with shared variance. |
| <b>multinom</b> ( <code>&lt;p=&gt; <math>p</math></code> )                                                                                                                                                                                                                                                                                                                                      | Multinomial distribution with probability vector $p$                                                                                                                                                                                                                                                                  |

## Options for the MODEL Statement

The *options* in the MODEL statement apply only when there are missing values in the response variable. You can specify the following options:

### **INITIAL**=*SAS-data-set* | *constant* | *numeric-list*

specifies the initial values of the missing values. By default, PROC MCMC uses a sample average of the nonmissing values of a response variable as the starting values for all missing values in the simulation for that variable. You can use the INITIAL= option to start the Markov chain at a different place.

If you use a *SAS-data-set* to store initial values, the data set must consist of variable names that agree with the missing variable names that are used by PROC MCMC. The easiest way to find the names of the internally created variables is to run a default analysis with a very small number of simulations and check the variable names in the **OUTPOST**= data set. You can provide a subset of the initial values in the *SAS-data-set*, and PROC MCMC uses a default mechanism to fill in the rest of the missing initial values.

For example, the following statement creates a data set with initial values for the first three missing values of a response variable:

```
data RandomInit;
 input y_1 y_2 y_3;
 datalines;
 2.3 3 -3
;
```

The following MODEL statement uses the values in the RandomInit data set as the initial values of the corresponding missing values in the model:

```
model y ~ normal(0, var=s2u) init=randominit;
```

Specifying a *constant* assigns that constant as the initial value to all missing values in that response variable. For example, the following statement assigns the value 5 to be used as an initial value for all missing  $y_i$  in the model:

```
model y ~ normal(0, var=s2u) init=5;
```

If you have a multidimensional response variable, you can provide a list of numbers that have the same length as the dimension of your response array. Each number is then given to all corresponding missing variables in order. For example, the following statement assigns the value 2 to be used as an initial value for all missing  $w_{1i}$  and the value 3 to be used for all missing  $w_{2i}$  in the model:

```
array w[2] w1 w2;
model w ~ mvn(mu, cov) init=(2 3);
```

### **MONITOR**=(*symbol-list* | *number-list* | **RANDOM**(*number*))

outputs analysis for selected missing data variables. You can choose to monitor the missing values by listing the response variable names, the missing data variable names, or indices, or you can have them randomly selected by PROC MCMC.

For example, suppose that the data set contains 10 observations and the response variable  $y$  has missing values in observations 2, 3, 7, 9, and 10. To monitor all missing data variables (five in total), you specify the response variable name in the `MONITOR=` option:

```
model y ~ normal(0, var=s2u) monitor=(y);
```

Suppose you want to monitor the missing data variables that correspond to the missing values in observations 2, 3, and 10. You have two options: provide either a list of variable names or a list of indices.

The following statement selects monitored variables by their variable names:

```
model y ~ normal(0, var=s2u) monitor=(y_2 y_3 y_10);
```

The variable names must match the internally created variable names for each missing value. See `NAMESUFFIX=` option for the naming convention of the variables. By default, the names are created by concatenating the response variable with the observation index; hence you use the `name_obs` format to construct the names. The numbers 2, 3, and 10 are the corresponding observation indices to the missing values in the input data set.

The following statement selects monitored variables by indices:

```
model y ~ normal(0, var=s2u) monitor=(1 2 5);
```

The indices are not a list of the observation numbers, but rather the order by which the missing values appear in the data set: PROC MCMC reports back the first, the second, and the fifth missing value variables that it creates. The actual variable names that appear in the output are still `y_2`, `y_3`, and `y_10`, honoring the control of the `NAMESUFFIX=` option.

Lastly, PROC MCMC can randomly choose a subset of the variables to monitor. The following statement randomly selects 3 variables to monitor:

```
model y ~ normal(0, var=s2u) monitor=(random(3));
```

The list of the random indices is controlled by the `SEED=` option in the PROC MCMC statement. Therefore, the selected variables will be the same when the `SEED=` option is the same.

### **NAMESUFFIX=OBSERVATION | POSITION | ORDER**

specifies how the names of the missing data variables are created. By default, the names are created by concatenating the response variable symbol, an underscore (“\_”), and the observation number of the missing value.

`NAMESUFFIX=OBSERVATION` constructs the parameter names by appending the observation number to the response variable symbol. This is the default. `NAMESUFFIX=POSITION` or `NAMESUFFIX=ORDER` construct the parameter names by appending the numbers 1, 2, 3, and so on, where the number indicates the order in which the missing values appear in the data set.

For example, suppose you have a response variable  $y$  with 10 observations in total, of which five are missing (observations 2, 3, 7, 9, and 10). By default, PROC MCMC creates five variable names `y_2`, `y_3`, `y_7`, `y_9`, and `y_10`. Using `NAMESUFFIX=POSITION` changes the names to `y_1`, `y_2`, `y_3`, `y_4`, and `y_5`.

## NOOUTPOST

suppresses the output of the posterior samples of missing data variables to the posterior output data set (which is specified in the **OUTPOST=** option in the PROC MCMC statement). In models with a large number of missing values (for example, tens of thousands), PROC MCMC can run faster if it does not save the posterior samples.

When you specify both the NOOUTPOST option and the **MONITOR=** option, PROC MCMC outputs the list of variables that are monitored.

The maximum number of variables that can be saved to an **OUTPOST=** data set is 32,767. If the total number of parameters in your model, including the number of missing data variables, exceeds the limit, the NOOUTPOST option is evoked automatically and PROC MCMC does not save the missing value draws to the posterior output data set. You can use the **MONITOR=** option to select a subset of the parameters to store in the **OUTPOST=** data set.

---

## PARMS Statement

```
PARMS name |(name-list)<=> <{> number | number-list <}>
 < name |(name-list)<=> <{> number | number-list <}> ... >
 </ options> ;
```

The PARS statement lists the names of the parameters in the model and specifies optional initial values for these parameters. These parameters are referred to as the *model parameters*. You can specify multiple PARS statements. Each PARS statement defines a block of parameters, and the blocked Metropolis algorithm updates the parameters in each block simultaneously. See the section “Blocking of Parameters” on page 4466 for more details. PROC MCMC generates missing initial values from the prior distributions whenever needed, as long as they are the standard distributions and not the **GENERAL** or **DGENERAL** function.

If your model contains a multidimensional parameter (for example, a parameter with a multivariate normal prior distribution), you must declare the parameter as an array (using the **ARRAY** statement). You can use braces { } after the parameter name in the PARM statement to assign initial values. For example:

```
array mu[3];
parms mu {1 2 3};
```

You cannot use the **ARRAY** statement to assign initial values. If you use the **ARRAY** statement to store values in array elements, the declared array becomes a constant array and cannot be used as parameters in the PARS statement. For example, the following statement assigns three numbers to mu:

```
array mu[3] (1 2 3);
```

The array mu can no longer be a model parameter.

Every parameter in the PARS statement must have a corresponding prior distribution in the PRIOR statement. The program exits if this one-to-one requirement is not satisfied.

You can specify the following *options* to control different samplers explicitly for that block of parameters.

**NORMAL | N**

uses the normal proposal distribution in the random walk Metropolis. This is the default.

**T <(df)>**

uses the t distribution with  $df$  degrees of freedom as an alternative proposal distribution. A t distribution with a small number of degrees of freedom has thicker tails and can sometimes improve the mixing of the Markov chain. When  $df > 100$ , the normal distribution is used instead.

**SLICE**

applies the slice sampler to each parameter in the PARMS statement individually. See the section “[Slice Sampler](#)” on page 136 for details. PROC MCMC does not implement a multidimensional version of the slice sampler. Because the slice sampler usually requires multiple evaluations of the objective function (the posterior distribution) in each iteration, the associated computational cost could be potentially high with this sampling algorithm.

**UDS**

implements a user-defined sampler for any of the parameters in the block. See the section “[UDS Statement](#)” on page 4462 for details and “[Example 55.19: Implement a New Sampling Algorithm](#)” on page 4645 for a realistic example. When you specify the UDS option, PROC MCMC hands off the sampling of these parameters to you at each iteration and relies on your sampler to return a random draw from the conditional posterior distribution. This option is useful if you have a model-specific sampler that you want to implement or a new algorithm that can improve the convergence and mixing of the Markov chain. This functionality is for advanced users, and you should proceed with caution.

---

## PREDDIST Statement

**PREDDIST** < *label* > **OUTPRED**=*SAS-data-set* < **NSIM**=*n* > < **COVARIATES**=*SAS-data-set* >  
< **STATISTICS**=*options* > ;

The PREDDIST statement creates a new SAS data set that contains random samples from the posterior predictive distribution of the response variable. The posterior predictive distribution is the distribution of unobserved observations (prediction) conditional on the observed data. Let  $\mathbf{y}$  be the observed data,  $\mathbf{X}$  be the covariates,  $\theta$  be the parameter, and  $\mathbf{y}_{\text{pred}}$  be the unobserved data. The posterior predictive distribution is defined to be the following:

$$\begin{aligned} p(\mathbf{y}_{\text{pred}}|\mathbf{y}, \mathbf{X}) &= \int p(\mathbf{y}_{\text{pred}}, \theta|\mathbf{y}, \mathbf{X})d\theta \\ &= \int p(\mathbf{y}_{\text{pred}}|\theta, \mathbf{y}, \mathbf{X})p(\theta|\mathbf{y}, \mathbf{X})d\theta \end{aligned}$$

Given the assumption that the observed and unobserved data are conditional independent given  $\theta$ , the posterior predictive distribution can be further simplified as the following:

$$p(\mathbf{y}_{\text{pred}}|\mathbf{y}, \mathbf{X}) = \int p(\mathbf{y}_{\text{pred}}|\theta)p(\theta|\mathbf{y}, \mathbf{X})d\theta$$

The posterior predictive distribution is an integral of the likelihood function  $p(y_{\text{pred}}|\theta)$  with respect to the posterior distribution  $p(\theta|y)$ . The PREDDIST statement generates samples from a posterior predictive distribution based on draws from the posterior distribution of  $\theta$ .

The PREDDIST statement works only on response variables that have standard distributions, and it does not support either the GENERAL or DGENERAL functions. Multiple PREDDIST statements can be specified, and an optional label (specified as a quoted string) helps identify the output.

The following list explains specifications in the PREDDIST statement:

**COVARIATES=***SAS-data-set*

names the SAS data set that contains the sets of explanatory variable values for which the predictions are established. This data set must contain data with the same variable names as are used in the likelihood function. If you omit the COVARIATES= option, the DATA= data set specified in the PROC MCMC statement is used instead.

**NSIM=***n*

specifies the number of simulated predicted values. By default, NSIM= uses the NMC= option value specified in the PROC MCMC statement.

**OUTPRED=***SAS-data-set*

creates an output data set to contain the samples from the posterior predictive distribution. The output variable names are listed as *resp\_1*–*resp\_m*, where *resp* is the name of the response variable and *m* is the number of observations in the COVARIATES= data set in the PREDDIST statement. If the COVARIATES= data set is not specified, *m* is the number of observations in the DATA= data set specified in the PROC statement.

**STATISTICS**< (*global-stats-options*) > = **NONE** | **ALL** | *stats-request*

**STATS**< (*global-stats-options*) > = **NONE** | **ALL** | *stats-request*

specifies options for calculating posterior statistics. This option works identically to the STATISTICS= option in the PROC statement. By default, this option takes the specification of the STATISTICS= option in the PROC MCMC statement.

For an example that uses the PREDDIST statement, see “[Posterior Predictive Distribution](#)” on page 4514.

---

## PRIOR/HYPERPRIOR Statement

**PRIOR** *parameter-list* ~ *distribution* ;

**HYPERPRIOR** *parameter-list* ~ *distribution* ;

**HYPER** *parameter-list* ~ *distribution* ;

The PRIOR statement specifies the prior distribution of the model parameters. You must specify a single parameter or a list of parameters, a tilde ~, and then a distribution with its parameters.

You can specify multiple **PRIOR** statements to define models with multiple prior components. Your model can have as many hierarchical levels as you want. But in many cases, such as random-effects models, it is better to use the **RANDOM** statements to build up the model hierarchy. The log of the prior is the sum of the log prior values from each of the **PRIOR** statements. Similar to the **MODEL** statement, you can use the **PRIOR** statement to specify marginal or conditional prior distributions. See the section “**MODEL Statement**” on page 4443 for the names of the standard distributions and the section “**Standard Distributions**” on page 4476 for density specification.

The **PRIOR** statements are processed twice at every Markov chain simulation—that is, twice per pass through the data set. The statements are called at the first and the last observation of the data set, just as the **BEGINNODATA** and **ENDNODATA** statements are processed. If you run a Monte Carlo simulation that is data-independent, you can specify the **NOLOGDIST** option in the **PROC MCMC** statement to omit the calculation of the prior distribution. Omitting this calculation enables **PROC MCMC** to run faster.

The **HYPERPRIOR** statement is treated internally the same as the **PRIOR** statement. It provides a notational convenience in case you want to fit a multilevel hierarchical model. It specifies the hyperprior distribution of the prior distribution parameters. The log of the hyperprior is the sum of the log hyperprior values from each of the **HYPERPRIOR** statements.

Parameters in the **PRIOR** statements can appear as hyperparameters in the **RANDOM** statement. The reverse is not allowed: random-effects parameters cannot be hyperparameters in a **PRIOR** statement.

You can have a program that contains a **RANDOM** statement but no **PRIOR** statements. (In SAS 9.3 and earlier, each program had to contain a **PRIOR** statement.) A program that contains a **RANDOM** statement but no **PRIOR** statements could be a random-effects model with no fixed-effects parameters or hyperparameters to the random effects. A **MODEL** statement is still required in every program.

---

## Programming Statements

This section lists the programming statements available in **PROC MCMC** to compute the priors and log-likelihood functions. This section also documents the differences between programming statements in **PROC MCMC** and programming statements in the **DATA** step. The syntax of programming statements used in **PROC MCMC** is identical to that used in the **NLMIXED** procedure (see Chapter 64, “**The NLMIXED Procedure**”) and the **MODEL** procedure (see Chapter 19, “**The MODEL Procedure**” (*SAS/ETS User’s Guide*)). Most of the programming statements that can be used in the **DATA** step can also be used in **PROC MCMC**. See *SAS Language Reference: Dictionary* for a description of SAS programming statements.

There are also a number of unique functions in **PROC MCMC** that calculate the log density of various distributions in the procedure. You can find them at the section “**Using Density Functions in the Programming Statements**” on page 4491.

For the list of matrix-based functions that is supported in **PROC MCMC**, see the section “**Matrix Functions in PROC MCMC**” on page 4498.

The following are valid statements:

```

ABORT;
ARRAY arrayname < [dimensions] > < $ > < variables-and-constants >;
CALL name < (expression < , expression ... >) >;
DELETE;
DO < variable = expression < TO expression > < BY expression > >
 < , expression < TO expression > < BY expression > > ...
 < WHILE expression > < UNTIL expression >;
END;
GOTO statement-label;
IF expression;
IF expression THEN program-statement;
 ELSE program-statement;
variable = expression;
variable + expression;
LINK statement-label;
PUT < variable > < = > ...;
RETURN;
SELECT < (expression) >;
STOP;
SUBSTR(variable, index, length)= expression;
WHEN (expression)program-statement;
 OTHERWISE program-statement;

```

For the most part, the SAS programming statements work the same as they do in the DATA step, as documented in *SAS Language Reference: Concepts*. However, there are several differences:

- The ABORT statement does not allow any arguments.
- The DO statement does not allow a character index variable. Thus

```
do i = 1, 2, 3;
```

is supported; however, the following statement is not supported:

```
do i = 'A', 'B', 'C';
```

- The PUT statement, used mostly for program debugging in PROC MCMC (see the section “[Handling Error Messages](#)” on page 4530), supports only some of the features of the DATA step PUT statement, and it has some features that are not available with the DATA step PUT statement:
  - The PROC MCMC PUT statement does not support line pointers, factored lists, iteration factors, overprinting, \_INFILE\_, \_OBS\_, the colon (:) format modifier, or “\$”.
  - The PROC MCMC PUT statement does support expressions, but the expression must be enclosed in parentheses. For example, the following statement displays the square root of x:

```
put (sqrt(x));
```

- The WHEN and OTHERWISE statements enable you to specify more than one target statement. That is, DO/END groups are not necessary for multiple statement WHENs. For example, the following syntax is valid:

```

select;
 when (exp1) stmt1;
 stmt2;
 when (exp2) stmt3;
 stmt4;
end;

```

You should avoid defining variables that begin with an underscore (\_). They might conflict with internal variables created by PROC MCMC. The **MODEL** statement must come after any SAS programming statements that define or modify terms used in the construction of the log likelihood.

---

## RANDOM Statement

**RANDOM** *random-effect* ~ *distribution* **SUBJECT=***variable* < *options* > ;

The **RANDOM** statement defines a single random effect and its prior distribution or an array of random effects and their prior distribution. The *random-effect* must be represented by either a symbol or an array. The **RANDOM** statement must consist of the *random-effect*, a tilde (~), the distribution for the random effect, and then a **SUBJECT=** variable.

**SUBJECT=***variable* | **\_OBS\_**

identifies the subjects in the random-effects model. The *variable* must be part of the input data set, and it can be either a numeric variable or character literal. The *variable* does not need to be sorted, and the input data set does not need to be clustered according to it. **SUBJECT=\_OBS\_** enables you fit an observation-level random-effects model (each observation has its own random effect) without specifying a subject variable in the input data set.

The random-effects parameters associated with each subject in the same **RANDOM** statement are assumed to be conditionally independent of each other, given other parameters and data set variables in the model. The other parameters include model parameters (declared in the **PARMS** statements), random-effects parameters (from other **RANDOM** statements), and missing data variables.

Table 55.4 shows the distributions that you can specify in the **RANDOM** statement.

**Table 55.4** Valid Distributions in the **RANDOM** Statement

| Distribution Name                                                                                                                                                                    | Definition                                                                                                                 |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>beta</b> (< <b>a</b> => $\alpha$ , < <b>b</b> => $\beta$ )                                                                                                                        | Beta distribution with shape parameters $\alpha$ and $\beta$                                                               |
| <b>binary</b> (< <b>prob</b>   <b>p</b> => $p$ )                                                                                                                                     | Binary (Bernoulli) distribution with probability of success $p$ . You can use the alias <b>bern</b> for this distribution. |
| <b>gamma</b> (< <b>shape</b>   <b>sp</b> => $a$ , <b>scale</b>   <b>s</b> = $\lambda$ )<br><b>gamma</b> (< <b>shape</b>   <b>sp</b> => $a$ , <b>iscale</b>   <b>is</b> = $\lambda$ ) | Gamma distribution with shape $a$ and scale or inverse-scale $\lambda$                                                     |

Table 55.4 (continued)

| Distribution Name                                                                                                                                                                                        | Definition                                                                                                                                                                                                                                |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>dgeneral</b> (//)                                                                                                                                                                                     | General log-prior function that you construct using SAS programming statements for univariate or multivariate discrete random effects. See the section “ <a href="#">Specifying a New Distribution</a> ” on page 4490 for more details.   |
| <b>general</b> (//)                                                                                                                                                                                      | General log-prior function that you construct using SAS programming statements for univariate or multivariate continuous random effects. See the section “ <a href="#">Specifying a New Distribution</a> ” on page 4490 for more details. |
| <b>igamma</b> (< shape sp= > a, scale s= $\lambda$ )<br><b>igamma</b> (< shape sp= > a, iscale is= $\lambda$ )                                                                                           | Inverse-gamma distribution with shape $a$ and scale or inverse-scale $\lambda$                                                                                                                                                            |
| <b>laplace</b> (< location loc = > $\theta$ , scale s= $\lambda$ )<br><b>laplace</b> (< location loc = > $\theta$ , iscale is= $\lambda$ )                                                               | Laplace distribution with location $\theta$ and scale or inverse-scale $\lambda$ . This is also known as the <i>double exponential</i> distribution. You can use the alias <b>dexpon</b> for this distribution.                           |
| <b>normal</b> (< mean m= > $\mu$ , sd= $\lambda$ )<br><b>normal</b> (< mean m= > $\mu$ , var v= $\lambda$ )<br><b>normal</b> (< mean m= > $\mu$ , prec= $\lambda$ )                                      | Normal (Gaussian) distribution with mean $\mu$ and a value of $\lambda$ for the standard deviation, variance, or precision. You can use the aliases <b>gaussian</b> , <b>norm</b> , or <b>n</b> for this distribution.                    |
| <b>poisson</b> (< mean m= > $\lambda$ )                                                                                                                                                                  | Poisson distribution with mean $\lambda$                                                                                                                                                                                                  |
| <b>mvn</b> (< mu= > $\mu$ , < cov= > $\Sigma$ )                                                                                                                                                          | Multivariate normal distribution with mean vector $\mu$ and covariance matrix $\Sigma$                                                                                                                                                    |
| <b>mvnar</b> (< mu= > $\mu$ , sd= $\lambda$ , < rho= > $\rho$ )<br><b>mvnar</b> (< mu= > $\mu$ , var= $\lambda$ , < rho= > $\rho$ )<br><b>mvnar</b> (< mu= > $\mu$ , prec= $\lambda$ , < rho= > $\rho$ ) | Multivariate normal distribution with mean vector $\mu$ and a covariance matrix $\Sigma$ . The covariance matrix $\Sigma$ is a multiple of the scale and a matrix with a first-order autoregressive structure                             |

The following RANDOM statement specifies a scale effect, where `s2u` can be a constant or a model parameter and `index` is a data set variable that indicates group membership of the random effect `u`:

```
random u ~ normal(0,var=s2u) subject=index;
```

The following statements specify multidimensional effects, where `mu` and `cov` can be either parameters in the model or constant arrays:

```
array w[2];
array mu[2];
array cov[2,2];
random w ~ mvn(mu, cov) subject=index;
```

You can specify multiple RANDOM statements. Hyperparameters in the prior distribution of a random effect can be other random effects in the model. For example, the following statements are allowed because the random effect *g* appears in the distribution for the random effect *u*:

```
random g ~ normal(0, var=s2g) subject=month;
random u ~ normal(g, var=s2u) subject=day;
```

These two RANDOM statements specify a nested hierarchical model in which the random-effects *g* is the hyperparameter of the random-effects *u*. You can build the hierarchical structure as deep as you want. You can also use multiple RANDOM statements to build non-nested random-effects models, where the effects could enter the model on different levels but not in the same hierarchy of each other.

The number of random-effects parameters in each RANDOM statement is determined by the number of unique values in the **SUBJECT=** variable, which can be either unsorted numeric or unsorted character literal. Unlike the model parameters that are explicitly declared in the **PARMS** statement (with therefore a fixed total number), the number of random-effects parameters in a program depends on the values of the **SUBJECT=** data set variable. That number can change from one BY group to another.

The names of the random-effects parameters are created internally. See the **NAMESUFFIX=** option for the naming convention of the random-effects parameters. The random-effects parameters are updated conditionally in the simulation. All posterior draws are saved to the **OUTPOST=** output data set by default, and you can use the **MONITOR=** option to monitor any of the parameters. For more information about available sampling algorithms, see the **ALGORITHM=** option. For more information about how to set a random-effects parameter to a constant (also known as corner-point constraint), see the **CONSTRAINT** option.

You can specify the following *options* in the RANDOM statement:

**ALGORITHM=***option*

**ALG=***option*

specifies the algorithm to use to sample the posterior distribution. The following *options* are available:

**RWM**

uses the random-walk Metropolis algorithm with normal proposal.

**SLICE**

uses the slice sampling algorithm.

**GEO**

uses the discrete random-walk Metropolis with symmetric geometric proposal.

When possible, PROC MCMC samples directly from the full conditional distribution. Otherwise, the default sampling algorithm is the RWM.

**CONSTRAINT(VALUE=***value***) =** **FIRST** | **LAST** | **NONE** | '*formatted-value*'

**ZERO=****FIRST** | **LAST** | **NONE** | '*formatted-value*'

sets one of the random-effects parameters to a fixed value. The default is **ZERO=NONE**, which does not fix any of the parameters to be a constant. This option enables you to eliminate one of the parameters.

For example, this option could be useful if you want to fit a regression model with categorical covariates and, instead of creating a design matrix, you treat the parameters as “random effects” and fit an equivalent random-effects model.

Suppose you have a regression that includes a categorical variable  $X$  with  $J$  levels. You can construct a full-rank design matrix with  $J-1$  dummy variables ( $X_2 \cdots X_J$  with  $X_1$  being the base group) and fit a regression such as the following:

$$\mu_i = \beta_0 + \beta_2 \cdot X_2 \cdots \beta_J \cdot X_J$$

The following statements in a PROC MCMC step fit such a hypothetical regression model:

```
parms beta0 betax2 ... betaxJ;
prior beta: ~ n(0, sd=100);
mu = beta0 + betax2 * x2 + ... betaxJ * xJ;
...
```

Equivalently, you can also treat this model as a random-effects model such as the following, where  $\beta_j$  are random effects for each category in  $X$ :

$$\mu_i = \beta_0 + \beta_j \text{ for } j = 1, \dots, J$$

However, this random-effects model is over-parameterized. The ZERO= option rids the model with one random-effects parameter of choice and fixes it to be zero. The following example statements fit such a hypothetical random-effects model:

```
parms beta0;
prior beta0 ~ n(0, sd=100);
random beta ~ n(0, sd=100) subject=x zero=first;
mu = beta0 + beta;
...
```

The specification ZERO=FIRST sets the first random-effects parameter to 0, implying  $\beta_1 = 0$ . This random-effects parameter corresponds to the first category in the SUBJECT= variable. The category is what the first observation of the SUBJECT= variable takes.

The specification ZERO=LAST sets the last random-effects parameter to be 0, implying  $\beta_J = 0$ . This random-effects parameter corresponds to the last category in the SUBJECT= variable. The category is not necessarily the same category that the last observation of the SUBJECT= variable takes because the SUBJECT= variable does not need to be sorted.

The specification ZERO='formatted-value' sets the random-effects parameter for the category (in the SUBJECT= variable) with a formatted value that matches 'formatted-value' to 0. For example, ZERO='3' sets  $\beta_3 = 0$ .

The CONSTRAINT(VALUE=value) option works similarly to the ZERO= option. You can assign an arbitrary value to any one of the random-effects parameter. For example, the specification CONSTRAINT(VALUE=0)=FIRST is equivalent to ZERO=FIRST.

**INITIAL**=*SAS-data-set* | *constant* | *numeric-list*

specifies the initial values of the random-effects parameters. By default, PROC MCMC uses the same option as specified in the **INIT**= option to generate initial values for the random-effects parameter: either it uses the mode of the prior density or it randomly draws a sample from that distribution. You can start the Markov chain at different places by providing a *SAS-data-set*, a constant, or a *numeric-list* for multivariate random-effects parameters.

If you use a *SAS-data-set*, the data set must consist of variable names that agree with the random-effects parameters in the model (see the **NAMESUFFIX**= option for the naming convention of the random-effects parameters). The easiest way to find the names of the internally created parameter names is to run a default analysis with a very small number of simulations and check the variable names in the **OUTPOST**= data set. You can provide a subset of the initial values in the *SAS-data-set* and PROC MCMC will use the default mechanism to fill in the rest of the random-effects parameters.

For example, the following statement creates a data set with initial values for the random-effects parameters `u_1`, `u_2`, and `u_3`:

```
data RandomInit;
 input u_1 u_2 u_3;
 datalines;
 2.3 3 -3
;
```

The following **RANDOM** statement takes the values in the `RandomInit` data set to be the initial values of the corresponding random-effects parameters in the model:

```
random u ~ normal(0,var=s2u) subject=index init=randominit;
```

Specifying a *constant* assigns that constant as the initial value to all random-effects parameters in the statement. For example, the following statement assigns the value 5 to be used as an initial value for all  $u_i$  in the model:

```
random u ~ normal(0,var=s2u) subject=index init=5;
```

If you have multiple effects, you can provide a list of numbers, where the length of the list the same as the dimension of your random-effects array. Each number is then given to all corresponding random-effects parameters in order. For example, the following statement assigns the value 2 to be used as an initial value for all  $w_{1i}$  and the value 3 to be used for all  $w_{2i}$  in the model:

```
array w[2] w1 w2;
random w ~ mvn(mu, cov) subject=index init=(2 3);
```

If you use the **GENERAL** or **DGENERAL** functions in the **RANDOM** statement, you must provide initial values for these parameters.

**MONITOR**=(*symbol-list* | *number-list* | **RANDOM**(*number*))

outputs analysis for selected random-effects parameters. You can choose to monitor the random-effects parameters by listing the effect names or effect indices, or you can have them randomly selected by PROC MCMC.

To monitor all random-effects parameters, you specify the effect name in the **MONITOR**= option:

```
random u ~ normal(0,var=s2u) subject=index monitor=(u);
```

You have three options for monitoring a subset of the random-effects parameters. You can provide a list of the parameter names, you can provide a number list of the parameter indices, or you can have PROC MCMC randomly choose a subset of parameters for you.

For example, if you want to monitor analysis for parameters `u_1` through `u_10`, `u_23`, and `u_57`, you can provide the names as follows:

```
random u ~ normal(0,var=s2u) subject=index monitor=(u_1-u_10 u_23 u_57);
```

The naming convention in the *symbol-list* must agree with the `NAMESUFFIX=` option, which controls how the parameter names of the *random-effect* are created. By default, `NAMESUFFIX=SUBJECT`, and the *symbol-list* must use suffixes that correspond to the formatted values<sup>1</sup> in the `SUBJECT=` data set variable. With the `NAMESUFFIX=POSITION` option, the *symbol-list* must use suffixes that agree with the input order of the `SUBJECT=` variable. If the `SUBJECT=` variable has a character value, you cannot use the hyphen (-) in the *symbol-list* to indicate a range of variables.

To monitor the same list of random-effects parameters, you can provide their indices:

```
random u ~ normal(0,var=s2u) subject=index monitor=(1 to 10 by 1 23 57);
```

PROC MCMC can also randomly choose a subset of the parameters to monitor:

```
random u ~ normal(0,var=s2u) subject=index monitor=(random(12));
```

The sequence of the random indices is controlled by the `SEED=` option in the PROC MCMC statement.

By default, PROC MCMC does not monitor any random-effects parameters. When you specify this option, it takes the specification of the `STATISTICS=` and `PLOTS=` options in the PROC MCMC statement. By default, PROC MCMC outputs all the posterior samples of all random-effects parameters to the `OUTPOST=` output data set. You can use the `NOOUTPOST` option to suppress the saving of the random-effects parameters.

### **NAMESUFFIX=option**

specifies how the names of the random-effects parameters are internally created from the `SUBJECT=variable` that is specified in the RANDOM statement. PROC MCMC creates the names by concatenating the *random-effect* symbol with an underscore and a series of numbers or characters. The following *options* control the type of methods that are used in such construction:

### **SUBJECT**

constructs the parameter names by appending the formatted values of the `SUBJECT=variable` in the input data set<sup>1</sup>.

<sup>1</sup>In SAS/STAT 9.3, the random-effects parameters were created using the unformatted values of the `SUBJECT=variable`.

**POSITION**

constructs the parameter names by appending the numbers 1, 2, 3, and so on, where the number indicates the order in which the **SUBJECT= variable** appears in the data set.

For example, suppose you have an input data set with four observations and the **SUBJECT=** variable `zipcode` has four values (with three of them unique): 27513, 01440, 27513, and 15217. The following SAS statement creates three random-effects parameters named `u_27513`, `u_01440`, and `u_15217`:

```
random u ~ normal(0,var=10) subject=zipcode namesuffix=subject;
```

On the other hand, using **NAMESUFFIX=POSITION** creates three parameters named as `u_1`, `u_2`, and `u_3`:

```
random u ~ normal(0,var=10) subject=zipcode namesuffix=position;
```

By default, **NAMESUFFIX=SUBJECT**.

**NOOUTPOST**

suppresses the output of the posterior samples of random-effects parameters to the **OUTPOST=** data set. In models with a large number of random-effects parameters (for example, tens of thousands), PROC MCMC can run faster if it does not save the posterior samples of the random-effects parameters.

When you specify both the **NOOUTPOST** option and the **MONITOR=** option, PROC MCMC outputs the list of variables that are monitored.

The maximum number of variables that can be saved to an **OUTPOST=** data set is 32,767. If you run a large-scale random-effects model with the number of parameters exceeding the limit, the **NOOUTPOST** option is evoked automatically and PROC MCMC does not save the random-effects parameter draws to the posterior output data set. You can use the **MONITOR=** option to select a subset of the parameters to store in the **OUTPOST=** data set.

**UDS Statement**

```
UDS subroutine-name (subroutine-argument-list) ;
```

UDS stands for user defined sampler. The UDS statement enables you to use a separate algorithm, other than the default random walk Metropolis, to update parameters in the model. The purpose of the UDS statement is to give you a greater amount of flexibility and better control over the updating schemes of the Markov chain. Multiple UDS statements are allowed.

For the UDS statement to work properly, you have to do the following:

- write a subroutine by using PROC FCMP (see the FCMP Procedure in the *Base SAS Procedures Guide*) and save it to a SAS catalog (see the example in this section). The subroutine must update some parameters in the model. These are the UDS parameters. The subroutine is called the UDS subroutine.

- declare any UDS parameters in the **PARMS** statement with a sampling option, as in `</ UDS >` (see the section “**PARMS Statement**” on page 4451).
- specify the prior distributions for all UDS parameters, using the **PRIOR** statements.

**NOTE:** All UDS parameters must appear in three places: the UDS statement, the **PARMS** statement, and the **PRIOR** statement. Otherwise, PROC MCMC exits.

To obtain a valid Markov chain, a UDS subroutine must update a parameter from its full posterior conditional distribution and not the posterior marginal distribution. The posterior conditional is something that you need to provide. This conditional is implicitly based on a prior distribution. PROC MCMC has no means to verify that the implied prior in the UDS subroutine is the same as the prior that you specified in the **PRIOR** statement. You need to make sure that the two distributions agree; otherwise, you will get misleading results.

The priors in the **PRIOR** statements do not directly affect the sampling of the UDS parameters. They could affect the sampling of the other parameters in the model, which, in turn, changes the behavior of the Markov chain. You can see this by noting cases where the hyperparameters of the UDS parameters are model parameters; the priors should be part of the posterior conditional distributions of these hyperparameters, and they cannot be omitted.

Some additional information is listed to help you better understand the UDS statement:

- Most features of the SAS programming language can be used in subroutines processed by PROC FCMP (see the FCMP Procedure in the *Base SAS Procedures Guide*).
- The UDS statement does not support FCMP functions—a FCMP function returns a value, while a subroutine does not. A subroutine updates some of its subroutine arguments. These arguments are called OUTARGS arguments.
- The UDS parameters cannot be in the same block as other parameters. The optional argument `</ UDS >` in the **PARMS** statement prevents parameters that use the default Metropolis from being mixed with those that are updated by the UDS subroutines.
- You can put all the UDS parameters in the same **PARMS** statement or have a separate UDS statement for each of them.
- The same subroutine can be used in multiple UDS statements. This feature comes in handy if you have a generic sampler that can be applied to different parameters.
- PROC MCMC updates the UDS parameters by calling the UDS subroutines directly. At every iteration, PROC MCMC first samples parameters that use the Metropolis algorithm, then the UDS parameters. Sampling of the UDS parameters proceeds in the order in which the UDS statements are listed.
- A UDS subroutine accepts any symbols in the program as well as any input data set variables as its arguments.
- Only the OUTARGS arguments in a UDS subroutine are updated in PROC MCMC. You can modify other arguments in the subroutine, but the changes are not global in PROC MCMC.
- If a UDS subroutine has an argument that is a SAS data set variable, PROC MCMC steps through the data set while updating the UDS parameters. The subroutine is called once per observation in the data set for every iteration.

- If a UDS subroutine does not have any arguments that are data set variables, PROC MCMC does not access the data set while executing the subroutine. The subroutine is called once per iteration.
- To reduce the overhead in calling the UDS subroutine and accessing the data set repeatedly, you might consider reading all the input data set variables into arrays and using the arrays as the subroutine arguments. See the section “[BEGINCNST/ENDCNST Statement](#)” on page 4441 about how to use the [BEGINCNST](#) and [ENDCNST](#) statements to store data set variables.

For an example that uses the UDS statement, see “[Example 55.19: Implement a New Sampling Algorithm](#)” on page 4645.

---

## Details: MCMC Procedure

---

### How PROC MCMC Works

PROC MCMC is a simulation-based procedure that applies a variety of sampling algorithms to the program at hand. The default sampling methods include conjugate sampling (from full conditional), direct sampling from the marginal distribution, inverse cumulative distribution function, random walk Metropolis with normal proposal, and discretized random walk Metropolis with normal proposal. You can request alternate sampling algorithms, such as random walk Metropolis with  $t$  distribution proposal, discretized random walk Metropolis with symmetric geometric proposal, and the slice sampling algorithm.

PROC MCMC applies the more efficient sampling algorithms first, whenever possible. When a parameter does not appear in the conditional distributions of other random variables in the program, PROC MCMC generates samples directly from its prior distribution (which is also its marginal distribution). This usually occurs in data-independent Monte Carlo simulation programs (see “[Example 55.1: Simulating Samples From a Known Density](#)” on page 4540 for an example) or missing data problems, where the missing response variables are generated directly from the conditional sampling distribution (or the conditional likelihood). When conjugacy is detected, PROC MCMC uses random number generators to draw values from the full conditional distribution. (For information about detecting conjugacy, see the section “[Conjugate Sampling](#)” on page 4472.) In other situations, PROC MCMC resorts to the random walk Metropolis with normal proposal to generate posterior samples for continuous parameters and a discretized version for discrete parameters. See the section “[Metropolis and Metropolis-Hastings Algorithms](#)” on page 134 for details about the Metropolis algorithm. For the actual implementation details of the Metropolis algorithm in PROC MCMC, such as tuning of the covariance matrices, see the section “[Tuning the Proposal Distribution](#)” on page 4469.

A key component of the Metropolis algorithm is the calculation of the objective function. In most cases, the objective function that PROC MCMC uses in a Metropolis step is the logarithm of the joint posterior distribution, which is calculated with the inclusion of all data and parameters. The rest of this section describes how PROC MCMC calculates the objective function for parameters that use the Metropolis algorithm.

## Model Parameters

To calculate the log of the posterior density, PROC MCMC assumes that all observations in the data set are independent,

$$\log(p(\theta|\mathbf{y})) = \log(\pi(\theta)) + \sum_{i=1}^n \log(f(y_i|\theta))$$

where  $\theta$  is a parameter or a vector of parameters that are defined in the **PARMS** statements (referred to as the *model parameters*). The term  $\log(\pi(\theta))$  is the sum of the log of the prior densities specified in the **PRIOR** and **HYPERPRIOR** statements. The term  $\log(f(y_i|\theta))$  is the log likelihood specified in the **MODEL** statement. The **MODEL** statement specifies the log likelihood for a single observation in the data set.

If you want to model dependent data—that is,  $\log(f(\mathbf{y}|\theta)) \neq \sum_i \log(f(y_i|\theta))$ —you can use the **JOINT-MODEL** option in the PROC MCMC statement. See the section “**Modeling Joint Likelihood**” on page 4504 for more details.

The statements in PROC MCMC are similar to DATA step statements; PROC MCMC evaluates every statement in order for each observation. At the beginning of the data set, the log likelihood is set to be 0. As PROC MCMC steps through the data set, it cumulatively adds the log likelihood for each observation. Statements between the **BEGINNODATA** and **ENDNODATA** statements are evaluated only at the first and the last observations. At the last observation, the log of the prior and hyperprior distributions is added to the sum of the log likelihood to obtain the log of the posterior distribution.

Calculation of the  $\log(p(\theta|\mathbf{y}))$  objective function involves a complete pass through the data set, making it potentially computationally expensive. If  $\theta = \{\theta_1, \theta_2\}$  is multidimensional, you can choose to update a portion of the parameters at each iteration step by declaring them in separate **PARMS** statements (see the section “**Blocking of Parameters**” on page 4466 for more information). PROC MCMC updates each block of parameters while holding others constant. The objective functions that are used in each update are the same as the log of the joint posterior density:

$$\log(p(\theta_1|\mathbf{y}, \theta_2)) = \log(p(\theta_2|\mathbf{y}, \theta_1)) = \log(p(\theta|\mathbf{y}))$$

In other words, PROC MCMC does not derive the conditional distribution explicitly for each block of parameters, and it uses the full joint distribution in the Metropolis step for every block update.

## Random-Effects Models

For programs that require **RANDOM** statements, PROC MCMC includes the sum of the density evaluation of the random-effects parameters in the calculation of the objective function for  $\theta$ ,

$$\log(p(\theta|\boldsymbol{\gamma}, \mathbf{y})) = \log(\pi(\theta)) + \sum_{j=1}^J \log(\pi(\gamma_j|\theta)) + \sum_{i=1}^n \log(f(y_i|\theta, \boldsymbol{\gamma}))$$

where  $\boldsymbol{\gamma} = \{\gamma_1, \dots, \gamma_J\}$  are random-effects parameters and  $\pi(\gamma_j|\theta)$  is the prior distribution of the random-effects parameters. The likelihood function can be conditional on  $\boldsymbol{\gamma}$ , but the prior distributions of  $\theta$ , which must be independent of  $\boldsymbol{\gamma}$ , cannot.

The objective function used in the Metropolis step for the random-effects parameter  $\gamma_j$  contains only the portion of the data that belong to the  $j$ th cluster:

$$\log(p(\gamma_j|\theta, \mathbf{y})) = \log(\pi(\gamma_j|\theta)) + \sum_{i \in \{j\text{th cluster}\}} \log(f(y_i|\theta, \gamma_j))$$

The calculation does not include  $\log(\theta)$ , the prior density piece, because that is a known constant. Evaluation of this objective function involves only a portion of the data set, making it more computationally efficient. In fact, updating every random-effects parameters in a single **RANDOM** statement involves only one pass through the data set.

You can have multiple **RANDOM** statements in a program, which adds more pieces to the posterior calculation, such as

$$\log(p(\theta|\boldsymbol{\gamma}, \boldsymbol{\alpha}, \mathbf{y})) = \log(\pi(\theta)) + \sum_{j=1}^J \log(\pi(\gamma_j|\theta)) + \sum_{k=1}^K \log(\pi(\alpha_k|\theta)) + \sum_{i=1}^n \log(f(y_i|\theta, \boldsymbol{\gamma}, \boldsymbol{\alpha}))$$

where  $\boldsymbol{\alpha} = \{\alpha_1, \dots, \alpha_K\}$  is another random effect. The random effects  $\boldsymbol{\gamma}$  and  $\boldsymbol{\alpha}$  can form their own hierarchy (as in a nested model), or they can enter the program in a non-nested fashion. The objective functions for  $\gamma_j$  and  $\alpha_k$  are calculated using only observations that belong to their respective clusters.

### Models with Missing Values

Missing values in the response variables of the **MODEL** statement are treated as random variables, and they add another layer in the conditional updates in the simulation. Suppose that

$$\mathbf{y} = \{\mathbf{y}_{\text{obs}}, \mathbf{y}_{\text{mis}}\}$$

The response variable  $\mathbf{y}$  consists of  $n_1$  observed values  $\mathbf{y}_{\text{obs}}$  and  $n_2$  missing values  $\mathbf{y}_{\text{mis}}$ . The log of the posterior distribution is thus formed by

$$\log(p(\theta|\boldsymbol{\gamma}, \mathbf{y}_{\text{mis}}, \mathbf{y}_{\text{obs}})) = \log(\pi(\theta)) + \sum_{j=1}^J \log(\pi(\gamma_j|\theta)) + \sum_{i=1}^{n_2} \log(f(y_{\text{mis},i}|\theta, \boldsymbol{\gamma})) + \sum_{i=1}^{n_1} \log(f(y_{\text{obs},i}|\theta, \boldsymbol{\gamma}))$$

where the expression is evaluated at the drawn  $\boldsymbol{\gamma}$  and  $\mathbf{y}_{\text{obs}}$  values.

The conditional distribution of the random-effects parameter  $\gamma_j$  is

$$\log(p(\gamma_j|\theta, \mathbf{y})) = \log(\pi(\gamma_j|\theta)) + \sum_{i \in \{j\text{th cluster}\}} \log(f(y_i|\theta, \gamma_j))$$

where the  $y_i$  are either the observed or the imputed values of the response variable.

The missing values are usually sampled directly from the sampling distribution and do not require the Metropolis sampler. When a response variable takes on a **GENERAL** function, the objective function is simply the likelihood function:  $\log(f(y_{\text{mis},i}|\theta, \gamma_j))$ .

---

### Blocking of Parameters

In a multivariate parameter model, if all  $k$  parameters are proposed with one joint distribution  $q(\cdot)$ , acceptance or rejection would occur for all of them. This can be rather inefficient, especially when parameters have vastly different scales. A way to avoid this difficulty is to allocate the  $k$  parameters into  $d$  blocks and update them separately. The **PARMS** statement puts model parameters in separate blocks, and each block of parameters is updated sequentially in the procedure.

Suppose you want to sample from a multivariate distribution with probability density function  $p(\theta|\mathbf{y})$  where  $\theta = \{\theta_1, \theta_2, \dots, \theta_k\}$ . Now suppose that these  $k$  parameters are separated into  $d$  blocks—for example,  $p(\theta|\mathbf{x}) = f_d(z)$  where  $z = \{z_1, z_2, \dots, z_d\}$ , where each  $z_j$  contains a nonempty subset of the  $\{\theta_i\}$ , and where each  $\theta_i$  is contained in one and only one  $z_j$ . In the MCMC context, the  $z$ 's are blocks of parameters. In the blocked algorithm, a proposal consists of several parts. Instead of proposing a simultaneous move for all the  $\theta$ 's, a proposal is made for the  $\theta_i$ 's in  $z_1$  only, then for the  $\theta_i$ 's in  $z_2$ , and so on for  $d$  subproposals. Any accepted proposal can involve any number of the blocks moving. The parameters do not necessarily all move at once as in the all-at-once Metropolis algorithm.

Formally, the blocked Metropolis algorithm is as follows. Let  $w_j$  be the collection of  $\theta_i$  that are in block  $z_j$ , and let  $q_j(\cdot|w_j)$  be a symmetric multivariate distribution that is centered at the current values of  $w_j$ .

1. Let  $t = 0$ . Choose points for all  $w_j^t$ . A point can be an arbitrary point as long as  $p(w_j^t|\mathbf{y}) > 0$ .

2. For  $j = 1, \dots, d$ :

a) Generate a new sample,  $w_{j,\text{new}}$ , using the proposal distribution  $q_j(\cdot|w_j^t)$ .

b) Calculate the following quantity:

$$r = \min \left\{ \frac{p(w_{j,\text{new}}|w_1^t, \dots, w_{j-1}^t, w_{j+1}^{t-1}, \dots, w_d^t, \mathbf{y})}{p(w_j^t|w_1^t, \dots, w_{j-1}^t, w_{j-1}^{t+1}, \dots, w_d^t, \mathbf{y})}, 1 \right\}.$$

c) Sample  $u$  from the uniform distribution  $U(0, 1)$ .

d) Set  $w_j^{t+1} = w_{j,\text{new}}$  if  $r < u$ ;  $w_j^{t+1} = w_j^t$  otherwise.

3. Set  $t = t + 1$ . If  $t < T$ , the number of desired samples, go back to Step 2; otherwise, stop.

With PROC MCMC, you can sample all parameters simultaneously by putting them all in a single PARMS statement, you can sample parameters individually by putting each parameter in its own PARMS statement, or you can sample certain subsets of parameters together by grouping each subset in its own PARMS statements. For example, if the model you are interested in has five parameters, alpha, beta, gamma, phi, sigma, the all-at-once strategy is as follows:

```
parms alpha beta gamma phi sigma;
```

The one-at-a-time strategy is as follows:

```
parms alpha;
parms beta;
parms gamma;
parms phi;
parms sigma;
```

A two-block strategy could be as follows:

```
parms alpha beta gamma;
parms phi sigma;
```

The exceptions to the previously described blocking strategies are parameters that are sampled directly (either from their full conditional or marginal distributions) and parameters that are array-based (with multivariate prior distributions). In these cases, the parameters are taken out of an existing block and are updated individually. You can use the sampling options in the **PARMS** statement to override the default behavior.

One of the greatest challenges in MCMC sampling is achieving good mixing of the chains—the chains should quickly traverse the support of the stationary distribution. A number of factors determine the behavior of a Metropolis sampler; blocking is one of them, so you want to be extremely careful when you choose a good design. Generally speaking, forming blocks of parameters has its advantages, but it is not true that the larger the block the faster the convergence.

When simultaneously sampling a large number of parameters, the algorithm might find it difficult to achieve good mixing. As the number of parameters gets large, it is much more likely to have (proposal) samples that fall well into the tails of the target distribution, producing too small a test ratio. As a result, few proposed values are accepted and convergence is slow. On the other hand, when the algorithm samples each parameter individually, the computational cost increases linearly. Each block of Metropolis parameters requires one additional pass through the data set, so a five-block updating strategy could take five times longer than a single-block updating strategy. In addition, there is a chance that the chain might mix far too slowly because the conditional distributions (of  $\theta_i$  given all other  $\theta$ 's) might be very “narrow,” as a result of posterior correlation among the parameters. When that happens, it takes a long time for the chain to fully explore that dimension alone. There are no theoretical results that can help determine an optimal “blocking” for an arbitrary parametric model. A rule followed in practice is to form small groups of correlated parameters that belong to the same context in the formulation of the model. The best mixing is usually obtained with a blocking strategy somewhere between the all-at-once and one-at-a-time strategies.

---

## Sampling Methods

When suitable, PROC MCMC chooses the optimal sampling method for each parameter. That involves direct sampling either from the conditional posterior via conjugacy (see the section “[Conjugate Sampling](#)” on page 4472) or via the marginal posterior (see the section “[Direct Sampling](#)” on page 4472). Alternatively, PROC MCMC samples according to [Table 55.5](#). Each block of parameters is classified by the nature of the prior distributions. “Continuous” means all priors of the parameters in the same block have a continuous distribution. “Discrete” means all priors are discrete. “Mixed” means that some parameters are continuous and others are discrete. Parameters that have binary priors are treated differently, as indicated in the table.

**Table 55.5** Sampling Methods in PROC MCMC

| <b>Blocks</b>                | <b>Default Method</b>     | <b>Alternative Method</b>             |
|------------------------------|---------------------------|---------------------------------------|
| Continuous                   | Multivariate normal (MVN) | Multivariate $t$ (MVT); slice sampler |
| Discrete (other than binary) | Binned MVN                | Binned MVT or symmetric geometric     |
| Mixed                        | MVN                       | MVT                                   |
| Binary (single dimensional)  | Inverse CDF               |                                       |
| Binary (multidimensional)    | Independence sampler      |                                       |

For a block of continuous parameters, PROC MCMC uses a multivariate normal distribution as the default proposal distribution. In the tuning phase, PROC MCMC finds an optimal scale  $c$  and a tuning covariance matrix  $\Sigma$ .

For a discrete block of parameters, PROC MCMC uses a discretized multivariate normal distribution as the default proposal distribution. The scale  $c$  and covariance matrix  $\Sigma$  are tuned. Alternatively, you can use an independent symmetric geometric proposal distribution. The density has form  $\frac{p(1-p)^{|\theta|}}{2(1-p)}$  and has variance  $\frac{(2-p)(1-p)}{p^2}$ . In the tuning phase, the procedure finds an optimal proposal probability  $p$  for every parameter in the block.

You can change the proposal distribution, from the normal to a  $t$  distribution. You can either use the PROC option `PROPDIST=T(df)` or `PARMS` statement option `</ T(df)>` to make the change. The  $t$  distributions have thicker tails, and they can propose to the tail areas more efficiently than the normal distribution. It can help with the mixing of the Markov chain if some of the parameters have a skewed tails. See “[Example 55.6: Nonlinear Poisson Regression Models](#)” on page 4570. The independence sampler (see the section “[Independence Sampler](#)” on page 137) is used for a block of binary parameters. The inverse CDF method is used for a block that consists of a single binary parameter.

For parameters with continuous prior distributions, you can use the slice sampler as an alternative sampling algorithm. To do so, specify the `SLICE` option in the `PARMS`. When you specify the `SLICE` option, all parameters are updated individually. PROC MCMC does not support a multivariate version of the slice sampler. For more in information about the slice sampler, see the section “[Slice Sampler](#)” on page 136.

The sampling algorithms for the random-effects parameters are chosen in a similar fashion. The preferred algorithms are the direct method either from the full conditional or the marginal. When these are not attainable, Metropolis with normal proposal becomes the default for continuous random-effects parameters, and discrete Metropolis with normal proposal becomes the default for discrete random-effects parameters. You can use the `ALGORITHM=` option in the `RANDOM` statement to choose the slice sampler or discrete Metropolis with symmetric geometric as the alternatives.

The sampling preference of the missing data variables is the same as the random-effects parameters. The reserve sampling algorithm is the Metropolis. There is no alternative sampling method available for the missing data variables.

---

## Tuning the Proposal Distribution

One key factor in achieving high efficiency of a Metropolis-based Markov chain is finding a good proposal distribution for each block of parameters. This process is referred to as tuning. The tuning phase consists of a number of loops. The minimum number of loops is controlled by the option `MINTUNE=`, with a default value of 2. The option `MAXTUNE=` controls the maximum number of tuning loops, with a default value of 24. Each loop lasts for `NTU=` iterations, where by default `NTU=` 500. At the end of every loop, PROC MCMC examines the acceptance probability for each block. The acceptance probability is the percentage of `NTU=` proposals that have been accepted. If the probability falls within the acceptance tolerance range (see the section “[Scale Tuning](#)” on page 4470), the current configuration of  $c/\Sigma$  or  $p$  is kept. Otherwise, these parameters are modified before the next tuning loop.

### Continuous Distribution: Normal or $t$ Distribution

A good proposal distribution should resemble the actual posterior distribution of the parameters. Large sample theory states that the posterior distribution of the parameters approaches a multivariate normal distribution (see Gelman et al. 2004, Appendix B, and Schervish 1995, Section 7.4). That is why a normal proposal distribution often works well in practice. The default proposal distribution in PROC MCMC is

the normal distribution:  $q_j(\theta_{\text{new}}|\theta^t) = \text{MVN}(\theta_{\text{new}}|\theta^t, c^2\Sigma)$ . As an alternative, you can choose a multivariate  $t$  distribution as the proposal distribution. It is a good distribution to use if you think that the posterior distribution has thick tails and a  $t$  distribution can improve the mixing of the Markov chain. See “Example 55.6: Nonlinear Poisson Regression Models” on page 4570.

### Scale Tuning

The acceptance rate is closely related to the sampling efficiency of a Metropolis chain. For a random walk Metropolis, high acceptance rate means that most new samples occur right around the current data point. Their frequent acceptance means that the Markov chain is moving rather slowly and not exploring the parameter space fully. On the other hand, a low acceptance rate means that the proposed samples are often rejected; hence the chain is not moving much. An efficient Metropolis sampler has an acceptance rate that is neither too high nor too low. The scale  $c$  in the proposal distribution  $q(\cdot|\cdot)$  effectively controls this acceptance probability. Roberts, Gelman, and Gilks (1997) showed that if both the target and proposal densities are normal, the optimal acceptance probability for the Markov chain should be around 0.45 in a single dimensional problem, and asymptotically approaches 0.234 in higher dimensions. The corresponding optimal scale is 2.38, which is the initial scale set for each block.

Due to the nature of stochastic simulations, it is impossible to fine-tune a set of variables such that the Metropolis chain has the exact desired acceptance rate. In addition, Roberts and Rosenthal (2001) empirically demonstrated that an acceptance rate between 0.15 and 0.5 is at least 80% efficient, so there is really no need to fine-tune the algorithms to reach acceptance probability that is within small tolerance of the optimal values. PROC MCMC works with a probability range, determined by the PROC options `TARGACCEPT ± ACCEPTTOL`. The default value of `TARGACCEPT` is a function of the number of parameters in the model, as outlined in Roberts, Gelman, and Gilks (1997). The default value of `ACCEPTTOL` is 0.075. If the observed acceptance rate in a given tuning loop is less than the lower bound of the range, the scale is reduced; if the observed acceptance rate is greater than the upper bound of the range, the scale is increased. During the tuning phase, a scale parameter in the normal distribution is adjusted as a function of the observed acceptance rate and the target acceptance rate. The following updating scheme is used in PROC MCMC<sup>2</sup>:

$$c_{\text{new}} = \frac{c_{\text{cur}} \cdot \Phi^{-1}(p_{\text{opt}}/2)}{\Phi^{-1}(p_{\text{cur}}/2)}$$

where  $c_{\text{cur}}$  is the current scale,  $p_{\text{cur}}$  is the current acceptance rate,  $p_{\text{opt}}$  is the optimal acceptance probability.

### Covariance Tuning

To tune a covariance matrix, PROC MCMC takes a weighted average of the old proposal covariance matrix and the recent observed covariance matrix, based on `NTU` samples in the current loop. The `TUNEWT=w` option determines how much weight is put on the recently observed covariance matrix. The formula used to update the covariance matrix is as follows:

$$\text{COV}_{\text{new}} = w \text{COV}_{\text{cur}} + (1 - w)\text{COV}_{\text{old}}$$

There are two ways to initialize the covariance matrix:

<sup>2</sup> Roberts, Gelman, and Gilks (1997) and Roberts and Rosenthal (2001) demonstrate that the relationship between acceptance probability and scale in a random walk Metropolis is  $p = 2\Phi(-\sqrt{I}c/2)$ , where  $c$  is the scale,  $p$  is the acceptance rate,  $\Phi$  is the CDF of a standard normal, and  $I \equiv E_f[(f'(x)/f(x))^2]$ ,  $f(x)$  is the density function of samples. This relationship determines the updating scheme, with  $I$  being replaced by the identity matrix to simplify calculation.

- The default is an identity matrix multiplied by the initial scale of 2.38 (controlled by the PROC option `SCALE=`) and divided by the square root of the number of estimated parameters in the model. It can take a number of tuning phases before the proposal distribution is tuned to its optimal stage, since the Markov chain needs to spend time learning about the posterior covariance structure. If the posterior variances of your parameters vary by more than a few orders of magnitude, if the variances of your parameters are much different from 1, or if the posterior correlations are high, then the proposal tuning algorithm might have difficulty with forming an acceptable proposal distribution.
- Alternatively, you can use a numerical optimization routine, such as the quasi-Newton method, to find a starting covariance matrix. The optimization is performed on the joint posterior distribution, and the covariance matrix is a quadratic approximation at the posterior mode. In some cases this is a better and more efficient way of initializing the covariance matrix. However, there are cases, such as when the number of parameters is large, where the optimization could fail to find a matrix that is positive definite. In that case, the tuning covariance matrix is reset to the identity matrix.

A side product of the optimization routine is that it also finds the *maximum a posteriori* (MAP) estimates with respect to the posterior distribution. The MAP estimates are used as the initial values of the Markov chain.

If any of the parameters are discrete, then the optimization is performed conditional on these discrete parameters at their respective fixed initial values. On the other hand, if all parameters are continuous, you can in some cases skip the tuning phase (by setting `MAXTUNE=0`) or the burn-in phase (by setting `NBI=0`).

### Discrete Distribution: Symmetric Geometric

By default, PROC MCMC uses the normal density as the proposal distribution in all Metropolis random walks. For parameters that have discrete prior distributions, PROC MCMC discretizes proposed samples. You can choose an alternative symmetric geometric proposal distribution by specifying the option `DIS-CRETE=GEO`.

The density of the symmetric geometric proposal distribution is as follows:

$$\frac{p_g(1-p_g)^{|\theta|}}{2(1-p_g)}$$

where the symmetry centers at  $\theta$ . The distribution has a variance of

$$\sigma^2 = \frac{(2-p_g)(1-p_g)}{p_g^2}$$

Tuning for the proposal  $p_g$  uses the following formula:

$$\frac{\sigma_{\text{new}}}{\sigma_{\text{cur}}} = \frac{\Phi^{-1}(p_{\text{opt}}/2)}{\Phi^{-1}(p_{\text{cur}}/2)}$$

where  $\sigma_{\text{new}}$  is the standard deviation of the new proposal geometric distribution,  $\sigma_{\text{cur}}$  is the standard deviation of the current proposal distribution,  $p_{\text{opt}}$  is the target acceptance probability, and  $p_{\text{cur}}$  is the current acceptance probability for the discrete parameter block.

The updated  $p_g$  is the solution to the following equation that is between 0 and 1 :

$$\sqrt{\frac{(2-p_g)(1-p_g)}{p_g^2}} = \frac{\sigma_{\text{cur}} \cdot \Phi^{-1}(p_{\text{opt}}/2)}{\Phi^{-1}(p_{\text{cur}}/2)}$$

## Binary Distribution: Independence Sampler

Blocks consisting of a single parameter with a binary prior do not require any tuning; the inverse-CDF method applies. Blocks that consist of multiple parameters with binary prior are sampled by using an independence sampler with binary proposal distributions. See the section “[Independence Sampler](#)” on page 137. During the tuning phase, the success probability  $p$  of the proposal distribution is taken to be the probability of acceptance in the current loop. Ideally, an independence sampler works best if the acceptance rate is 100%, but that is rarely achieved. The algorithm stops when the probability of success exceeds the `TARGACCEPTI=value`, which has a default value of 0.6.

## Direct Sampling

The word “direct” is reserved for sampling that is done directly from the prior distribution of a model or a random-effects parameter or from the sampling distribution of a missing data variable. If the parameter is updated via sampling from its full conditional posterior distribution, the sampling method is referred to as conjugate sampling. (See the section “[Conjugate Sampling](#)” on page 4472.)

Whenever a parameter does not appear in the hierarchy of another parameter in the model, PROC MCMC samples directly from its distribution. For a model parameter or a random-effects parameter, this distribution is its prior distribution. For a missing data variable, this distribution is the sampling distribution of the response variable. Therefore, direct sampling takes place most frequently in data-independent Monte Carlo simulations or the sampling of missing response variables.

## Conjugate Sampling

Conjugate prior is a family of prior distributions in which the prior and the posterior distributions are of the same family of distributions. For example, if you model an independently and identically distributed random variable  $y_i$  using a normal likelihood with known variance  $\sigma^2$ ,

$$y_i \sim \text{normal}(\mu, \sigma^2)$$

a normal prior on  $\mu$

$$\mu \sim \text{normal}(\mu_0, \sigma_0^2)$$

is a conjugate prior because the posterior distribution of  $\mu$  is also a normal distribution given  $y = \{y_i\}$ ,  $\sigma^2$ ,  $\mu_0$ , and  $\sigma_0^2$ :

$$\mu|y \sim \text{normal} \left( \left( \frac{1}{\sigma_0^2} + \frac{n}{\sigma^2} \right)^{-1} \cdot \left( \frac{\mu_0}{\sigma_0^2} + \frac{n \cdot \bar{y}}{\sigma^2} \right), \left( \frac{1}{\sigma_0^2} + \frac{n}{\sigma^2} \right)^{-1} \right)$$

Conjugate sampling is efficient because it enables the Markov chain to obtain samples from the target distribution directly. When appropriate, PROC MCMC uses conjugate sampling methods to draw conditional posterior samples. [Table 55.6](#) lists scenarios that lead to conjugate sampling in PROC MCMC.

**Table 55.6** Conjugate Sampling in PROC MCMC

| Family                                                                  | Parameter               | Prior                |
|-------------------------------------------------------------------------|-------------------------|----------------------|
| Normal with known $\mu$                                                 | Variance $\sigma^2$     | Inverse gamma family |
| Normal with known $\mu$                                                 | Precision $\tau$        | Gamma family         |
| Normal with known scale parameter ( $\sigma^2$ , $\sigma$ , or $\tau$ ) | Mean $\mu$              | Normal               |
| Multivariate normal with known $\Sigma$                                 | Mean $\boldsymbol{\mu}$ | Multivariate normal  |
| Multivariate normal with known $\boldsymbol{\mu}$                       | Covariance $\Sigma$     | Inverse Wishart      |
| Multinomial                                                             | $\mathbf{p}$            | Dirichlet            |
| Binomial/binary                                                         | $p$                     | Beta                 |
| Poisson                                                                 | $\lambda$               | Gamma family         |

In most cases, Family in [Output 55.6](#) refers to the likelihood function. However, it does not necessarily have to be the case. The Family is a distribution that is conditional on the parameter of interest, and it can appear in any level of the hierarchical model, including on the random-effects level.

PROC MCMC can detect conjugacy only if the model parameter (not a function or a transformation of the model parameter) is used in the prior and Family distributions. For example, the following statements lead to a conjugate sampler being used on the parameter mu:

```
parm mu;
prior mu ~ n(0, sd=1000);
model y ~ n(mu, var=s2);
```

However, if you modify the program slightly in the following way, although the conjugacy still holds in theory, PROC MCMC cannot detect conjugacy on mu because the parameter enters the normal likelihood function through the symbol w:

```
parm mu;
prior mu ~ n(0, sd=1000);
w = mu;
model y ~ n(w, var=s2);
```

In this case, PROC MCMC resorts to the default sampling algorithm, which is a random walk Metropolis based on a normal kernel.

Similarly, the following statements also prevent PROC MCMC from detecting conjugacy on the parameter mu:

```
parm mu;
prior mu ~ n(0, sd=1000);
model y ~ n(mu + 2, var=s2);
```

In a normal family, an often-used and often-confused conjugate prior on the variance is the inverse gamma distribution, and a conjugate prior on the precision is the gamma distribution. See “[Gamma and Inverse-Gamma Distributions](#)” on page 4512 for typical usages of these prior distributions.

When conjugacy is detected in a model, PROC MCMC performs a numerical optimization on the joint posterior distribution at the start of the MCMC simulation. If the only sampling methods required in the program are conjugate samplers or direct samplers, PROC MCMC omits this optimization step. To turn off this optimization routine, use the `PROPCOV=IND` option in the PROC MCMC statement.

---

## Initial Values of the Markov Chains

There are three types of parameters in a PROC MCMC program: the *model parameters* in the **PARMS** statement, the *random-effects parameters* in the **RANDOM** statement, and the *missing data variables* in the **MODEL** statement. The last category is used to model missing values in the input data set.

When the model parameters and random-effects parameters have missing initial values, PROC MCMC generates initial values based on the prior distributions. PROC MCMC either uses the mode value (the default) or draws a random number (if the **INIT=****RANDOM** option is specified). For distributions that do not have modes, such as the uniform distribution, PROC MCMC uses the mean instead. In general, PROC MCMC avoids using starting values that are close to the boundary of support of the prior distribution. For example, the exponential prior has a mode at 0, and PROC MCMC starts an initial value at the mean. This avoids some potential numerical problems. If you use the **GENERAL** or **DGENERAL** function in the **PRIOR** statements, you must provide initial values for those parameters.

With missing data variables, PROC MCMC uses the sample average of the nonmissing values (of the response variable) as the initial value. If all values of a particular variable are missing, PROC MCMC resorts to using the mode value or a random number from the sampling distribution (the likelihood), depending on the specification of the **INIT=** option.

To assign a different set of initial values to the model parameters, you use either the **PARMS** statements or programming statements within the **BEGINCNST** and **ENDCNST** statements. See the section “Assignments of Parameters” on page 4474 for more information about how to assign parameter values within the **BEGINCNST** and **ENDCNST** statements.

To assign initial values to the random-effects parameters, you can use the **INIT=** option in the **RANDOM** statement. Either you can give a constant value to all random-effects parameters that are associated with that statement (for example, use **init=3**), or you can assign values individually by providing a data set that stores different values for different parameters.

A mirroring **INIT=** option in the **MODEL** statement enables you to assign different initial values to the missing data variables.

If you use the **PROPCOV=** optimization option in the PROC MCMC statement, PROC MCMC starts the tuning at the optimized values. PROC MCMC overwrites the initial values that you might have provided at the beginning of the Markov chain unless you use the option **INIT=REINIT**.

---

## Assignments of Parameters

In general, you cannot alter the values of any model parameters in PROC MCMC. For example, the following assignment statement produces an error:

```
parms alpha;
alpha = 27;
```

This restriction prevents incorrect calculation of the posterior density—assignments of parameters in the program would override the parameter values generated by PROC MCMC and lead to an incorrect value of the density function.

However, you can modify parameter values and assign initial values to parameters within the block defined by the `BEGINCNST` and `ENDCNST` statements. The following syntax is allowed:

```
parms alpha;
begincnst;
 alpha = 27;
endcnst;
```

The initial value of alpha is 27. Assignments within the `BEGINCNST/ENDCNST` block override initial values specified in the `PARMS` statement. For example, with the following statements, the Markov chain starts at alpha = 27, not 23.

```
parms alpha 23;
begincnst;
 alpha = 27;
endcnst;
```

This feature enables you to systematically assign initial values. Suppose that `z` is an array parameter of the same length as the number of observations in the input data set. You want to start the Markov chain with each  $z_i$  having a different value depending on the data set variable `y`. The following statements set  $z_i = |y|$  for the first half of the observations and  $z_i = 2.3$  for the rest:

```
/* a rather artificial input data set. */
data inputdata;
 do ind = 1 to 10;
 y = rand('normal');
 output;
 end;
run;

proc mcmc data=inputdata;
 array z[10];
 begincnst;
 if ind <= 5 then z[ind] = abs(y);
 else z[ind] = 2.3;
 endcnst;
 parms z;
 prior z: ~ normal(0, sd=1);
 model general(0);
run;
```

Elements of `z` are modified as PROC MCMC executes the programming statements between the `BEGINCNST` and `ENDCNST` statements. This feature could be useful when you use the `GENERAL` function and you find that the `PARMS` statements are too cumbersome for assigning starting values.

## Standard Distributions

The section “Univariate Distributions” on page 4476 (Table 55.7 through Table 55.34) lists all univariate distributions that PROC MCMC recognizes. The section “Multivariate Distributions” on page 4486 (Table 55.35 through Table 55.39) lists all multivariate distributions that PROC MCMC recognizes. With the exception of the multinomial distribution, all these distributions can be used in the MODEL, PRIOR, and HYPERPRIOR statements. The multinomial distribution is supported only in the MODEL statement. The RANDOM statement supports a limited number of distributions; see Table 55.4 for the complete list.

See the section “Using Density Functions in the Programming Statements” on page 4491 for information about how to use distributions in the programming statements. To specify an arbitrary distribution, you can use the GENERAL and DGENERAL functions. See the section “Specifying a New Distribution” on page 4490 for more details. See the section “Truncation and Censoring” on page 4494 for tips about how to work with truncated distributions and censoring data.

## Univariate Distributions

**Table 55.7 Beta Distribution**

|                       |                                                                                                                                                                                                                                                                                                                                           |

| Random number         | Generate $x_1 \sim \text{gamma}(a, \text{scale} = b)$ , and $\theta = 1/x_1$ is a draw from the $\text{igamma}(a, \text{iscale} = b)$ distribution. |                                                                  |

<sup>3</sup>The random variable  $\theta$  is the total number of failures in an experiment *before* the first success. This density function is not to be confused with another popular formulation,  $p(1-p)^{\theta-1}$ , which counts the total number of trials *until* the first success.

Relationship to the gamma distribution  $\theta \sim \text{gamma}(a, \text{iscale} = b) \Leftrightarrow 1/\theta \sim \text{igamma}(a, \text{scale} = b)$

## Usage of Multivariate Distributions

The following simple example illustrates the usage of the multivariate distributions in PROC MCMC. Suppose you are interested in estimating the mean and covariance of multivariate data using this multivariate normal model:

$$\begin{pmatrix} x_1 \\ x_2 \end{pmatrix} \sim \text{MVN} \left( \boldsymbol{\mu} = \begin{pmatrix} \mu_1 \\ \mu_2 \end{pmatrix}, \boldsymbol{\Sigma} = \begin{pmatrix} \sigma_{11} & \sigma_{12} \\ \sigma_{21} & \sigma_{22} \end{pmatrix} \right)$$

where

$$\boldsymbol{\mu} = \begin{pmatrix} 1 \\ 2 \end{pmatrix}$$

$$\boldsymbol{\Sigma} = \begin{pmatrix} 2.4 & 3 \\ 3 & 8.1 \end{pmatrix}$$

You can use the following independent prior on  $\boldsymbol{\mu}$  and  $\boldsymbol{\Sigma}$ :

$$\boldsymbol{\mu} \sim \text{MVN} \left( \boldsymbol{\mu}_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \boldsymbol{\Sigma}_0 = \begin{pmatrix} 100 & 0 \\ 0 & 100 \end{pmatrix} \right)$$

$$\boldsymbol{\Sigma} \sim \text{iWishart} \left( \nu = 2, \mathbf{S} = \begin{pmatrix} 1 & 0 \\ 0 & 1 \end{pmatrix} \right)$$

The following IML procedure statements simulate 100 random multivariate normal samples:

```

title 'An Example that Uses Multivariate Distributions';
proc iml;
 N = 100;
 Mean = {1 2};
 Cov = {2.4 3, 3 8.1};
 call randseed(1);
 x = RANDNORMAL(N, Mean, Cov);

 SampleMean = x[:,];
 n = nrow(x);
 y = x - repeat(SampleMean, n);
 SampleCov = y`*y / (n-1);
 print SampleMean Mean, SampleCov Cov;

 cname = {"x1", "x2"};
 create inputdata from x [colname = cname];
 append from x;
 close inputdata;
quit;

```

Figure 55.13 prints the sample mean and covariance of the simulated data, in addition to the true mean and covariance matrix.

**Figure 55.13** Simulated Multivariate Normal Data

| An Example that Uses Multivariate Distributions |           |             |     |
|-------------------------------------------------|-----------|-------------|-----|
| <b>SampleMean</b>                               |           | <b>Mean</b> |     |
| 0.9987751                                       | 2.115693  | 1           | 2   |
| <b>SampleCov</b>                                |           | <b>Cov</b>  |     |
| 2.8252975                                       | 3.7190704 | 2.4         | 3   |
| 3.7190704                                       | 9.2916805 | 3           | 8.1 |

The following PROC MCMC statements estimate the posterior mean and covariance of the multivariate normal data:

```
proc mcmc data=inputdata seed=17 nmc=3000 diag=none;
 ods select PostSummaries PostIntervals;
 array data[2] x1 x2;
 array mu[2];
 array Sigma[2,2];
 array mu0[2] (0 0);
 array Sigma0[2,2] (100 0 0 100);
 array S[2,2] (1 0 0 1);
 parm mu Sigma;
 prior mu ~ mvn(mu0, Sigma0);
 prior Sigma ~ iwish(2, S);
 model data ~ mvn(mu, Sigma);
run;
```

To use the multivariate distribution, you must specify parameters (or random variables in the MODEL statement) in an array form. The first ARRAY statement creates an one-dimensional array data, which contains two numeric variables, x1 and x2, from the input data set. The data variable is your response variable. The subsequent statements defines two array-parameters (mu and Sigma) and three constant array-hyperparameters (mu0, Sigma0, and S). The PARMs statement declares mu and Sigma to be model parameters. The two PRIOR statements specify the multivariate normal and inverse Wishart distributions as the prior for mu and Sigma, respectively. The MODEL statement specifies the multivariate normal likelihood with data as the random variable, mu as the mean, and Sigma as the covariance matrix.

Figure 55.14 lists the estimated posterior mean and covariance matrix.

## Specifying a New Distribution

To work with a new density that is not listed in the section “Standard Distributions” on page 4476, you can use the `GENERAL` and `DGENERAL` functions. The letter “D” stands for discrete. The new distributions have to be specified on the logarithm scale.

Suppose you want to use the inverse-beta distribution:

$$p(\alpha|a, b) = \frac{\Gamma(a + b)}{\Gamma(a) + \Gamma(b)} \cdot \alpha^{(a-1)} \cdot (1 + \alpha)^{-(a+b)}$$

The following statements in PROC MCMC define the density on its log scale:

```
a = 3; b = 5;
const = lgamma(a + b) - lgamma(a) - lgamma(b);
lp = const + (a - 1) * log(alpha) - (a + b) * log(1 + alpha);
prior alpha ~ general(lp);
```

The symbol `lp` is the expression for the log of an inverse-beta ( $a = 3$ ,  $b = 5$ ). The function `general(lp)` assigns that distribution to `alpha`. The constant term, `const`, can be omitted because the Markov simulation requires only the log of the density kernel.

You can use the `GENERAL` function to specify a distribution for a single variable or for multiple variables. It is important to emphasize that the argument `lp` is an expression for the log of the joint distribution for

these variables. On the contrary, any standard distribution is applied separately to each random variable in the statement.

When you use the `GENERAL` function in the `MODEL` statement, you do not need to specify the dependent variable on the left of the tilde  $\sim$ . The log-likelihood function takes the dependent variable into account; hence, there is no need to explicitly state the dependent variable in the `MODEL` statement. However, in the `PRIOR` and `RANDOM` statements, you need to explicitly state the parameter names and a tilde with the `GENERAL` function.

You can specify any distribution function by using the `GENERAL` and `DGENERAL` functions as long as the distribution function is programmable with SAS statements. When the function is used in the `PRIOR` statements, you must supply initial values in either the `PARMS` statement or within the `BEGINCNST` and `ENDCNST` statements. See the sections “`PARMS` Statement” on page 4451 and “`BEGINCNST/ENDCNST` Statement” on page 4441. When the function is used in the `RANDOM` statement, you must use the `INITIAL=` option in the `RANDOM` statement to supply initial values

**NOTE:** PROC MCMC does not verify that the `GENERAL` function you specify is a valid distribution—that is, an integrable density. You must use the function with caution.

---

## Using Density Functions in the Programming Statements

### Density Functions in PROC MCMC

PROC MCMC has a number of internally defined log-density functions for univariate and multivariate distributions. These functions have the basic form of `LPDF $dist(x, parm-list)$` , where *dist* is the name of the distribution (see [Table 55.40](#) for univariate distributions and [Table 55.41](#) for multivariate distributions). The argument *x* is the random variable, and *parm-list* is the list of parameters.

In addition, the univariate functions allow for optional boundary arguments, such as `LPDF $dist(x, parm-list, <lower>, <upper>)$` , where *lower* and *upper* are optional but positional boundary arguments. With the exception of the Bernoulli and uniform distribution, you can specify limits on all univariate distributions.

To set a lower bound on the normal density:

```
lpdfnorm(x, 0, 1, -2);
```

To set just an upper bound, specify a missing value for the lower bound argument:

```
lpdfnorm(x, 0, 1, ., 2);
```

Leaving both limits out gives you the unbounded density. You can also specify both bounds:

```
lpdfnorm(x, 0, 1);
lpdfnorm(x, 0, 1, -3, 4);
```

See [Table 55.40](#) for the function names of univariate distributions and [Table 55.41](#) for multivariate distributions.

**Table 55.40** Logarithm of Univariate Density Functions in PROC MCMC

| Distribution Name                   | Function Call                                                                  |

| Multinomial         | <b>lpdfmnom</b> ( <i>x_array</i> , <i>p_array</i> );                    |

### Standard Distributions, the LOGPDF Functions, and the LPDF $_{dist}$ Functions

Standard distributions listed in the section “Standard Distributions” on page 4476 are *names* only, and they can be used only in the **MODEL**, **PRIOR**, and **HYPERPRIOR** statements to specify either a prior distribution or a conditional distribution of the data given parameters. They do not return any values, and you cannot use them in the programming statements.

The LOGPDF functions are DATA step functions that compute the logarithm of various probability density (mass) functions. For example,

```
logpdf("beta", x, 2, 15);
```

returns the log of a beta density with parameters  $a = 2$  and  $b = 15$ , evaluated at  $x$ . All the LOGPDF functions are supported in PROC MCMC.

The LPDF $_{dist}$  functions are unique to PROC MCMC. They compute the logarithm of various probability density (mass) functions. The functions are the same as the LOGPDF functions when it comes to calculating

the log density. For example,

```
lpdfbeta(x, 2, 15);
```

returns the same value as

```
logpdf("beta", x, 2, 15);
```

The *LPDFdist* functions cover a greater class of probability density functions, and the univariate distribution functions take the optional but positional boundary arguments. There are no corresponding *LCDFdist* or *LSDFdist* functions in PROC MCMC. To work with the cumulative probability function or the survival functions, you need to use the LOGCDF and the LOGSDF DATA step functions.

## Truncation and Censoring

### Truncated Distributions

To specify a truncated distribution, you can use the LOWER= and/or UPPER= options. Almost all of the standard distributions, including the **GENERAL** and **DGENERAL** functions, take these optional truncation arguments. The exceptions are the binary and uniform distributions.

For example, you can specify the following:

```
prior alpha ~ normal(mean = 0, sd = 1, lower = 3, upper = 45);
```

or

```
parms beta;
a = 3; b = 7;
ll = (a + 1) * log(b / beta);
prior beta ~ general(ll, upper = b + 17);
```

The preceding statements state that if beta is less than b+17, the log of the prior density is ll, as calculated by the equation; otherwise, the log of the prior density is missing—the log of zero.

When the same distribution is applied to multiple parameters in a **PRIOR** statement, the LOWER= and UPPER= truncations apply to all parameters in that statement. For example, the following statements define a Poisson density for theta and gamma:

```
parms theta gamma;
lambda = 7;
ll = theta * log(lambda) - lgamma(1 + theta);
l2 = gamma * log(lambda) - lgamma(1 + gamma);
ll = ll + l2;
prior theta gamma ~ dgeneral(ll, lower = 1);
```

The LOWER=1 condition is applied to both theta and gamma, meaning that for the assignment to ll to be meaningful, both theta and gamma have to be greater than 1. If either of the parameters is less than 1, the log of the joint prior density becomes a missing value.

With the exceptions of the normal distribution and the **GENERAL** and **DGENERAL** functions, the LOWER= and UPPER= options cannot be parameters or functions of parameters. The reason is that most

of the truncated distributions are not normalized. Unnormalized densities do not lead to wrong MCMC answers as long as the bounds are constants. However if the bounds involve model parameters, then the normalizing constant, which is a function of these parameters, must be taken into account in the posterior. Without specifying the normalizing constant, inferences on these boundary parameters are incorrect.

It is not difficult to construct a truncated distribution with a normalizing constant. Any truncated distribution has the probability distribution:

$$p(\theta|a < \theta < b) = \frac{p(\theta)}{F(a) - F(b)}$$

where  $p(\cdot)$  is the density function and  $F(\cdot)$  is the cumulative distribution function. In SAS functions,  $p(\cdot)$  is probability density function and  $F(\cdot)$  is cumulative distribution function. The following example shows how to construct a truncated gamma prior on theta, with SHAPE = 3, SCALE = 2, LOWER = a, and UPPER = b:

```
lp = logpdf('gamma', theta, 3, 2)
 - log(cdf('gamma', a, 3, 2) - cdf('gamma', b, 3, 2));
prior theta ~ general(lp);
```

Note the difference from a naive definition of the density, without taking into account of the normalizing constant:

```
lp = logpdf('gamma', theta, 3, 2);
prior theta ~ general(lp, lower=a, upper=b);
```

If a or b are parameters, you get very different results from the two formulations.

## Censoring

There is no built-in mechanism in PROC MCMC that models censoring automatically. You need to construct the density function (using a combination of the LOGPDF, LOGCDF, and LOGSDF functions and IF-ELSE statements) for the censored data.

Suppose you partition the data into four categories: uncensored (with observation x), left censored (with observation xl), right censored (with observation xr), and interval censored (with observations xl and xr). The likelihood is the normal with mean mu and standard deviation s. The following statements construct the corresponding log likelihood for the observed data:

```
if uncensored then
 ll = logpdf('normal', x, mu, s);
else if leftcensored then
 ll = logcdf('normal', x1, mu, s);
else if rightcensored then
 ll = logsdf('normal', xr, mu, s);
else /* this is the case of interval censored. */
 ll = log(cdf('normal', xr, mu, s) - cdf('normal', x1, mu, s));
model general(ll);
```

See “[Example 55.17: Normal Regression with Interval Censoring](#)” on page 4638.

## Some Useful SAS Functions

**Table 55.42** Some Useful SAS Functions

| SAS Function                    | Definition                                                        |
|---------------------------------|-------------------------------------------------------------------|
| <b>abs(x);</b>                  | $ x $                                                             |
| <b>airy(x);</b>                 | Returns the value of the AIRY function.                           |
| <b>beta(x1, x2);</b>            | $\int_0^1 z^{x1-1}(1-z)^{x2-1} dz$                                |
| <b>call logistic(x);</b>        | $\frac{\exp(x)}{1+\exp(x)}$                                       |
| <b>call softmax(x1,...,xn);</b> | Each element is replaced by $\exp(x_j) / \sum \exp(x_j)$          |
| <b>call stdize(x1,...,xn);</b>  | Standardize values                                                |
| <b>cdf();</b>                   | Cumulative distribution function                                  |
| <b>cdf('normal', x, 0, 1);</b>  | Standard normal cumulative distribution function                  |
| <b>comb(x1, x2);</b>            | $\frac{x1!}{x2!(x1-x2)!}$                                         |
| <b>constant('.');</b>           | Calculate commonly used constants                                 |
| <b>cos(x);</b>                  | cosine(x)                                                         |
| <b>css(x1, ..., xn);</b>        | $\sum_i (x_i - \bar{x})^2$                                        |
| <b>cv(x1, ..., xn);</b>         | std(x) / mean(x) * 100                                            |
| <b>dairy(x);</b>                | Derivative of the AIRY function                                   |
| <b>dimN(m);</b>                 | Returns the numbers of elements in the Nth dim of array <i>m</i>  |
| <b>x1 eq x2</b>                 | Returns 1 if x1 = x2; 0 otherwise                                 |
| <b>x1**x2</b>                   | $x1^{x2}$                                                         |
| <b>geomean(x1, ..., xn);</b>    | $\exp\left(\frac{\log(x1)+\dots+\log(xn)}{n}\right)$              |
| <b>difN(x);</b>                 | Returns differences between the argument and its Nth lag          |
| <b>digamma(x1);</b>             | $\frac{\Gamma'(x1)}{\Gamma(x1)}$                                  |
| <b>erf(x);</b>                  | $\frac{2}{\sqrt{\pi}} \int_0^x \exp(-z^2) dz$                     |
| <b>erfc(x);</b>                 | 1 - erf(x)                                                        |
| <b>fact(x);</b>                 | $x!$                                                              |
| <b>floor(x);</b>                | Greatest integer $\leq x$                                         |
| <b>gamma(x);</b>                | $\int_0^\infty z^{x-1} \exp(-1) dz$                               |
| <b>harmean(x1, ..., xn);</b>    | $\frac{n}{1/x1+\dots+1/xn}$                                       |
| <b>ibessel(nu, x, kode);</b>    | Modified Bessel function of order <i>nu</i> evaluated at <i>x</i> |
| <b>jbessel(nu, x);</b>          | Bessel function of order <i>nu</i> evaluated at <i>x</i>          |
| <b>lagN(x);</b>                 | Returns values from a queue                                       |
| <b>largest(k, x1, ..., xn);</b> | Returns the $k^{th}$ largest element                              |
| <b>lgamma(x);</b>               | $\ln(\Gamma(x))$                                                  |
| <b>lgamma(x+1);</b>             | $\ln(x!)$                                                         |
| <b>log(x, logN(x));</b>         | $\ln(x)$                                                          |
| <b>logbeta(x1, x2);</b>         | $\lgamma(x1) + \lgamma(x2) - \lgamma(x1 + x2)$                    |
| <b>logcdf();</b>                | Log of a left cumulative distribution function                    |
| <b>logpdf();</b>                | Log of a probability density (mass) function                      |
| <b>logsdf();</b>                | Log of a survival function                                        |
| <b>max(x1, x2);</b>             | Returns $x_1$ if $x_1 > x_2$ ; $x_2$ otherwise                    |
| <b>mean(of x1-xn);</b>          | $\sum_i x_i / n$                                                  |

Table 55.42 (continued)

| SAS Function                                  | Definition                                                   |
|-----------------------------------------------|--------------------------------------------------------------|
| <b>median</b> (of $x_1$ - $x_n$ );            | Returns the median of nonmissing values                      |
| <b>min</b> ( $x_1$ , $x_2$ );                 | Returns $x_1$ if $x_1 < x_2$ ; $x_2$ otherwise               |
| <b>missing</b> ( $x$ );                       | Returns 1 if $x$ is missing; 0 otherwise                     |
| <b>mod</b> ( $x_1$ , $x_2$ );                 | Returns the remainder from $x_1/x_2$                         |
| <b>n</b> ( $x_1$ , ..., $x_n$ );              | Returns number of nonmissing values                          |
| <b>nmiss</b> (of $y_1$ - $y_n$ );             | Number of missing values                                     |
| <b>quantile</b> ();                           | Computes the quantile from a specific distribution           |
| <b>pdf</b> ();                                | Probability density (mass) functions                         |
| <b>perm</b> ( $n$ , $r$ );                    | $\frac{n!}{(n-r)!}$                                          |
| <b>put</b> ();                                | Returns a value that uses a specified format                 |
| <b>round</b> ( $x$ );                         | Rounds $x$                                                   |
| <b>rms</b> (of $x_1$ - $x_n$ );               | $\sqrt{\frac{x_1^2 + \dots + x_n^2}{n}}$                     |
| <b>sdf</b> ();                                | Survival function                                            |
| <b>sign</b> ( $x$ );                          | Returns -1 if $x < 0$ ; 0 if $x = 0$ ; 1 if $x > 0$          |
| <b>sin</b> ( $x$ );                           | sine( $x$ )                                                  |
| <b>smallest</b> ( $s$ , $x_1$ , ..., $x_n$ ); | Returns the $s^{th}$ smallest component of $x_1, \dots, x_n$ |
| <b>sortn</b> (of $x_1$ - $x_n$ );             | Sorts the values of the variables                            |
| <b>sqrt</b> ( $x$ );                          | $\sqrt{x}$                                                   |
| <b>std</b> ( $x_1$ , ..., $x_n$ );            | Standard deviation of $x_1, \dots, x_n$ (n-1 in denominator) |
| <b>sum</b> (of $x$ );                         | $\sum_i x_i$                                                 |
| <b>trigamma</b> ( $x$ );                      | Derivative of the DIGAMMA( $x$ ) function                    |
| <b>uss</b> (of $x_1$ - $x_n$ );               | Uncorrected sum of squares                                   |

Here are examples of some commonly used transformations:

- logit

```
mu = beta0 + beta1 * z1;
call logistic(mu);
```

- log

```
w = beta0 + beta1 * z1;
mu = exp(w);
```

- probit

```
w = beta0 + beta1 * z1;
mu = cdf('normal', w, 0, 1);
```

- cloglog

```
w = beta0 + beta1 * z1;
mu = 1 - exp(-exp(w));
```

## Matrix Functions in PROC MCMC

The MCMC procedure provides you with a number of CALL routines for performing simple matrix operations on declared arrays. With the exception of FILLMATRIX, IDENTITY, and ZEROMATRIX, the CALL routines listed in Table 55.43 do not support matrices or arrays that contain missing values.

**Table 55.43** Matrix Functions in PROC MCMC

| CALL Routine   | Description                                                                                                                                     |
|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------|
| ADDMATRIX      | Performs an element-wise addition of two matrices or of a matrix and a scalar.                                                                  |
| CHOL           | Calculates the Cholesky decomposition for a particular symmetric matrix.                                                                        |
| DET            | Calculates the determinant of a specified matrix, which must be square.                                                                         |
| ELEMMULT       | Performs an element-wise multiplication of two matrices.                                                                                        |
| FILLMATRIX     | Replaces all of the element values of the input matrix with the specified value. You can use this routine with multidimensional numeric arrays. |
| IDENTITY       | Converts the input matrix to an identity matrix. Diagonal element values of the matrix are set to 1, and the rest of the values are set to 0.   |
| INV            | Calculates a matrix that is the inverse of the input matrix. The input matrix must be a square, nonsingular matrix.                             |
| MULT           | Calculates the matrix product of two input matrices.                                                                                            |
| SUBTRACTMATRIX | Performs an element-wise subtraction of two matrices or of a matrix and a scalar.                                                               |
| TRANSPOSE      | Returns the transpose of a matrix.                                                                                                              |
| ZEROMATRIX     | Replaces all of the element values of the numeric input matrix with 0.                                                                          |

### ADDMATRIX CALL Routine

The ADDMATRIX CALL routine performs an element-wise addition of two matrices or of a matrix and a scalar.

The syntax of the ADDMATRIX CALL routine is

```
CALL ADDMATRIX (X, Y, Z);
```

where

$X$  specifies a scalar or an input matrix with dimensions  $m \times n$  (that is,  $X[m, n]$ )

$Y$  specifies a scalar or an input matrix with dimensions  $m \times n$  (that is,  $Y[m, n]$ )

$Z$  specifies an output matrix with dimensions  $m \times n$  (that is,  $Z[m, n]$ )

such that

$$Z = X + Y$$

## CHOL CALL Routine

The CHOL CALL routine calculates the Cholesky decomposition for a particular symmetric matrix.

The syntax of the CHOL CALL routine is

**CALL CHOL** (*X*, *Y* <, *validate*>) ;

where

*X* specifies a symmetric positive-definite input matrix with dimensions  $m \times m$  (that is,  $X[m, m]$ )

*Y* is a variable that contains the Cholesky decomposition and specifies an output matrix with dimensions  $m \times m$  (that is,  $Y[m, m]$ )

*validate* specifies an optional argument that can increase the processing speed by avoiding error checking:

If *validate* = 0 or is not specified, then the matrix *X* is checked for symmetry.

If *validate* = 1, then the matrix *X* is assumed to be symmetric.

such that

$$X = YY^*$$

where *Y* is a lower triangular matrix with strictly positive diagonal entries and  $Y^*$  denotes the conjugate transpose of *Y*.

Both input and output matrices must be square and have the same dimensions. If *X* is symmetric positive-definite, *Y* is a lower triangle matrix. If *X* is not symmetric positive-definite, *Y* is filled with missing values.

## DET CALL Routine

The determinant, the product of the eigenvalues, is a single numeric value. If the determinant of a matrix is zero, then that matrix is singular (that is, it does not have an inverse). The routine performs an LU decomposition and collects the product of the diagonals.

The syntax of the DET CALL routine is

**CALL DET** (*X*, *a*) ;

where

*X* specifies an input matrix with dimensions  $m \times m$  (that is,  $X[m, m]$ )

*a* specifies the returned determinate value

such that

$$a = |X|$$

**ELEMMULT CALL Routine**

The ELEMMULT CALL routine performs an element-wise multiplication of two matrices.

The syntax of the ELEMMULT CALL routine is

**CALL ELEMMULT (X, Y, Z) ;**

where

$X$  specifies an input matrix with dimensions  $m \times n$  (that is,  $X[m, n]$ )

$Y$  specifies an input matrix with dimensions  $m \times n$  (that is,  $Y[m, n]$ )

$Z$  specifies an output matrix with dimensions  $m \times n$  (that is,  $Z[m, n]$ )

**FILLMATRIX CALL Routine**

The FILLMATRIX CALL routine replaces all of the element values of the input matrix with the specified value. You can use the FILLMATRIX CALL routine with multidimensional numeric arrays.

The syntax of the FILLMATRIX CALL routine is

**CALL FILLMATRIX (X, Y) ;**

where

$X$  specifies an input numeric matrix

$Y$  specifies the numeric value that is used to fill the matrix

**IDENTITY CALL Routine**

The IDENTITY CALL routine converts the input matrix to an identity matrix. Diagonal element values of the matrix are set to 1, and the rest of the values are set to 0.

The syntax of the IDENTITY CALL routine is

**CALL IDENTITY (X) ;**

where

$X$  specifies an input matrix with dimensions  $m \times m$  (that is,  $X[m, m]$ )

**INV CALL Routine**

The INV CALL routine calculates a matrix that is the inverse of the input matrix. The input matrix must be a square, nonsingular matrix.

The syntax of the INV CALL routine is

**CALL INV (X, Y) ;**

where

$X$  specifies an input matrix with dimensions  $m \times m$  (that is,  $X[m, m]$ )

$Y$  specifies an output matrix with dimensions  $m \times m$  (that is,  $Y[m, m]$ )

### MULT CALL Routine

The MULT CALL routine calculates the matrix product of two input matrices.

The syntax of the MULT CALL routine is

**CALL MULT** ( $X, Y, Z$ ) ;

where

$X$  specifies an input matrix with dimensions  $m \times n$  (that is,  $X[m, n]$ )

$Y$  specifies an input matrix with dimensions  $n \times p$  (that is,  $Y[n, p]$ )

$Z$  specifies an output matrix with dimensions  $m \times p$  (that is,  $Z[m, p]$ )

The number of columns for the first input matrix must be the same as the number of rows for the second matrix. The calculated matrix is the last argument.

### SUBTRACTMATRIX CALL Routine

The SUBTRACTMATRIX CALL routine performs an element-wise subtraction of two matrices or of a matrix and a scalar.

The syntax of the SUBTRACTMATRIX CALL routine is

**CALL SUBTRACTMATRIX** ( $X, Y, Z$ ) ;

where

$X$  specifies a scalar or an input matrix with dimensions  $m \times n$  (that is,  $X[m, n]$ )

$Y$  specifies a scalar or an input matrix with dimensions  $m \times n$  (that is,  $Y[m, n]$ )

$Z$  specifies an output matrix with dimensions  $m \times n$  (that is,  $Z[m, n]$ )

such that

$$Z = X - Y$$

### TRANSPOSE CALL Routine

The TRANSPOSE CALL routine returns the transpose of a matrix.

The syntax of the TRANSPOSE CALL routine is

**CALL TRANSPOSE** ( $X, Y$ ) ;

where

$X$  specifies an input matrix with dimensions  $m \times n$  (that is,  $X[m, n]$ )

$Y$  specifies an output matrix with dimensions  $n \times m$  (that is,  $Y[n, m]$ )

## ZEROMATRIX CALL Routine

The ZEROMATRIX CALL routine replaces all of the element values of the numeric input matrix with 0. You can use the ZEROMATRIX CALL routine with multidimensional numeric arrays.

The syntax of the ZEROMATRIX CALL routine is

```
CALL ZEROMATRIX (X) ;
```

where

*X* specifies a numeric input matrix.

## Create Design Matrix

PROC MCMC does not support a CLASS statement; therefore you need to construct the right design matrix (with dummy or indicator variables) prior to calling PROC MCMC. The best tool to use is the TRANSREG procedure (see Chapter 97, “[The TRANSREG Procedure](#)”). This procedure offers both indicator and effects coding methods. You can specify any categorical variables in the CLASS expansion, and use the ZERO= option to select a reference category. You can also specify any other data set variables (predictors, the responses, and so on) to the output data set in the ID statement.

For example, the following statements create a data set that contains two categorical variables (City and G), and two continuous variables (x and resp):

```
title 'Create Design Matrix';
data categorical;
 input City$ G$ x resp @@;
 datalines;
Chicago F 69.0 112.5 Chicago F 56.5 84.0
Chicago M 65.3 98.0 Chicago M 59.8 84.5
NewYork M 62.8 102.5 NewYork M 63.5 102.5
NewYork F 57.3 83.0 NewYork M 57.5 85.0
;
```

Suppose you are interested in creating a design matrix that uses dummy variable coding for the categorical variables City, G and their interaction City \* G. You can use the following PROC TRANSREG statements:

```
proc transreg data=categorical design;
 model class(city g city*g / zero=last);
 id x resp;
 output out=input_mcmc(drop=_: Int:);
run;
```

The DESIGN option specifies that the primary goal is to code the design matrix. The MODEL statement indicates the variable of interest. The CLASS option in the MODEL statement expands the variables of interest to a list of “dummy” variables. The ZERO=LAST option sets the reference level. The ID statement includes x and resp in the OUT= data set. And the OUTPUT statement creates a new data set Input\_MCMC that stores the design matrix and original variables from the original data set.

A quick call of the PRINT procedure shows the output from the PROC TRANSREG call:

```
proc print data=input_mcmc;
run;
```

Figure 55.15 prints the design matrix that is generated by PROC TRANSREG. The Input\_mcmc data set contains all the variables from the original Categorical data set, in addition to corresponding dummy variables (CityChicago, GF, and CityChicagoGF) for the categorical variables.

**Figure 55.15** Design Matrix Generated by PROC TRANSREG

| Create Design Matrix |         |    |         |         |   |      |       |
|----------------------|---------|----|---------|---------|---|------|-------|
| Obs                  | City    | GF | City    | City    | G | x    | resp  |
|                      | Chicago |    | Chicago |         |   |      |       |
| 1                    | 1       | 1  | 1       | Chicago | F | 69.0 | 112.5 |
| 2                    | 1       | 1  | 1       | Chicago | F | 56.5 | 84.0  |
| 3                    | 1       | 0  | 0       | Chicago | M | 65.3 | 98.0  |
| 4                    | 1       | 0  | 0       | Chicago | M | 59.8 | 84.5  |
| 5                    | 0       | 0  | 0       | NewYork | M | 62.8 | 102.5 |
| 6                    | 0       | 0  | 0       | NewYork | M | 63.5 | 102.5 |
| 7                    | 0       | 1  | 0       | NewYork | F | 57.3 | 83.0  |
| 8                    | 0       | 0  | 0       | NewYork | M | 57.5 | 85.0  |

You can now proceed to call PROC MCMC using this input data set Input\_mcmc and the corresponding dummy variables.

PROC TRANSREG automatically creates a macro variable, &\_TRGIND, which contains a list of variable names that it creates. The %put &\_trgind; statement prints the following:

```
CityChicago GF CityChicagoGF
```

The macro variable &\_TRGIND can come handy if you want to build a regression model; you can refer to &\_TRGIND in the following way:

```
proc mcmc data=input_mcmc;
 array data[5] 1 &_trgind x;
 array beta[5] beta0-beta4;
 ...;
 call mult(beta, data, mu);
 ...;
```

The first ARRAY statement defines a one-dimensional array of length 5, and it takes on five values: a constant 1 and variables CityChicago, GF, CityChicagoGF, and x. The second ARRAY statement defines an array of beta, which are the model parameters. Later in the program, you can use the CALL MULT function to calculate the regression mean and store the value in the symbol mu.

## Modeling Joint Likelihood

PROC MCMC assumes that the input observations are independent and that the joint log likelihood is the sum of individual log-likelihood functions. You specify the log likelihood of one observation in the **MODEL** statement. PROC MCMC evaluates that function for each observation in the data set and cumulatively sums them up. If observations are not independent of each other, this summation produces the incorrect log likelihood.

There are two ways to model dependent data. You can either use the DATA step LAG function or use the PROC option **JOINTMODEL**. The LAG function returns values of a variable from a queue. As PROC MCMC steps through the data set, the LAG function queues each data set variable, and you have access to the current value as well as to all previous values of any variable. If the log likelihood for observation  $x_i$  depends only on observations 1 to  $i$  in the data set, you can use this SAS function to construct the log-likelihood function for each observation. Note that the LAG function enables you to access observations from different rows, but the log-likelihood function in the **MODEL** statement must be generic enough that it applies to all observations. See “[Example 55.14: Time Independent Cox Model](#)” on page 4617 and “[Example 55.15: Time Dependent Cox Model](#)” on page 4625 for how to use this LAG function.

A second option is to create arrays, store all relevant variables in the arrays, and construct the joint log likelihood for the entire data set instead of for each observation. Following is a simple example that illustrates the usage of this option. For a more realistic example that models dependent data, see “[Example 55.14: Time Independent Cox Model](#)” on page 4617 and “[Example 55.15: Time Dependent Cox Model](#)” on page 4625.

```
/* allocate the sample size. */
data exi;
 call streaminit(17);
 do ind = 1 to 100;
 y = rand("normal", 2.3, 1);
 output;
 end;
run;
```

The log-likelihood function for each observation is as follows:

$$\log(f(y_i|\mu, \sigma)) = \log(\phi(y_i; \mu, \text{var} = \sigma^2))$$

The joint log-likelihood function is as follows:

$$\log(f(\mathbf{y}|\mu, \sigma)) = \sum_i \log(\phi(y_i; \mu, \text{var} = \sigma^2))$$

The following statements fit a simple model with an unknown mean ( $\mu$ ) in PROC MCMC, with the variance in the likelihood assumed known. The **MODEL** statement indicates a normal likelihood for each observation  $y$ .

```
proc mcmc data=exi seed=7 outpost=p1;
 parm mu;
 prior mu ~ normal(0, sd=10);
 model y ~ normal(mu, sd=1);
run;
```

The following statements show how you can specify the log-likelihood function for the entire data set:

```

data a;
run;

proc mcmc data=a seed=7 outpost=p2 jointmodel;
 array data[1] / nosymbols;
 begincnst;
 rc = read_array("exi", data, "y");
 n = dim(data, 1);
 endcnst;

 parm mu;
 prior mu ~ normal(0, sd=10);
 ll = 0;
 do i = 1 to n;
 ll = ll + lpdfnorm(data[i], mu, 1);
 end;
 model general(ll);
run;

```

The **JOINTMODEL** option indicates that the function used in the **MODEL** statement calculates the log likelihood for the entire data set, rather than just for one observation. Given this option, PROC MCMC no longer steps through the input data during the simulation. Consequently, you can no longer use any data set variables to construct the log-likelihood function. Instead, you store the data set in arrays and use arrays instead of data set variables to calculate the log likelihood.

The **ARRAY** statement allocates a temporary array (data). The **READ\_ARRAY** function selects the y variable from the **exi** data set and stores it in the data array. See the section “**READ\_ARRAY Function**” on page 4442. In the programming statements, you use a **DO** loop to construct the joint log likelihood. The expression **ll** in the **GENERAL** function now takes the value of the joint log likelihood for all data.

You can run the following statements to see that two PROC MCMC runs produce identical results.

```

proc compare data=p1 compare=p2;
 var mu;
run;

```

---

## Regenerating Diagnostics Plots

By default, PROC MCMC generates three plots: the trace plot, the autocorrelation plot, and the kernel density plot. Unless ODS Graphics is enabled before calling the procedure, it is hard to generate the same graph afterwards. Directly using the **Stat.MCMC.Graphics.TraceAutocorrDensity** template is not feasible. The easiest way to regenerate the same graph is with the **%TADPlot** autocall macro. The **%TADPlot** macro requires you to specify an input data set (which usually is the output data set from a previous PROC MCMC call) and a list of variables that you want to plot.

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

A simple regression example, with three parameters, is used here for illustrational purposes. For an explanation of the regression model and the data involved, see the section “Simple Linear Regression” on page 4408. The following statements generate a SAS data set and fit a regression model:

```

title 'Regenerating Diagnostics Plots';

data Class;
 input Name $ Height Weight @@;
 datalines;
Alfred 69.0 112.5 Alice 56.5 84.0 Barbara 65.3 98.0
Carol 62.8 102.5 Henry 63.5 102.5 James 57.3 83.0
Jane 59.8 84.5 Janet 62.5 112.5 Jeffrey 62.5 84.0
John 59.0 99.5 Joyce 51.3 50.5 Judy 64.3 90.0
Louise 56.3 77.0 Mary 66.5 112.0 Philip 72.0 150.0
Robert 64.8 128.0 Ronald 67.0 133.0 Thomas 57.5 85.0
William 66.5 112.0
;

ods select none;
proc mcmc data=class nmc=50000 thin=5 outpost=classout seed=246810;
 parms beta0 0 beta1 0;
 parms sigma2 1;
 prior beta0 beta1 ~ normal(0, var = 1e6);
 prior sigma2 ~ igamma(3/10, scale = 10/3);
 mu = beta0 + beta1*height;
 model weight ~ normal(mu, var = sigma2);
run;
ods select all;

```

The output data set Classout contains posterior draws for beta0, beta1, and sigma2. It also stores the log of the prior density (LogPrior), log of the likelihood (LogLike), and the log of the posterior density (LogPost). If you want to examine the beta0 and LogPost variable, you can use the following statements to generate the graphs:

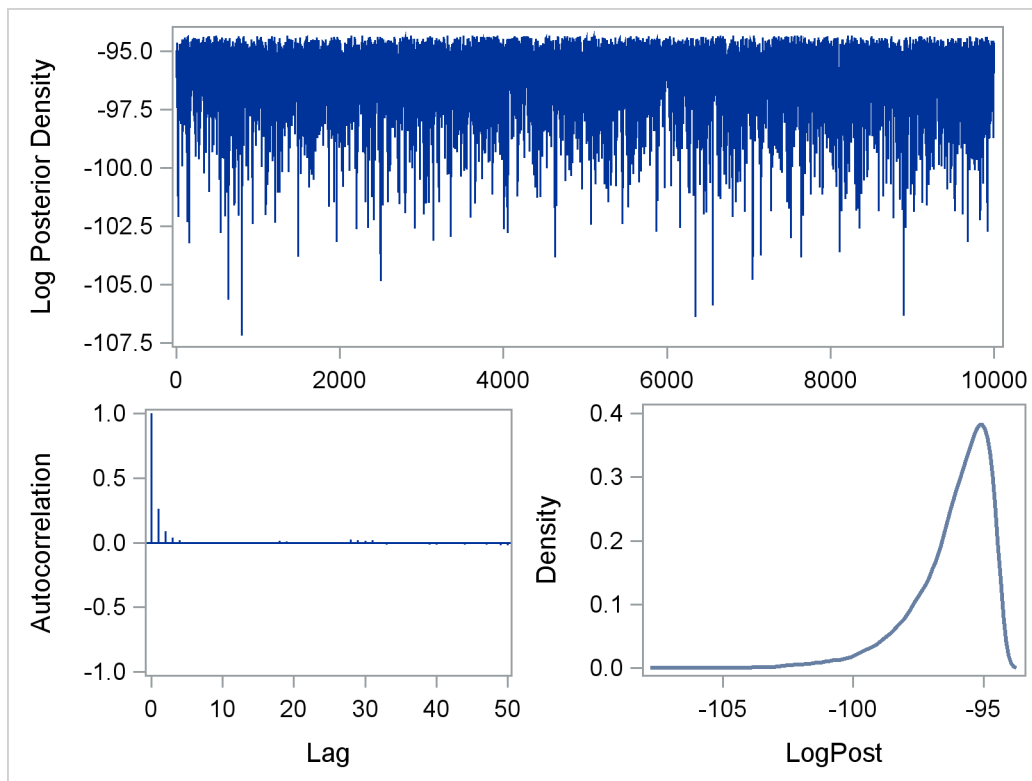

```

ods graphics on;
%tadplot(data=classout, var=beta0 logpost);
ods graphics off;

```

Figure 55.16 displays the regenerated diagnostics plots for variables beta0 and Logpost from the data set Classout.

**Figure 55.16** Regenerated Diagnostics Plots for beta0 and Logpost

## Caterpillar Plot

The caterpillar plot is a side-by-side bar plot of 95% intervals for multiple parameters. Typically, it is used to visualize and compare random-effects parameters, which can come in large numbers in certain models. You can use the %CATER autocall macro to create a caterpillar plot. The %CATER macro requires you specify an input data set and a list of variables that you want to plot.

A random-effects model that has 21 random-effects parameters is used here for illustrational purpose. For an explanation of the random-effects model and the data involved, see “[Example 55.7: Logistic Regression Random-Effects Model](#)” on page 4579. The following statements generate a SAS data set and fit the model:

```

title 'Create a Caterpillar Plot';

data seeds;
 input r n seed extract @@;
 ind = _N_;
 datalines;
10 39 0 0 23 62 0 0 23 81 0 0 26 51 0 0
17 39 0 0 5 6 0 1 53 74 0 1 55 72 0 1
32 51 0 1 46 79 0 1 10 13 0 1 8 16 1 0
10 30 1 0 8 28 1 0 23 45 1 0 0 4 1 0
 3 12 1 1 22 41 1 1 15 30 1 1 32 51 1 1
 3 7 1 1
;

ods select none;
proc mcmc data=seeds outpost=postout seed=332786 nmc=20000;
 parms beta0 0 beta1 0 beta2 0 beta3 0 s2 1;
 prior s2 ~ igamma(0.01, s=0.01);
 prior beta: ~ general(0);
 w = beta0 + beta1*seed + beta2*extract + beta3*seed*extract;
 random delta ~ normal(w, var=s2) subject=ind;
 pi = logistic(delta);
 model r ~ binomial(n = n, p = pi);
run;
ods select all;

```

The output data set Postout contains posterior draws for all 21 random-effects parameters, delta\_1 ... delta\_21. You can use the following statements to generate a caterpillar plot for the 21 parameters:

```

ods graphics on;
%CATER(data=postout, var=delta:);
ods graphics off;

```

Figure 55.17 is a caterpillar plot of the random-effects parameters delta\_1–delta\_21.

Figure 55.17 Caterpillar Plot of the Random-Effects Parameters

If you want to change the display of the caterpillar plot, such as using a different line pattern, color, or size of the markers, you need to first modify the `Stat.MCMC.Graphics.Caterpillar` template and then call the `%CATER` macro again.

You can use the following statements to view the source of the `Stat.MCMC.Graphics.Caterpillar` template:

```
proc template;
 path sashelp.tmplmst;
 source Stat.MCMC.Graphics.Caterpillar;
run;
```

Figure 55.18 lists the source statements of the template that is used to generate the template for the caterpillar plot.

**Figure 55.18** Source Statements for Stat.MCMC.Graphics.Caterpillar Template

```

define statgraph Stat.MCMC.Graphics.Caterpillar;
 dynamic _OverallMean _VarName _VarMean _XLower _XUpper _byline_ _bytitle_
 byfootnote;
 begingraph;
 entrytitle "Caterpillar Plot";
 layout overlay / yaxisopts=(offsetmin=0.05 offsetmax=0.05 display=(line
 ticks tickvalues)) xaxisopts=(display=(line ticks tickvalues));
 referenceline x=_OVERALLMEAN / lineattrs=(color=
 GraphReference:ContrastColor);
 HighLowPlot y=_VARNAME high=_XUPPER low=_XLOWER / lineattrs=
 GRAPHCONFIDENCE;
 scatterplot y=_VARNAME x=_VARMEAN / markerattrs=(size=5 symbol=
 circlefilled);
 endlayout;
 if (_BYTITLE_)
 entrytitle _BYLINE_ / textattrs=GRAPHVALUETEXT;
 else
 if (_BYFOOTNOTE_)
 entryfootnote halign=left _BYLINE_;
 endif;
 endif;
endgraph;
end;

```

You can use the `TEMPLATE` procedure (see Chapter 21, “Statistical Graphics Using ODS”) to run any modified SAS/GRAPH graph template definition and then call the `%CATER` macro again. The `%CATER` macro picks up the change you made to the Caterpillar template and displays the new graph accordingly.

## Autocall Macros for Postprocessing

Although PROC MCMC provides a number of convergence diagnostic tests and posterior summary statistics, PROC MCMC performs the calculations only if you specify the options in advance. If you wish to analyze the posterior draws of unmonitored parameters or functions of the parameters that are calculated in later DATA step calls, you can use the autocall macros in Table 55.44.

**Table 55.44** Postprocessing Autocall Macros

| Macro                            | Description                   |
|----------------------------------|-------------------------------|
| <code>%ESS</code>                | Effective sample sizes        |
| <code>%GEWEKE<sup>4</sup></code> | Geweke diagnostic             |
| <code>%HEIDEL<sup>4</sup></code> | Heidelberger-Welch diagnostic |
| <code>%MCSE</code>               | Monte Carlo standard errors   |
| <code>%RAFTERY</code>            | Raftery diagnostic            |
| <code>%POSTACF</code>            | Autocorrelation               |
| <code>%POSTCOR</code>            | Correlation matrix            |

<sup>4</sup>The `%GEWEKE` and `%HEIDEL` macros use a different optimization routine than that used in PROC MCMC. As a result, there might be numerical differences in some cases, especially when the sample size is small.

**Table 55.44** (continued)

| Macro    | Description                  |
|----------|------------------------------|
| %POSTCOV | Covariance matrix            |
| %POSTINT | Equal-tail and HPD intervals |
| %POSTSUM | Summary statistics           |

Table 55.45 lists options that are shared by all postprocessing autocall macros. See Table 55.46 for macro-specific options.

**Table 55.45** Shared Options

| Option            | Description                                                             |
|-------------------|-------------------------------------------------------------------------|
| DATA=SAS-data-set | Input data set that contains posterior samples                          |
| VAR=variable-list | Specifies the variables on which you want to carry out the calculation. |
| PRINT=YES   NO    | Displays the results. The default is YES.                               |
| OUT=SAS-data-set  | Specifies a name for the output SAS data set to contain the results.    |

Suppose that the data set that contains posterior samples is called `post` and that the variables of interest are defined in the macro variable `&PARMS`. The following statements call the `%ESS` macro and calculates the effective sample sizes for each variable:

```
%let parms = alpha beta u_1-u_17;
%ESS(data=post, var=&parms);
```

By default, the ESS estimates are displayed. You can choose not to display the result and save the output to a data set with the following statement:

```
%ESS(data=post, var=&parms, print=NO, out=eout);
```

Some of the macros can take additional options, which are listed in Table 55.46.

**Table 55.46** Macro-Specific Options

| Macro   | Option             | Description                                                                                                                                                                                           |
|---------|--------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %ESS    | AUTOCORLAG=numeric | Specifies the maximum number of autocorrelation lags used in computing the ESS estimates. By default, AUTOCORLAG=MIN(500, NOBS/4), where NOBS is the sample size of the input data set.               |
|         | HIST=YES NO        | Displays a histogram of all ESS estimates. The default is NO.                                                                                                                                         |
| %HEIDEL | SALPHA=numeric     | Specifies the $\alpha$ level for the stationarity test. By default, SALPHA=0.05.                                                                                                                      |
|         | HALPHA=numeric     | Specifies the $\alpha$ level for the halfwidth test. By default, HALPHA=0.05.                                                                                                                         |
|         | EPS=numeric        | Specifies a small positive number $\epsilon$ such that if the halfwidth is less than $\epsilon$ times the sample mean of the remaining iterations, the halfwidth test is passed. By default, EPS=0.1. |

Table 55.46 (continued)

| Option   | Description                      |                                                                                                                                                                                                                |
|----------|----------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| %GEWEKE  | FRAC1= <i>numeric</i>            | Specifies the earlier portion of the Markov chain used in the test. By default, FRAC1=0.1.                                                                                                                     |
|          | FRAC2= <i>numeric</i>            | Specifies the latter portion of the Markov chain used in the test. By default, FRAC2=0.5.                                                                                                                      |
| %MCSE    | AUTOCORLAG= <i>numeric</i>       | Specifies the maximum number of autocorrelation lags used in computing the Monte Carlo standard error estimates. By default, AUTOCORLAG=MIN(500, NOBS/4), where NOBS is the sample size of the input data set. |
| %RAFTERY | Q= <i>numeric</i>                | Specifies the order of the quantile of interest. By default, Q=0.025.                                                                                                                                          |
|          | R= <i>numeric</i>                | Specifies the margin of error for measuring the accuracy of estimation of the quantile. By default, R=0.005.                                                                                                   |
|          | S= <i>numeric</i>                | Specifies the probability of attaining the accuracy of the estimation of the quantile. By default, S=0.95.                                                                                                     |
|          | EPS= <i>numeric</i>              | Specifies the tolerance level for the stationary test. By default, EPS=0.001.                                                                                                                                  |
| %POSTACF | LAGS=%str( <i>numeric-list</i> ) | Specifies autocorrelation lags calculated. The default values are 1, 5, 10, and 50.                                                                                                                            |
| %POSTINT | ALPHA= <i>value</i>              | Specifies the $\alpha$ level ( $0 < \alpha < 1$ ) for the interval estimates. By default, ALPHA=0.05.                                                                                                          |

For example, the following statement calculates and displays autocorrelation at lags 1, 6, 11, 50, and 100. Note that the lags in the *numeric-list* need to be separated by commas “,”.

```
%PostACF(data=post, var=&parms, lags=%str(1 to 15 by 5, 50, 100));
```

## Gamma and Inverse-Gamma Distributions

The gamma and inverse gamma distributions are widely used in Bayesian analysis. With their respective scale and inverse scale parameterizations, they are a frequent source of confusion in the field. This section aims to clarify their parameterizations and common usages.

The gamma distribution is often used as the conjugate prior for the precision parameter ( $\tau = 1/\sigma^2$ ) in a normal distribution. See Table 55.19 in the section “Standard Distributions” on page 4476 for the density definitions. You can specify the distribution in two ways:

- `gamma(shape=, scale=)` which has mean  $\text{shape} \cdot \text{scale}$  and variance  $\text{shape} \cdot \text{scale}^2$
- `gamma(shape=, iscale=)` which has mean  $\frac{\text{shape}}{\text{iscale}}$  and variance  $\frac{\text{shape}}{\text{iscale}^2}$

The parameterization of the gamma distribution that is preferred by most Bayesian analysts is to have the same number in both hyperparameter positions, which results in a prior distribution that has mean 1. To do this, you should use the `iscale=` parameterization. In addition, if you choose a small value (for example,

0.01), the prior distribution takes on a large variance (100 in this example). To specify this prior in PROC MCMC, use `gamma(shape=0.01, iscale=0.01)`<sup>5</sup>, *not* `gamma(shape=0.01, scale=0.01)`.

If you specify the `scale=` parameterization, as in `gamma(shape=0.01, scale=0.01)`, you would get a prior distribution that has mean 0.0001 and variance 0.000001. This would lead to a completely different posterior inference: the prior would push the precision parameter estimate close to 0, or the variance estimate to a large value.

The inverse-gamma distribution is often used as the conjugate prior of the variance parameter ( $\sigma^2$ ) in a normal distribution. See Table 55.22 in the section “Standard Distributions” on page 4476 for the density definitions. Similar to the gamma distribution, you can specify the inverse-gamma distribution in two ways:

- `igamma(shape=, scale=)`
- `igamma(shape=, iscale=)`

The inverse gamma distribution does not have a mean when the shape parameter is less than or equal to 1 and does not have a variance when the shape parameter is less than or equal to 2.

A gamma prior distribution on the precision is the equivalent to an inverse gamma prior distribution on the variance. The equivalency is the following:

$$\tau \sim \text{gamma}(\text{shape}=0.01, \text{iscale}=0.01) \Leftrightarrow \sigma^2 \sim \text{igamma}(\text{shape}=0.01, \text{scale}=0.01)$$

**NOTE:** This mnemonic might help you remember the parameterization scheme of the distributions. If you prefer to have identical hyperparameter values in the distribution, you should specify one and only one “i.”. When the “i” appears in the `igamma` distribution name for the variance parameter, choose the `scale=` parameterization; when the “i” appears in the `iscale=` parameterization, choose the `gamma` distribution for the precision parameter.

If you are not sure about the choices of other hyperparameter values and what type of prior distributions they induce, you can write a simple PROC MCMC program and see the distributions as in the following example:

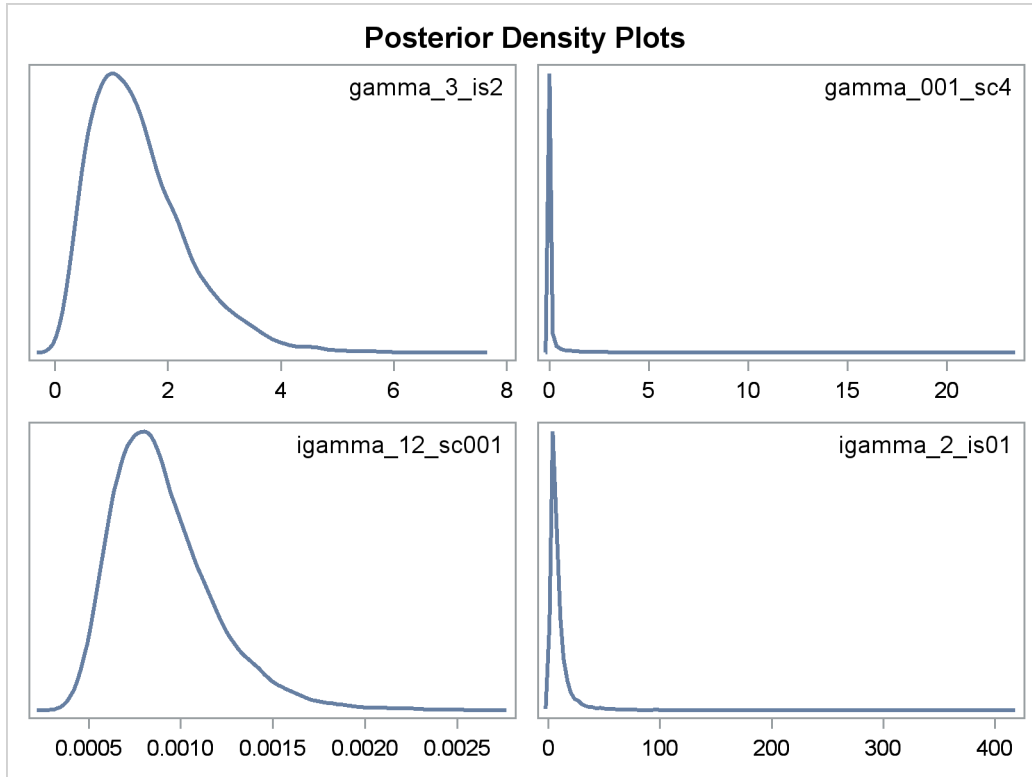

```
data a;
run;

ods graphics on;
ods select DensityPanel;
proc mcmc data=a stats=none diag=none nmc=10000 outpost=gout
 plots=density seed=1;
 parms gamma_3_is2 gamma_001_sc4 igamma_12_sc001 igamma_2_is01;
 prior gamma_3_is2 ~ gamma(shape=3, iscale=2);
 prior gamma_001_sc4 ~ gamma(shape=0.01, scale=4);
 prior igamma_12_sc001 ~ igamma(shape=12, scale=0.01);
 prior igamma_2_is01 ~ igamma(shape=2, iscale=0.1);
 model general(0);
run;
ods graphics off;
```

<sup>5</sup>Specifying the same number at both positions and choosing a small value has been popularized by the WinBUGS software program. The WinBUGS’s distribution specification of `dgamma(0.01, 0.01)` is equivalent to specifying `gamma(shape=0.01, iscale=0.01)` in PROC MCMC.

The preceding statements specify four different gamma and inverse gamma distributions with various scale and inverse scale parameter values. The output of kernel density plots of these four prior distributions is shown in Figure 55.19. Note how the X axis scales vary across different distributions.

**Figure 55.19** Density Plots of Different Gamma and Inverse Gamma Distributions

## Posterior Predictive Distribution

The posterior predictive distribution

$$p(\mathbf{y}_{\text{pred}}|\mathbf{y}) = \int p(\mathbf{y}_{\text{pred}}|\theta)p(\theta|\mathbf{y})d\theta$$

can often be used to check whether the model is consistent with data. For more information about using predictive distribution as a model checking tool, see Gelman et al. 2004, Chapter 6 and the bibliography in that chapter. The idea is to generate replicate data from  $p(\mathbf{y}_{\text{pred}}|\mathbf{y})$ —call them  $\mathbf{y}_{\text{pred}}^i$ , for  $i = 1, \dots, M$ , where  $M$  is the total number of replicates—and compare them to the observed data to see whether there are any large and systematic differences. Large discrepancies suggest a possible model misfit. One way to compare the replicate data to the observed data is to first summarize the data to some test quantities, such as the mean, standard deviation, order statistics, and so on. Then compute the tail-area probabilities of the test statistics (based on the observed data) with respect to the estimated posterior predictive distribution that uses the  $M$  replicate  $\mathbf{y}_{\text{pred}}$  samples.

Let  $T(\cdot)$  denote the function of the test quantity,  $T(\mathbf{y})$  the test quantity that uses the observed data, and  $T(\mathbf{y}_{\text{pred}}^i)$  the test quantity that uses the  $i$ th replicate data from the posterior predictive distribution. You

calculate the tail-area probability by using the following formula:

$$\Pr(T(\mathbf{y}_{\text{pred}}) > T(\mathbf{y})|\theta)$$

The following example shows how you can use PROC MCMC to estimate this probability.

### An Example for the Posterior Predictive Distribution

This example uses a normal mixed model to analyze the effects of coaching programs for the scholastic aptitude test (SAT) in eight high schools. For the original analysis of the data, see Rubin (1981). The presentation here follows the analysis and posterior predictive check presented in Gelman et al. (2004). The data are as follows:

```

title 'An Example for the Posterior Predictive Distribution';

data SAT;
 input effect se @@;
 ind=_n_;
 datalines;
28.39 14.9 7.94 10.2 -2.75 16.3
6.82 11.0 -0.64 9.4 0.63 11.4
18.01 10.4 12.16 17.6
;

```

The variable `effect` is the reported test score difference between coached and uncoached students in eight schools. The variable `se` is the corresponding estimated standard error for each school. In a normal mixed effect model, the variable `effect` is assumed to be normally distributed:

$$\text{effect}_i \sim \text{normal}(\mu_i, \text{se}^2) \quad \text{for } i = 1, \dots, 8$$

The parameter  $\mu_i$  has a normal prior with hyperparameters  $(m, v)$ :

$$\mu_i \sim \text{normal}(m, \text{var} = v)$$

The hyperprior distribution on  $m$  is a uniform prior on the real axis, and the hyperprior distribution on  $v$  is a uniform prior from 0 to infinity.

The following statements fit a normal mixed model and use the `PREDDIST` statement to generate draws from the posterior predictive distribution.

```

ods listing close;
proc mcmc data=SAT outpost=out nmc=40000 seed=12;
 parms m 0;
 parms v 1 /slice;
 prior m ~ general(0);
 prior v ~ general(1, lower=0);
 random mu ~ normal(m, var=v) subject=ind monitor=(mu);
 model effect ~ normal(mu, sd=se);
 preddist outpred=pout nsim=5000;
run;
ods listing;

```

The ODS LISTING CLOSE statement disables the listing output because you are primarily interested in the samples of the predictive distribution. The `HYPER`, `PRIOR`, and `MODEL` statements specify the Bayesian model of interest. The `PREDDIST` statement generates samples from the posterior predictive distribution and stores the samples in the Pout data set. The predictive variables are named `effect_1`, `...`, `effect_8`. When no `COVARIATES` option is specified, the covariates in the original input data set SAT are used in the prediction. The `NSIM=` option specifies the number of predictive simulation iterations.

The following statements use the Pout data set to calculate the four test quantities of interest: the average (mean), the sample standard deviation (sd), the maximum effect (max), and the minimum effect (min). The output is stored in the Pred data set.

```
data pred;
 set pout;
 mean = mean(of effect:);
 sd = std(of effect:);
 max = max(of effect:);
 min = min(of effect:);
run;
```

The following statements compute the corresponding test statistics, the mean, standard deviation, and the minimum and maximum statistics on the real data and store them in macro variables. You then calculate the tail-area probabilities by counting the number of samples in the data set Pred that are greater than the observed test statistics based on the real data.

```
proc means data=SAT noprint;
 var effect;
 output out=stat mean=mean max=max min=min stddev=sd;
run;

data _null_;
 set stat;
 call symputx('mean',mean);
 call symputx('sd',sd);
 call symputx('min',min);
 call symputx('max',max);
run;

data _null_;
 set pred end=eof nobs=nobs;
 ctmean + (mean>&mean);
 ctmin + (min>&min);
 ctmax + (max>&max);
 ctsd + (sd>&sd);
 if eof then do;
 pmean = ctmean/nobs; call symputx('pmean',pmean);
 pmin = ctmin/nobs; call symputx('pmin',pmin);
 pmax = ctmax/nobs; call symputx('pmax',pmax);
 psd = ctsd/nobs; call symputx('psd',psd);
 end;
run;
```

You can plot histograms of each test quantity to visualize the posterior predictive distributions. In addition, you can see where the estimated  $p$ -values fall on these densities. [Figure 55.20](#) shows the histograms. To

put all four histograms on the same panel, you need to use PROC TEMPLATE to define a new graph template. (See Chapter 21, “Statistical Graphics Using ODS.”) The following statements define the template `twobytwo`:

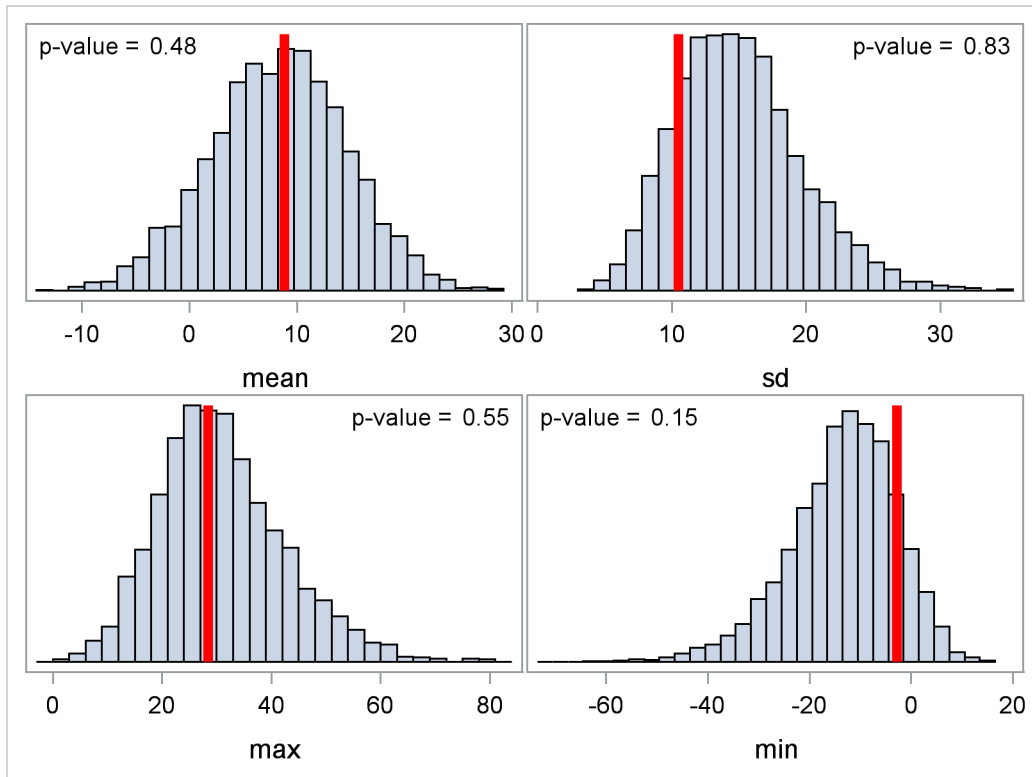

```
proc template;
 define statgraph twobytwo;
 begingraph;
 layout lattice / rows=2 columns=2;
 layout overlay / yaxisopts=(display=none)
 xaxisopts=(label="mean");
 layout gridded / columns=2 border=false
 autoalign=(topleft topright);
 entry halign=right "p-value =";
 entry halign=left eval(strip(put(&pmean, 12.2)));
 endlayout;
 histogram mean / binaxis=false;
 lineparm x=&mean y=0 slope=. /
 lineattrs=(color=red thickness=5);
 endlayout;
 layout overlay / yaxisopts=(display=none)
 xaxisopts=(label="sd");
 layout gridded / columns=2 border=false
 autoalign=(topleft topright);
 entry halign=right "p-value =";
 entry halign=left eval(strip(put(&psd, 12.2)));
 endlayout;
 histogram sd / binaxis=false;
 lineparm x=&sd y=0 slope=. /
 lineattrs=(color=red thickness=5);
 endlayout;
 layout overlay / yaxisopts=(display=none)
 xaxisopts=(label="max");
 layout gridded / columns=2 border=false
 autoalign=(topleft topright);
 entry halign=right "p-value =";
 entry halign=left eval(strip(put(&pmax, 12.2)));
 endlayout;
 histogram max / binaxis=false;
 lineparm x=&max y=0 slope=. /
 lineattrs=(color=red thickness=5);
 endlayout;
 layout overlay / yaxisopts=(display=none)
 xaxisopts=(label="min");
 layout gridded / columns=2 border=false
 autoalign=(topleft topright);
 entry halign=right "p-value =";
 entry halign=left eval(strip(put(&pmin, 12.2)));
 endlayout;
 histogram min / binaxis=false;
 lineparm x=&min y=0 slope=. /
 lineattrs=(color=red thickness=5);
 endlayout;
 endlayout;
 endgraph;
 end;
run;
```

You call PROC SGRENDER to create the graph, which is shown in Figure 55.20. (See the SGRENDER procedure in the *SAS/GRAPH: Statistical Graphics Procedures Guide*.) There are no extreme  $p$ -values observed; this supports the notion that the predicted results are similar to the actual observations and that the model fits the data.

```
proc sgrender data=pred template=twobytwo;
run;
```

**Figure 55.20** Posterior Predictive Distribution Check for the SAT example

Note that the posterior predictive distribution is not the same as the prior predictive distribution. The prior predictive distribution is  $p(\mathbf{y})$ , which is also known as the marginal distribution of the data. The prior predictive distribution is an integral of the likelihood function with respect to the prior distribution

$$p(\mathbf{y}_{\text{pred}}) = \int p(\mathbf{y}_{\text{pred}}|\theta)p(\theta)d\theta$$

and the distribution is not conditional on observed data.

## Handling of Missing Data

PROC MCMC automatically augments missing values<sup>6</sup> via the use of the `MODEL` statement. PROC MCMC treats missing values as unknown parameters, assigns distributions to the variables, and incorporates the sampling of the missing data as part of Markov chain.

<sup>6</sup>A missing value is usually, although not necessarily, represented by a single period (.) in the input data set.

(In SAS/STAT 9.3 and earlier releases, by default, PROC MCMC discarded all observations that had missing or partial missing values. PROC MCMC could not model missing values.)

You can use the `MISSING=` option in the PROC MCMC statement to specify how you want PROC MCMC to handle the missing values. If you specify `MISSING=CC` (CC stands for complete cases), PROC MCMC discards all observations that have missing or partial missing values before carrying out the simulation. If you specify `MISSING=AC` (AC stands for all cases), PROC MCMC neither discards any missing values nor augments them.

Generally speaking, there are three types of missing data models, as discussed by Rubin (1976). Also see Little and Rubin (2002) for a comprehensive treatment of missing data analysis. The rest of this section provides an overview of these three types of missing data models and explains how to use PROC MCMC to fit them.

### Missing Completely at Random (MCAR)

Data are said to be MCAR if the probability of a missing value (or the failure of observing a value) does not depend on any other observations in the data set, regardless of whether they are observed or missing. That is, the observed and unobserved values are independent of each other: if  $y_i$  is missing, it is MCAR if the probability of observing  $y_i$  is independent of other  $y_j$  (and other covariates  $x_i$ ) in the data set. Under this assumption, both the observed and unobserved data are random samples of all the data; hence, fitting a model based only on the observed data does not introduce any biases. This type of analysis is called a complete-case analysis. To carry out a complete-case analysis, you must specify `MISSING=CC` in the PROC MCMC statement. (In SAS/STAT 9.3 and earlier, PROC MCMC performed a complete-case analysis when the data contained missing values.)

### Missing at Random (MAR)

Data are said to be MAR if the probability of a missing value can depend on some observed quantities but does not depend on any unobserved data. For example, suppose that  $x_i$  are completely observed for all observations and some  $y_i$  are missing. MAR states that the probability of observing  $y_i$  is independent of other missing  $y_j$  (values that could have been observed) and that it depends only on  $x_i$  (and, potentially, observed  $y_j$ ).

The MAR assumption states that the missing  $y_i$  are no longer random samples and that they need to be modeled (via the likelihood specification of the missing values). At the same time, the independence assumption of the missing values on the unobserved quantities states that the missing mechanism (usually a binary indicator variable such that  $r_i = 1$  if  $y_i$  is missing and  $r_i = 0$  otherwise) can be ignored and does not need to be taken into account. Hence, MAR is sometimes referred to as *ignorably missing*. It is not the missing values that can be ignored, it is the missing mechanism that can be ignored.

By default, PROC MCMC treats the missing data as MAR (this assumes that you do not input a binary indicator variable  $r_i$  and model it specifically): each missing value becomes an extra parameter and PROC MCMC updates it in every iteration. PROC MCMC assumes that both the missing values and observed values arise from the same distribution (which is specified in the `MODEL` statement),

$$\mathbf{y} = \{\mathbf{y}_{\text{obs}}, \mathbf{y}_{\text{mis}}\} \sim f(\mathbf{y}|\theta)$$

where  $\mathbf{y}$  consists of observed ( $\mathbf{y}_{\text{obs}}$ ) and missing ( $\mathbf{y}_{\text{mis}}$ ) values, and  $f(\mathbf{y}|\theta)$  is the likelihood function with parameters  $\theta$ .

You can use the **MODEL** statement to model missing covariates. Using multiple **MODEL** statements enables you to specify, for example, a marginal distribution for missing values in covariate  $x$  and a conditional distribution for the response variable  $y$  given  $x$  as follows:

```
model x ~ normal(alpha, var=s2_x);
model y ~ normal(beta * x, var=s2_y);
```

In each iteration, PROC MCMC draws samples for every missing value in variable  $x$ , then every missing value in variable  $y$ , conditional on the drawn values of the  $x$  variable.

### Missing Not at Random (MNAR)

Data are said to be MNAR if the probability of a missing value depends on unobserved data (or data that could have been observed): the probability that  $y_i$  is missing depends on the missing values of other  $y_j$ . This is a very general scenario that assumes that the missing mechanism is no longer ignorable (it is sometimes referred to as *nonignorably missing*) and that a model for the missing mechanism is required in order to make correct inferences about the model parameters.

Let  $\mathbf{R} = (r_1, \dots, r_n)$  be the missing value indicator for  $\mathbf{Y} = (y_1, \dots, y_n)$ , where  $r_i = 1$  if  $y_i$  is missing and  $r_i = 0$  otherwise. This  $\mathbf{R}$  is usually part of an input data set where you preprocess the response variable and create this missing value indicator variable. Modeling MNAR data implies that you must specify a joint likelihood function over  $\mathbf{R}$  and  $\mathbf{Y}$ :  $f(\mathbf{R}, \mathbf{Y}|\mathbf{X}, \boldsymbol{\theta})$ , where  $\mathbf{X}$  represents the covariates and  $\boldsymbol{\theta}$  represents the model parameters. This joint distribution can be factored in two ways: a pattern-mixture model and a selection model.

The *selection model* factors the joint distribution  $\mathbf{R}$  and  $\mathbf{Y}$  into a marginal distribution for  $\mathbf{Y}$  and a conditional distribution for  $\mathbf{R}$ ,

$$f(\mathbf{R}, \mathbf{Y}|\mathbf{X}, \boldsymbol{\theta}) \propto f(\mathbf{Y}|\mathbf{X}, \boldsymbol{\alpha}) \cdot f(\mathbf{R}|\mathbf{Y}, \mathbf{X}, \boldsymbol{\beta})$$

where  $\boldsymbol{\theta} = (\boldsymbol{\alpha}, \boldsymbol{\beta})$ ,  $f(\mathbf{R}|\mathbf{Y}, \mathbf{X}, \boldsymbol{\alpha})$  is usually a binary model with a logit or probit link that involves regression parameters  $\boldsymbol{\alpha}$ , and  $f(\mathbf{Y}|\mathbf{X}, \boldsymbol{\beta})$  is the sampling distribution that generates  $y_i$  with model parameters  $\boldsymbol{\beta}$ .

The *pattern-mixture model* factors the opposite way, a marginal distribution for  $\mathbf{R}$  and a conditional distribution for  $\mathbf{Y}$ ,

$$f(\mathbf{R}, \mathbf{Y}|\mathbf{X}, \boldsymbol{\theta}) \propto f(\mathbf{R}|\mathbf{X}, \boldsymbol{\gamma}) \cdot f(\mathbf{Y}|\mathbf{R}, \mathbf{X}, \boldsymbol{\delta})$$

where  $\boldsymbol{\theta} = (\boldsymbol{\gamma}, \boldsymbol{\delta})$ .

You can use PROC MCMC to fit either model by specifying multiple **MODEL** statements: one for the marginal distribution and one for the conditional distribution. Suppose that the variable  $r$  is the missing data indicator, which is modeled using a logit model, and that the response variable  $y$  is a Poisson regression that includes the missing variable indicator as one of its covariates. The following statements are a PROC MCMC program that fits a pattern-mixture model:

```
pi = logistic(alpha * x1);
model r ~ binary(pi);
mu = beta0 + beta1 * x2 + beta3 * r;
model y ~ poisson(exp(mu));
```

The first **MODEL** statement uses a binary model with logit link to model the missing mechanism, and the second **MODEL** statement models the response variable with a Poisson regression that includes the missing

value indicator as one of its covariates. Each of the two sets of regression has its covariates and regression coefficients. If this hypothetical data set contained missing values in covariates  $x_1$  and  $x_2$ , you could add two more **MODEL** statements to handle each variable as follows:

```
model x1 ~ normal(mu1, var=s2_x1);
pi = logistic(alpha * x1);
model r ~ binary(pi);
model x2 ~ normal(mu2, var=s2_x2);
mu = beta0 + beta1 * x2 + beta3 * r;
model y ~ poisson(exp(mu));
```

---

## Functions of Random-Effects Parameters

When you specify a **RANDOM** statement in a program, PROC MCMC internally creates a random-effects parameter for every unique value in the **SUBJECT=** variable. You can calculate any transformations of these random-effects parameters by applying SAS functions to the effect, and you can use the transformed variable in the subsequent statements. For example, the following statements perform a logit transformation of an effect:

```
random u ~ normal(mu, var=s2) subject=students;
p = logistic(u);
...
```

The value of the variable  $p$  changes with  $u$  as the procedure steps through the input data set: for different unique values of the **students** variable,  $u$  takes on a different parameter value, and  $p$  changes accordingly.

To save all the transformed values in  $p$  to the **OUTPOST=** data set, you cannot just specify the **MONITOR=(p)** option in the PROC MCMC statement. With such a specification, PROC MCMC can save only one value of  $p$  (usually the value associated with the last observation in the data set); it cannot save all values. To output all transformed values, you must create an array to store every transformation and use the **MONITOR=** option to save the entire array to the **OUTPOST=** data set. The difficult part of the programming involves the creation of the correct array index to use in different types of the **SUBJECT=** variables. The rest of this section describes how to monitor functions of random-effects parameters in different situations.

### Indexing Subject Variable

This subsection describes how to monitor transformation of an effect  $u$  when the **students** variable is an indexing subject variable. An indexing subject variable is an integer variable that takes value from one to the total number of unique subjects in a variable. In other words, the variable can be used as an index in a SAS array. The indexing subject variable does not need to be sorted for the example code in this section to work. An example of an indexing variable takes the values of (1 2 3 4 5 1 2 3 4 5), where the total number of observation is  $n=10$  and the number of unique values is  $m=5$ .

The following statements create an indexing variable **students** in the data set **a**:

```
data a;
 input students @@;
 datalines;
 1 1 2 2 3 3 4 4 5 5 6 6 7 7 8 8 9 9 10 10
;
```

The following statements run a random-effects model without any response variables. There are only random-effects parameters in the model; the program calculates the logit transformation of each effect, saves the results to the `OUTPOST=` data set, and produces [Figure 55.21](#):

```
proc mcmc data=a monitor=(p) diag=none stats=none outpost=a1
 plots=none seed=1;
 array p[10];
 random u ~ n(0, sd=1) subject=students;
 p[students] = logistic(u);
 model general(0);
run;

proc print data=a1(obs=3);
run;
```

The `ARRAY` statement creates an array `p` of size 10, which is the number of unique values in `students`. The `p` array stores all the transformed values. The `RANDOM` statement declares `u` to be an effect with the subject variable `students`. The `P[STUDENTS]` assignment statement calculates the logit transformations of `u` and saves them in appropriate array elements—this is why the `students` variable must be an indexing variable. Because the `students` variable used in the `p[]` array is also the subject variable in the `RANDOM` statement, PROC MCMC can match each random-effects parameter with the corresponding element in array `p`. The `MONITOR=` option monitors all elements in `p` and saves the output to the `a1` data set. The `a1` data set contains variables `p1–p10`. [Figure 55.21](#) shows the first three observations of the `OUTPOST=` data set.

**Figure 55.21** Monitor Functions of Random Effect `u`

| Obs | Iteration | p1     | p2      | p3      | p4      | p5       | p6      | p7       |         |
|-----|-----------|--------|---------|---------|---------|----------|---------|----------|---------|
| 1   | 1         | 0.5050 | 0.7334  | 0.5375  | 0.5871  | 0.6862   | 0.4944  | 0.5740   |         |
| 2   | 2         | 0.5563 | 0.4254  | 0.7260  | 0.5280  | 0.4593   | 0.5797  | 0.5813   |         |
| 3   | 3         | 0.6132 | 0.8031  | 0.4735  | 0.3135  | 0.7047   | 0.5273  | 0.6761   |         |
| Obs |           | p8     | p9      | p10     | u_1     | u_2      | u_3     | u_4      | u_5     |
| 1   | 0.5991    | 0.6812 | 0.8678  | 0.0198  | 1.0120  | 0.1504   | 0.3521  | 0.7826   |         |
| 2   | 0.7360    | 0.9079 | 0.3351  | 0.2261  | -0.3006 | 0.9742   | 0.1120  | -0.1630  |         |
| 3   | 0.2379    | 0.2938 | 0.3986  | 0.4607  | 1.4058  | -0.1060  | -0.7837 | 0.8698   |         |
| Obs |           | u_6    | u_7     | u_8     | u_9     | u_10     | LogReff | LogLike  | LogPost |
| 1   | -0.0225   | 0.2983 | 0.4019  | 0.7595  | 1.8819  | -12.2658 | 0       | -12.2658 |         |
| 2   | 0.3213    | 0.3281 | 1.0253  | 2.2887  | -0.6854 | -13.2393 | 0       | -13.2393 |         |
| 3   | 0.1092    | 0.7361 | -1.1641 | -0.8772 | -0.4112 | -12.3984 | 0       | -12.3984 |         |

The variable `p1` is the logit transformation of the variable `u_1`, `p2` is the logit transformation of the variable `u_2`, and so on.

The same idea works for a `students` variable that is unsorted. The following statements create an unsorted indexing variable `students` with repeated measures in each subject, fit the same model, and produce [Figure 55.22](#):

```

data a;
 input students @@;
 datalines;
 1 1 1 3 5 3 4 5 3 1 5 5 4 4 2 2 2 2 4 3
;
proc mcmc data=a monitor=(p) diag=none stats=none outpost=a1
 plots=none seed=1;
 array p[5];
 random u ~ n(0, sd=1) subject=students;
 p[students] = logistic(u);
 model general(0);
run;

proc print data=a1(obs=3);
run;

```

**Figure 55.22** Monitor Functions of Random Effect u When the students Variable is Unsorted

| Obs | Iteration | p1     | p2     | p3      | p4      | p5      | u_1     |
|-----|-----------|--------|--------|---------|---------|---------|---------|
| 1   | 1         | 0.5050 | 0.6862 | 0.7334  | 0.5871  | 0.5375  | 0.0198  |
| 2   | 2         | 0.4944 | 0.8678 | 0.5740  | 0.6812  | 0.5991  | -0.0225 |
| 3   | 3         | 0.5563 | 0.4593 | 0.4254  | 0.5280  | 0.7260  | 0.2261  |
| Obs | u_3       | u_5    | u_4    | u_2     | LogReff | LogLike | LogPost |
| 1   | 1.0120    | 0.1504 | 0.3521 | 0.7826  | -5.4865 | 0       | -5.4865 |
| 2   | 0.2983    | 0.4019 | 0.7595 | 1.8819  | -6.7793 | 0       | -6.7793 |
| 3   | -0.3006   | 0.9742 | 0.1120 | -0.1630 | -5.1595 | 0       | -5.1595 |

There are five random-effects parameters in this example, and the array p also has five elements. The values p1–p5 are the transformations of u\_1–u\_5, respectively. The u variables are not sorted from u\_1 to u\_5 because PROC MCMC creates the names according to the order by which the subject variable appears in the input data set. Nevertheless, because students is an indexing variable, the first element p[1] stores the transformation that corresponds to **students=1** (which is u\_1), the second element p[2] stores the transformation that corresponds to **students=2**, and so on.

### Non-Indexing Subject Variable

A non-indexing subject variable can take values of character literals (for example, names) or numerals (for example, ZIP code or a person’s weight). This section illustrates how to monitor functions of random-effects parameters in these situations.

Suppose you have unsorted character literals as the subject variable:

```

data a;
 input students$ @@;
 datalines;
 smith john john mary kay smith lizzy ben ben dylan
 ben toby abby mary kay kay lizzy ben dylan mary
;

```

A statement such as following does not work anymore because a character variable cannot be used as an array index:

```
p[students] = logistic(u);
```

In this situation, you usually need to do two things: (1) find out the number of unique values in the subject variable, and (2) create a numeric index variable that replaces the students array index. You can use the following statements to do the first task:

```

proc sql noprint;
 select count(distinct(students)) into :nuniq from a;
quit;
%put &nuniq;

```

The PROC SQL call counts the distinct values in the students variable and saves the count to the macro variable &nuniq. The macro variable is used later to specify the element size of the p array. In this example, the a data set contains 20 observations and 9 unique elements (the value of &nuniq).

The following statements create an Index variable in the a data set that is in the order by which the students names appear in the data set:

```

proc freq data=a order=data noprint;
 tables students / out=_f(keep=students);
run;

proc print data=_f;
run;

data a(drop=n);
 set a;
 do i = 1 to nobs until(students=n);
 set _f(keep=students rename=(students=n)) point=i nobs=nobs;
 Index = i;
 end;
run;

proc print data=a;
run;

```

The PROC FREQ call identifies the unique students names and saves them to the \_f data set, which is displayed in [Figure 55.23](#).

**Figure 55.23** Unique Names in the Variable Students

| Obs | students |
|-----|----------|
| 1   | smith    |
| 2   | john     |
| 3   | mary     |
| 4   | kay      |
| 5   | lizzy    |
| 6   | ben      |
| 7   | dylan    |
| 8   | toby     |
| 9   | abby     |

The DATA step steps through the a data set and creates an Index variable to match the order in which the students names appear in the data set. The new a data set<sup>7</sup> is displayed in [Figure 55.24](#).

**Figure 55.24** New Index Variable in the a Data Set

| Obs | students | Index |
|-----|----------|-------|
| 1   | smith    | 1     |
| 2   | john     | 2     |
| 3   | john     | 2     |
| 4   | mary     | 3     |
| 5   | kay      | 4     |
| 6   | smith    | 1     |
| 7   | lizzy    | 5     |
| 8   | ben      | 6     |
| 9   | ben      | 6     |
| 10  | dylan    | 7     |
| 11  | ben      | 6     |
| 12  | toby     | 8     |
| 13  | abby     | 9     |
| 14  | mary     | 3     |
| 15  | kay      | 4     |
| 16  | kay      | 4     |
| 17  | lizzy    | 5     |
| 18  | ben      | 6     |
| 19  | dylan    | 7     |
| 20  | mary     | 3     |

Student smith is the first subject, and his Index value is one. The same student appears again in the sixth observation, which is given the same Index value. Now, this Index variable can be used to index the p array, in a similar fashion as demonstrated in previous programs:

<sup>7</sup>The programming code that creates and adds the Index variable to the data set a keeps all variables from the original data set and does not discard them.

```

data _f;
 set _f;
 subj = compress('p_'||students);
run;
proc sql noprint;
 select subj into :pnames separated by ' ' from _f;
quit;
%put &pnames;

proc mcmc data=a monitor=(p) diag=none stats=none outpost=a1
 plots=none seed=1;
 array p[&nuniq] &pnames;
 random u ~ n(0, sd=1) subject=students;
 p[index] = logistic(u);
 model general(0);
run;

proc print data=a1(obs=3);
run;

```

The first part of the DATA step and the PROC SQL call create array names for the `p` array that match the subject names in the `students` variable. It is not necessary to include these steps for the PROC MCMC program to work, but it makes the output more readable. The first DATA step steps through the `_f` data set and creates a `subj` variable that concatenates the prefix characters `p_` with the names of the students. The PROC SQL calls put all the `subj` values to a macro called `&pnames`, which looks like the following:

```
p_smith p_john p_mary p_kay p_lizzy p_ben p_dylan p_toby p_abby
```

In the PROC MCMC program, the `ARRAY` statement defines an `p` array with size `&nuniq` (9), and use the macro variable `&pnames` to name the array elements. The `P[INDEX]` assignment statement uses the `index` variable to find the correct array element to store the transformation. Figure 55.25 displays the first few observations of the `OUTPOST=a1` data set.

**Figure 55.25** First Few Observations of the Outpost Data Set

| Obs | Iteration | p_smith | p_john  | p_mary   | p_kay   | p_lizzy  | p_ben   | p_dylan |
|-----|-----------|---------|---------|----------|---------|----------|---------|---------|
| 1   | 1         | 0.5050  | 0.7334  | 0.5375   | 0.5871  | 0.6862   | 0.4944  | 0.5740  |
| 2   | 2         | 0.8678  | 0.5563  | 0.4254   | 0.7260  | 0.5280   | 0.4593  | 0.5797  |
| 3   | 3         | 0.9079  | 0.3351  | 0.6132   | 0.8031  | 0.4735   | 0.3135  | 0.7047  |
| Obs | p_toby    | p_abby  | u_smith | u_john   | u_mary  | u_kay    | u_lizzy | u_ben   |
| 1   | 0.5991    | 0.6812  | 0.0198  | 1.0120   | 0.1504  | 0.3521   | 0.7826  | -0.0225 |
| 2   | 0.5813    | 0.7360  | 1.8819  | 0.2261   | -0.3006 | 0.9742   | 0.1120  | -0.1630 |
| 3   | 0.5273    | 0.6761  | 2.2887  | -0.6854  | 0.4607  | 1.4058   | -0.1060 | -0.7837 |
| Obs | u_dylan   | u_toby  | u_abby  | LogReff  | LogLike | LogPost  |         |         |
| 1   | 0.2983    | 0.4019  | 0.7595  | -9.5761  | 0       | -9.5761  |         |         |
| 2   | 0.3213    | 0.3281  | 1.0253  | -11.2370 | 0       | -11.2370 |         |         |
| 3   | 0.8698    | 0.1092  | 0.7361  | -13.1867 | 0       | -13.1867 |         |         |

There are nine random-effects parameters ( $u_{\text{smith}}$ ,  $u_{\text{john}}$ , and so on). There are nine elements of the  $p$  array ( $p_{\text{smith}}$ ,  $p_{\text{john}}$ , and so on); each is the logit transformation of corresponding  $u$  elements.

You can use the same statements for subject variables that are numeric non-indexing variables. The following statements create a `students` variable that take large numbers that cannot be used as indices to an array. The rest of the program monitors functions of the effect  $u$ . The output is not displayed here.

```

data a;
 call streaminit(1);
 do i = 1 to 20;
 students = rand("poisson", 20);
 output;
 end;
 drop i;
run;

proc sql noprint;
 select count(distinct(students)) into :nuniq from a;
quit;
%put &nuniq;

proc freq data=a order=data noprint;
 tables students / out=_f(keep=students);
run;

data a(drop=n);
 set a;
 do i = 1 to nobs until(students=n);
 set _f(keep=students rename=(students=n)) point=i nobs=nobs;
 Index = i;
 end;
run;

data _f;
 set _f;
 subj = compress('p_'||students);
proc sql noprint;
 select subj into :pnames separated by ' ' from _f;
quit;
%put &pnames;

proc mcmc data=a monitor=(p) diag=none stats=none outpost=a1
 plots=none seed=1;
 array p[&nuniq] &pnames;
 random u ~ n(0, sd=1) subject=students;
 p[index] = logistic(u);
 model general(0);
run;

proc print data=a1(obs=3);
run;

```

---

## Floating Point Errors and Overflows

When performing a Markov chain Monte Carlo simulation, you must calculate a proposed jump and an objective function (usually a posterior density). These calculations might lead to arithmetic exceptions and overflows. A typical cause of these problems is parameters with widely varying scales. If the posterior variances of your parameters vary by more than a few orders of magnitude, the numerical stability of the optimization problem can be severely reduced and can result in computational difficulties. A simple remedy is to rescale all the parameters so that their posterior variances are all approximately equal. Changing the `SCALE=` option might help if the scale of your parameters is much different than one. Another source of numerical instability is highly correlated parameters. Often a model can be reparameterized to reduce the posterior correlations between parameters.

If parameter rescaling does not help, consider the following actions:

- provide different initial values or try a different seed value
- use boundary constraints to avoid the region where overflows might happen
- change the algorithm (specified in programming statements) that computes the objective function

## Problems Evaluating Code for Objective Function

The initial values must define a point for which the programming statements can be evaluated. However, during simulation, the algorithm might iterate to a point where the objective function cannot be evaluated. If you program your own likelihood, priors, and hyperpriors by using SAS statements and the `GENERAL` function in the `MODEL`, `PRIOR`, and `HYPERPRIOR` statements, you can specify that an expression cannot be evaluated by setting the value you pass back through the `GENERAL` function to missing. This tells the PROC MCMC that the proposed set of parameters is invalid, and the proposal will not be accepted. If you use the shorthand notation that the `MODEL`, `PRIOR`, and `HYPERPRIOR` statements provide, this error checking is done for you automatically.

## Long Run Times

PROC MCMC can take a long time to run for problems with complex models, many parameters, or large input data sets. Although the techniques used by PROC MCMC are some of the best available, they are not guaranteed to converge or proceed quickly for all problems. Ill-posed or misspecified models can cause the algorithms to use more extensive calculations designed to achieve convergence, and this can result in longer run times. You should make sure that your model is specified correctly, that your parameters are scaled to the same order of magnitude, and that your data reasonably match the model that you are specifying.

To speed general computations, you should check over your programming statements to minimize the number of unnecessary operations. For example, you can use the proportional kernel in the priors or the likelihood and not add constants in the densities. You can also use the `BEGINCNST` and `ENDCNST` to reduce unnecessary computations on constants, and the `BEGINNODATA` and `ENDNODATA` statements to reduce observation-level calculations.

Reducing the number of blocks (the number of the `PARMS` statements) can speed up the sampling process. A single-block program is approximately three times faster than a three-block program for the same number

of iterations. On the other hand, you do not want to put too many parameters in a single block, because blocks with large size tend not to produce well-mixed Markov chains.

If some parameters satisfy the conditional independence assumption, such as in the random-effects models or latent variable models, consider using the **RANDOM** statement to model these parameters. This statement takes advantage of the conditional independence assumption and can sample a larger number of parameters at a more efficient pace.

## Slow or No Convergence

If the simulator is slow or fails to converge, you can try changing the model as follows:

- Change the number of Monte Carlo iterations (**NMC=**), or the number of burn-in iterations (**NBI=**), or both. Perhaps the chain just needs to run a little longer. Note that after the simulation, you can always use the **DATA** step or the **FIRSTOBS** data set option to throw away initial observations where the algorithm has not yet burned in, so it is not always necessary to set **NBI=** to a large value.
- Increase the number of tuning. The proposal tuning can often work better in large models (models that have more parameters) with larger values of **NTU=**. The idea of tuning is to find a proposal distribution that is a good approximation to the posterior distribution. Sometimes 500 iterations per tuning phase (the default) is not sufficient to find a good approximating covariance.
- Change the initial values to more feasible starting values. Sometimes the proposal tuning starts badly if the initial values are too far away from the main mass of the posterior density, and it might not be able to recover.
- Use the **PROPCOV=** option to start the Markov chain at better starting values. With the **PROPCOV=QUANEW** option, PROC MCMC optimizes the object function and uses the posterior mode as the starting value of the Markov chain. In addition, a quadrature approximation to the posterior mode is used as the proposal covariance matrix. This option works well in many cases and can improve the mixing of the chain and shorten the tuning and burn-in time.
- Parameterize your model to include conjugacy, such as using the gamma prior on the precision parameter in a normal distribution or using an inverse gamma on the variance parameter. For a list of conjugate sampling methods that PROC MCMC supports, see the section “[Conjugate Sampling](#)” on page 4472.
- Change the blocking by using the **PARMS** statements. Sometimes poor mixing and slow convergence can be attributed to highly correlated parameters being in different parameter blocks.
- Modify the target acceptance rate. A target acceptance rate of about 25% works well for many multi-parameter problems, but if the mixing is slow, a lower target acceptance rate might be better.
- Change the initial scaling or the **TUNEWT=** option to possibly help the proposal tuning.
- Consider using a different proposal distribution. If from a trace plot you see that a chain traverses to the tail area and sometimes takes quite a few simulations before it comes back, you can consider using a  $t$  proposal distribution. You can do this by either using the PROC option **PROPDIST=T** or using a **PARMS** statement option **T**.

- Transform parameters and sample on a different scale. For example, if a parameter has a gamma distribution, sample on the logarithm scale instead. A parameter  $a$  that has a gamma distribution is equivalent to  $\log(a)$  that has an egamma distribution, with the same distribution specification. For example, the following two formulations are equivalent:

```
parm a;
prior a ~ gamma(shape = 0.001, scale = 0.001);
```

and

```
parm la;
prior la ~ egamma(shape = 0.001, scale = 0.001);
a = exp(la);
```

See “[Example 55.6: Nonlinear Poisson Regression Models](#)” on page 4570 and “[Example 55.20: Using a Transformation to Improve Mixing](#)” on page 4654. You can also use the logit transformation on parameters that have  $\text{uniform}(0, 1)$  priors. This prior is often used on probability parameters. The logit transformation is as follows:  $q = \log\left(\frac{p}{1-p}\right)$ . The distribution on  $q$  is the Jacobian of the transformation:  $\exp(-q)(1 + \exp(-q))^{-2}$ . Again, the following two formulations are equivalent:

```
parm p;
prior p ~ uniform(0, 1);
```

and

```
parm q;
lp = -q - 2 * log(1 + exp(-q));
prior q ~ general(lp);
p = 1 / (1 + exp(-q));
```

## Precision of Solution

In some applications, PROC MCMC might produce parameter values that are not precise enough. Usually, this means that there were not enough iterations in the simulation. At best, the precision of MCMC estimates increases with the square of the simulation sample size. Autocorrelation in the parameter values deflate the precision of the estimates. For more information about autocorrelations in Markov chains, see the section “[Autocorrelations](#)” on page 152.

---

## Handling Error Messages

PROC MCMC does not have a debugger. This section covers a few ways to debug and resolve error messages.

## Using the PUT Statement

Adding the PUT statement often helps to find errors in a program. The following statements produce an error:

```
data a;
run;

proc mcmc data=a seed=1;
 parms sigma lt w;

 beginnodata;
 prior sigma ~ unif(0.001,100);
 s2 = sigma*sigma;
 prior lt ~ gamma(shape=1, iscale=0.001);
 t = exp(lt);
 c = t/s2;
 d = 1/(s2);
 prior w ~ gamma(shape=c, iscale=d);
 endnodata;

 model general(0);
run;
```

```
ERROR: PROC MCMC is unable to generate an initial value for the
 parameter w. The first parameter in the prior distribution is
 missing.
```

To find out why the shape parameter *c* is missing, you can add the put statement and examine all the calculations that lead up to the assignment of *c*:

```
proc mcmc data=a seed=1;
 parms sigma lt w;

 beginnodata;
 prior sigma ~ unif(0.001,100);
 s2 = sigma*sigma;
 prior lt ~ gamma(shape=1, iscale=0.001);
 t = exp(lt);
 c = t/s2;
 d = 1/(s2);
 put c= t= s2= lt=; /* display the values of these symbols. */
 prior w ~ gamma(shape=c, iscale=d);
 endnodata;

 model general(0);
run;
```

In the log file, you see the following:

```
c=. t=. s2=. lt=.
c=. t=. s2=2500.0500003 lt=1000
c=. t=. s2=2500.0500003 lt=1000
```

```
ERROR: PROC MCMC is unable to generate an initial value for the parameter w.
 The first parameter in the prior distribution is missing.
```

You can ignore the first few lines. They are the results of initial set up by PROC MCMC. The last line is important. The variable `c` is missing because `t` is the exponential of a very large number, 1000, in `lt`. The value 1000 is assigned to `lt` by PROC MCMC because none was given. The gamma prior with shape of 1 and inverse scale of 0.001 has mode 0 (see “[Standard Distributions](#)” on page 4476 for more details). PROC MCMC avoids starting the Markov chain at the boundary of the support of the distribution, and it uses the mean value here instead. The mean of the gamma prior is 1000, hence the problem. You can change how the initial value is generated by using the PROC statement `INIT=RANDOM`. Remember to take out the `put` statement once you identify the problem. Otherwise, you will see a voluminous output in the log file.

## Using the HYPER Statement

You can use the `HYPER` statement to narrow down possible errors in the prior distribution specification. With multiple `PRIOR` statements in a program, you might see the following error message if one of the prior distributions is not specified correctly:

```
ERROR: The initial prior parameter specifications must yield log
 of positive prior density values.
```

This message is displayed when PROC MCMC detects an error in the prior distribution calculation but cannot pinpoint the specific parameter at fault. It is frequently, although not necessarily, associated with parameters that have `GENERAL` or `DGENERAL` distributions. If you have a complicated model with many `PRIOR` statements, finding the parameter at fault can be time consuming. One way is to change a subset of the `PRIOR` statements to `HYPER` statements. The two statements are treated the same in PROC MCMC and the simulation is not affected, but you get a different message if the hyperprior distributions are calculated incorrectly:

```
ERROR: The initial hyperprior parameter specifications must yield
 log of positive hyperprior density values.
```

This message can help you identify more easily which distributions are producing the error, and you can then use the `PUT` statement to further investigate.

---

## Computational Resources

It is impossible to estimate how long it will take for a general Markov chain to converge to its stationary distribution. It takes a skilled and thoughtful analysis of the chain to decide whether it has converged to the target distribution and whether the chain is mixing rapidly enough. In some cases, you might be able to estimate how long a particular simulation might take. The running time of a program that does not have `RANDOM` statements is approximately linear to the following factors: the number of samples in the input data set, the number of simulations, the number of blocks in the program, and the speed of your computer. For an analysis that uses a data set of size `nsamples`, a simulation length of `nsim`, and a block design of

nblocks, PROC MCMC evaluates the log-likelihood function the following number of times, excluding the tuning phase:

$$\text{nsamples} \times \text{nsim} \times \text{nblocks}$$

The faster your computer evaluates a single log-likelihood function, the faster this program runs. Suppose you have nsamples equal to 200, nsim equal to 55,000, and nblocks equal to 3. PROC MCMC evaluates the log-likelihood function approximately  $3.3 \times 10^7$  times. If your computer can evaluate the log likelihood for one observation  $10^6$  times per second, this program takes approximately a half a minute to run. If you want to increase the number of simulations five-fold, the run time increases approximately five-fold.

Each **RANDOM** statement adds one pass through the input data at each iteration. If the Metropolis algorithm is used to sample the random-effects parameter, the conditional density (objective function) is calculated twice per pass through the data, which requires a computational resource that is approximately equivalent to adding two blocks of parameters.

Of course, larger problems take longer than shorter ones, and if your model is amenable to frequentist treatment, then one of the other SAS procedures might be more suitable. With “regular” likelihoods and a lot of data, the results of standard frequentist analysis are often asymptotically equivalent to a Bayesian approach. If PROC MCMC requires too much CPU time, then perhaps another SAS/STAT tool would be suitable.

## Displayed Output

This section describes the output that PROC MCMC displays. For a quick reference of all ODS table names, see the section “[ODS Table Names](#)” on page 4537. ODS tables are arranged under four groups, which are listed in the following sections: “[Model and Data Related ODS Tables](#)” on page 4533, “[Sampling Related ODS Tables](#)” on page 4534, “[Posterior Statistics Related ODS Tables](#)” on page 4535, “[Convergence Diagnostics Related ODS Tables](#)” on page 4535, and “[Optimization Related ODS Tables](#)” on page 4536.

### Model and Data Related ODS Tables

#### ***Missing Data Information Table***

The “Missing Data Information” table (ODS table name MISSDATAINFO) displays the name of the response variable that contains missing values, the number of missing observations, the corresponding observation indices in the input data set, and the sampling method used in the simulation for the missing values.

#### ***Number of Observation Table***

The “NObs” table (ODS table name NOBS) shows the number of observations that is in the data set and the number of observations that is used in the analysis. By default, observations with missing values are not used (see the section “[Handling of Missing Data](#)” on page 4518 for more details). This table is displayed by default.

#### ***Parameters***

The “Parameters” table (ODS table name Parameters) shows the name of each parameter, the block number of each parameter, the sampling method used for the block, the initial values, and the prior or hyperprior distributions. This table is displayed by default.

**REObsInfo**

The “Random Effect Observation Information” table (ODS table name REObsInfo) lists the name of the random effect, each subject value, the number of observations in each subject, and their corresponding observation indices in the input data set. You can request this table by specifying the **REOBSINFO** option.

**REParameters**

The “REParameters” table (ODS table name REParameters) lists the name of the random effect, sampling algorithm, the subject variable, the number of subjects, unique values of the subject variable, and the prior distribution. This table is displayed by default if a **RANDOM** statement is used in the program.

**Sampling Related ODS Tables****Burn-In History**

The “Burn-In History” table (ODS table name BurnInHistory) shows the scales and acceptance rates for each parameter block in the burn-in phase. The table is not displayed by default and can be requested by specifying the option **MCHISTORY=BRIEF | DETAILED**.

**Parameters Initial Value Table**

The “Parameters Initial” table (ODS table name ParametersInit) shows the value of each parameter after the tuning phase. This table is not displayed by default and can be requested by specifying the option **INIT=PINIT**.

**Posterior Samples**

The “Posterior Samples” table (ODS table name PosteriorSample) stores posterior draws of all parameters. It is not printed by PROC MCMC. You can create an ODS output data set of the chain by specifying the following:

```
ODS OUTPUT PosteriorSample = SAS-data-set;
```

**Sampling History**

The “Sampling History” table (ODS table name SamplingHistory) shows the scales and acceptance rates for each parameter block in the main sampling phase. The table is not displayed by default and can be requested by specifying the option **MCHISTORY=BRIEF | DETAILED**.

**Tuning Covariance**

The “Tuning Covariance” table (ODS table name TuneCov) shows the proposal covariance matrices for each parameter block after the tuning phase. The table is not displayed by default and can be requested by specifying the option **INIT=PINIT**. For more details about proposal tuning, see the section “**Tuning the Proposal Distribution**” on page 4469.

**Tuning History**

The “Tuning History” table (ODS table name TuningHistory) shows the number of tuning phases used in establishing the proposal distribution. The table also displays the scales and acceptance rates for each parameter block at each of the tuning phases. For more information about the self-adapting proposal tuning algorithm used by PROC MCMC, see the section “**Tuning the Proposal Distribution**” on page 4469. The table is not displayed by default and can be requested by specifying the option **MCHISTORY=BRIEF | DETAILED**.

***Tuning Probability Vector***

The “Tuning Probability” table (ODS table name TuneP) shows the proposal probability vector for each discrete parameter block (when the option DISCRETE=GEO is specified and the geometric proposal distribution is used for discrete parameters) after the tuning phase. The table is not displayed by default and can be requested by specifying the option INIT=PINIT. For more information about proposal tuning, see the section “Tuning the Proposal Distribution” on page 4469.

**Posterior Statistics Related ODS Tables**

PROC MCMC calculates some essential posterior statistics and outputs them to a number of ODS tables that you can request and save individually. For details of the calculations, see the section “Summary Statistics” on page 153.

***Summary Statistics***

The “Posterior Summaries” table (ODS table name PostSummaries) contains basic statistics for each parameter. The table lists the number of posterior samples, the posterior mean and standard deviation estimates, and the percentile estimates. This table is displayed by default.

***Correlation Matrix***

The “Posterior Correlation Matrix” table (ODS table name Corr) contains the posterior correlation of model parameters. The table is not displayed by default and can be requested by specifying the option STATS=CORR.

***Covariance Matrix***

The “Posterior Covariance Matrix” table (ODS table name Cov) contains the posterior covariance of model parameters. The table is not displayed by default and can be requested by specifying the option STATISTICS=COV.

***Deviance Information Criterion***

The “Deviance Information Criterion” table (ODS table name DIC) contains the DIC of the model. The table is not displayed by default and can be requested by specifying the option DIC. For details of the calculations, see the section “Deviance Information Criterion (DIC)” on page 155.

***Interval Statistics***

The “Posterior Intervals” table (ODS table name PostIntervals) contains the equal-tail and highest posterior density (HPD) interval estimates for each parameter. The default  $\alpha$  value is 0.05, and you can change it to other levels by using the STATISTICS= option. This table is displayed by default.

**Convergence Diagnostics Related ODS Tables**

PROC MCMC has convergence diagnostic tests that check for Markov chain convergence. PROC MCMC produces a number of ODS tables that you can request and save individually. For details in calculation, see the section “Statistical Diagnostic Tests” on page 144.

***Autocorrelation***

The “Autocorrelations” table (ODS table name AUTOCORR) contains the first order autocorrelations of the posterior samples for each parameter. The “Parameter” column states the name of the parameter. By default,

PROC MCMC displays lag 1, 5, 10, and 50 estimates of the autocorrelations. You can request different autocorrelations by using the `DIAGNOSTICS = AUTOCORR(LAGS=)` option. This table is displayed by default.

### **Effective Sample Size**

The “Effective Sample Sizes” table (ODS table name ESS) calculates the effective sample size of each parameter. See the section “Effective Sample Size” on page 152 for more details. The table is displayed by default.

### **Monte Carlo Standard Errors**

The “Monte Carlo Standard Errors” table (ODS table name MCSE) calculates the standard errors of the posterior mean estimate. See the section “Standard Error of the Mean Estimate” on page 153 for more details. The table is displayed by default.

### **Geweke Diagnostics**

The “Geweke Diagnostics” table (ODS table name Geweke) lists the result of the Geweke diagnostic test. See the section “Geweke Diagnostics” on page 146 for more details. The table is displayed by default.

### **Heidelberger-Welch Diagnostics**

The “Heidelberger-Welch Diagnostics” table (ODS table name Heidelberger) lists the result of the Heidelberger-Welch diagnostic test. The test is consisted of two parts: a stationary test and a half-width test. See the section “Heidelberger and Welch Diagnostics” on page 148 for more details. The table is not displayed by default and can be requested by specifying `DIAGNOSTICS = HEIDEL`.

### **Raftery-Lewis Diagnostics**

The “Raftery-Lewis Diagnostics” table (ODS table name Raftery) lists the result of the Raftery-Lewis diagnostic test. See the section “Raftery and Lewis Diagnostics” on page 149 for more details. The table is not displayed by default and can be requested by specifying `DIAGNOSTICS = RAFTERY`.

### **Summary Statistics for Prediction**

The “Posterior Summaries for Prediction” table (ODS table name PredSummaries) contains basic statistics for each prediction. The table lists the number of posterior samples, the posterior mean and standard deviation estimates, and the percentile estimates. This table is displayed by default if any `PREDDIST` statement is used in the program.

### **Interval Statistics for Prediction**

The “Posterior Intervals for Prediction” table (ODS table name PredIntervals) contains the equal-tail and highest posterior density (HPD) interval estimates for each prediction. The default  $\alpha$  value is 0.05, and you can change it to other levels by using the `STATISTICS` option in a `PREDDIST` statement, or the `STATISTICS=` option in the PROC MCMC statement if the option is not specified in a statement. This table is displayed by default if any `PREDDIST` statement is used in the program.

## **Optimization Related ODS Tables**

PROC MCMC can perform optimization on the joint posterior distribution. This is requested by the `PROPCOV=` option. The most commonly used optimization method is the quasi-Newton method: `PROPCOV=QUANEW(ITPRINT)`. The `ITPRINT` option displays the ODS tables, listed as follows:

**Input Options**

The “Input Options” table (ODS table name InputOptions) lists optimization options used in the procedure.

**Optimization Start**

The “Optimization Start” table (ODS table name ProblemDescription) shows the initial state of the optimization.

**Iteration History**

The “Iteration History” table (ODS table name IterHist) shows iteration history of the optimization.

**Optimization Results**

The “Optimization Results” table (ODS table name IterStop) shows the results of the optimization, includes information about the number of function calls, and the optimized objective function, which is the joint log posterior density.

**Convergence Status**

The “Convergence Status” table (ODS table name ConvergenceStatus) shows whether the convergence criterion is satisfied.

**Parameters Value After Optimization Table**

The “Parameter Values After Optimization” table (ODS table name OptiEstimates) lists the parameter values that maximize the joint log posterior. These are the maximum a posteriori point estimates, and they are used to start the Markov chain.

**Covariance Matrix After Optimization Table**

The “Proposal Covariance” table (ODS table name OptiCov) lists covariance matrices for each block parameter by using quadrature approximation at the posterior mode. These covariance matrices are used in the proposal distribution.

---

## ODS Table Names

PROC MCMC assigns a name to each table it creates. You can use these names to refer to the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 55.47. For more information about ODS, see Chapter 21, “Statistical Graphics Using ODS.”

**Table 55.47** ODS Tables Produced in PROC MCMC

| ODS Table Name    | Description                                   | Statement or Option        |
|-------------------|-----------------------------------------------|----------------------------|
| AutoCorr          | Autocorrelation statistics for each parameter | Default                    |
| BurnInHistory     | History of burn-in phase sampling             | MCHISTORY=BRIEF   DETAILED |
| ConvergenceStatus | Optimization convergence status               | PROPCOV=method(ITPRINT)    |
| Corr              | Correlation matrix of the posterior samples   | STATS=CORR                 |

Table 55.47 (continued)

| ODS Table Name     | Description                                                                                                               | Statement or Option                     |
|--------------------|---------------------------------------------------------------------------------------------------------------------------|-----------------------------------------|
| Cov                | Covariance matrix of the posterior samples                                                                                | STATS=COV                               |
| DIC                | Deviance information criterion                                                                                            | DIC                                     |
| ESS                | Effective sample size for each parameter                                                                                  | Default                                 |
| MCSE               | Monte Carlo standard error for each parameter                                                                             | Default                                 |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC MCMC generates are listed in [Table 55.48](#).

**Table 55.48** Graphs Produced by PROC MCMC

| ODS Graph Name | Plot Description                           | Statement & Option       |
|----------------|--------------------------------------------|--------------------------|
| ADPanel        | Autocorrelation function and density panel | PLOTS=(AUTOCORR DENSITY) |
| AutocorrPanel  | Autocorrelation function panel             | PLOTS=AUTOCORR           |
| AutocorrPlot   | Autocorrelation function plot              | PLOTS(UNPACK)=AUTOCORR   |
| DensityPanel   | Density panel                              | PLOTS=DENSITY            |
| DensityPlot    | Density plot                               | PLOTS(UNPACK)=DENSITY    |

Table 55.48 *continued*

| ODS Graph Name | Plot Description                                   | Statement & Option             |
|----------------|----------------------------------------------------|--------------------------------|
| TAPanel        | Trace and autocorrelation function panel           | PLOTS=(TRACE AUTOCORR)         |
| TADPanel       | Trace, density, and autocorrelation function panel | PLOTS=(TRACE AUTOCORR DENSITY) |
| TDPanel        | Trace and density panel                            | PLOTS=(TRACE DENSITY)          |
| TracePanel     | Trace panel                                        | PLOTS=TRACE                    |
| TracePlot      | Trace plot                                         | PLOTS(UNPACK)=TRACE            |

## Examples: MCMC Procedure

### Example 55.1: Simulating Samples From a Known Density

This example illustrates how you can obtain random samples from a known function. The target distributions are the normal distribution (a standard distribution) and a mixture of the normal distributions (a nonstandard distribution). For more information, see the sections “[Standard Distributions](#)” on page 4476 and “[Specifying a New Distribution](#)” on page 4490). This example also shows how you can use PROC MCMC to estimate an integral (area under a curve). Monte Carlo simulation is data-independent; hence, you do not need an input data set from which to draw random samples from the desired distribution.

#### Sampling from a Normal Density

When you run a simulation without an input data set, the posterior distribution is the same as the prior distribution. Hence, if you want to generate samples from a distribution, you declare the distribution in the **PRIOR** statement and set the likelihood function to a constant. Although there is no contribution from any data set variable to the likelihood calculation, you still must specify a data set and the **MODEL** statement needs a distribution. You can input an empty data set and use the **GENERAL** function to provide a flat likelihood. The following statements generate 10,000 samples from a standard normal distribution:

```

title 'Simulating Samples from a Normal Density';
data x;
run;

ods graphics on;
proc mcmc data=x outpost=simout seed=23 nmc=10000
 statistics=(summary interval) diagnostics=none;
 ods exclude nob;
 parm alpha 0;
 prior alpha ~ normal(0, sd=1);
 model general(0);
run;

```

The ODS GRAPHICS ON statement enables ODS Graphics. The PROC MCMC statement specifies the input and output data sets, a random number seed, and the size of the simulation sample. The STATISTICS= option displays only the summary and interval statistics. The ODS EXCLUDE statement excludes the display of the NObs table. PROC MCMC draws independent samples from the normal distribution directly (see Output 55.1.1). Therefore, the simulation does not require any tuning, and PROC MCMC omits the default burn-in phrase.

**Output 55.1.1** Parameters Information

| Simulating Samples from a Normal Density |           |                 |               |                    |
|------------------------------------------|-----------|-----------------|---------------|--------------------|
| The MCMC Procedure                       |           |                 |               |                    |
| Parameters                               |           |                 |               |                    |
| Block                                    | Parameter | Sampling Method | Initial Value | Prior Distribution |
| 1                                        | alpha     | Direct          | 0             | normal(0, sd=1)    |

The summary statistics (Output 55.1.2) are what you would expect from a standard normal distribution.

**Output 55.1.2** MCMC Summary and Interval Statistics from a Normal Target Distribution

| Simulating Samples from a Normal Density |       |                     |                    |              |         |        |
|------------------------------------------|-------|---------------------|--------------------|--------------|---------|--------|
| The MCMC Procedure                       |       |                     |                    |              |         |        |
| Posterior Summaries                      |       |                     |                    |              |         |        |
| Parameter                                | N     | Mean                | Standard Deviation | Percentiles  |         |        |
|                                          |       |                     |                    | 25%          | 50%     | 75%    |
| alpha                                    | 10000 | 0.00195             | 0.9949             | -0.6544      | 0.00965 | 0.6709 |
| Posterior Intervals                      |       |                     |                    |              |         |        |
| Parameter                                | Alpha | Equal-Tail Interval |                    | HPD Interval |         |        |
| alpha                                    | 0.050 | -1.9485             | 1.9507             | -1.9664      | 1.9302  |        |

The trace plot (Output 55.1.3) shows perfect mixing with no autocorrelation in the lag plot. This is expected because these are independent draws.

**Output 55.1.3** Diagnostics Plots for  $\alpha$ 

You can overlay the estimated kernel density with the true density to visually compare the densities, as displayed in [Output 55.1.4](#). To create the kernel comparison plot, you first call PROC KDE (see Chapter 48, “The KDE Procedure”) to obtain a kernel density estimate of the posterior density on  $\alpha$ . Then you evaluate a grid of  $\alpha$  values on a normal density. The following statements evaluate kernel density and compute the corresponding normal density:

```
proc kde data=simout;
 ods exclude inputs controls;
 univar alpha /out=sample;
run;

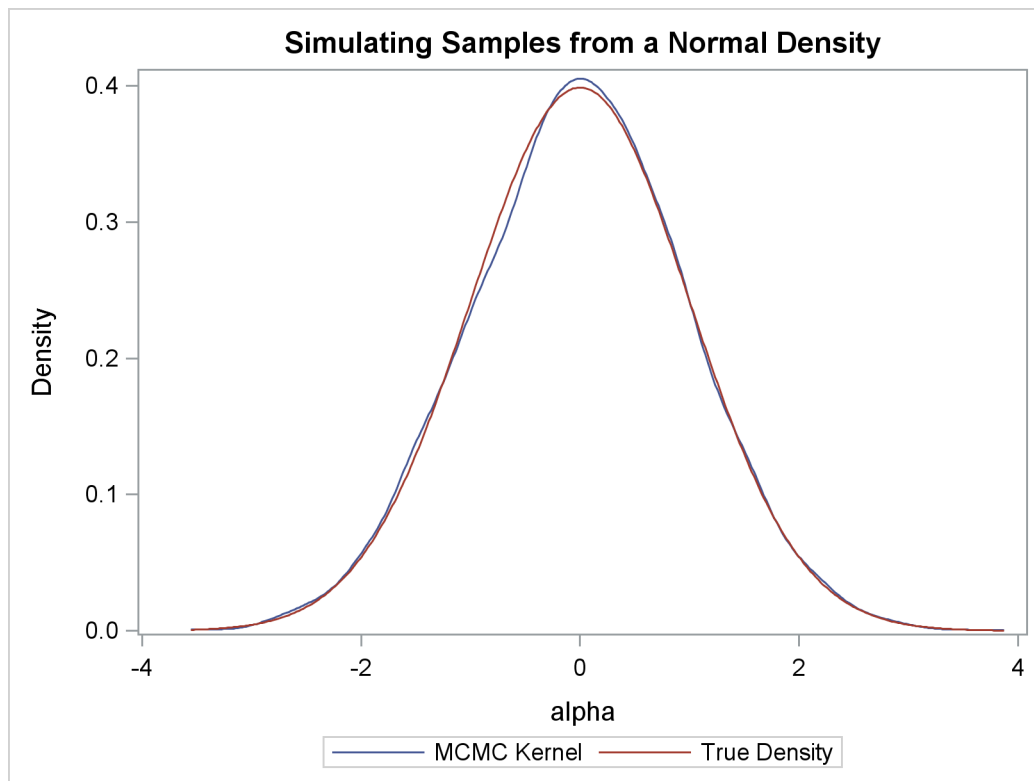

data den;
 set sample;
 alpha = value;
 true = pdf('normal', alpha, 0, 1);
 keep alpha density true;
run;
```

Next you plot the two curves on top of each other by using PROC SGPLOT (see Chapter 21, “Statistical Graphics Using ODS”) as follows:

```
proc sgplot data=den;
 yaxis label="Density";
 series y=density x=alpha / legendlabel = "MCMC Kernel";
 series y=true x=alpha / legendlabel = "True Density";
 discretelegend;
run;
```

Output 55.1.4 shows the result. You can see that the kernel estimate and the true density are very similar to each other.

**Output 55.1.4** Estimated Density versus the True Density

### Density Visualization Macro

In programs that do not involve any data set variables, PROC MCMC samples directly from the (joint) prior distributions of the parameters. The modification makes the sampling from a known distribution more efficient and more precise. For example, you can write simple programs, such as the following macro, to understand different aspects of a prior distribution of interest, such as its moments, intervals, shape, spread, and so on:

```

%macro density(dist=, seed=0);
 %let savenote = %sysfunc(getoption(notes));
 options nonotes;
 title "&dist distribution.";
 data _a;
 run;

 ods select densitypanel postsummaries postintervals;
 proc mcmc data=_a nmc=10000 diag=none nologdist
 plots=density seed=&seed;
 parms alpha;
 prior alpha ~ &dist;
 model general(0);
 run;

 proc datasets nolist;
 delete _a;
 run;
 options &savenote;
%mend;

%density(dist=beta(4, 12), seed=1);

```

The macro %density creates an empty data set, invokes PROC MCMC, draws 10,000 samples from a beta(4, 12) distribution, displays summary and interval statistics, and generates a kernel density plot. Summary and interval statistics from the beta distribution are displayed in [Output 55.1.5](#).

**Output 55.1.5** Beta Distribution Statistics

| beta(4, 12) distribution. |       |                     |                       |              |        |        |

The distribution is displayed in [Output 55.1.6](#).

Output 55.1.6 Density Plot

## Calculation of Integrals

One advantage of MCMC methods is to estimate any integral under the curve of a target distribution. This can be done fairly easily using the MCMC procedure. Suppose you are interested in estimating the following cumulative probability:

$$\int_{\alpha=0}^{1.3} \phi(\alpha|0, 1) d\alpha$$

To estimate this integral, PROC MCMC draws samples from the distribution and counts the portion of the simulated values that fall within the desired range of [0, 1.3]. This becomes a Monte Carlo estimate of the integral. The following statements simulate samples from a standard normal distribution and estimate the integral:

```
proc mcmc data=x outpost=simout seed=23 nmc=10000 nologdist
 monitor=(int) statistics=(summary) diagnostics=none;
 ods select postsummaries;
 parm alpha 0;
 prior alpha ~ normal(0, sd=1);
 int = (0 <= alpha <= 1.3);
 model general(0);
run;
```

The ODS SELECT statement displays the posterior summary statistics table. The MONITOR= option outputs analysis on the variable int (the integral estimate). The STATISTICS= option computes the summary

statistics. The `NOLOGDIST` option omits the calculation of the log of the prior distribution at each iteration, shortening the simulation time<sup>8</sup>. The `INT` assignment statement sets `int` to be 1 if the simulated alpha value falls between 0 and 1.3, and 0 otherwise. PROC MCMC supports the usage of the IF-ELSE logical control if you need to account for more complex conditions. Output 55.1.7 displays the estimated integral value:

**Output 55.1.7** Monte Carlo Integral from a Normal Distribution

| beta(4, 12) distribution. |       |        |                       |             |     |        |
|---------------------------|-------|--------|-----------------------|-------------|-----|--------|
| The MCMC Procedure        |       |        |                       |             |     |        |
| Posterior Summaries       |       |        |                       |             |     |        |
| Parameter                 | N     | Mean   | Standard<br>Deviation | Percentiles |     |        |
|                           |       |        |                       | 25%         | 50% | 75%    |
| int                       | 10000 | 0.4079 | 0.4915                | 0           | 0   | 1.0000 |

In this simulation, 4079 samples fall between 0 and 1.3, making the expected probability 0.4079. In this example, you can verify the actual cumulative probability by calling the CDF function in the DATA step:

```
data _null_;
 int = cdf("normal", 1.3, 0, 1) - cdf("normal", 0, 0, 1);
 put int=;
run;
```

The value is 0.4032.

## Sampling from a Mixture of Normal Densities

Suppose you are interested in generating samples from a three-component mixture of normal distributions, with the density specified as follows:

$$p(\alpha) = 0.3 \cdot \phi(-3, \sigma = 2) + 0.4 \cdot \phi(2, \sigma = 1) + 0.3 \cdot \phi(10, \sigma = 4)$$

The distribution is not one of the standard distributions that PROC MCMC supports. Hence you need to construct the density function and supply it to the procedure. The following statements generate random samples from this mixture density:

```
title 'Simulating Samples from a Mixture of Normal Densities';
data x;
run;

proc mcmc data=x outpost=simout seed=1234 nmc=30000;
 ods select TADpanel;
 parm alpha 0.3;
 lp = logpdf('normalmix', alpha, 3, 0.3, 0.4, 0.3, -3, 2, 10, 2, 1, 4);
 prior alpha ~ general(lp);
 model general(0);
run;
```

<sup>8</sup>In this example, the `NOLOGDIST` option saves only a fraction of the time. But in more complex simulation schemes that involve a larger number of distributions and parameters, the time reduction could be significant.

The ODS SELECT statement displays the diagnostic plots. All other tables, such as the NObs tables, are excluded. The PROC MCMC statement uses the input data set X, saves output to the Simout data set, sets a random number seed, and draws 30,000 samples.

The LP assignment statement evaluates the log density of alpha at the mixture density, using the SAS function LOGPDF. The number 3 after alpha in the LOGPDF function indicates that the density is a three-component normal mixture. The following three numbers, 0.3, 0.4, and 0.3, are the weights in the mixture; -3, 2, and 10 are the means; 2, 1, and 4 are the standard deviations. The PRIOR statement assigns this log density function to alpha as its prior. Note that the GENERAL function interprets the density on the log scale, and not the original scale—you must use the LOGPDF function, not the PDF function. Output 55.1.8 displays the results. The kernel density clearly shows three modes.

**Output 55.1.8** Plots of Posterior Samples from a Mixture Normal Distribution

Using the following set of statements similar to the previous example, you can overlay the estimated kernel density with the true density. The comparison is shown in Output 55.1.9.

```
proc kde data=simout;
 ods exclude inputs controls;
 univar alpha /out=sample;
run;

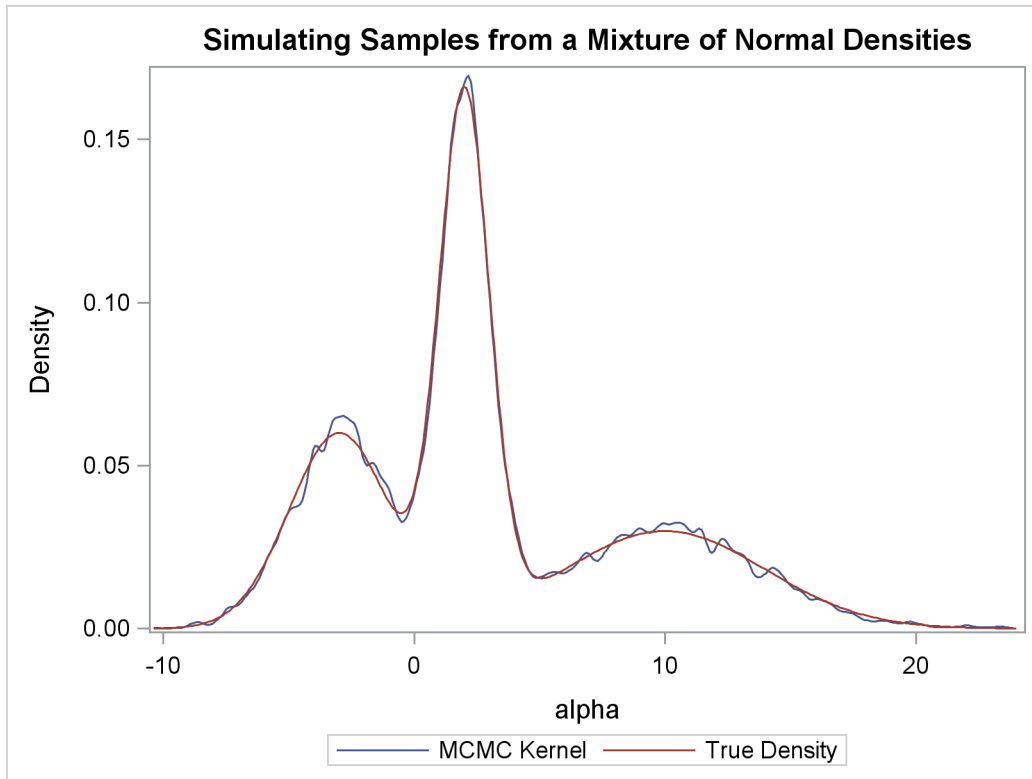

data den;
 set sample;
 alpha = value;
 true = pdf('normalmix', alpha, 3, 0.3, 0.4, 0.3, -3, 2, 10, 2, 1, 4);
 keep alpha density true;
run;
```

```

proc sgplot data=den;
 yaxis label="Density";
 series y=density x=alpha / legendlabel = "MCMC Kernel";
 series y=true x=alpha / legendlabel = "True Density";
 discretelegend;
run;

```

**Output 55.1.9** Estimated Density versus the True Density

## Example 55.2: Box-Cox Transformation

Box-Cox transformations (Box and Cox 1964) are often used to find a power transformation of a dependent variable to ensure the normality assumption in a linear regression model. This example illustrates how you can use PROC MCMC to estimate a Box-Cox transformation for a linear regression model. Two different priors on the transformation parameter  $\lambda$  are considered: a continuous prior and a discrete prior. You can estimate the probability of  $\lambda$  being 0 with a discrete prior but not with a continuous prior. The IF-ELSE statements are demonstrated in the example.

## Using a Continuous Prior on $\lambda$

The following statements create a SAS data set with measurements of  $y$  (the response variable) and  $x$  (a single dependent variable):

```

title 'Box-Cox Transformation, with a Continuous Prior on Lambda';
data boxcox;
 input y x @@;
 datalines;
10.0 3.0 72.6 8.3 59.7 8.1 20.1 4.8 90.1 9.8 1.1 0.9
78.2 8.5 87.4 9.0 9.5 3.4 0.1 1.4 0.1 1.1 42.5 5.1
57.0 7.5 9.9 1.9 0.5 1.0 121.1 9.9 37.5 5.9 49.5 6.7

... more lines ...

2.6 1.8 58.6 7.9 81.2 8.1 37.2 6.9
;

```

The Box-Cox transformation of  $y$  takes on the form of:

$$y(\lambda) = \begin{cases} \frac{y^{\lambda}-1}{\lambda} & \text{if } \lambda \neq 0; \\ \log(y) & \text{if } \lambda = 0. \end{cases}$$

The transformed response  $y(\lambda)$  is assumed to be normally distributed:

$$y_i(\lambda) \sim \text{normal}(\beta_0 + \beta_1 x_i, \sigma^2)$$

The likelihood with respect to the original response  $y_i$  is as follows:

$$p(y_i|\lambda, \beta, \sigma^2, x_i) \propto \phi(y_i|\beta_0 + \beta_1 x_i, \sigma^2) \cdot J(\lambda, y_i)$$

where  $J(\lambda, y_i)$  is the Jacobian:

$$J(\lambda, y) = \begin{cases} y_i^{\lambda-1} & \text{if } \lambda \neq 0; \\ 1/y_i & \text{if } \lambda = 0. \end{cases}$$

And on the log-scale, the Jacobian becomes:

$$\log(J(\lambda, y)) = \begin{cases} (\lambda - 1) \cdot \log(y_i) & \text{if } \lambda \neq 0; \\ -\log(y_i) & \text{if } \lambda = 0. \end{cases}$$

There are four model parameters:  $\lambda$ ,  $\boldsymbol{\beta} = \{\beta_0, \beta_1\}$ , and  $\sigma^2$ . You can consider using a flat prior on  $\boldsymbol{\beta}$  and a gamma prior on  $\sigma^2$ .

To consider only power transformations ( $\lambda \neq 0$ ), you can use a continuous prior (for example, a uniform prior from  $-2$  to  $2$ ) on  $\lambda$ . One issue with using a continuous prior is that you cannot estimate the probability of  $\lambda = 0$ . To do so, you need to consider a discrete prior that places positive probability mass on the point  $0$ . See “[Modeling  \$\lambda = 0\$](#) ” on page 4553.

The following statements fit a Box-Cox transformation model:

```

ods graphics on;
proc mcmc data=boxcox nmc=50000 thin=10 propcov=quanew seed=12567
 monitor=(lda);
 ods select PostSummaries PostIntervals TADpanel;

 parms beta0 0 beta1 0 lda 1 s2 1;

 beginnodata;
 prior beta: ~ general(0);
 prior s2 ~ gamma(shape=3, scale=2);
 prior lda ~ unif(-2,2);
 sd = sqrt(s2);
 endnodata;

 ys = (y**lda-1)/lda;
 mu = beta0+beta1*x;
 ll = (lda-1)*log(y)+lpdfnorm(ys, mu, sd);
 model general(ll);
run;

```

The **PROPCOV=** option initializes the Markov chain at the posterior mode and uses the estimated inverse Hessian matrix as the initial proposal covariance matrix. The **MONITOR=** option selects  $\lambda$  as the variable to report. The ODS SELECT statement displays the summary statistics table, the interval statistics table, and the diagnostic plots.

The **PARMS** statement puts all four parameters,  $\beta_0$ ,  $\beta_1$ ,  $\lambda$ , and  $\sigma^2$ , in a single block and assigns initial values to each of them. Three **PRIOR** statements specify previously stated prior distributions for these parameters. The assignment to **sd** transforms a variance to a standard deviation. It is better to place the transformation inside the **BEGINNODATA** and **ENDNODATA** statements to save computational time.

The assignment to the symbol **ys** evaluates the Box-Cox transformation of  $y$ , where  $\mu$  is the regression mean and  $\ell$  is the log likelihood of the transformed variable  $ys$ . Note that the log of the Jacobian term is included in the calculation of  $\ell$ .

Summary statistics and interval statistics for  $\lambda$  are listed in [Output 55.2.1](#).

### Output 55.2.1 Box-Cox Transformation

| Box-Cox Transformation, with a Continuous Prior on Lambda |      |        |                       |             |        |        |
|-----------------------------------------------------------|------|--------|-----------------------|-------------|--------|--------|
| The MCMC Procedure                                        |      |        |                       |             |        |        |
| Posterior Summaries                                       |      |        |                       |             |        |        |
| Parameter                                                 | N    | Mean   | Standard<br>Deviation | Percentiles |        |        |
|                                                           |      |        |                       | 25%         | 50%    | 75%    |
| lda                                                       | 5000 | 0.4702 | 0.0284                | 0.4515      | 0.4703 | 0.4884 |

**Output 55.2.1** *continued*

| Parameter | Alpha | Posterior Intervals |        |              |        |
|-----------|-------|---------------------|--------|--------------|--------|
|           |       | Equal-Tail Interval |        | HPD Interval |        |
| lda       | 0.050 | 0.4162              | 0.5269 | 0.4197       | 0.5298 |

The posterior mean of  $\lambda$  is 0.47, with a 95% equal-tail interval of [0.42, 0.53] and a similar HPD interval. The preferred power transformation would be 0.5 (rounding  $\lambda$  up to the square root transformation).

Output 55.2.2 shows diagnostics plots for lda. The chain appears to converge, and you can proceed to make inferences. The density plot shows that the posterior density is relatively symmetric around its mean estimate.

**Output 55.2.2** Diagnostic Plots for  $\lambda$ 

To verify the results, you can use PROC TRANSREG (see Chapter 97, “The TRANSREG Procedure”) to find the estimate of  $\lambda$ .

```
proc transreg data=boxcox details pbo;
 ods output boxcox = bc;
 model boxcox(y / convenient lambda=-2 to 2 by 0.01) = identity(x);
 output out=trans;
run;
```

Output from PROC TRANSREG is shown in [Output 55.2.5](#) and [Output 55.2.4](#). PROC TRANSREG produces a similar point estimate of  $\lambda = 0.46$ , and the 95% confidence interval is shown in [Output 55.2.5](#).

**Output 55.2.3** Box-Cox Transformation Using PROC TRANSREG

**Output 55.2.4** Estimates Reported by PROC TRANSREG

```

Box-Cox Transformation, with a Continuous Prior on Lambda

The TRANSREG Procedure

Model Statement Specification Details

Type DF Variable Description Value
Dep 1 BoxCox(y) Lambda Used 0.5
 Lambda 0.46
 Log Likelihood -167.0
 Conv. Lambda 0.5
 Conv. Lambda LL -168.3
 CI Limit -169.0
 Alpha 0.05
 Options Convenient Lambda Used
Ind 1 Identity(x) DF 1

```

The ODS data set `Bc` contains the 95% confidence interval estimates produced by PROC TRANSREG. This ODS table is rather large, and you want to see only the relevant portion. The following statements generate the part of the table that is important and display [Output 55.2.5](#):

```
proc print noobs label data=bc(drop=rmse);
 title2 'Confidence Interval';
 where ci ne ' ' or abs(lambda - round(lambda, 0.5)) < 1e-6;
 label convenient = '00'x ci = '00'x;
run;
```

The estimated 90% confidence interval is [0.41, 0.51], which is very close to the reported Bayesian credible intervals. The resemblance of the intervals is probably due to the noninformative prior that you used in this analysis.

**Output 55.2.5** Estimated Confidence Interval on  $\lambda$

| Box-Cox Transformation, with a Continuous Prior on Lambda |        |          |                |

### Modeling $\lambda = 0$

With a continuous prior on  $\lambda$ , you can get only a continuous posterior distribution, and this makes the probability of  $\Pr(\lambda = 0|\text{data})$  equal to 0 by definition. To consider  $\lambda = 0$  as a viable solution to the Box-Cox transformation, you need to use a discrete prior that places some probability mass on the point 0 and allows for a meaningful posterior estimate of  $\Pr(\lambda = 0|\text{data})$ .

This example uses a simulation study where the data are generated from an exponential likelihood. The simulation implies that the correct transformation should be the logarithm and  $\lambda$  should be 0. Consider the

following exponential model:

$$y = \exp(x + \epsilon),$$

where  $\epsilon \sim \text{normal}(0, 1)$ . The transformed data can be fitted with a linear model:

$$\log(y) = x + \epsilon$$

The following statements generate a SAS data set with a gridded  $x$  and corresponding  $y$ :

```

title 'Box-Cox Transformation, Modeling Lambda = 0';
data boxcox;
 do x = 1 to 8 by 0.025;
 ly = x + normal(7);
 y = exp(ly);
 output;
 end;
run;

```

The log-likelihood function, after taking the Jacobian into consideration, is as follows:

$$\log p(y_i | \lambda, x_i) = \begin{cases} (\lambda - 1) \log(y_i) - \frac{1}{2} \left( \log \sigma^2 + \frac{(y_i^\lambda - 1)/\lambda - x_i}{\sigma^2} \right)^2 + C_1 & \text{if } \lambda \neq 0; \\ -\log(y_i) - \frac{1}{2} \left( \log \sigma^2 + \frac{(\log(y_i) - x_i)^2}{\sigma^2} \right) + C_2 & \text{if } \lambda = 0. \end{cases}$$

where  $C_1$  and  $C_2$  are two constants.

You can use the function [DGENERAL](#) to place a discrete prior on  $\lambda$ . The function is similar to the function [GENERAL](#), except that it indicates a discrete distribution. For example, you can specify a discrete uniform prior from  $-2$  to  $2$  using

```
prior lda ~ dgeneral(1, lower=-2, upper=2);
```

This places equal probability mass on five points,  $-2$ ,  $-1$ ,  $0$ ,  $1$ , and  $2$ . This prior might not work well here because the grid is too coarse. To consider smaller values of  $\lambda$ , you can sample a parameter that takes a wider range of integer values and transform it back to the  $\lambda$  space. For example, set  $\alpha$  as your model parameter and give it a discrete uniform prior from  $-200$  to  $200$ . Then define  $\lambda$  as  $\alpha/100$  so  $\lambda$  can take values between  $-2$  and  $2$  but on a finer grid.

The following statements fit a Box-Cox transformation by using a discrete prior on  $\lambda$ :

```

proc mcmc data=boxcox outpost=simout nmc=50000 thin=10 seed=12567
 monitor=(lda);

 ods select PostSummaries PostIntervals;
 parms s2 1 alpha 10;

 beginnodata;
 prior s2 ~ gamma(shape=3, scale=2);
 if alpha=0 then lp = log(2);
 else lp = log(1);
 prior alpha ~ dgeneral(lp, lower=-200, upper=200);
 lda = alpha * 0.01;
 sd = sqrt(s2);
endnodata;

```

```

if alpha=0 then
 ll = -ly+lpdfnorm(ly, x, sd);
else do;
 ys = (y**lda - 1)/lda;
 ll = (lda-1)*ly+lpdfnorm(ys, x, sd);
end;
model general(ll);
run;

```

There are two parameters, `s2` and `alpha`, in the model. They are placed in a single **PARMS** statement so that they are sampled in the same block.

The parameter `s2` takes a gamma distribution, and `alpha` takes a discrete prior. The IF-ELSE statements state that `alpha` takes twice as much prior density when it is 0 than otherwise. Note that on the original scale,  $\Pr(\alpha = 0) = 2 \cdot \Pr(\alpha \neq 0)$ . Translating that to the log scale, the densities become  $\log(2)$  and  $\log(1)$ , respectively. The LDA assignment statement transforms `alpha` to the parameter of interest: `lda` takes values between  $-2$  and  $2$ . You can model `lda` on an even smaller scale by dividing `alpha` by a larger constant. However, an increment of 0.01 in the Box-Cox transformation is usually sufficient. The SD assignment statement calculates the square root of the variance term.

The log-likelihood function uses another set of IF-ELSE statements, separating the case of  $\lambda = 0$  from the others. The formulas are stated previously. The output of the program is shown in [Output 55.2.6](#).

#### Output 55.2.6 Box-Cox Transformation

| Box-Cox Transformation, Modeling Lambda = 0 |       |                     |                       |              |     |     |
|---------------------------------------------|-------|---------------------|-----------------------|--------------|-----|-----|
| The MCMC Procedure                          |       |                     |                       |              |     |     |
| Posterior Summaries                         |       |                     |                       |              |     |     |
| Parameter                                   | N     | Mean                | Standard<br>Deviation | Percentiles  |     |     |
|                                             |       |                     |                       | 25%          | 50% | 75% |
| lda                                         | 5000  | -0.00002            | 0.00201               | 0            | 0   | 0   |
| Posterior Intervals                         |       |                     |                       |              |     |     |
| Parameter                                   | Alpha | Equal-Tail Interval |                       | HPD Interval |     |     |
| lda                                         | 0.050 | 0                   | 0                     | 0            | 0   |     |

From the summary statistics table, you see that the point estimate for  $\lambda$  is 0 and both of the 95% equal-tail and HPD credible intervals are 0. This strongly suggests that  $\lambda = 0$  is the best estimate for this problem. In addition, you can also count the frequency of  $\lambda$  among posterior samples to get a more precise estimate on the posterior probability of  $\lambda$  being 0.

The following statements use PROC FREQ to produce [Output 55.2.7](#) and [Output 55.2.8](#):

```

proc freq data=simout;
 ods select onewayfreqs freqplot;
 tables lda /nocum plot=freqplot(scale=percent);
run;
ods graphics off;

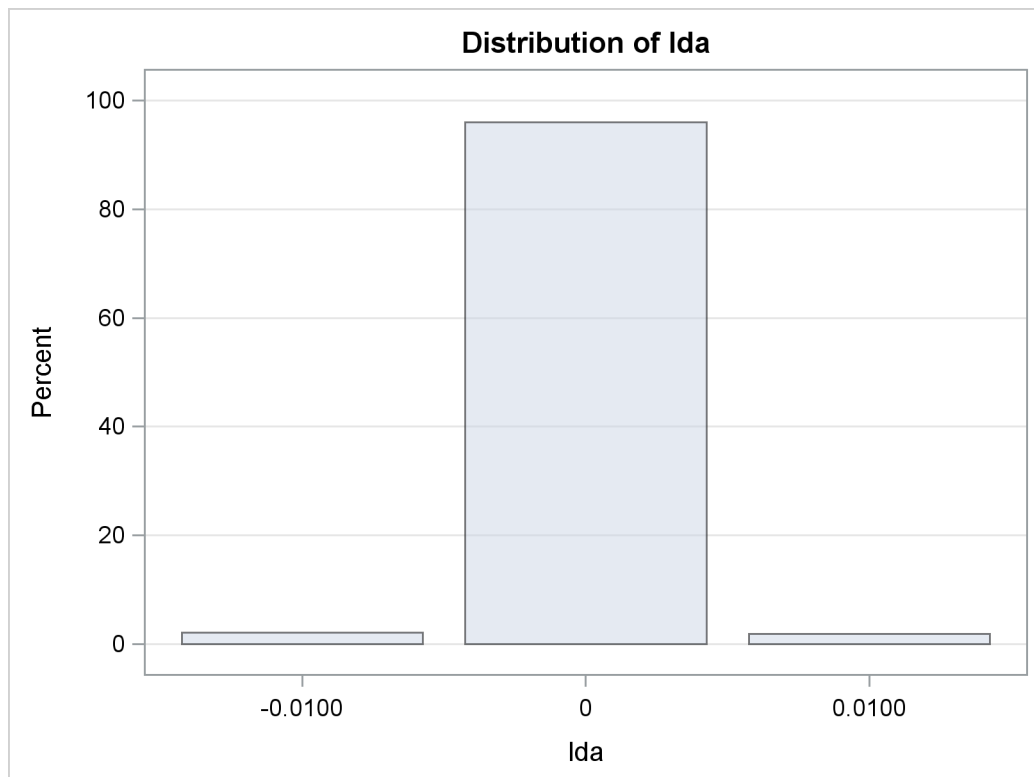

```

Output 55.2.7 shows the frequency count table. An estimate of  $\Pr(\lambda = 0|\text{data})$  is 96%. The conclusion is that the log transformation should be the appropriate transformation used here, which agrees with the simulation setup. Output 55.2.8 shows the histogram of  $\lambda$ .

**Output 55.2.8** Histogram of  $\lambda$

## Example 55.3: Logistic Regression Model with a Diffuse Prior

This example illustrates how to fit a logistic regression model with a diffuse prior in PROC MCMC. You can also use the BAYES statement in PROC GENMOD. See Chapter 40, “The GENMOD Procedure.”

The following statements create a SAS data set with measurements of the number of deaths,  $y$ , among  $n$  beetles that have been exposed to an environmental contaminant  $x$ :

```

title 'Logistic Regression Model with a Diffuse Prior';
data beetles;
 input n y x @@;
 datalines;
6 0 25.7 8 2 35.9 5 2 32.9 7 7 50.4 6 0 28.3
7 2 32.3 5 1 33.2 8 3 40.9 6 0 36.5 6 1 36.5
6 6 49.6 6 3 39.8 6 4 43.6 6 1 34.1 7 1 37.4
8 2 35.2 6 6 51.3 5 3 42.5 7 0 31.3 3 2 40.6
;

```

You can model the data points  $y_i$  with a binomial distribution,

$$y_i | p_i \sim \text{binomial}(n_i, p_i)$$

where  $p_i$  is the success probability and links to the regression covariate  $x_i$  through a logit transformation:

$$\text{logit}(p_i) = \log\left(\frac{p_i}{1-p_i}\right) = \alpha + \beta x_i$$

The priors on  $\alpha$  and  $\beta$  are both diffuse normal:

$$\begin{aligned} \alpha &\sim \text{normal}(0, \text{var} = 10000) \\ \beta &\sim \text{normal}(0, \text{var} = 10000) \end{aligned}$$

These statements fit a logistic regression with PROC MCMC:

```

ods graphics on;
proc mcmc data=beetles ntu=1000 nmc=20000 nthin=2 propcov=quanew
 diag=(mcse ess) outpost=beetleout seed=246810;
 ods select PostSummaries PostIntervals mcse ess TADpanel;
 parms (alpha beta) 0;
 prior alpha beta ~ normal(0, var = 10000);
 p = logistic(alpha + beta*x);
 model y ~ binomial(n,p);
run;

```

The key statement in the program is the assignment to  $p$  that calculates the probability of death. The SAS function LOGISTIC does the proper transformation. The MODEL statement specifies that the response variable,  $y$ , is binomially distributed with parameters  $n$  (from the input data set) and  $p$ . The summary statistics table, interval statistics table, the Monte Carlo standard error table, and the effective sample sizes table are shown in [Output 55.3.1](#).

| alpha                                          | 2470.1  | 4.0484                  |                       | 0.2470       |          |          |
| beta                                           | 2435.4  | 4.1060                  |                       | 0.2435       |          |          |

The summary statistics table shows that the sample mean of the output chain for the parameter alpha is  $-11.7707$ . This is an estimate of the mean of the marginal posterior distribution for the intercept parameter alpha. The estimated posterior standard deviation for alpha is  $2.0997$ . The two 95% credible intervals for alpha are both negative, which indicates with very high probability that the intercept term is negative. On the other hand, you observe a positive effect on the regression coefficient beta. Exposure to the environment contaminant increases the probability of death.

The Monte Carlo standard errors of each parameter are significantly small relative to the posterior standard deviations. A small MCSE/SD ratio indicates that the Markov chain has stabilized and the mean estimates do not vary much over time. Note that the precision in the parameter estimates increases with the square of the MCMC sample size, so if you want to double the precision, you must quadruple the MCMC sample size.

MCMC chains do not produce independent samples. Each sample point depends on the point before it. In this case, the correlation time estimate, read from the effective sample sizes table, is roughly 4. This means that it takes four observations from the MCMC output to make inferences about alpha with the same precision that you would get from using an independent sample. The effective sample size of 2470 reflects this loss of efficiency. The coefficient beta has similar efficiency. You can often observe that some parameters have significantly better mixing (better efficiency) than others, even in a single Markov chain run.

**Output 55.3.2** Plots for Parameters in the Logistic Regression Example

Output 55.3.2 continued

Trace plots and autocorrelation plots of the posterior samples are shown in [Output 55.3.2](#). Convergence looks good in both parameters; there is good mixing in the trace plot and quick drop-off in the ACF plot.

One advantage of Bayesian methods is the ability to directly answer scientific questions. In this example, you might want to find out the posterior probability that the environmental contaminant increases the probability of death—that is,  $\Pr(\beta > 0|y)$ . This can be estimated using the following steps:

```
proc format;
 value betafmt low=0 = 'beta <= 0' 0<-high = 'beta > 0';
run;

proc freq data=beetleout;
 tables beta /nocum;
 format beta betafmt.;
run;
```

Output 55.3.3 Frequency Counts

| Logistic Regression Model with a Diffuse Prior |           |         |
|------------------------------------------------|-----------|---------|
| The FREQ Procedure                             |           |         |
| beta                                           | Frequency | Percent |
| beta > 0                                       | 10000     | 100.00  |

All of the simulated values for  $\beta$  are greater than zero, so the sample estimate of the posterior probability that  $\beta > 0$  is 100%. The evidence overwhelmingly supports the hypothesis that increased levels of the environmental contaminant increase the probability of death.

If you are interested in making inference based on any quantities that are transformations of the random variables, you can either do it directly in PROC MCMC or by using the DATA step after you run the simulation. Transformations sometimes can make parameter inference quite formidable using direct analytical methods, but with simulated chains, it is easy to compute chains for any set of parameters. Suppose you are interested in the lethal dose and want to estimate the level of the covariate  $x$  that corresponds to a probability of death,  $p$ . Abbreviate this quantity as  $ldp$ . In other words, you want to solve the logit transformation with a fixed value  $p$ . The lethal dose is as follows:

$$ldp = \frac{\log\left(\frac{p}{1-p}\right) - \alpha}{\beta}$$

You can obtain an estimate of any  $ldp$  by using the posterior mean estimates for  $\alpha$  and  $\beta$ . For example,  $lp95$ , which corresponds to  $p = 0.95$ , is calculated as follows:

$$lp95 = \frac{\log\left(\frac{0.95}{1-0.95}\right) + 11.77}{0.29} = 50.79$$

where  $-11.77$  and  $0.29$  are the posterior mean estimates of  $\alpha$  and  $\beta$ , respectively, and  $50.79$  is the estimated lethal dose that leads to a 95% death rate.

While it is easy to obtain the point estimates, it is harder to estimate other posterior quantities, such as the standard deviation directly. However, with PROC MCMC, you can trivially get estimates of any posterior quantities of  $lp95$ . Consider the following program in PROC MCMC:

```
proc mcmc data=beetles ntu=1000 nmc=20000 nthin=2 propcov=quanew
 outpost=beetleout seed=246810 plot=density
 monitor=(pi30 ld05 ld50 ld95);
 ods select PostSummaries PostIntervals densitypanel;
 parms (alpha beta) 0;
 begincnst;
 c1 = log(0.05 / 0.95);
 c2 = -c1;
 endcnst;

 beginnodata;
 prior alpha beta ~ normal(0, var = 10000);
 pi30 = logistic(alpha + beta*30);
 ld05 = (c1 - alpha) / beta;
 ld50 = - alpha / beta;
 ld95 = (c2 - alpha) / beta;
 endnodata;
 pi = logistic(alpha + beta*x);
 model y ~ binomial(n,pi);
run;
ods graphics off;
```

The program estimates four additional posterior quantities. The three  $lpd$  quantities,  $ld05$ ,  $ld50$ , and  $ld95$ , are the three levels of the covariate that kills 5%, 50%, and 95% of the population, respectively. The predicted probability when the covariate  $x$  takes the value of 30 is  $\pi_{30}$ . The `MONITOR=` option selects the quantities of interest. The `PLOTS=` option selects kernel density plots as the only ODS graphical output, excluding the trace plot and autocorrelation plot.

Programming statements between the `BEGINCNST` and `ENDCNST` statements define two constants. These statements are executed once at the beginning of the simulation. The programming statements between the `BEGINNODATA` and `ENDNODATA` statements evaluate the quantities of interest. The symbols,  $\pi_{30}$ ,  $ld05$ ,  $ld50$ , and  $ld95$ , are functions of the parameters  $\alpha$  and  $\beta$  only. Hence, they should not be processed at the observation level and should be included in the `BEGINNODATA` and `ENDNODATA` statements. [Output 55.3.4](#) lists the posterior summary and [Output 55.3.5](#) shows the density plots of these posterior quantities.

The posterior mean estimate of  $lp_{95}$  is 50.82, which is close to the estimate of 50.79 by using the posterior mean estimates of the parameters. With PROC MCMC, in addition to the mean estimate, you can get the standard deviation, quantiles, and interval estimates at any level of significance.

From the density plots, you can see, for example, that the sample distribution for  $\pi_{30}$  is skewed to the right, and almost all of your posterior belief concerning  $\pi_{30}$  is concentrated in the region between zero and 0.15.

**Output 55.3.5** Density Plots of Quantities of Interest in the Logistic Regression Example

It is easy to use the DATA step to calculate these quantities of interest. The following DATA step uses the simulated values of  $\alpha$  and  $\beta$  to create simulated values from the posterior distributions of  $ld_{05}$ ,  $ld_{50}$ ,  $ld_{95}$ , and  $\pi_{30}$ :

```
data transout;
 set beetleout;
 pi30 = logistic(alpha + beta*30);
 ld05 = (log(0.05 / 0.95) - alpha) / beta;
 ld50 = (log(0.50 / 0.50) - alpha) / beta;
 ld95 = (log(0.95 / 0.05) - alpha) / beta;
run;
```

Subsequently, you can use SAS/INSIGHT, or the UNIVARIATE, CAPABILITY, or KDE procedures to analyze the posterior sample. If you want to regenerate the default ODS graphs from PROC MCMC, see “Regenerating Diagnostics Plots” on page 4505.

---

### Example 55.4: Logistic Regression Model with Jeffreys' Prior

A controlled experiment was run to study the effect of the rate and volume of air inspired on a transient reflex vasoconstriction in the skin of the fingers. Thirty-nine tests under various combinations of rate and volume of air inspired were obtained (Finney 1947). The result of each test is whether or not vasoconstriction occurred. Pregibon (1981) uses this set of data to illustrate the diagnostic measures he proposes for detecting influential observations and to quantify their effects on various aspects of the maximum likelihood fit. The following statements create the data set Vaso:

```

title 'Logistic Regression Model with Jeffreys Prior';
data vaso;
 input vol rate resp @@;
 lvol = log(vol);
 lrate = log(rate);
 ind = _n_;
 cnst = 1;

;

```

The variable `resp` represents the outcome of a test. The variable `lvol` represents the log of the volume of air intake, and the variable `lrate` represents the log of the rate of air intake. You can model the data by using logistic regression. You can model the response with a binary likelihood:

$$\text{resp}_i \sim \text{binary}(p_i)$$

with

$$p_i = \frac{1}{1 + \exp(-(\beta_0 + \beta_1 \text{lvol}_i + \beta_2 \text{lrate}_i))}$$

Let  $\mathbf{X}$  be the design matrix in the regression. Jeffreys' prior for this model is

$$p(\boldsymbol{\beta}) \propto |\mathbf{X}'\mathbf{M}\mathbf{X}|^{1/2}$$

where  $\mathbf{M}$  is a 39 by 39 matrix with off-diagonal elements being 0 and diagonal elements being  $p_i(1 - p_i)$ . For details on Jeffreys' prior, see "Jeffreys' Prior" on page 129. You can use a number of matrix functions, such as the determinant function, in PROC MCMC to construct Jeffreys' prior. The following statements illustrate how to fit a logistic regression with Jeffreys' prior:

```

%let n = 39;
proc mcmc data=vaso nmc=10000 outpost=mcmcout seed=17;
 ods select PostSummaries PostIntervals;

 array beta[3] beta0 beta1 beta2;
 array m[&n, &n];
 array x[1] / nosymbols;
 array xt[3, &n];
 array xtm[3, &n];
 array xmx[3, 3];
 array p[&n];

 parms beta0 1 beta1 1 beta2 1;

```

```

begincnst;
 if (ind eq 1) then do;
 rc = read_array("vaso", x, "cnst", "lvol", "lrate");
 call transpose(x, xt);
 call zeromatrix(m);
 end;
endcnst;

beginnodata;
call mult(x, beta, p); /* p = x * beta */
do i = 1 to &n;
 p[i] = 1 / (1 + exp(-p[i])); /* p[i] = 1/(1+exp(-x*beta)) */
 m[i,i] = p[i] * (1-p[i]);
end;
call mult (xt, m, xtm); /* xtm = xt * m */
call mult (xtm, x, xmx); /* xmx = xtm * x */
call det (xmx, lp); /* lp = det(xmx) */
lp = 0.5 * log(lp); /* lp = -0.5 * log(lp) */
prior beta: ~ general(lp);
endnodata;

model resp ~ bern(p[ind]);
run;

```

The first `ARRAY` statement defines an array `beta` with three elements: `beta0`, `beta1`, and `beta2`. The subsequent statements define arrays that are used in the construction of Jeffreys' prior. These include `m` (the  $M$  matrix), `x` (the design matrix), `xt` (the transpose of `x`), and some additional work spaces.

The explanatory variables `lvol` and `lrate` are saved in the array `x` in the `BEGINCNST` and `ENDCNST` statements. See “[BEGINCNST/ENDCNST Statement](#)” on page 4441 for details. After all the variables are read into `x`, you transpose the `x` matrix and store it to `xt`. The `ZEROMATRIX` function call assigns all elements in matrix `m` the value zero. To avoid redundant calculation, it is best to perform these calculations as the last observation of the data set is processed—that is, when `ind` is 39.

You calculate Jeffreys' prior in the `BEGINNODATA` and `ENDNODATA` statements. The probability vector `p` is the product of the design matrix `x` and parameter vector `beta`. The diagonal elements in the matrix `m` are  $p_i(1 - p_i)$ . The expression `lp` is the logarithm of Jeffreys' prior. The `PRIOR` statement assigns `lp` as the prior for the  $\beta$  regression coefficients. The `MODEL` statement assigns a binary likelihood to `resp`, with probability `p[ind]`. The `p` array is calculated earlier using the matrix function `MULT`. You use the `ind` variable to pick out the right probability value for each `resp`.

Posterior summary statistics are displayed in [Output 55.4.1](#).

| beta2                                         | 10000 | 4.6889              | 1.8189                | 3.3570       | 4.4914  | 5.8547  |
| Posterior Intervals                           |       |                     |                       |              |         |         |
| Parameter                                     | Alpha | Equal-Tail Interval |                       | HPD Interval |         |         |
| beta0                                         | 0.050 | -5.8247             | -0.7435               | -5.5936      | -0.6027 |         |
| beta1                                         | 0.050 | 2.3001              | 9.3789                | 1.8590       | 8.7222  |         |
| beta2                                         | 0.050 | 1.6788              | 8.6643                | 1.3611       | 8.2490  |         |

You can also use PROC GENMOD to fit the same model by using the following statements:

```
proc genmod data=vaso descending;
 ods select PostSummaries PostIntervals;
 model resp = lvol lrate / d=bin link=logit;
 bayes seed=17 coeffprior=jeffreys nmc=20000 thin=2;
run;
```

The MODEL statement indicates that `resp` is the response variable and `lvol` and `lrate` are the covariates. The options in the MODEL statement specify a binary likelihood and a logit link function. The BAYES statement requests Bayesian capability. The SEED=, NMC=, and THIN= arguments work in the same way as in PROC MCMC. The COEFFPRIOR=JEFFREYS option requests Jeffreys' prior in this analysis.

The PROC GENMOD statements produce [Output 55.4.2](#), with estimates very similar to those reported in [Output 55.4.1](#). Note that you should not expect to see identical output from PROC GENMOD and PROC MCMC, even with the simulation setup and identical random number seed. The two procedures use different sampling algorithms. PROC GENMOD uses the adaptive rejection metropolis algorithm (ARMS) (Gilks and Wild 1992; Gilks 2003) while PROC MCMC uses a random walk Metropolis algorithm. The asymptotic answers, which means that you let both procedures run an very long time, would be the same as they both generate samples from the same posterior distribution.

## Output 55.4.2 PROC GENMOD Results

---

**Example 55.5: Poisson Regression**

You can use the Poisson distribution to model the distribution of cell counts in a multiway contingency table. Aitkin et al. (1989) have used this method to model insurance claims data. Suppose the following hypothetical insurance claims data are classified by two factors: age group (with two levels) and car type (with three levels). The following statements create the data set:

```

title 'Poisson Regression';
data insure;
 input n c car $ age;
 ln = log(n);
 datalines;
500 42 small 0
1200 37 medium 0
100 1 large 0
400 101 small 1
500 73 medium 1
300 14 large 1
;

proc transreg data=insure design;
 model class(car / zero=last);
 id n c age ln;
 output out=input_insure(drop=_: Int:);
run;

```

The variable *n* represents the number of insurance policy holders and the variable *c* represents the number of insurance claims. The variable *car* is the type of car involved (classified into three groups), and it is coded into two levels. The variable *age* is the age group of a policy holder (classified into two groups).

Assume that the number of claims *c* has a Poisson probability distribution and that its mean,  $\mu_i$ , is related to the factors *car* and *age* for observation *i* by

$$\begin{aligned}\log(\mu_i) &= \log(n_i) + \mathbf{x}'\boldsymbol{\beta} \\ &= \log(n_i) + \beta_0 + \\ &\quad \text{car}_i(1)\beta_1 + \text{car}_i(2)\beta_2 + \text{car}_i(3)\beta_3 + \\ &\quad \text{age}_i(1)\beta_4 + \text{age}_i(2)\beta_5\end{aligned}$$

The indicator variables  $\text{car}_i(j)$  is associated with the *j*th level of the variable *car* for observation *i* in the following way:

$$\text{car}_i(j) = \begin{cases} 1 & \text{if } \text{car} = j \\ 0 & \text{if } \text{car} \neq j \end{cases}$$

A similar coding applies to *age*. The  $\boldsymbol{\beta}$ 's are parameters. The logarithm of the variable *n* is used as an offset—that is, a regression variable with a constant coefficient of 1 for each observation. Having the offset constant in the model is equivalent to fitting an expanded data set with 3000 observations, each with response variable *y* observed on an individual level. The log link relates the mean and the factors *car* and *age*.

The following statements run PROC MCMC:

```
proc mcmc data=input_insure outpost=insureout nmc=5000 propcov=quanew
 maxtune=0 seed=7;
 ods select PostSummaries PostIntervals;
 array data[4] 1 &_trgind age;
 array beta[4] alpha beta_car1 beta_car2 beta_age;
 parms alpha beta;
 prior alpha beta: ~ normal(0, prec = 1e-6);
 call mult(data, beta, mu);
 model c ~ poisson(exp(mu+ln));
run;
```

The analysis uses a relatively flat prior on all the regression coefficients, with mean at 0 and precision at  $10^{-6}$ . The option `MAXTUNE=0` skips the tuning phase because the optimization routine (`PROPCOV=QUANEW`) provides good initial values and proposal covariance matrix.

There are four parameters in the model: *alpha* is the intercept; *beta\_car1* and *beta\_car2* are coefficients for the class variable *car*, which has three levels; and *beta\_age* is the coefficient for *age*. The symbol *mu* connects the regression model and the Poisson mean by using the log link. The `MODEL` statement specifies a Poisson likelihood for the response variable *c*.

Posterior summary and interval statistics are shown in [Output 55.5.1](#).

### Output 55.5.1 MCMC Results

To fit the same model by using PROC GENMOD, you can do the following. Note that the default normal prior on the coefficients  $\beta$  is  $N(0, \text{prec} = 1e - 6)$ , the same as used in the PROC MCMC. The following statements run PROC GENMOD and create [Output 55.5.2](#):

```
proc genmod data=insure;
 ods select PostSummaries PostIntervals;
 class car age(descending);
 model c = car age / dist=poisson link=log offset=ln;
 bayes seed=17 nmc=5000 coeffprior=normal;
run;
```

To compare, posterior summary and interval statistics from PROC GENMOD are reported in [Output 55.5.2](#), and they are very similar to PROC MCMC results in [Output 55.5.1](#).

## Output 55.5.2 PROC GENMOD Results

| age1                | 0.050 | 1.0455              | 1.5871  | 1.0266       | 1.5629  |

Note that the descending option in the CLASS statement reverses the sort order of the class variable `age` so that the results agree with PROC MCMC. If this option is not used, the estimate for `age` has a reversed sign as compared to [Output 55.5.2](#).

## Example 55.6: Nonlinear Poisson Regression Models

This example illustrates how to fit a nonlinear Poisson regression with PROC MCMC. In addition, it shows how you can improve the mixing of the Markov chain by selecting a different proposal distribution or by sampling on the transformed scale of a parameter. This example shows how to analyze count data for calls to a technical support help line in the weeks immediately following a product release. This information could be used to decide upon the allocation of technical support resources for new products. You can model the number of daily calls as a Poisson random variable, with the average number of calls modeled as a nonlinear function of the number of weeks that have elapsed since the product's release. The data are input into a SAS data set as follows:

```

title 'Nonlinear Poisson Regression';
data calls;
 input weeks calls @@;
 datalines;
1 0 1 2 2 2 1 3 1 3 3
4 5 4 8 5 5 5 9 6 17 6 9
7 24 7 16 8 23 8 27
;

```

During the first several weeks after a new product is released, the number of questions that technical support receives concerning the product increases in a sigmoidal fashion. The expression for the mean value in the classic Poisson regression involves the log link. There is some theoretical justification for this link, but with MCMC methodologies, you are not constrained to exploring only models that are computationally convenient. The number of calls to technical support tapers off after the initial release, so in this example you can use a logistic-type function to model the mean number of calls received weekly for the time period immediately following the initial release. The mean function  $\lambda(t)$  is modeled as follows:

$$\lambda_i = \frac{\gamma}{1 + \exp[-(\alpha + \beta t_i)]}$$

The likelihood for every observation  $\text{calls}_i$  is

$$\text{calls}_i \sim \text{Poisson}(\lambda_i)$$

Past experience with technical support data for similar products suggests the following prior distributions:

$$\begin{aligned} \gamma &\sim \text{gamma}(\text{shape} = 3.5, \text{scale} = 12) \\ \alpha &\sim \text{normal}(-5, \text{sd} = 0.5) \\ \beta &\sim \text{normal}(0.75, \text{sd} = 0.5) \end{aligned}$$

The following PROC MCMC statements fit this model:

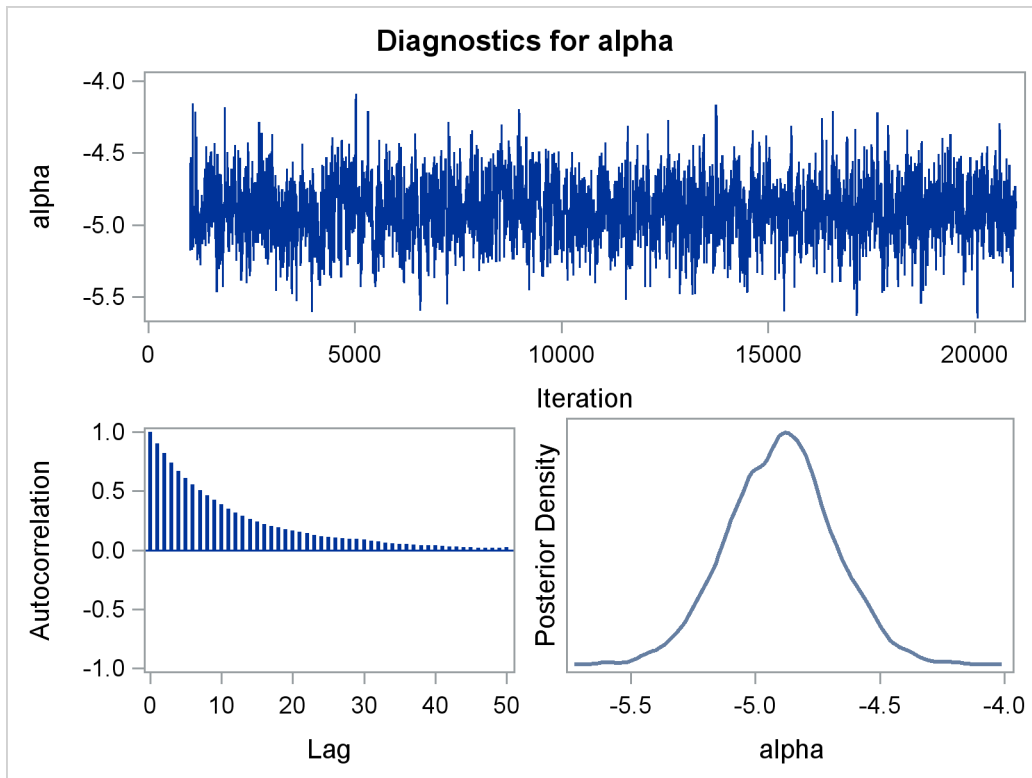

```
ods graphics on;
proc mcmc data=calls outpost=callout seed=53197 ntu=1000 nmc=20000
 propcov=quanew stats=none diag=ess;
 ods select TADpanel ess;
 parms alpha -4 beta 1 gamma 2;
 prior gamma ~ gamma(3.5, scale=12);
 prior alpha ~ normal(-5, sd=0.25);
 prior beta ~ normal(0.75, sd=0.5);
 lambda = gamma*logistic(alpha+beta*weeks);
 model calls ~ poisson(lambda);
run;
```

The one **PARMS** statement defines a block of all parameters and sets their initial values individually. The **PRIOR** statements specify the informative prior distributions for the three parameters. The assignment statement defines  $\lambda$ , the mean number of calls. Instead of using the SAS function LOGISTIC, you can use the following statement to calculate  $\lambda$  and get the same result:

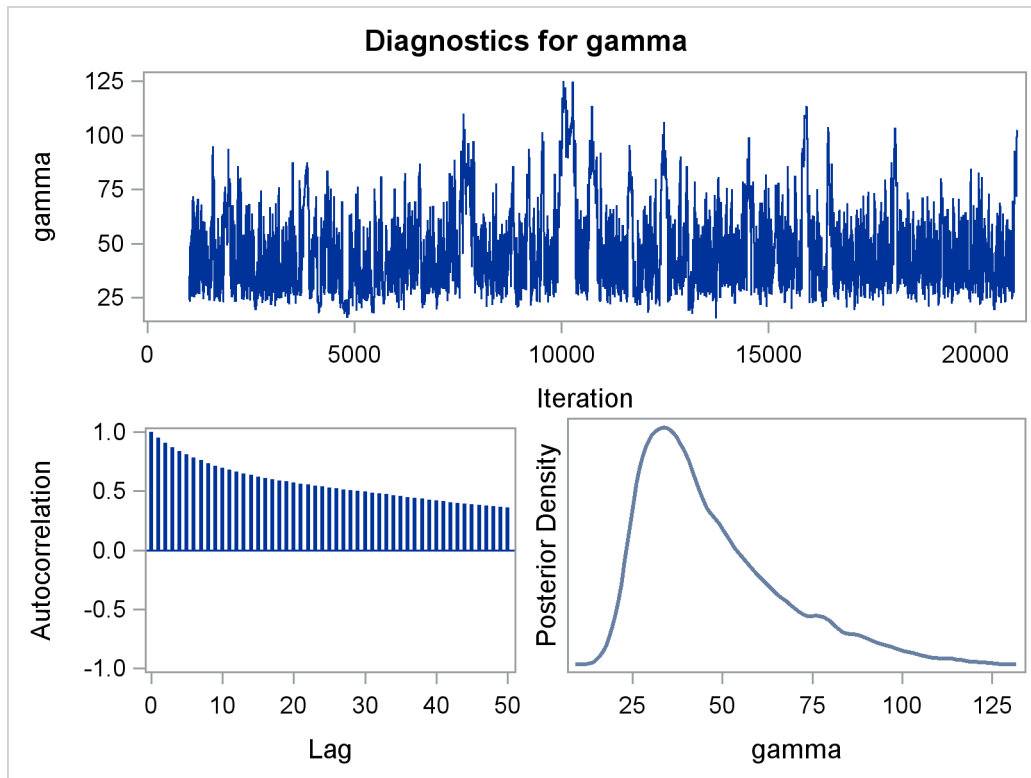

```
lambda = gamma / (1 + exp(-(alpha+beta*weeks)));
```

Mixing is not particularly good with this run of PROC MCMC. The ODS SELECT statement displays the diagnostic graphs and effective sample sizes (ESS) calculation while excluding all other output. The graphical output is shown in [Output 55.6.1](#), and the ESS of each parameters are all relatively low ([Output 55.6.2](#)).

Output 55.6.1 Plots for Parameters

Output 55.6.1 continued

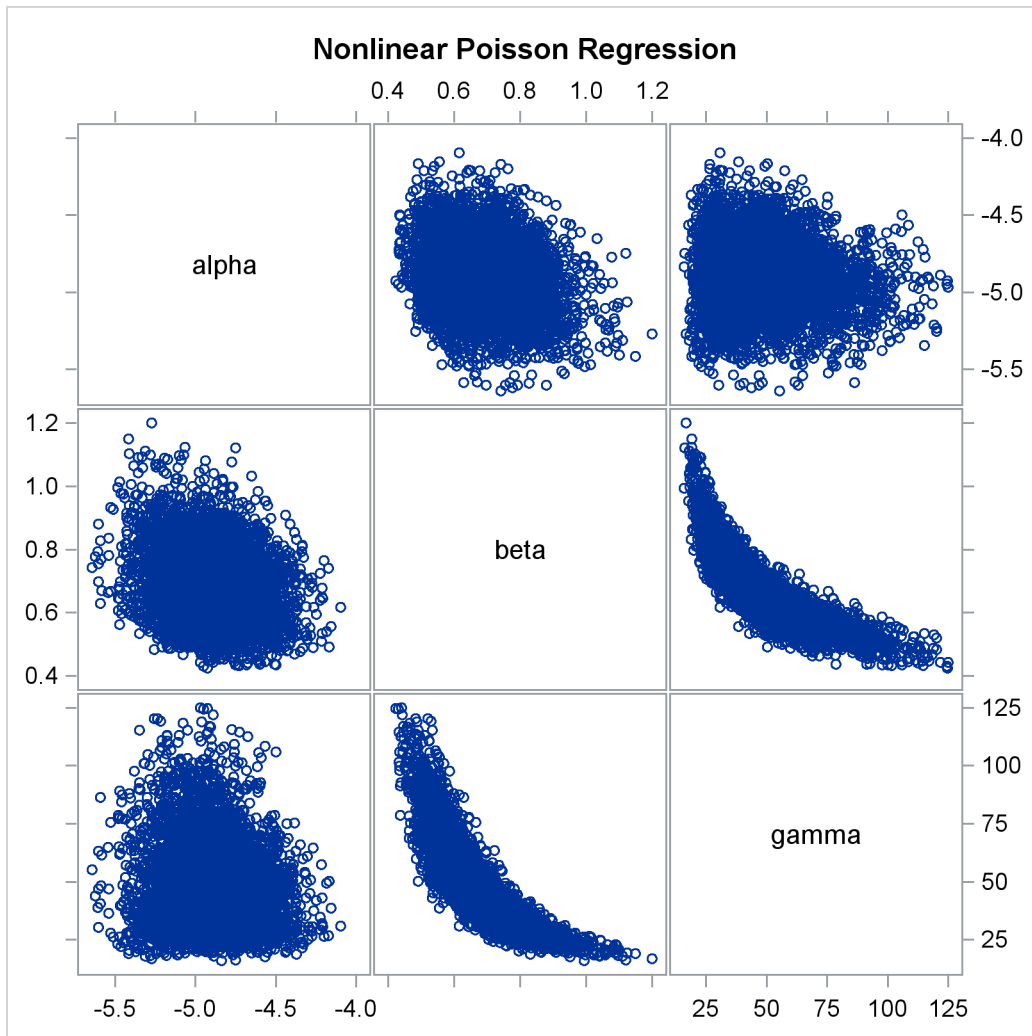

Output 55.6.2 Effective Sample Sizes

| Nonlinear Poisson Regression |       |                 |            |
|------------------------------|-------|-----------------|------------|

|                              |       | Time            | Efficiency |
| alpha                        | 897.4 | 22.2870         | 0.0449     |
| beta                         | 231.6 | 86.3540         | 0.0116     |
| gamma                        | 162.9 | 122.8           | 0.0081     |

Often a simple scatter plot of the posterior samples can reveal a potential cause of the bad mixing. You can use PROC SGSCATTER to generate pairwise scatter plots of the three model parameters. The following statements generate Output 55.6.3:

```
proc sgscatter data=callout;
 matrix alpha beta gamma;
run;
```

**Output 55.6.3** Pairwise Scatter Plots of the Parameters

The nonlinearity in parameters **beta** and **gamma** stands out immediately. This explains why a random walk Metropolis with normal proposal has a difficult time exploring the joint distribution efficiently—the algorithm works best when the target distribution is unimodal and symmetric (normal-like). When there is nonlinearity in the parameters, it is impossible to find a single proposal scale parameter that optimally adapts to different regions of the joint parameter space. As a result, the Markov chain can be inefficient in traversing some parts of the distribution. This is evident in examining the trace plot of the **gamma** parameter. You see that the Markov chain sometimes gets stuck in the far-right tail and does not travel back to the high-density area quickly. This effect can be seen around the simulations 8,000 and 18,000 in [Output 55.6.1](#).

Reparameterization can often improve the mixing of the Markov chain. Note that the parameter **gamma** has a positive support and that the posterior distribution is right-skewed. This suggests that the chain might mix more rapidly if you sample on the logarithm of the parameter **gamma**.

Let  $\delta = \log(\gamma)$ , and reparameterize the mean function as follows:

$$\lambda_i = \frac{\exp(\delta)}{1 + \exp[-(\alpha + \beta t_i)]}$$

To obtain the same inference, you use an induced prior on  $\delta$  based on the gamma prior on the gamma parameter. This involves a transformation of variables, and you can obtain the following equivalency, where  $|\exp(\delta)|$  is the Jacobian:

$$\pi(\gamma) = \text{gamma}(\gamma; a, \text{scale} = b) = \frac{1}{b^a \Gamma(a)} \gamma^{a-1} \exp(-\gamma/b)$$

$$\Leftrightarrow \pi(\delta) = \text{gamma}(\gamma = \exp(\delta); a, \text{scale} = b) \cdot |\exp(\delta)|$$

The distribution on  $\delta$  simplifies to the following:

$$\pi(\delta) = \frac{1}{b^a \Gamma(a)} \exp(a\delta) \exp(-\exp(\delta)/b)$$

PROC MCMC supports such a distribution on the logarithm transformation of a gamma random variable. It is called the [ExpGamma](#) distribution.

In the original model, you specify a prior on gamma:

```
prior gamma ~ gamma(3.5, scale=12);
```

You can obtain the same inference by specifying an [ExpGamma](#) prior on delta and take an exponential transformation to get back to gamma:

```
prior delta ~ egamma(3.5, scale=12);
gamma = exp(delta);
```

The following statements produce [Output 55.6.6](#) and [Output 55.6.4](#):

```
proc mcmc data=calls outpost=tcallout seed=53197 ntu=1000 nmc=20000
 propcov=quanew diag=ess plots=(trace) monitor=(alpha beta gamma);
 ods select PostSummaries PostIntervals ESS TRACEpanel;
 parms alpha -4 beta 1 delta 2;
 prior alpha ~ normal(-5, sd=0.25);
 prior beta ~ normal(0.75, sd=0.5);
 prior delta ~ egamma(3.5, scale=12);
 gamma = exp(delta);
 lambda = gamma*logistic(alpha+beta*weeks);
 model calls ~ poisson(lambda);
run;
```

The [PARMS](#) statement declares delta, instead of gamma, as a model parameter. The prior distribution of delta is [egamma](#), as opposed to the [gamma](#) distribution. The [GAMMA](#) assignment statement transforms delta to gamma. The [LAMBDA](#) assignment statement calculates the mean for the Poisson by using the gamma parameter. The [MODEL](#) statement specifies a Poisson likelihood for the calls response.

The trace plots in [Output 55.6.4](#) show better mixing of the parameters, and the effective sample sizes in [Output 55.6.5](#) show substantial improvements over the original formulation of the model. The improvements are especially obvious in beta and gamma, where the increase is fivefold to tenfold.

| Posterior Intervals          |       |                     |                       |              |         |         |
| Parameter                    | Alpha | Equal-Tail Interval |                       | HPD Interval |         |         |
| alpha                        | 0.050 | -5.3392             | -4.4659               | -5.3217      | -4.4544 |         |
| beta                         | 0.050 | 0.4919              | 0.9327                | 0.4841       | 0.9169  |         |
| gamma                        | 0.050 | 23.2996             | 96.7209               | 19.6588      | 86.2425 |         |

Note that the delta parameter has a more symmetric density than the skewed gamma parameter. A pairwise scatter plot (Output 55.6.7) shows a more linear relationship between beta and delta. The Metropolis algorithm always works better if the target distribution is approximately normal.

```
proc sgscatter data=tcallout;
 matrix alpha beta delta;
run;
```

**Output 55.6.7** Pairwise Scatter Plots of the Transformed Parameters

If you are still unsatisfied with the slight nonlinearity in the parameters **beta** and **delta**, you can try another transformation on **beta**. Normally you would not want to do a logarithm transformation on a parameter that has support on the real axis, because you would risk taking the logarithm of negative values. However, because all the **beta** samples are positive and the marginal posterior distribution is away from 0, you can try a such a transformation.

Let  $\kappa = \log(\beta)$ . The prior distribution on  $\kappa$  is the following:

$$\pi(\kappa) = \text{normal}(\beta = \exp(\kappa); \mu, \sigma^2) \cdot |\exp(\kappa)|$$

You can specify the prior distribution in PROC MCMC by using a **GENERAL** function:

```
parms kappa;
lprior = logpdf("normal", exp(kappa), 0.75, 0.5) + kappa;
prior kappa ~ general(lp);
beta = exp(kappa);
```

The **PARMS** statement declares the transformed parameter kappa, which will be sampled. The **LPRIOR** assignment statement defines the logarithm of the prior distribution on kappa. The **LOGPDF** function is used here to simplify the specification of the distribution. The **PRIOR** statement specifies the nonstandard distribution as the prior on kappa. Finally, the **BETA** assignment statement transforms kappa back to the beta parameter.

Applying logarithm transformations on both beta and gamma yields the best mixing. (The results are not shown here, but you can find the code in the file *mcmcex6.sas* in the SAS Sample Library.) The transformed parameters kappa and delta have much clearer linear correlation. However, the improvement over the case where gamma alone is transformed is only marginally significant (50% increase in ESS).

This example illustrates that PROC MCMC can fit Bayesian nonlinear models just as easily as Bayesian linear models. More importantly, transformations can sometimes improve the efficiency of the Markov chain, and that is something to always keep in mind. Also see “[Example 55.20: Using a Transformation to Improve Mixing](#)” on page 4654 for another example of how transformations can improve mixing of the Markov chains.

---

## Example 55.7: Logistic Regression Random-Effects Model

This example illustrates how you can use PROC MCMC to fit random-effects models. In the example “[Random-Effects Model](#)” on page 4419 in “[Getting Started: MCMC Procedure](#)” on page 4408, you already saw PROC MCMC fit a linear random-effects model. This example shows how to fit a logistic random-effects model in PROC MCMC. Although you can use PROC MCMC to analyze random-effects models, you might want to first consider some other SAS procedures. For example, you can use PROC MIXED (see Chapter 59, “[The MIXED Procedure](#)”) to analyze linear mixed effects models, PROC NL MIXED (see Chapter 64, “[The NL MIXED Procedure](#)”) for nonlinear mixed effects models, and PROC GLIMMIX (see Chapter 41, “[The GLIMMIX Procedure](#)”) for generalized linear mixed effects models. In addition, a sampling-based Bayesian analysis is available in the MIXED procedure through the **PRIOR** statement (see “[PRIOR Statement](#)” on page 4935).

The data are taken from Crowder (1978). The *Seeds* data set is a  $2 \times 2$  factorial layout, with two types of seeds, *O. aegyptiaca* 75 and *O. aegyptiaca* 73, and two root extracts, *bean* and *cucumber*. You observe *r*, which is the number of germinated seeds, and *n*, which is the total number of seeds. The independent variables are *seed* and *extract*.

The following statements create the data set:

```

title 'Logistic Regression Random-Effects Model';
data seeds;
 input r n seed extract @@;
 ind = _N_;
 datalines;

You can model each observation  $r_i$  as having its own probability of success  $p_i$ , and the likelihood is as follows:

$$r_i \sim \text{binomial}(n_i, p_i)$$

You can use the logit link function to link the covariates of each observation, `seed` and `extract`, to the probability of success,

$$\begin{aligned}\mu_i &= \beta_0 + \beta_1 \cdot \text{seed}_i + \beta_2 \cdot \text{extract}_i + \beta_3 \cdot \text{seed}_i \cdot \text{extract}_i \\ p_i &= \text{logistic}(\mu_i + \delta_i)\end{aligned}$$

where  $\delta_i$  is assumed to be an iid random effect with a normal prior:

$$\delta_i \sim \text{normal}(0, \text{var} = \sigma^2)$$

The four  $\beta$  regression coefficients and the standard deviation  $\sigma^2$  in the random effects are model parameters; they are given noninformative priors as follows:

$$\begin{aligned}\pi(\beta_0, \beta_1, \beta_2, \beta_3) &\propto 1 \\ \sigma^2 &\sim \text{igamma}(\text{shape} = 0.01, \text{scale} = 0.01)\end{aligned}$$

Another way of expressing the same model is as

$$p_i = \text{logistic}(\delta_i)$$

where

$$\delta_i \sim \text{normal}(\beta_0 + \beta_1 \cdot \text{seed}_i + \beta_2 \cdot \text{extract}_i + \beta_3 \cdot \text{seed}_i \cdot \text{extract}_i, \sigma^2)$$

The two models are equivalent. In the first model, the random effects  $\delta_i$  centers at 0 in the normal distribution, and in the second model,  $\delta_i$  centers at the regression mean. This hierarchical centering can sometimes improve mixing.

The following statements fit the second model and generate [Output 55.7.1](#):

```
proc mcmc data=seeds outpost=postout seed=332786 nmc=20000;
 ods select PostSummaries PostIntervals;
 parms beta0 0 beta1 0 beta2 0 beta3 0 s2 1;
 prior s2 ~ igamma(0.01, s=0.01);
 prior beta: ~ general(0);
 w = beta0 + beta1*seed + beta2*extract + beta3*seed*extract;
 random delta ~ normal(w, var=s2) subject=ind;
 pi = logistic(delta);
 model r ~ binomial(n = n, p = pi);
run;
```

The PROC MCMC statement specifies the input and output data sets, sets a seed for the random number generator, and requests a large simulation size. The ODS SELECT statement displays the summary statistics and interval statistics tables. The PARMs statement declares the model parameters, and the PRIOR statements specify the prior distributions for  $\beta$  and  $\sigma^2$ .

The symbol  $w$  calculates the regression mean, and the **RANDOM** statement specifies the random effect, with a normal prior distribution, centered at  $w$  with variance  $\sigma^2$ . Note that the variable  $w$  is a function of the input data set variables. You can use data set variable in constructing the hyperparameters of the random-effects parameters, as long as the hyperparameters remain constant within each subject group. The **SUBJECT=** option indicates the group index for the random-effects parameters.

The symbol  $\pi$  is the logit transformation. The **MODEL** specifies the response variable  $r$  as a binomial distribution with parameters  $n$  and  $\pi$ .

Output 55.7.1 lists the posterior mean and interval estimates of the regression parameters.

### Example 55.8: Nonlinear Poisson Regression Multilevel Random-Effects Model

This example uses the pump failure data of Gaver and O’Muircheartaigh (1987) to illustrate how to fit a multilevel random-effects model with PROC MCMC. The number of failures and the time of operation are recorded for 10 pumps. Each of the pumps is classified into one of two groups that correspond to either continuous or intermittent operation. The following statements generate the data set:

```

title 'Nonlinear Poisson Regression Random-Effects Model';
data pump;
 input y t group @@;
 pump = _n_;
 logtstd = log(t) - 2.4564900;
 datalines;
5 94.320 1 1 15.720 2 5 62.880 1
14 125.760 1 3 5.240 2 19 31.440 1
 1 1.048 2 1 1.048 2 4 2.096 2
22 10.480 2
;

```

Each row denotes data for a single pump, and the variable `logtstd` contains the centered operation times. Letting  $y_{ij}$  denote the number of failures for the  $j$ th pump in the  $i$ th group, Draper (1996) considers the following hierarchical model for these data, where the data set variable `logtstd` is  $\log t_{ij} - \overline{\log t}$ :

$$\begin{aligned}
 y_{ij} | \lambda_{ij} &\sim \text{Poisson}(\lambda_{ij}) \\
 \log \lambda_{ij} &= \alpha_i + \beta_i (\log t_{ij} - \overline{\log t}) + e_{ij}
 \end{aligned}$$

This model specifies different intercepts and slopes for each group ( $i = 1, 2$ ), and the random effect  $e_{ij}$  is a mechanism for accounting for overdispersion. You can use noninformative priors on the parameters  $\alpha_i$ ,  $\beta_i$ , and  $\sigma^2$ , and a normal prior on  $e_{ij}$ ,

$$\begin{aligned}
 u_i &= \begin{pmatrix} \alpha_i \\ \beta_i \end{pmatrix} \sim \text{mvn} \left( \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \begin{pmatrix} 1e6 & 0 \\ 0 & 1e6 \end{pmatrix} \right) \text{ for } i = 1, 2 \\
 \sigma^2 &\sim \text{igamma}(\text{shape} = 0.01, \text{scale} = 0.01) \\
 e_{ij} | \sigma^2 &\sim \text{normal}(0, \sigma^2)
 \end{aligned}$$

where  $u_i$  is a multidimensional random effect. The following statements fit such a random-effects model:

```

ods graphics on;
proc mcmc data=pump outpost=postout seed=248601 nmc=10000
 plots=trace stats=none diag=none;
 ods select tracepanel;
 array u[2] alpha beta;
 array mu[2] (0 0);
 parms s2;
 prior s2 ~ igamma(0.01, scale=0.01);
 random u ~ mvn(mu, sd=1e6, rho=0) subject=group monitor=(u);
 random e ~ normal(0, var=s2) subject=pump monitor=(random(1));
 w = alpha + beta * logtstd;
 lambda = exp(w+e);
 model y ~ poisson(lambda);
run;

```

The PROC MCMC statement specifies the input data set (Pump), the output data set (Postout), a seed for the random number generator, and a simulation sample size of 10,000. The program requests that only trace plots be produced, disabling all posterior calculations and convergence diagnostics tests. The ODS SELECT statement displays the trace plots, which are the primary focus.

The first **ARRAY** statement declares an array  $u$  of size 2 and names the elements  $\alpha$  and  $\beta$ . The array  $u$  stores the random-effects parameters  $\alpha$  and  $\beta$ . The next **ARRAY** statement defines the mean of the multivariate normal prior on  $u$ .

The **PARMS** statement declares the only model parameter here, the variance  $s^2$  in the prior distribution for the random effect  $e_{ij}$ . The **PRIOR** statement specifies an inverse-gamma prior on the variance. The first **RANDOM** statement specifies a multivariate normal prior on  $u$ . The **mvn** distribution is a multivariate normal distribution with a first-order autoregressive covariance. When the argument  $\rho$  is set to 0, this distribution simplifies to a multivariate normal distribution with a shared variance. The **RANDOM** statement also indicates the group variable as its subject index and monitors all elements  $u$ . The second **RANDOM** statement specifies a normal prior on the effect  $e$ , where the subject index variable is `pump`. The **MONITOR=** option requests that PROC MCMC randomly choose one of the 10  $e$  random-effects parameters to monitor.

Next, programming statements construct the mean of the Poisson likelihood, and the **MODEL** statement specifies the likelihood function for each observation.

Output 55.8.1 shows trace plots for  $\sigma^2$ ,  $\alpha_1$ ,  $\alpha_2$ ,  $\beta_1$ ,  $\beta_2$ , and  $e_8$ . You can see that the chains are mixing poorly.

**Output 55.8.1** Trace Plots of  $\sigma^2$ ,  $\alpha$ ,  $\beta$ , and  $e_8$  without Hierarchical Centering

Output 55.8.1 continued

To improve mixing, you can repeat the same analysis by using a hierarchical centering technique, where instead of using a normal prior centered at 0 on  $e_{ij}$ , you center the random effects on the group means:

$$y_{ij} | \lambda_{ij} \sim \text{Poisson}(\lambda_{ij})$$

$$\log \lambda_{ij} \sim \text{normal}(\alpha_i + \beta_i (\log t_{ij} - \overline{\log t}), \text{var} = \sigma^2)$$

The following statements illustrate how to fit a multilevel hierarchical centering random-effects model:

```
proc mcmc data=pump outpost=postout_c seed=248601 nmc=10000
 plots=trace diag=none;
 ods select tracepanel postsummaries postintervals;
 array u[2] alpha beta;
 array mu[2] (0 0);
 parms s2 1;
 prior s2 ~ igamma(0.01, scale=0.01);
 random u ~ mvn(mu, sd=1e6, rho=0) subject=group monitor=(u);
 w = alpha + beta * logtstd;
 random llambda ~ normal(w, var = s2) subject=pump monitor=(random(1));
 lambda = exp(llambda);
 model y ~ poisson(lambda);
run;
```

The difference between these statements and the previous statements on page 4582 is that these statements have the variable  $w$  as the prior mean of the random effect  $\lambda$ . The symbol  $\lambda$  is the exponential of the corresponding  $\log \lambda_{ij}$  ( $\lambda$ ), and the `MODEL` statement assigns the response variable  $y$  a Poisson likelihood with a mean parameter  $\lambda$ , the same way it did in the previous statements.

The trace plots of the monitored parameters are shown in [Output 55.8.2](#). The mixing is significantly improved over the previous model. The posterior summary and interval statistics tables are shown in [Output 55.8.3](#).

**Output 55.8.2** Trace Plots of  $\sigma^2$ ,  $\alpha$ , and  $\beta$  with Hierarchical Centering

Output 55.8.2 *continued*

Output 55.8.3 Posterior Summary Statistics

You can generate a caterpillar plot (Output 55.8.4) of the random-effects parameters by calling the %CATER macro:

```
%CATER(data=postout_c, var=llambda_);
ods graphics off;
```

Varying llambda indicates nonconstant dispersion in the Poisson model.

**Output 55.8.4** Caterpillar Plots of the Random-Effects Parameters

## Example 55.9: Multivariate Normal Random-Effects Model

Gelfand et al. (1990) use a multivariate normal hierarchical model to estimate growth regression coefficients for the growth of 30 young rats in a control group over a period of 5 weeks. The following statements create a SAS data set with measurements of Weight, Age (in days), and Subject.

```

title 'Multivariate Normal Random-Effects Model';
data rats;
 array days[5] (8 15 22 29 36);

;

```

The model assumes normal measurement errors,

$$\text{Weight}_{ij} \sim \text{normal}(\alpha_i + \beta_i \text{Age}_{ij}, \sigma^2), \quad i = 1 \dots 30; j = 1 \dots 5$$

where  $i$  indexes rat (Subject variable),  $j$  indexes the time period,  $\text{Weight}_{ij}$  and  $\text{Age}_{ij}$  denote the weight and age of the  $i$ th rat in week  $j$ , and  $\sigma^2$  is the variance in the normal likelihood. The individual intercept and slope coefficients are modeled as the following:

$$\theta_i = \begin{pmatrix} \alpha_i \\ \beta_i \end{pmatrix} \sim \text{MVN} \left( \theta_c = \begin{pmatrix} \alpha_c \\ \beta_c \end{pmatrix}, \Sigma_c \right), \quad i = 1, \dots, 30$$

You can use the following independent prior distributions on  $\theta_c$ ,  $\Sigma_c$ , and  $\sigma^2$ :

$$\begin{aligned} \theta_c &\sim \text{MVN} \left( \mu_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}, \Sigma_0 = \begin{pmatrix} 1000 & 0 \\ 0 & 1000 \end{pmatrix} \right) \\ \Sigma_c &\sim \text{iwishart} \left( \rho = 2, S = \rho \cdot \begin{pmatrix} 0.01 & 0 \\ 0 & 10 \end{pmatrix} \right) \\ \sigma^2 &\sim \text{igamma}(\text{shape} = 0.01, \text{scale} = 0.01) \end{aligned}$$

The following statements fit this multivariate normal random-effects model:

```
proc mcmc data=rats nmc=10000 outpost=postout
 seed=17 init=random;
 ods select Parameters REParameters PostSummaries;
 array theta[2] alpha beta;
 array theta_c[2];
 array Sig_c[2,2];
 array mu0[2] (0 0);
 array Sig0[2,2] (1000 0 0 1000);
 array S[2,2] (0.02 0 0 20);

 parms theta_c Sig_c {121 0 0 0.26} var_y;
 prior theta_c ~ mvn(mu0, Sig0);
 prior Sig_c ~ iwish(2, S);
 prior var_y ~ igamma(0.01, scale=0.01);

 random theta ~ mvn(theta_c, Sig_c) subject=subject
 monitor=(alpha_9 beta_9 alpha_25 beta_25);
 mu = alpha + beta * age;
 model weight ~ normal(mu, var=var_y);
run;
```

The ODS SELECT statement displays information about model parameters, random-effects parameters, and the posterior summary statistics. The ARRAY statements allocate memory space for the multivariate parameters and hyperparameters in the model. The parameters are  $\theta$  (theta where the variable name of each element is alpha or beta),  $\theta_c$  (theta\_c), and  $\Sigma_c$  (Sig\_c). The hyperparameters are  $\mu_0$  (mu0),  $\Sigma_0$  (Sig0), and S (S). The multivariate hyperparameters are assigned with constant values using parentheses ( ).

The PARMs statement declares model parameters and assigns initial values to Sig\_c using braces { }. The PRIOR statements specify the prior distributions. The RANDOM statement defines an array random effect theta and specifies a multivariate normal prior distribution. The SUBJECT= option indicates cluster membership for each of the random-effects parameter. The MONITOR= option monitors the individual intercept and slope coefficients of subjects 9 and 25.

You can use the following syntax in the RANDOM statement to monitor all parameters in an array random effect:

```
monitor=(theta)
```

This would produce posterior summary statistics on  $\alpha_1 \cdots \alpha_{30}$  and  $\beta_1 \cdots \beta_{30}$ .

The following syntax monitors all  $\alpha_i$  parameters:

```
monitor=(alpha)
```

If you did not name elements of theta to be alpha and beta, the SAS System creates variable names automatically in a consecutive fashion, as in theta1 and theta2.

| alpha_25                                 | 10000 | 86.5673 | 6.3694                | 82.4621     | 86.7183 | 90.7307 |
| beta_9                                   | 10000 | 7.4670  | 0.2382                | 7.3109      | 7.4730  | 7.6260  |
| beta_25                                  | 10000 | 6.7804  | 0.2612                | 6.6144      | 6.7756  | 6.9526  |

Output 55.9.2 displays posterior summary statistics for model parameters and the random-effects parameters for subjects 9 and 25. You can see that there is a substantial difference in the intercepts and growth rates between the two rats.

A seemingly confusing message might occur if a symbol name matches an internally generated variable name for elements of an array. For example, if, instead of using the symbol `var_y` in the SAS program for the model variance  $\sigma^2$ , you used `s2`, the SAS System produces the following error message:

```
ERROR: The initial value 0 for the parameter S2 is outside of the prior
distribution support set.
```

This is confusing because the program does not assign an initial value for the parameter `s2` in the `PARMS` statement, and you might expect that PROC MCMC would not generate an invalid initial value. The confusion is caused by the `ARRAY` statement that defines the array variable `S`:

```
array S[2,2] (0.02 0 0 20);
```

Elements of `S` are automatically given names `s1`–`s4`. PROC MCMC interprets `s2` as an element in `S` that was given a value of 0, hence producing this error message.

---

## Example 55.10: Missing at Random Analysis

This example illustrates how PROC MCMC treats missing at random (MAR) data. For a short overview of missing data problems, see the section “Handling of Missing Data” on page 4518.

Researchers studied the effects of air pollution on respiratory disease in children. The response variable ( $y$ ) represented whether a child exhibited wheezing symptoms; it was recorded as 1 for symptoms exhibited and

0 for no symptoms exhibited. City of residency ( $x_1$ ) and maternal smoking status ( $x_2$ ) were the explanatory variables. The variable  $x_1$  was coded as 1 if the child lived in the more polluted city, Steel City, and 0 if the child lived in Green Hills. The variable  $x_2$  was the number of cigarettes the mother reported that she smoked per day. Both the covariates contain missing values: 17 for  $x_1$  and 30 for  $x_2$ , respectively. The total number of observations in the data set is 390. The following statements generate the data set `air`:

```

title 'Missing at Random Analysis';

;

```

Suppose you want to fit a logistic regression model for whether the subject develops wheezing symptoms with density for the  $i = 1, \dots, 390$  subjects as follows:

$$\begin{aligned}
 y_i &\sim \text{binary}(p_i) \\
 \text{logit}(p_i) &= \beta_0 + \beta_1 \cdot x_{1i} + \beta_2 \cdot x_{2i} \\
 \pi(\beta_0), \pi(\beta_1), \pi(\beta_2) &= \text{normal}(0, \sigma^2 = 10)
 \end{aligned}$$

Suppose you specify a joint distribution of  $x_1$  and  $x_2$  in terms of the product of a conditional and marginal distribution; that is,

$$p(x_1, x_2 | \alpha) = p(x_1 | x_2, \alpha_{10}, \alpha_{11}) p(x_2 | \alpha_{20})$$

where  $p(x_1 | x_2, \alpha_{10}, \alpha_{11})$  could be a logistic model and  $p(x_2 | \alpha_{20})$  could be a Poisson distribution that models the following counts:

$$\begin{aligned}
 p(x_1 | x_2, \alpha_{10}, \alpha_{11}) &= \text{binary}(p_{c,i}) \\
 \text{logit}(p_{c,i}) &= \alpha_{10} + \alpha_{11} \cdot x_{2i} \\
 \pi(\alpha_{10}), \pi(\alpha_{11}) &= \text{normal}(0, \sigma^2 = 10) \\
 p(x_2 | \alpha_{20}) &= \text{Poisson}(e^{\alpha_{20}}) \\
 \pi(\alpha_{20}) &= \text{normal}(0, \sigma^2 = 2)
 \end{aligned}$$

The researchers are interested in interpreting how the odds of developing a wheeze changes for a child living in the more polluted city. The odds ratio can be written as the follows:

$$OR_{x1} = \exp(\beta_1)$$

Similarly, the odds ratio for the maternal smoking effect can be written as follows:

$$OR_{x2} = \exp(\beta_2)$$

The following statements fit a Bayesian logistic regression with missing covariates:

```
proc mcmc data=air seed=1181 nmc=10000 monitor=(_parms_ orx1 orx2)
 stats=(summary interval) diag=none plots=none;
 parms beta0 -1 beta1 0.1 beta2 .01;
 parms alpha10 0 alpha11 0 alpha20 0;

 prior beta: alpha1: ~ normal(0,var=10);
 prior alpha20 ~ normal(0,var=2);

 beginnodata;
 pm = exp(alpha20);
 orx1 = exp(beta1);
 orx2 = exp(beta2);
 endnodata;
 model x2 ~ poisson(pm) monitor=(1 3 10);
 p1 = logistic(alpha10 + alpha11 * x2);
 model x1 ~ binary(p1) monitor=(random(3));
 p = logistic(beta0 + beta1*x1 + beta2*x2);
 model y ~ binary(p);
run;
```

The **PARMS** statements specify the parameters in the model and assign initial values to each of them. The **PRIOR** statements specify priors for all the model parameters. The notations **beta:** and **alpha:** in the **PRIOR** statements are shorthand for all variables that start with “beta,” and “alpha,” respectively. The shorthand notation is not necessary, but it keeps your code succinct.

The **BEGINNODATA** and **ENDNODATA** statements enclose three programming statements that calculate the Poisson mean (**pm**) and the two odds ratios (**ORX1** and **ORX2**). These enclosed statements are independent of any data set variables, and they are run only once per iteration to reduce unnecessary observation-level computations.

The first **MODEL** statement assigns a Poisson likelihood with mean **pm** to **x2**. The statement models missing values in **x2** automatically, creating one variable for each of the missing values, and augments them accordingly. By default, PROC MCMC does not output analyses of the posterior samples of the missing values. You can use the **MONITOR=** option to choose the missing values that you want to monitor. In the example, the first, third, and tenth missing values are monitored.

The P1 assignment statement calculates  $p_{c.i}$ . The second **MODEL** statement assigns a binary likelihood with probability p1 and requests a random choice of three missing data variables of x1 to monitor.

The P assignment statement calculates  $p_i$  in the logistic model. The third **MODEL** statement specifies the complete data likelihood function for Y.

**Output 55.10.1** displays the number of observations read from the DATA= data set, the number of observations used in the analysis, and the “Missing Data Information” table. No observations were omitted from the data set in the analysis.

The “Missing Data Information” table lists the variables that contain missing values, which are x1 and x2, the number of missing observations in each variable, the observation indices of these missing values, and the sampling algorithms used. By default, the first 20 observation indices of each variable are printed in the table.

**Output 55.10.1** Observation Information and Missing Data Information

|                                |                       |                          |                 |

There are 30 missing values in the variable x2, and 17 in x1. Internally, PROC MCMC creates 30 and 17 variables for the missing values in x2 and x1, respectively. The default naming convention for these missing values is to concatenate the response variable and the observation number. For example, the first missing value in x2 is the fourteenth observation, and the corresponding variable is x2\_14.

**Output 55.10.2** displays the summary and interval statistics for each parameter, the odds ratios, and the monitored missing values.

## Output 55.10.2 Posterior Summary and Interval Statistics

The odds ratio for x1 is the multiplicative change in the odds of a child wheezing in Steel City compared to the odds of the child wheezing in Green Hills. The estimated odds ratio (ORX1) value is 1.6736 with a corresponding 95% equal-tail credible interval of (1.0248, 2.5939). City of residency is a significant factor in a child's wheezing status. The estimated odds ratio for x2 is the multiplicative change in the odds of developing a wheeze for each additional reported cigarette smoked per day. The odds ratio of ORX2 indicates that the odds of a child developing a wheeze is 1.0150 times higher for each reported cigarette a mother smokes. The corresponding 95% equal-tail credible interval is (0.9695, 1.0619). Since this interval contains the value 1, maternal smoking is not considered to be an influential effect.

## Example 55.11: Nonignorably Missing Data (MNAR) Analysis

This example illustrates how to fit a nonignorably missing data model (MNAR) with PROC MCMC. For a short overview of missing data problems, see the section “Handling of Missing Data” on page 4518.

This data set comes from an environmental study that involve workers in a cotton factory. A similar data set was analyzed from Ibrahim, Chen, and Lipsitz (2001). There are 912 workers in the data set, and the response variable of interest is whether they develop dyspnea (difficult or labored respiration). The data are collected over three time points, and there are six covariates. The following statements create the data set:

```

title 'Nonignorably Missing Data Analysis';
data dyspnea;
 input smoke1 smoke2 smoke3 y1 y2 y3 yrswrk1 yrswrk2 yrswrk3
 age expd sex hgt;
 datalines;
0 0 0 0 0 0 28.1 33.1 39.1 48 1 1 165.0
0 0 0 0 . 0 5.1 10.1 16.1 45 1 0 147.0
0 0 0 0 . 0 26.0 31.0 37.0 46 1 0 156.0

... more lines ...

1 1 1 0 . . 6.0 11.0 17.0 25 0 1 180.0
0 0 0 0 . . 20.0 25.0 31.0 42 0 0 159.0
;

```

The following variables are included in the data set:

- y1, y2, and y3: dichotomous outcome at the three time periods, which takes the value 1 if the worker has dyspnea, 0 if not (there are missing values in y2 and y3)
- smoke1, smoke2, smoke3: smoking status (0=no, and 1=yes)
- yrswrk1, yrswrk2, yrswrk3: years worked at the cotton factory
- age: age of the worker
- expd: cotton dust exposure (0=no, 1=yes)
- sex: gender (0=female, 1=male)
- hgt: height of the worker

Prior to the analysis, three missing data indicator variables (r1, r2, and r3, one for each of the response variables) are created, and they are set to 1 if the response variable is missing, and 0 otherwise. The covariates age, hgt, yrswrk1, yrswrk2, and yrswrk3 are standardized:

```

data dyspnea;
 array y[3] y1-y3;
 array r[3];
 set dyspnea;
 do i = 1 to 3;
 if y[i] = . then r[i] = 1;
 else r[i] = 0;
 end;
 output;
run;

proc standard data=dyspnea out=dyspnea mean=0 std=1;
 var age hgt yrswrk;
run;

```

There are no missing values in response variable  $y_1$ , 128 missing values in  $y_2$ , and 131 in  $y_3$ . Ibrahim, Chen, and Lipsitz (2001) used a logistic regression for each of the response variables, where  $\delta_i$  is a scalar random effect on the observational level:

$$\begin{aligned}
 y_{ki} &\sim \text{binary}(p_{ki}) \quad k = 1, 2, 3; \quad i = 1, \dots, 912 \\
 p_{ki} &= \text{logistic}(\mu_{ki} + \delta_i) \\
 \mu_{ki} &= \beta_1 + \beta_2 \cdot \text{expd}_i + \beta_3 \cdot \text{sex}_i + \beta_4 \cdot \text{hgt}_i + \beta_5 \cdot \text{age}_i + \beta_6 \cdot \text{yrswrk}_{ki} + \beta_7 \cdot \text{smoke}_{ki} \\
 \delta_i &\sim n(0, \sigma^2)
 \end{aligned}$$

Ibrahim, Chen, and Lipsitz (2001) noted that taking  $\delta_i$  to be higher dimensional (3) would make the model either not identifiable or nearly not identifiable because of the multiple missing values for some subjects.

The first response variable  $y_1$  does not contain any missing values, making it meaningless to model the corresponding  $r_1$  because every value is 1. Hence, only  $r_2$  and  $r_3$  are considered in the missing mechanism part of the model. Ibrahim, Chen, and Lipsitz (2001) suggest the following logistic regression for  $r_2$  and  $r_3$ , where the regression mean for each  $r$  depends not only on the current response variable  $y$  but also the response from previous time period:

$$\begin{aligned}
 r_{ki} &\sim \text{binary}(q_{ki}) \quad k = 2, 3; \quad i = 1, \dots, 912 \\
 q_{ki} &= \text{logistic}(v_{ki}) \\
 \mu_c &= \phi_1 + \phi_2 \cdot \text{expd}_i + \phi_3 \cdot \text{sex}_i + \phi_4 \cdot \text{hgt}_i + \phi_5 \cdot \text{age}_i + \phi_6 \cdot \text{yrswrk}_{ki} + \phi_7 \cdot \text{smoke}_{ki} \\
 v_{2i} &= \mu_c + \phi_8 \cdot y_{1i} + \phi_9 \cdot y_{2i} \\
 v_{3i} &= \mu_c + \phi_9 \cdot y_{2i} + \phi_{10} \cdot y_{3i}
 \end{aligned}$$

The missing mechanism model introduces an additional 10 parameters to the model. Normal priors with large standard deviations are used here.

The following statements fit a nonignorably missing model to the dyspnea data set:

```

ods select MissDataInfo REParameters PostSummaries PostIntervals;
proc mcmc data=dyspnea seed=17 outpost=dysp2 nmc=20000
 propcov=simplex diag=none monitor=(beta1-beta7);
 array p[3];
 array yrswrk[3];
 array smoke[3];

 parms beta1-beta7 s2;
 parms phi1-phi10;
 prior beta: phi: ~ n(0, var=1e6);
 prior s2 ~ igamma(2, scale=2);
 random d ~ n(0, var=s2) subject=_obs_;
 mu = beta1 + beta2*expd + beta3*sex + beta4*hgt + beta5*age + d;
 do i = 1 to 3;
 p[i] = logistic(mu + beta6*yrswrk[i] + beta7*smoke[i]);
 end;
 model y1 ~ binary(p1);
 model y2 ~ binary(p2);
 model y3 ~ binary(p3);

 nu = phi1 + phi2*expd + phi3*sex + phi4*hgt + phi5*age;
 q2 = logistic(nu + phi6*yrswrk[2] + phi7*smoke[2] +
 phi8*y1 + phi9*y2);
 model r2 ~ binary(q2);
 q3 = logistic(nu + phi6*yrswrk[3] + phi7*smoke[3] +
 phi9*y2 + phi10*y3);
 model r3 ~ binary(q3);
run;

```

The first **ARRAY** statement declares an array `p` of size 3. This array stores three binary probabilities of the response variables. The next two **ARRAY** statements create storage arrays for some of `yrswrk` and `smoke` variables for later programming convenience. The first **PARMS** statement declares eight parameters,  $\beta_1 - \beta_7$  and  $\sigma^2$ . The second **PARMS** statement declares the 10  $\phi$  parameters for the missing mechanism model. The **PRIOR** statements assign prior distributions to these parameters.

The **RANDOM** statement defines an observational-level random effect `d` that has a normal prior with variance `s2`. The **SUBJECT=\_OBS\_** option enables the specification of individual random effects without an explicit input data set variable.

The **MU** assignment statement and the following **DO** loop statements calculate the binary probabilities for the three response variables. Note that different `yrswrk` and `smoke` variables are used in the **DO** loop for different years. The three **MODEL** statements assign three binary distributions to the response variables.

The **NU** assignment statement starts the calculation for the regression mean in the logistic model for `r2` and `r3`. The variables `q2` and `q3` are the binary probabilities for the missing mechanisms. Note that their calculations are conditional on the response variables `y` (pattern mixture model). The last two **MODEL** statements for `r2` and `r3` complete the specification of the models.

Missing data information and random-effects parameters information are displayed in [Output 55.11.1](#). You can read the total number of missing observations from each variable and its indices from the table. The missing values are sampled using the inverse CDF method. There are 912 random-effects parameters in the model.

**Output 55.11.1** Missing Data and Random-Effects Information

The posterior summary and interval statistics of all the  $\beta$  parameters are shown in [Output 55.11.2](#). There are a number of significant regression coefficients in modeling the probability of a worker developing dyspnea, including those for  $\text{expd}$  ( $\beta_2$ ),  $\text{sex}$  ( $\beta_3$ ),  $\text{age}$  ( $\beta_5$ ), and  $\text{smoke}$  ( $\beta_7$ ).

**Output 55.11.2** Posterior Summary Statistics for  $\beta$

**Example 55.12: Change Point Models**

Consider the data set from Bacon and Watts (1971), where  $y_i$  is the logarithm of the height of the stagnant surface layer and the covariate  $x_i$  is the logarithm of the flow rate of water. The following statements create the data set:

```

title 'Change Point Model';
data stagnant;
 input y x @@;
 ind = _n_;
 datalines;
1.12 -1.39 1.12 -1.39 0.99 -1.08 1.03 -1.08
0.92 -0.94 0.90 -0.80 0.81 -0.63 0.83 -0.63
0.65 -0.25 0.67 -0.25 0.60 -0.12 0.59 -0.12
0.51 0.01 0.44 0.11 0.43 0.11 0.43 0.11
0.33 0.25 0.30 0.25 0.25 0.34 0.24 0.34
0.13 0.44 -0.01 0.59 -0.13 0.70 -0.14 0.70
-0.30 0.85 -0.33 0.85 -0.46 0.99 -0.43 0.99
-0.65 1.19
;

```

A scatter plot (Output 55.12.1) shows the presence of a nonconstant slope in the data. This suggests a change point regression model (Carlin, Gelfand, and Smith 1992). The following statements generate the scatter plot in Output 55.12.1:

```

ods graphics on;
proc sgplot data=stagnant;
 scatter x=x y=y;
run;

```

**Output 55.12.1** Scatter Plot of the Stagnant Data Set

Let the change point be  $cp$ . Following formulation by Spiegelhalter et al. (1996b), the regression model is as follows:

$$y_i \sim \begin{cases} \text{normal}(\alpha + \beta_1(x_i - cp), \sigma^2) & \text{if } x_i < cp \\ \text{normal}(\alpha + \beta_2(x_i - cp), \sigma^2) & \text{if } x_i \geq cp \end{cases}$$

You might consider the following diffuse prior distributions:

$$\begin{aligned} cp &\sim \text{uniform}(-1.3, 1.1) \\ \alpha, \beta_1, \beta_2 &\sim \text{normal}(0, \text{var} = 1e6) \\ \sigma^2 &\sim \text{uniform}(0, 5) \end{aligned}$$

The following statements generate [Output 55.12.2](#):

```
proc mcmc data=stagnant outpost=postout seed=24860 ntu=1000
 nmc=20000;
 ods select PostSummaries;
 ods output PostSummaries=ds;

 array beta[2];
 parms alpha cp beta1 beta2;
 parms s2;

 prior cp ~ unif(-1.3, 1.1);
 prior s2 ~ uniform(0, 5);
```

```

prior alpha beta: ~ normal(0, v = 1e6);

j = 1 + (x >= cp);
mu = alpha + beta[j] * (x - cp);
model y ~ normal(mu, var=s2);
run;

```

The PROC MCMC statement specifies the input data set (Stagnant), the output data set (Postout), a random number seed, a tuning sample of 1000, and an MCMC sample of 20000. The ODS SELECT statement displays only the summary statistics table. The ODS OUTPUT statement saves the summary statistics table to the data set Ds.

The ARRAY statement allocates an array of size 2 for the beta parameters. You can use beta1 and beta2 as parameter names without allocating an array, but having the array makes it easier to construct the likelihood function. The two PARMs statements put the five model parameters in two blocks. The three PRIOR statements specify the prior distributions for these parameters.

The symbol j indicates the segment component of the regression. When x is less than the change point, ( $x < cp$ ) returns 0 and j is assigned the value 1; if x is greater than or equal to the change point, ( $x \geq cp$ ) returns 1 and j is 2. The symbol mu is the mean for the jth segment, and beta[j] changes between the two regression coefficients depending on the segment component. The MODEL statement assigns the normal model to the response variable y.

Posterior summary statistics are shown in [Output 55.12.2](#).

#### Output 55.12.2 MCMC Estimates of the Change Point Regression Model

| Change Point Model  |       |          |                       |             |          |          |

| cp                  | 20000 | 0.0283   | 0.0314                | 0.00728     | 0.0303   | 0.0493   |
| beta1               | 20000 | -0.4200  | 0.0146                | -0.4293     | -0.4198  | -0.4111  |
| beta2               | 20000 | -1.0136  | 0.0167                | -1.0248     | -1.0136  | -1.0023  |
| s2                  | 20000 | 0.000451 | 0.000145              | 0.000348    | 0.000425 | 0.000522 |

You can use PROC SGPLOT to visualize the model fit. [Output 55.12.3](#) shows the fitted regression lines over the original data. In addition, on the bottom of the plot is the kernel density of the posterior marginal distribution of cp, the change point. The kernel density plot shows the relative variability of the posterior distribution on the data plot. You can use the following statements to create the plot:

```

data _null_;
 set ds;
 call symputx(parameter, mean);
run;

data b;
 missing A;
 input x1 @@;
 if x1 eq .A then x1 = &cp;
 if _n_ <= 2 then y1 = &alpha + &beta1 * (x1 - &cp);
 else y1 = &alpha + &beta2 * (x1 - &cp);
 datalines;
-1.5 A 1.2
;

proc kde data=postout;
 univar cp / out=m1 (drop=count);
run;

data m1;
 set m1;
 density = (density / 25) - 0.653;
run;

data all;
 set stagnant b m1;
run;

proc sgplot data=all noautolegend;
 scatter x=x y=y;
 series x=x1 y=y1 / lineattrs = graphdata2;
 series x=value y=density / lineattrs = graphdata1;
run;
ods graphics off;

```

The macro variables &alpha, &beta1, &beta2, and &cp store the posterior mean estimates from the data set Ds. The data set b contains three predicted values, at the minimum and maximum values of x and the estimated change point &cp. These input values give you fitted values from the regression model. Data set M1 contains the kernel density estimates of the parameter cp. The density is scaled down so the curve would fit in the plot. Finally, you use PROC SGPLOT to overlay the scatter plot, regression line and kernel density plots in the same graph.

**Output 55.12.3** Estimated Fit to the Stagnant Data Set

---

### Example 55.13: Exponential and Weibull Survival Analysis

This example covers two commonly used survival analysis models: the exponential model and the Weibull model. The deviance information criterion (DIC) is used to do model selections, and you can also find programs that visualize posterior quantities. Exponential and Weibull models are widely used for survival analysis. This example shows you how to use PROC MCMC to analyze the treatment effect for the E1684 melanoma clinical trial data. These data were collected to assess the effectiveness of using interferon alpha-2b in chemotherapeutic treatment of melanoma. The following statements create the data set:

```

data e1684;
 input t t_cen treatment @@;
 if t = . then do;
 t = t_cen;
 v = 0;
 end;
 else
 v = 1;
 ifn = treatment - 1;
 et = exp(t);
 lt = log(t);
 drop t_cen;
 datalines;
1.57808 0.00000 2 1.48219 0.00000 2 . 7.33425 1
2.23288 0.00000 1 . 9.38356 2 3.27671 0.00000 1
. 9.64384 1 1.66575 0.00000 2 0.94247 0.00000 1
1.68767 0.00000 2 2.34247 0.00000 2 0.89863 0.00000 1

... more lines ...

3.39178 0.00000 1 . 4.36164 2 . 4.81918 2
;

```

The data set E1684 contains the following variables:  $t$  is the failure time that equals the censoring time whether the observation was censored,  $v$  indicates whether the observation is an actual failure time or a censoring time,  $treatment$  indicates two levels of treatments, and  $ifn$  indicates the use of interferon as a treatment. The variables  $et$  and  $lt$  are the exponential and logarithm transformation of the time  $t$ . The published data contains other potential covariates that are not listed here. This example concentrates on the effectiveness of the interferon treatment.

## Exponential Survival Model

The density function for exponentially distributed survival times is as follows:

$$p(t_i | \lambda_i) = \lambda_i \exp(-\lambda_i t_i)$$

Note that this formulation of the exponential distribution is different from what is used in the SAS probability function PDF. The definition used in PDF for the exponential distributions is as follows:

$$p(t_i | v_i) = \frac{1}{v_i} \exp\left(-\frac{t_i}{v_i}\right)$$

The relationship between  $\lambda$  and  $v$  is as follows:

$$\lambda_i = \frac{1}{v_i}$$

The corresponding survival function, using the  $\lambda_i$  formulation, is as follows:

$$S(t_i | \lambda_i) = \exp(-\lambda_i t_i)$$

If you have a sample  $\{t_i\}$  of  $n$  independent exponential survival times, each with mean  $\lambda_i$ , then the likelihood function in terms of  $\lambda$  is as follows:

$$\begin{aligned} L(\lambda|t) &= \prod_{i=1}^n p(t_i|\lambda_i)^{v_i} S(t_i|\lambda_i)^{1-v_i} \\ &= \prod_{i=1}^n (\lambda_i \exp(-\lambda_i t_i))^{v_i} (\exp(-\lambda_i t_i))^{1-v_i} \\ &= \prod_{i=1}^n \lambda_i^{v_i} \exp(-\lambda_i t_i) \end{aligned}$$

If you link the covariates to  $\lambda$  with  $\lambda_i = \exp \mathbf{x}_i' \boldsymbol{\beta}$ , where  $\mathbf{x}_i$  is the vector of covariates corresponding to the  $i$ th observation and  $\boldsymbol{\beta}$  is a vector of regression coefficients, then the log-likelihood function is as follows:

$$l(\boldsymbol{\beta}|t, \mathbf{x}) = \sum_{i=1}^n v_i \mathbf{x}_i' \boldsymbol{\beta} - t_i \exp(\mathbf{x}_i' \boldsymbol{\beta})$$

In the absence of prior information about the parameters in this model, you can choose diffuse normal priors for the  $\boldsymbol{\beta}$ :

$$\boldsymbol{\beta} \sim \text{normal}(0, \text{sd}=10000)$$

There are two ways to program the log-likelihood function in PROC MCMC. You can use the SAS functions LOGPDF and LOGSDF. Alternatively, you can use the simplified log-likelihood function, which is more computationally efficient. You get identical results by using either approaches.

The following PROC MCMC statements fit an exponential model with simplified log-likelihood function:

```

title 'Exponential Survival Model';
ods graphics on;
proc mcmc data=e1684 outpost=expurvout nmc=10000 seed=4861;
 ods select PostSummaries PostIntervals TADpanel
 ess mcse;
 parms (beta0 beta1) 0;
 prior beta: ~ normal(0, sd = 10000);
 /* *****
 /* (1) the logpdf and logsdf functions are not used */
 /* *****
 /* nu = 1/exp(beta0 + beta1*ifn);
 /* llike = v*logpdf("exponential", t, nu) +
 /* (1-v)*logsdf("exponential", t, nu);
 /*
 /* *****
 /* (2) the simplified likelihood formula is used */
 /* *****
 l_h = beta0 + beta1*ifn;
 llike = v*(l_h) - t*exp(l_h);
 model general(llike);
run;

```

The two assignment statements that are commented out calculate the log-likelihood function by using the SAS functions LOGPDF and LOGSDF for the exponential distribution. The next two assignment statements calculate the log likelihood by using the simplified formula. The first approach is slower because of the redundant calculation involved in calling both LOGPDF and LOGSDF.

An examination of the trace plots for  $\beta_0$  and  $\beta_1$  (see [Output 55.13.1](#)) reveals that the sampling has gone well with no particular concerns about the convergence or mixing of the chains.

**Output 55.13.1** Posterior Plots for  $\beta_0$  and  $\beta_1$  in the Exponential Survival Analysis

The MCMC results are shown in [Output 55.13.2](#).

**Output 55.13.2** Posterior Summary and Interval Statistics

| Exponential Survival Model |       |         |                       |             |         |         |

The Monte Carlo standard errors and effective sample sizes are shown in [Output 55.13.3](#). The posterior means for  $\beta_0$  and  $\beta_1$  are estimated with high precision, with small standard errors with respect to the standard deviation. This indicates that the mean estimates have stabilized and do not vary greatly in the course of the simulation. The effective sample sizes are roughly the same for both parameters.

**Output 55.13.3** MCSE and ESS

| beta1                  | 1107.2 | 9.0319                  | 0.1107     |

The next part of this example shows fitting a Weibull regression to the data and then comparing the two models with DIC to see which one provides a better fit to the data.

## Weibull Survival Model

The density function for Weibull distributed survival times is as follows:

$$p(t_i | \alpha, \lambda_i) = \alpha t_i^{\alpha-1} \exp(\lambda_i - \exp(\lambda_i) t_i^\alpha)$$

Note that this formulation of the Weibull distribution is different from what is used in the SAS probability function PDF. The definition used in PDF is as follows:

$$p(t_i | \alpha, \gamma_i) = \exp\left(-\left(\frac{t_i}{\gamma_i}\right)^\alpha\right) \frac{\alpha}{\gamma_i} \left(\frac{t_i}{\gamma_i}\right)^{\alpha-1}$$

The relationship between  $\lambda$  and  $\gamma$  in these two parameterizations is as follows:

$$\lambda_i = -\alpha \log \gamma_i$$

The corresponding survival function, using the  $\lambda_i$  formulation, is as follows:

$$S(t_i | \alpha, \lambda_i) = \exp(-\exp(\lambda_i) t_i^\alpha)$$

If you have a sample  $\{t_i\}$  of  $n$  independent Weibull survival times, with parameters  $\alpha$ , and  $\lambda_i$ , then the likelihood function in terms of  $\alpha$  and  $\lambda$  is as follows:

$$\begin{aligned} L(\alpha, \lambda | t) &= \prod_{i=1}^n p(t_i | \alpha, \lambda_i)^{v_i} S(t_i | \alpha, \lambda_i)^{1-v_i} \\ &= \prod_{i=1}^n (\alpha t_i^{\alpha-1} \exp(\lambda_i - \exp(\lambda_i) t_i^\alpha))^{v_i} (\exp(-\exp(\lambda_i) t_i^\alpha))^{1-v_i} \\ &= \prod_{i=1}^n (\alpha t_i^{\alpha-1} \exp(\lambda_i))^{v_i} (\exp(-\exp(\lambda_i) t_i^\alpha)) \end{aligned}$$

If you link the covariates to  $\lambda$  with  $\lambda_i = \mathbf{x}_i' \boldsymbol{\beta}$ , where  $\mathbf{x}_i$  is the vector of covariates corresponding to the  $i$ th observation and  $\boldsymbol{\beta}$  is a vector of regression coefficients, the log-likelihood function becomes this:

$$l(\alpha, \boldsymbol{\beta} | t, \mathbf{x}) = \sum_{i=1}^n v_i (\log(\alpha) + (\alpha - 1) \log(t_i) + \mathbf{x}_i' \boldsymbol{\beta}) - \exp(\mathbf{x}_i' \boldsymbol{\beta}) t_i^\alpha$$

As with the exponential model, in the absence of prior information about the parameters in this model, you can use diffuse normal priors on  $\boldsymbol{\beta}$ . You might want to choose a diffuse gamma distribution for  $\alpha$ . Note that when  $\alpha = 1$ , the Weibull survival likelihood reduces to the exponential survival likelihood. Equivalently, by looking at the posterior distribution of  $\alpha$ , you can conclude whether fitting an exponential survival model would be more appropriate than the Weibull model.

PROC MCMC also enables you to make inference on any functions of the parameters. Quantities of interest in survival analysis include the value of the survival function at specific times for specific treatments and the relationship between the survival curves for different treatments. With PROC MCMC, you can compute a sample from the posterior distribution of the interested survival functions at any number of points. The data in this example range from about 0 to 10 years, and the treatment of interest is the use of interferon.

Like in the previous exponential model example, there are two ways to fit this model: using the SAS functions LOGPDF and LOGSDF, or using the simplified log likelihood functions. The example uses the latter method. The following statements run PROC MCMC and produce [Output 55.13.4](#):

```

title 'Weibull Survival Model';
proc mcmc data=e1684 outpost=weisurvout nmc=10000 seed=1234

```

The `MONITOR=` option indicates the parameters and quantities of interest that PROC MCMC tracks. The symbol `_PARMS_` specifies all model parameters. The array `surv_ifn` stores the expected survival probabilities for patients who received interferon over a period of 10 years. Similarly, `surv_noifn` stores the expected survival probabilities for patients who did not received interferon.

The `BEGINNODATA` and `ENDNODATA` statements enclose the calculations for the survival probabilities. The assignment statements proceeding the `MODEL` statement calculate the log likelihood for the Weibull survival model. The `MODEL` statement specifies the log likelihood that you programmed.

An examination of the trace plots for  $\alpha$ ,  $\beta_0$ , and  $\beta_1$  (not displayed here) reveals that the sampling has gone well, with no particular concerns about the convergence or mixing of the chains.

Output 55.13.4 displays the posterior summary statistics.

## Output 55.13.4 Posterior Summary Statistics

| Weibull Survival Model |       |         |                       |             |         |         |

| surv_noifn10           | 10000 | 0.2069  | 0.0389                | 0.1803      | 0.2035  | 0.2312  |

An examination of the  $\alpha$  parameter reveals that the exponential model might not be inappropriate here. The estimated posterior mean of  $\alpha$  is 0.7856 with a posterior standard deviation of 0.0533. As noted previously, if  $\alpha = 1$ , then the Weibull survival distribution is the exponential survival distribution. With these data, you can see that the evidence is in favor of  $\alpha < 1$ . The value 1 is almost 4 posterior standard deviations away from the posterior mean. The following statements compute the posterior probability of the hypothesis that  $\alpha < 1$ .

```
proc format;
 value alphafmt low-<1 = 'alpha < 1' 1-high = 'alpha >= 1';
run;

proc freq data=weisurvout;
 tables alpha /nocum;
 format alpha alphafmt.;
run;
```

The PROC FREQ results are shown in [Output 55.13.5](#).

**Output 55.13.5** Frequency Analysis of  $\alpha$ 

| Weibull Survival Model |           |         |
|------------------------|-----------|---------|
| The FREQ Procedure     |           |         |
| alpha                  | Frequency | Percent |
| alpha < 1              | 9998      | 99.98   |
| alpha >= 1             | 2         | 0.02    |

The output from PROC FREQ shows that 100% of the 10000 simulated values for  $\alpha$  are less than 1. This is a very strong indication that the exponential model is too restrictive to model these data well.

You can examine the estimated survival probabilities over time individually, either through the posterior summary statistics or by looking at the kernel density plots. Alternatively, you might find it more informative to examine these quantities in relation with each other. For example, you can use a side-by-side box plot to display these posterior distributions by using PROC SGPLOT (“[Statistical Graphics Using ODS](#)” on page 579). First you need to take the posterior output data set `Weisurvout` and stack variables that you want to plot. For example, to plot all the survival times for patients who received interferon, you want to stack `surv_inf1–surv_inf10`. The macro `%Stackdata` takes an input data set `dataset`, stacks the wanted variables `vars`, and outputs them into the output data set.

The following statements define the macro `stackdata`:

```

/* define macro stackdata */
%macro StackData(dataset,output,vars);
 data &output;
 length var $ 32;
 if 0 then set &dataset nobs=nnn;
 array l11[*] &vars;
 do jjj=1 to dim(l11);
 do iii=1 to nnn;
 set &dataset point=iii;
 value = l11[jjj];
 call vname(l11[jjj],var);
 output;
 end;
 end;
 stop;
 keep var value;
run;
%mend;

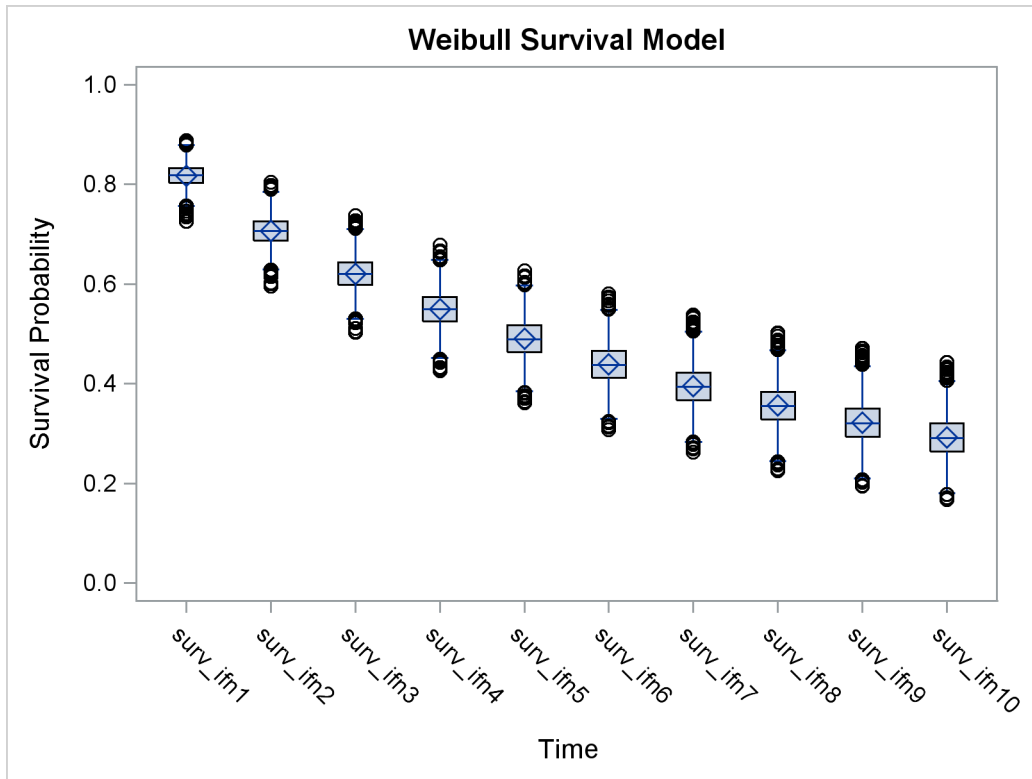

/* stack the surv_ifn variables and saved them to survifn. */
%StackData(weisurvout, survifn, surv_ifn1–surv_ifn10);

```

Once you stack the data, use PROC SGPLOT to create the side-by-side box plots. The following statements generate [Output 55.13.6](#):

```
proc sgplot data=survifn;
 yaxis label='Survival Probability' values=(0 to 1 by 0.2);
 xaxis label='Time' discreteorder=data;
 vbox value / category=var;
run;
```

**Output 55.13.6** Side-by-Side Box Plots of Estimated Survival Probabilities

There is a clear decreasing trend over time of the survival probabilities for patients who receive the treatment. You might ask how does this group compare to those who did not receive the treatment? In this case, you want to overlay the two predicted curves for the two groups of patients and add the corresponding credible interval. See [Output 55.13.7](#). To generate the graph, you first take the posterior mean estimates from the ODS output table ds and the lower and upper HPD interval estimates is, store them in the data set Surv, and draw the figure by using PROC SGPLOT.

The following statements generate data set Surv:

```
data surv;
 set ds;
 if _n_ >= 4 then do;
 set is point=_n_;
 group = 'with interferon ';
 time = _n_ - 3;
 if time > 10 then do;
 time = time - 10;
 group = 'without interferon';
 end;
 end;
```

```

output;
end;
keep time group mean hpdlower hpdupper;
run;

```

The following SGLOT statements generate [Output 55.13.7](#):

```

proc sgplot data=surv;
 yaxis label="Survival Probability" values=(0 to 1 by 0.2);
 series x=time y=mean / group = group name='i';
 band x=time lower=hpdlower upper=hpdupper / group = group transparency=0.7;
 keylegend 'i';
run;
ods graphics off;

```

In [Output 55.13.7](#), the solid line is the survival curve for patients who received interferon; the shaded region centers at the solid line is the 95% HPD intervals; the medium-dashed line is the survival curve for patients who did not receive interferon; and the shaded region around the dashed line is the corresponding 95% HPD intervals.

**Output 55.13.7** Predicted Survival Probability Curves with 95% HPD Intervals

The plot suggests that there is an effect of using interferon because patients who received interferon have sustained better survival probabilities than those who did not. However, the effect might not be very significant, as the 95% credible intervals of the two groups do overlap. For more on these interferon studies, see Ibrahim, Chen, and Lipsitz (2001).

## Weibull or Exponential?

Although the evidence from the Weibull model fit shows that the posterior distribution of  $\alpha$  has a significant amount of density mass less than 1, suggesting that the Weibull model is a better fit to the data than the exponential model, you might still be interested in comparing the two models more formally. You can use the Bayesian model selection criterion (see the section “[Deviance Information Criterion \(DIC\)](#)” on page 155) to determine which model fits the data better.

The PROC MCMC [DIC](#) option requests the calculation of DIC, and the procedure displays the ODS output table [DIC](#). The table includes the posterior mean of the deviation,  $\overline{D(\theta)}$ , deviation at the estimate,  $D(\hat{\theta})$ , effective number of parameters,  $p_D$ , and DIC. It is important to remember that the standardizing term,  $p(y)$ , which is a function of the data alone, is not taken into account in calculating the DIC. This term is irrelevant only if you compare two models that have the *same* likelihood function. If you do not have identical likelihood functions, using DIC for model selection purposes without taking this standardizing term into account can produce incorrect results. In addition, you want to be careful in interpreting the DIC whenever you use the [GENERAL](#) function to construct the log-likelihood, as the case in this example. Using the [GENERAL](#) function, you can obtain identical posterior samples with two log-likelihood functions that differ only by a constant. This difference translates to a difference in the DIC calculation, which could be very misleading.

If  $\alpha = 1$ , the Weibull likelihood is identical to the exponential likelihood. It is safe in this case to directly compare DICs from these two models. However, if you do not want to work out the mathematical detail or you are uncertain of the equivalence, a better way of comparing the DICs is to run the Weibull model twice: once with  $\alpha$  being a parameter and once with  $\alpha = 1$ . This ensures that the likelihood functions are the same, and the DIC comparison is meaningful.

The following statements fit a Weibull model:

```

title 'Model Comparison between Weibull and Exponential';
proc mcmc data=e1684 outpost=weisurvout nmc=10000 seed=4861 dic;
 ods select dic;
 parms alpha 1 (beta0 beta1) 0;
 prior beta: ~ normal(0, var=10000);
 prior alpha ~ gamma(0.001, is=0.001);

 lambda = beta0 + beta1*ifn;
 llike = v*(log(alpha) + (alpha-1)*log(t) + lambda) -
 exp(lambda)*(t**alpha);
 model general(llike);
run;

```

The DIC option requests the calculation of DIC, and the table is displayed in [Output 55.13.8](#).

**Output 55.13.8** DIC Table from the Weibull Model

| Model Comparison between Weibull and Exponential                                                                                                                                                                                                 |         |
|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|---------|
| The MCMC Procedure                                                                                                                                                                                                                               |         |
| Deviance Information Criterion                                                                                                                                                                                                                   |         |
| Dbar (posterior mean of deviance)                                                                                                                                                                                                                | 858.623 |
| Dmean (deviance evaluated at posterior mean)                                                                                                                                                                                                     | 855.633 |
| pD (effective number of parameters)                                                                                                                                                                                                              | 2.990   |
| DIC (smaller is better)                                                                                                                                                                                                                          | 861.614 |
| <p>The GENERAL or DGENERAL function is used in this program. To make meaningful comparisons, you must ensure that all GENERAL or DGENERAL functions include appropriate normalizing constants. Otherwise, DIC comparisons can be misleading.</p> |         |

The note in [Output 55.13.8](#) reminds you of the importance of ensuring identical likelihood functions when you use the GENERAL function. The DIC value is 861.6.

Based on the same set of code, the following statements fit an exponential model by setting  $\alpha = 1$ :

```
proc mcmc data=e1684 outpost=expsurvout nmc=10000 seed=4861 dic;
 ods select dic;
 parms beta0 beta1 0;
 prior beta: ~ normal(0, var=10000);
 begincnst;
 alpha = 1;
 endcnst;

 lambda = beta0 + beta1*ifn;
 llike = v*(log(alpha) + (alpha-1)*log(t) + lambda) -
 exp(lambda)*(t**alpha);
 model general(llike);
run;
```

[Output 55.13.9](#) displays the DIC table.

**Output 55.13.9** DIC Table from the Exponential Model

| Model Comparison between Weibull and Exponential |         |
|--------------------------------------------------|---------|
| The MCMC Procedure                               |         |
| Deviance Information Criterion                   |         |
| Dbar (posterior mean of deviance)                | 870.133 |
| Dmean (deviance evaluated at posterior mean)     | 868.190 |
| pD (effective number of parameters)              | 1.943   |
| DIC (smaller is better)                          | 872.075 |

The GENERAL or DGENERAL function is used in this program. To make meaningful comparisons, you must ensure that all GENERAL or DGENERAL functions include appropriate normalizing constants. Otherwise, DIC comparisons can be misleading.

The DIC value of 872.075 is greater than 861. A smaller DIC indicates a better fit to the data; hence, you can conclude that the Weibull model is more appropriate for this data set. You can see the equivalencing of the exponential model you fitted in “[Exponential Survival Model](#)” on page 4605 by running the following comparison.

The following statements are taken from the section “[Exponential Survival Model](#)” on page 4605, and they fit the same exponential model:

```
proc mcmc data=e1684 outpost=expsurvout1 nmc=10000 seed=4861 dic;
 ods select none;
 parms (beta0 beta1) 0;
 prior beta: ~ normal(0, sd = 10000);
 l_h = beta0 + beta1*ifn;
 llike = v*(l_h) - t*exp(l_h);
 model general(llike);
run;

proc compare data=expsurvout compare=expsurvout1;
 var beta0 beta1;
run;
```

The posterior samples of beta0 and beta1 in the data set Expsurvout1 are identical to those in the data set Expsurvout. The comparison results are not shown here.

---

## Example 55.14: Time Independent Cox Model

This example has two purposes. One is to illustrate how to use PROC MCMC to fit a Cox proportional hazard model. Specifically, the time independent model. See “[Example 55.15: Time Dependent Cox Model](#)” on page 4625 for an example on fitting time dependent Cox model. Note that it is much easier to fit a Bayesian Cox model by specifying the BAYES statement in PROC PHREG (see Chapter 67, “[The PHREG Procedure](#)”). If you are interested only in fitting a Cox regression survival model, you should use PROC PHREG.

The second objective of this example is to demonstrate how to model data that are not independent. That is the case where the likelihood for observation  $i$  depends on other observations in the data set. In other words, if you work with a likelihood function that cannot be broken down simply as  $L(\mathbf{y}) = \prod_i^n L(y_i)$ , you can use this example for illustrative purposes. By default, PROC MCMC assumes that the programming statements and model specification is intended for a single row of observations in the data set. The Cox model is chosen because the complexity in the data structure requires more elaborate coding.

The Cox proportional hazard model is widely used in the analysis of survival time, failure time, or other duration data to explain the effect of exogenous explanatory variables. The data set used in this example is taken from Krall, Uthoff, and Harley (1975), who analyzed data from a study on myeloma in which researchers treated 65 patients with alkylating agents. Of those patients, 48 died during the study and 17 survived. The following statements generate the data set that is used in this example:

```
data Myeloma;
 input Time Vstatus LogBUN HGB Platelet Age LogWBC Frac
 LogPBM Protein SCalc;
 label Time='survival time'
 VStatus='0=alive 1=dead';
 datalines;
 1.25 1 2.2175 9.4 1 67 3.6628 1 1.9542 12 10
 1.25 1 1.9395 12.0 1 38 3.9868 1 1.9542 20 18
 2.00 1 1.5185 9.8 1 81 3.8751 1 2.0000 2 15
 2.00 1 1.7482 11.3 0 75 3.8062 1 1.2553 0 12

 ... more lines ...

 77.00 0 1.0792 14.0 1 60 3.6812 0 0.9542 0 12
;

proc sort data = Myeloma;
 by descending time;
run;

data _null_;
 set Myeloma nobs=_n;
 call symputx('N', _n);
 stop;
run;
```

The variable Time represents the survival time in months from diagnosis. The variable VStatus consists of two values, 0 and 1, indicating whether the patient was alive or dead, respectively, at the end of the study. If the value of VStatus is 0, the corresponding value of Time is censored. The variables thought to be related to survival are LogBUN (log(BUN) at diagnosis), HGB (hemoglobin at diagnosis), Platelet (platelets at diagnosis: 0=abnormal, 1=normal), Age (age at diagnosis in years), LogWBC (log(WBC) at diagnosis), Frac (fractures at diagnosis: 0=none, 1=present), LogPBM (log percentage of plasma cells in bone marrow), Protein (proteinuria at diagnosis), and SCalc (serum calcium at diagnosis). Interest lies in identifying important prognostic factors from these explanatory variables. In addition, there are 65 (&n) observations in the data set Myeloma. The likelihood used in these examples is the Breslow likelihood:

$$L(\boldsymbol{\beta}) = \prod_{i=1}^n \left[ \prod_{j=1}^{d_i} \frac{\exp(\boldsymbol{\beta}'\mathbf{Z}_j(t_i))}{\sum_{l \in \mathcal{R}_i} \exp(\boldsymbol{\beta}'\mathbf{Z}_l(t_i))} \right]^{v_i}$$

where

- $\beta$  is the vector parameters
- $n$  is the total number of observations in the data set
- $t_i$  is the  $i$ th time, which can be either event time or censored time
- $\mathbf{Z}_l(t)$  is the vector explanatory variables for the  $l$ th individual at time  $t$
- $d_i$  is the multiplicity of failures at  $t_i$ . If there are no ties in time,  $d_i$  is 1 for all  $i$ .
- $\mathcal{R}_i$  is the risk set for the  $i$ th time  $t_i$ , which includes all observations that have survival time greater than or equal to  $t_i$
- $v_i$  indicates whether the patient is censored. The value 0 corresponds to censoring. Note that the censored time  $t_i$  enters the likelihood function only through the formation of the risk set  $\mathcal{R}_i$ .

Priors on the coefficients are independent normal priors with very large variance (1e6). Throughout this example, the symbol  $\mathbf{bZ}$  represents the regression term  $\beta' \mathbf{Z}_j(t_i)$  in the likelihood, and the symbol  $\mathbf{S}$  represents the term  $\sum_{l \in \mathcal{R}_i} \exp(\beta' \mathbf{Z}_l(t_i))$ .

The regression model considered in this example uses the following formula:

$$\begin{aligned} \beta' \mathbf{Z}_j = & \beta_1 \text{logbun} + \beta_2 \text{hgb} + \beta_3 \text{platelet} + \beta_4 \text{age} + \\ & \beta_5 \text{logwbc} + \beta_6 \text{frac} + \beta_7 \text{logpbm} + \beta_8 \text{protein} + \beta_9 \text{scal} \end{aligned}$$

The hard part of coding this in PROC MCMC is the construction of the risk set  $\mathcal{R}_i$ .  $\mathcal{R}_i$  contains all observations that have survival time greater than or equal to  $t_i$ . First suppose that there are no ties in time. Sorting the data set by the variable time into descending order gives you  $\mathcal{R}_i$  that is in the right order. Observation  $i$ 's risk set consists of all data points  $j$  such that  $j \leq i$  in the data set. You can cumulatively increment  $\mathbf{S}$  in the SAS statements.

With potential ties in time, at observation  $i$ , you need to know whether any subsequent observations,  $i + 1$  and so on, have the same survival time as  $t_i$ . Suppose that the  $i$ th, the  $i + 1$ , and the  $i + 2$  observations all have the same survival time; all three of them need to be included in the risk set calculation. This means that to calculate the likelihood for some observations, you need to access both the previous and subsequent observations in the data set. There are two ways to do this. One is to use the LAG function; the other is to use the option `JOINTMODEL`.

The LAG function returns values from a queue (see *SAS Language Reference: Dictionary*). So for the  $i$ th observation, you can use LAG1 to access variables from the previous row in the data set. You want to compare the lag1 value of time with the current time value. Depending on whether the two time values are equal, you can add correction terms in the calculation for the risk set  $\mathbf{S}$ .

The following statements sort the data set by time into descending order, with the largest survival time on top:

```

title 'Cox Model with Time Independent Covariates';
proc freq data=myeloma;
 ods select none;
 tables time / out=freqs;
run;

proc sort data = freqs;
 by descending time;
run;

data myelomaM;
 set myeloma;
 ind = _N_;
run;
ods select all;

```

The following statements run PROC MCMC and produce [Output 55.14.1](#):

```

proc mcmc data=myelomaM outpost=outi nmc=50000 ntu=3000 seed=1;
 ods select PostSummaries PostIntervals;
 array beta[9];
 parms beta: 0;
 prior beta: ~ normal(0, var=1e6);

 bZ = beta1 * LogBUN + beta2 * HGB + beta3 * Platelet
 + beta4 * Age + beta5 * LogWBC + beta6 * Frac +
 beta7 * LogPEM + beta8 * Protein + beta9 * SCalc;

 if ind = 1 then do; /* first observation */
 S = exp(bZ);
 l = vstatus * bZ;
 v = vstatus;
 end;
 else if (1 < ind < &N) then do;
 if (lag1(time) ne time) then do;
 l = vstatus * bZ;
 l = l - v * log(S); /* correct the loglike value */
 v = vstatus; /* reset v count value */
 S = S + exp(bZ);
 end;
 else do; /* still a tie */
 l = vstatus * bZ;
 S = S + exp(bZ);
 v = v + vstatus; /* add # of nonsensored values */
 end;
 end;
 else do; /* last observation */
 if (lag1(time) ne time) then do;
 l = - v * log(S); /* correct the loglike value */
 S = S + exp(bZ);
 l = l + vstatus * (bZ - log(S));
 end;
 else do;

```

```

 S = S + exp(bZ) ;
 l = vstatus * bZ - (v + vstatus) * log(S) ;
 end;
 end;
 model general(l) ;
run;

```

The symbol `bZ` is the regression term, which is independent of the time variable. The symbol `ind` indexes observation numbers in the data set. The symbol `S` keeps track of the risk set term for every observation. The symbol `l` calculates the log likelihood for each observation. Note that the value of `l` for observation `ind` is not necessarily the correct log likelihood value for that observation, especially in cases where the observation `ind` is in the tied times. Correction terms are added to subsequent values of `l` when the time variable becomes different in order to make up the difference. The total sum of `l` calculated over the entire data set is correct. The symbol `v` keeps track of the sum of `vstatus`, as censored data do not enter the likelihood and need to be taken out.

You use the function `LAG1` to detect if two adjacent time values are different. If they are, you know that the current observation is in a different risk set than the last one. You then need to add a correction term to the log likelihood value of `l`. The IF-ELSE statements break the observations into three parts: the first observation, the last observation and everything in the middle.

**Output 55.14.1** Summary Statistics on Cox Model with Time Independent Explanatory Variables and Ties in the Survival Time, Using PROC MCMC

An alternative to using the LAG function is to use the PROC option `JOINTMODEL`. With this option, the log-likelihood function you specify applies not to a single observation but to the entire data set. See “Modeling Joint Likelihood” on page 4504 for details on how to properly use this option. The basic idea is that you store all necessary data set variables in arrays and use only the arrays to construct the log likelihood of the entire data set. This approach works here because for every observation  $i$ , you can use index to access different values of arrays to construct the risk set  $S$ . To use the `JOINTMODEL` option, you need to do some additional data manipulation. You want to create a stop variable for each observation, which indicates the observation number that should be included in  $S$  for that observation. For example, if observations 4, 5, 6 all have the same survival time, the stop value for all of them is 6.

The following statements generate a new data set MyelomaM that contains the stop variable:

```
data myelomaM;
 merge myelomaM freqs(drop=percent);
 by descending time;
 retain stop;
 if first.time then do;
 stop = _n_ + count - 1;
 end;
run;
```

The following SAS program fits the same Cox model by using the `JOINTMODEL` option:

```
data a;
run;

proc mcmc data=a outpost=outa nmc=50000 ntu=3000 seed=1 jointmodel;
 ods select none;
 array beta[9];
 array data[1] / nosymbols;
 array timeA[1] / nosymbols;
 array vstatusA[1] / nosymbols;
 array stopA[1] / nosymbols;
 array bZ[&n];
 array S[&n];

 beginncnst;
```

```

rc = read_array("myelomam", data, "logbun", "hgb", "platelet",
 "age", "logwbc", "frac", "logpbm", "protein", "scalc");
rc = read_array("myelomam", timeA, "time");
rc = read_array("myelomam", vstatusA, "vstatus");
rc = read_array("myelomam", stopA, "stop");
endcnst;

parms (beta:) 0;
prior beta: ~ normal(0, var=1e6);

jl = 0;
/* calculate each bZ and cumulatively adding S as if there are no ties.*/
call mult(data, beta, bZ);
S[1] = exp(bZ[1]);
do i = 2 to &n;
 S[i] = S[i-1] + exp(bZ[i]);
end;

do i = 1 to &n;
 /* correct the S[i] term, when needed. */
 if(stopA[i] > i) then do;
 do j = (i+1) to stopA[i];
 S[i] = S[i] + exp(bZ[j]);
 end;
 end;
 jl = jl + vstatusA[i] * (bZ[i] - log(S[i]));
end;
model general(jl);
run;
ods select all;

```

No output tables were produced because this PROC MCMC run produces identical posterior samples as does the previous example.

Because the `JOINTMODEL` option is specified here, you do not need to specify `myelomaM` as the input data set. An empty data set `a` is used to speed up the procedure run.

Multiple `ARRAY` statements allocate array symbols that are used to store the parameters (`beta`), the response and the covariates (`data`, `timeA`, `vstatusA`, and `stopA`), and the work space (`bZ` and `S`). The `data`, `timeA`, `vstatusA`, and `stopA` arrays are declared with the `/NOSYMBOLS` option. This option enables PROC MCMC to dynamically resize these arrays to match the dimensions of the input data set. See the section “[READ\\_ARRAY Function](#)” on page 4442. The `bZ` and `S` arrays store the regression term and the risk set term for every observation.

The `BEGINCNST` and `ENDCNST` statements enclose programming statements that read the data set variables into these arrays. The rest of the programming statements construct the log likelihood for the entire data set.

The `CALL MULT` function calculates the regression term in the model and stores the result in the array `bZ`. In the first `DO` loop, you sum the risk set term `S` as if there are no ties in time. This underevaluates some of the `S` elements. For observations that have a tied time, you make the necessary correction to the corresponding `S` values. The correction takes place in the second `DO` loop. Any observation that has a tied time also has a `stopA[i]` that is different from `i`. You add the right terms to `S` and sum up the joint log likelihood `jl`. The `MODEL` statement specifies that the log likelihood takes on the value of `jl`.

To see that you get identical results from these two approaches, use PROC COMPARE to compare the posterior samples from two runs:

```
proc compare data=outi compare=outa;
 ods select comparesummary;
 var beta1-beta9;
run;
```

The output is not shown here.

Generally, the **JOINTMODEL** option can be slightly faster than using the default setup. The savings come from avoiding the overhead cost of accessing the data set repeatedly at every iteration. However, the speed gain is not guaranteed because it largely depends on the efficiency of your programs.

PROC PHREG fits the same model, and you get very similar results to PROC MCMC. The following statements fit the model using PROC PHREG and produce [Output 55.14.2](#):

```
proc phreg data=Myeloma;
 ods select PostSummaries PostIntervals;
 model Time*VStatus(0)=LogBUN HGB Platelet Age LogWBC
 Frac LogPBM Protein SCalc;
 bayes seed=1 nmc=10000 outpost=phout;
run;
```

**Output 55.14.2** Summary Statistics for Cox Model with Time Independent Explanatory Variables and Ties in the Survival Time, Using PROC PHREG

**Example 55.15: Time Dependent Cox Model**

This example uses the same Myeloma data set as in “[Example 55.14: Time Independent Cox Model](#)” on page 4617, and illustrates the fitting of a time dependent Cox model. The following statements generate the data set once again:

```
data Myeloma;
 input Time Vstatus LogBUN HGB Platelet Age LogWBC Frac
 LogPBM Protein SCalc;
 label Time='survival time'
 VStatus='0=alive 1=dead';
 datalines;
 1.25 1 2.2175 9.4 1 67 3.6628 1 1.9542 12 10
 1.25 1 1.9395 12.0 1 38 3.9868 1 1.9542 20 18
 2.00 1 1.5185 9.8 1 81 3.8751 1 2.0000 2 15
 2.00 1 1.7482 11.3 0 75 3.8062 1 1.2553 0 12

 ... more lines ...

 77.00 0 1.0792 14.0 1 60 3.6812 0 0.9542 0 12
;
```

To model  $\mathbf{Z}_i(t_i)$  as a function of the survival time, you can relate time  $t_i$  to covariates by using this formula:

$$\boldsymbol{\beta}'\mathbf{Z}_j(t_i) = (\beta_1 + \beta_2 t_i)\text{logbun} + (\beta_3 + \beta_4 t_i)\text{hgb} + (\beta_5 + \beta_6 t_i)\text{platelet}$$

For illustrational purposes, only three explanatory variables, LOGBUN, HGB, and PLATELET, are used in this example.

Since  $\mathbf{Z}_j(t_i)$  depends on  $t_i$ , every term in the summation of  $\sum_{l \in \mathcal{R}_i} \exp(\boldsymbol{\beta}'\mathbf{Z}_l(t_i))$  is a product of the current time  $t_i$  and all observations that are in the risk set. You can use the **JOINTMODEL** option, as in the last example, or you can modify the input data set such that every row contains not only the current observation but also all observations that are in the corresponding risk set. When you construct the log likelihood for each observation, you have all the relevant data at your disposal.

The following statements illustrate how you can create a new data set with different risk sets at different rows:

```

title 'Cox Model with Time Dependent Covariates';
proc sort data = Myeloma;
 by descending time;
run;

data _null_;
 set Myeloma nobs=_n;
 call symputx('N', _n);
 stop;
run;

ods select none;
proc freq data=myeloma;
 tables time / out=freqs;
run;
ods select all;

proc sort data = freqs;
 by descending time;
run;

data myelomaM;
 set myeloma;
 ind = _N_;
run;

data myelomaM;
 merge myelomaM freqs(drop=percent); by descending time;
 retain stop;
 if first.time then do;
 stop = _n_ + count - 1;
 end;
run;

%macro array(list);
 %global mcmccarray;
 %let mcmccarray = ;
 %do i = 1 %to 32000;
 %let v = %scan(&list, &i, %str());
 %if %nrbquote(&v) ne %then %do;
 array _&v[&n];
 %let mcmccarray = &mcmccarray array _&v[&n] _&v.1 - _&v.&n%str(;;);
 do i = 1 to stop;
 set myelomaM(keep=&v) point=i;
 _&v[i] = &v;
 end;
 %end;
 %else %let i = 32001;
 %end;
%mend;

```

```

data z;
 set myelomaM;
 %array(logbun hgb platelet);
 drop vstatus logbun hgb platelet count stop;
run;

data myelomaM;
 merge myelomaM z; by descending time;
run;

```

The data set MyelomaM contains 65 observations and 209 variables. For each observation, you see added variables stop, \_logbun1 through \_logbun65, \_hgb1 through \_hgb65, and \_platelet1 through \_platelet65. The variable stop indicates the number of observations that are in the risk set of the current observation. The rest are transposed values of model covariates of the entire data set. The data set contains a number of missing values. This is due to the fact that only the relevant observations are kept, such as \_logbun1 to \_logbunstop. The rest of the cells are filled in with missing values. For example, the first observation has a unique survival time of 92 and stop is 1, making it a risk set of itself. You see nonmissing values only in \_logbun1, \_hgb1, and \_platelet1.

The following statements fit the Cox model by using PROC MCMC:

```

proc mcmc data=myelomaM outpost=outi nmc=50000 ntu=3000 seed=17
 missing=ac;
 ods select PostSummaries PostIntervals;
 array beta[6];
 &mcmcarray
 parms (beta:) 0;
 prior beta: ~ normal(0, prec=1e-6);

 b = (beta1 + beta2 * time) * logbun +
 (beta3 + beta4 * time) * hgb +
 (beta5 + beta6 * time) * platelet;
 S = 0;
 do i = 1 to stop;
 S = S + exp((beta1 + beta2 * time) * _logbun[i] +
 (beta3 + beta4 * time) * _hgb[i] +
 (beta5 + beta6 * time) * _platelet[i]);
 end;
 loglike = vstatus * (b - log(S));

 model general(loglike);
run;

```

Note that the option `MISSING=` is set to `AC`. This is due to missing cells in the input data set. You must use this option so that PROC MCMC retains observations that contain missing values.

The macro variable `&mcmcarray` is defined in the earlier part in this example. You can use a `%put` statement to print its value:

```
%put &mcmcarray;
```

This statement prints the following:

```
array _logbun[65] _logbun1 - _logbun65; array _hgb[65] _hgb1 - _hgb65; array
```

```
_platelet[65] _platelet1 - _platelet65;
```

The macro uses the `ARRAY` statement to allocate three arrays, each of which links their corresponding data set variables. This makes it easier to reference these data set variables in the program. The `PARMS` statement puts all the parameters in the same block. The `PRIOR` statement gives them normal priors with large variance. The symbol `b` is the regression term, and `S` is cumulatively added from 1 to stop for each observation in the `DO` loop. The symbol `loglike` completes the construction of log likelihood for each observation and the `MODEL` statement completes the model specification.

Posterior summary and interval statistics are shown in [Output 55.15.1](#).

**Output 55.15.1** Summary Statistics on Cox Model with Time Dependent Explanatory Variables and Ties in the Survival Time, Using PROC MCMC

| Cox Model with Time Dependent Covariates |       |          |                    |             |          |          |

| beta3                                    | 50000 | -0.0369  | 0.1017             | -0.1064     | -0.0373  | 0.0315   |
| beta4                                    | 50000 | -0.00409 | 0.00360            | -0.00656    | -0.00408 | -0.00167 |
| beta5                                    | 50000 | 0.3548   | 0.7359             | -0.1634     | 0.3530   | 0.8445   |
| beta6                                    | 50000 | -0.0417  | 0.0359             | -0.0661     | -0.0423  | -0.0181  |

| Posterior Intervals |       |                     |         |              |         |
|---------------------|-------|---------------------|---------|--------------|---------|
| Parameter           | Alpha | Equal-Tail Interval |         | HPD Interval |         |
| beta1               | 0.050 | 1.6399              | 4.8667  | 1.6664       | 4.8752  |
| beta2               | 0.050 | -0.2351             | -0.0509 | -0.2294      | -0.0458 |
| beta3               | 0.050 | -0.2337             | 0.1642  | -0.2272      | 0.1685  |
| beta4               | 0.050 | -0.0111             | 0.00282 | -0.0112      | 0.00264 |
| beta5               | 0.050 | -1.0317             | 1.8202  | -1.0394      | 1.8100  |
| beta6               | 0.050 | -0.1107             | 0.0295  | -0.1122      | 0.0269  |

You can also use the option `JOINTMODEL` to get the same inference and avoid transposing the data for every observation:

```
proc mcmc data=myelomaM outpost=outa nmc=50000 ntu=3000 seed=17 jointmodel;
ods select none;
array beta[6]; array timeA[&n]; array vstatusA[&n];
array logbunA[&n]; array hgbA[&n]; array plateletA[&n];
array stopA[&n]; array bZ[&n]; array S[&n];

beginncst;
timeA[ind]=time; vstatusA[ind]=vstatus;
```

```

 logbunA[ind]=logbun; hgbA[ind]=hgb;
 plateletA[ind]=platelet; stopA[ind]=stop;
endcnst;

parms (beta:) 0;
prior beta: ~ normal(0, prec=1e-6);

j1 = 0;
do i = 1 to &n;
 v1 = beta1 + beta2 * timeA[i];
 v2 = beta3 + beta4 * timeA[i];
 v3 = beta5 + beta6 * timeA[i];
 bZ[i] = v1 * logbunA[i] + v2 * hgbA[i] + v3 * plateletA[i];

 /* sum over risk set without considering ties in time. */
 S[i] = exp(bZ[i]);
 if (i > 1) then do;
 do j = 1 to (i-1);
 b1 = v1 * logbunA[j] + v2 * hgbA[j] + v3 * plateletA[j];
 S[i] = S[i] + exp(b1);
 end;
 end;
end;

/* make correction to the risk set due to ties in time. */
do i = 1 to &n;
 if(stopA[i] > i) then do;
 v1 = beta1 + beta2 * timeA[i];
 v2 = beta3 + beta4 * timeA[i];
 v3 = beta5 + beta6 * timeA[i];
 do j = (i+1) to stopA[i];
 b1 = v1 * logbunA[j] + v2 * hgbA[j] + v3 * plateletA[j];
 S[i] = S[i] + exp(b1);
 end;
 end;
 j1 = j1 + vstatusA[i] * (bZ[i] - log(S[i]));
end;
model general(j1);
run;

```

The multiple **ARRAY** statements allocate array symbols that are used to store the parameters (beta), the response (timeA), the covariates (vstatusA, logbunA, hgbA, plateletA, and stopA), and work space (bZ and S). The bZ and S arrays store the regression term and the risk set term for every observation. Programming statements in the **BEGINCNST** and **ENDCNST** statements input the response and covariates from the data set to the arrays.

Using the same technique shown in the example “[Example 55.14: Time Independent Cox Model](#)” on page 4617, the next **DO** loop calculates the regression term and corresponding S for every observation, pretending that there are no ties in time. This means that the risk set for observation *i* involves only observation 1 to *i*. The correction terms are added to the corresponding S[i] in the second **DO** loop, conditional on whether the stop variable is greater than the observation count itself. The symbol j1 cumulatively adds the log likelihood for the entire data set, and the **MODEL** statement specifies the joint log-likelihood function.

The following statements run PROC COMPARE and show that the output data set outa contains identical posterior samples as outi:

```
proc compare data=outi compare=outa;
 ods select comparesummary;
 var beta1-beta6;
run;
```

The results are not shown here.

The following statements use PROC PHREG to fit the same time dependent Cox model:

```
proc phreg data=Myeloma;
 ods select PostSummaries PostIntervals;
 model Time*VStatus(0)=LogBUN z2 hgb z3 platelet z4;
 z2 = Time*logbun;
 z3 = Time*hgb;
 z4 = Time*platelet;
 bayes seed=1 nmc=10000 outpost=phout;
run;
```

Coding is simpler than PROC MCMC. See [Output 55.15.2](#) for posterior summary and interval statistics:

## Example 55.16: Piecewise Exponential Frailty Model

This example illustrates how to fit a piecewise exponential frailty model using PROC MCMC. Part of the notation and presentation in this example follows Clayton (1991) and the Luek example in Spiegelhalter et al. (1996a).

Generally speaking, the proportional hazards model assumes the hazard function,

$$\lambda_i(t|\mathbf{z}_i) = \lambda_0(t) \exp\{\boldsymbol{\beta}'\mathbf{z}_i\}$$

where  $i = 1 \cdots n$  indexes subject,  $\lambda_0(t)$  is the baseline hazard function, and  $\mathbf{z}_i$  are the covariates for subject  $i$ . If you define  $N_i(t)$  to be the number of observed failures of the  $i$ th subject up to time  $t$ , then the hazard function for the  $i$ th subject can be seen as a special case of a *multiplicative intensity model* (Clayton 1991). The intensity process for  $N_i(t)$  becomes

$$I_i(t) = Y_i(t)\lambda_0(t) \exp(\boldsymbol{\beta}'\mathbf{z}_i)$$

where  $Y_i(t)$  indicates observation of the subject at time  $t$  (taking the value of 1 if the subject is observed and 0 otherwise). Under *noninformative censoring*, the corresponding likelihood is proportional to

$$\prod_{i=1}^n \left[ \prod_{t \geq 0} I_i(t) \right]^{dN_i(t)} \exp \left[ - \int_{t \geq 0} I_i(t) dt \right]$$

where  $dN_i(t)$  is the increment of  $N_i(t)$  over the small time interval  $[t, t + dt)$ : it takes a value of 1 if the subject  $i$  fails in the time interval, 0 otherwise. This is a Poisson kernel with the random variable being the increments of  $dN_i$  and the means  $I_i(t)dt$

$$dN_i(t) \sim \text{Poisson}(I_i(t)dt)$$

where

$$I_i(t)dt = Y_i(t) \exp(\boldsymbol{\beta}'\mathbf{z}_i) d\Lambda_0(t)$$

and

$$\Lambda_0(t) = \int_0^t \lambda_0(u) du.$$

The integral is the increment in the integrated baseline hazard function that occurs during the time interval  $[t, t + dt)$ .

This formulation provides an alternative way to fit a piecewise exponential model. You partition the time axis to a few intervals, where each interval has its own hazard rate,  $\Lambda_0(t)$ . You count the  $Y_i(t)$  and  $dN_i(t)$  in each interval, and fit a Poisson model to each count.

The following DATA step creates the data set Blind (Lin 1994) that represents 197 diabetic patients who have a high risk of experiencing blindness in both eyes as defined by DRS criteria:

```

One eye of each patient is treated with laser photocoagulation. The hypothesis of interest is whether the laser treatment delays the occurrence of blindness. The following variables are included in `Blind`:

- ID, patient's identification
- Time, failure time
- Status, event indicator (0=censored and 1=uncensored)
- Treatment, treatment received (1=laser photocoagulation and 0=otherwise)
- DiabeticType, type of diabetes (0=juvenile onset with age of onset at 20 or under, and 1= adult onset with age of onset over 20)

For illustrational purposes, a piecewise exponential model that ignores the patient-level frailties is first fit to the entire data set. The formulation of the Poisson counting process makes it straightforward to add the frailty terms, as it is demonstrated later.

The following statements create a partition (of length 8) along the time axis, with  $s_0 < s_1 < s_2 < \dots < s_J$ , with  $s_0 = 0.1 < y_i$  and  $s_J = 80 > y_i$  for all  $i$ . The time intervals are stored in the `Partition` data set:

```

data partition;
 input int_1-int_9;
 datalines;
 0.1 6.545 13.95 26.47 38.8 45.88 54.35 62 80
;

```

To obtain reasonable estimates, placing an equal number of observations in each interval is recommended. You can find the partition points by calculating the percentile statistics of the time variable (for example, by using the `UNIVARIATE` procedure).

The following regression model and prior distributions are used in the analysis:

$$\begin{aligned}\beta'z_i &= \beta_1\text{treatment} + \beta_2\text{diabetictype} + \beta_3\text{treatment} * \text{diabetictype} \\ \beta_1, \beta_2, \beta_3 &\sim \text{normal}(0, \text{var} = 1e6) \\ \lambda_j &\sim \text{gamma}(\text{shape} = 0.01, \text{iscale} = 0.01) \quad \text{for } j = 1 \cdots 8\end{aligned}$$

The following statements calculate  $Y_i(t)$  for each observation  $i$ , at every time point  $t$  in the Partition data set. The statements also find the observed failure time interval,  $dN_i(t)$ , for each observation:

```
%let n = 8;
data _a;
 set blind;
 if _n_ eq 1 then set partition;
 array int[*] int_;
 array Y[&n];
 array dN[&n];
 do k = 1 to (dim(int)-1);
 Y[k] = (time - int[k] + 0.001 >= 0);
 dN[k] = Y[k] * (int[k+1] - time - 0.001 >= 0) * status;
 end;
 output;
 drop int_ : k;
run;
```

The DATA step reads in the Blind data set. At the first observation, it also reads in the Partition data set. The first ARRAY statement creates the int array and name the elements int\_. Because the names match the variable names in the Partition data set, all values of the int\_ variables (there is only one observation) in the Partition data set are therefore stored in the int array. The next two ARRAY statements create arrays Y and dN, each with length 8. They store values of  $Y_i(t)$  and  $dN_i(t)$ , resulting from each failure time in the Blind data set.

The following statements print the first 10 observations of the constructed data set \_a and display them in [Output 55.16.1](#):

```
proc print data=_a(obs=10);
run;
```

**Output 55.16.1** First 10 Observations of the Data Set \_a

| Piecewise Exponential Model |        |                                                                                             |             |             |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |        |

| 9                           | 29     | 38.77                                                                                       | 0           | 0           | 1      | 1      | 1      | 1      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |
| 10                          | 29     | 0.30                                                                                        | 1           | 0           | 0      | 1      | 0      | 0      | 0      | 0      | 0      | 0      | 1      | 0      | 0      | 0      | 0      | 0      | 0      | 0      |

The first subject in `_a` experienced blindness in the left eye at time 46.23, and the time falls in the sixth interval as defined in the Partition data set. Therefore, Y1 through Y6 all take a value of 1, and Y7 and Y8 are 0. The variable `dn#` takes on a value of 1 if the subject is observed to go blind in that interval. Since the first observation is censored (`status == 1`), the actual failure time is unknown. Hence all `dn#` are 0. The first observed failure time occurs in observation number 4 (the right eye of the second subject), where the time variable takes a value of 31.30, Y1 through Y4 are 1, and `dn4` is 1.

Note that each observation in the `_a` data set has 8 Y and 8 `dn`, meaning that you would need eight `MODEL` statements in a PROC MCMC call, each for a Poisson likelihood. Alternatively, you can expand `_a`, put one Y and one `dn` in every observation, and fit the data using a single `MODEL` statement in PROC MCMC. The following statements expand the data set `_a` and save the results in the data set `_b`:

```
data _b;
 set _a;
 array y[*] y;;
 array dn[*] dn;;
 do i = 1 to (dim(y));
 y_val = y[i];
 dn_val = dn[i];
 int_index = i;
 output;
 end;
 keep y_ : dn_ : diabetictype treatment int_index id;
run;
```

```

data _b;
 set _b;
 rename y_val=Y dn_val=dN;
run;

```

You can use the following PROC PRINT statements to see the first few observations in `_b`:

```

proc print data=_b(obs=10);
run;

```

**Output 55.16.2** First 20 Observations of the Data Set `_b`

| Obs | ID | Diabetic<br>Type | Treatment | Y | dN | int_<br>index |
|-----|----|------------------|-----------|---|----|---------------|
| 1   | 5  | 1                | 1         | 1 | 0  | 1             |
| 2   | 5  | 1                | 1         | 1 | 0  | 2             |
| 3   | 5  | 1                | 1         | 1 | 0  | 3             |
| 4   | 5  | 1                | 1         | 1 | 0  | 4             |
| 5   | 5  | 1                | 1         | 1 | 0  | 5             |
| 6   | 5  | 1                | 1         | 1 | 0  | 6             |
| 7   | 5  | 1                | 1         | 0 | 0  | 7             |
| 8   | 5  | 1                | 1         | 0 | 0  | 8             |
| 9   | 5  | 1                | 0         | 1 | 0  | 1             |
| 10  | 5  | 1                | 0         | 1 | 0  | 2             |

The data set `_b` now contains 3,152 observations (see [Output 55.16.2](#) for the first few observations). The Time and Status variables are no longer needed; hence they are discarded from the data set. The `int_index` variable is an index variable that indicates interval membership of each observation.

Because the variable `Y` does not contribute to the likelihood calculation when it takes a value of 0 (it amounts to a Poisson likelihood that has a mean and response variable that are both 0), you can remove these observations. This speeds up the calculation in PROC MCMC:

```

data inputdata;
 set _b;
 if Y > 0;
run;

```

The data set `inputdata` has 1,775 observations, as opposed to 3,152 observations in `_b`. The following statements fit a piecewise exponential model in PROC MCMC:

```

proc mcmc data=inputdata nmc=10000 outpost=postout seed=12351
 maxtune=5 stats=summary diag=none;
ods select PostSummaries;
parms beta1-beta3 0;
prior beta: ~ normal(0, var = 1e6);
random lambda ~ gamma(0.01, iscale = 0.01) subject=int_index;
bZ = beta1*treatment + beta2*diabetictype + beta3*treatment*diabetictype;
idt = exp(bZ) * lambda;
model dN ~ poisson(idt);
run;

```

The **PARMS** statement declares three regression parameters, beta1–beta3. The **PRIOR** statement specifies a noninformative normal prior on the regression coefficients. The **RANDOM** statement specifies the random effect, lambda, its prior distribution, and interval membership which is indexed by the data set variable int\_index.

The symbol bZ calculates the regression mean, and the symbol idt is the mean of the Poisson likelihood. It corresponds to the equation

$$I_i(t)dt = Y_i(t) \exp(\beta'z) d\Lambda_0(t)$$

Note that the  $Y_i(t)$  term is omitted in the assignment statement because Y takes only the value of 1 in the input data set.

Output 55.16.3 displays posterior estimates of the three regression parameters.

**Output 55.16.3** Posterior Summary Statistics

| beta2               | 10000 | 0.3138  | 0.1956                | 0.1881      | 0.3121  | 0.4387  |
| beta3               | 10000 | -0.7899 | 0.3308                | -0.9999     | -0.7935 | -0.5741 |

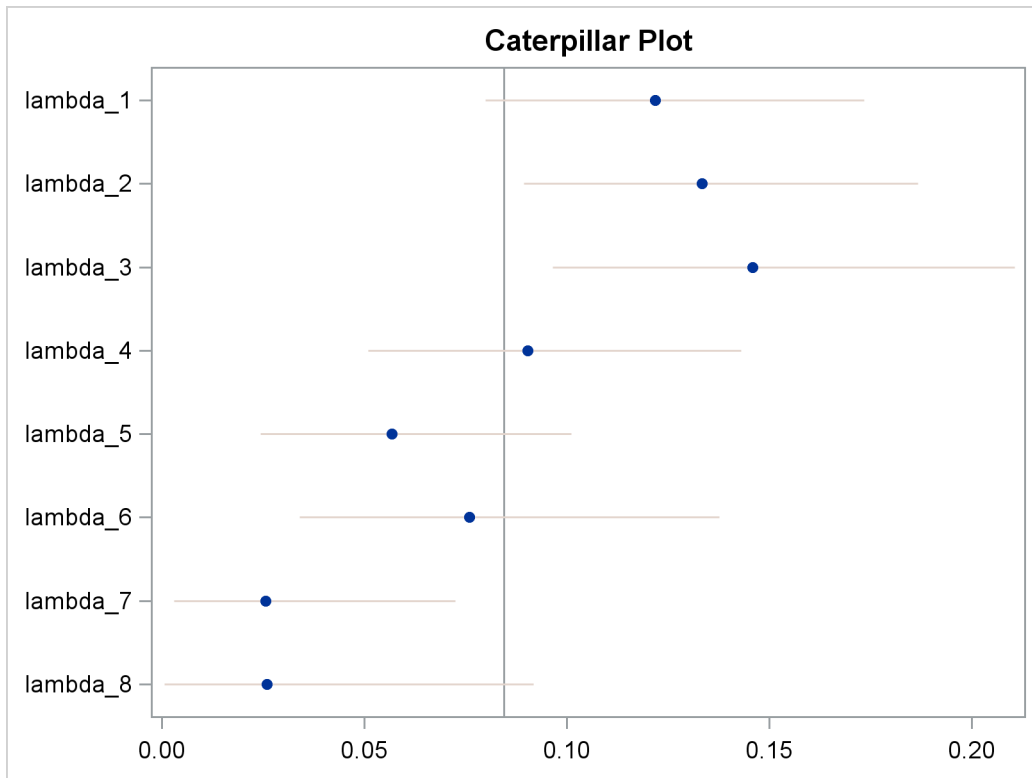

To understand the results, you can create a  $2 \times 2$  table (Table 55.49) and plug in the posterior mean estimates to the regression model. A  $-0.41$  estimate for subjects who received laser treatment and had juvenile diabetes suggests that the laser treatment is effective in delaying blindness. And the effect is much more pronounced ( $-0.80$ ) for adult subjects who have diabetes and received treatment.

**Table 55.49** Estimates of Regression Effects in the Survival Model

| $\hat{\beta}'z$ |   | Diabetic Type |       |
|-----------------|---|---------------|-------|
|                 |   | 0             | 1     |
| Treatment       | 0 | 0             | 0.32  |
|                 | 1 | -0.41         | -0.80 |

You can also use the macro %CATER (“Caterpillar Plot” on page 4508) to draw a caterpillar plot to visualize the eight hazards in the model:

```
ods graphics on;
%cater(data=postout, var=lambda_);
ods graphics off;
```

**Output 55.16.4** Caterpillar Plot of the Hazards in the Piecewise Exponential Model

The fitted hazards show a nonconstant underlying hazard function (read along the y-axis as lambda\_# are hazards along the time-axis) in the model.

Now suppose you want to include patient-level information and fit a frailty model to the blind data set, where the random effect enters the model through the regression term, where the subject is indexed by the variable ID in the data.

$$\begin{aligned}\beta'z_i &= \beta_1\text{treatment} + \beta_2\text{diabetictype} + \beta_3\text{treatment} * \text{diabetictype} + u_{id} \\ u_{id} &\sim \text{normal}(0, \text{var} = \sigma^2) \\ \sigma^2 &\sim \text{igamma}(\text{shape} = 0.01, \text{scale} = 0.01)\end{aligned}$$

where id indexes patient.

The actual coding in PROC MCMC of a piecewise exponential frailty model is rather straightforward:

```
ods select none;
proc mcmc data=inputdata nmc=10000 outpost=postout seed=12351
 stats=summary diag=none;
 parms beta1-beta3 0 s2;
 prior beta: ~ normal(0, var = 1e6);
 prior s2 ~ igamma(0.01, scale=0.01);
 random lambda ~ gamma(0.01, iscale = 0.01) subject=int_index;
 random u ~ normal(0, var=s2) subject=id;
 bZ = beta1*treatment + beta2*diabetictype + beta3*treatment*diabetictype + u;
 idt = exp(bZ) * lambda;
 model dN ~ poisson(idt);
run;
```

A second **RANDOM** statement defines a subject-level random effect  $u$ , and the random-effects parameters enter the model in the term for the regression mean,  $bZ$ . An additional model parameter,  $s2$ , the variance of the random-effects parameters, is needed for the model. The results are not shown here.

### Example 55.17: Normal Regression with Interval Censoring

You can use PROC MCMC to fit failure time data that can be right, left, or interval censored. To illustrate, a normal regression model is used in this example.

Assume that you have the following simple regression model with no covariates:

$$y = \mu + \sigma\epsilon$$

where  $y$  is a vector of response values (the failure times),  $\mu$  is the grand mean,  $\sigma$  is an unknown scale parameter, and  $\epsilon$  are errors from the standard normal distribution. Instead of observing  $y_i$  directly, you only observe a truncated value  $t_i$ . If the true  $y_i$  occurs after the censored time  $t_i$ , it is called *right censoring*. If  $y_i$  occurs before the censored time, it is called *left censoring*. A failure time  $y_i$  can be censored at both ends, and this is called *interval censoring*. The likelihood for  $y_i$  is as follows:

$$p(y_i|\mu) = \begin{cases} \phi(y_i|\mu, \sigma) & \text{if } y_i \text{ is uncensored} \\ S(t_{l,i}|\mu) & \text{if } y_i \text{ is right censored by } t_{l,i} \\ 1 - S(t_{r,i}|\mu) & \text{if } y_i \text{ is left censored by } t_{r,i} \\ S(t_{l,i}|\mu) - S(t_{r,i}|\mu) & \text{if } y_i \text{ is interval censored by } t_{l,i} \text{ and } t_{r,i} \end{cases}$$

where  $S(\cdot)$  is the survival function,  $S(t) = \Pr(T > t)$ .

Gentleman and Geyer (1994) uses the following data on cosmetic deterioration for early breast cancer patients treated with radiotherapy:

```

title 'Normal Regression with Interval Censoring';
data cosmetic;
 label tl = 'Time to Event (Months)';
 input tl tr @@;
 datalines;
45 . 6 10 . 7 46 . 46 . 7 16 17 . 7 14
37 44 . 8 4 11 15 . 11 15 22 . 46 . 46 .
25 37 46 . 26 40 46 . 27 34 36 44 46 . 36 48
37 . 40 . 17 25 46 . 11 18 38 . 5 12 37 .
. 5 18 . 24 . 36 . 5 11 19 35 17 25 24 .
32 . 33 . 19 26 37 . 34 . 36 .
;

```

The data consist of time interval endpoints (in months). Nonmissing equal endpoints ( $tl = tr$ ) indicates noncensoring; a nonmissing lower endpoint ( $tl \neq .$ ) and a missing upper endpoint ( $tr = .$ ) indicates right censoring; a missing lower endpoint ( $tl = .$ ) and a nonmissing upper endpoint ( $tr \neq .$ ) indicates left censoring; and nonmissing unequal endpoints ( $tl \neq tr$ ) indicates interval censoring.

With this data set, you can consider using proper but diffuse priors on both  $\mu$  and  $\sigma$ , for example:

$$\begin{aligned} \mu &\sim \text{normal}(0, \text{sd} = 1000) \\ \sigma &\sim \text{gamma}(0.001, \text{iscale} = 0.001) \end{aligned}$$

The following SAS statements fit an interval censoring model and generate [Output 55.17.1](#):

```
proc mcmc data=cosmetic outpost=postout seed=1 nmc=20000 missing=AC;
 ods select PostSummaries PostIntervals;
 parms mu 60 sigma 50;

 prior mu ~ normal(0, sd=1000);
 prior sigma ~ gamma(shape=0.001, iscale=0.001);

 if (tl^=. and tr^=. and tl=tr) then
 llike = logpdf('normal', tr, mu, sigma);
 else if (tl^=. and tr=.) then
 llike = logsdf('normal', tl, mu, sigma);
 else if (tl=. and tr^=.) then
 llike = logcdf('normal', tr, mu, sigma);
 else
 llike = log(sdf('normal', tl, mu, sigma) -
 sdf('normal', tr, mu, sigma));

 model general(llike);
run;
```

Because there are missing cells in the input data, you want to use the `MISSING=AC` option so that PROC MCMC does not delete any observations that contain missing values. The IF-ELSE statements distinguish different censoring cases for  $y_i$ , according to the likelihood. The SAS functions LOGCDF, LOGSDF, LOGPDF, and SDF are useful here. The `MODEL` statement assigns `llike` as the log likelihood to the response. The Markov chain appears to have converged in this example (evidence not shown here), and the posterior estimates are shown in [Output 55.17.1](#).

## Example 55.18: Constrained Analysis

Conjoint analysis uses regression techniques to model consumer preferences and to estimate consumer utility functions. A problem with conventional conjoint analysis is that sometimes your estimated utilities do not make sense. Your results might suggest, for example, that the consumers would prefer to spend more on a product than to spend less. With PROC MCMC, you can specify constraints on the part-worth utilities (parameter estimates). Suppose that the consumer product being analyzed is an off-road motorcycle. The relevant attributes are how large each motorcycle is (less than 300cc, 301–550cc, and more than 551cc), how much it costs (less than \$5000, \$5001–\$6000, \$6001–\$7000, and more than \$7000), whether or not it has an electric starter, whether or not the engine is counter-balanced, and whether the bike is from Japan or Europe. The preference variable is a ranking of the bikes. You could perform an ordinary conjoint analysis with PROC TRANSREG (see Chapter 97, “The TRANSREG Procedure”) as follows:

```
options validvarname=any;
proc format;
 value sizef 1 = '< 300cc' 2 = '300–550cc' 3 = '> 551cc';
 value pricef 1 = '< $5000' 2 = '$5000 - $6000'
 3 = '$6001 - $7000' 4 = '> $7000';
 value startf 1 = 'Electric Start' 2 = 'Kick Start';
 value balf 1 = 'Counter Balanced' 2 = 'Unbalanced';
 value orif 1 = 'Japanese' 2 = 'European';
run;

data bikes;
 input Size Price Start Balance Origin Rank @@;
 format size sizef. price pricef. start startf.
 balance balf. origin orif.;
 datalines;
2 1 2 1 2 3 1 4 2 2 2 7 1 2 1 1 2 6
3 3 1 1 2 1 1 3 2 1 1 5 3 4 2 2 2 12
2 3 2 2 1 9 1 1 1 2 1 8 2 2 1 2 2 10
2 4 1 1 1 4 3 1 1 2 1 11 3 2 2 1 1 2
;

title 'Ordinary Conjoint Analysis by PROC TRANSREG';
proc transreg data=bikes utilities cprefix=0 lprefix=0;
 ods select Utilities;
 model identity(rank / reflect) =
 class(size price start balance origin / zero=sum);
 output out=coded(drop=intercept) replace;
run;
```

The DATA step reads the experimental design and dependent variable Rank and assigns formats to label the factor levels. PROC TRANSREG is run specifying UTILITIES, which requests a conjoint analysis. The rank variable is reflected around its mean ( $1 \rightarrow 12$ ,  $2 \rightarrow 11$ , ...,  $12 \rightarrow 1$ ) so that in the analysis, larger part-worth utilities correspond to higher preference. The OUT=CODED data set contains the reflected ranks and a binary coding of the factors that can be used in other analyses. See Kuhfeld (2004) for more information about conjoint analysis and coding with PROC TRANSREG.

The Utilities table from the conjoint analysis is shown in [Output 55.18.1](#). Notice the part-worth utilities for price. The part-worth utility for < \$5000 is 0.25. As price increases to the \$5000–\$6000 range, utility

decreases to  $-0.5$ . Then as price increases to the \$6001–\$7000 range, part-worth utility *increases* to 0.5. Finally, for the most expensive bikes, utility decreases again to  $-0.25$ . In cases like this, you might want to impose constraints on the solution so that the part-worth utility for price never increases as prices go up.

### Output 55.18.1 Ordinary Conjoint Analysis by PROC TRANSREG

| European                                              | 0.1250  | 1.01550        |                              | Class.European         |

You could run PROC TRANSREG again, specifying monotonicity constraints on the part-worth utilities for price:

```

title 'Constrained Conjoint Analysis by PROC TRANSREG';
proc transreg data=bikes utilities cprefix=0 lprefix=0;
ods select ConservUtilities;
model identity(rank / reflect) =
 monotone(price / tstandard=center)
 class(size start balance origin / zero=sum);
run;

```

The output from this PROC TRANSREG step is shown in [Output 55.18.2](#).

**Output 55.18.2** Constrained Conjoint Analysis by PROC TRANSREG

| Constrained Conjoint Analysis by PROC TRANSREG           |         |                |                              |                        |

This monotonicity constraint is one of the few constraints on the part-worth utilities that you can specify in PROC TRANSREG. In contrast, PROC MCMC enables you to specify any constraint that can be written in the DATA step language. You can perform the restricted conjoint analysis with PROC MCMC by using the coded factors that were output from PROC TRANSREG. The data set is Coded.

The likelihood is a simple regression model:

$$\text{rank}_i \sim \text{normal}(x_i' \beta, \sigma)$$

where rank is the response, the covariates are '< 300cc'n, '300-500cc'n, '< \$5000'n, '\$5000 - \$6000'n, '\$6001 - \$7000'n, 'Electric Start'n, 'Counter Balanced'n, and Japanese. Note that OPTIONS VALIDVAR-NAME=ANY enables PROC TRANSREG to create names for the coded variables with blanks and special characters. That is why the name-literal notation ('*variable-name*'n) is used for the input data set variables.

Suppose that there are two constraints you want to put on some of the parameters: one is that the parameters for '< \$5000'n, '\$5000 - \$6000'n, and '\$6001 - \$7000'n decrease in order, and the other is that the parameter for 'Counter Balanced'n is strictly positive. You can consider a truncated multivariate normal prior as follows:

$$(\beta_{< \$5000'n}, \beta_{\$5000 - \$6000'n}, \beta_{\$6001 - \$7000'n}, \beta_{\text{Counter Balanced'n}}) \sim \text{MVN}(0, \sigma \mathbf{I})$$

with the following set of constraints:

$$\beta_{< \$5000'n} > \beta_{\$5000 - \$6000'n} > \beta_{\$6001 - \$7000'n} > 0$$

$$\beta_{\text{Counter Balanced'n}} > 0$$

The condition that  $\beta_{\$6001 - \$7000'n} > 0$  reflects an implied constraint that, by definition, 0 is the utility for the highest price range,  $> \$7000$ , which is the reference level for the binary coded price variable. The following statements fit the desired model:

```

 model rank ~ normal(mean, prec=tau);
run;

```

The two [ARRAY](#) statements allocate a  $4 \times 4$  dimensional array for the prior covariance and an array of size 4 for the prior means. In the [BEGINCNST](#) and [ENDCNST](#) statements, the [CALL IDENTITY](#) function sets sigma to be an identity matrix; the [CALL MULT](#) function sets sigma's diagonal elements to be 100 (the diagonal variance terms); and the [CALL ZEROMATRIX](#) function sets mu to be a vector of zeros (the prior

means). For matrix functions in PROC MCMC, see the section “Matrix Functions in PROC MCMC” on page 4498.

There are two **PARMS** statements, with each of them naming a block of parameters. The first **PARMS** statement blocks the following: the intercept, the two size parameters, the one start-type parameter, the one origin parameter, and the precision. The second **PARMS** statement blocks the three price parameters and the one balance parameter, parameters that have the constraint multivariate normal prior. The second **PARMS** statement also specifies initial values for the parameter estimates. The initial values reflect the constraints on these parameters. The initial part-worth utilities all decrease from 0.3 to 0.2 to 0.1 to 0.0 (for the implicit reference level) as the prices increase. Also, the initial part-worth utility for the counter-balanced engine is set to a positive value, 1.

In the **PRIOR** statements, regression coefficients without constraints are given an independent normal prior with mean at 0 and variance of 100. The next IF-ELSE construction imposes the constraints. When these constraints are met, pw5000, pw5000\_6000, pw6001\_7000, pwCounterBalanced are jointly distributed as a multivariate normal prior with mean  $\mu$  and covariance  $\sigma$ . Otherwise, the prior is not defined and  $\mu$  is assigned a missing value. The parameter tau is given a gamma prior, which is a conjugate prior for that parameter.

The model specification is linear. The mean is comprised of an intercept and the sum of terms like pw300cc \* '< 300cc'n, which is a parameter times an input data set variable. The **MODEL** statement specifies that the linear model for rank is normally distributed with mean  $\mu$  and precision tau.

The MCMC results are shown in [Output 55.18.3](#).

The estimates of the part-worth utility for the price categories are ordered as expected. This agrees with the intuition that there is a higher preference for a less expensive motor bike when all other things are equal, and that is what you see when you look at the estimated posterior means for the price part-worths. The estimated standard deviations of the price part-worths in this model are of approximately the same order of magnitude as the posterior means. This indicates that the part-worth utilities for this subject are

not significantly far from each other, and that this subject's ranking of the options was not significantly influenced by the difference in price.

One advantage of Bayesian analysis is that you can incorporate prior information in the data analysis. Constraints on the parameter space are one possible source of information that you might have before you examine the data. This example shows that it can be accomplished in PROC MCMC.

---

## Example 55.19: Implement a New Sampling Algorithm

This example illustrates using the UDS statement to implement a new Markov chain sampler. The algorithm demonstrated here is proposed by Holmes and Held (2006), hereafter referred to as HH. They presented a Gibbs sampling algorithm for generating draws from the posterior distribution of the parameters in a probit regression model. The notation follows closely to HH.

The data used here is the remission data set from a PROC LOGISTIC example:

```

title 'Implement a New Sampling Algorithm';
data inputdata;
 input remiss cell smear infil li blast temp;
 ind = _n_;
 cnst = 1;
 label remiss='Complete Remission';
 datalines;
 1 0.8 0.83 0.66 1.9 1.1 0.996
 ... more lines ...
 0 1 0.73 0.73 0.7 0.398 0.986
;

```

The variable `remiss` is the cancer remission indicator variable with a value of 1 for remission and a value of 0 for nonremission. There are six explanatory variables: `cell`, `smear`, `infil`, `li`, `blast`, and `temp`. These variables are the risk factors thought to be related to cancer remission. The binary regression model is as follows:

$$\text{remiss}_i \sim \text{binary}(p_i)$$

where the covariates are linked to  $p_i$  through a probit transformation:

$$\text{probit}(p_i) = \mathbf{x}'\boldsymbol{\beta}$$

$\boldsymbol{\beta}$  are the regression coefficients and  $\mathbf{x}'$  the explanatory variables. Suppose you want to use independent normal priors on the regression coefficients:

$$\beta_i \sim \text{normal}(0, \text{var} = 25)$$

Fitting a probit model with PROC MCMC is straightforward. You can use the following statements:

```

proc mcmc data=inputdata nmc=100000 propcov=quanew seed=17
 outpost=mcmcout;
 ods select PostSummaries ess;
 parms beta0-beta6;

```

```

prior beta: ~ normal(0,var=25);
mu = beta0 + beta1*cell + beta2*smear +
 beta3*infil + beta4*li + beta5*blast + beta6*temp;
p = cdf('normal', mu, 0, 1);
model remiss ~ bern(p);
run;

```

The expression `mu` is the regression mean, and the CDF function links `mu` to the probability of remission `p` in the binary likelihood.

The summary statistics and effective sample sizes tables are shown in [Output 55.19.1](#). There are high autocorrelations among the posterior samples, and efficiency is relatively low. The correlation time is reduced only after a large amount of thinning.

**Output 55.19.1** Random Walk Metropolis

As an alternative to the random walk Metropolis, you can use the Gibbs algorithm to sample from the posterior distribution. The Gibbs algorithm is described in the section “[Gibbs Sampler](#)” on page 135. While the Gibbs algorithm generally applies to a wide range of statistical models, the actual implementation can be problem-specific. In this example, performing a Gibbs sampler involves introducing a class of auxil-

inary variables (also known as latent variables). You first reformulate the model by adding a  $z_i$  for each observation in the data set:

$$\begin{aligned}
 y_i &= \begin{cases} 1 & \text{if } z_i > 0 \\ 0 & \text{otherwise} \end{cases} \\
 z_i &= \mathbf{x}'_i \boldsymbol{\beta} + \epsilon_i \\
 \epsilon &\sim \text{normal}(0, 1) \\
 \boldsymbol{\beta} &\sim \pi(\boldsymbol{\beta})
 \end{aligned}$$

If  $\boldsymbol{\beta}$  has a normal prior, such as  $\pi(\boldsymbol{\beta}) = N(\mathbf{b}, \mathbf{v})$ , you can work out a closed form solution to the full conditional distribution of  $\boldsymbol{\beta}$  given the data and the latent variables  $z_i$ . The full conditional distribution is also a multivariate normal, due to the conjugacy of the problem. See the section “Conjugate Priors” on page 129. The formula is shown here:

$$\begin{aligned}
 \boldsymbol{\beta} | \mathbf{z}, \mathbf{x} &\sim \text{normal}(\mathbf{B}, \mathbf{V}) \\
 \mathbf{B} &= \mathbf{V}((\mathbf{v})^{-1} \mathbf{b} + \mathbf{x}' \mathbf{z}) \\
 \mathbf{V} &= (\mathbf{v}^{-1} + \mathbf{x}' \mathbf{x})^{-1}
 \end{aligned}$$

The advantage of creating the latent variables is that the full conditional distribution of  $\mathbf{z}$  is also easy to work with. The distribution is a truncated normal distribution:

$$z_i | \boldsymbol{\beta}, \mathbf{x}_i, y_i \sim \begin{cases} \text{normal}(\mathbf{x}_i \boldsymbol{\beta}, 1) I(z_i > 0) & \text{if } y_i = 1 \\ \text{normal}(\mathbf{x}_i \boldsymbol{\beta}, 1) I(z_i \leq 0) & \text{otherwise} \end{cases}$$

You can sample  $\boldsymbol{\beta}$  and  $z$  iteratively, by drawing  $\boldsymbol{\beta}$  given  $z$  and vice versa. HH point out that a high degree of correlation could exist between  $\boldsymbol{\beta}$  and  $z$ , and it makes this iterative way of sampling inefficient. As an improvement, HH proposed an algorithm that samples  $\boldsymbol{\beta}$  and  $\mathbf{z}$  jointly. At each iteration, you sample  $z_i$  from the posterior marginal distribution (this is the distribution that is conditional only on the data and not on any parameters) and then sample  $\boldsymbol{\beta}$  from the same posterior full conditional distribution as described previously:

1. Sample  $z_i$  from its posterior marginal distribution:

$$\begin{aligned}
 z_i | \mathbf{z}_{-i}, y_i &\sim \begin{cases} \text{normal}(m_i, v_i) I(z_i > 0) & \text{if } y_i = 1 \\ \text{normal}(m_i, v_i) I(z_i \leq 0) & \text{otherwise} \end{cases} \\
 m_i &= \mathbf{x}_i \mathbf{B} - w_i (z_i - \mathbf{x}_i \mathbf{B}) \\
 v_i &= 1 + w_i \\
 w_i &= h_i / (1 - h_i) \\
 h_i &= (\mathbf{H})_i i, \mathbf{H} = \mathbf{x} \mathbf{V} \mathbf{x}'
 \end{aligned}$$

2. Sample  $\boldsymbol{\beta}$  from the same posterior full conditional distribution described previously.

For a detailed description of each of the conditional terms, refer to the original paper.

PROC MCMC cannot sample from the probit model by using this sampling scheme but you can implement the algorithm by using the UDS statement. To sample  $z_i$  from its marginal, you need a function that draws random variables from a truncated normal distribution. The functions, RLTNORM and RRTNORM, generate left- and right-truncated normal variates, respectively. The algorithm is taken from Robert (1995).

The functions are written in PROC FCMP (see the FCMP Procedure in the *Base SAS Procedures Guide*):

```

proc fcmp outlib=sasuser.funcs.uds;
 /*****
 /* Generate left-truncated normal variate */
 *****/
 function rltnorm(mu, sig, lwr);
 if lwr < mu then do;
 ans = lwr - 1;
 do while (ans < lwr);
 ans = rand('normal', mu, sig);
 end;
 end;
 else do;
 mul = (lwr - mu) / sig;
 alpha = (mul + sqrt(mul**2 + 4)) / 2;
 accept = 0;
 do while (accept = 0);
 z = mul + rand('exponential') / alpha;
 lrho = -(z - alpha)**2 / 2;
 u = rand('uniform');
 lu = log(u);
 if lu <= lrho then accept = 1;
 end;
 ans = sig * z + mu;
 end;
 return(ans);
endsub;

 /*****
 /* Generate right-truncated normal variate */
 *****/
 function rrtnorm(mu, sig, uppr);
 ans = 2 * mu - rltnorm(mu, sig, 2 * mu - uppr);
 return(ans);
endsub;
run;

```

The function call to RLTNORM(mu, sig, lwr) generates a random number from the left-truncated normal distribution:

$$\theta \sim \text{normal}(\mu, \text{sd} = \text{sig}) I(\theta > \text{lwr})$$

Similarly, the function call to `RRTNORM(mu,sig,uppr)` generates a random number from the right-truncated normal distribution:

$$\theta \sim \text{normal}(\mu, \text{sd} = \text{sig})I(\theta < \text{uppr})$$

These functions are used to generate the latent variables  $z_i$ .

Using the algorithm A1 from the HH paper as an example, [Output 55.50](#) lists a line-by-line implementation with the PROC MCMC coding style. The table is broken into three portions: set up the constants, initialize the parameters, and sample one draw from the posterior distribution. The left column of the table is identical to the A1 algorithm stated in the appendix of HH. The right column of the table lists SAS statements.

**Table 55.50** Holmes and Held (2006), algorithm A1. Side-by-Side Comparison to SAS

The following statements define the subroutine HH (algorithm A1) in PROC FCMP and store it in library `sasuser.funcs.uds`:

```

/* define the HH algorithm in PROC FCMP. */
%let n = 27;
%let p = 7;
options cmplib=sasuser.funcs;
proc fcmp outlib=sasuser.funcs.uds;
 subroutine HH(beta[*],Z[*],B[*],x[*,*],y[*],W[*],sQ[*],S[*,*],L[*,*]);
 outargs beta, Z, B;
 array T[&p] / nosym;
 do j=1 to &n;
 zold = Z[j];
 m = 0;
 do k = 1 to &p;
 m = m + X[j,k] * B[k];
 end;
 m = m - W[j]*(Z[j]-m);
 if (y[j]=1) then
 Z[j] = rlnorm(m,sQ[j],0);
 else
 Z[j] = rrtnorm(m,sQ[j],0);
 diff = Z[j] - zold;
 do k = 1 to &p;
 B[k] = B[k] + diff * S[k,j];
 end;
 end;
 endsubr;
endproc;

```

```

end;
do j=1 to &p;
 T[j] = rand('normal');
end;
call mult(L,T,T);
call addmatrix(B,T,beta);
endsub;
run;

```

Note that one-dimensional array arguments take the form of *name*[\*] and two-dimensional array arguments take the form of *name*[\*,\*]. Three variables, *beta*, *Z*, and *B*, are OUTARGS variables, making them the only arguments that can be modified in the subroutine. For the **UDS** statement to work, all OUTARGS variables have to be model parameters. Technically, only *beta* and *Z* are model parameters, and *B* is not. The reason that *B* is declared as an OUTARGS is because the array must be updated throughout the simulation, and this is the only way to modify its values. The input array *x* contains all of the explanatory variables, and the array *y* stores the response. The rest of the input arrays, *W*, *sQ*, *S*, and *L*, store constants as detailed in the algorithm. The following statements illustrate how to fit a Bayesian probit model by using the HH algorithm:

```

options cmplib=sasuser.funcs;

proc mcmc data=inputdata nmc=5000 monitor=(beta) outpost=hhout;
 ods select PostSummaries ess;
 array xtx[&p,&p]; /* work space */
 array xt[&p,&n]; /* work space */
 array v[&p,&p]; /* work space */
 array HatMat[&n,&n]; /* work space */
 array S[&p,&n]; /* V * Xt */
 array W[&n];
 array y[1]/ nosymbols; /* y stores the response variable */
 array x[1]/ nosymbols; /* x stores the explanatory variables */
 array sQ[&n]; /* sqrt of the diagonal elements of Q */
 array B[&p]; /* conditional mean of beta */
 array L[&p,&p]; /* Cholesky decomp of conditional cov */
 array Z[&n]; /* latent variables Z */
 array beta[&p] beta0-beta6; /* regression coefficients */

 beginncst;
 call streaminit(83101);

 call mult(x,S,HatMat);
 end;
 end;
run;

```

```

do j=1 to &n;
 H = HatMat[j, j];
 W[j] = H/(1-H);
 sQ[j] = sqrt(W[j] + 1);
end;

do j=1 to &n;
 if(y[j]=1) then
 Z[j] = rltnorm(0,1,0);
 else
 Z[j] = rrtnorm(0,1,0);
 end;
 call mult(S,Z,B);
end;
endcnst;

uds HH(beta,Z,B,x,y,W,sQ,S,L);
parms z: beta: 0 B1-B7 / uds;
prior z: beta: B1-B7 ~ general(0);

model general(0);
run;

```

The `OPTIONS` statement names the catalog of FCMP subroutines to use. The `cmplib` library stores the subroutine `HH`. You do not need to set a random number seed in the `PROC MCMC` statement because all random numbers are generated from the `HH` subroutine. The initialization of the `rand` function is controlled by the `streaminit` function, which is called in the program with a seed value of 83101.

A number of arrays are allocated. Some of them, such as `xtx`, `xt`, `v`, and `HatMat`, allocate work space for constant arrays. Other arrays are used in the subroutine sampling. Explanations of the arrays are shown in comments in the statements.

In the `BEGINCNST` and `ENDCNST` statement block, you read data set variables in the arrays `x` and `y`, calculate all the constant terms, and assign initial values to `Z` and `B`. For the `READ_ARRAY` function, see the section “[READ\\_ARRAY Function](#)” on page 4442. For listings of all array functions and their definitions, see the section “[Matrix Functions in PROC MCMC](#)” on page 4498.

The `UDS` statement declares that the subroutine `HH` is used to sample the parameters `beta`, `Z`, and `B`. You also specify the `UDS` option in the `PARMS` statement. Because all parameters are updated through the `UDS` interface, it is not necessary to declare the actual form of the prior for any of the parameters. Each parameter is declared to have a prior of `general(0)`. Similarly, it is not necessary to declare the actual form of the likelihood. The `MODEL` statement also takes a flat likelihood of the form `general(0)`.

Summary statistics and effective sample sizes are shown in [Output 55.19.2](#). The posterior estimates are very close to what was shown in [Output 55.19.1](#). The `HH` algorithm produces samples that are much less correlated.

It is interesting to compare the two approaches of fitting a generalized linear model. The random walk Metropolis on a seven-dimensional parameter space produces autocorrelations that are substantially higher than the HH algorithm. A much longer chain is needed to produce roughly equivalent effective sample sizes. On the other hand, the Metropolis algorithm is faster to run. The running time of these two examples is roughly the same, with the random walk Metropolis with 100000 samples, a 20-fold increase over that in the HH algorithm example. The speed difference can be attributed to a number of factors, ranging from the implementation of the software and the overhead cost of calling PROC FCMP subroutine and functions. In addition, the HH algorithm requires more parameters by creating an equal number of latent variables as the sample size. Sampling more parameters takes time. A larger number of parameters also increases the challenge in convergence diagnostics, because it is imperative to have convergence in all parameters before you make valid posterior inferences. Finally, you might feel that coding in PROC MCMC is easier. However, this really is not a fair comparison to make here. Writing a Metropolis algorithm from scratch would have probably taken just as much, if not more, effort than the HH algorithm.

## Example 55.20: Using a Transformation to Improve Mixing

Proper transformations of parameters can often improve the mixing in PROC MCMC. You already saw this in “[Example 55.6: Nonlinear Poisson Regression Models](#)” on page 4570, which sampled using the log scale of parameters that priors that are strictly positive, such as the gamma priors. This example shows another useful transformation: the logit transformation on parameters that take a uniform prior on  $[0, 1]$ .

The data set is taken from Sharples (1990). It is used in Chaloner and Brant (1988) and Chaloner (1994) to identify outliers in the data set in a two-level hierarchical model. Congdon (2003) also uses this data set to demonstrate the same technique. This example uses the data set to illustrate how mixing can be improved using transformation and does not address the question of outlier detection as in those papers. The following statements create the data set:

```
data inputdata;
 input nobobs grp y @@;
 ind = _n_;
 datalines;
1 1 24.80 2 1 26.90 3 1 26.65
4 1 30.93 5 1 33.77 6 1 63.31
1 2 23.96 2 2 28.92 3 2 28.19
4 2 26.16 5 2 21.34 6 2 29.46
1 3 18.30 2 3 23.67 3 3 14.47
4 3 24.45 5 3 24.89 6 3 28.95
1 4 51.42 2 4 27.97 3 4 24.76
4 4 26.67 5 4 17.58 6 4 24.29
1 5 34.12 2 5 46.87 3 5 58.59
4 5 38.11 5 5 47.59 6 5 44.67
;
```

There are five groups ( $\text{grp}$ ,  $j = 1, \dots, 5$ ) with six observations ( $\text{nobobs}$ ,  $i = 1, \dots, 6$ ) in each. The two-level hierarchical model is specified as follows:

$$\begin{aligned}
 y_{ij} &\sim \text{normal}(\theta_j, \text{prec} = \tau_w) \\
 \theta_j &\sim \text{normal}(\mu, \text{prec} = \tau_b) \\
 \mu &\sim \text{normal}(0, \text{prec} = 1e - 6) \\
 \tau &\sim \text{gamma}(0.001, \text{iscale} = 0.001) \\
 p &\sim \text{uniform}(0, 1)
 \end{aligned}$$

with the precision parameters related to each other in the following way:

$$\begin{aligned}
 \tau_b &= \tau/p \\
 \tau_w &= \tau_b - \tau
 \end{aligned}$$

The total number of parameters in this model is eight:  $\theta_1, \dots, \theta_5, \mu, \tau$ , and  $p$ .

The following statements fit the model:

```
ods graphics on;
proc mcmc data=inputdata nmc=50000 thin=10 outpost=m1 seed=17
 plot=trace;
 ods select ess tracepanel;
 parms p;
 parms tau;
 parms mu;

 prior p ~ uniform(0,1);
 prior tau ~ gamma(shape=0.001, iscale=0.001);
 prior mu ~ normal(0, prec=0.00000001);
 beginnodata;
 taub = tau/p;
 tauw = taub-tau;
 endnodata;

 random theta ~ normal(mu, prec=taub) subject=grp monitor=(theta);
 model y ~ normal(theta, prec=tauw);
run;
```

The ODS SELECT statement displays the effective sample size table and the trace plots. The ODS GRAPHICS ON statement enables ODS Graphics. The PROC MCMC statement specifies the usual options for the procedure run and produces trace plots (**PLOTS=TRACE**). The three **PARMS** statements put three model parameters,  $p$ ,  $\tau$ , and  $\mu$ , in three different blocks. The **PRIOR** statements specify the prior distributions, and the programming statements enclosed with the **BEGINNODATA** and **ENDNODATA** statements calculate the transformation to  $\tau_{\text{aub}}$  and  $\tau_{\text{aw}}$ . The **RANDOM** statement specifies the random effect, its prior distribution, and the subject variable. The resulting trace plots are shown in [Output 55.20.1](#), and the effective sample size table is shown in [Output 55.20.2](#).

| theta_2                            | 2739.7 | 1.8250               | 0.5479     |
| theta_3                            | 1346.6 | 3.7130               | 0.2693     |
| theta_4                            | 4897.5 | 1.0209               | 0.9795     |
| theta_5                            | 338.1  | 14.7866              | 0.0676     |

The trace plots show that most parameters have relatively good mixing. Two exceptions appear to be  $p$  and  $\tau$ . The trace plot of  $p$  shows a slow periodic movement. The  $\tau$  parameter does not have good mixing either. When the values are close to zero, the chain stays there for periods of time. An inspection of the effective sample sizes table reveals the same conclusion:  $p$  and  $\tau$  have much smaller ESSs than the rest of the parameters.

A scatter plot of the posterior samples of  $p$  and  $\tau$  reveals why mixing is bad in these two dimensions. The following statements generate the scatter plot in [Output 55.20.3](#):

```
title 'Scatter Plot of Parameters on Original Scales';

proc sgplot data=m1;
 yaxis label = 'p';
 xaxis label = 'tau' values=(0 to 0.4 by 0.1);
 scatter x = tau y = p;
run;
```

**Output 55.20.3** Scatter Plot of  $\tau$  versus  $p$

The two parameters clearly have a nonlinear relationship. It is not surprising that the Metropolis algorithm does not work well here. The algorithm is designed for cases where the parameters are linearly related with each other.

To improve on mixing, you can sample on the log of  $\tau$ , instead of sampling on  $\tau$ . The formulation is:

$$\begin{aligned}\tau &\sim \text{gamma}(\text{shape} = 0.001, \text{iscale} = 0.001) \\ \log(\tau) &\sim \text{egamma}(\text{shape} = 0.001, \text{iscale} = 0.001)\end{aligned}$$

See the section “[Standard Distributions](#)” on page 4476 for the definitions of the [gamma](#) and [egamma](#) distributions. In addition, you can sample on the logit of  $p$ . Note that

$$p \sim \text{uniform}(0, 1)$$

is equivalent to

$$\text{lgp} = \text{logit}(p) \sim \text{logistic}(0, 1)$$

The following statements fit the same model by using transformed parameters:

```
proc mcmc data=inputdata nmc=50000 thin=10 outpost=m2 seed=17
 monitor=(p tau mu) plot=trace;
 ods select ess tracepanel;
 parms ltau lgp mu ;

 prior ltau ~ egamma(shape=0.001, iscale=0.001);
 prior lgp ~ logistic(0,1);
 prior mu ~ normal(0, prec=0.00000001);

 beginnodata;
 tau = exp(ltau);
 p = logistic(lgp);
 taub = tau/p;
 tauw = taub-tau;
 endnodata;

 random theta ~ normal(mu, prec=taub) subject=grp monitor=(theta);
 model y ~ normal(theta, prec=tauw);
run;
```

The variable `lgp` is the logit transformation of  $p$ , and `ltau` is the log transformation of  $\tau$ . The prior for `ltau` is [egamma](#), and the prior for `lgp` is [logistic](#). The `TAU` and `P` assignment statements transform the parameters back to their original scales. The rest of the programs remain unchanged. Trace plots ([Output 55.20.4](#)) and effective sample size ([Output 55.20.5](#)) both show significant improvements in the mixing for both  $p$  and  $\tau$ .

**Output 55.20.4** Trace Plots after Transformation

**Output 55.20.4** *continued*

**Output 55.20.5** Effective Sample Sizes after Transformation

| theta_5                | 4054.8 | 1.2331          | 0.8110     |

The following statements generate [Output 55.20.6](#) and [Output 55.20.7](#):

```

title 'Scatter Plot of Parameters on Transformed Scales';

proc sgplot data=m2;
 yaxis label = 'logit(p)';
 xaxis label = 'log(tau)';
 scatter x = ltau y = lgp;
run;

title 'Scatter Plot of Parameters on Original Scales';

proc sgplot data=m2;
 yaxis label = 'p';
 xaxis label = 'tau' values=(0 to 5.0 by 1);
 scatter x = tau y = p;
run;
ods graphics off;

```

**Output 55.20.6** Scatter Plot of  $\log(\tau)$  versus  $\text{logit}(p)$ , After Transformation

**Output 55.20.7** Scatter Plot of  $\tau$  versus  $p$ , After Transformation

The scatter plot of  $\log(\tau)$  versus  $\text{logit}(p)$  shows a linear relationship between the two transformed parameters, and this explains the improvement in mixing. In addition, the transformations also help the Markov chain better explore in the original parameter space. [Output 55.20.7](#) shows a scatter plot of  $\tau$  versus  $p$ . The plot is similar to [Output 55.20.3](#). However, note that  $\tau$  has a far longer tail in [Output 55.20.7](#), extending all the way to 5 as opposed to 0.15 in [Output 55.20.3](#). This means that the second Markov chain can explore this dimension of the parameter more efficiently, and as a result, you are able to draw more precise inference with an equal number of simulations.

---

## Example 55.21: Gelman-Rubin Diagnostics

PROC MCMC does not have the Gelman-Rubin test (see the section “[Gelman and Rubin Diagnostics](#)” on page 145) as a part of its diagnostics. The Gelman-Rubin diagnostics rely on parallel chains to test whether they all converge to the same posterior distribution. This example demonstrates how you can carry out this convergence test. The regression model from the section “[Simple Linear Regression](#)” on page 4408 is used. The model has three parameters:  $\beta_0$  and  $\beta_1$  are the regression coefficients, and  $\sigma^2$  is the variance of the error distribution.

The following statements generate the data set:

```

title 'Simple Linear Regression, Gelman-Rubin Diagnostics';

data Class;
 input Name $ Height Weight @@;
 datalines;
Alfred 69.0 112.5 Alice 56.5 84.0 Barbara 65.3 98.0
Carol 62.8 102.5 Henry 63.5 102.5 James 57.3 83.0
Jane 59.8 84.5 Janet 62.5 112.5 Jeffrey 62.5 84.0
John 59.0 99.5 Joyce 51.3 50.5 Judy 64.3 90.0
Louise 56.3 77.0 Mary 66.5 112.0 Philip 72.0 150.0
Robert 64.8 128.0 Ronald 67.0 133.0 Thomas 57.5 85.0
William 66.5 112.0
;

```

To run a Gelman-Rubin diagnostic test, you want to start Markov chains at different places in the parameter space. Suppose you want to start  $\beta_0$  at 10, -15, and 0;  $\beta_1$  at -5, 10, and 0; and  $\sigma^2$  at 1, 20, and 50. You can put these starting values in the following Init SAS data set:

```

data init;
 input Chain beta0 beta1 sigma2;
 datalines;
1 10 -5 1
2 -15 10 20
3 0 0 50
;

```

The following statements run PROC MCMC three times, each with starting values specified in the data set Init:

```

/* define constants */
%let nchain = 3;
%let nparm = 3;
%let nsim = 50000;
%let var = beta0 beta1 sigma2;

%macro gcmc;
 %do i=1 %to &nchain;
 data _null_;
 set init;
 if Chain=&i;
 %do j = 1 %to &nparm;
 call symputx("init&j", %scan(&var, &j));
 %end;
 stop;
 run;

 proc mcmc data=class outpost=out&i init=reinit nbi=0 nmc=&nsim
 stats=none seed=7;
 parms beta0 &init1 beta1 &init2;
 parms sigma2 &init3 / n;
 prior beta0 beta1 ~ normal(0, var = 1e6);
 prior sigma2 ~ igamma(3/10, scale = 10/3);

```

```

 mu = beta0 + beta1*height;
 model weight ~ normal(mu, var = sigma2);
 run;
%end;
%mend;

ods listing close;
%gcmc;
ods listing;

```

The macro variables `nchain`, `nparm`, `nsim`, and `var` define the number of chains, the number of parameters, the number of Markov chain simulations, and the parameter names, respectively. The macro `GMCMC` gets initial values from the data set `lnit`, assigns them to the macro variables `init1`, `init2` and `init3`, starts the Markov chain at these initial values, and stores the posterior draws to three output data sets: `Out1`, `Out2`, and `Out3`.

In the `PROC MCMC` statement, the `INIT=REINIT` option restarts the Markov chain after tuning at the assigned initial values. No burn-in is requested.

You can use the autocall macro `GELMAN` to calculate the Gelman-Rubin statistics by using the three chains. The `GELMAN` macro has the following arguments:

```
%macro gelman(dset, nparm, var, nsim, nc=3, alpha=0.05);
```

The argument `dset` is the name of the data set that stores the posterior samples from all the runs, `nparm` is the number of parameters, `var` is the name of the parameters, `nsim` is the number of simulations, `nc` is the number of chains with a default value of 3, and `alpha` is the  $\alpha$  significant level in the test with a default value of 0.05. This macro creates two data sets: `_Gelman_Ests` stores the diagnostic estimates and `_Gelman_Parms` stores the names of the parameters.

The following statements calculate the Gelman-Rubin diagnostics:

```

data all;
 set out1(in=in1) out2(in=in2) out3(in=in3);
 if in1 then Chain=1;
 if in2 then Chain=2;
 if in3 then Chain=3;
run;

%gelman(all, &nparm, &var, &nsim);

data GelmanRubin(label='Gelman-Rubin Diagnostics');
 merge _Gelman_Parms _Gelman_Ests;
run;

proc print data=GelmanRubin;
run;

```

The Gelman-Rubin statistics are shown in [Output 55.21.1](#).

**Output 55.21.1** Gelman-Rubin Diagnostics of the Regression Example

| Simple Linear Regression, Gelman-Rubin Diagnostics |           |               |              |          |             |
|----------------------------------------------------|-----------|---------------|--------------|----------|-------------|
| Obs                                                | Parameter | Between-chain | Within-chain | Estimate | Upper Bound |
| 1                                                  | beta0     | 5384.76       | 1168.64      | 1.0002   | 1.0001      |
| 2                                                  | beta1     | 1.20          | 0.30         | 1.0002   | 1.0002      |
| 3                                                  | sigma2    | 8034.41       | 2890.00      | 1.0010   | 1.0011      |

The Gelman-Rubin statistics do not reveal any concerns about the convergence or the mixing of the multiple chains. To get a better visual picture of the multiple chains, you can draw overlapping trace plots of these parameters from the three Markov chains runs.

The following statements create [Output 55.21.2](#):

```

/* plot the trace plots of three Markov chains. */
%macro trace;
 %do i = 1 %to &nparm;
 proc sgplot data=all cycleattrs;
 series x=Iteration y=%scan(&var, &i) / group=Chain;
 run;
 %end;
%mend;
%trace;

```

**Output 55.21.2** Trace Plots of Three Chains for Each of the Parameters

Output 55.21.2 continued

The trace plots show that three chains all eventually converge to the same regions even though they started at very different locations. In addition to the trace plots, you can also plot the potential scale reduction factor (PSRF). See the section “[Gelman and Rubin Diagnostics](#)” on page 145 for definition and details.

The following statements calculate PSRF for each parameter. They use the GELMAN macro repeatedly and can take a while to run:

```

/* define sliding window size */
%let nwin = 200;
data PSRF;
run;

%macro PSRF(nsim);
 %do k = 1 %to %sysevalf(&nsim/&nwin, floor);
 %gelman(all, &nparm, &var, nsim=%sysevalf(&k*&nwin));
 data GelmanRubin;
 merge _Gelman_Parms _Gelman_Ests;
 run;

 data PSRF;
 set PSRF GelmanRubin;
 run;
 %end;
%mend PSRF;

options nonotes;
%PSRF(&nsim);
options notes;

data PSRF;
 set PSRF;
 if _n_ = 1 then delete;
run;

proc sort data=PSRF;
 by Parameter;
run;

%macro sepPSRF(nparm=, var=, nsim=);
 %do k = 1 %to &nparm;
 data save&k; set PSRF;
 if _n_ > %sysevalf(&k*&nsim/&nwin, floor) then delete;
 if _n_ < %sysevalf((&k-1)*&nsim/&nwin + 1, floor) then delete;
 Iteration + &nwin;
 run;

 proc sgplot data=save&k(firstobs=10) cycleattrs;
 series x=Iteration y=Estimate;
 series x=Iteration y=upperbound;
 yaxis label="%scan(&var, &k)";
 run;
 %end;
%mend sepPSRF;

%sepPSRF(nparm=&nparm, var=&var, nsim=&nsim);

```

Output 55.21.3 PSRF Plot for Each Parameter

## Output 55.21.3 continued

PSRF is the square root of the ratio of the between-chain variance and the within-chain variance. A large PSRF indicates that the between-chain variance is substantially greater than the within-chain variance, so that longer simulation is needed. You want the PSRF to converge to 1 eventually, as it appears to be the case in this simulation study.

## Overview: MDS Procedure

Multidimensional scaling (MDS) refers to a class of methods. These methods estimate coordinates for a set of objects in a space of specified dimensionality. The input data are measurements of distances between pairs of objects. A variety of models can be used that include different ways of computing distances and various functions relating the distances to the actual data. The MDS procedure fits two- and three-way, metric and nonmetric multidimensional scaling models.

The data for the MDS procedure consist of one or more square symmetric or asymmetric matrices of similarities or dissimilarities between *objects* or *stimuli* (Kruskal and Wish 1978, pp. 7–11). Such data are also called *proximity* data. In psychometric applications, each matrix typically corresponds to a *subject*, and models that fit different parameters for each subject are called *individual difference* models.

Missing values are permitted. In particular, if the data are all missing except within some off-diagonal rectangle, the analysis is called *unfolding*. There are, however, many difficulties intrinsic to unfolding models (Heiser 1981). PROC MDS does not perform external unfolding; for analyses requiring external unfolding, use the TRANSREG procedure instead.

The MDS procedure estimates the following parameters by nonlinear least squares:

|                           |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|---------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| configuration             | the coordinates of each object in a Euclidean (Kruskal and Wish 1978, pp. 17–19) or weighted Euclidean space (Kruskal and Wish 1978, pp. 61–63) of one or more dimensions                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| dimension coefficients    | for each data matrix, the coefficients that multiply each coordinate of the <i>common</i> or <i>group</i> weighted Euclidean space to yield the <i>individual</i> unweighted Euclidean space. These coefficients are the square roots of the <i>subject weights</i> (Kruskal and Wish 1978, pp. 61–63). A plot of the dimension coefficients is directly interpretable in that it shows how a unit square in the group space is transformed to a rectangle in each individual space. A plot of subject weights has no such simple interpretation. The weighted Euclidean model is related to the INDSCAL model (Carroll and Chang 1970). |
| transformation parameters | intercept, slope, or exponent in a linear, affine, or power transformation relating the distances to the data (Kruskal and Wish 1978, pp. 19–22). For a nonmetric analysis, monotone transformations involving no explicit parameters are used (Kruskal and Wish 1978, pp. 22–25). For a discussion of metric versus nonmetric transformations, see Kruskal and Wish (1978, pp. 76–78).                                                                                                                                                                                                                                                  |

Depending on the LEVEL= option, PROC MDS fits either a regression model of the form

$$fit(datum) = fit(trans(distance)) + error$$

or a measurement model of the form

$$fit(trans(datum)) = fit(distance) + error$$

where

|                 |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>fit</i>      | is a predetermined power or logarithmic transformation specified by the FIT= option.                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| <i>trans</i>    | is an estimated (“optimal”) linear, affine, power, or monotone transformation specified by the LEVEL= option.                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <i>datum</i>    | is a measure of the similarity or dissimilarity of two objects or stimuli.                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| <i>distance</i> | is a distance computed from the estimated coordinates of the two objects and estimated dimension coefficients in a space of one or more dimensions. If there are no dimension coefficients (COEF=IDENTITY), this is an unweighted Euclidean distance. If dimension coefficients are used (COEF=DIAGONAL), this is a weighted Euclidean distance where the weights are the squares of the dimension coefficients; alternatively, you can multiply each dimension by its coefficient and compute an unweighted Euclidean distance. |
| <i>error</i>    | is an error term assumed to have an approximately normal distribution and to be independently and identically distributed for all data. Under these assumptions, least-squares estimation is statistically appropriate.                                                                                                                                                                                                                                                                                                          |

For an introduction to multidimensional scaling, see Kruskal and Wish (1978) and Arabie, Carroll, and DeSarbo (1987). A more advanced treatment is given by Young (1987). Many practical issues of data collection and analysis are discussed in Schiffman, Reynolds, and Young (1981). The fundamentals of psychological measurement, including both unidimensional and multidimensional scaling, are expounded by Torgerson (1958). Nonlinear least-squares estimation of PROC MDS models is discussed in Null and Sarle (1982).

## Getting Started: MDS Procedure

The simplest application of PROC MDS is to reconstruct a map from a table of distances between points on the map (Kruskal and Wish 1978, pp. 7–9). A data set containing a table of flying mileages between 10 U.S. cities is available in the Sashelp library.

Since the flying mileages are very good approximations to Euclidean distance, no transformation is needed to convert distances from the model to data. The analysis can therefore be done at the absolute level of measurement, as displayed in the following PROC MDS step (LEVEL=ABSOLUTE). The following statements produce Figure 56.1 and Figure 56.2:

```

title 'Analysis of Flying Mileages between Ten U.S. Cities';

ods graphics on;

proc mds data=sashelp.mileages level=absolute;
 id city;
run;

```

PROC MDS first displays the iteration history. In this example, only one iteration is required. The badness-of-fit criterion 0.001689 indicates that the data fit the model extremely well. You can also see that the fit is excellent in the fit plot in Figure 56.2.

**Figure 56.1** Iteration History from PROC MDS

| Analysis of Flying Mileages between Ten U.S. Cities  |         |                                 |                        |                        |
|------------------------------------------------------|---------|---------------------------------|------------------------|------------------------|
| Multidimensional Scaling: Data=SASHELP.MILEAGES.DATA |         |                                 |                        |                        |
| Shape=TRIANGLE Condition=MATRIX Level=ABSOLUTE       |         |                                 |                        |                        |
| Coef=IDENTITY Dimension=2 Formula=1 Fit=1            |         |                                 |                        |                        |
| Gconverge=0.01 Maxiter=100 Over=1 Ridge=0.0001       |         |                                 |                        |                        |
| Iteration                                            | Type    | Badness-<br>of-Fit<br>Criterion | Change in<br>Criterion | Convergence<br>Measure |
| 0                                                    | Initial | 0.003273                        | .                      | 0.8562                 |
| 1                                                    | Lev-Mar | 0.001689                        | 0.001584               | 0.005128               |
| Convergence criterion is satisfied.                  |         |                                 |                        |                        |

While PROC MDS can recover the relative positions of the cities, it cannot determine absolute location or orientation. In this case, north is toward the bottom of the plot. (See the first plot in [Figure 56.2](#).)

## Syntax: MDS Procedure

The following statements are available in the MDS procedure:

```
PROC MDS < options > ;
 VAR variables ;
 INVAR variables ;
 ID | OBJECT variable ;
 MATRIX | SUBJECT variable ;
 WEIGHT variables ;
 BY variables ;
```

The PROC MDS statement is required. All other statements are optional.

## PROC MDS Statement

**PROC MDS** < options > ;

The PROC MDS statement invokes the MDS procedure. PROC MDS produces an iteration history by default. Graphical displays are produced when ODS Graphics is enabled. Additional displayed output is controlled by the interaction of the PCONFIG, PCOEF, PTRANS, PFIT, and PFITROW options with the PININ, PINIT, PITER, and PFINAL options. The PCONFIG, PCOEF, PTRANS, PFIT, and PFITROW options specify *which* estimates and fit statistics are to be displayed. The PININ, PINIT, PITER, and PFINAL options specify *when* the estimates and fit statistics are to be displayed. If you specify at least one of the PCONFIG, PCOEF, PTRANS, PFIT, and PFITROW options but none of the PININ, PINIT, PITER, and PFINAL options, the final results (PFINAL) are displayed. If you specify at least one of the PININ, PINIT, PITER, and PFINAL options but none of the PCONFIG, PCOEF, PTRANS, PFIT, and PFITROW options, all estimates (PCONFIG, PCOEF, PTRANS) and the fit statistics for each matrix and for the entire sample (PFIT) are displayed. If you do not specify any of these nine options, no estimates or fit statistics are displayed (except the badness-of-fit criterion in the iteration history).

The types of estimates written to the OUT= data set are determined by the OCONFIG, OCOEF, OTRANS, and OCRIT options. If you do not specify any of these four options, the estimates of all the parameters of the PROC MDS model and the value of the badness-of-fit criterion appear in the OUT= data set. If you specify one or more of these options, only the information requested by the specified options appears in the OUT= data set. Also, the OITER option causes these statistics to be written to the OUT= data set after initialization and on each iteration, as well as after the iterations have terminated.

Table 56.2 summarizes the options available in the PROC MDS statement.

**Table 56.2** Summary of PROC MDS Statement Options

| Option                  | Description                                                |
|-------------------------|------------------------------------------------------------|
| <b>Data Set Options</b> |                                                            |
| DATA=                   | Specifies the input SAS data set                           |
| INITIAL=                | Specifies the input SAS data set containing initial values |
| OUT=                    | Specifies the output data set                              |
| OUTFIT=                 | Specifies the output fit data set                          |
| OUTRES=                 | Specifies the output residual data set                     |
| <b>Input Control</b>    |                                                            |
| CUTOFF=                 | Replaces data values with missing values                   |
| SHAPE=                  | Specifies the shape of the input data matrices             |
| SIMILAR=                | Specifies that the data are similarity measurements        |
| <b>Model</b>            |                                                            |
| COEF=                   | Specifies the type of matrix for the coefficients          |
| CONDITION=              | Specifies the conditionality of the data                   |
| DIMENSION=              | Specifies the number of dimensions                         |
| LEVEL=                  | Specifies the measurement level                            |
| NEGATIVE                | Permits slopes or powers to be negative                    |
| UNTIE                   | Permits tied data to be untied                             |

Table 56.2 *continued*

| Option                                  | Description                                                        |
|-----------------------------------------|--------------------------------------------------------------------|
| <b>Initialization</b>                   |                                                                    |
| INAV=                                   | Affects the computation of initial coordinates                     |
| NOULB                                   | Specifies the missing data initialization                          |
| RANDOM=                                 | Specifies initial random coordinates                               |
| <b>Estimation</b>                       |                                                                    |
| ALTERNATE=                              | Specifies the alternating-least-squares algorithm                  |
| CONVERGE=                               | Specifies the convergence criterion                                |
| EPSILON=                                | Specifies the amount added to squared distances                    |
| FIT=                                    | Specifies a predetermined transformation                           |
| FORMULA=                                | Specifies the badness-of-fit formula                               |
| GCONVERGE=                              | Specifies the gradient convergence criterion                       |
| MAXITER=                                | Specifies the maximum number of iterations                         |
| MCONVERGE=                              | Specifies the monotone convergence criterion                       |
| MINCRIT=                                | Specifies the minimum badness-of-fit criterion                     |
| NONORM                                  | Suppresses normalization of the initial and final estimates        |
| OVER=                                   | Specifies the maximum overrelaxation factor                        |
| RIDGE=                                  | Specifies the initial ridge value                                  |
| SINGULAR=                               | Specifies the singularity criterion                                |
| <b>Control Output Data Set Contents</b> |                                                                    |
| OCOEF                                   | Writes the dimension coefficients to the OUT= data set             |
| ONCONFIG                                | Writes the coordinates of the objects to the OUT= data set         |
| OCRIT                                   | Writes the badness-of-fit criterion to the OUT= data set           |
| OITER                                   | Writes current values after initialization and on every iteration  |
| OTRANS                                  | Writes the transformation parameter estimates to the OUT= data set |
| <b>Control Displayed Output</b>         |                                                                    |
| DECIMALS=                               | Specifies how many decimal places to use                           |
| NOPHIST                                 | Suppresses the iteration history                                   |
| PCOEF                                   | Displays the estimated dimension coefficients                      |
| PCONFIG                                 | Displays the estimated coordinates                                 |
| PDATA                                   | Displays each data matrix                                          |
| PFINAL                                  | Displays final estimates                                           |
| PFIT                                    | Displays the badness-of-fit criterion                              |
| PFITROW                                 | Displays the badness-of-fit criterion for each row                 |
| PINAVDATA                               | Displays INAV= data set information                                |
| PINEIGVAL                               | Displays the initial eigenvalues                                   |
| PINEIGVEC                               | Displays the initial eigenvectors                                  |
| PININ                                   | Displays values read from the INITIAL= data set                    |
| PINIT                                   | Displays initial values                                            |
| PITER                                   | Displays estimates on each iteration                               |
| PLOTS=                                  | Controls the graphical displays                                    |
| PTRANS                                  | Displays the estimated transformation parameters                   |

**ALTERNATE | ALT=NONE | NO | N**

**ALTERNATE | ALT=MATRIX | MAT | M | SUBJECT | SUB | S**

**ALTERNATE | ALT=ROW | R < =n >**

determines what form of alternating-least-squares algorithm is used. The default depends on the amount of memory available. The following ALTERNATE= options are listed in order of decreasing memory requirements:

**ALT=NONE** causes all parameters to be adjusted simultaneously on each iteration. This option is usually best for a small number of subjects and objects.

**ALT=MATRIX** adjusts all the parameters for the first subject, then all the parameters for the second subject, and so on, and finally adjusts all parameters that do not correspond to a subject, such as coordinates and unconditional transformations. This option usually works best for a large number of subjects with a small number of objects.

**ALT=ROW** treats subject parameters the same way as the ALTERNATE=MATRIX option but also includes separate stages for unconditional parameters and for subsets of the objects. The ALT=ROW option usually works best for a large number of objects. Specifying ALT=ROW=*n* divides the objects into subsets of *n* objects each, except possibly for one subset when *n* does not divide the number of objects evenly. If you omit =*n*, the number of objects in the subsets is determined from the amount of memory available. The smaller the value of *n*, the less memory is required.

When you specify the LEVEL=ORDINAL option, the monotone transformation is always computed in a separate stage and is listed as a separate iteration in the iteration history. In this case, estimation is done by iteratively reweighted least squares. The weights are recomputed according to the FORMULA= option on each monotone iteration; hence, it is possible for the badness-of-fit criterion to increase after a monotone iteration.

**COEF=IDENTITY | IDEN | I**

**COEF=DIAGONAL | DIAG | D**

specifies the type of matrix for the dimension coefficients.

**COEF=IDENTITY** is the default, which yields Euclidean distances.

**COEF=DIAGONAL** produces weighted Euclidean distances, in which each subject can have different weights for the dimensions. The dimension coefficients that PROC MDS outputs are related to the square roots of what are called subject weights in PROC ALSCAL; the normalization in PROC MDS also differs from that in PROC ALSCAL. The weighted Euclidean model is related to the INDSCAL model (Carroll and Chang 1970).

**CONDITION | COND=UN | U****CONDITION | COND=MATRIX | MAT | M | SUBJECT | SUB | S****CONDITION | COND=ROW | R**

specifies the conditionality of the data (Young 1987, pp. 60–63). The data are divided into disjoint subsets called *partitions*. Within each partition, a separate transformation is applied, as specified by the LEVEL= option. The three types of conditionality are as follows:

- COND=UN                    (unconditional) puts all the data into a single partition.  
 COND=MATRIX            (matrix conditional) makes each data matrix a partition.  
 COND=ROW                (row conditional) makes each row of each data matrix a partition.

The default is CONDITION=MATRIX. The CONDITION= option also determines the default value for the SHAPE= option. If you specify the CONDITION=ROW option and omit the SHAPE= option, each data matrix is stored as a square and possibly asymmetric matrix. If you specify the CONDITION=UN or CONDITION=MATRIX option and omit the SHAPE= option, only one triangle is stored. See the SHAPE= option for details.

**CONVERGE | CONV= $\rho$** 

sets both the gradient convergence criterion and the monotone convergence criterion to  $\rho$ , where  $0 \leq \rho \leq 1$ . The default is CONVERGE=0.01; smaller values might greatly increase the number of iterations required. Values less than 0.0001 might be impossible to satisfy because of the limits of machine precision. (See the GCONVERGE= and MCONVERGE= options.)

**CUTOFF= $n$** 

replaces data values less than  $n$  with missing values. The default is CUTOFF=0.

**DATA=SAS-data-set**

specifies the SAS data set containing one or more square matrices to be analyzed. In typical psychometric data, each matrix contains judgments from one subject, so there is a one-to-one correspondence between data matrices and subjects.

The data matrices contain similarity or dissimilarity measurements to be modeled and, optionally, weights for these data. The data are generally assumed to be dissimilarities unless you use the SIMILAR option. However, if there are nonmissing diagonal values and these values are predominantly larger than the off-diagonal values, the data are assumed to be similarities and are treated as if the SIMILAR option is specified. The diagonal elements are not otherwise used in fitting the model.

Each matrix must have exactly the same number of observations as the number of variables specified by the VAR statement or determined by defaults. This number is the number of objects or stimuli.

The first observation and variable are assumed to contain data for the first object, the second observation and variable are assumed to contain data for the second object, and so on.

When there are two or more matrices, the observations in each matrix must correspond to the same objects in the same order as in the first matrix.

The matrices can be symmetric or asymmetric, as specified by the SHAPE= option.

**DECIMALS | DEC=*n***

specifies how many decimal places to use when displaying the parameter estimates and fit statistics. The default is DECIMALS=2, which is generally reasonable except in conjunction with the LEVEL=ABSOLUTE option and very large or very small data.

**DIMENSION | DIMENS | DIM=*n* < TO *m* < BY=*i* > >**

specifies the number of dimensions to use in the MDS model, where  $1 \leq n, m < \text{number of objects}$ . The parameter *i* can be either positive or negative but not zero. If you specify different values for *n* and *m*, a separate model is fitted for each requested dimension. If you specify only DIMENSION=*n*, then only *n* dimensions are fitted. The default is DIMENSION=2 if there are three or more objects; otherwise, DIMENSION=1 is the only valid specification. The analyses for each number of dimensions are done independently. For information about choosing the dimensionality, see Kruskal and Wish (1978, pp. 48–60).

**EPSILON | EPS=*n***

specifies a number *n*,  $0 < n < 1$ , that determines the amount added to squared distances computed from the model to avoid numerical problems such as division by 0. This amount is computed as  $\epsilon$  equal to *n* times the mean squared distance in the initial configuration. The distance in the MDS model is thus computed as

$$\text{distance} = \sqrt{\text{sqdist} + \epsilon}$$

where *sqdist* is the squared Euclidean distance or the weighted squared Euclidean distance.

The default is EPSILON=1E-12, which is small enough to have no practical effect on the estimates unless the FIT= value is nonpositive and there are dissimilarities that are very close to 0. Hence, when the FIT= value is nonpositive, dissimilarities less than *n* times 100 times the maximum dissimilarity are not permitted.

**FIT=DISTANCE | DIS | D****FIT=SQUARED | SQU | S****FIT=LOG | L****FIT=*n***

specifies a predetermined (not estimated) transformation to apply to both sides of the MDS model before the error term is added.

The default is FIT=DISTANCE or, equivalently, FIT=1, which fits data to distances.

The option FIT=SQUARED or FIT=2 fits squared data to squared distances. This gives greater importance to large data and distances and lesser importance to small data and distances in fitting the model.

The FIT=LOG or FIT=0 option fits log data to log distances. This gives lesser importance to large data and distances and greater importance to small data and distances in fitting the model.

In general, the FIT=*n* option fits *n*th-power data to *n*th-power distances. Values of *n* that are large in absolute value can cause floating-point overflows.

If the FIT= value is 0 or negative, the data must be strictly positive (see the EPSILON= option). Negative data might produce strange results with any value other than FIT=1.

**FORMULA | FOR=0 | OLS | O****FORMULA | FOR=1 | USS | U****FORMULA | FOR=2 | CSS | C**

determines how the badness-of-fit criterion is standardized in correspondence with stress formulas 1 and 2 (Kruskal and Wish 1978, pp. 24–26). The default is FORMULA=1 unless you specify FIT=LOG, in which case the default is FORMULA=2. Data partitions are defined by the CONDITION= option.

**FORMULA=0** fits a regression model by ordinary least squares (Null and Sarle 1982) without standardizing the partitions; this option cannot be used with the LEVEL=ORDINAL option. The badness-of-fit criterion is the square root of the error sum of squares.

**FORMULA=1** standardizes each partition by the uncorrected sum of squares of the (possibly transformed) data; this option should not be used with the FIT=LOG option. With the FIT=DISTANCE and LEVEL=ORDINAL options, this is equivalent to Kruskal's stress formula 1 or an obvious generalization thereof. With the FIT=SQUARED and LEVEL=ORDINAL options, this is equivalent to Young's s-stress formula 1 or an obvious generalization thereof. The badness-of-fit criterion is analogous to  $\sqrt{1 - R^2}$ , where R is a multiple correlation about the origin.

**FORMULA=2** standardizes each partition by the corrected sum of squares of the (possibly transformed) data; this option is the recommended method for unfolding. With the FIT=DISTANCE and LEVEL=ORDINAL options, this is equivalent to Kruskal's stress formula 2 or an obvious generalization thereof. With the FIT=SQUARED and LEVEL=ORDINAL options, this is equivalent to Young's s-stress formula 2 or an obvious generalization thereof. The badness-of-fit criterion is analogous to  $\sqrt{1 - R^2}$ , where R is a multiple correlation computed with a denominator corrected for the mean.

**GCONVERGE | GCONV= $p$** 

sets the gradient convergence criterion to  $p$ , where  $0 \leq p \leq 1$ . The default is GCONVERGE=0.01; smaller values might greatly increase the number of iterations required. Values less than 0.0001 might be impossible to satisfy because of the limits of machine precision.

The gradient convergence measure is the multiple correlation of the Jacobian matrix with the residual vector, uncorrected for the mean. (See the CONVERGE= and MCONVERGE= options.)

**INAV=DATA | D****INAV=SSCP | S**

affects the computation of initial coordinates. The default is INAV=DATA.

**INAV=DATA** computes a weighted average of the data matrices. Its value is estimated only if an element is missing from every data matrix. The weighted average of the data matrices with missing values filled in is then converted to a scalar products matrix (or what would be a scalar products matrix if the fit were perfect), from which the initial coordinates are computed.

**INAV=SSCP** estimates missing values in each data matrix and converts each data matrix to a scalar products matrix. The initial coordinates are computed from the unweighted average of the scalar products matrices.

**INITIAL** | **IN=SAS-data-set**

specifies a SAS data set containing initial values for some or all of the parameters of the MDS model. If the INITIAL= option is omitted, the initial values are computed from the data.

**LEVEL=ABSOLUTE** | **ABS** | **A****LEVEL=RATIO** | **RAT** | **R****LEVEL=INTERVAL** | **INT** | **I****LEVEL=LOGINTERVAL** | **LOG** | **L****LEVEL=ORDINAL** | **ORD** | **O**

specifies the measurement level of the data and hence the type of estimated (optimal) transformations applied to the data or distances (Young 1987, pp. 57–60; Krantz et al. 1971, pp. 9–12) within each partition as specified by the CONDITION= option. LEVEL=ORDINAL specifies a nonmetric analysis, while all other LEVEL= options specify metric analyses. The default is LEVEL=ORDINAL.

|                   |                                                                                                                                                                                                                                                                      |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LEVEL=ABSOLUTE    | permits no optimal transformations. Hence, the distinction between regression and measurement models is irrelevant.                                                                                                                                                  |
| LEVEL=RATIO       | fits a regression model in which the distances are multiplied by a slope parameter in each partition (a linear transformation). In this case, the regression model is equivalent to the measurement model with the slope parameter reciprocated.                     |
| LEVEL=INTERVAL    | fits a regression model in which the distances are multiplied by a slope parameter and added to an intercept parameter in each partition (an affine transformation). In this case, the regression and measurement models differ if there is more than one partition. |
| LEVEL=LOGINTERVAL | fits a regression model in which the distances are raised to a power and multiplied by a slope parameter in each partition (a power transformation).                                                                                                                 |
| LEVEL=ORDINAL     | fits a measurement model in which a least-squares monotone increasing transformation is applied to the data in each partition. At the ordinal measurement level, the regression and measurement models differ.                                                       |

**MAXITER** | **ITER=n**

specifies the maximum number of iterations, where  $n \geq 0$ . The default is MAXITER=100.

**MCONVERGE** | **MCONV=p**

sets the monotone convergence criterion to  $p$ , where  $0 \leq p \leq 1$ , for use with the LEVEL=ORDINAL option. The default is MCONVERGE=0.01; if you want greater precision, MCONVERGE=0.001 is usually reasonable, but smaller values might greatly increase the number of iterations required.

The monotone convergence criterion is the Euclidean norm of the change in the optimally scaled data divided by the Euclidean norm of the optimally scaled data, averaged across partitions defined by the CONDITION= option. (See the CONVERGE= and GCONVERGE= options.)

**MINCRIT** | **CRITMIN=n**

causes iteration to terminate when the badness-of-fit criterion is less than or equal to  $n$ , where  $n \geq 0$ . The default is MINCRIT=1E-6.

**NEGATIVE**

permits slopes or powers to be negative with the LEVEL=RATIO, INTERVAL, or LOGINTERVAL option.

**NONORM**

suppresses normalization of the initial and final estimates.

**NOPHIST | NOPRINT | NOP**

suppresses the output of the iteration history.

**NOULB**

causes missing data to be estimated during initialization by the average nonmissing value, where the average is computed according to the FIT= option. Otherwise, missing data are estimated by interpolating between the Rabinowitz (1976) upper and lower bounds.

**OCOEF**

writes the dimension coefficients to the OUT= data set. See the OUT= option for interactions with other options.

**OCONFIG**

writes the coordinates of the objects to the OUT= data set. See the OUT= option for interactions with other options.

**OCRIT**

writes the badness-of-fit criterion to the OUT= data set. See the OUT= option for interactions with other options.

**OITER | OUTITER**

writes current values to the output data sets after initialization and on every iteration. Otherwise, only the final values are written to any output data sets. (See the OUT=, OUTFIT=, and OUTRES= options.)

**OTRANS**

writes the transformation parameter estimates to the OUT= data set if any such estimates are computed. There are no transformation parameters with the LEVEL=ORDINAL option. See the OUT= option for interactions with other options.

**OUT=SAS-data-set**

creates a SAS data set containing, by default, the estimates of all the parameters of the PROC MDS model and the value of the badness-of-fit criterion. However, if you specify one or more of the OCONFIG, OCOEF, OTRANS, and OCRIT options, only the information requested by the specified options appears in the OUT= data set. (See also the OITER option.)

**OUTFIT=SAS-data-set**

creates a SAS data set containing goodness-of-fit and badness-of-fit measures for each partition as well as for the entire data set. (See also the OITER option.)

**OUTRES=SAS-data-set**

creates a SAS data set containing one observation for each nonmissing data value from the DATA= data set. Each observation contains the original data value, the estimated distance computed from the MDS model, transformed data and distances, and the residual. (See also the OITER option.)

**OVER=*n***

specifies the maximum overrelaxation factor, where  $n \geq 1$ . Values between 1 and 2 are generally reasonable. The default is OVER=2 with the LEVEL=ORDINAL, ALTERNATE=MATRIX, or ALTERNATE=ROW option; otherwise, the default is OVER=1. Use this option only if you have convergence problems.

**PCOEF**

produces the estimated dimension coefficients.

**PCONFIG**

produces the estimated coordinates of the objects in the configuration.

**PDATA**

displays each data matrix.

**PFINAL**

displays final estimates.

**PFIT**

displays the badness-of-fit criterion and various types of correlations between the data and fitted values for each data matrix, as well as for the entire sample.

**PFITROW**

displays the badness-of-fit criterion and various types of correlations between the data and fitted values for each row, as well as for each data matrix and for the entire sample. This option works only with the CONDITION=ROW option.

**PINAVDATA**

displays the sum of the weights and the weighted average of the data matrices computed during initialization with the INAV=DATA option.

**PINEIGVAL**

displays the eigenvalues computed during initialization.

**PINEIGVEC**

displays the eigenvectors computed during initialization.

**PININ**

displays values read from the INITIAL= data set. Since these values might be incomplete, the PFIT and PFITROW options do not apply.

**PINIT**

displays initial values.

**PITER**

displays estimates on each iteration.

**PLOTS**< (*global-plot-option*) > <= *plot-request* < (*options*) > >

**PLOTS**< (*global-plot-options*) > <= (*plot-request* < (*options*) > < ... *plot-request* < (*options*) > > >

specifies options that control the details of the plots. When you specify only one plot request, you can omit the parentheses around the plot request.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc mds plots(flip);
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

The global plot option is as follows:

#### **FLIP**

flips or interchanges the X-axis and Y-axis dimensions for configuration and coefficient plots.

The plot requests include the following:

#### **COEFFICIENTS(ONE)**

combines the INDSCAL coefficients panel of plots into a single plot. By default, the display consists of a panel with two plots. The vectors are displayed in the left plot, and the labels are displayed in the right plot. The right plot provides a magnification of the region of the vector endpoints. In contrast, the single display, requested by COEFFICIENTS(ONE), is more compact, but there is less room for vector labels. It is often easier to identify the vectors in the default display.

#### **NONE**

suppresses all plots.

By default, a fit plot is produced. When more than one dimension is requested, plots of the configuration are also plotted. For individual differences models with more than one dimension, the subject weights or coefficients are plotted. When more than one value is specified for the DIMENSION= option, the badness-of-fit plot is produced.

#### **PTRANS**

displays the estimated transformation parameters if any are computed. There are no transformation parameters with the LEVEL=ORDINAL option.

#### **RANDOM< =seed >**

causes initial coordinate values to be pseudo-random numbers. In one dimension, the pseudo-random numbers are uniformly distributed on an interval. In two or more dimensions, the pseudo-random numbers are uniformly distributed on the circumference of a circle or the surface of a (hyper)sphere.

**RIDGE=*n***

specifies the initial ridge value, where  $n \geq 0$ . The default is `RIDGE=1E-4`.

If you get a floating-point overflow in the first few iterations, specify a larger value such as `RIDGE=0.01`, `RIDGE=1`, or `RIDGE=100`.

If you know that the initial estimates are very good, using `RIDGE=0` might speed convergence.

**SHAPE=TRIANGULAR | TRIANGLE | TRI | T****SHAPE=SQUARE | SQU | S**

determines whether the entire data matrix for each subject or only one triangle of the matrix is stored and analyzed. If you specify the `CONDITION=ROW` option, the default is `SHAPE=SQUARE`. Otherwise, the default is `SHAPE=TRIANGLE`.

`SHAPE=SQUARE` causes the entire matrix to be stored and analyzed. The matrix can be asymmetric.

`SHAPE=TRIANGLE` causes only one triangle to be stored. However, PROC MDS reads both upper and lower triangles to look for nonmissing values and to symmetrize the data if needed. If corresponding elements in the upper and lower triangles both contain nonmissing values, only the average of the two values is stored and analyzed (Kruskal and Wish 1978, p. 74). Also, if an `OUTRES=` data set is requested, only the average of the two corresponding elements is output.

**SIMILAR | SIM<=*max*>**

causes the data to be treated as similarity measurements rather than dissimilarities. If `=max` is not specified, each data value is converted to a dissimilarity by subtracting it from the maximum value in the data set or BY group. If `=max` is specified, each data value is subtracted from the maximum of `max` and the data. The diagonal data are included in computing these maxima.

By default, the data are assumed to be dissimilarities unless there are nonmissing diagonal values and these values are predominantly larger than the off-diagonal values. In this case, the data are assumed to be similarities and are treated as if the `SIMILAR` option is specified.

**SINGULAR=*p***

specifies the singularity criterion  $p$ ,  $0 \leq p \leq 1$ . The default is `SINGULAR=1E-8`.

**UNTIE**

permits tied data to be assigned different optimally scaled values with the `LEVEL=ORDINAL` option. Otherwise, tied data are assigned equal optimally scaled values. The `UNTIE` option has no effect with values of the `LEVEL=` option other than `LEVEL=ORDINAL`.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC MDS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MDS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

If the INITIAL= data set contains the BY variables, the BY groups must appear in the same order as in the DATA= data set. If the BY variables are not in the INITIAL= data set, the entire data set is used to provide initial values for each BY group in the DATA= data set.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## ID Statement

**ID | OBJECT | OBJ variable ;**

The ID statement specifies a variable in the DATA= data set that contains descriptive labels for the objects. The labels are used in the output and are copied to the OUT= data set. If there is more than one data matrix, only the ID values from the observations containing the first data matrix are used.

The ID variable is not used to establish any correspondence between observations and variables.

If the ID statement is omitted, the variable labels or names are used as object labels.

---

## INVAR Statement

**INVAR variables ;**

The INVAR statement specifies the numeric variables in the INITIAL= data set that contain initial parameter estimates. The first variable corresponds to the first dimension, the second variable to the second dimension, and so on.

If the INVAR statement is omitted, the variables Dim1, . . . , Dim $m$  are used, where  $m$  is the maximum number of dimensions.

---

## MATRIX Statement

**MATRIX | MAT | SUBJECT | SUB** *variable* ;

The MATRIX statement specifies a variable in the DATA= data set that contains descriptive labels for the data matrices or subjects. The labels are used in the output and are copied to the OUT= and OUTRES= data sets. Only the first observation from each data matrix is used to obtain the label for that matrix.

If the MATRIX statement is omitted, the matrices are labeled 1, 2, 3, and so on.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement specifies the numeric variables in the DATA= data set that contain similarity or dissimilarity measurements on a set of objects or stimuli. Each variable corresponds to one object.

If the VAR statement is omitted, all numeric variables that are not specified in another statement are used.

To analyze a subset of the objects in a data set, you can specify the variable names corresponding to the columns in the subset, but you must also use a DATA step or a WHERE clause to specify the rows in the subset. PROC MDS expects to read one or more square matrices, and you must ensure that the rows in the data set correctly correspond to the columns in number and order.

---

## WEIGHT Statement

**WEIGHT** *variables* ;

The WEIGHT statement specifies numeric variables in the DATA= data set that contain weights for each similarity or dissimilarity measurement. These weights are used to compute weighted least-squares estimates. The number of WEIGHT variables must be the same as the number of VAR variables, and the variables in the WEIGHT statement must be in the same order as the corresponding variables in the VAR statement.

If the WEIGHT statement is omitted, all data within a partition are assigned equal weights.

Data with zero or negative weights are ignored in fitting the model but are included in the OUTRES= data set and in monotone transformations.

---

## Details: MDS Procedure

---

### Formulas

The following notation is used:

|              |                                                                                                                                    |
|--------------|------------------------------------------------------------------------------------------------------------------------------------|
| $A_p$        | intercept for partition $p$                                                                                                        |
| $B_p$        | slope for partition $p$                                                                                                            |
| $C_p$        | power for partition $p$                                                                                                            |
| $D_{rcs}$    | distance computed from the model between objects $r$ and $c$ for subject $s$                                                       |
| $F_{rcs}$    | data weight for objects $r$ and $c$ for subject $s$ obtained from the $c$ th WEIGHT variable, or 1 if there is no WEIGHT statement |
| $f$          | value of the FIT= option                                                                                                           |
| $N$          | number of objects                                                                                                                  |
| $O_{rcs}$    | observed dissimilarity between objects $r$ and $c$ for subject $s$                                                                 |
| $P_{rcs}$    | partition index for objects $r$ and $c$ for subject $s$                                                                            |
| $Q_{rcs}$    | dissimilarity after applying any applicable estimated transformation for objects $r$ and $c$ for subject $s$                       |
| $R_{rcs}$    | residual for objects $r$ and $c$ for subject $s$                                                                                   |
| $S_p$        | standardization factor for partition $p$                                                                                           |
| $T_p(\cdot)$ | estimated transformation for partition $p$                                                                                         |
| $V_{sd}$     | coefficient for subject $s$ on dimension $d$                                                                                       |
| $X_{nd}$     | coordinate for object $n$ on dimension $d$                                                                                         |

Summations are taken over nonmissing values.

Distances are computed from the model as

$$\begin{aligned}
 D_{rcs} &= \sqrt{\sum_d (X_{rd} - X_{cd})^2} && \text{for COEF=IDENTITY:} \\
 &&& \text{Euclidean distance} \\
 &= \sqrt{\sum_d V_{sd}^2 (X_{rd} - X_{cd})^2} && \text{for COEF=DIAGONAL:} \\
 &&& \text{weighted Euclidean distance}
 \end{aligned}$$

Partition indexes are

$$\begin{aligned}
 P_{rcs} &= 1 && \text{for CONDITION=UN} \\
 &= s && \text{for CONDITION=MATRIX} \\
 &= (s - 1)N + r && \text{for CONDITION=ROW}
 \end{aligned}$$

The estimated transformation for each partition is

$$\begin{aligned} T_p(d) &= d && \text{for LEVEL=ABSOLUTE} \\ &= B_p d && \text{for LEVEL=RATIO} \\ &= A_p + B_p d && \text{for LEVEL=INTERVAL} \\ &= B_p d^{C_p} && \text{for LEVEL=LOGINTERVAL} \end{aligned}$$

For LEVEL=ORDINAL,  $T_p(\cdot)$  is computed as a least-squares monotone transformation.

For LEVEL=ABSOLUTE, RATIO, or INTERVAL, the residuals are computed as

$$\begin{aligned} Q_{rcs} &= O_{rcs} \\ R_{rcs} &= Q_{rcs}^f - [T_{P_{rcs}}(D_{rcs})]^f \end{aligned}$$

For LEVEL=ORDINAL, the residuals are computed as

$$\begin{aligned} Q_{rcs} &= T_{P_{rcs}}(O_{rcs}) \\ R_{rcs} &= Q_{rcs}^f - D_{rcs}^f \end{aligned}$$

If  $f$  is 0, then natural logarithms are used in place of the  $f$ th powers.

For each partition, let

$$U_p = \frac{\sum_{r,c,s} F_{rcs}}{\sum_{r,c,s|P_{rcs}=p} F_{rcs}}$$

and

$$\bar{Q}_p = \frac{\sum_{r,c,s|P_{rcs}=p} Q_{rcs} F_{rcs}}{\sum_{r,c,s|P_{rcs}=p} F_{rcs}}$$

Then the standardization factor for each partition is

$$\begin{aligned} S_p &= 1 && \text{for FORMULA=0} \\ &= U_p \sum_{r,c,s|P_{rcs}=p} Q_{rcs}^2 F_{rcs} && \text{for FORMULA=1} \\ &= U_p \sum_{r,c,s|P_{rcs}=p} (Q_{rcs} - \bar{Q}_p)^2 F_{rcs} && \text{for FORMULA=2} \end{aligned}$$

The badness-of-fit criterion that the MDS procedure tries to minimize is

$$\sqrt{\sum_{r,c,s} \frac{R_{rcs}^2 F_{rcs}}{S_{P_{rcs}}}}$$

---

## OUT= Data Set

The OUT= data set contains the following variables:

- BY variables, if any
- `_ITER_` (if the OUTITER option is specified), a numeric variable containing the iteration number
- `_DIMENS_`, a numeric variable containing the number of dimensions
- `_MATRIX_` or the variable in the MATRIX statement, identifying the data matrix or subject to which the observation pertains. This variable contains a missing value for observations that pertain to the data set as a whole and not to a particular matrix, such as the coordinates (`_TYPE_='CONFIG'`).
- `_TYPE_`, a character variable of length 10 identifying the type of information in the observation

The values of `_TYPE_` are as follows:

|           |                                                           |
|-----------|-----------------------------------------------------------|
| CONFIG    | the estimated coordinates of the configuration of objects |
| DIAGCOEF  | the estimated dimension coefficients for COEF=DIAGONAL    |
| INTERCEPT | the estimated intercept parameters                        |
| SLOPE     | the estimated slope parameters                            |
| POWER     | the estimated power parameters                            |
| CRITERION | the badness-of-fit criterion                              |

- `_LABEL_` or the variable in the ID statement, containing the variable label or value of the ID variable of the object to which the observation pertains. This variable contains a missing value for observations that do not pertain to a particular object or dimension.
- `_NAME_`, a character variable containing the variable name of the object or dimension to which the observation pertains. This variable contains a missing value for observations that do not pertain to a particular object or dimension.
- Dim1, . . . , Dim $m$ , where  $m$  is the maximum number of dimensions

---

## OUTFIT= Data Set

The OUTFIT= data set contains various measures of goodness and badness of fit. There is one observation for the entire sample plus one observation for each matrix. For the CONDITION=ROW option, there is also one observation for each row.

The OUTFIT= data set contains the following variables:

- BY variables, if any
- `_ITER_` (if the OUTITER option is specified), a numeric variable containing the iteration number

- `_DIMENS_`, a numeric variable containing the number of dimensions
- `_MATRIX_` or the variable in the `MATRIX` statement, identifying the data matrix or subject to which the observation pertains
- `_LABEL_` or the variable in the `ID` statement, containing the variable label or value of the `ID` variable of the object to which the observation pertains when `CONDITION=ROW`
- `_NAME_`, a character variable containing the variable name of the object or dimension to which the observation pertains when `CONDITION=ROW`
- `N`, the number of nonmissing data
- `WEIGHT`, the weight of the partition
- `CRITER`, the badness-of-fit criterion
- `DISCORR`, the correlation between the transformed data and the distances for `LEVEL=ORDINAL` or the correlation between the data and the transformed distances otherwise
- `UDISCORR`, the correlation uncorrected for the mean between the transformed data and the distances for `LEVEL=ORDINAL` or the correlation between the data and the transformed distances otherwise
- `FITCORR`, the correlation between the fit-transformed data and the fit-transformed distances
- `UFITCORR`, the correlation uncorrected for the mean between the fit-transformed data and the fit-transformed distances

---

## OUTRES= Data Set

The `OUTRES=` data set has one observation for each nonmissing data value. It contains the following variables:

- `BY` variables, if any
- `_ITER_` (if the `OUTITER` option is specified), a numeric variable containing the iteration number
- `_DIMENS_`, a numeric variable containing the number of dimensions
- `_MATRIX_` or the variable in the `MATRIX` statement, identifying the data matrix or subject to which the observation pertains
- `_ROW_`, containing the variable label or value of the `ID` variable of the row to which the observation pertains
- `_COL_`, containing the variable label or value of the `ID` variable of the column to which the observation pertains
- `DATA`, the original data value
- `TRANDATA`, the optimally transformed data value when `LEVEL=ORDINAL`

- DISTANCE, the distance computed from the PROC MDS model
- TRANSDIST, the optimally transformed distance when the LEVEL= option is not ORDINAL or ABSOLUTE
- FITDATA, the data value further transformed according to the FIT= option
- FITDIST, the distance further transformed according to the FIT= option
- WEIGHT, the combined weight of the data value based on the WEIGHT variable(s), if any, and the standardization specified by the FORMULA= option
- RESIDUAL, FITDATA minus FITDIST

If you assign a nonmissing data value a weight of zero, PROC MDS will ignore it when the model is fit, but the value will still appear in the OUTRES= data set (see the section “WEIGHT Statement” on page 4693).

---

## INITIAL= Data Set

The INITIAL= data set has the same structure as the OUT= data set but is not required to have all of the variables or observations that appear in the OUT= data set. You can use an OUT= data set previously created by PROC MDS (without the OUTITER option) as an INITIAL= data set in a subsequent invocation of the procedure.

The only variables that are required are Dim1, . . . , Dim $m$  (where  $m$  is the maximum number of dimensions) or equivalent variables specified in the INVAR statement. If these are the only variables, then all the observations are assumed to contain coordinates of the configuration; you cannot read dimension coefficients or transformation parameters.

To read initial values for the dimension coefficients or transformation parameters, the INITIAL= data set must contain the \_TYPE\_ variable and either the variable specified in the ID statement or, if no ID statement is used, the variable \_NAME\_. In addition, if there is more than one data matrix, either the variable specified in the MATRIX statement or, if no MATRIX statement is used, the variable \_MATRIX\_ or \_MATNUM\_ is required.

If the INITIAL= data set contains the variable \_DIMENS\_, initial values are obtained from observations with the corresponding number of dimensions. If there is no \_DIMENS\_ variable, the same observations are used for each number of dimensions analyzed.

If you want PROC MDS to read initial values from some but not all of the observations in the INITIAL= data set, use the WHERE= data set option to select the desired observations.

---

## Missing Values

Missing data in the similarity or dissimilarity matrices are ignored in fitting the model and are omitted from the OUTRES= data set. Any matrix that is completely missing is omitted from the analysis.

Missing weights are treated as 0.

Missing values are also permitted in the INITIAL= data set, but a large number of missing values might yield a degenerate initial configuration.

---

## Normalization of the Estimates

In multidimensional scaling models, the parameter estimates are not uniquely determined; the estimates can be transformed in various ways without changing their badness of fit. The initial and final estimates from PROC MDS are, therefore, normalized (unless you specify the NONORM option) to make it easier to compare results from different analyses.

The configuration always has a mean of 0 for each dimension.

With the COEF=IDENTITY option, the configuration is rotated to a principal-axis orientation. Unless you specify the LEVEL=ABSOLUTE option, the entire configuration is scaled so that the root-mean-square element is 1, and the transformations are adjusted to compensate.

With the COEF=DIAGONAL option, each dimension is scaled to a root-mean-square value of 1, and the dimension coefficients are adjusted to compensate. Unless you specify the LEVEL=ABSOLUTE option, the dimension coefficients are normalized as follows. If you specify the CONDITION=UN option, all of the dimension coefficients are scaled to a root-mean-square value of 1. For other values of the CONDITION= option, the dimension coefficients are scaled separately for each subject to a root-mean-square value of 1. In either case, the transformations are adjusted to compensate.

Each dimension is reflected to give a positive rank correlation with the order of the objects in the data set.

For the LEVEL=ORDINAL option, if the intercept, slope, or power parameters are fitted, the transformed data are normalized to eliminate these parameters if possible.

---

## Comparison with Earlier Procedures

PROC MDS shares many of the features of the ALSCAL procedure (Young, Lewyckyj, and Takane 1986; Young 1982), as well as some features of the MLSCALE procedure (Ramsay 1986). Both PROC ALSCAL and PROC MLSCALE are no longer a part of SAS; however, they are described in the *SUGI Supplemental Library User's Guide, Version 5 Edition*. The MDS procedure generally produces results similar to those from the ALSCAL procedure (Young, Lewyckyj, and Takane 1986; Young 1982) if you use the following options in PROC MDS:

- FIT=SQUARED
- FORMULA=1 except for unfolding data, which require FORMULA=2
- PFINAL to get output similar to that from PROC ALSCAL

Running the MDS procedure with certain options generally produces results similar to those from using the MLSCALE procedure (Ramsay 1986) with other options. This is illustrated with the following statements:

```
proc mds fit=log level=loginterval ... ;
```

```
proc mlscale stvarnce=constant suvarnce=constant ... ;
```

Alternatively, using the FIT=DISTANCE option in the PROC MDS statement produces results similar to those from specifying the NORMAL option in the PROC MLSCALE statement.

## Displayed Output

Unless you specify the NOPHIST option, PROC MDS displays the iteration history containing the following:

- Iteration number
- Type of iteration:
 

|          |                          |
|----------|--------------------------|
| Initial  | initial configuration    |
| Monotone | monotone transformation  |
| Gau-New  | Gauss-Newton step        |
| Lev-Mar  | Levenberg-Marquardt step |
- Badness-of-Fit Criterion
- Change in Criterion
- Convergence Measures:
 

|          |                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monotone | the Euclidean norm of the change in the optimally scaled data divided by the Euclidean norm of the optimally scaled data, averaged across partitions |
| Gradient | the multiple correlation of the Jacobian matrix with the residual vector, uncorrected for the mean                                                   |

Depending on what options are specified, PROC MDS can also display the following tables:

- Data Matrix and possibly Weight Matrix for each subject
- Eigenvalues from the computation of the initial coordinates
- Sum of Data Weights and Pooled Data Matrix computed during initialization with INAV=DATA
- Configuration, the estimated coordinates of the objects
- Dimension Coefficients
- A table of transformation parameters, including one or more of the following:
 

|           |
|-----------|
| Intercept |
| Slope     |
| Power     |
- A table of fit statistics for each matrix and possibly each row, including the following:
 

|                                                                                              |
|----------------------------------------------------------------------------------------------|
| Number of Nonmissing Data                                                                    |
| Weight of the matrix or row, permitting both observation weights and standardization factors |
| Badness-of-Fit Criterion                                                                     |

Distance Correlation computed between the distances and data with optimal transformation  
 Uncorrected Distance Correlation not corrected for the mean  
 Fit Correlation computed after applying the FIT= transformation to both distances and data  
 Uncorrected Fit Correlation not corrected for the mean

---

## ODS Table Names

PROC MDS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 56.3. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 56.3** ODS Tables Produced by PROC MDS

| ODS Table Name    | Description                  | Option                                            |
|-------------------|------------------------------|---------------------------------------------------|
| ConvergenceStatus | Convergence status           | default                                           |
| DimensionCoef     | Dimension coefficients       | PCOEF with COEF= not IDENTITY                     |
| FitMeasures       | Measures of fit              | PFIT                                              |
| IterHistory       | Iteration history            | default                                           |
| PConfig           | Configuration of coordinates | PCONFIG                                           |
| PData             | Data matrices                | PDATA                                             |
| PInAvData         | INAV= data set information   | PINAVDATA                                         |
| PInEigval         | Initial eigenvalues          | PINEIGVAL                                         |
| PInEigvec         | Initial eigenvectors         | PINEIGVEC                                         |
| PInWeight         | Initialization weights       | PINWEIGHT                                         |
| Transformations   | Transformation parameters    | PTRANS with LEVEL=RATIO,<br>INTERVAL, LOGINTERVAL |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

All graphs are produced by default when they are appropriate. You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC MDS generates are listed in Table 56.4, along with the required options.

**Table 56.4** Graphs Produced by PROC MDS

| ODS Graph Name   | Plot Description        | Option                                              |
|------------------|-------------------------|-----------------------------------------------------|
| BadnessPlot      | Badness of fit          | DIMENSION= <i>range</i>                             |
| CoefficientsPlot | Individual coefficients | DIMENSION= <i>n</i> , <i>n</i> > 1<br>COEF=DIAGONAL |
| ConfigPlot       | Configuration           | DIMENSION= <i>n</i> , <i>n</i> > 1                  |
| FitPlot          | Fit                     | default                                             |

## Example: MDS Procedure

---

### Example 56.1: Jacobowitz Body Parts Data from Children and Adults

Jacobowitz (1975) collected conditional rank-order data regarding perceived similarity of parts of the body from children of ages 6, 8, and 10 years and from college sophomores. The data set includes data from 15 children (6-year-olds) and 15 sophomores. The method of data collection and some results of an analysis are also described by Young (1987, pp. 4–10). The following statements create the input data set:

```

data body;
 title 'Jacobowitz Body Parts Data from 6-Year-Olds and Adults';
 title2 'First 15 Subjects (obs 1–225) Are Children';
 title3 'Second 15 Subjects (obs 226–450) Are Adults';
 input (Cheek Face Mouth Head Ear Body Arm Elbow Hand
 Palm Finger Leg Knee Foot Toe) (2.);
 if _n_ <= 225 then Subject='C'; else subject='A';
 datalines;
0 2 1 3 4 10 5 9 6 7 8 11 12 13 14
2 0 12 1 13 3 8 10 11 9 7 4 5 6 14
3 2 0 1 4 9 5 11 6 7 8 10 13 12 14
2 1 3 0 4 9 5 6 11 7 8 10 12 13 14

... more lines ...

10 12 11 13 9 14 8 7 4 6 2 3 5 1 0
;

```

The data are analyzed as row conditional (CONDITION=ROW) at the ordinal level of measurement (LEVEL=ORDINAL) by using the weighted Euclidean model (COEF=DIAGONAL) in three dimensions (DIMENSION=3). The final estimates are displayed (PFINAL). The estimates (OUT=OUT) and fitted values (OUTRES=RES) are saved in output data sets. The following statements produce [Output 56.1.1](#):

```
ods graphics on;

proc mds data=body condition=row level=ordinal coef=diagonal
 dimension=3 pfinal out=out outres=res;
 subject subject;
 title5 'Nonmetric Weighted MDS';
run;
```

**Output 56.1.1** Analysis of Body Parts Data

| Jacobowitz Body Parts Data from 6-Year-Olds and Adults                         |          |                                 |                        |                      |          |
|--------------------------------------------------------------------------------|----------|---------------------------------|------------------------|----------------------|----------|
| First 15 Subjects (obs 1-225) Are Children                                     |          |                                 |                        |                      |          |
| Second 15 Subjects (obs 226-450) Are Adults                                    |          |                                 |                        |                      |          |

Often the output of greatest interest in an MDS analysis is the graphical output. The first plots show two-dimensional view of the three-dimensional configuration. Next, the coefficients are plotted. The last plot is the fit plot.

In the fit plot, the transformed data are plotted on the vertical axis, and the distances from the model are plotted on the horizontal axis. If the model fits perfectly, all points lie on a diagonal line from lower left to upper right. The vertical departure of each point from this diagonal line represents the residual of the corresponding observation.

The configuration has a tripodal shape with **Body** at the apex. The three legs of the tripod can be distinguished in the plot of dimension 2 by dimension 1, which shows three distinct clusters with **Body** in the center. Dimension 1 separates head parts from arm and leg parts. Dimension 2 separates arm parts from leg parts. The plot of dimension 3 by dimension 1 shows the tripod from the side. Dimension 3 distinguishes the more inclusive body parts (at the top) from the less inclusive body parts (at the bottom).

The plots of dimension coefficients show that children differ from adults primarily in the emphasis given to dimension 2. Children give about the same weight (approximately 1) to each dimension. Adults are much more variable than children, but all have coefficients less than 1.0 for dimension 2, with an average of about 0.7. Referring back to the configuration plot, you can see that adults consider arm parts to be more similar to leg parts than children do. Many adults also give a high weight to dimension 1, indicating that they consider head parts to be more dissimilar from arm and leg parts than children do. Dimension 3 shows considerable variability for both children and adults.

## Overview: MI Procedure

Missing values are an issue in a substantial number of statistical analyses. Most SAS statistical procedures exclude observations with any missing variable values from the analysis. These observations are called incomplete cases. While using only complete cases is simple, you lose information that is in the incomplete cases. Excluding observations with missing values also ignores the possible systematic difference between the complete cases and incomplete cases, and the resulting inference might not be applicable to the population of all cases, especially with a smaller number of complete cases.

Some SAS procedures use all the available cases in an analysis—that is, cases with useful information. For example, the CORR procedure estimates a variable mean by using all cases with nonmissing values for this variable, ignoring the possible missing values in other variables. The CORR procedure also estimates a correlation by using all cases with nonmissing values for this pair of variables. This estimation might make better use of the available data, but the resulting correlation matrix might not be positive definite.

Another strategy is single imputation, in which you substitute a value for each missing value. Standard statistical procedures for complete data analysis can then be used with the filled-in data set. For example, each missing value can be imputed from the variable mean of the complete cases. This approach treats missing values as if they were known in the complete-data analyses. Single imputation does not reflect the uncertainty about the predictions of the unknown missing values, and the resulting estimated variances of the parameter estimates are biased toward zero (Rubin 1987, p. 13).

Instead of filling in a single value for each missing value, multiple imputation replaces each missing value with a set of plausible values that represent the uncertainty about the right value to impute (Rubin 1976, 1987). The multiply imputed data sets are then analyzed by using standard procedures for complete data and combining the results from these analyses. No matter which complete-data analysis is used, the process of combining results from different data sets is essentially the same.

Multiple imputation does not attempt to estimate each missing value through simulated values, but rather to represent a random sample of the missing values. This process results in valid statistical inferences that properly reflect the uncertainty due to missing values; for example, valid confidence intervals for parameters.

Multiple imputation inference involves three distinct phases:

1. The missing data are filled in  $m$  times to generate  $m$  complete data sets.
2. The  $m$  complete data sets are analyzed by using standard procedures.
3. The results from the  $m$  complete data sets are combined for the inference.

The MI procedure is a multiple imputation procedure that creates multiply imputed data sets for incomplete  $p$ -dimensional multivariate data. It uses methods that incorporate appropriate variability across the  $m$  imputations. The imputation method of choice depends on the patterns of missingness in the data and the type of the imputed variable.

A data set with variables  $Y_1, Y_2, \dots, Y_p$  (in that order) is said to have a *monotone missing pattern* when the event that a variable  $Y_j$  is missing for a particular individual implies that all subsequent variables  $Y_k$ ,  $k > j$ , are missing for that individual.

For data sets with monotone missing patterns, the variables with missing values can be imputed sequentially with covariates constructed from their corresponding sets of preceding variables. To impute missing values

for a continuous variable, you can use a regression method (Rubin 1987, pp. 166–167), a predictive mean matching method (Heitjan and Little 1991; Schenker and Taylor 1996), or a propensity score method (Rubin 1987, pp. 124, 158; Lavori, Dawson, and Shera 1995). To impute missing values for a classification variable, you can use a logistic regression method when the classification variable has a binary or ordinal response, or use a discriminant function method when the classification variable has a binary or nominal response.

For data sets with arbitrary missing patterns, you can use either of the following methods to impute missing values: a Markov chain Monte Carlo (MCMC) method (Schafer 1997) that assumes multivariate normality, or a fully conditional specification (FCS) method (Brand 1999; van Buuren 2007) that assumes the existence of a joint distribution for all variables.

You can use the MCMC method to impute either all the missing values or just enough missing values to make the imputed data sets have monotone missing patterns. With a monotone missing data pattern, you have greater flexibility in your choice of imputation models, such as the monotone regression method that do not use Markov chains. You can also specify a different set of covariates for each imputed variable.

An FCS method does not start with an explicitly specified multivariate distribution for all variables, but rather uses a separate conditional distribution for each imputed variable. For each imputation, the process contains two phases: the preliminary filled-in phase followed by the imputation phase. At the filled-in phase, the missing values for all variables are filled in sequentially over the variables taken one at a time. These filled-in values provide starting values for these missing values at the imputation phase. At the imputation phase, the missing values for each variable are imputed sequentially for a number of burn-in iterations before the imputation.

As in methods for data sets with monotone missing patterns, you can use a regression method or a predictive mean matching method to impute missing values for a continuous variable, a logistic regression method to impute missing values for a classification variable with a binary or ordinal response, and a discriminant function method to impute missing values for a classification variable with a binary or nominal response.

After the  $m$  complete data sets are analyzed using standard SAS procedures, the MIANALYZE procedure can be used to generate valid statistical inferences about these parameters by combining results from the  $m$  analyses.

Often, as few as three to five imputations are adequate in multiple imputation (Rubin 1996, p. 480). The relative efficiency of the small  $m$  imputation estimator is high for cases with little missing information (Rubin 1987, p. 114). (Also see the section “[Multiple Imputation Efficiency](#)” on page 4771.)

Multiple imputation inference assumes that the model (variables) you used to analyze the multiply imputed data (the analyst’s model) is the same as the model used to impute missing values in multiple imputation (the imputer’s model). But in practice, the two models might not be the same. The consequences for different scenarios (Schafer 1997, pp. 139–143) are discussed in the section “[Imputer’s Model Versus Analyst’s Model](#)” on page 4771.

---

## Getting Started: MI Procedure

The Fitness data described in the REG procedure are measurements of 31 individuals in a physical fitness course. See Chapter 79, “[The REG Procedure](#),” for more information.

The Fitness1 data set is constructed from the Fitness data set and contains three variables: Oxygen, RunTime, and RunPulse. Some values have been set to missing, and the resulting data set has an arbitrary pattern of missingness in these three variables.

```

Suppose that the data are multivariate normally distributed and the missing data are missing at random (MAR). That is, the probability that an observation is missing can depend on the observed variable values of the individual, but not on the missing variable values of the individual. See the section “[Statistical Assumptions for Multiple Imputation](#)” on page 4745 for a detailed description of the MAR assumption.

The following statements invoke the MI procedure and impute missing values for the Fitness1 data set:

```

proc mi data=Fitness1 seed=501213 mu0=50 10 180 out=outmi;
 mcmc;
 var Oxygen RunTime RunPulse;
run;

```

The “Model Information” table in [Figure 57.1](#) describes the method used in the multiple imputation process. By default, the MCMC statement uses the Markov chain Monte Carlo (MCMC) method with a single chain to create five imputations. The posterior mode, the highest observed-data posterior density, with a noninformative prior, is computed from the expectation-maximization (EM) algorithm and is used as the starting value for the chain.

**Figure 57.1** Model Information

| The MI Procedure                 |                   |
|----------------------------------|-------------------|
| Model Information                |                   |
| Data Set                         | WORK.FITNESS1     |
| Method                           | MCMC              |
| Multiple Imputation Chain        | Single Chain      |
| Initial Estimates for MCMC       | EM Posterior Mode |
| Start                            | Starting Value    |
| Prior                            | Jeffreys          |
| Number of Imputations            | 5                 |
| Number of Burn-in Iterations     | 200               |
| Number of Iterations             | 100               |
| Seed for random number generator | 501213            |

The MI procedure takes 200 burn-in iterations before the first imputation and 100 iterations between imputations. In a Markov chain, the information in the current iteration influences the state of the next iteration. The burn-in iterations are iterations in the beginning of each chain that are used both to eliminate the series of dependence on the starting value of the chain and to achieve the stationary distribution. The between-imputation iterations in a single chain are used to eliminate the series of dependence between the two imputations.

The “Missing Data Patterns” table in [Figure 57.2](#) lists distinct missing data patterns with their corresponding frequencies and percentages. An “X” means that the variable is observed in the corresponding group, and a “.” means that the variable is missing. The table also displays group-specific variable means. The MI procedure sorts the data into groups based on whether the analysis variables are observed or missing. For a detailed description of missing data patterns, see the section “[Missing Data Patterns](#)” on page 4746.

**Figure 57.2** Missing Data Patterns

| Missing Data Patterns |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |
| 1                     | X      | X        | X         | 21   | 67.74   |
| 2                     | X      | X        | .         | 4    | 12.90   |
| 3                     | X      | .        | .         | 3    | 9.68    |
| 4                     | .      | X        | X         | 1    | 3.23    |

| 5                     | .         | 9.885000  | .          |

After the completion of  $m$  imputations, the “Variance Information” table in Figure 57.3 displays the between-imputation variance, within-imputation variance, and total variance for combining complete-data inferences. It also displays the degrees of freedom for the total variance. The relative increase in variance due to missing values, the fraction of missing information, and the relative efficiency (in units of variance) for each variable are also displayed. A detailed description of these statistics is provided in the section “Combining Inferences from Multiply Imputed Data Sets” on page 4769.

**Figure 57.3** Variance Information

| Variance Information |                    |          |          |        |
|----------------------|--------------------|----------|----------|--------|
| Variable             | -----Variance----- |          |          | DF     |
|                      | Between            | Within   | Total    |        |
| Oxygen               | 0.056930           | 0.954041 | 1.022356 | 25.549 |
| RunTime              | 0.000811           | 0.064496 | 0.065469 | 27.721 |
| RunPulse             | 0.922032           | 3.269089 | 4.375528 | 15.753 |

| Variance Information |                               |                              |                     |
|----------------------|-------------------------------|------------------------------|---------------------|
| Variable             | Relative Increase in Variance | Fraction Missing Information | Relative Efficiency |
| Oxygen               | 0.071606                      | 0.068898                     | 0.986408            |
| RunTime              | 0.015084                      | 0.014968                     | 0.997015            |
| RunPulse             | 0.338455                      | 0.275664                     | 0.947748            |

The “Parameter Estimates” table in Figure 57.4 displays the estimated mean and standard error of the mean for each variable. The inferences are based on the  $t$  distribution. The table also displays a 95% confidence interval for the mean and a  $t$  statistic with the associated  $p$ -value for the hypothesis that the population mean is equal to the value specified with the MU0= option. A detailed description of these statistics is provided in the section “Combining Inferences from Multiply Imputed Data Sets” on page 4769.

**Figure 57.4** Parameter Estimates

| Parameter Estimates |            |           |                       |          |        |
|---------------------|------------|-----------|-----------------------|----------|--------|
| Variable            | Mean       | Std Error | 95% Confidence Limits |          | DF     |
| Oxygen              | 47.094040  | 1.011116  | 45.0139               | 49.1742  | 25.549 |

| RunPulse            | 171.787793 | 2.091776  | 167.3478              | 176.2278 | 15.753 |

| Parameter Estimates |            |            |            |                       |         |
|---------------------|------------|------------|------------|-----------------------|---------|
| Variable            | Minimum    | Maximum    | Mu0        | t for H0:<br>Mean=Mu0 | Pr >  t |
| Oxygen              | 46.783898  | 47.395550  | 50.000000  | -2.87                 | 0.0081  |
| RunTime             | 10.526392  | 10.599616  | 10.000000  | 2.24                  | 0.0336  |
| RunPulse            | 170.774818 | 173.122002 | 180.000000 | -3.93                 | 0.0012  |

In addition to the output tables, the procedure also creates a data set with imputed values. The imputed data sets are stored in the outmi data set, with the index variable `_Imputation_` indicating the imputation numbers. The data set can now be analyzed using standard statistical procedures with `_Imputation_` as a BY variable.

The following statements list the first 10 observations of data set outmi:

```
proc print data=outmi (obs=10);
 title 'First 10 Observations of the Imputed Data Set';
run;
```

The table in Figure 57.5 shows that the precision of the imputed values differs from the precision of the observed values. You can use the `ROUND=` option to make the imputed values consistent with the observed values.

**Figure 57.5** Imputed Data Set

| First 10 Observations of the Imputed Data Set |              |         |         |              |
|-----------------------------------------------|--------------|---------|---------|--------------|
| Obs                                           | _Imputation_ | Oxygen  | RunTime | Run<br>Pulse |
| 1                                             | 1            | 44.6090 | 11.3700 | 178.000      |
| 2                                             | 1            | 45.3130 | 10.0700 | 185.000      |
| 3                                             | 1            | 54.2970 | 8.6500  | 156.000      |
| 4                                             | 1            | 59.5710 | 8.0747  | 155.925      |
| 5                                             | 1            | 49.8740 | 9.2200  | 176.837      |
| 6                                             | 1            | 44.8110 | 11.6300 | 176.000      |
| 7                                             | 1            | 42.8857 | 11.9500 | 176.000      |
| 8                                             | 1            | 46.9992 | 10.8500 | 173.099      |
| 9                                             | 1            | 39.4420 | 13.0800 | 174.000      |
| 10                                            | 1            | 60.0550 | 8.6300  | 170.000      |

## Syntax: MI Procedure

The following statements are available in the MI procedure:

```
PROC MI < options > ;
 BY variables ;
 CLASS variables ;
 EM < options > ;
 FCS < options > ;
 FREQ variable ;
 MCMC < options > ;
 MONOTONE < options > ;
 TRANSFORM transform (variables< / options >) < . . . transform (variables< / options >) > ;
 VAR variables ;
```

The `BY` statement specifies groups in which separate multiple imputation analyses are performed.

The `CLASS` statement lists the classification variables in the `VAR` statement. Classification variables can be either character or numeric.

The EM statement uses the EM algorithm to compute the maximum likelihood estimate (MLE) of the data with missing values, assuming a multivariate normal distribution for the data.

The FREQ statement specifies the variable that represents the frequency of occurrence for other values in the observation.

For a data set with a monotone missing pattern, you can use the MONOTONE statement to specify applicable monotone imputation methods; otherwise, you can use either the MCMC statement assuming multivariate normality or the FCS method assuming a joint distribution for variables exists. Note that you can specify no more than one of these statements. When none of these three statements is specified, the MCMC method with its default options is used.

The FCS statement uses a multivariate imputation by chained equations method to impute values for a data set with an arbitrary missing pattern, assuming a joint distribution exists for the data.

The MCMC statement uses a Markov chain Monte Carlo method to impute values for a data set with an arbitrary missing pattern, assuming a multivariate normal distribution for the data.

The MONOTONE statement specifies monotone methods to impute continuous and classification variables for a data set with a monotone missing pattern.

The TRANSFORM statement specifies the variables to be transformed before the imputation process; the imputed values of these transformed variables are reverse-transformed to the original forms before the imputation.

The VAR statement lists the numeric variables to be analyzed. If you omit the VAR statement, all numeric variables not listed in other statements are used.

The PROC MI statement is the only required statement for the MI procedure. The rest of this section provides detailed syntax information for each of these statements, beginning with the PROC MI statement. The remaining statements are presented in alphabetical order.

---

## PROC MI Statement

**PROC MI** < options > ;

The PROC MI statement invokes the MI procedure. [Table 57.1](#) summarizes the options available in the PROC MI statement.

**Table 57.1** Summary of PROC MI Options

| Option                    | Description                                          |
|---------------------------|------------------------------------------------------|
| <b>Data Sets</b>          |                                                      |
| DATA=                     | Specifies the input data set                         |
| OUT=                      | Specifies the output data set with imputed values    |
| <b>Imputation Details</b> |                                                      |
| NIMPUTE=                  | Specifies the number of imputations                  |
| SEED=                     | Specifies the seed to begin random number generator  |
| ROUND=                    | Specifies units to round imputed variable values     |
| MAXIMUM=                  | Specifies maximum values for imputed variable values |
| MINIMUM=                  | Specifies minimum values for imputed variable values |

Table 57.1 *continued*

| Option                      | Description                                                                        |
|-----------------------------|------------------------------------------------------------------------------------|
| MINMAXITER=                 | Specifies the maximum number of iterations to impute values in the specified range |
| SINGULAR=                   | Specifies the singularity criterion                                                |
| <b>Statistical Analysis</b> |                                                                                    |
| ALPHA=                      | Specifies the level for the confidence interval, $(1 - \alpha)$                    |
| MU0=                        | Specifies means under the null hypothesis                                          |
| <b>Printed Output</b>       |                                                                                    |
| NOPRINT                     | Suppresses all displayed output                                                    |
| SIMPLE                      | Displays univariate statistics and correlations                                    |

The following options can be used in the PROC MI statement. They are listed in alphabetical order.

**ALPHA= $\alpha$** 

specifies that confidence limits be constructed for the mean estimates with confidence level  $100(1 - \alpha)\%$ , where  $0 < \alpha < 1$ . The default is ALPHA=0.05.

**DATA=SAS-data-set**

names the SAS data set to be analyzed by PROC MI. By default, the procedure uses the most recently created SAS data set.

**MAXIMUM=numbers**

specifies maximum values for imputed variables. When an intended imputed value is greater than the maximum, PROC MI redraws another value for imputation. If only one number is specified, that number is used for all variables. If more than one number is specified, you must use a VAR statement, and the specified numbers must correspond to variables in the VAR statement. The default number is a missing value, which indicates no restriction on the maximum for the corresponding variable

The MAXIMUM= option is related to the MINIMUM= and ROUND= options, which are used to make the imputed values more consistent with the observed variable values. These options are applicable only if you use the MCMC method or the monotone regression method.

When specifying a maximum for the first variable only, you must also specify a missing value after the maximum. Otherwise, the maximum is used for all variables.

For example, the “MAXIMUM= 100 .” option sets a maximum of 100 for the first analysis variable only and no maximum for the remaining variables. The “MAXIMUM= . 100” option sets a maximum of 100 for the second analysis variable only and no maximum for the other variables.

**MINIMUM=numbers**

specifies the minimum values for imputed variables. When an intended imputed value is less than the minimum, PROC MI redraws another value for imputation. If only one number is specified, that number is used for all variables. If more than one number is specified, you must use a VAR statement, and the specified numbers must correspond to variables in the VAR statement. The default number is a missing value, which indicates no restriction on the minimum for the corresponding variable

**MINMAXITER=number**

specifies the maximum number of iterations for imputed values to be in the specified range when the option MINIMUM or MAXIMUM is also specified. The default is MINMAXITER=100.

**MU0=numbers****THETA0=numbers**

specifies the parameter values  $\mu_0$  under the null hypothesis  $\mu = \mu_0$  for the population means corresponding to the analysis variables. Each hypothesis is tested with a  $t$  test. If only one number is specified, that number is used for all variables. If more than one number is specified, you must use a VAR statement, and the specified numbers must correspond to variables in the VAR statement. The default is MU0=0.

If a variable is transformed as specified in a TRANSFORM statement, then the same transformation for that variable is also applied to its corresponding specified MU0= value in the  $t$  test. If the parameter values  $\mu_0$  for a transformed variable are not specified, then a value of zero is used for the resulting  $\mu_0$  after transformation.

**NIMPUTE=number**

specifies the number of imputations. The default is NIMPUTE=5. You can specify NIMPUTE=0 to skip the imputation. In this case, only tables of model information, missing data patterns, descriptive statistics (SIMPLE option), and MLE from the EM algorithm (EM statement) are displayed.

**NOPRINT**

suppresses the display of all output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “Using the Output Delivery System,” for more information.

**OUT=SAS-data-set**

creates an output SAS data set that contains imputation results. The data set includes an index variable, `_Imputation_`, to identify the imputation number. For each imputation, the data set contains all variables in the input data set with missing values being replaced by the imputed values. See the section “Output Data Sets” on page 4767 for a description of this data set.

**ROUND=numbers**

specifies the units to round variables in the imputation. If only one number is specified, that number is used for all continuous variables. If more than one number is specified, you must use a VAR statement, and the specified numbers must correspond to variables in the VAR statement. When the classification variables are listed in the VAR statement, their corresponding roundoff units are not used. The default number is a missing value, which indicates no rounding for imputed variables.

When specifying a roundoff unit for the first variable only, you must also specify a missing value after the roundoff unit. Otherwise, the roundoff unit is used for all variables. For example, the option “ROUND= 10 .” sets a roundoff unit of 10 for the first analysis variable only and no rounding for the remaining variables. The option “ROUND= . 10” sets a roundoff unit of 10 for the second analysis variable only and no rounding for other variables.

The ROUND= option sets the precision of imputed values. For example, with a roundoff unit of 0.001, each value is rounded to the nearest multiple of 0.001. That is, each value has three significant digits after the decimal point. See [Example 57.3](#) for an illustration of this option.

**SEED=number**

specifies a positive integer to start the pseudo-random number generator. The default is a value generated from reading the time of day from the computer's clock. However, in order to duplicate the results under identical situations, you must use the same value of the seed explicitly in subsequent runs of the MI procedure.

The seed information is displayed in the "Model Information" table so that the results can be reproduced by specifying this seed with the SEED= option. You need to specify the same seed number in the future to reproduce the results.

**SIMPLE**

displays simple descriptive univariate statistics and pairwise correlations from available cases. For a detailed description of these statistics, see the section "Descriptive Statistics" on page 4743.

**SINGULAR=p**

specifies the criterion for determining the singularity of a covariance matrix based on standardized variables, where  $0 < p < 1$ . The default is SINGULAR=1E-8.

Suppose that  $\mathbf{S}$  is a covariance matrix and  $v$  is the number of variables in  $\mathbf{S}$ . Based on the spectral decomposition  $\mathbf{S} = \mathbf{\Gamma}\mathbf{\Lambda}\mathbf{\Gamma}'$ , where  $\mathbf{\Lambda}$  is a diagonal matrix of eigenvalues  $\lambda_j$ ,  $j = 1, \dots, v$ , where  $\lambda_i \geq \lambda_j$  when  $i < j$ , and  $\mathbf{\Gamma}$  is a matrix with the corresponding orthonormal eigenvectors of  $\mathbf{S}$  as columns,  $\mathbf{S}$  is considered singular when an eigenvalue  $\lambda_j$  is less than  $p\bar{\lambda}$ , where the average  $\bar{\lambda} = \sum_{k=1}^v \lambda_k / v$ .

**BY Statement****BY variables ;**

You can specify a BY statement with PROC MI to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MI procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variables* ;

The CLASS statement specifies the classification variables in the VAR statement. Classification variables can be either character or numeric. The CLASS statement must be used in conjunction with either an FCS or MONOTONE statement.

Classification levels are determined from the formatted values of the classification variables. See “The FORMAT Procedure” in the *Base SAS Procedures Guide* for details.

---

## EM Statement

**EM** < *options* > ;

The expectation-maximization (EM) algorithm is a technique for maximum likelihood estimation in parametric models for incomplete data. The EM statement uses the EM algorithm to compute the MLE for  $(\mu, \Sigma)$ , the means and covariance matrix, of a multivariate normal distribution from the input data set with missing values. Either the means and covariances from complete cases or the means and standard deviations from available cases can be used as the initial estimates for the EM algorithm. You can also specify the correlations for the estimates from available cases.

You can also use the EM statement with the NIMPUTE=0 option in the PROC MI statement to compute the EM estimates without multiple imputation, as shown in [Example 57.1](#).

The following seven options are available with the EM statement (in alphabetical order):

**CONVERGE**= $p$

**XCONV**= $p$

sets the convergence criterion. The value must be between 0 and 1. The iterations are considered to have converged when the change in the parameter estimates between iteration steps is less than  $p$  for each parameter—that is, for each of the means and covariances. For each parameter, the change is a relative change if the parameter is greater than 0.01 in absolute value; otherwise, it is an absolute change. By default, CONVERGE=1E-4.

**INITIAL**=CC | AC | AC(R= $r$ )

sets the initial estimates for the EM algorithm. The INITIAL=CC option uses the means and covariances from complete cases; the INITIAL=AC option uses the means and standard deviations from available cases, and the correlations are set to zero; and the INITIAL=AC( R=  $r$ ) option uses the means and standard deviations from available cases with correlation  $r$ , where  $-1/(p - 1) < r < 1$  and  $p$  is the number of variables to be analyzed. The default is INITIAL=AC.

**ITPRINT**

prints the iteration history in the EM algorithm.

**MAXITER**=*number*

specifies the maximum number of iterations used in the EM algorithm. The default is MAXITER=200.

**OUT=SAS-data-set**

creates an output SAS data set that contains results from the EM algorithm. The data set contains all variables in the input data set, with missing values being replaced by the expected values from the EM algorithm. See the section “[Output Data Sets](#)” on page 4767 for a description of this data set.

**OUTEM=SAS-data-set**

creates an output SAS data set of TYPE=COV that contains the MLE of the parameter vector ( $\mu$ ,  $\Sigma$ ). These estimates are computed with the EM algorithm. See the section “[Output Data Sets](#)” on page 4767 for a description of this output data set.

**OUTITER <( options )> =SAS-data-set**

creates an output SAS data set of TYPE=COV that contains parameters for each iteration. The data set includes a variable named `_iteration_` to identify the iteration number. The parameters in the output data set depend on the options specified. You can specify the MEAN and COV options to output the mean and covariance parameters. When no options are specified, the output data set contains the mean parameters for each iteration. See the section “[Output Data Sets](#)” on page 4767 for a description of this data set.

---

## FCS Statement

**FCS** < options > ;

The FCS statement specifies a multivariate imputation by fully conditional specification methods. If you specify an FCS statement, you must also specify a VAR statement.

Table 57.2 summarizes the options available for the FCS statement.

**Table 57.2** Summary of Options in FCS

| Option                     | Description                                    |
|----------------------------|------------------------------------------------|
| <b>Imputation Details</b>  |                                                |
| NBITER=                    | Specifies the number of burn-in iterations     |
| <b>Data Set</b>            |                                                |
| OUTITER=                   | Outputs parameter estimates used in iterations |
| <b>ODS Output Graphics</b> |                                                |
| PLOTS=TRACE                | Displays trace plots                           |
| <b>Imputation Methods</b>  |                                                |
| DISCRIM                    | Specifies the discriminant function method     |
| LOGISTIC                   | Specifies the logistic regression method       |
| REG                        | Specifies the regression method                |
| REGPMM                     | Specifies the predictive mean matching method  |

The following options are available for the FCS statement in addition to the imputation methods specified (in alphabetical order):

**NBITER=number**

specifies the number of burn-in iterations before each imputation. The default is NBITER=20.

**OUTITER <( options )> =SAS-data-set**

creates an output SAS data set of TYPE=COV that contains parameters used in the imputation step for each iteration. The data set includes variables named `_Imputation_` and `_Iteration_` to identify the imputation number and iteration number.

The parameters in the output data set depend on the options specified. You can specify the options MEAN and STD to output parameters of means and standard deviations, respectively. When no options are specified, the output data set contains the mean parameters used in the imputation step for each iteration. See the section “Output Data Sets” on page 4767 for a description of this data set.

**PLOTS <( LOG )> <= TRACE <( trace-options ) >>**

requests statistical graphics of trace plots from iterations via the Output Delivery System (ODS).

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc mi data=Fitness1 seed=501213 mu0=50 10 180;
 mcmc plots=(trace(mean(Oxygen)) acf(mean(Oxygen)));
 var Oxygen RunTime RunPulse;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The global plot option LOG requests that the logarithmic transformations of parameters be used. The default is PLOTS=TRACE(MEAN).

The available *trace-options* are as follows:

**MEAN <( variables ) >**

displays plots of means for continuous variables in the list. When the MEAN option is specified without variables, all continuous variables are used.

**STD <( variables ) >**

displays plots of standard deviations for continuous variables in the list. When the STD option is specified without variables, all continuous variables are used.

The discriminant function, logistic regression, regression, and predictive mean matching methods are available in the FCS statement. You specify each method with the syntax

```
method < (<imputed <= effects >> </ options>) >
```

That is, for each method, you can specify the imputed variables and, optionally, a set of effects to impute these variables. Each effect is a variable or a combination of variables in the VAR statement. The syntax for the specification of effects is the same as for the GLM procedure. See Chapter 42, “The GLM Procedure,” for more information.

One general form of an effect involving several variables is

$$X1 * X2 * A * B * C ( D E )$$

where A, B, C, D, and E are classification variables and X1 and X2 are continuous variables.

When an FCS statement is used without specifying any methods, the regression method is used for all continuous variables and the discriminant function method is used for all classification variables. For each imputed variable, all other variables in the VAR statement are used as the covariates.

When a method for continuous variables is specified without imputed variables, the method is used for all continuous variables in the VAR statement that are not specified in other methods. Similarly, when a method for classification variables is specified without imputed variables, the method is used for all classification variables in the VAR statement that are not specified in other methods.

For each imputed variable, if no covariates are specified, then all other variables in the VAR statement are used as the covariates. That is, each continuous variable is used as a regressor effect, and each classification variable is used as a main effect. For the discriminant function method, only the continuous variables can be used as covariate effects.

With an FCS statement, the variables are imputed sequentially in the order specified in the VAR statement. For a continuous variable, you can use a regression method or a regression predicted mean matching method to impute missing values. For a nominal classification variable, you can use a discriminant function method to impute missing values without using the ordering of the class levels. For an ordinal classification variable, you can use a logistic regression method to impute missing values by using the ordering of the class levels. For a binary classification variable, either a discriminant function method or a logistic regression method can be used. By default, a regression method is used for a continuous variable, and a discriminant function method is used for a classification variable.

Note that except for the regression method, all other methods impute values from the observed values. See the section “[FCS Methods for Data Sets with Arbitrary Missing Patterns](#)” on page 4755 for a detailed description of the FCS methods.

You can specify the following imputation methods in an FCS statement (in alphabetical order):

**DISCRIM** *< ( imputed < = effects > < / options > ) >*

specifies the discriminant function method of classification variables. The available options are DETAILS, PCOV=, PRIOR=, and CLASSEFFECTS=. The DETAILS option displays the group means and pooled covariance matrix used in each imputation. The PCOV= option specifies the pooled covariance used in the discriminant method. Valid values for the PCOV= option are as follows:

|           |                                                                      |
|-----------|----------------------------------------------------------------------|
| FIXED     | uses the observed-data pooled covariance matrix for each imputation. |
| POSTERIOR | draws a pooled covariance matrix from its posterior distribution.    |

The default is PCOV=POSTERIOR. See the section “[Monotone and FCS Discriminant Function Methods](#)” on page 4752 for a detailed description of the method.

The PRIOR= option specifies the prior probabilities of group membership. Valid values for the PRIOR= option are as follows:

|              |                                                                    |
|--------------|--------------------------------------------------------------------|
| EQUAL        | sets the prior probabilities equal for all groups.                 |
| PROPORTIONAL | sets the prior probabilities proportion to the group sample sizes. |

JEFFREYS < =*c* > specifies a noninformative prior,  $0 < c < 1$ . If the number *c* is not specified, JEFFREYS=0.5.

RIDGE < =*d* > specifies a ridge prior,  $d > 0$ . If the number *d* is not specified, RIDGE=0.25.

The default is PRIOR=JEFFREYS. See the section “[Monotone and FCS Discriminant Function Methods](#)” on page 4752 for a detailed description of the method.

The CLASSEFFECTS= option specifies whether the CLASS variables are used as covariate effects. Valid values for the CLASSEFFECTS= option are as follows:

EXCLUDE excludes the CLASS variables from covariate effects.

INCLUDE includes the CLASS variables as covariate effects.

The default is CLASSEFFECTS=EXCLUDE.

**LOGISTIC** < ( *imputed* < = *effects* > < / *options* > ) >

specifies the logistic regression method of classification variables. The available options are DETAILS, ORDER=, and DESCENDING. The DETAILS option displays the regression coefficients in the logistic regression model used in each imputation.

When the imputed variable has more than two response levels, the ordinal logistic regression method is used. The ORDER= option specifies the sort order for the levels of the response variable. Valid values for the ORDER= option are as follows:

DATA sorts by the order of appearance in the input data set.

FORMATTED sorts by their external formatted values.

FREQ sorts by the descending frequency counts.

INTERNAL sorts by the unformatted values.

By default, ORDER=FORMATTED.

The option DESCENDING reverses the sort order for the levels of the response variables.

See the section “[Monotone and FCS Logistic Regression Methods](#)” on page 4754 for a detailed description of the method.

**REG | REGRESSION** < ( *imputed* < = *effects* > < / **DETAILS** > ) >

specifies the regression method of continuous variables. The DETAILS option displays the regression coefficients in the regression model used in each imputation.

With a regression method, the MAXIMUM=, MINIMUM=, and ROUND= options can be used to make the imputed values more consistent with the observed variable values.

See the section “[Monotone and FCS Regression Methods](#)” on page 4749 for a detailed description of the method.

**REGPMM** < ( *imputed* < = *effects* > < *options* > ) >

**REGPREDMEANMATCH** < ( *imputed* < = *effects* > < *options* > ) >

specifies the predictive mean matching method for continuous variables. This method is similar to the regression method except that it imputes a value randomly from a set of observed values whose predicted values are closest to the predicted value for the missing value from the simulated regression model (Heitjan and Little 1991; Schenker and Taylor 1996).

The available options are DETAILS and K=. The DETAILS option displays the regression coefficients in the regression model used in each imputation. The K= option specifies the number of closest observations to be used in the selection. The default is K=5.

See the section “[Monotone and FCS Predictive Mean Matching Methods](#)” on page 4750 for a detailed description of the method.

With an FCS statement, the missing values of variables in the VAR statement are imputed. After the initial filled in, these variables with missing values are imputed sequentially in the order specified in the VAR statement. For example, the following MI procedure statements use the regression method to impute variable y1 from effect y2, the regression method to impute variable y3 from effects y1 and y2, the logistic regression method to impute variable c1 from effects y1, y2, and y1 \* y2, and the default regression method for continuous variables to impute variable y2 from effects y1, y3, and c1:

```
proc mi;
 class c1;
 fcs reg(y1= y2) reg(y3= y1 y2) logistic(c1= y1 y2 y1*y2);
 var y1 y2 y3 c1;
run;
```

---

## FREQ Statement

**FREQ** *variable* ;

To run a procedure on an input data set that contains observations that occur multiple times, you can use a variable in the data set to represent how frequently observations occur and specify a FREQ statement with the name of that variable as its argument (*variable*) when you run the procedure.

When you specify a FREQ statement in other SAS procedures, they treat the data set as if each observation appeared *n* times, where *n* is the value of *variable* in the observation. However, PROC MI treats the data set differently because as PROC MI imputes each missing value in each observation, it generates only one imputed value for that missing value. That is, when you specify a FREQ *variable*, each imputed observation (with its imputed value in place of the missing value) is treated as if it appeared *n* times. In contrast, if an observation actually occurs *n* times in the data set, the missing value at each occurrence is imputed separately, and the resulting *n* observations are not identical.

PROC MI uses only the integer portion of each value of *variable*; if any value is less than 1, PROC MI does not use the corresponding observation in the analysis. When PROC MI calculates significance probabilities, it considers the total number of observations to be equal to the sum of the values of *variable*.

---

## MCMC Statement

**MCMC** < options > ;

The MCMC statement specifies the details of the MCMC method for imputation.

Table 57.3 summarizes the options available for the MCMC statement.

**Table 57.3** Summary of Options in MCMC

| Option                      | Description                                                       |
|-----------------------------|-------------------------------------------------------------------|
| <b>Data Sets</b>            |                                                                   |
| INEST=                      | Inputs parameter estimates for imputations                        |
| OUTEST=                     | Outputs parameter estimates used in imputations                   |
| OUTITER=                    | Outputs parameter estimates used in iterations                    |
| <b>Imputation Details</b>   |                                                                   |
| IMPUTE=                     | Specifies monotone or full imputation                             |
| CHAIN=                      | Specifies single or multiple chain                                |
| NBITER=                     | Specifies the number of burn-in iterations for each chain         |
| NITER=                      | Specifies the number of iterations between imputations in a chain |
| INITIAL=                    | Specifies initial parameter estimates for MCMC                    |
| PRIOR=                      | Specifies the prior parameter information                         |
| START=                      | Specifies starting parameters                                     |
| <b>ODS Output Graphics</b>  |                                                                   |
| PLOTS=TRACE                 | Displays trace plots                                              |
| PLOTS=ACF                   | Displays autocorrelation plots                                    |
| <b>Traditional Graphics</b> |                                                                   |
| TIMEPLOT                    | Displays trace plots                                              |
| ACFPLOT                     | Displays autocorrelation plots                                    |
| GOUT=                       | Specifies the graphics catalog name for saving graphics output    |
| <b>Printed Output</b>       |                                                                   |
| WLF                         | Displays the worst linear function                                |
| DISPLAYINIT                 | Displays initial parameter values for MCMC                        |

The following options are available for the MCMC statement (in alphabetical order).

**ACFPLOT** < (options< / display-options >) >

displays the traditional autocorrelation function plots of parameters from iterations. The ACFPLOT option is applicable only if ODS Graphics is not enabled.

The available options are as follows.

**COV** <( < *variables* > < *variable1\*variable2* > < ... *variable1\*variable2* > ) >

displays plots of variances for variables in the list and covariances for pairs of variables in the list. When the option COV is specified without variables, variances for all variables and covariances for all pairs of variables are used.

**MEAN** <( *variables* ) >

displays plots of means for variables in the list. When the option MEAN is specified without variables, all variables are used.

**WLF**

displays the plot for the worst linear function.

When the ACFPLOT is specified without the preceding options, the procedure displays plots of means for all variables that are used.

The display options provide additional information for the autocorrelation function plots. The available display options are as follows:

**CCONF**=*color*

specifies the color of the displayed confidence limits. The default is CCONF=BLACK.

**CFRAME**=*color*

specifies the color for filling the area enclosed by the axes and the frame. By default, this area is not filled.

**CNEEDLES**=*color*

specifies the color of the vertical line segments (needles) that connect autocorrelations to the reference line. The default is CNEEDLES=BLACK.

**CREF**=*color*

specifies the color of the displayed reference line. The default is CREF=BLACK.

**CSYMBOL**=*color*

specifies the color of the displayed data points. The default is CSYMBOL=BLACK.

**HSYMBOL**=*number*

specifies the height of data points in percentage screen units. The default is HSYMBOL=1.

**LCONF**=*linetype*

specifies the line type for the displayed confidence limits. The default is LCONF=1, a solid line.

**LOG**

requests that the logarithmic transformations of parameters be used to compute the autocorrelations; it is generally used for the variances of variables. When a parameter has values less than or equal to zero, the corresponding plot is not created.

**LREF**=*linetype*

specifies the line type for the displayed reference line. The default is LREF=3, a dashed line.

**NAME=***'string'*

specifies a descriptive name, up to eight characters, that appears in the name field of the PROC GREPLAY master menu. The default is NAME='MI'.

**NLAG=***number*

specifies the maximum lag of the series. The default is NLAG=20. The autocorrelations at each lag are displayed in the graph.

**SYMBOL=***value*

specifies the symbol for data points in percentage screen units. The default is SYMBOL=STAR.

**TITLE=***'string'*

specifies the title to be displayed in the autocorrelation function plots. The default is TITLE='Autocorrelation Plot'.

**WCONF=***number*

specifies the width of the displayed confidence limits in percentage screen units. If you specify the WCONF=0 option, the confidence limits are not displayed. The default is WCONF=1.

**WNEEDLES=***number*

specifies the width of the displayed needles that connect autocorrelations to the reference line, in percentage screen units. If you specify the WNEEDLES=0 option, the needles are not displayed. The default is WNEEDLES=1.

**WREF=***number*

specifies the width of the displayed reference line in percentage screen units. If you specify the WREF=0 option, the reference line is not displayed. The default is WREF=1.

For example, the following statement requests autocorrelation function plots for the means and variances of the variable *y1*, respectively:

```
acfplot (mean(y1) cov(y1) /log);
```

Logarithmic transformations of both the means and variances are used in the plots. For a detailed description of the autocorrelation function plot, see the section “[Autocorrelation Function Plot](#)” on page 4765; see also Schafer (1997, pp. 120–126) and the *SAS/ETS User's Guide*.

**CHAIN=SINGLE | MULTIPLE**

specifies whether a single chain is used for all imputations or a separate chain is used for each imputation. The default is CHAIN=SINGLE.

**DISPLAYINIT**

displays initial parameter values in the MCMC method for each imputation.

**GOUT=***graphics-catalog*

specifies the graphics catalog for saving graphics output from PROC MI. The default is WORK.GSEG. For more information, see “The GREPLAY Procedure” in *SAS/GRAPH: Reference*.

**IMPUTE=FULL | MONOTONE**

specifies whether a full-data imputation is used for all missing values or a monotone-data imputation is used for a subset of missing values to make the imputed data sets have a monotone missing pattern. The default is `IMPUTE=FULL`. When `IMPUTE=MONOTONE` is specified, the order in the `VAR` statement is used to complete the monotone pattern.

**INEST=SAS-data-set**

names a SAS data set of `TYPE=EST` that contains parameter estimates for imputations. These estimates are used to impute values for observations in the `DATA=` data set. A detailed description of the data set is provided in the section “[Input Data Sets](#)” on page 4766.

**INITIAL=EM <(options)>****INITIAL=INPUT=SAS-data-set**

specifies the initial mean and covariance estimates for the MCMC method. The default is `INITIAL=EM`.

You can specify `INITIAL=INPUT=SAS-data-set` to read the initial estimates of the mean and covariance matrix for each imputation from a SAS data set. See the section “[Input Data Sets](#)” on page 4766 for a description of this data set.

With `INITIAL=EM`, PROC MI derives parameter estimates for a posterior mode, the highest observed-data posterior density, from the EM algorithm. The MLE from the EM algorithm is used to start the EM algorithm for the posterior mode, and the resulting EM estimates are used to begin the MCMC method. The prior information specified in the `PRIOR=` option is also used in the process to compute the posterior mode.

The following four options are available with `INITIAL=EM`:

**BOOTSTRAP <=number >**

requests bootstrap resampling, which uses a simple random sample with replacement from the input data set for the initial estimate. You can explicitly specify the number of observations in the random sample. Alternatively, you can implicitly specify the number of observations in the random sample by specifying the proportion  $p$ ,  $0 < p \leq 1$ , to request  $[np]$  observations in the random sample, where  $n$  is the number of observations in the data set and  $[np]$  is the integer part of  $np$ . This produces an overdispersed initial estimate that provides different starting values for the MCMC method. If you specify the `BOOTSTRAP` option without the number,  $p = 0.75$  is used by default.

**CONVERGE= $\rho$** **XCONV= $\rho$** 

sets the convergence criterion. The value must be between 0 and 1. The iterations are considered to have converged when the change in the parameter estimates between iteration steps is less than  $\rho$  for each parameter—that is, for each of the means and covariances. For each parameter, the change is a relative change if the parameter is greater than 0.01 in absolute value; otherwise, it is an absolute change. By default, `CONVERGE=1E-4`.

**ITPRINT**

prints the iteration history in the EM algorithm for the posterior mode.

**MAXITER=number**

specifies the maximum number of iterations used in the EM algorithm. The default is MAXITER=200.

**NBITER=number**

specifies the number of burn-in iterations before the first imputation in each chain. The default is NBITER=200.

**NITER=number**

specifies the number of iterations between imputations in a single chain. The default is NITER=100.

**OUTEST=SAS-data-set**

creates an output SAS data set of TYPE=EST. The data set contains parameter estimates used in each imputation. The data set also includes a variable named `_Imputation_` to identify the imputation number. See the section “[Output Data Sets](#)” on page 4767 for a description of this data set.

**OUTITER < ( options ) > =SAS-data-set**

creates an output SAS data set of TYPE=COV that contains parameters used in the imputation step for each iteration. The data set includes variables named `_Imputation_` and `_Iteration_` to identify the imputation number and iteration number.

The parameters in the output data set depend on the options specified. You can specify the options MEAN, STD, COV, LR, LR\_POST, and WLF to output parameters of means, standard deviations, covariances,  $-2 \log$  LR statistic,  $-2 \log$  LR statistic of the posterior mode, and the worst linear function, respectively. When no options are specified, the output data set contains the mean parameters used in the imputation step for each iteration. See the section “[Output Data Sets](#)” on page 4767 for a description of this data set.

**PLOTS < ( LOG ) > < = plot-request >****PLOTS < ( LOG ) > < = ( plot-request < ... plot-request > ) >**

requests statistical graphics via the Output Delivery System (ODS). To request these graphs, ODS Graphics must be enabled and you must specify options in the MCMC statement. For more information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).”

The global plot option LOG requests that the logarithmic transformations of parameters be used. The plot request options include the following:

**ACF < ( acf-options ) >**

displays plots of the autocorrelation function of parameters from iterations. The default is ACF(MEAN).

**ALL**

produces all appropriate plots.

**NONE**

suppresses all plots.

**TRACE < ( trace-options ) >**

displays trace plots of parameters from iterations. The default is TRACE(MEAN).

The available *acf-options* are as follows:

**NLAG=*n***

specifies the maximum lag of the series. The default is NLAG=20. The autocorrelations at each lag are displayed in the graph.

**COV < ( < *variables* > < *variable1\*variable2* > ... ) >**

displays plots of variances for variables in the list and covariances for pairs of variables in the list. When the option COV is specified without variables, variances for all variables and covariances for all pairs of variables are used.

**MEAN < ( *variables* ) >**

displays plots of means for variables in the list. When the option MEAN is specified without variables, all variables are used.

**WLF**

displays the plot for the worst linear function.

The available *trace-options* are as follows:

**COV < ( < *variables* > < *variable1\*variable2* > ... ) >**

displays plots of variances for variables in the list and covariances for pairs of variables in the list. When the option COV is specified without variables, variances for all variables and covariances for all pairs of variables are used.

**MEAN < ( *variables* ) >**

displays plots of means for variables in the list. When the option MEAN is specified without variables, all variables are used.

**WLF**

displays the plot of the worst linear function.

**PRIOR=*name***

specifies the prior information for the means and covariances. Valid values for *name* are as follows:

JEFFREYS specifies a noninformative prior.

RIDGE=*number* specifies a ridge prior.

INPUT=*SAS-data-set* specifies a data set that contains prior information.

For a detailed description of the prior information, see the section “[Bayesian Estimation of the Mean Vector and Covariance Matrix](#)” on page 4759 and the section “[Posterior Step](#)” on page 4759. If you do not specify the PRIOR= option, the default is PRIOR=JEFFREYS.

The PRIOR=INPUT= option specifies a TYPE=COV data set from which the prior information of the mean vector and the covariance matrix is read. See the section “[Input Data Sets](#)” on page 4766 for a description of this data set.

**START=VALUE | DIST**

specifies that the initial parameter estimates are used either as the starting value (START=VALUE) or as the starting distribution (START=DIST) in the first imputation step of each chain. If the IMPUTE=MONOTONE option is specified, then START=VALUE is used in the procedure. The default is START=VALUE.

**TIMEPLOT** < ( *options* < / *display-options* > ) >

displays the traditional trace (time series) plots of parameters from iterations. The TIMEPLOT option is applicable only if ODS Graphics is not enabled.

The available options are as follows:

**COV** < ( < *variables* > < *variable1\*variable2* > ... ) >

displays plots of variances for variables in the list and covariances for pairs of variables in the list. When the option COV is specified without variables, variances for all variables and covariances for all pairs of variables are used.

**MEAN** < (*variables*)>

displays plots of means for variables in the list. When the option MEAN is specified without variables, all variables are used.

**WLF**

displays the plot of the worst linear function.

When the TIMEPLOT is specified without the preceding options, the procedure displays plots of means for all variables that are used.

The display options provide additional information for the trace plots. The available display options are as follows:

**CCONNECT**=*color*

specifies the color of the line segments that connect data points in the trace plots. The default is CCONNECT=BLACK.

**CFRAME**=*color*

specifies the color for filling the area enclosed by the axes and the frame. By default, this area is not filled.

**CSYMBOL**=*color*

specifies the color of the data points to be displayed in the trace plots. The default is CSYMBOL=BLACK.

**HSYMBOL**=*number*

specifies the height of data points in percentage screen units. The default is HSYMBOL=1.

**LCONNECT**=*linetype*

specifies the line type for the line segments that connect data points in the trace plots. The default is LCONNECT=1, a solid line.

**LOG**

requests that the logarithmic transformations of parameters be used; it is generally used for the variances of variables. When a parameter value is less than or equal to zero, the value is not displayed in the corresponding plot.

**NAME=***string*

specifies a descriptive name, up to eight characters, that appears in the name field of the PROC GREPLAY master menu. The default is NAME='MI'.

**SYMBOL=***value*

specifies the symbol for data points in percentage screen units. The default is SYMBOL=PLUS.

**TITLE=***string*

specifies the title to be displayed in the trace plots. The default is TITLE='Trace Plot'.

**WCONNECT=***number*

specifies the width of the line segments that connect data points in the trace plots, in percentage screen units. If you specify the WCONNECT=0 option, the data points are not connected. The default is WCONNECT=1.

For a detailed description of the trace plot, see the section “[Trace Plot](#)” on page 4765 and Schafer (1997, pp. 120–126).

**WLF**

displays the worst linear function of parameters. This scalar function of parameters  $\mu$  and  $\Sigma$  is “worst” in the sense that its values from iterations converge most slowly among parameters. For a detailed description of this statistic, see the section “[Worst Linear Function of Parameters](#)” on page 4764.

---

## MONOTONE Statement

```
MONOTONE <method <(<imputed <= effects>> </options>)>>
 <...method <(<imputed <= effects>> </options>)>> ;
```

The MONOTONE statement specifies imputation methods for data sets with monotone missingness. You must also specify a VAR statement, and the data set must have a monotone missing pattern with variables ordered in the VAR list.

Table 57.4 summarizes the options available for the MONOTONE statement.

**Table 57.4** Summary of Imputation Methods in MONOTONE Statement

| Option     | Description                                   |
|------------|-----------------------------------------------|
| DISCRIM    | Specifies the discriminant function method    |
| LOGISTIC   | Specifies the logistic regression method      |
| PROPENSITY | Specifies the propensity scores method        |
| REG        | Specifies the regression method               |
| REGPMM     | Specifies the predictive mean matching method |

For each method, you can specify the imputed variables and, optionally, a set of the effects to impute these variables. Each effect is a variable or a combination of variables preceding the imputed variable in the VAR statement. The syntax for specification of effects is the same as for the GLM procedure. See Chapter 42, “The GLM Procedure,” for more information.

One general form of an effect involving several variables is

$$X1 * X2 * A * B * C ( D E )$$

where A, B, C, D, and E are classification variables and X1 and X2 are continuous variables.

If no covariates are specified, then all preceding variables are used as the covariates. That is, each preceding continuous variable is used as a regressor effect, and each preceding classification variable is used as a main effect. For the discriminant function method, only the continuous variables can be used as covariate effects.

When a method for continuous variables is specified without imputed variables, the method is used for all continuous variables in the VAR statement that are not specified in other methods. Similarly, when a method for classification variables is specified without imputed variables, the method is used for all classification variables in the VAR statement that are not specified in other methods.

When a MONOTONE statement is used without specifying any methods, the regression method is used for all continuous variables and the discriminant function method is used for all classification variables. The preceding variables of each imputed variable in the VAR statement are used as the covariates.

With a MONOTONE statement, the variables are imputed sequentially in the order given by the VAR statement. For a continuous variable, you can use a regression method, a regression predicted mean matching method, or a propensity score method to impute missing values.

For a nominal classification variable, you can use a discriminant function method to impute missing values without using the ordering of the class levels. For an ordinal classification variable, you can use a logistic regression method to impute missing values by using the ordering of the class levels. For a binary classification variable, either a discriminant function method or a logistic regression method can be used.

Note that except for the regression method, all other methods impute values from the observed observation values. You can specify the following methods in a MONOTONE statement.

**DISCRIM** < ( *imputed* < = *effects* > < / *options* > ) >

specifies the discriminant function method of classification variables. The available options are DETAILS, PCOV=, PRIOR=, and CLASSEFFECTS=. The DETAILS option displays the group means and pooled covariance matrix used in each imputation. The PCOV= option specifies the pooled covariance used in the discriminant method. Valid values for the PCOV= option are as follows:

|           |                                                                      |
|-----------|----------------------------------------------------------------------|
| FIXED     | uses the observed-data pooled covariance matrix for each imputation. |
| POSTERIOR | draws a pooled covariance matrix from its posterior distribution.    |

The default is PCOV=POSTERIOR. See the section “[Monotone and FCS Discriminant Function Methods](#)” on page 4752 for a detailed description of the method.

The PRIOR= option specifies the prior probabilities of group membership. Valid values for the PRIOR= option are as follows:

|              |                                                                    |
|--------------|--------------------------------------------------------------------|
| EQUAL        | sets the prior probabilities equal for all groups.                 |
| PROPORTIONAL | sets the prior probabilities proportion to the group sample sizes. |

**JEFFREYS** < =*c* > specifies a noninformative prior,  $0 < c < 1$ . If the number *c* is not specified, JEFFREYS=0.5.

**RIDGE** < =*d* > specifies a ridge prior,  $d > 0$ . If the number *d* is not specified, RIDGE=0.25.

The default is PRIOR=JEFFREYS. See the section “[Monotone and FCS Discriminant Function Methods](#)” on page 4752 for a detailed description of the method.

The CLASSEFFECTS= option specifies whether the CLASS variables are used as covariate effects. Valid values for the CLASSEFFECTS= option are as follows:

**EXCLUDE** excludes the CLASS variables from covariate effects.

**INCLUDE** includes the CLASS variables as covariate effects.

The default is CLASSEFFECTS=EXCLUDE.

**LOGISTIC** < ( *imputed* < = *effects* > < / *options* > ) >

specifies the logistic regression method of classification variables. The available options are DETAILS, ORDER=, and DESCENDING. The DETAILS option displays the regression coefficients in the logistic regression model used in each imputation.

When the imputed variable has more than two response levels, the ordinal logistic regression method is used. The ORDER= option specifies the sort order for the levels of the response variable. Valid values for the ORDER= option are as follows:

**DATA** sorts by the order of appearance in the input data set.

**FORMATTED** sorts by their external formatted values.

**FREQ** sorts by the descending frequency counts.

**INTERNAL** sorts by the unformatted values.

By default, ORDER=FORMATTED.

The option DESCENDING reverses the sort order for the levels of the response variables.

See the section “[Monotone and FCS Logistic Regression Methods](#)” on page 4754 for a detailed description of the method.

**PROPNENSITY** < ( *imputed* < = *effects* > < / *options* > ) >

specifies the propensity scores method of variables. Each variable is either a classification variable or a continuous variable. The available options are DETAILS and NGROUPS=. The DETAILS option displays the regression coefficients in the logistic regression model for propensity scores. The NGROUPS= option specifies the number of groups created based on propensity scores. The default is NGROUPS=5.

See the section “[Monotone Propensity Score Method](#)” on page 4751 for a detailed description of the method.

**REG | REGRESSION** < ( *imputed* < = *effects* > < / **DETAILS** > ) >

specifies the regression method of continuous variables. The DETAILS option displays the regression coefficients in the regression model used in each imputation.

With a regression method, the MAXIMUM=, MINIMUM=, and ROUND= options can be used to make the imputed values more consistent with the observed variable values.

See the section “[Monotone and FCS Regression Methods](#)” on page 4749 for a detailed description of the method.

**REGPMM** < ( *imputed* < = *effects* > < *options* > ) >

**REGPREDMEANMATCH** < ( *imputed* < = *effects* > < *options* > ) >

specifies the predictive mean matching method for continuous variables. This method is similar to the regression method except that it imputes a value randomly from a set of observed values whose predicted values are closest to the predicted value for the missing value from the simulated regression model (Heitjan and Little 1991; Schenker and Taylor 1996).

The available options are DETAILS and K=. The DETAILS option displays the regression coefficients in the regression model used in each imputation. The K= option specifies the number of closest observations to be used in the selection. The default is K=5.

See the section “[Monotone and FCS Predictive Mean Matching Methods](#)” on page 4750 for a detailed description of the method.

With a MONOTONE statement, the missing values of a variable are imputed when the variable is either explicitly specified in the method or implicitly specified when a method is specified without imputed variables. These variables are imputed sequentially in the order specified in the VAR statement. For example, the following MI procedure statements use the logistic regression method to impute variable c1 from effects y1, y2, and y1 \* y2 first, and then use the regression method to impute variable y3 from effects y1, y2, and c1:

```
proc mi;
 class c1;
 var y1 y2 c1 y3;
 monotone reg(y3= y1 y2 c1) logistic(c1= y1 y2 y1*y2);
run;
```

The variables y1 and y2 are not imputed since y1 is the leading variable in the VAR statement and y2 is not specified as an imputed variable in the MONOTONE statement.

---

## TRANSFORM Statement

**TRANSFORM** *transform* (*variables*</ *options*>)< . . . *transform* (*variables*</ *options*>)> ;

The TRANSFORM statement lists the transformations and their associated variables to be transformed. The options are transformation options that provide additional information for the transformation.

The MI procedure assumes that the data are from a multivariate normal distribution when either the regression method or the MCMC method is used. When some variables in a data set are clearly non-normal, it is useful to transform these variables to conform to the multivariate normality assumption. With a TRANSFORM statement, variables are transformed before the imputation process, and these transformed variable values are displayed in all of the results. When you specify an OUT= option, the variable values are back-transformed to create the imputed data set.

The following transformations can be used in the TRANSFORM statement:

**BOXCOX**

specifies the Box-Cox transformation of variables. The variable  $Y$  is transformed to  $\frac{(Y+c)^\lambda - 1}{\lambda}$ , where  $c$  is a constant such that each value of  $Y + c$  must be positive. If the specified constant  $\lambda = 0$ , the logarithmic transformation is used.

**EXP**

specifies the exponential transformation of variables. The variable  $Y$  is transformed to  $e^{(Y+c)}$ , where  $c$  is a constant.

**LOG**

specifies the logarithmic transformation of variables. The variable  $Y$  is transformed to  $\log(Y + c)$ , where  $c$  is a constant such that each value of  $Y + c$  must be positive.

**LOGIT**

specifies the logit transformation of variables. The variable  $Y$  is transformed to  $\log\left(\frac{Y/c}{1-Y/c}\right)$ , where the constant  $c > 0$  and the values of  $Y/c$  must be between 0 and 1.

**POWER**

specifies the power transformation of variables. The variable  $Y$  is transformed to  $(Y + c)^\lambda$ , where  $c$  is a constant such that each value of  $Y + c$  must be positive and the constant  $\lambda \neq 0$ .

The following options provide the constant  $c$  and  $\lambda$  values in the transformations.

**C=number**

specifies the  $c$  value in the transformation. The default is  $c = 1$  for logit transformation and  $c = 0$  for other transformations.

**LAMBDA=number**

specifies the  $\lambda$  value in the power and Box-Cox transformations. You must specify the  $\lambda$  value for these two transformations.

For example, the following statement requests that variables  $\log(y1)$ , a logarithmic transformation for the variable  $y1$ , and  $\sqrt{y2 + 1}$ , a power transformation for the variable  $y2$ , be used in the imputation:

```
transform log(y1) power(y2/c=1 lambda=.5);
```

If the MU0= option is used to specify a parameter value  $\mu_0$  for a transformed variable, the same transformation for the variable is also applied to its corresponding MU0= value in the  $t$  test. Otherwise,  $\mu_0 = 0$  is used for the transformed variable. See [Example 57.10](#) for a usage of the TRANSFORM statement.

## VAR Statement

**VAR** *variables* ;

The VAR statement lists the variables to be analyzed. The variables can be either character or numeric. If you omit the VAR statement, all continuous variables not mentioned in other statements are used. The VAR statement is required if you specify either an FCS statement, a MONOTONE statement, an IMPUTE=MONOTONE option in the MCMC statement, or more than one number in the MU0=, MAXIMUM=, MINIMUM=, or ROUND= option.

The classification variables in the VAR statement, which can be either character or numeric, are further specified in the CLASS statement.

---

## Details: MI Procedure

---

### Descriptive Statistics

Suppose  $\mathbf{Y} = (\mathbf{y}_1, \mathbf{y}_2, \dots, \mathbf{y}_n)'$  is the  $(n \times p)$  matrix of complete data, which might not be fully observed,  $n_0$  is the number of observations fully observed, and  $n_j$  is the number of observations with observed values for variable  $Y_j$ .

With complete cases, the sample mean vector is

$$\bar{\mathbf{y}} = \frac{1}{n_0} \sum \mathbf{y}_i$$

and the CSSCP matrix is

$$\sum (\mathbf{y}_i - \bar{\mathbf{y}})(\mathbf{y}_i - \bar{\mathbf{y}})'$$

where each summation is over the fully observed observations.

The sample covariance matrix is

$$\mathbf{S} = \frac{1}{n_0 - 1} \sum (\mathbf{y}_i - \bar{\mathbf{y}})(\mathbf{y}_i - \bar{\mathbf{y}})'$$

and is an unbiased estimate of the covariance matrix.

The correlation matrix  $\mathbf{R}$ , which contains the Pearson product-moment correlations of the variables, is derived by scaling the corresponding covariance matrix:

$$\mathbf{R} = \mathbf{D}^{-1} \mathbf{S} \mathbf{D}^{-1}$$

where  $\mathbf{D}$  is a diagonal matrix whose diagonal elements are the square roots of the diagonal elements of  $\mathbf{S}$ .

With available cases, the corrected sum of squares for variable  $Y_j$  is

$$\sum (y_{ji} - \bar{y}_j)^2$$

where  $\bar{y}_j = \frac{1}{n_j} \sum y_{ji}$  is the sample mean and each summation is over observations with observed values for variable  $Y_j$ .

The variance is

$$s_{jj}^2 = \frac{1}{n_j - 1} \sum (y_{ji} - \bar{y}_j)^2$$

The correlations for available cases contain pairwise correlations for each pair of variables. Each correlation is computed from all observations that have nonmissing values for the corresponding pair of variables.

## EM Algorithm for Data with Missing Values

The EM algorithm (Dempster, Laird, and Rubin 1977) is a technique that finds maximum likelihood estimates in parametric models for incomplete data. For a detailed description and applications of the EM algorithm, see the books by Little and Rubin (2002); Schafer (1997); McLachlan and Krishnan (1997).

The EM algorithm is an iterative procedure that finds the MLE of the parameter vector by repeating the following steps:

### 1. The expectation E-step

Given a set of parameter estimates, such as a mean vector and covariance matrix for a multivariate normal distribution, the E-step calculates the conditional expectation of the complete-data log likelihood given the observed data and the parameter estimates.

### 2. The maximization M-step

Given a complete-data log likelihood, the M-step finds the parameter estimates to maximize the complete-data log likelihood from the E-step.

The two steps are iterated until the iterations converge.

In the EM process, the observed-data log likelihood is nondecreasing at each iteration. For multivariate normal data, suppose there are  $G$  groups with distinct missing patterns. Then the observed-data log likelihood being maximized can be expressed as

$$\log L(\theta|Y_{obs}) = \sum_{g=1}^G \log L_g(\theta|Y_{obs})$$

where  $\log L_g(\theta|Y_{obs})$  is the observed-data log likelihood from the  $g$ th group, and

$$\log L_g(\theta|Y_{obs}) = -\frac{n_g}{2} \log |\Sigma_g| - \frac{1}{2} \sum_{i_g} (\mathbf{y}_{i_g} - \boldsymbol{\mu}_g)' \Sigma_g^{-1} (\mathbf{y}_{i_g} - \boldsymbol{\mu}_g)$$

where  $n_g$  is the number of observations in the  $g$ th group, the summation is over observations in the  $g$ th group,  $\mathbf{y}_{i_g}$  is a vector of observed values corresponding to observed variables,  $\boldsymbol{\mu}_g$  is the corresponding mean vector, and  $\Sigma_g$  is the associated covariance matrix.

A sample covariance matrix is computed at each step of the EM algorithm. If the covariance matrix is singular, the linearly dependent variables for the observed data are excluded from the likelihood function. That is, for each observation with linear dependency among its observed variables, the dependent variables are excluded from the likelihood function. Note that this can result in an unexpected change in the likelihood between iterations prior to the final convergence.

See Schafer (1997, pp. 163–181) for a detailed description of the EM algorithm for multivariate normal data.

PROC MI uses the means and standard deviations from available cases as the initial estimates for the EM algorithm. The correlations are set to zero. These initial estimates provide a good starting value with positive definite covariance matrix. For a discussion of suggested starting values for the algorithm, see Schafer (1997, p. 169).

You can specify the convergence criterion with the `CONVERGE=` option in the EM statement. The iterations are considered to have converged when the maximum change in the parameter estimates between iteration steps is less than the value specified. You can also specify the maximum number of iterations used in the EM algorithm with the `MAXITER=` option.

The MI procedure displays tables of the initial parameter estimates used to begin the EM process and the MLE parameter estimates derived from EM. You can also display the EM iteration history with the `ITPRINT` option. PROC MI lists the iteration number, the likelihood  $-2 \log L$ , and the parameter values  $\mu$  at each iteration. You can also save the MLE derived from the EM algorithm in a SAS data set by specifying the `OUTEM=` option.

---

## Statistical Assumptions for Multiple Imputation

The MI procedure assumes that the data are from a continuous multivariate distribution and contain missing values that can occur for any of the variables. It also assumes that the data are from a multivariate normal distribution when either the regression method or the MCMC method is used.

Suppose  $\mathbf{Y}$  is the  $n \times p$  matrix of complete data, which is not fully observed, and denote the observed part of  $\mathbf{Y}$  by  $\mathbf{Y}_{obs}$  and the missing part by  $\mathbf{Y}_{mis}$ . The MI and MIANALYZE procedures assume that the missing data are missing at random (MAR); that is, the probability that an observation is missing can depend on  $\mathbf{Y}_{obs}$ , but not on  $\mathbf{Y}_{mis}$  (Rubin 1976, 1987, p. 53).

To be more precise, suppose that  $\mathbf{R}$  is the  $n \times p$  matrix of response indicators whose elements are zero or one depending on whether the corresponding elements of  $\mathbf{Y}$  are missing or observed. Then the MAR assumption is that the distribution of  $\mathbf{R}$  can depend on  $\mathbf{Y}_{obs}$  but not on  $\mathbf{Y}_{mis}$ :

$$\text{pr}(\mathbf{R} | \mathbf{Y}_{obs}, \mathbf{Y}_{mis}) = \text{pr}(\mathbf{R} | \mathbf{Y}_{obs})$$

For example, consider a trivariate data set with variables  $Y_1$  and  $Y_2$  fully observed, and a variable  $Y_3$  that has missing values. MAR assumes that the probability that  $Y_3$  is missing for an individual can be related to the individual's values of variables  $Y_1$  and  $Y_2$ , but not to its value of  $Y_3$ . On the other hand, if a complete case and an incomplete case for  $Y_3$  with exactly the same values for variables  $Y_1$  and  $Y_2$  have systematically different values, then there exists a response bias for  $Y_3$ , and MAR is violated.

The MAR assumption is not the same as missing completely at random (MCAR), which is a special case of MAR. Under the MCAR assumption, the missing data values are a simple random sample of all data values; the missingness does not depend on the values of any variables in the data set.

Although the MAR assumption cannot be verified with the data and it can be questionable in some situations, the assumption becomes more plausible as more variables are included in the imputation model (Schafer 1997, pp. 27–28; van Buuren, Boshuizen, and Knook 1999, p. 687).

Furthermore, the MI and MIANALYZE procedures assume that the parameters  $\theta$  of the data model and the parameters  $\phi$  of the model for the missing-data indicators are distinct. That is, knowing the values of  $\theta$  does not provide any additional information about  $\phi$ , and vice versa. If both the MAR and distinctness assumptions are satisfied, the missing-data mechanism is said to be ignorable Rubin 1987, pp. 50–54; Schafer 1997, pp. 10–11).

## Missing Data Patterns

The MI procedure sorts the data into groups based on whether the analysis variables are observed or missing. Note that the input data set does not need to be sorted in any order.

For example, with variables  $Y_1$ ,  $Y_2$ , and  $Y_3$  (in that order) in a data set, up to eight groups of observations can be formed from the data set. Figure 57.6 displays the eight groups of observations and an unique missing pattern for each group.

**Figure 57.6** Missing Data Patterns

| Missing Data Patterns |    |    |    |  |
|-----------------------|----|----|----|--|
| Group                 | Y1 | Y2 | Y3 |  |
| 1                     | X  | X  | X  |  |
| 2                     | X  | X  | .  |  |
| 3                     | X  | .  | X  |  |
| 4                     | X  | .  | .  |  |
| 5                     | .  | X  | X  |  |
| 6                     | .  | X  | .  |  |
| 7                     | .  | .  | X  |  |
| 8                     | .  | .  | .  |  |

Here, an “X” means that the variable is observed in the corresponding group and a “.” means that the variable is missing.

The variable order is used to derive the order of the groups from the data set, and thus determines the order of missing values in the data to be imputed. If you specify a different order of variables in the VAR statement, then the results are different even if the other specifications remain the same.

A data set with variables  $Y_1, Y_2, \dots, Y_p$  (in that order) is said to have a *monotone missing pattern* when the event that a variable  $Y_j$  is missing for a particular individual implies that all subsequent variables  $Y_k, k > j$ , are missing for that individual. Alternatively, when a variable  $Y_j$  is observed for a particular individual, it is assumed that all previous variables  $Y_k, k < j$ , are also observed for that individual.

For example, Figure 57.7 displays a data set of three variables with a monotone missing pattern.

**Figure 57.7** Monotone Missing Patterns

| Monotone Missing Data Patterns |    |    |    |  |
|--------------------------------|----|----|----|--|
| Group                          | Y1 | Y2 | Y3 |  |
| 1                              | X  | X  | X  |  |
| 2                              | X  | X  | .  |  |
| 3                              | X  | .  | .  |  |

Figure 57.8 displays a data set of three variables with a non-monotone missing pattern.

**Figure 57.8** Non-monotone Missing Patterns

| Non-monotone Missing Data Patterns |    |    |    |  |
|------------------------------------|----|----|----|--|
| Group                              | Y1 | Y2 | Y3 |  |
| 1                                  | X  | X  | X  |  |
| 2                                  | X  | .  | X  |  |
| 3                                  | .  | X  | .  |  |
| 4                                  | .  | .  | X  |  |

A data set with an *arbitrary missing pattern* is a data set with either a monotone missing pattern or a non-monotone missing pattern.

## Imputation Methods

This section describes the methods for multiple imputation that are available in the MI procedure. The method of choice depends on the pattern of missingness in the data and the type of the imputed variable, as summarized in Table 57.5.

**Table 57.5** Imputation Methods in PROC MI

| Pattern of Missingness | Type of Imputed Variable | Type of Covariates | Available Methods                                                                                                                                        |
|------------------------|--------------------------|--------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------|
| Monotone               | Continuous               | Arbitrary          | <ul style="list-style-type: none"> <li>• Monotone regression</li> <li>• Monotone predicted mean matching</li> <li>• Monotone propensity score</li> </ul> |
| Monotone               | Classification (ordinal) | Arbitrary          | <ul style="list-style-type: none"> <li>• Monotone logistic regression</li> </ul>                                                                         |
| Monotone               | Classification (nominal) | Arbitrary          | <ul style="list-style-type: none"> <li>• Monotone discriminant function</li> </ul>                                                                       |
| Arbitrary              | Continuous               | Continuous         | <ul style="list-style-type: none"> <li>• MCMC full-data imputation</li> <li>• MCMC monotone-data imputation</li> </ul>                                   |
| Arbitrary              | Continuous               | Arbitrary          | <ul style="list-style-type: none"> <li>• FCS regression</li> <li>• FCS predicted mean matching</li> </ul>                                                |
| Arbitrary              | Classification (ordinal) | Arbitrary          | <ul style="list-style-type: none"> <li>• FCS logistic regression</li> </ul>                                                                              |
| Arbitrary              | Classification (nominal) | Arbitrary          | <ul style="list-style-type: none"> <li>• FCS discriminant function</li> </ul>                                                                            |

To impute missing values for a continuous variable in data sets with monotone missing patterns, you should use either a parametric method that assumes multivariate normality or a nonparametric method that uses propensity scores (Rubin 1987, pp. 124, 158; Lavori, Dawson, and Shera 1995). Parametric methods available include the regression method (Rubin 1987, pp. 166–167) and the predictive mean matching method (Heitjan and Little 1991; Schenker and Taylor 1996).

To impute missing values for a classification variable in data sets with monotone missing patterns, you should use the logistic regression method or the discriminant function method. Use the logistic regression method when the classification variable has a binary or ordinal response, and use the discriminant function method when the classification variable has a binary or nominal response.

For data sets with arbitrary missing patterns, you can use either of the following methods to impute missing values: a Markov chain Monte Carlo (MCMC) method (Schafer 1997) that assumes multivariate normality, or a fully conditional specification (FCS) method (van Buuren 2007; Brand 1999) that assumes the existence of a joint distribution for all variables.

For continuous variables in data sets with arbitrary missing patterns, you can use the MCMC method to impute either all the missing values or just enough missing values to make the imputed data sets have monotone missing patterns. With a monotone missing data pattern, you have greater flexibility in your choice of imputation models. In addition to the MCMC method, you can implement other methods, such as the regression method, that do not use Markov chains. You can also specify a different set of covariates for each imputed variable.

Although the regression and MCMC methods assume multivariate normality, inferences based on multiple imputation can be robust to departures from multivariate normality if the amount of missing information is not large, because the imputation model is effectively applied not to the entire data set but only to its missing part (Schafer 1997, pp.147–148).

To impute missing values for both continuous and classification variables in data sets with arbitrary missing patterns, you can use FCS methods to impute missing values for all variables assuming a joint distribution for these variables exists (Brand 1999; van Buuren 2007). Similar to the methods of imputing missing values for variables in data sets with monotone missing patterns, you can use the regression and predictive mean matching methods to impute missing values for a continuous variable, and use the logistic regression method to impute missing values for a classification variable when the variable has a binary or ordinal response, or use the discriminant function method when the variable has a binary or nominal response.

You can also use a TRANSFORM statement to transform variables to conform to the multivariate normality assumption. Variables are transformed before the imputation process and then are reverse-transformed to create the imputed data set. All continuous variables are standardized before the imputation process and then are transformed back to the original scale after the imputation process.

Li (1988) presents a theoretical argument for convergence of the MCMC method in the continuous case and uses it to create imputations for incomplete multivariate continuous data. In practice, however, it is not easy to check the convergence of a Markov chain, especially for a large number of parameters. PROC MI generates statistics and plots that you can use to check for convergence of the MCMC method. The details are described in the section “[Checking Convergence in MCMC](#)” on page 4764.

---

## Monotone Methods for Data Sets with Monotone Missing Patterns

For data sets with monotone missing data patterns, you can use monotone methods to impute missing values for the variables. A monotone method creates multiple imputations by imputing missing values sequentially over the variables taken one at a time.

For example, with variables  $Y_1, Y_2, \dots, Y_p$  (in that order) in the VAR statement, a monotone method sequentially simulates a draw for missing values for variables  $Y_2, \dots, Y_p$ . That is, the missing values are imputed by using the sequence

$$\begin{aligned}
\theta_2^{(*)} &\sim P(\theta_2 | Y_{1(obs)}, Y_{2(obs)}) \\
Y_2^{(*)} &\sim P(Y_2 | \theta_2^{(*)}) \\
&\dots \\
&\dots \\
\theta_p^{(*)} &\sim P(\theta_p | Y_{1(obs)}, \dots, Y_{p(obs)}) \\
Y_p^{(*)} &\sim P(Y_p | \theta_p^{(*)})
\end{aligned}$$

where  $Y_{j(obs)}$  is the set of observed  $Y_j$  values,  $\theta_j^{(*)}$  is the set of simulated parameters for the conditional distribution of  $Y_j$  given covariates constructed from variables  $Y_1, Y_2, \dots, Y_{j-1}$ , and  $Y_j^{(*)}$  is the set of imputed  $Y_j$  values.

The missing values for the leading variable  $Y_1$  are not imputed, and missing values for  $Y_2, \dots, Y_p$  are not imputed for those observations with missing  $Y_1$  values. For each subsequent variable  $Y_j$  with missing values, the corresponding imputation method is used to fit a model with covariates constructed from its preceding variables  $Y_1, Y_2, \dots, Y_{j-1}$ . The observed observations for  $Y_j$ , which include only observations with observed values for  $Y_1, Y_2, \dots, Y_{j-1}$ , are used in the model fitting. With this resulting model, a new model is drawn and then used to impute missing values for  $Y_j$ .

You can specify a separate monotone method for each imputed variable. If a method is not specified for the variable, then the default method is used. That is, a regression method is used for a continuous variable and a discriminant function method is used for a classification variable. For each imputed variable, you can also specify a set of covariates that are constructed from its preceding variables. If a set of covariates is not specified for the variable, all preceding variables in the VAR list are used as covariates.

You can use a regression method, a predictive mean matching method, or a propensity score method to impute missing values for a continuous variable; a logistic regression method for a classification variable with a binary or ordinal response; and a discriminant function method for a classification variable with a binary or nominal response. See the sections “[Monotone and FCS Regression Methods](#)” on page 4749, “[Monotone and FCS Predictive Mean Matching Methods](#)” on page 4750, “[Monotone Propensity Score Method](#)” on page 4751, “[Monotone and FCS Discriminant Function Methods](#)” on page 4752, and “[Monotone and FCS Logistic Regression Methods](#)” on page 4754 for these methods.

---

## Monotone and FCS Regression Methods

The regression method is the default imputation method in the MONOTONE and FCS statements for continuous variables.

In the regression method, a regression model is fitted for a continuous variable with the covariates constructed from a set of effects. Based on the fitted regression model, a new regression model is simulated from the posterior predictive distribution of the parameters and is used to impute the missing values for each variable (Rubin 1987, pp. 166–167). That is, for a continuous variable  $Y_j$  with missing values, a model

$$Y_j = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k$$

is fitted using observations with observed values for the variable  $Y_j$  and its covariates  $X_1, X_2, \dots, X_k$ .

The fitted model includes the regression parameter estimates  $\hat{\boldsymbol{\beta}} = (\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k)$  and the associated covariance matrix  $\hat{\sigma}_j^2 \mathbf{V}_j$ , where  $\mathbf{V}_j$  is the usual  $\mathbf{X}'\mathbf{X}$  inverse matrix derived from the intercept and covariates  $X_1, X_2, \dots, X_k$ .

The following steps are used to generate imputed values for each imputation:

1. New parameters  $\boldsymbol{\beta}_* = (\beta_{*0}, \beta_{*1}, \dots, \beta_{*(k)})$  and  $\sigma_{*j}^2$  are drawn from the posterior predictive distribution of the parameters. That is, they are simulated from  $(\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k)$ ,  $\sigma_j^2$ , and  $\mathbf{V}_j$ . The variance is drawn as

$$\sigma_{*j}^2 = \hat{\sigma}_j^2 (n_j - k - 1) / g$$

where  $g$  is a  $\chi_{n_j - k - 1}^2$  random variate and  $n_j$  is the number of nonmissing observations for  $Y_j$ . The regression coefficients are drawn as

$$\boldsymbol{\beta}_* = \hat{\boldsymbol{\beta}} + \sigma_{*j} \mathbf{V}'_{hj} \mathbf{Z}$$

where  $\mathbf{V}_{hj}$  is the upper triangular matrix in the Cholesky decomposition,  $\mathbf{V}_j = \mathbf{V}'_{hj} \mathbf{V}_{hj}$ , and  $\mathbf{Z}$  is a vector of  $k + 1$  independent random normal variates.

2. The missing values are then replaced by

$$\beta_{*0} + \beta_{*1} x_1 + \beta_{*2} x_2 + \dots + \beta_{*(k)} x_k + z_i \sigma_{*j}$$

where  $x_1, x_2, \dots, x_k$  are the values of the covariates and  $z_i$  is a simulated normal deviate.

## Monotone and FCS Predictive Mean Matching Methods

The predictive mean matching method is also an imputation method available for continuous variables. It is similar to the regression method except that for each missing value, it imputes a value randomly from a set of observed values whose predicted values are closest to the predicted value for the missing value from the simulated regression model (Heitjan and Little 1991; Schenker and Taylor 1996).

Following the description of the model in the section “[Monotone and FCS Regression Methods](#)” on page 4749, the following steps are used to generate imputed values:

1. New parameters  $\boldsymbol{\beta}_* = (\beta_{*0}, \beta_{*1}, \dots, \beta_{*(k)})$  and  $\sigma_{*j}^2$  are drawn from the posterior predictive distribution of the parameters. That is, they are simulated from  $(\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k)$ ,  $\sigma_j^2$ , and  $\mathbf{V}_j$ . The variance is drawn as

$$\sigma_{*j}^2 = \hat{\sigma}_j^2 (n_j - k - 1) / g$$

where  $g$  is a  $\chi_{n_j - k - 1}^2$  random variate and  $n_j$  is the number of nonmissing observations for  $Y_j$ . The regression coefficients are drawn as

$$\boldsymbol{\beta}_* = \hat{\boldsymbol{\beta}} + \sigma_{*j} \mathbf{V}'_{hj} \mathbf{Z}$$

where  $\mathbf{V}_{hj}$  is the upper triangular matrix in the Cholesky decomposition,  $\mathbf{V}_j = \mathbf{V}'_{hj} \mathbf{V}_{hj}$ , and  $\mathbf{Z}$  is a vector of  $k + 1$  independent random normal variates.

2. For each missing value, a predicted value

$$y_{i*} = \beta_{*0} + \beta_{*1} x_1 + \beta_{*2} x_2 + \dots + \beta_{*(k)} x_k$$

is computed with the covariate values  $x_1, x_2, \dots, x_k$ .

3. A set of  $k_0$  observations whose corresponding predicted values are closest to  $y_{i*}$  is generated. You can specify  $k_0$  with the `K=` option.
4. The missing value is then replaced by a value drawn randomly from these  $k_0$  observed values.

The predictive mean matching method requires the number of closest observations to be specified. A smaller  $k_0$  tends to increase the correlation among the multiple imputations for the missing observation and results in a higher variability of point estimators in repeated sampling. On the other hand, a larger  $k_0$  tends to lessen the effect from the imputation model and results in biased estimators (Schenker and Taylor 1996, p. 430).

The predictive mean matching method ensures that imputed values are plausible; it might be more appropriate than the regression method if the normality assumption is violated (Horton and Lipsitz 2001, p. 246).

---

## Monotone Propensity Score Method

The propensity score method is another imputation method available for continuous variables when the data set has a monotone missing pattern.

A propensity score is generally defined as the conditional probability of assignment to a particular treatment given a vector of observed covariates (Rosenbaum and Rubin 1983). In the propensity score method, for a variable with missing values, a propensity score is generated for each observation to estimate the probability that the observation is missing. The observations are then grouped based on these propensity scores, and an approximate Bayesian bootstrap imputation (Rubin 1987, p. 124) is applied to each group (Lavori, Dawson, and Shera 1995).

The propensity score method uses the following steps to impute values for variable  $Y_j$  with missing values:

1. Creates an indicator variable  $R_j$  with the value 0 for observations with missing  $Y_j$  and 1 otherwise.
2. Fits a logistic regression model

$$\text{logit}(p_j) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k$$

where  $X_1, X_2, \dots, X_k$  are covariates for  $Y_j$ ,  $p_j = \Pr(R_j = 0 | X_1, X_2, \dots, X_k)$ , and  $\text{logit}(p) = \log(p/(1-p))$ .

3. Creates a propensity score for each observation to estimate the probability that it is missing.
4. Divides the observations into a fixed number of groups (typically assumed to be five) based on these propensity scores.
5. Applies an approximate Bayesian bootstrap imputation to each group. In group  $k$ , suppose that  $Y_{obs}$  denotes the  $n_1$  observations with nonmissing  $Y_j$  values and  $Y_{mis}$  denotes the  $n_0$  observations with missing  $Y_j$ . The approximate Bayesian bootstrap imputation first draws  $n_1$  observations randomly with replacement from  $Y_{obs}$  to create a new data set  $Y_{obs}^*$ . This is a nonparametric analog of drawing parameters from the posterior predictive distribution of the parameters. The process then draws the  $n_0$  values for  $Y_{mis}$  randomly with replacement from  $Y_{obs}^*$ .

Steps 1 through 5 are repeated sequentially for each variable with missing values.

The propensity score method was originally designed for a randomized experiment with repeated measures on the response variables. The goal was to impute the missing values on the response variables. The method uses only the covariate information that is associated with whether the imputed variable values are missing; it does not use correlations among variables. It is effective for inferences about the distributions of individual imputed variables, such as a univariate analysis, but it is not appropriate for analyses that involve relationship among variables, such as a regression analysis (Schafer 1999, p. 11). It can also produce badly biased estimates of regression coefficients when data on predictor variables are missing (Allison 2000).

## Monotone and FCS Discriminant Function Methods

The discriminant function method is the default imputation method in the MONOTONE and FCS statements for classification variables.

For a nominal classification variable  $Y_j$  with responses  $1, \dots, g$  and a set of effects from its preceding variables, if the covariates  $X_1, X_2, \dots, X_k$  associated with these effects within each group are approximately multivariate normal and the within-group covariance matrices are approximately equal, the discriminant function method (Brand 1999, pp. 95–96) can be used to impute missing values for the variable  $Y_j$ .

Denote the group-specific means for covariates  $X_1, X_2, \dots, X_k$  by

$$\bar{\mathbf{X}}_t = (\bar{X}_{t1}, \bar{X}_{t2}, \dots, \bar{X}_{tk}), t = 1, 2, \dots, g$$

then the pooled covariance matrix is computed as

$$\mathbf{S} = \frac{1}{n - g} \sum_{t=1}^g (n_t - 1) \mathbf{S}_t$$

where  $\mathbf{S}_t$  is the within-group covariance matrix,  $n_t$  is the group-specific sample size, and  $n = \sum_{t=1}^g n_t$  is the total sample size.

In each imputation, new parameters of the group-specific means ( $\mathbf{m}_{*t}$ ), pooled covariance matrix ( $\mathbf{S}_*$ ), and prior probabilities of group membership ( $q_{*t}$ ) can be drawn from their corresponding posterior distributions (Schafer 1997, p. 356).

## Pooled Covariance Matrix and Group-Specific Means

For each imputation, the MI procedure uses either the fixed observed pooled covariance matrix (PCOV=FIXED) or a drawn pooled covariance matrix (PCOV=POSTERIOR) from its posterior distribution with a noninformative prior. That is,

$$\Sigma | \mathbf{X} \sim W^{-1}(n - g, (n - g)\mathbf{S})$$

where  $W^{-1}$  is an inverted Wishart distribution.

The group-specific means are then drawn from their posterior distributions with a noninformative prior

$$\mu_t | (\Sigma, \bar{\mathbf{X}}_t) \sim N\left(\bar{\mathbf{X}}_t, \frac{1}{n_t} \Sigma\right)$$

See the section “Bayesian Estimation of the Mean Vector and Covariance Matrix” on page 4759 for a complete description of the inverted Wishart distribution and posterior distributions that use a noninformative prior.

### Prior Probabilities of Group Membership

The prior probabilities are computed through the drawing of new group sample sizes. When the total sample size  $n$  is considered fixed, the group sample sizes  $(n_1, n_2, \dots, n_g)$  have a multinomial distribution. New multinomial parameters (group sample sizes) can be drawn from their posterior distribution by using a Dirichlet prior with parameters  $(\alpha_1, \alpha_2, \dots, \alpha_g)$ .

After the new sample sizes are drawn from the posterior distribution of  $(n_1, n_2, \dots, n_g)$ , the prior probabilities  $q_{*t}$  are computed proportionally to the drawn sample sizes.

See Schafer (1997, pp. 247–255) for a complete description of the Dirichlet prior.

### Imputation Steps

The discriminant function method uses the following steps in each imputation to impute values for a nominal classification variable  $Y_j$  with  $g$  responses:

1. Draw a pooled covariance matrix  $\mathbf{S}_*$  from its posterior distribution if the PCOV=POSTERIOR option is used.
2. For each group, draw group means  $\mathbf{m}_{*t}$  from the observed group mean  $\bar{\mathbf{X}}_t$  and either the observed pooled covariance matrix (PCOV=FIXED) or the drawn pooled covariance matrix  $\mathbf{S}_*$  (PCOV=POSTERIOR).
3. For each group, compute or draw  $q_{*t}$ , prior probabilities of group membership, based on the PRIOR=option:
  - PRIOR=EQUAL,  $q_{*t} = 1/g$ , prior probabilities of group membership are all equal.
  - PRIOR=PROPORTIONAL,  $q_{*t} = n_t/n$ , prior probabilities are proportional to their group sample sizes.
  - PRIOR=JEFFREYS= $c$ , a noninformative Dirichlet prior with  $\alpha_t = c$  is used.
  - PRIOR=RIDGE= $d$ , a ridge prior is used with  $\alpha_t = d * n_t/n$  for  $d \geq 1$  and  $\alpha_t = d * n_t$  for  $d < 1$ .
4. With the group means  $\mathbf{m}_{*t}$ , the pooled covariance matrix  $\mathbf{S}_*$ , and the prior probabilities of group membership  $q_{*t}$ , the discriminant function method derives linear discriminant function and computes the posterior probabilities of an observation belonging to each group

$$p_t(\mathbf{x}) = \frac{\exp(-0.5D_t^2(\mathbf{x}))}{\sum_{u=1}^g \exp(-0.5D_u^2(\mathbf{x}))}$$

where  $D_t^2(\mathbf{x}) = (\mathbf{x} - \mathbf{m}_{*t})' \mathbf{S}_*^{-1} (\mathbf{x} - \mathbf{m}_{*t}) - 2 \log(q_{*t})$  is the generalized squared distance from  $\mathbf{x}$  to group  $t$ .

5. Draw a random uniform variate  $u$ , between 0 and 1, for each observation with missing group value. With the posterior probabilities,  $p_1(\mathbf{x}) + p_2(\mathbf{x}) + \dots + p_g(\mathbf{x}) = 1$ , the discriminant function method imputes  $Y_j = 1$  if the value of  $u$  is less than  $p_1(\mathbf{x})$ ,  $Y_j = 2$  if the value is greater than or equal to  $p_1(\mathbf{x})$  but less than  $p_1(\mathbf{x}) + p_2(\mathbf{x})$ , and so on.

---

## Monotone and FCS Logistic Regression Methods

The logistic regression method is another imputation method available for classification variables. In the logistic regression method, a logistic regression model is fitted for a classification variable with a set of covariates constructed from the effects. For a binary classification variable, based on the fitted regression model, a new logistic regression model is simulated from the posterior predictive distribution of the parameters and is used to impute the missing values for each variable (Rubin 1987, pp. 167–170).

For a binary variable  $Y_j$  with responses 1 and 2, a logistic regression model is fitted using observations with observed values for the imputed variable  $Y_j$  and its covariates  $X_1, X_2, \dots, X_k$ :

$$\text{logit}(p_j) = \beta_0 + \beta_1 X_1 + \beta_2 X_2 + \dots + \beta_k X_k$$

where  $X_1, X_2, \dots, X_k$  are covariates for  $Y_j$ ,  $p_j = \Pr(R_j = 1|X_1, X_2, \dots, X_k)$ , and  $\text{logit}(p) = \log(p/(1-p))$ .

The fitted model includes the regression parameter estimates  $\hat{\boldsymbol{\beta}} = (\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_k)$  and the associated covariance matrix  $\mathbf{V}_j$ .

The following steps are used to generate imputed values for a binary variable  $Y_j$  with responses 1 and 2:

1. New parameters  $\boldsymbol{\beta}_* = (\beta_{*0}, \beta_{*1}, \dots, \beta_{*(k)})$  are drawn from the posterior predictive distribution of the parameters.

$$\boldsymbol{\beta}_* = \hat{\boldsymbol{\beta}} + \mathbf{V}'_{hj} \mathbf{Z}$$

where  $\mathbf{V}_{hj}$  is the upper triangular matrix in the Cholesky decomposition,  $\mathbf{V}_j = \mathbf{V}'_{hj} \mathbf{V}_{hj}$ , and  $\mathbf{Z}$  is a vector of  $k+1$  independent random normal variates.

2. For an observation with missing  $Y_j$  and covariates  $x_1, x_2, \dots, x_k$ , compute the expected probability that  $Y_j = 1$ :

$$p_j = \frac{\exp(\mu_j)}{1 + \exp(\mu_j)}$$

where  $\mu_j = \beta_{*0} + \beta_{*1} x_1 + \beta_{*2} x_2 + \dots + \beta_{*(k)} x_k$ .

3. Draw a random uniform variate,  $u$ , between 0 and 1. If the value of  $u$  is less than  $p_j$ , impute  $Y_j = 1$ ; otherwise impute  $Y_j = 2$ .

The preceding logistic regression method can be extended to include the ordinal classification variables with more than two levels of responses. The options ORDER= and DESCENDING can be used to specify the sort order for the levels of the imputed variables.

## FCS Methods for Data Sets with Arbitrary Missing Patterns

For a data set with an arbitrary missing data pattern, you can use FCS methods to impute missing values for all variables, assuming the existence of a joint distribution for these variables (Brand 1999; van Buuren 2007). FCS method involves two phases in each imputation: the preliminary filled-in phase followed by the imputation phase.

At the filled-in phase, the missing values for all variables are filled in sequentially over the variables taken one at a time. The missing values for each variable are filled in using the specified method, or the default method for the variable if a method is not specified, with preceding variables serving as the covariates. These filled-in values provide starting values for these missing values at the imputation phase.

At the imputation phase, the missing values for each variable are imputed using the specified method and covariates at each iteration. The default method for the variable is used if a method is not specified, and the remaining variables are used as covariates if the set of covariates is not specified. After a number of iterations, as specified with the NBITER= option, the imputed values in each variable are used for the imputation. At each iteration, the missing values are imputed sequentially over the variables taken one at a time.

The MI procedure orders the variables as they are ordered in the VAR statement. For example, if the order of the  $p$  variables in the VAR statement is  $Y_1, Y_2, \dots, Y_p$ , then  $Y_1, Y_2, \dots, Y_p$  (in that order) are used in the filled-in and imputation phases.

The filled-in phase replaces missing values with filled-in values for each variable. That is, with  $p$  variables  $Y_1, Y_2, \dots, Y_p$  (in that order), the missing values are filled in by using the sequence,

$$\begin{aligned}
 \theta_1^{(0)} &\sim P(\theta_1 | Y_{1(obs)}) \\
 Y_{1(*)}^{(0)} &\sim P(Y_1 | \theta_1^{(0)}) \\
 Y_1^{(0)} &= (Y_{1(obs)}, Y_{1(*)}^{(0)}) \\
 &\dots \\
 &\dots \\
 \theta_p^{(0)} &\sim P(\theta_p | Y_1^{(0)}, \dots, Y_{p-1}^{(0)}, Y_{p(obs)}) \\
 Y_{p(*)}^{(0)} &\sim P(Y_p | \theta_p^{(0)}) \\
 Y_p^{(0)} &= (Y_{p(obs)}, Y_{p(*)}^{(0)})
 \end{aligned}$$

where  $Y_{j(obs)}$  is the set of observed  $Y_j$  values,  $Y_{j(*)}^{(0)}$  is the set of filled-in  $Y_j$  values,  $Y_j^{(0)}$  is the set of both observed and filled-in  $Y_j$  values, and  $\theta_j^{(0)}$  is the set of simulated parameters for the conditional distribution of  $Y_j$  given variables  $Y_1, Y_2, \dots, Y_{j-1}$ .

For each variable  $Y_j$  with missing values, the corresponding imputation method is used to fit the model with covariates  $Y_1, Y_2, \dots, Y_{j-1}$ . The observed observations for  $Y_j$ , which might include observations with filled-in values for  $Y_1, Y_2, \dots, Y_{j-1}$ , are used in the model fitting. With this resulting model, a new model is drawn and then used to impute missing values for  $Y_j$ .

The imputation phase replaces these filled-in values  $Y_{j(*)}^{(0)}$  with imputed values for each variable sequentially at each iteration. That is, with  $p$  variables  $Y_1, Y_2, \dots, Y_p$  (in that order), the missing values are imputed with the sequence at iteration  $t + 1$ ,

$$\begin{aligned} \theta_1^{(t+1)} &\sim P(\theta_1 | Y_{1(obs)}, Y_2^{(t)}, \dots, Y_p^{(t)}) \\ Y_{1(*)}^{(t+1)} &\sim P(Y_1 | \theta_1^{(t+1)}) \\ Y_1^{(t+1)} &= (Y_{1(obs)}, Y_{1(*)}^{(t+1)}) \\ &\dots \\ &\dots \\ \theta_p^{(t+1)} &\sim P(\theta_p | Y_1^{(t+1)}, \dots, Y_{p-1}^{(t+1)}, Y_{p(obs)}) \\ Y_{p(*)}^{(t+1)} &\sim P(Y_p | \theta_p^{(t+1)}) \\ Y_p^{(t+1)} &= (Y_{p(obs)}, Y_{p(*)}^{(t+1)}) \end{aligned}$$

where  $Y_{j(obs)}$  is the set of observed  $Y_j$  values,  $Y_{j(*)}^{(t+1)}$  is the set of imputed  $Y_j$  values at iteration  $t + 1$ ,  $Y_{j(*)}^{(t)}$  is the set of filled-in  $Y_j$  values ( $t = 0$ ) or the set of imputed  $Y_j$  values at iteration  $t$  ( $t > 0$ ),  $Y_j^{(t+1)}$  is the set of both observed and imputed  $Y_j$  values at iteration  $t + 1$ , and  $\theta_j^{(t+1)}$  is the set of simulated parameters for the conditional distribution of  $Y_j$  given covariates constructed from  $Y_1, \dots, Y_{j-1}, Y_{j+1}, \dots, Y_p$ .

At each iteration, a specified model is fitted for each variable with missing values by using observed observations for that variable, which might include observations with imputed values for other variables. With this resulting model, a new model is drawn and then used to impute missing values for the imputed variable.

The steps are iterated long enough for the results to reliably simulate an approximately independent draw of the missing values for an imputed data set.

The imputation methods used in the filled-in and imputation phases are similar to the corresponding monotone methods for monotone missing data. You can use a regression method or a predictive mean matching method to impute missing values for a continuous variable, a logistic regression method for a classification variable with a binary or ordinal response, and a discriminant function method for a classification variable with a binary or nominal response. See the sections “[Monotone and FCS Regression Methods](#)” on page 4749, “[Monotone and FCS Predictive Mean Matching Methods](#)” on page 4750, “[Monotone and FCS Discriminant Function Methods](#)” on page 4752, and “[Monotone and FCS Logistic Regression Methods](#)” on page 4754 for these methods.

The FCS method requires fewer iterations than the MCMC method (van Buuren 2007). Often, as few as five or 10 iterations are enough to produce satisfactory results (van Buuren 2007; Brand 1999).

---

## Checking Convergence in FCS Methods

The parameters used in the imputation step at each iteration can be saved in an output data set with the `OUTITER=` option. These include the means and standard deviations. You can then monitor the convergence by displaying trace plots for those parameter values with the `PLOTS=TRACE` option.

A trace plot for a parameter  $\xi$  is a scatter plot of successive parameter estimates  $\xi_i$  against the iteration number  $i$ . The plot provides a simple way to examine the convergence behavior of the estimation algorithm

for  $\xi$ . Long-term trends in the plot indicate that successive iterations are highly correlated and that the series of iterations has not converged.

You can display trace plots for the variable means and standard deviations. You can also request logarithmic transformations for positive parameters in the plots with the LOG option. With the LOG option, if a parameter value is less than or equal to zero, then the value is not displayed in the corresponding plot.

See [Example 57.8](#) for a usage of the trace plot.

## MCMC Method for Arbitrary Missing Multivariate Normal Data

The Markov chain Monte Carlo (MCMC) method originated in physics as a tool for exploring equilibrium distributions of interacting molecules. In statistical applications, it is used to generate pseudorandom draws from multidimensional and otherwise intractable probability distributions via Markov chains. A Markov chain is a sequence of random variables in which the distribution of each element depends only on the value of the previous element.

In MCMC simulation, you construct a Markov chain long enough for the distribution of the elements to stabilize to a stationary distribution, which is the distribution of interest. Repeatedly simulating steps of the chain simulates draws from the distribution of interest. See Schafer (1997) for a detailed discussion of this method.

In Bayesian inference, information about unknown parameters is expressed in the form of a posterior probability distribution. This posterior distribution is computed using Bayes' theorem,

$$p(\boldsymbol{\theta}|y) = \frac{p(y|\boldsymbol{\theta})p(\boldsymbol{\theta})}{\int p(y|\boldsymbol{\theta})p(\boldsymbol{\theta})d\boldsymbol{\theta}}$$

MCMC has been applied as a method for exploring posterior distributions in Bayesian inference. That is, through MCMC, you can simulate the entire joint posterior distribution of the unknown quantities and obtain simulation-based estimates of posterior parameters that are of interest.

In many incomplete-data problems, the observed-data posterior  $p(\boldsymbol{\theta}|Y_{obs})$  is intractable and cannot easily be simulated. However, when  $Y_{obs}$  is augmented by an estimated or simulated value of the missing data  $Y_{mis}$ , the complete-data posterior  $p(\boldsymbol{\theta}|Y_{obs}, Y_{mis})$  is much easier to simulate. Assuming that the data are from a multivariate normal distribution, data augmentation can be applied to Bayesian inference with missing data by repeating the following steps:

### 1. The imputation I-step

Given an estimated mean vector and covariance matrix, the I-step simulates the missing values for each observation independently. That is, if you denote the variables with missing values for observation  $i$  by  $Y_{i(mis)}$  and the variables with observed values by  $Y_{i(obs)}$ , then the I-step draws values for  $Y_{i(mis)}$  from a conditional distribution for  $Y_{i(mis)}$  given  $Y_{i(obs)}$ .

### 2. The posterior P-step

Given a complete sample, the P-step simulates the posterior population mean vector and covariance matrix. These new estimates are then used in the next I-step. Without prior information about the parameters, a noninformative prior is used. You can also use other informative priors. For example, a prior information about the covariance matrix can help to stabilize the inference about the mean vector for a near singular covariance matrix.

That is, with a current parameter estimate  $\theta^{(t)}$  at the  $t$ th iteration, the I-step draws  $Y_{mis}^{(t+1)}$  from  $p(Y_{mis}|Y_{obs}, \theta^{(t)})$  and the P-step draws  $\theta^{(t+1)}$  from  $p(\theta|Y_{obs}, Y_{mis}^{(t+1)})$ . The two steps are iterated long enough for the results to reliably simulate an approximately independent draw of the missing values for a multiply imputed data set (Schafer 1997).

This creates a Markov chain  $(Y_{mis}^{(1)}, \theta^{(1)})$ ,  $(Y_{mis}^{(2)}, \theta^{(2)})$ , ..., which converges in distribution to  $p(Y_{mis}, \theta|Y_{obs})$ . Assuming the iterates converge to a stationary distribution, the goal is to simulate an approximately independent draw of the missing values from this distribution.

To validate the imputation results, you should repeat the process with different random number generators and starting values based on different initial parameter estimates.

The next three sections provide details for the imputation step, Bayesian estimation of the mean vector and covariance matrix, and the posterior step.

## Imputation Step

In each iteration, starting with a given mean vector  $\mu$  and covariance matrix  $\Sigma$ , the imputation step draws values for the missing data from the conditional distribution  $Y_{mis}$  given  $Y_{obs}$ .

Suppose  $\mu = [\mu'_1, \mu'_2]'$  is the partitioned mean vector of two sets of variables,  $Y_{obs}$  and  $Y_{mis}$ , where  $\mu_1$  is the mean vector for variables  $Y_{obs}$  and  $\mu_2$  is the mean vector for variables  $Y_{mis}$ .

Also suppose

$$\Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma'_{12} & \Sigma_{22} \end{bmatrix}$$

is the partitioned covariance matrix for these variables, where  $\Sigma_{11}$  is the covariance matrix for variables  $Y_{obs}$ ,  $\Sigma_{22}$  is the covariance matrix for variables  $Y_{mis}$ , and  $\Sigma_{12}$  is the covariance matrix between variables  $Y_{obs}$  and variables  $Y_{mis}$ .

By using the sweep operator (Goodnight 1979) on the pivots of the  $\Sigma_{11}$  submatrix, the matrix becomes

$$\begin{bmatrix} \Sigma_{11}^{-1} & \Sigma_{11}^{-1}\Sigma_{12} \\ -\Sigma'_{12}\Sigma_{11}^{-1} & \Sigma_{22.1} \end{bmatrix}$$

where  $\Sigma_{22.1} = \Sigma_{22} - \Sigma'_{12}\Sigma_{11}^{-1}\Sigma_{12}$  can be used to compute the conditional covariance matrix of  $Y_{mis}$  after controlling for  $Y_{obs}$ .

For an observation with the preceding missing pattern, the conditional distribution of  $Y_{mis}$  given  $Y_{obs} = \mathbf{y}_1$  is a multivariate normal distribution with the mean vector

$$\mu_{2.1} = \mu_2 + \Sigma'_{12}\Sigma_{11}^{-1}(\mathbf{y}_1 - \mu_1)$$

and the conditional covariance matrix

$$\Sigma_{22.1} = \Sigma_{22} - \Sigma'_{12}\Sigma_{11}^{-1}\Sigma_{12}$$

## Bayesian Estimation of the Mean Vector and Covariance Matrix

Suppose that  $\mathbf{Y} = (\mathbf{y}'_1, \mathbf{y}'_2, \dots, \mathbf{y}'_n)'$  is an  $(n \times p)$  matrix made up of  $n$  ( $p \times 1$ ) independent vectors  $\mathbf{y}_i$ , each of which has a multivariate normal distribution with mean zero and covariance matrix  $\mathbf{\Lambda}$ . Then the SSCP matrix

$$\mathbf{A} = \mathbf{Y}'\mathbf{Y} = \sum_i \mathbf{y}_i \mathbf{y}'_i$$

has a Wishart distribution  $W(n, \mathbf{\Lambda})$ .

When each observation  $\mathbf{y}_i$  is distributed with a multivariate normal distribution with an unknown mean  $\boldsymbol{\mu}$ , then the CSSCP matrix

$$\mathbf{A} = \sum_i (\mathbf{y}_i - \bar{\mathbf{y}})(\mathbf{y}_i - \bar{\mathbf{y}})'$$

has a Wishart distribution  $W(n - 1, \mathbf{\Lambda})$ .

If  $\mathbf{A}$  has a Wishart distribution  $W(n, \mathbf{\Lambda})$ , then  $\mathbf{B} = \mathbf{A}^{-1}$  has an inverted Wishart distribution  $W^{-1}(n, \boldsymbol{\Psi})$ , where  $n$  is the degrees of freedom and  $\boldsymbol{\Psi} = \mathbf{\Lambda}^{-1}$  is the precision matrix (Anderson 1984).

Note that, instead of using the parameter  $\boldsymbol{\Psi} = \mathbf{\Lambda}^{-1}$  for the inverted Wishart distribution, Schafer (1997) uses the parameter  $\mathbf{\Lambda}$ .

Suppose that each observation in the data matrix  $\mathbf{Y}$  has a multivariate normal distribution with mean  $\boldsymbol{\mu}$  and covariance matrix  $\boldsymbol{\Sigma}$ . Then with a prior inverted Wishart distribution for  $\boldsymbol{\Sigma}$  and a prior normal distribution for  $\boldsymbol{\mu}$

$$\begin{aligned} \boldsymbol{\Sigma} &\sim W^{-1}(m, \boldsymbol{\Psi}) \\ \boldsymbol{\mu} | \boldsymbol{\Sigma} &\sim N\left(\boldsymbol{\mu}_0, \frac{1}{\tau} \boldsymbol{\Sigma}\right) \end{aligned}$$

where  $\tau > 0$  is a fixed number.

The posterior distribution (Anderson 1984, p. 270; Schafer 1997, p. 152) is

$$\begin{aligned} \boldsymbol{\Sigma} | \mathbf{Y} &\sim W^{-1}\left(n + m, (n - 1)\mathbf{S} + \boldsymbol{\Psi} + \frac{n\tau}{n + \tau}(\bar{\mathbf{y}} - \boldsymbol{\mu}_0)(\bar{\mathbf{y}} - \boldsymbol{\mu}_0)'\right) \\ \boldsymbol{\mu} | (\boldsymbol{\Sigma}, \mathbf{Y}) &\sim N\left(\frac{1}{n + \tau}(n\bar{\mathbf{y}} + \tau\boldsymbol{\mu}_0), \frac{1}{n + \tau}\boldsymbol{\Sigma}\right) \end{aligned}$$

where  $(n - 1)\mathbf{S}$  is the CSSCP matrix.

## Posterior Step

In each iteration, the posterior step simulates the posterior population mean vector  $\boldsymbol{\mu}$  and covariance matrix  $\boldsymbol{\Sigma}$  from prior information for  $\boldsymbol{\mu}$  and  $\boldsymbol{\Sigma}$ , and the complete sample estimates.

You can specify the prior parameter information by using one of the following methods:

- PRIOR=JEFFREYS, which uses a noninformative prior
- PRIOR=INPUT=, which provides a prior information for  $\boldsymbol{\Sigma}$  in the data set. Optionally, it also provides a prior information for  $\boldsymbol{\mu}$  in the data set.
- PRIOR=RIDGE=, which uses a ridge prior

The next four subsections provide details of the posterior step for different prior distributions.

### 1. A Noninformative Prior

Without prior information about the mean and covariance estimates, you can use a noninformative prior by specifying the PRIOR=JEFFREYS option. The posterior distributions (Schafer 1997, p. 154) are

$$\begin{aligned}\Sigma^{(t+1)}|\mathbf{Y} &\sim W^{-1}(n-1, (n-1)\mathbf{S}) \\ \mu^{(t+1)}|(\Sigma^{(t+1)}, \mathbf{Y}) &\sim N\left(\bar{\mathbf{y}}, \frac{1}{n}\Sigma^{(t+1)}\right)\end{aligned}$$

### 2. An Informative Prior for $\mu$ and $\Sigma$

When prior information is available for the parameters  $\mu$  and  $\Sigma$ , you can provide it with a SAS data set that you specify with the PRIOR=INPUT= option:

$$\begin{aligned}\Sigma &\sim W^{-1}(d^*, d^*\mathbf{S}^*) \\ \mu|\Sigma &\sim N\left(\mu_0, \frac{1}{n_0}\Sigma\right)\end{aligned}$$

To obtain the prior distribution for  $\Sigma$ , PROC MI reads the matrix  $\mathbf{S}^*$  from observations in the data set with \_TYPE\_='COV', and it reads  $n^* = d^* + 1$  from observations with \_TYPE\_='N'.

To obtain the prior distribution for  $\mu$ , PROC MI reads the mean vector  $\mu_0$  from observations with \_TYPE\_='MEAN', and it reads  $n_0$  from observations with \_TYPE\_='N\_MEAN'. When there are no observations with \_TYPE\_='N\_MEAN', PROC MI reads  $n_0$  from observations with \_TYPE\_='N'.

The resulting posterior distribution, as described in the section “Bayesian Estimation of the Mean Vector and Covariance Matrix” on page 4759, is given by

$$\begin{aligned}\Sigma^{(t+1)}|\mathbf{Y} &\sim W^{-1}(n+d^*, (n-1)\mathbf{S} + d^*\mathbf{S}^* + \mathbf{S}_m) \\ \mu^{(t+1)}|(\Sigma^{(t+1)}, \mathbf{Y}) &\sim N\left(\frac{1}{n+n_0}(n\bar{\mathbf{y}} + n_0\mu_0), \frac{1}{n+n_0}\Sigma^{(t+1)}\right)\end{aligned}$$

where

$$\mathbf{S}_m = \frac{nn_0}{n+n_0}(\bar{\mathbf{y}} - \mu_0)(\bar{\mathbf{y}} - \mu_0)'$$

### 3. An Informative Prior for $\Sigma$

When the sample covariance matrix  $\mathbf{S}$  is singular or near singular, prior information about  $\Sigma$  can also be used without prior information about  $\mu$  to stabilize the inference about  $\mu$ . You can provide it with a SAS data set that you specify with the PRIOR=INPUT= option.

To obtain the prior distribution for  $\Sigma$ , PROC MI reads the matrix  $\mathbf{S}^*$  from observations in the data set with \_TYPE\_='COV', and it reads  $n^*$  from observations with \_TYPE\_='N'.

The resulting posterior distribution for  $(\mu, \Sigma)$  (Schafer 1997, p. 156) is

$$\begin{aligned}\Sigma^{(t+1)}|\mathbf{Y} &\sim W^{-1}(n+d^*, (n-1)\mathbf{S} + d^*\mathbf{S}^*) \\ \mu^{(t+1)}|(\Sigma^{(t+1)}, \mathbf{Y}) &\sim N\left(\bar{\mathbf{y}}, \frac{1}{n}\Sigma^{(t+1)}\right)\end{aligned}$$

Note that if the PRIOR=INPUT= data set also contains observations with \_TYPE\_='MEAN', then a complete informative prior for both  $\mu$  and  $\Sigma$  will be used.

#### 4. A Ridge Prior

A special case of the preceding adjustment is a ridge prior with  $\mathbf{S}^* = \text{Diag}(\mathbf{S})$  (Schafer 1997, p. 156). That is,  $\mathbf{S}^*$  is a diagonal matrix with diagonal elements equal to the corresponding elements in  $\mathbf{S}$ .

You can request a ridge prior by using the PRIOR=RIDGE= option. You can explicitly specify the number  $d^* \geq 1$  in the PRIOR=RIDGE= $d^*$  option. Or you can implicitly specify the number by specifying the proportion  $p$  in the PRIOR=RIDGE= $p$  option to request  $d^* = (n - 1)p$ .

The posterior is then given by

$$\begin{aligned} \Sigma^{(t+1)} | \mathbf{Y} &\sim W^{-1} (n + d^*, (n - 1)\mathbf{S} + d^*\text{Diag}(\mathbf{S})) \\ \mu^{(t+1)} | (\Sigma^{(t+1)}, \mathbf{Y}) &\sim N \left( \bar{\mathbf{y}}, \frac{1}{n} \Sigma^{(t+1)} \right) \end{aligned}$$

---

## Producing Monotone Missingness with the MCMC Method

The monotone data MCMC method was first proposed by Li (1988) and Liu (1993) described the algorithm. The method is useful especially when a data set is close to having a monotone missing pattern. In this case, the method needs to impute only a few missing values to the data set to have a monotone missing pattern in the imputed data set. Compared to a full data imputation that imputes all missing values, the monotone data MCMC method imputes fewer missing values in each iteration and achieves approximate stationarity in fewer iterations (Schafer 1997, p. 227).

You can request the monotone MCMC method by specifying the option IMPUTE=MONOTONE in the MCMC statement. The “Missing Data Patterns” table now denotes the variables with missing values by “.” or “O”. The value “.” means that the variable is missing and will be imputed, and the value “O” means that the variable is missing and will not be imputed. The “Variance Information” and “Parameter Estimates” tables are not created.

You must specify the variables in the VAR statement. The variable order in the list determines the monotone missing pattern in the imputed data set. With a different order in the VAR list, the results will be different because the monotone missing pattern to be constructed will be different.

Assuming that the data are from a multivariate normal distribution, then like the MCMC method, the monotone MCMC method repeats the following steps:

### 1. The imputation I-step

Given an estimated mean vector and covariance matrix, the I-step simulates the missing values for each observation independently. Only a subset of missing values are simulated to achieve a monotone pattern of missingness.

### 2. The posterior P-step

Given a new sample with a monotone pattern of missingness, the P-step simulates the posterior population mean vector and covariance matrix with a noninformative Jeffreys prior. These new estimates are then used in the next I-step.

## Imputation Step

The I-step is almost identical to the I-step described in the section “MCMC Method for Arbitrary Missing Multivariate Normal Data” on page 4757 except that only a subset of missing values need to be simulated. To state this precisely, denote the variables with observed values for observation  $i$  by  $Y_{i(obs)}$  and the variables with missing values by  $Y_{i(mis)} = (Y_{i(m1)}, Y_{i(m2)})$ , where  $Y_{i(m1)}$  is a subset of the missing variables that will cause a monotone missingness when their values are imputed. Then the I-step draws values for  $Y_{i(m1)}$  from a conditional distribution for  $Y_{i(m1)}$  given  $Y_{i(obs)}$ .

## Posterior Step

The P-step is different from the P-step described in the section “MCMC Method for Arbitrary Missing Multivariate Normal Data” on page 4757. Instead of simulating the  $\mu$  and  $\Sigma$  parameters from the full imputed data set, this P-step simulates the  $\mu$  and  $\Sigma$  parameters through simulated regression coefficients from regression models based on the imputed data set with a monotone pattern of missingness. The step is similar to the process described in the section “Monotone and FCS Regression Methods” on page 4749.

That is, for the variable  $Y_j$ , a model

$$Y_j = \beta_0 + \beta_1 Y_1 + \beta_2 Y_2 + \dots + \beta_{j-1} Y_{j-1}$$

is fitted using  $n_j$  nonmissing observations for variable  $Y_j$  in the imputed data sets.

The fitted model consists of the regression parameter estimates  $\hat{\beta} = (\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_{j-1})$  and the associated covariance matrix  $\hat{\sigma}_j^2 \mathbf{V}_j$ , where  $\mathbf{V}_j$  is the usual  $\mathbf{X}'\mathbf{X}$  inverse matrix from the intercept and variables  $Y_1, Y_2, \dots, Y_{j-1}$ .

For each imputation, new parameters  $\beta_* = (\beta_{*0}, \beta_{*1}, \dots, \beta_{*(j-1)})$  and  $\sigma_{*j}^2$  are drawn from the posterior predictive distribution of the parameters. That is, they are simulated from  $(\hat{\beta}_0, \hat{\beta}_1, \dots, \hat{\beta}_{j-1}), \sigma_j^2$ , and  $\mathbf{V}_j$ . The variance is drawn as

$$\sigma_{*j}^2 = \hat{\sigma}_j^2 (n_j - j) / g$$

where  $g$  is a  $\chi_{n_j - p + j - 1}^2$  random variate and  $n_j$  is the number of nonmissing observations for  $Y_j$ . The regression coefficients are drawn as

$$\beta_* = \hat{\beta} + \sigma_{*j} \mathbf{V}_{hj}' \mathbf{Z}$$

where  $\mathbf{V}_{hj}$  is the upper triangular matrix in the Cholesky decomposition,  $\mathbf{V}_j = \mathbf{V}_{hj}' \mathbf{V}_{hj}$ , and  $\mathbf{Z}$  is a vector of  $j$  independent random normal variates.

These simulated values of  $\beta_*$  and  $\sigma_{*j}^2$  are then used to re-create the parameters  $\mu$  and  $\Sigma$ . For a detailed description of how to produce monotone missingness with the MCMC method for a multivariate normal data, see Schafer (1997, pp. 226–235).

---

## MCMC Method Specifications

With the MCMC method, you can impute either all missing values (IMPUTE=FULL) or just enough missing values to make the imputed data set have a monotone missing pattern (IMPUTE=MONOTONE). In the process, either a single chain for all imputations (CHAIN=SINGLE) or a separate chain for each imputation

(CHAIN=MULTIPLE) is used. The single chain might be somewhat more precise for estimating a single quantity such as a posterior mean (Schafer 1997, p. 138). See Schafer (1997, pp. 137–138) for a discussion of single versus multiple chains.

You can specify the number of initial burn-in iterations before the first imputation with the NBITER= option. This number is also used for subsequent chains for multiple chains. For a single chain, you can also specify the number of iterations between imputations with the NITER= option.

You can explicitly specify initial parameter values for the MCMC method with the INITIAL=INPUT= data set option. Alternatively, you can use the EM algorithm to derive a set of initial parameter values for MCMC with the option INITIAL=EM. These estimates are used as either the starting value (START=VALUE) or the starting distribution (START=DIST) for the MCMC method. For multiple chains, these estimates are used again as either the starting value (START=VALUE) or the starting distribution (START=DIST) for the subsequent chains.

You can specify the prior parameter information in the PRIOR= option. You can use a noninformative prior (PRIOR=JEFFREYS), a ridge prior (PRIOR=RIDGE), or an informative prior specified in a data set (PRIOR=INPUT).

The parameter estimates used to generate imputed values in each imputation can be saved in a data set with the OUTEST= option. Later, this data set can be read with the INEST= option to provide the reference distribution for imputing missing values for a new data set.

By default, the MCMC method uses a single chain to produce five imputations. It completes 200 burn-in iterations before the first imputation and 100 iterations between imputations. The posterior mode computed from the EM algorithm with a noninformative prior is used as the starting values for the MCMC method.

## INITIAL=EM Specifications

The EM algorithm is used to find the maximum likelihood estimates for incomplete data in the EM statement. You can also use the EM algorithm to find a posterior mode, the parameter estimates that maximize the observed-data posterior density. The resulting posterior mode provides a good starting value for the MCMC method.

With the INITIAL=EM option, PROC MI uses the MLE of the parameter vector as the initial estimates in the EM algorithm for the posterior mode. You can use the ITPRINT option within the INITIAL=EM option to display the iteration history for the EM algorithm.

You can use the CONVERGE= option to specify the convergence criterion in deriving the EM posterior mode. The iterations are considered to have converged when the maximum change in the parameter estimates between iteration steps is less than the value specified. By default, CONVERGE=1E-4.

You can also use the MAXITER= option to specify the maximum number of iterations of the EM algorithm. By default, MAXITER=200.

With the BOOTSTRAP option, you can use overdispersed starting values for the MCMC method. In this case, PROC MI applies the EM algorithm to a bootstrap sample, a simple random sample with replacement from the input data set, to derive the initial estimates for each chain (Schafer 1997, p. 128).

## Checking Convergence in MCMC

The theoretical convergence of the MCMC method has been explored under various conditions, as described in Schafer (1997, p. 70). However, in practice, verification of convergence is not a simple matter.

The parameters used in the imputation step for each iteration can be saved in an output data set with the `OUTITER=` option. These include the means, standard deviations, covariances, worst linear function, and observed-data LR statistics. You can then monitor the convergence in a single chain by displaying trace plots and autocorrelations for those parameter values (Schafer 1997, p. 120). The trace and autocorrelation function plots for parameters such as variable means, covariances, and the worst linear function can be displayed by specifying the `TIMEPLOT` and `ACFPLOT` options, respectively.

You can apply the EM algorithm to a bootstrap sample to obtain overdispersed starting values for multiple chains (Gelman and Rubin 1992). This provides a conservative estimate of the number of iterations needed before each imputation.

The next four subsections describe useful statistics and plots that can be used to check the convergence of the MCMC method.

### LR Statistics

You can save the observed-data likelihood ratio (LR) statistic in each iteration with the `LR` option in the `OUTITER=` data set. The statistic is based on the observed-data likelihood with parameter values used in the iteration and the observed-data maximum likelihood derived from the EM algorithm.

In each iteration, the LR statistic is given by

$$-2 \log \left( \frac{f(\hat{\theta}_i)}{f(\hat{\theta})} \right)$$

where  $f(\hat{\theta})$  is the observed-data maximum likelihood derived from the EM algorithm and  $f(\hat{\theta}_i)$  is the observed-data likelihood for  $\hat{\theta}_i$  used in the iteration.

Similarly, you can also save the observed-data LR posterior mode statistic for each iteration with the `LR_POST` option. This statistic is based on the observed-data posterior density with parameter values used in each iteration and the observed-data posterior mode derived from the EM algorithm for posterior mode.

For large samples, these LR statistics tends to be approximately  $\chi^2$  distributed with degrees of freedom equal to the dimension of  $\theta$  (Schafer 1997, p. 131). For example, with a large number of iterations, if the values of the LR statistic do not behave like a random sample from the described  $\chi^2$  distribution, then there is evidence that the MCMC method has not converged.

### Worst Linear Function of Parameters

The worst linear function (WLF) of parameters (Schafer 1997, pp. 129–131) is a scalar function of parameters  $\mu$  and  $\Sigma$  that is “worst” in the sense that its function values converge most slowly among parameters in the MCMC method. The convergence of this function is evidence that other parameters are likely to converge as well.

For linear functions of parameters  $\theta = (\mu, \Sigma)$ , a worst linear function of  $\theta$  has the highest asymptotic rate of missing information. The function can be derived from the iterative values of  $\theta$  near the posterior mode in the EM algorithm. That is, an estimated worst linear function of  $\theta$  is

$$w(\theta) = \mathbf{v}'(\theta - \hat{\theta})$$

where  $\hat{\theta}$  is the posterior mode and the coefficients  $\mathbf{v} = \hat{\theta}_{(-1)} - \hat{\theta}$  are the difference between the estimated value of  $\theta$  one step prior to convergence and the converged value  $\hat{\theta}$ .

You can display the coefficients of the worst linear function,  $\mathbf{v}$ , by specifying the WLF option in the MCMC statement. You can save the function value from each iteration in an OUTITER= data set by specifying the WLF option within the OUTITER option. You can also display the worst linear function values from iterations in an autocorrelation plot or a trace plot by specifying WLF as an ACFPLOT or TIMEPLOT option, respectively.

Note that when the observed-data posterior is nearly normal, the WLF is one of the slowest functions to approach stationarity. When the posterior is not close to normal, other functions might take much longer than the WLF to converge, as described in Schafer (1997, p.130).

## Trace Plot

A trace plot for a parameter  $\xi$  is a scatter plot of successive parameter estimates  $\xi_i$  against the iteration number  $i$ . The plot provides a simple way to examine the convergence behavior of the estimation algorithm for  $\xi$ . Long-term trends in the plot indicate that successive iterations are highly correlated and that the series of iterations has not converged.

You can display trace plots for worst linear function, variable means, variable variances, and covariances of variables. You can also request logarithmic transformations for positive parameters in the plots with the LOG option. When a parameter value is less than or equal to zero, the value is not displayed in the corresponding plot.

By default, the MI procedure uses solid line segments to connect data points in a trace plot. You can use the CCONNECT=, LCONNECT=, and WCONNECT= options to change the color, line type, and width of the line segments, respectively. When WCONNECT=0 is specified, the data points are not connected, and the procedure uses the plus sign (+) as the plot symbol to display the points with a height of one (percentage screen unit) in a trace plot. You can use the SYMBOL=, CSYMBOL=, and HSYMBOL= options to change the shape, color, and height of the plot symbol, respectively.

By default, the plot title “Trace Plot” is displayed in a trace plot. You can request another title by using the TITLE= option in the TIMEPLOT option. When another title is also specified in a TITLE statement, this title is displayed as the main title and the plot title is displayed as a subtitle in the plot.

You can use options in the GOPTIONS statement to change the color and height of the title. See the chapter “The SAS/GRAPH Statements” in *SAS/GRAPH: Reference* for an illustration of title options. See [Example 57.11](#) for a usage of the trace plot.

## Autocorrelation Function Plot

To examine relationships of successive parameter estimates  $\xi$ , the autocorrelation function (ACF) can be used. For a stationary series,  $\xi_i, i \geq 1$ , in trace data, the autocorrelation function at lag  $k$  is

$$\rho_k = \frac{\text{Cov}(\xi_i, \xi_{i+k})}{\text{Var}(\xi_i)}$$

The sample  $k$ th order autocorrelation is computed as

$$r_k = \frac{\sum_{i=1}^{n-k} (\xi_i - \bar{\xi})(\xi_{i+k} - \bar{\xi})}{\sum_{i=1}^n (\xi_i - \bar{\xi})^2}$$

You can display autocorrelation function plots for the worst linear function, variable means, variable variances, and covariances of variables. You can also request logarithmic transformations for parameters in the plots with the LOG option. When a parameter has values less than or equal to zero, the corresponding plot is not created.

You specify the maximum number of lags of the series with the NLAG= option. The autocorrelations at each lag less than or equal to the specified lag are displayed in the graph. In addition, the plot also displays approximate 95% confidence limits for the autocorrelations. At lag  $k$ , the confidence limits indicate a set of approximate 95% critical values for testing the hypothesis  $\rho_j = 0$ ,  $j \geq k$ .

By default, the MI procedure uses the star (\*) as the plot symbol to display the points with a height of one (percentage screen unit) in the plot, a solid line to display the reference line of zero autocorrelation, vertical line segments to connect autocorrelations to the reference line, and a pair of dashed lines to display approximately 95% confidence limits for the autocorrelations.

You can use the SYMBOL=, CSYMBOL=, and HSYMBOL= options to change the shape, color, and height of the plot symbol, respectively, and the CNEEDLES= and WNEEDLES= options to change the color and width of the needles, respectively. You can also use the LREF=, CREF=, and WREF= options to change the line type, color, and width of the reference line, respectively. Similarly, you can use the LCONF=, CCONF=, and WCONF= options to change the line type, color, and width of the confidence limits, respectively.

By default, the plot title “Autocorrelation Plot” is displayed in an autocorrelation function plot. You can request another title by using the TITLE= option within the ACFPLOT option. When another title is also specified in a TITLE statement, this title is displayed as the main title and the plot title is displayed as a subtitle in the plot.

You can use options in the GOPTIONS statement to change the color and height of the title. See the chapter “The SAS/GRAPH Statements” in *SAS/GRAPH: Reference* for a description of title options. See [Example 57.8](#) for an illustration of the autocorrelation function plot.

## Input Data Sets

You can specify the input data set with missing values by using the DATA= option in the PROC MI statement. When an MCMC method is used, you can specify the data set that contains the reference distribution information for imputation with the INEST= option, the data set that contains initial parameter estimates for the MCMC method with the INITIAL=INPUT= option, and the data set that contains information for the prior distribution with the PRIOR=INPUT= option in the MCMC statement.

### DATA=SAS-data-set

The input DATA= data set is an ordinary SAS data set that contains multivariate data with missing values.

**INEST=SAS-data-set**

The input INEST= data set is a TYPE=EST data set and contains a variable `_Imputation_` to identify the imputation number. For each imputation, PROC MI reads the point estimate from the observations with `_TYPE_='PARM'` or `_TYPE_='PARMS'` and the associated covariances from the observations with `_TYPE_='COV'` or `_TYPE_='COVB'`. These estimates are used as the reference distribution to impute values for observations in the DATA= data set. When the input INEST= data set also contains observations with `_TYPE_='SEED'`, PROC MI reads the seed information for the random number generator from these observations. Otherwise, the SEED= option provides the seed information.

**INITIAL=INPUT=SAS-data-set**

The input INITIAL=INPUT= data set is a TYPE=COV or CORR data set and provides initial parameter estimates for the MCMC method. The covariances derived from the TYPE=COV/CORR data set are divided by the number of observations to get the correct covariance matrix for the point estimate (sample mean).

If TYPE=COV, PROC MI reads the number of observations from the observations with `_TYPE_='N'`, the point estimate from the observations with `_TYPE_='MEAN'`, and the covariances from the observations with `_TYPE_='COV'`.

If TYPE=CORR, PROC MI reads the number of observations from the observations with `_TYPE_='N'`, the point estimate from the observations with `_TYPE_='MEAN'`, the correlations from the observations with `_TYPE_='CORR'`, and the standard deviations from the observations with `_TYPE_='STD'`.

**PRIOR=INPUT=SAS-data-set**

The input PRIOR=INPUT= data set is a TYPE=COV data set that provides information for the prior distribution. You can use the data set to specify a prior distribution for  $\Sigma$  of the form

$$\Sigma \sim W^{-1}(d^*, d^*S^*)$$

where  $d^* = n^* - 1$  is the degrees of freedom. PROC MI reads the matrix  $S^*$  from observations with `_TYPE_='COV'` and reads  $n^*$  from observations with `_TYPE_='N'`.

You can also use this data set to specify a prior distribution for  $\mu$  of the form

$$\mu \sim N\left(\mu_0, \frac{1}{n_0}\Sigma\right)$$

PROC MI reads the mean vector  $\mu_0$  from observations with `_TYPE_='MEAN'` and reads  $n_0$  from observations with `_TYPE_='N_MEAN'`. When there are no observations with `_TYPE_='N_MEAN'`, PROC MI reads  $n_0$  from observations with `_TYPE_='N'`.

---

**Output Data Sets**

You can specify the output data set of imputed values with the OUT= option in the PROC MI statement. When an EM statement is used, you can specify the data set that contains the original data set with missing values being replaced by the expected values from the EM algorithm by using the OUT= option in the EM statement. You can also specify the data set that contains MLE computed with the EM algorithm by using the OUTEM= option.

When an MCMC method is used, you can specify the data set that contains parameter estimates used in each imputation with the `OUTEST=` option in the MCMC statement, and you can specify the data set that contains parameters used in the imputation step for each iteration with the `OUTITER` option in the MCMC statement.

### **OUT=SAS-data-set in the PROC MI statement**

The `OUT=` data set contains all the variables in the original data set and a new variable named `_Imputation_` that identifies the imputation. For each imputation, the data set contains all variables in the input `DATA=` data set with missing values being replaced by imputed values. Note that when the `NIMPUTE=1` option is specified, the variable `_Imputation_` is not created.

### **OUT=SAS-data-set in an EM statement**

The `OUT=` data set contains the original data set with missing values being replaced by expected values from the EM algorithm.

### **OUTEM=SAS-data-set**

The `OUTEM=` data set is a `TYPE=COV` data set and contains the MLE computed with the EM algorithm. The observations with `_TYPE_='MEAN'` contain the estimated mean and the observations with `_TYPE_='COV'` contain the estimated covariances.

### **OUTEST=SAS-data-set**

The `OUTEST=` data set is a `TYPE=EST` data set and contains parameter estimates used in each imputation in the MCMC method. It also includes an index variable named `_Imputation_`, which identifies the imputation.

The observations with `_TYPE_='SEED'` contain the seed information for the random number generator. The observations with `_TYPE_='PARM'` or `_TYPE_='PARMS'` contain the point estimate, and the observations with `_TYPE_='COV'` or `_TYPE_='COVB'` contain the associated covariances. These estimates are used as the parameters of the reference distribution to impute values for observations in the `DATA=` dataset.

Note that these estimates are the values used in the I-step before each imputation. These are not the parameter values simulated from the P-step in the same iteration. See [Example 57.12](#) for a usage of this option.

### **OUTITER <(options)> =SAS-data-set in an EM statement**

The `OUTITER=` data set in an EM statement is a `TYPE=COV` data set and contains parameters for each iteration. It also includes a variable `_Iteration_` that provides the iteration number.

The parameters in the output data set depend on the options specified. You can specify the `MEAN` and `COV` options for `OUTITER`. With the `MEAN` option, the output data set contains the mean parameters in observations with the variable `_TYPE_='MEAN'`. Similarly, with the `COV` option, the output data set contains the covariance parameters in observations with the variable `_TYPE_='COV'`. When no options are specified, the output data set contains the mean parameters for each iteration.

**OUTITER <(options)> =SAS-data-set in an FCS statement**

The OUTITER= data set in an FCS statement is a TYPE=COV data set and contains parameters for each iteration. It also includes variables named `_Imputation_` and `_Iteration_`, which provide the imputation number and iteration number.

The parameters in the output data set depend on the options specified. You can specify the MEAN and STD options for OUTITER. With the MEAN option, the output data set contains the mean parameters used in the imputation in observations with the variable `_TYPE_='MEAN'`. Similarly, with the STD option, the output data set contains the standard deviation parameters used in the imputation in observations with the variable `_TYPE_='STD'`. When no options are specified, the output data set contains the mean parameters for each iteration.

**OUTITER <(options)> =SAS-data-set in an MCMC statement**

The OUTITER= data set in an MCMC statement is a TYPE=COV data set and contains parameters used in the imputation step for each iteration. It also includes variables named `_Imputation_` and `_Iteration_`, which provide the imputation number and iteration number.

The parameters in the output data set depend on the options specified. [Table 57.6](#) summarizes the options available for OUTITER and the corresponding values for the output variable `_TYPE_`.

**Table 57.6** Summary of Options for OUTITER in an MCMC statement

| Option  | Output Parameters                         | _TYPE_   |
|---------|-------------------------------------------|----------|
| MEAN    | mean parameters                           | MEAN     |
| STD     | standard deviations                       | STD      |
| COV     | covariances                               | COV      |
| LR      | -2 log LR statistic                       | LOG_LR   |
| LR_POST | -2 log LR statistic of the posterior mode | LOG_POST |
| WLF     | worst linear function                     | WLF      |

When no options are specified, the output data set contains the mean parameters used in the imputation step for each iteration. For a detailed description of the worst linear function and LR statistics, see the section “[Checking Convergence in MCMC](#)” on page 4764.

---

## Combining Inferences from Multiply Imputed Data Sets

With  $m$  imputations,  $m$  different sets of the point and variance estimates for a parameter  $Q$  can be computed. Suppose  $\hat{Q}_i$  and  $\hat{W}_i$  are the point and variance estimates from the  $i$ th imputed data set,  $i = 1, 2, \dots, m$ . Then the combined point estimate for  $Q$  from multiple imputation is the average of the  $m$  complete-data estimates:

$$\bar{Q} = \frac{1}{m} \sum_{i=1}^m \hat{Q}_i$$

Suppose  $\overline{W}$  is the within-imputation variance, which is the average of the  $m$  complete-data estimates,

$$\overline{W} = \frac{1}{m} \sum_{i=1}^m \hat{W}_i$$

and  $B$  is the between-imputation variance

$$B = \frac{1}{m-1} \sum_{i=1}^m (\hat{Q}_i - \overline{Q})^2$$

Then the variance estimate associated with  $\overline{Q}$  is the total variance (Rubin 1987)

$$T = \overline{W} + \left(1 + \frac{1}{m}\right)B$$

The statistic  $(Q - \overline{Q})T^{-(1/2)}$  is approximately distributed as  $t$  with  $v_m$  degrees of freedom (Rubin 1987), where

$$v_m = (m-1) \left[ 1 + \frac{\overline{W}}{(1+m^{-1})B} \right]^2$$

The degrees of freedom  $v_m$  depend on  $m$  and the ratio

$$r = \frac{(1+m^{-1})B}{\overline{W}}$$

The ratio  $r$  is called the relative increase in variance due to nonresponse (Rubin 1987). When there is no missing information about  $Q$ , the values of  $r$  and  $B$  are both zero. With a large value of  $m$  or a small value of  $r$ , the degrees of freedom  $v_m$  will be large and the distribution of  $(Q - \overline{Q})T^{-(1/2)}$  will be approximately normal.

Another useful statistic is the fraction of missing information about  $Q$ :

$$\hat{\lambda} = \frac{r + 2/(v_m + 3)}{r + 1}$$

Both statistics  $r$  and  $\lambda$  are helpful diagnostics for assessing how the missing data contribute to the uncertainty about  $Q$ .

When the complete-data degrees of freedom  $v_0$  are small, and there is only a modest proportion of missing data, the computed degrees of freedom,  $v_m$ , can be much larger than  $v_0$ , which is inappropriate. For example, with  $m = 5$  and  $r = 10\%$ , the computed degrees of freedom  $v_m = 484$ , which is inappropriate for data sets with complete-data degrees of freedom less than 484.

Barnard and Rubin (1999) recommend the use of adjusted degrees of freedom

$$v_m^* = \left[ \frac{1}{v_m} + \frac{1}{\hat{v}_{obs}} \right]^{-1}$$

where  $\hat{v}_{obs} = (1 - \gamma)v_0(v_0 + 1)/(v_0 + 3)$  and  $\gamma = (1 + m^{-1})B/T$ .

Note that the MI procedure uses the adjusted degrees of freedom,  $v_m^*$ , for inference.

## Multiple Imputation Efficiency

The relative efficiency (RE) of using the finite  $m$  imputation estimator, rather than using an infinite number for the fully efficient imputation, in units of variance, is approximately a function of  $m$  and  $\lambda$  (Rubin 1987, p. 114):

$$\text{RE} = \left(1 + \frac{\lambda}{m}\right)^{-1}$$

Table 57.7 shows relative efficiencies with different values of  $m$  and  $\lambda$ .

**Table 57.7** Relative Efficiencies

| m  | $\lambda$ |        |        |        |        |
|----|-----------|--------|--------|--------|--------|
|    | 10%       | 20%    | 30%    | 50%    | 70%    |
| 3  | 0.9677    | 0.9375 | 0.9091 | 0.8571 | 0.8108 |
| 5  | 0.9804    | 0.9615 | 0.9434 | 0.9091 | 0.8772 |
| 10 | 0.9901    | 0.9804 | 0.9709 | 0.9524 | 0.9346 |
| 20 | 0.9950    | 0.9901 | 0.9852 | 0.9756 | 0.9662 |

The table shows that for situations with little missing information, only a small number of imputations are necessary. In practice, the number of imputations needed can be informally verified by replicating sets of  $m$  imputations and checking whether the estimates are stable between sets (Horton and Lipsitz 2001, p. 246).

## Imputer's Model Versus Analyst's Model

Multiple imputation inference assumes that the model you used to analyze the multiply imputed data (the analyst's model) is the same as the model used to impute missing values in multiple imputation (the imputer's model). But in practice, the two models might not be the same (Schafer 1997, p. 139).

Schafer (1997, pp. 139–143) provides comprehensive coverage of this topic, and the following example is based on his work.

Consider a trivariate data set with variables  $Y_1$  and  $Y_2$  fully observed, and a variable  $Y_3$  with missing values. An imputer creates multiple imputations with the model  $Y_3 = Y_1 Y_2$ . However, the analyst can later use the simpler model  $Y_3 = Y_1$ . In this case, the analyst assumes more than the imputer. That is, the analyst assumes there is no relationship between variables  $Y_3$  and  $Y_2$ .

The effect of the discrepancy between the models depends on whether the analyst's additional assumption is true. If the assumption is true, the imputer's model still applies. The inferences derived from multiple imputations will still be valid, although they might be somewhat conservative because they reflect the additional uncertainty of estimating the relationship between  $Y_3$  and  $Y_2$ .

On the other hand, suppose that the analyst models  $Y_3 = Y_1$ , and there is a relationship between variables  $Y_3$  and  $Y_2$ . Then the model  $Y_3 = Y_1$  will be biased and is inappropriate. Appropriate results can be generated only from appropriate analyst models.

Another type of discrepancy occurs when the imputer assumes more than the analyst. For example, suppose that an imputer creates multiple imputations with the model  $Y_3 = Y_1$ , but the analyst later fits a model  $Y_3 = Y_1 Y_2$ . When the assumption is true, the imputer's model is a correct model and the inferences still hold.

On the other hand, suppose there is a relationship between  $Y_3$  and  $Y_2$ . Imputations created under the incorrect assumption that there is no relationship between  $Y_3$  and  $Y_2$  will make the analyst's estimate of the relationship biased toward zero. Multiple imputations created under an incorrect model can lead to incorrect conclusions.

Thus, generally you should include as many variables as you can when doing multiple imputation. The precision you lose with included unimportant predictors is usually a relatively small price to pay for the general validity of analyses of the resultant multiply imputed data set (Rubin 1996). But at the same time, you need to keep the model building and fitting feasible (Barnard and Meng 1999, pp. 19–20).

To produce high-quality imputations for a particular variable, the imputation model should also include variables that are potentially related to the imputed variable and variables that are potentially related to the missingness of the imputed variable (Schafer 1997, p. 143).

Similar suggestions were also given by van Buuren, Boshuizen, and Knook (1999, p. 687). They recommend that the imputation model include three sets of covariates: variables in the analyst's model, variables associated with the missingness of the imputed variable, and variables correlated with the imputed variable. They also recommend the removal of the covariates not in the analyst's model if they have too many missing values for observations with missing imputed variables.

Note that it is good practice to include a description of the imputer's model with the multiply imputed data set (Rubin 1996, p. 479). That way, the analysts will have information about the variables involved in the imputation and which relationships among the variables have been implicitly set to zero.

---

## Parameter Simulation versus Multiple Imputation

As an alternative to multiple imputation, parameter simulation can also be used to analyze the data for many incomplete-data problems. Although the MI procedure does not offer parameter simulation, the trade-offs between the two methods (Schafer 1997, pp. 89–90, 135–136) are examined in this section.

The parameter simulation method simulates random values of parameters from the observed-data posterior distribution and makes simple inferences about these parameters (Schafer 1997, p. 89). When a set of well-defined population parameters  $\theta$  are of interest, parameter simulation can be used to directly examine and summarize simulated values of  $\theta$ . This usually requires a large number of iterations, and involves calculating appropriate summaries of the resulting dependent sample of the iterates of the  $\theta$ . If only a small set of parameters are involved, parameter simulation is suitable (Schafer 1997).

Multiple imputation requires only a small number of imputations. Generating and storing a few imputations can be more efficient than generating and storing a large number of iterations for parameter simulation.

When fractions of missing information are low, methods that average over simulated values of the missing data, as in multiple imputation, can be much more efficient than methods that average over simulated values of  $\theta$  as in parameter simulation (Schafer 1997).

---

## Summary of Issues in Multiple Imputation

This section summarizes issues that are encountered in applications of the MI procedure.

### The MAR Assumption

The missing at random (MAR) assumption is needed for the imputation methods in the MI procedure. Although this assumption cannot be verified with the data, it becomes more plausible as more variables are included in the imputation model (Schafer 1997, pp. 27–28; van Buuren, Boshuizen, and Knook 1999, p. 687).

### Number of Imputations

Based on the theory of multiple imputation, only a small number of imputations are needed for a data set with little missing information (Rubin 1987, p. 114). The number of imputations can be informally verified by replicating sets of  $m$  imputations and checking whether the estimates are stable (Horton and Lipsitz 2001, p. 246).

### Imputation Model

Generally you should include as many variables as you can in the imputation model (Rubin 1996). At the same time, however, it is important to keep the number of variables in control, as discussed by Barnard and Meng (1999, pp. 19–20). For the imputation of a particular variable, the model should include variables in the complete-data model, variables that are correlated with the imputed variable, and variables that are associated with the missingness of the imputed variable (Schafer 1997, p. 143; van Buuren, Boshuizen, and Knook 1999, p. 687).

### Multivariate Normality Assumption

Although the regression and MCMC methods assume multivariate normality, inferences based on multiple imputation can be robust to departures from the multivariate normality if the amount of missing information is not large (Schafer 1997, pp. 147–148).

You can use variable transformations to make the normality assumption more tenable. Variables are transformed before the imputation process and then back-transformed to create imputed values.

### Monotone Regression Method

With the multivariate normality assumption, either the regression method or the predictive mean matching method can be used to impute continuous variables in data sets with monotone missing patterns.

The predictive mean matching method ensures that imputed values are plausible and might be more appropriate than the regression method if the normality assumption is violated (Horton and Lipsitz 2001, p. 246).

### Monotone Propensity Score Method

The propensity score method can also be used to impute continuous variables in data sets with monotone missing patterns.

The propensity score method does not use correlations among variables and is not appropriate for analyses involving relationship among variables, such as a regression analysis (Schafer 1999, p. 11). It can also produce badly biased estimates of regression coefficients when data on predictor variables are missing (Allison 2000).

### MCMC Monotone-Data Imputation

The MCMC method is used to impute continuous variables in data sets with arbitrary missing patterns, assuming a multivariate normal distribution for the data. It can also be used to impute just enough missing values to make the imputed data sets have a monotone missing pattern. Then, a more flexible monotone imputation method can be used for the remaining missing values.

### Checking Convergence in MCMC

In an MCMC method, parameters are drawn after the MCMC is run long enough to converge to its stationary distribution. In practice, however, it is not simple to verify the convergence of the process, especially for a large number of parameters.

You can check for convergence by examining the observed-data likelihood ratio statistic and worst linear function of the parameters in each iteration. You can also check for convergence by examining a plot of autocorrelation function, as well as a trace plot of parameters (Schafer 1997, p. 120).

### EM Estimates

The EM algorithm can be used to compute the MLE of the mean vector and covariance matrix of the data with missing values, assuming a multivariate normal distribution for the data. However, the covariance matrix associated with the estimate of the mean vector cannot be derived from the EM algorithm.

In the MI procedure, you can use the EM algorithm to compute the posterior mode, which provides a good starting value for the MCMC method (Schafer 1997, p. 169).

---

## ODS Table Names

PROC MI assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in Table 57.8. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 57.8** ODS Tables Produced by PROC MI

| ODS Table Name    | Description                   | Statement | Option               |
|-------------------|-------------------------------|-----------|----------------------|
| Corr              | Pairwise correlations         |           | SIMPLE               |
| EMEstimates       | EM (MLE) estimates            | EM        |                      |
| EMInitEstimates   | EM initial estimates          | EM        |                      |
| EMIterHistory     | EM (MLE) iteration history    | EM        | ITPRINT              |
| EMPostEstimates   | EM (posterior mode) estimates | MCMC      | INITIAL=EM           |
| EMPostIterHistory | EM (posterior mode)           | MCMC      | INITIAL=EM (ITPRINT) |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

PROC MI assigns a name to each graph it creates using ODS. You can use these names to reference the graphs when using ODS. To request these graphs, ODS Graphics must be enabled and you must specify the options indicated in [Table 57.9](#).

**Table 57.9** Graphs Produced by PROC MI

| ODS Graph Name | Description | Statement | Option       |
|----------------|-------------|-----------|--------------|
| ACFPlot        | ACF plot    | MCMC      | PLOTS=ACF    |
| TracePlot      | Trace plot  | MCMC      | PLOTS= TRACE |
|                |             | FCS       | PLOTS= TRACE |

## Examples: MI Procedure

The Fish data described in the STEPDISC procedure are measurements of 159 fish of seven species caught in Finland’s lake Laengelmavesi. For each fish, the length, height, and width are measured. Three different length measurements are recorded: from the nose of the fish to the beginning of its tail (Length1), from the nose to the notch of its tail (Length2), and from the nose to the end of its tail (Length3). See Chapter 89, “The STEPDISC Procedure,” for more information.

The Fish1 data set is constructed from the Fish data set and contains only one species of the fish and the three length measurements. Some values have been set to missing, and the resulting data set has a monotone missing pattern in the variables Length1, Length2, and Length3. The Fish1 data set is used in [Example 57.2](#) with the propensity score method and in [Example 57.3](#) with the regression method.

The Fish2 data set is also constructed from the Fish data set and contains two species of fish. Some values have been set to missing, and the resulting data set has a monotone missing pattern in the variables Length, Height, Width, and Species. The Fish2 data set is used in [Example 57.4](#) with the logistic regression method and in [Example 57.5](#) with the discriminant function method. Note that some values of the variable Species have also been altered in the data set.

The Fish3 data set is similar to the data set Fish2 except some additional values have been set to missing and the resulting data set has an arbitrary missing pattern. The Fish3 data set is used in [Example 57.7](#) and in [Example 57.8](#).

The Fitness1 data set created in the section “Getting Started: MI Procedure” on page 4716 is used in other examples.

The following statements create the Fish1 data set:

```

-----Fish1 Data-----
| The data set contains one species of the fish (Bream) and |
| three measurements: Length1, Length2, Length3. |
| Some values have been set to missing, and the resulting data set |
| has a monotone missing pattern in the variables |
| Length1, Length2, and Length3. |

### Example 57.1: EM Algorithm for MLE

This example uses the EM algorithm to compute the maximum likelihood estimates for parameters of multivariate normally distributed data with missing values. The following statements invoke the MI procedure and request the EM algorithm to compute the MLE for  $(\mu, \Sigma)$  of a multivariate normal distribution from the input data set Fitness1:

```

proc mi data=Fitness1 seed=1518971 simple nimpute=0;
 em itprint outem=outem;
 var Oxygen RunTime RunPulse;
run;

```

Note that when you specify the NIMPUTE=0 option, the missing values are not imputed.

The “Model Information” table in [Output 57.1.1](#) describes the method and options used in the procedure if a positive number is specified in the NIMPUTE= option.

**Output 57.1.1** Model Information

| The MI Procedure                 |                   |
|----------------------------------|-------------------|
| Model Information                |                   |
| Data Set                         | WORK.FITNESS1     |

| 12                         | 254.482800      | 47.104077     | 10.554858      | 171.381669      |

The “EM (MLE) Parameter Estimates” table in [Output 57.1.7](#) displays the maximum likelihood estimates for  $\mu$  and  $\Sigma$  of a multivariate normal distribution from the data set Fitness1.

**Output 57.1.7** EM (MLE) Parameter Estimates

| EM (MLE) Parameter Estimates |             |               |                |                 |
|------------------------------|-------------|---------------|----------------|-----------------|
| <u>TYPE</u>                  | <u>NAME</u> | <u>Oxygen</u> | <u>RunTime</u> | <u>RunPulse</u> |
| MEAN                         |             | 47.104077     | 10.554858      | 171.381669      |
| COV                          | Oxygen      | 27.797931     | -6.457975      | -18.031298      |
| COV                          | RunTime     | -6.457975     | 2.015514       | 3.516287        |
| COV                          | RunPulse    | -18.031298    | 3.516287       | 97.766857       |

You can also output the EM (MLE) parameter estimates to an output data set with the OUTEM= option. The following statements list the observations in the output data set outem:

```
proc print data=outem;
 title 'EM Estimates';
run;
```

The output data set outem in [Output 57.1.8](#) is a TYPE=COV data set. The observation with TYPE='MEAN' contains the MLE for the parameter  $\mu$ , and the observations with TYPE='COV' contain the MLE for the parameter  $\Sigma$  of a multivariate normal distribution from the data set Fitness1.

**Output 57.1.8** EM Estimates

| EM Estimates |        |          |          |         |          |
|--------------|--------|----------|----------|---------|----------|
| Obs          | _TYPE_ | _NAME_   | Oxygen   | RunTime | RunPulse |
| 1            | MEAN   |          | 47.1041  | 10.5549 | 171.382  |
| 2            | COV    | Oxygen   | 27.7979  | -6.4580 | -18.031  |
| 3            | COV    | RunTime  | -6.4580  | 2.0155  | 3.516    |
| 4            | COV    | RunPulse | -18.0313 | 3.5163  | 97.767   |

## Example 57.2: Monotone Propensity Score Method

This example uses the propensity score method to impute missing values for variables in a data set with a monotone missing pattern. The following statements invoke the MI procedure and request the propensity score method. The resulting data set is named `outex2`.

```
proc mi data=Fish1 seed=899603 out=outex2;
 monotone propensity;
 var Length1 Length2 Length3;
run;
```

Note that the VAR statement is required and the data set must have a monotone missing pattern with variables as ordered in the VAR statement.

The “Model Information” table in [Output 57.2.1](#) describes the method and options used in the multiple imputation process. By default, five imputations are created for the missing data.

**Output 57.2.1** Model Information

| The MI Procedure                 |            |
|----------------------------------|------------|
| Model Information                |            |
| Data Set                         | WORK.FISH1 |
| Method                           | Monotone   |
| Number of Imputations            | 5          |
| Seed for random number generator | 899603     |

When monotone methods are used in the imputation, MONOTONE is displayed as the method. The “Monotone Model Specification” table in [Output 57.2.2](#) displays the detailed model specification. By default, the observations are sorted into five groups based on their propensity scores.

**Output 57.2.2** Monotone Model Specification

| Monotone Model Specification |                   |         |
|------------------------------|-------------------|---------|
| Method                       | Imputed Variables |         |
| Propensity( Groups= 5)       | Length2           | Length3 |

Without covariates specified for imputed variables Length2 and Length3, the variable Length1 is used as the covariate for Length2, and the variables Length1 and Length2 are used as covariates for Length3.

The “Missing Data Patterns” table in [Output 57.2.3](#) lists distinct missing data patterns with corresponding frequencies and percentages. Here, values of “X” and “.” indicate that the variable is observed or missing, respectively, in the corresponding group. The table confirms a monotone missing pattern for these three variables.

**Output 57.2.3** Missing Data Patterns

| Missing Data Patterns |         |         |         |      |         |
|-----------------------|---------|---------|---------|------|---------|
| Group                 | Length1 | Length2 | Length3 | Freq | Percent |
| 1                     | X       | X       | X       | 30   | 85.71   |
| 2                     | X       | X       | .       | 3    | 8.57    |
| 3                     | X       | .       | .       | 2    | 5.71    |

| Missing Data Patterns |                       |           |           |
|-----------------------|-----------------------|-----------|-----------|
| Group                 | -----Group Means----- |           |           |
|                       | Length1               | Length2   | Length3   |
| 1                     | 30.603333             | 33.436667 | 38.720000 |
| 2                     | 29.033333             | 31.666667 | .         |
| 3                     | 27.750000             | .         | .         |

For the imputation process, first, missing values of Length2 in group 3 are imputed using observed values of Length1. Then the missing values of Length3 in group 2 are imputed using observed values of Length1 and Length2. And finally, the missing values of Length3 in group 3 are imputed using observed values of Length1 and imputed values of Length2.

After the completion of  $m$  imputations, the “Variance Information” table in [Output 57.2.4](#) displays the between-imputation variance, within-imputation variance, and total variance for combining complete-data inferences. It also displays the degrees of freedom for the total variance. The relative increase in variance due to missingness, the fraction of missing information, and the relative efficiency for each variable are also displayed. A detailed description of these statistics is provided in the section “[Combining Inferences from Multiply Imputed Data Sets](#)” on page 4769.

**Output 57.2.4** Variance Information

| Variance Information |                    |          |          |        |
|----------------------|--------------------|----------|----------|--------|
| Variable             | -----Variance----- |          |          | DF     |
|                      | Between            | Within   | Total    |        |
| Length2              | 0.001500           | 0.465422 | 0.467223 | 32.034 |
| Length3              | 0.049725           | 0.547434 | 0.607104 | 27.103 |

| Variance Information |                               |                              |                     |
|----------------------|-------------------------------|------------------------------|---------------------|
| Variable             | Relative Increase in Variance | Fraction Missing Information | Relative Efficiency |
| Length2              | 0.003869                      | 0.003861                     | 0.999228            |
| Length3              | 0.108999                      | 0.102610                     | 0.979891            |

The “Parameter Estimates” table in [Output 57.2.5](#) displays the estimated mean and standard error of the mean for each variable. The inferences are based on the  $t$  distributions. For each variable, the table also displays a 95% mean confidence interval and a  $t$  statistic with the associated  $p$ -value for the hypothesis that the population mean is equal to the value specified in the MU0= option, which is zero by default.

**Output 57.2.5** Parameter Estimates

| Parameter Estimates |           |           |                       |          |        |
|---------------------|-----------|-----------|-----------------------|----------|--------|
| Variable            | Mean      | Std Error | 95% Confidence Limits |          | DF     |

|                     |           |           | Mu0       | Mean=Mu0 | Pr >  t |
| Length2             | 32.957143 | 33.060000 | 0         | 48.29    | <.0001  |
| Length3             | 38.080000 | 38.545714 | 0         | 49.23    | <.0001  |

The following statements list the first 10 observations of the data set outex2, as shown in [Output 57.2.6](#). The missing values are imputed from observed values with similar propensity scores.

```
proc print data=outex2(obs=10);
 title 'First 10 Observations of the Imputed Data Set';
run;
```

**Output 57.2.6** Imputed Data Set

| First 10 Observations of the Imputed Data Set |              |         |         |         |
|-----------------------------------------------|--------------|---------|---------|---------|
| Obs                                           | _Imputation_ | Length1 | Length2 | Length3 |
| 1                                             | 1            | 23.2    | 25.4    | 30.0    |
| 2                                             | 1            | 24.0    | 26.3    | 31.2    |
| 3                                             | 1            | 23.9    | 26.5    | 31.1    |
| 4                                             | 1            | 26.3    | 29.0    | 33.5    |
| 5                                             | 1            | 26.5    | 29.0    | 38.6    |
| 6                                             | 1            | 26.8    | 29.7    | 34.7    |
| 7                                             | 1            | 26.8    | 29.0    | 35.0    |
| 8                                             | 1            | 27.6    | 30.0    | 35.0    |
| 9                                             | 1            | 27.6    | 30.0    | 35.1    |
| 10                                            | 1            | 28.5    | 30.7    | 36.2    |

**Example 57.3: Monotone Regression Method**

This example uses the regression method to impute missing values for all variables in a data set with a monotone missing pattern. The following statements invoke the MI procedure and request the regression method for the variable Length2 and the predictive mean matching method for variable Length3. The resulting data set is named outex3.

```
proc mi data=Fish1 round=.1 mu0= 0 35 45
 seed=13951639 out=outex3;
 monotone reg(Length2/ details)
 regpmm(Length3= Length1 Length2 Length1*Length2/ details);
 var Length1 Length2 Length3;
run;
```

The ROUND= option is used to round the imputed values to the same precision as observed values. The values specified with the ROUND= option are matched with the variables Length1, Length2, and Length3 in the order listed in the VAR statement. The MU0= option requests *t* tests for the hypotheses that the population means corresponding to the variables in the VAR statement are Length2=35 and Length3=45.

The “Missing Data Patterns” table lists distinct missing data patterns with corresponding frequencies and percentages. It is identical to the table in Output 57.2.3 in Example 57.2.

The “Monotone Model Specification” table in [Output 57.3.1](#) displays the model specification.

**Output 57.3.1** Monotone Model Specification

| The MI Procedure             |                   |
|------------------------------|-------------------|
| Monotone Model Specification |                   |
| Method                       | Imputed Variables |
| Regression                   | Length2           |
| Regression-PMM( K= 5)        | Length3           |

When you use the DETAILS option, the parameters estimated from the observed data and the parameters used in each imputation are displayed in [Output 57.3.2](#) and [Output 57.3.3](#).

**Output 57.3.2** Regression Model

After the completion of five imputations by default, the “Variance Information” table in [Output 57.3.4](#) displays the between-imputation variance, within-imputation variance, and total variance for combining complete-data inferences. The relative increase in variance due to missingness, the fraction of missing information, and the relative efficiency for each variable are also displayed. These statistics are described in the section “Combining Inferences from Multiply Imputed Data Sets” on page 4769.

**Output 57.3.4** Variance Information

| Variance Information |                    |          |          |        |

The following statements list the first 10 observations of the data set outex3 in [Output 57.3.6](#). Note that the imputed values of Length2 are rounded to the same precision as the observed values.

```
proc print data=outex3(obs=10);
 title 'First 10 Observations of the Imputed Data Set';
run;
```

**Output 57.3.6** Imputed Data Set

| First 10 Observations of the Imputed Data Set |              |         |         |         |  |
|-----------------------------------------------|--------------|---------|---------|---------|--|
| Obs                                           | _Imputation_ | Length1 | Length2 | Length3 |  |
| 1                                             | 1            | 23.2    | 25.4    | 30.0    |  |
| 2                                             | 1            | 24.0    | 26.3    | 31.2    |  |
| 3                                             | 1            | 23.9    | 26.5    | 31.1    |  |
| 4                                             | 1            | 26.3    | 29.0    | 33.5    |  |
| 5                                             | 1            | 26.5    | 29.0    | 34.7    |  |
| 6                                             | 1            | 26.8    | 29.7    | 34.7    |  |
| 7                                             | 1            | 26.8    | 28.8    | 34.7    |  |
| 8                                             | 1            | 27.6    | 30.0    | 35.0    |  |
| 9                                             | 1            | 27.6    | 30.0    | 35.1    |  |
| 10                                            | 1            | 28.5    | 30.7    | 36.2    |  |

## Example 57.4: Monotone Logistic Regression Method for CLASS Variables

This example uses logistic regression method to impute values for a binary variable in a data set with a monotone missing pattern.

In the following statements, the logistic regression method is used for the binary CLASS variable Species:

```
proc mi data=Fish2 seed=1305417 out=outex4;
 class Species;
 monotone reg(Length Width/ details)
 logistic(Species= Length Height Width Height*Width/ details);
 var Length Height Width Species;
run;
```

The “Model Information” table in [Output 57.4.1](#) describes the method and options used in the multiple imputation process.

**Output 57.4.1** Model Information

| The MI Procedure                 |            |
|----------------------------------|------------|
| Model Information                |            |
| Data Set                         | WORK.FISH2 |
| Method                           | Monotone   |
| Number of Imputations            | 5          |
| Seed for random number generator | 1305417    |

The “Monotone Model Specification” table in [Output 57.4.2](#) describes methods and imputed variables in the imputation model. The procedure uses the logistic regression method to impute the variable Species in the model. Missing values in other variables are not imputed.

**Output 57.4.2** Monotone Model Specification

| Monotone Model Specification |                   |
|------------------------------|-------------------|
| Method                       | Imputed Variables |
| Regression                   | Height Width      |
| Logistic Regression          | Species           |

The “Missing Data Patterns” table in [Output 57.4.3](#) lists distinct missing data patterns with corresponding frequencies and percentages. The table confirms a monotone missing pattern for these variables.

**Output 57.4.3** Missing Data Patterns

| Missing Data Patterns |        |        |       |         |      |         |
|-----------------------|--------|--------|-------|---------|------|---------|
| Group                 | Length | Height | Width | Species | Freq | Percent |
| 1                     | X      | X      | X     | X       | 43   | 82.69   |
| 2                     | X      | X      | X     | .       | 3    | 5.77    |
| 3                     | X      | X      | .     | .       | 4    | 7.69    |
| 4                     | X      | .      | .     | .       | 2    | 3.85    |

| Missing Data Patterns |           |           |          |
|-----------------------|-----------|-----------|----------|
| -----Group Means----- |           |           |          |
| Group                 | Length    | Height    | Width    |
| 1                     | 41.997674 | 12.819512 | 5.359860 |
| 2                     | 38.433333 | 11.797667 | 4.587667 |
| 3                     | 42.275000 | 13.346750 | .        |
| 4                     | 40.150000 | .         | .        |

When you use the DETAILS option, parameters estimated from the observed data and the parameters used in each imputation are displayed in the “Logistic Models for Monotone Method” table in [Output 57.4.4](#).

**Output 57.4.4** Regression Model

| Regression Models for Monotone Method |           |          |                      |          |           |
|---------------------------------------|-----------|----------|----------------------|----------|-----------|
| Imputed Variable                      | Effect    | Obs-Data | -----Imputation----- |          |           |
|                                       |           |          | 1                    | 2        | 3         |
| Width                                 | Intercept | 0.00682  | 0.054140             | 0.018049 | -0.015137 |

| 5                                             | 1            | Bream   | 34.0   | 12.444 | 4.62964 |  |
| 6                                             | 1            | Bream   | 34.7   | 13.602 | 4.92700 |  |
| 7                                             | 1            | Bream   | 34.5   | 14.180 | 5.27900 |  |
| 8                                             | 1            | Bream   | 35.0   | 12.670 | 4.69000 |  |
| 9                                             | 1            | Bream   | 35.1   | 14.005 | 4.84400 |  |
| 10                                            | 1            | Bream   | 36.2   | 14.227 | 4.95900 |  |

Note that a missing value of the variable Species is not imputed if the corresponding covariates are missing and not imputed, as shown by observation 4 in the table.

## Example 57.5: Monotone Discriminant Function Method for CLASS Variables

This example uses discriminant monotone methods to impute values of a CLASS variable from the observed observation values in a data set with a monotone missing pattern.

The following statements impute the continuous variables Height and Width with the regression method and the classification variable Species with the discriminant function method:

```
proc mi data=Fish2 seed=7545417 nimpute=3 out=outex5;
 class Species;
 monotone reg(Height Width)
 discrim(Species= Length Height Width/ details);
 var Length Height Width Species;
run;
```

The “Model Information” table in [Output 57.5.1](#) describes the method and options used in the multiple imputation process.

**Output 57.5.1** Model Information

| The MI Procedure                 |            |
|----------------------------------|------------|
| Model Information                |            |
| Data Set                         | WORK.FISH2 |
| Method                           | Monotone   |
| Number of Imputations            | 3          |
| Seed for random number generator | 7545417    |

The “Monotone Model Specification” table in [Output 57.5.2](#) describes methods and imputed variables in the imputation model. The procedure uses the regression method to impute the variables Height and Width, and uses the logistic regression method to impute the variable Species in the model.

**Output 57.5.2** Monotone Model Specification

| Monotone Model Specification |                   |
|------------------------------|-------------------|
| Method                       | Imputed Variables |
| Regression                   | Height Width      |
| Discriminant Function        | Species           |

The “Missing Data Patterns” table in [Output 57.5.3](#) lists distinct missing data patterns with corresponding frequencies and percentages. The table confirms a monotone missing pattern for these variables.

**Output 57.5.3** Missing Data Patterns

| Missing Data Patterns |        |        |       |         |      |         |
|-----------------------|--------|--------|-------|---------|------|---------|
| Group                 | Length | Height | Width | Species | Freq | Percent |
| 1                     | X      | X      | X     | X       | 43   | 82.69   |
| 2                     | X      | X      | X     | .       | 3    | 5.77    |
| 3                     | X      | X      | .     | .       | 4    | 7.69    |
| 4                     | X      | .      | .     | .       | 2    | 3.85    |

| Missing Data Patterns |                       |           |          |
|-----------------------|-----------------------|-----------|----------|
| Group                 | -----Group Means----- |           |          |
|                       | Length                | Height    | Width    |
| 1                     | 41.997674             | 12.819512 | 5.359860 |
| 2                     | 38.433333             | 11.797667 | 4.587667 |
| 3                     | 42.275000             | 13.346750 | .        |
| 4                     | 40.150000             | .         | .        |

When you use the DETAILS option, the parameters estimated from the observed data and the parameters used in each imputation are displayed in [Output 57.5.4](#).

**Output 57.5.4** Discriminant Model

| Group Means for Monotone Discriminant Method |          |          |                      |           |           |
|----------------------------------------------|----------|----------|----------------------|-----------|-----------|
| Species                                      | Variable | Obs-Data | -----Imputation----- |           |           |
|                                              |          |          | 1                    | 2         | 3         |
| Bream                                        | Length   | -0.36712 | -0.198907            | -0.375696 | -0.307771 |
| Bream                                        | Height   | 0.64051  | 0.756448             | 0.684845  | 0.658337  |
| Bream                                        | Width    | 0.20882  | 0.465034             | 0.254438  | 0.252637  |
| Pike                                         | Length   | 0.85554  | 0.656521             | 0.677957  | 1.024069  |
| Pike                                         | Height   | -1.31185 | -1.431954            | -1.436355 | -1.119520 |
| Pike                                         | Width    | -0.25768 | -0.381503            | -0.420441 | -0.136188 |

The following statements list the first 10 observations of the data set outex5 in [Output 57.5.5](#). Note that all missing values of the variables Width and Species are imputed.

```
proc print data=outex5(obs=10);
 title 'First 10 Observations of the Imputed Data Set';
run;
```

**Output 57.5.5** Imputed Data Set

| First 10 Observations of the Imputed Data Set |              |         |        |        |         |
|-----------------------------------------------|--------------|---------|--------|--------|---------|
| Obs                                           | _Imputation_ | Species | Length | Height | Width   |
| 1                                             | 1            | Bream   | 30.0   | 11.520 | 4.02000 |
| 2                                             | 1            | Bream   | 31.2   | 12.480 | 4.30600 |
| 3                                             | 1            | Bream   | 31.1   | 12.378 | 4.69600 |
| 4                                             | 1            | Bream   | 33.5   | 12.730 | 4.45600 |
| 5                                             | 1            | Bream   | 34.0   | 12.444 | 4.46687 |
| 6                                             | 1            | Bream   | 34.7   | 13.602 | 4.92700 |
| 7                                             | 1            | Bream   | 34.5   | 14.180 | 5.27900 |
| 8                                             | 1            | Bream   | 35.0   | 12.670 | 4.69000 |
| 9                                             | 1            | Bream   | 35.1   | 14.005 | 4.84400 |
| 10                                            | 1            | Bream   | 36.2   | 14.227 | 4.95900 |

### Example 57.6: FCS Method for Continuous Variables

This example uses FCS regression methods to impute values for all continuous variables in a data set with an arbitrary missing pattern.

The following statements invoke the MI procedure and impute missing values for the Fitness1 data set:

```
proc mi data=Fitness1 seed=1213 nimpute=4 mu0=50 10 180 out=outex6;
 fcs nbiter=20 reg(/details);
 var Oxygen RunTime RunPulse;
run;
```

The NIMPUTE=4 option specifies the total number of imputations. The FCS statement requests multivariate imputations by FCS methods, and the NBITER=20 option (which is the default) specifies the number of burn-in iterations before each imputation.

The “Model Information” table in [Output 57.6.1](#) describes the method and options used in the multiple imputation process.

**Output 57.6.1** Model Information

| The MI Procedure                 |               |
|----------------------------------|---------------|
| Model Information                |               |
| Data Set                         | WORK.FITNESS1 |
| Method                           | FCS           |
| Number of Imputations            | 4             |
| Number of Burn-in Iterations     | 20            |
| Seed for random number generator | 1213          |

The “FCS Model Specification” table in [Output 57.6.2](#) describes methods and imputed variables in the imputation model. With the REG option in the FCS statement, the procedure uses the regression method to

impute variables RunTime, RunPulse, and Oxygen in the model.

**Output 57.6.2** FCS Model Specification

| FCS Model Specification |                   |         |          |
|-------------------------|-------------------|---------|----------|
| Method                  | Imputed Variables |         |          |
| Regression              | Oxygen            | RunTime | RunPulse |

The “Missing Data Patterns” table in [Output 57.6.3](#) lists distinct missing data patterns with corresponding frequencies and percentages.

**Output 57.6.3** Missing Data Patterns

| Missing Data Patterns |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |
| 1                     | X      | X        | X         | 21   | 67.74   |
| 2                     | X      | X        | .         | 4    | 12.90   |
| 3                     | X      | .        | .         | 3    | 9.68    |
| 4                     | .      | X        | X         | 1    | 3.23    |
| 5                     | .      | X        | .         | 2    | 6.45    |

| Missing Data Patterns |                       |           |            |
|-----------------------|-----------------------|-----------|------------|
| Group                 | -----Group Means----- |           |            |
|                       | Oxygen                | RunTime   | RunPulse   |
| 1                     | 46.353810             | 10.809524 | 171.666667 |
| 2                     | 47.109500             | 10.137500 | .          |
| 3                     | 52.461667             | .         | .          |
| 4                     | .                     | 11.950000 | 176.000000 |
| 5                     | .                     | 9.885000  | .          |

When you use the DETAILS option, the parameters used in each imputation are displayed in [Output 57.6.4](#), [Output 57.6.5](#), and [Output 57.6.6](#).

**Output 57.6.4** FCS Regression Model for Oxygen

| Regression Models for FCS Method |           |                      |           |           |           |

After the completion of the specified four imputations, the “Variance Information” table in [Output 57.6.8](#) displays the between-imputation variance, within-imputation variance, and total variance for combining complete-data inferences. The relative increase in variance due to missingness, the fraction of missing information, and the relative efficiency for each variable are also displayed. These statistics are described in the section “Combining Inferences from Multiply Imputed Data Sets” on page 4769.

**Output 57.6.8** Variance Information

| Variance Information |                    |          |          |        |

## Example 57.7: FCS Method for CLASS Variables

This example uses FCS methods to impute missing values in both continuous and CLASS variables in a data set with an arbitrary missing pattern. The following statements invoke the MI procedure and impute missing values for the Fish3 data set:

```
proc mi data=Fish3 seed=1305417 out=outex7;
 class Species;
 fcs nbiter=10 discrim(Species/details) reg(Height/details);
 var Species Length Height Width;
run;
```

The DISCRIM option uses the discriminant function method to impute the classification variable Species, and the REG option uses the regression method to impute the continuous variable Height. By default, the regression method is also used to impute other continuous variables, Length and Width.

The “Model Information” table in [Output 57.7.1](#) describes the method and options used in the multiple imputation process.

**Output 57.7.1** Model Information

| The MI Procedure                 |            |
|----------------------------------|------------|
| Model Information                |            |
| Data Set                         | WORK.FISH3 |
| Method                           | FCS        |
| Number of Imputations            | 5          |
| Number of Burn-in Iterations     | 10         |
| Seed for random number generator | 1305417    |

The “FCS Model Specification” table in [Output 57.7.2](#) describes methods and imputed variables in the imputation model. The procedure uses the discriminant function method to impute the variable Species, and the regression method to impute other variables.

**Output 57.7.2** FCS Model Specification

| FCS Model Specification |                     |
|-------------------------|---------------------|
| Method                  | Imputed Variables   |
| Regression              | Length Height Width |
| Discriminant Function   | Species             |

The “Missing Data Patterns” table in [Output 57.7.3](#) lists distinct missing data patterns with corresponding frequencies and percentages.

**Output 57.7.3** Missing Data Patterns

| Missing Data Patterns |         |        |        |       |      |         |
|-----------------------|---------|--------|--------|-------|------|---------|
| Group                 | Species | Length | Height | Width | Freq | Percent |
| 1                     | X       | X      | X      | X     | 38   | 73.08   |
| 2                     | X       | .      | X      | X     | 2    | 3.85    |
| 3                     | X       | .      | X      | .     | 1    | 1.92    |
| 4                     | .       | X      | X      | X     | 3    | 5.77    |
| 5                     | .       | X      | X      | .     | 3    | 5.77    |
| 6                     | .       | X      | .      | X     | 2    | 3.85    |
| 7                     | .       | X      | .      | .     | 2    | 3.85    |
| 8                     | .       | .      | X      | .     | 1    | 1.92    |

| Missing Data Patterns |           |           |          |
|-----------------------|-----------|-----------|----------|
| -----Group Means----- |           |           |          |
| Group                 | Length    | Height    | Width    |
| 1                     | 41.515789 | 12.531526 | 5.266474 |
| 2                     | .         | 14.448000 | 6.886000 |
| 3                     | .         | 18.037000 | .        |
| 4                     | 38.433333 | 11.797667 | 4.587667 |
| 5                     | 45.033333 | 13.647667 | .        |
| 6                     | 36.100000 | .         | 5.135000 |
| 7                     | 40.150000 | .         | .        |
| 8                     | .         | 12.444000 | .        |

With the specified DETAILS option for variables Species and Height, parameters used in each imputation for these two variables are displayed in the “Group Means for FCS Discriminant Method” table in [Output 57.7.4](#) and in the “Regression Models for FCS Method” table in [Output 57.7.5](#).

**Output 57.7.4** FCS Discrim Model for Species

| Group Means for FCS Discriminant Method |          |                      |           |           |           |

After the completion of five imputations by default, the “Variance Information” table in [Output 57.7.7](#) displays the between-imputation variance, within-imputation variance, and total variance for combining complete-data inferences for continuous variables. The relative increase in variance due to missingness, the fraction of missing information, and the relative efficiency for each variable are also displayed. These statistics are described in the section “[Combining Inferences from Multiply Imputed Data Sets](#)” on page 4769.

**Output 57.7.7** Variance Information

| Variance Information |                    |          |          |        |
|----------------------|--------------------|----------|----------|--------|

### Example 57.8: FCS Method with Trace Plot

This example uses FCS methods to impute missing values in both continuous and classification variables in a data set with an arbitrary missing pattern. The following statements use a logistic regression method to impute values of the classification variable Species:

```
ods graphics on;
proc mi data=Fish3 seed=1305417 out=outex8;
 class Species;
 fcs plots=trace
 logistic(Species= Height Width Height*Width /details);
 var Species Height Width;
run;
ods graphics off;
```

The “Model Information” table in [Output 57.8.1](#) describes the method and options used in the multiple imputation process. By default, a regression method is used to impute missing values in each continuous variable.

**Output 57.8.1** Model Information

| The MI Procedure                 |            |
|----------------------------------|------------|
| Model Information                |            |
| Data Set                         | WORK.FISH3 |
| Method                           | FCS        |
| Number of Imputations            | 5          |
| Number of Burn-in Iterations     | 20         |
| Seed for random number generator | 1305417    |

The “FCS Model Specification” table in [Output 57.8.2](#) describes methods and imputed variables in the imputation model. The procedure uses the logistic regression method to impute the variable Species, and the regression method to impute variables Height and Width.

**Output 57.8.2** FCS Model Specification

| FCS Model Specification |                   |
|-------------------------|-------------------|
| Method                  | Imputed Variables |
| Regression              | Height Width      |
| Logistic Regression     | Species           |

The “Missing Data Patterns” table in [Output 57.8.3](#) lists distinct missing data patterns with corresponding frequencies and percentages.

**Output 57.8.3** Missing Data Patterns

| Missing Data Patterns |         |        |       |      |         |                       |          |
|-----------------------|---------|--------|-------|------|---------|-----------------------|----------|
| Group                 | Species | Height | Width | Freq | Percent | -----Group Means----- |          |
|                       |         |        |       |      |         | Height                | Width    |
| 1                     | X       | X      | X     | 40   | 76.92   | 12.627350             | 5.347450 |
| 2                     | X       | X      | .     | 1    | 1.92    | 18.037000             | .        |
| 3                     | .       | X      | X     | 3    | 5.77    | 11.797667             | 4.587667 |
| 4                     | .       | X      | .     | 4    | 7.69    | 13.346750             | .        |
| 5                     | .       | .      | X     | 2    | 3.85    | .                     | 5.135000 |
| 6                     | O       | O      | O     | 2    | 3.85    | .                     | .        |

When you use the DETAILS keyword in the LOGISTIC option, parameters estimated from the observed data and the parameters used in each imputation are displayed in the “Logistic Models for FCS Method” table in [Output 57.8.4](#).

**Output 57.8.4** FCS Logistic Regression Model for Species

| Logistic Models for FCS Method |              |                      |            |            |            |
|--------------------------------|--------------|----------------------|------------|------------|------------|
| Imputed<br>Variable            | Effect       | -----Imputation----- |            |            |            |
|                                |              | 1                    | 2          | 3          | 4          |
| Species                        | Intercept    | 27.250540            | 27.240843  | 27.242699  | 27.254682  |
| Species                        | Height       | 59.970974            | 59.962249  | 59.964027  | 59.980855  |
| Species                        | Width        | -26.032805           | -26.021304 | -26.023556 | -26.028866 |
| Species                        | Height*Width | -6.760308            | -6.739118  | -6.742934  | -6.754780  |

| Logistic Models for FCS Method |              |                   |
|--------------------------------|--------------|-------------------|
| Imputed<br>Variable            | Effect       | -Imputation-<br>5 |
| Species                        | Intercept    | 27.251468         |
| Species                        | Height       | 59.971742         |
| Species                        | Width        | -26.033865        |
| Species                        | Height*Width | -6.762477         |

With ODS Graphics enabled, the PLOTS=TRACE option displays trace plots of means for all continuous variables by default, as shown in [Output 57.8.5](#) and [Output 57.8.6](#). The dashed vertical lines indicate the imputed iterations—that is, the variable values used in the imputations. The plot shows no apparent trends for the two variables.

Output 57.8.5 Trace Plot for Height

Output 57.8.6 Trace Plot for Width

The following statements list the first 10 observations of the data set outex8 in Output 57.8.7:

```
proc print data=outex8(obs=10);
 title 'First 10 Observations of the Imputed Data Set';
run;
```

**Output 57.8.7** Imputed Data Set

| First 10 Observations of the Imputed Data Set |              |         |         |         |         |
|-----------------------------------------------|--------------|---------|---------|---------|---------|
| Obs                                           | _Imputation_ | Species | Length  | Height  | Width   |
| 1                                             | 1            | Bream   | 30.0000 | 11.5200 | 4.02000 |
| 2                                             | 1            | Bream   | 31.2000 | 12.4800 | 4.30600 |

### Example 57.9: MCMC Method

This example uses the MCMC method to impute missing values for a data set with an arbitrary missing pattern. The following statements invoke the MI procedure and specify the MCMC method with six imputations:

```
proc mi data=Fitness1 seed=21355417 nimpute=6 mu0=50 10 180 ;
 mcmc chain=multiple displayinit initial=em(itprint);
 var Oxygen RunTime RunPulse;
run;
```

The “Model Information” table in [Output 57.9.1](#) describes the method used in the multiple imputation process. When you use the `CHAIN=MULTIPLE` option, the procedure uses multiple chains and completes the default 200 burn-in iterations before each imputation. The 200 burn-in iterations are used to make the iterations converge to the stationary distribution before the imputation.

**Output 57.9.1** Model Information

| The MI Procedure                 |                   |
|----------------------------------|-------------------|
| Model Information                |                   |
| Data Set                         | WORK.FITNESS1     |
| Method                           | MCMC              |
| Multiple Imputation Chain        | Multiple Chains   |
| Initial Estimates for MCMC       | EM Posterior Mode |
| Start                            | Starting Value    |
| Prior                            | Jeffreys          |
| Number of Imputations            | 6                 |
| Number of Burn-in Iterations     | 200               |
| Seed for random number generator | 21355417          |

By default, the procedure uses a noninformative Jeffreys prior to derive the posterior mode from the EM algorithm as the starting values for the MCMC method.

The “Missing Data Patterns” table in [Output 57.9.2](#) lists distinct missing data patterns with corresponding statistics.

**Output 57.9.2** Missing Data Patterns

| Missing Data Patterns |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |
| 1                     | X      | X        | X         | 21   | 67.74   |
| 2                     | X      | X        | .         | 4    | 12.90   |
| 3                     | X      | .        | .         | 3    | 9.68    |
| 4                     | .      | X        | X         | 1    | 3.23    |
| 5                     | .      | X        | .         | 2    | 6.45    |

| Missing Data Patterns |           |           |            |
|-----------------------|-----------|-----------|------------|
| -----Group Means----- |           |           |            |
| Group                 | Oxygen    | RunTime   | RunPulse   |
| 1                     | 46.353810 | 10.809524 | 171.666667 |
| 2                     | 47.109500 | 10.137500 | .          |
| 3                     | 52.461667 | .         | .          |
| 4                     | .         | 11.950000 | 176.000000 |
| 5                     | .         | 9.885000  | .          |

When you use the `ITPRINT` option within the `INITIAL=EM` option, the procedure displays the “EM (Posterior Mode) Iteration History” table in [Output 57.9.3](#).

**Output 57.9.3** EM (Posterior Mode) Iteration History

| EM (Posterior Mode) Iteration History |                 |                         |               |                |

| 7                                     | 171.382196      |

When you use the DISPLAYINIT option in the MCMC statement, the “Initial Parameter Estimates for MCMC” table in [Output 57.9.4](#) displays the starting mean and covariance estimates used in the MCMC method. The same starting estimates are used in the MCMC method for multiple chains because the EM algorithm is applied to the same data set in each chain. You can explicitly specify different initial estimates for different imputations, or you can use the bootstrap method to generate different parameter estimates from the EM algorithm for the MCMC method.

**Output 57.9.4** Initial Parameter Estimates

| Initial Parameter Estimates for MCMC |               |               |                |                 |
|--------------------------------------|---------------|---------------|----------------|-----------------|
| <u>_TYPE_</u>                        | <u>_NAME_</u> | <u>Oxygen</u> | <u>RunTime</u> | <u>RunPulse</u> |
| MEAN                                 |               | 47.103766     | 10.554320      | 171.382196      |
| COV                                  | Oxygen        | 24.549967     | -5.726112      | -15.926036      |

**Example 57.10: Producing Monotone Missingness with MCMC**

This example uses the MCMC method to impute just enough missing values for a data set with an arbitrary missing pattern so that each imputed data set has a monotone missing pattern based on the order of variables in the VAR statement.

The following statements invoke the MI procedure and specify the IMPUTE=MONOTONE option to create the imputed data set with a monotone missing pattern. You must specify a VAR statement to provide the order of variables in order for the imputed data to achieve a monotone missing pattern.

```
proc mi data=Fitness1 seed=17655417 out=outex10;
 mcmc impute=monotone;
 var Oxygen RunTime RunPulse;
run;
```

The “Model Information” table in [Output 57.10.1](#) describes the method used in the multiple imputation process.

#### Output 57.10.1 Model Information

| The MI Procedure                 |                    |
|----------------------------------|--------------------|
| Model Information                |                    |
| Data Set                         | WORK.FITNESS1      |
| Method                           | Monotone-data MCMC |
| Multiple Imputation Chain        | Single Chain       |

| Start                            | Starting Value     |
| Prior                            | Jeffreys           |
| Number of Imputations            | 5                  |
| Number of Burn-in Iterations     | 200                |
| Number of Iterations             | 100                |
| Seed for random number generator | 17655417           |

The “Missing Data Patterns” table in [Output 57.10.2](#) lists distinct missing data patterns with corresponding statistics. Here, an “X” means that the variable is observed in the corresponding group, a “.” means that the variable is missing and will be imputed to achieve the monotone missingness for the imputed data set, and an “O” means that the variable is missing and will not be imputed. The table also displays group-specific variable means.

**Output 57.10.2** Missing Data Patterns

| Missing Data Patterns |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |

| 1                     | 46.353810             | 10.809524 | 171.666667 |
| 2                     | 47.109500             | 10.137500 | .          |
| 3                     | 52.461667             | .         | .          |
| 4                     | .                     | 11.950000 | 176.000000 |
| 5                     | .                     | 9.885000  | .          |

As shown in the table in [Output 57.10.2](#), the MI procedure needs to impute only three missing values from group 4 and group 5 to achieve a monotone missing pattern for the imputed data set.

When you use the MCMC method to produce an imputed data set with a monotone missing pattern, tables of variance information and parameter estimates are not created.

The following statements are used just to show the monotone missingness of the output data set outex10:

```
proc mi data=outex10 seed=15541 nimpute=0;
 var Oxygen RunTime RunPulse;
run;
```

The “Missing Data Patterns” table in [Output 57.10.3](#) displays a monotone missing data pattern.

**Output 57.10.3** Monotone Missing Data Patterns

| The MI Procedure      |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Missing Data Patterns |        |          |           |      |         |
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |
| 1                     | X      | X        | X         | 110  | 70.97   |
| 2                     | X      | X        | .         | 30   | 19.35   |
| 3                     | X      | .        | .         | 15   | 9.68    |

| Missing Data Patterns |           |           |            |
|-----------------------|-----------|-----------|------------|
| -----Group Means----- |           |           |            |
| Group                 | Oxygen    | RunTime   | RunPulse   |
| 1                     | 46.152428 | 10.861364 | 171.863636 |
| 2                     | 47.796038 | 10.053333 | .          |
| 3                     | 52.461667 | .         | .          |

The following statements impute one value for each missing value in the monotone missingness data set outex10:

```
proc mi data=outex10 nimpute=1 seed=51343672 out=outex10a;
 monotone method=reg;
 var Oxygen RunTime RunPulse;
 by _Imputation_;
run;
```

You can then analyze these data sets by using other SAS procedures and combine these results by using the MIANALYZE procedure. Note that the VAR statement is required with a MONOTONE statement to provide the variable order for the monotone missing pattern.

---

## Example 57.11: Checking Convergence in MCMC

This example uses the MCMC method with a single chain. It also displays trace and autocorrelation plots to check convergence for the single chain.

The following statements use the MCMC method to create an iteration plot for the successive estimates of the mean of Oxygen. These statements also create an autocorrelation function plot for the variable Oxygen.

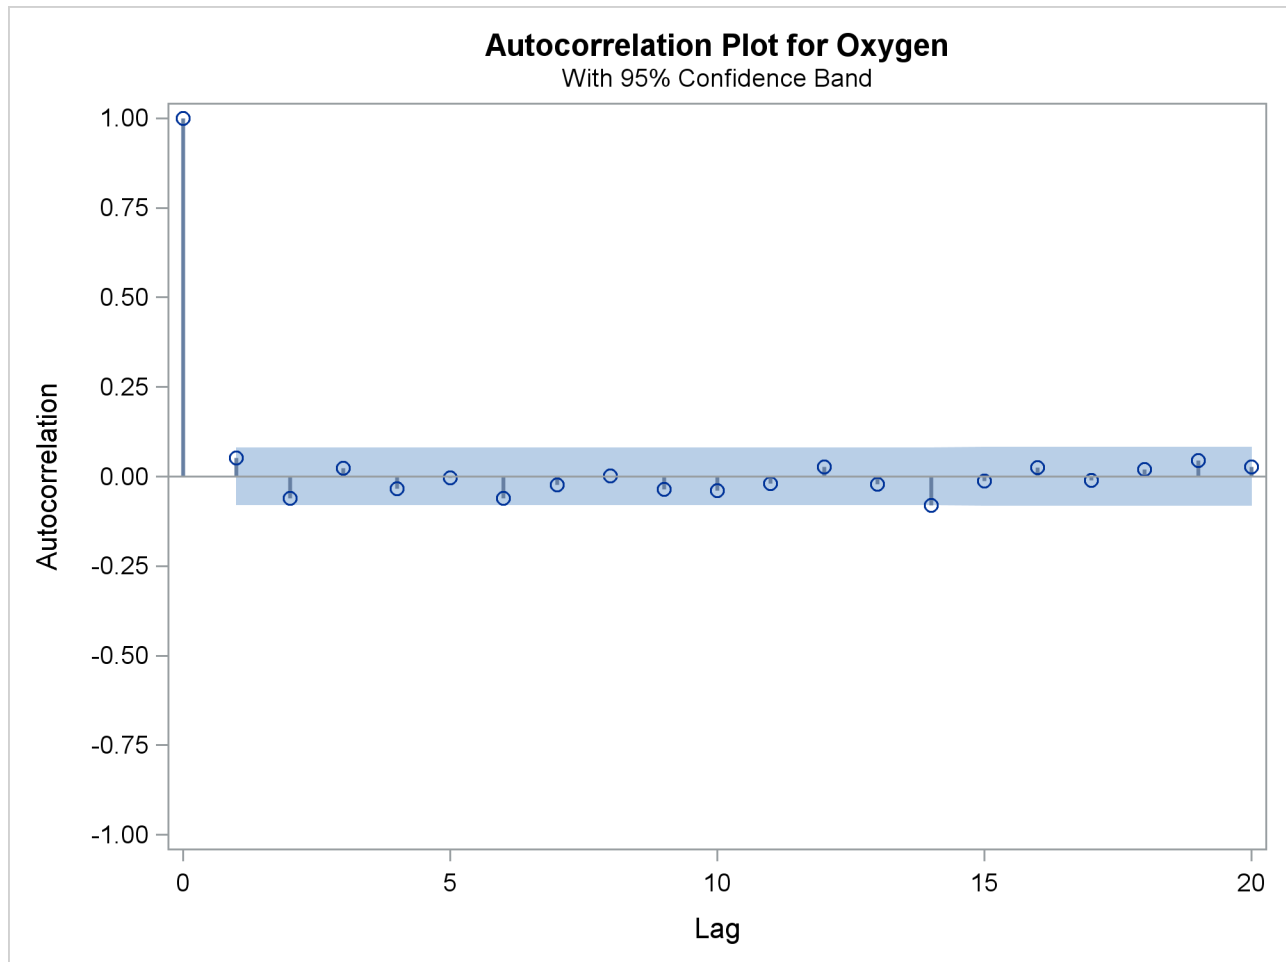

```
ods graphics on;
proc mi data=Fitness1 seed=501213 mu0=50 10 180;
 mcmc plots=(trace(mean(Oxygen)) acf(mean(Oxygen)));
 var Oxygen RunTime RunPulse;
run;
ods graphics off;
```

With ODS Graphics enabled, the TRACE(MEAN(OXYGEN)) option in the PLOTS= option displays the trace plot of means for the variable Oxygen, as shown in [Output 57.11.1](#). The dashed vertical lines indicate the imputed iterations—that is, the Oxygen values used in the imputations. The plot shows no apparent trends for the variable Oxygen.

**Output 57.11.1** Trace Plot for Oxygen

The ACF(MEAN(OXYGEN)) option in the PLOTS= option displays the autocorrelation plot of means for the variable Oxygen, as shown in [Output 57.11.2](#). The autocorrelation function plot shows no significant positive or negative autocorrelation.

**Output 57.11.2** Autocorrelation Function Plot for Oxygen

You can also create plots for the worst linear function, the means of other variables, the variances of variables, and the covariances between variables. Alternatively, you can use the `OUTITER` option to save statistics such as the means, standard deviations, covariances,  $-2 \log LR$  statistic,  $-2 \log LR$  statistic of the posterior mode, and worst linear function from each iteration in an output data set. Then you can do a more in-depth trace (time series) analysis of the iterations with other procedures, such as `PROC AUTOREG` and `PROC ARIMA` in the *SAS/ETS User's Guide*.

For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the MI procedure, see the section “[ODS Graphics](#)” on page 4775.

## Example 57.12: Saving and Using Parameters for MCMC

This example uses the MCMC method with multiple chains as specified in [Example 57.9](#). It saves the parameter values used for each imputation in an output data set of type EST called `miest`. This output data set can then be used to impute missing values in other similar input data sets. The following statements invoke the MI procedure and specify the MCMC method with multiple chains to create three imputations:

```
proc mi data=Fitness1 seed=21355417 nimpute=6 mu0=50 10 180;
 mcmc chain=multiple initial=em outest=miest;
 var Oxygen RunTime RunPulse;
run;
```

The following statements list the parameters used for the imputations in [Output 57.12.1](#). Note that the data set includes observations with `_TYPE_='SEED'` which contains the seed to start the next random number generator.

```
proc print data=miest(obs=15);
 title 'Parameters for the Imputations';
run;
```

**Output 57.12.1** OUTEST Data Set

| Parameters for the Imputations |              |        |          |               |               |               |
|--------------------------------|--------------|--------|----------|---------------|---------------|---------------|
| Obs                            | _Imputation_ | _TYPE_ | _NAME_   | Oxygen        | RunTime       | RunPulse      |

| 10                             | 2            | COV    | RunPulse | -21.18        | 1.25          | 125.67        |
| 11                             | 3            | SEED   |          | 137653011.00  | 137653011.00  | 137653011.00  |
| 12                             | 3            | PARM   |          | 48.21         | 10.36         | 170.52        |
| 13                             | 3            | COV    | Oxygen   | 23.59         | -5.25         | -19.76        |
| 14                             | 3            | COV    | RunTime  | -5.25         | 1.66          | 5.00          |
| 15                             | 3            | COV    | RunPulse | -19.76        | 5.00          | 110.99        |

The following statements invoke the MI procedure and use the `INEST=` option in the MCMC statement:

```
proc mi data=Fitness1 mu0=50 10 180;
 mcmc inest=miest;
 var Oxygen RunTime RunPulse;
run;
```

The “Model Information” table in [Output 57.12.2](#) describes the method used in the multiple imputation process. The remaining tables for the example are identical to the tables in [Output 57.9.2](#), [Output 57.9.4](#), [Output 57.9.5](#), and [Output 57.9.6](#) in [Example 57.9](#).

**Output 57.12.2** Model Information

### Example 57.13: Transforming to Normality

This example applies the MCMC method to the Fitness1 data set in which the variable Oxygen is transformed. Assume that Oxygen is skewed and can be transformed to normality with a logarithmic transformation. The following statements invoke the MI procedure and specify the transformation. The TRANSFORM statement specifies the log transformation for Oxygen. Note that the values displayed for Oxygen in all of the results correspond to transformed values.

```
proc mi data=Fitness1 seed=32937921 mu0=50 10 180 out=outex13;
 transform log(Oxygen);
 mcmc chain=multiple displayinit;
 var Oxygen RunTime RunPulse;
run;
```

The “Missing Data Patterns” table in [Output 57.13.1](#) lists distinct missing data patterns with corresponding statistics for the Fitness1 data. Note that the values of Oxygen shown in the tables are transformed values.

**Output 57.13.1** Missing Data Patterns

| The MI Procedure      |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Missing Data Patterns |        |          |           |      |         |
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |
| 1                     | X      | X        | X         | 21   | 67.74   |
| 2                     | X      | X        | .         | 4    | 12.90   |
| 3                     | X      | .        | .         | 3    | 9.68    |
| 4                     | .      | X        | X         | 1    | 3.23    |
| 5                     | .      | X        | .         | 2    | 6.45    |

| 4                                             | 1            | 59.5710 | 7.1440  | 167.012      |
| 5                                             | 1            | 49.8740 | 9.2200  | 170.092      |
| 6                                             | 1            | 44.8110 | 11.6300 | 176.000      |
| 7                                             | 1            | 38.5834 | 11.9500 | 176.000      |
| 8                                             | 1            | 43.7376 | 10.8500 | 158.851      |
| 9                                             | 1            | 39.4420 | 13.0800 | 174.000      |
| 10                                            | 1            | 60.0550 | 8.6300  | 170.000      |

Note that the results in [Output 57.13.6](#) can also be produced from the following statements without using a TRANSFORM statement. A transformed value of  $\log(50)=3.91202$  is used in the MU0= option.

```
data temp;
 set Fitness1;
 LogOxygen= log(Oxygen);
run;
proc mi data=temp seed=14337921 mu0=3.91202 10 180 out=outtemp;
 mcmc chain=multiple displayinit;
 var LogOxygen RunTime RunPulse;
run;
data outex13;
 set outtemp;
 Oxygen= exp(LogOxygen);
run;
```

---

### Example 57.14: Multistage Imputation

This example uses two separate imputation procedures to complete the imputation process. In the first case, the MI procedure statements use the MCMC method to impute just enough missing values for a data set with an arbitrary missing pattern so that each imputed data set has a monotone missing pattern. In the second case, the MI procedure statements use a MONOTONE statement to impute missing values for data sets with monotone missing patterns.

The following statements are identical to those in [Example 57.10](#). The statements invoke the MI procedure and specify the IMPUTE=MONOTONE option to create the imputed data set with a monotone missing pattern.

```
proc mi data=Fitness1 seed=17655417 out=outex14;
 mcmc impute=monotone;
 var Oxygen RunTime RunPulse;
run;
```

The “Missing Data Patterns” table in [Output 57.14.1](#) lists distinct missing data patterns with corresponding statistics. Here, an “X” means that the variable is observed in the corresponding group, a “.” means that the variable is missing and will be imputed to achieve the monotone missingness for the imputed data set, and an “O” means that the variable is missing and will not be imputed. The table also displays group-specific variable means.

**Output 57.14.1** Missing Data Patterns

| The MI Procedure      |        |          |           |      |         |
|-----------------------|--------|----------|-----------|------|---------|
| Missing Data Patterns |        |          |           |      |         |
| Group                 | Oxygen | Run Time | Run Pulse | Freq | Percent |
| 1                     | X      | X        | X         | 21   | 67.74   |
| 2                     | X      | X        | O         | 4    | 12.90   |
| 3                     | X      | O        | O         | 3    | 9.68    |
| 4                     | .      | X        | X         | 1    | 3.23    |
| 5                     | .      | X        | O         | 2    | 6.45    |

| Missing Data Patterns |           |           |            |
|-----------------------|-----------|-----------|------------|
| -----Group Means----- |           |           |            |
| Group                 | Oxygen    | RunTime   | RunPulse   |
| 1                     | 46.353810 | 10.809524 | 171.666667 |
| 2                     | 47.109500 | 10.137500 | .          |
| 3                     | 52.461667 | .         | .          |
| 4                     | .         | 11.950000 | 176.000000 |
| 5                     | .         | 9.885000  | .          |

As shown in the table, the MI procedure needs to impute only three missing values from group 4 and group 5 to achieve a monotone missing pattern for the imputed data set. When the MCMC method is used to produce an imputed data set with a monotone missing pattern, tables of variance information and parameter estimates are not created.

The following statements impute one value for each missing value in the monotone missingness data set outex14:

```
proc mi data=outex14
 nimpute=1 seed=51343672
 out=outex14a;
 monotone reg;
 var Oxygen RunTime RunPulse;
 by _Imputation_;
run;
```

You can then analyze these data sets by using other SAS procedures and combine these results by using the MIANALYZE procedure. Note that the VAR statement is required with a MONOTONE statement to provide the variable order for the monotone missing pattern.

The “Model Information” table in [Output 57.14.2](#) shows that a monotone method is used to generate imputed values in the first BY group.

**Output 57.14.2** Model Information

```

----- Imputation Number=1 -----
 The MI Procedure
 Model Information
Data Set WORK.OUTEX14
Method Monotone
Number of Imputations 1
Seed for random number generator 51343672

```

The “Monotone Model Specification” table in [Output 57.14.3](#) describes methods and imputed variables in the imputation model. The MI procedure uses the regression method to impute the variables RunTime and RunPulse in the model.

**Output 57.14.3** Monotone Model Specification

```

----- Imputation Number=1 -----
 Monotone Model Specification
Method Imputed
 Variables
Regression RunTime RunPulse

```

The “Missing Data Patterns” table in [Output 57.14.4](#) lists distinct missing data patterns with corresponding statistics. It shows a monotone missing pattern for the imputed data set.

**Output 57.14.4** Missing Data Patterns

```

----- Imputation Number=1 -----
Missing Data Patterns

 Group Oxygen Run Run
 Time Pulse Freq Percent
 1 X X X 22 70.97
 2 X X . 6 19.35
 3 X . . 3 9.68

Missing Data Patterns

-----Group Means-----
 Group Oxygen RunTime RunPulse
 1 46.057479 10.861364 171.863636
 2 46.745227 10.053333 .
 3 52.461667 . .

```

The following statements list the first 10 observations of the data set outex14a in [Output 57.14.5](#):

```

proc print data=outex14a(obs=10);
 title 'First 10 Observations of the Imputed Data Set';
run;

```

**Output 57.14.5** Imputed Data Set

```

First 10 Observations of the Imputed Data Set

 Obs _Imputation_ Oxygen RunTime Run
 Pulse
 1 1 44.6090 11.3700 178.000
 2 1 45.3130 10.0700 185.000
 3 1 54.2970 8.6500 156.000
 4 1 59.5710 7.1569 169.914
 5 1 49.8740 9.2200 159.315
 6 1 44.8110 11.6300 176.000
 7 1 39.8345 11.9500 176.000
 8 1 45.3196 10.8500 151.252
 9 1 39.4420 13.0800 174.000
 10 1 60.0550 8.6300 170.000

```

This example presents an alternative to the full-data MCMC imputation, in which imputation of only a few missing values is needed to achieve a monotone missing pattern for the imputed data set. The example uses a monotone MCMC method that imputes fewer missing values in each iteration and achieves approximate stationarity in fewer iterations (Schafer 1997, p. 227). The example also demonstrates how to combine the monotone MCMC method with a method for monotone missing data, which does not rely on iterations of steps.

## Overview: MIANALYZE Procedure

The MIANALYZE procedure combines the results of the analyses of imputations and generates valid statistical inferences. Multiple imputation provides a useful strategy for analyzing data sets with missing values. Instead of filling in a single value for each missing value, Rubin's (1976, 1987) multiple imputation strategy replaces each missing value with a set of plausible values that represent the uncertainty about the right value to impute.

Multiple imputation inference involves three distinct phases:

1. The missing data are filled in  $m$  times to generate  $m$  complete data sets.
2. The  $m$  complete data sets are analyzed using standard statistical analyses.
3. The results from the  $m$  complete data sets are combined to produce inferential results.

A companion procedure, PROC MI, creates multiply imputed data sets for incomplete multivariate data. It uses methods that incorporate appropriate variability across the  $m$  imputations.

The analyses of imputations are obtained by using standard SAS procedures (such as PROC REG) for complete data. No matter which complete-data analysis is used, the process of combining results from different imputed data sets is essentially the same and results in valid statistical inferences that properly reflect the uncertainty due to missing values. These results of analyses are combined in the MIANALYZE procedure to derive valid inferences.

The MIANALYZE procedure reads parameter estimates and associated standard errors or covariance matrix that are computed by the standard statistical procedure for each imputed data set. The MIANALYZE procedure then derives valid univariate inference for these parameters. With an additional assumption about the population between and within imputation covariance matrices, multivariate inference based on Wald tests can also be derived.

The MODELEFFECTS statement lists the effects to be analyzed, and the CLASS statement lists the classification variables in the MODELEFFECTS statement. The variables in the MODELEFFECTS statement that are not specified in a CLASS statement are assumed to be continuous.

When each effect in the MODELEFFECTS statement is a continuous variable by itself, a STDERR statement specifies the standard errors when both parameter estimates and associated standard errors are stored as variables in the same data set.

For some parameters of interest, you can use TEST statements to test linear hypotheses about the parameters. For others, it is not straightforward to compute estimates and associated covariance matrices with standard statistical SAS procedures. Examples include correlation coefficients between two variables and ratios of variable means. These special cases are described in the section “[Examples of the Complete-Data Inferences](#)” on page 4848.

## Getting Started: MIANALYZE Procedure

The Fitness data described in the REG procedure are measurements of 31 individuals in a physical fitness course. See Chapter 79, “The REG Procedure,” for more information. The Fitness1 data set is constructed from the Fitness data set and contains three variables: Oxygen, RunTime, and RunPulse. Some values have been set to missing, and the resulting data set has an arbitrary pattern of missingness in these three variables.

```

----- Data on Physical Fitness -----
| These measurements were made on men involved in a physical |
| fitness course at N.C. State University. |
| Only selected variables of |
| Oxygen (oxygen intake, ml per kg body weight per minute), |
| Runtime (time to run 1.5 miles in minutes), and |
| RunPulse (heart rate while running) are used. |
| Certain values were changed to missing for the analysis. |

47.467 10.50 170
;

```

Suppose that the data are multivariate normally distributed and that the missing data are missing at random (see the “Statistical Assumptions for Multiple Imputation” section in the chapter “The MI Procedure” for a description of these assumptions). The following statements use the MI procedure to impute missing values for the Fitness1 data set:

```

proc mi data=Fitness1 seed=3237851 noprint out=outmi;
 var Oxygen RunTime RunPulse;
run;

```

The MI procedure creates imputed data sets, which are stored in the outmi data set. A variable named `_Imputation_` indicates the imputation numbers. Based on  $m$  imputations,  $m$  different sets of the point and variance estimates for a parameter can be computed. In this example,  $m = 5$  is the default.

The following statements generate regression coefficients for each of the five imputed data sets:

```
proc reg data=outmi outest=outreg covout noprint;
 model Oxygen= RunTime RunPulse;
 by _Imputation_;
run;
```

The following statements display (in Figure 58.1) output parameter estimates and covariance matrices from PROC REG for the first two imputed data sets:

```
proc print data=outreg (obs=8);
 var _Imputation_ _Type_ _Name_
 Intercept RunTime RunPulse;
 title 'Parameter Estimates from Imputed Data Sets';
run;
```

**Figure 58.1** Parameter Estimates

| Parameter Estimates from Imputed Data Sets |              |        |           |           |          |          |
|--------------------------------------------|--------------|--------|-----------|-----------|----------|----------|
| Obs                                        | _Imputation_ | _TYPE_ | _NAME_    | Intercept | RunTime  | RunPulse |
| 1                                          | 1            | PARMS  |           | 86.544    | -2.82231 | -0.05873 |
| 2                                          | 1            | COV    | Intercept | 100.145   | -0.53519 | -0.55077 |
| 3                                          | 1            | COV    | RunTime   | -0.535    | 0.10774  | -0.00345 |
| 4                                          | 1            | COV    | RunPulse  | -0.551    | -0.00345 | 0.00343  |
| 5                                          | 2            | PARMS  |           | 83.021    | -3.00023 | -0.02491 |
| 6                                          | 2            | COV    | Intercept | 79.032    | -0.66765 | -0.41918 |
| 7                                          | 2            | COV    | RunTime   | -0.668    | 0.11456  | -0.00313 |
| 8                                          | 2            | COV    | RunPulse  | -0.419    | -0.00313 | 0.00264  |

The following statements combine the five sets of regression coefficients:

```
proc mianalyze data=outreg;
 modeleffects Intercept RunTime RunPulse;
run;
```

The “Model Information” table in Figure 58.2 lists the input data set(s) and the number of imputations.

**Figure 58.2** Model Information Table

| The MIANALYZE Procedure |             |
|-------------------------|-------------|
| Model Information       |             |
| Data Set                | WORK.OUTREG |
| Number of Imputations   | 5           |

The “Variance Information” table in Figure 58.3 displays the between-imputation, within-imputation, and total variances for combining complete-data inferences. It also displays the degrees of freedom for the total variance, the relative increase in variance due to missing values, the fraction of missing information, and the relative efficiency for each parameter estimate.

Figure 58.3 Variance Information Table

| Variance Information |                    |           |            |        |
|----------------------|--------------------|-----------|------------|--------|
| Parameter            | -----Variance----- |           |            | DF     |
|                      | Between            | Within    | Total      |        |
| Intercept            | 45.529229          | 76.543614 | 131.178689 | 23.059 |
| RunTime              | 0.019390           | 0.106220  | 0.129487   | 123.88 |
| RunPulse             | 0.001007           | 0.002537  | 0.003746   | 38.419 |

| Variance Information |             |             |          |
|----------------------|-------------|-------------|----------|
| Parameter            | Relative    | Fraction    | Relative |
|                      | Increase    | Missing     |          |
|                      | in Variance | Information |          |
| Intercept            | 0.713777    | 0.461277    | 0.915537 |
| RunTime              | 0.219051    | 0.192620    | 0.962905 |
| RunPulse             | 0.476384    | 0.355376    | 0.933641 |

The “Parameter Estimates” table in Figure 58.4 displays a combined estimate and standard error for each regression coefficient (parameter). Inferences are based on  $t$  distributions. The table displays a 95% confidence interval and a  $t$  test with the associated  $p$ -value for the hypothesis that the parameter is equal to the value specified with the THETA0= option (in this case, zero by default). The minimum and maximum parameter estimates from the imputed data sets are also displayed.

Figure 58.4 Parameter Estimates

| Parameter Estimates |           |           |                       |          |        |
|---------------------|-----------|-----------|-----------------------|----------|--------|

## Syntax: MIANALYZE Procedure

The following statements are available in the MIANALYZE procedure:

```
PROC MIANALYZE < options > ;
 BY variables ;
 CLASS variables ;
 MODELEFFECTS effects ;
 < label: > TEST equation1 < , ... , < equationk > > < / options > ;
 STDERR variables ;
```

The BY statement specifies groups in which separate analyses are performed.

The CLASS statement lists the classification variables in the MODELEFFECTS statement. Classification variables can be either character or numeric.

The required MODELEFFECTS statement lists the effects to be analyzed. The variables in the statement that are not specified in a CLASS statement are assumed to be continuous.

The STDERR statement lists the standard errors associated with the effects in the MODELEFFECTS statement when both parameter estimates and standard errors are saved as variables in the same DATA= data set. The STDERR statement can be used only when each effect in the MODELEFFECTS statement is a continuous variable by itself.

The TEST statement tests linear hypotheses about the parameters. An  $F$  statistic is used to jointly test the null hypothesis ( $H_0 : L_c = c$ ) specified in a single TEST statement. Several TEST statements can be used.

The PROC MIANALYZE and MODELEFFECTS statements are required for the MIANALYZE procedure. The rest of this section provides detailed syntax information for each of these statements, beginning with the PROC MIANALYZE statement. The remaining statements are in alphabetical order.

## PROC MIANALYZE Statement

```
PROC MIANALYZE < options > ;
```

The PROC MIANALYZE statement invokes the MIANALYZE procedure. Table 58.1 summarizes the options available in the PROC MIANALYZE statement.

**Table 58.1** Summary of PROC MIANALYZE Options

| Option                 | Description                                                        |
|------------------------|--------------------------------------------------------------------|
| <b>Input Data Sets</b> |                                                                    |
| DATA=                  | Specifies the COV, CORR, or EST type data set                      |
| DATA=                  | Specifies the data set for parameter estimates and standard errors |
| PARMS=                 | Specifies the data set for parameter estimates                     |
| PARMINFO=              | Specifies the data set for parameter information                   |
| COVB=                  | Specifies the data set for covariance matrices                     |
| XPXI=                  | Specifies the data set for $(X'X)^{-1}$ matrices                   |

Table 58.1 *continued*

| Option                      | Description                                       |
|-----------------------------|---------------------------------------------------|
| <b>Statistical Analysis</b> |                                                   |
| THETA0=                     | Specifies parameters under the null hypothesis    |
| ALPHA=                      | Specifies the level for the confidence interval   |
| EDF=                        | Specifies the complete-data degrees of freedom    |
| <b>Printed Output</b>       |                                                   |
| WCOV                        | Displays the within-imputation covariance matrix  |
| BCOV                        | Displays the between-imputation covariance matrix |
| TCOV                        | Displays the total covariance matrix              |
| MULT                        | Displays multivariate inferences                  |

The following options can be used in the PROC MIANALYZE statement. They are listed in alphabetical order.

**ALPHA= $\alpha$** 

specifies that confidence limits are to be constructed for the parameter estimates with confidence level  $100(1 - \alpha)\%$ , where  $0 < \alpha < 1$ . The default is ALPHA=0.05.

**BCOV**

displays the between-imputation covariance matrix.

**COVB <(EFFECTVAR=STACKING | ROWCOL)> =SAS-data-set**

names an input SAS data set that contains covariance matrices of the parameter estimates from imputed data sets. If you provide a COVB= data set, you must also provide a PARMS= data set.

The EFFECTVAR= option identifies the variables for parameters displayed in the covariance matrix and is used only when the PARMINFO= option is not specified. The default is EFFECTVAR= STACKING.

See the section “[Input Data Sets](#)” on page 4840 for a detailed description of the COVB= option.

**DATA=SAS-data-set**

names an input SAS data set.

If the input DATA= data set is not a specially structured SAS data set, the data set contains both the parameter estimates and associated standard errors. The parameter estimates are specified in the MODELEFFECTS statement and the standard errors are specified in the STDERR statement.

If the data set is a specially structured input SAS data set, it must have a TYPE of EST, COV, or CORR that contains estimates from imputed data sets:

- If TYPE=EST, the data set contains the parameter estimates and associated covariance matrices.
- If TYPE=COV, the data set contains the sample means, sample sizes, and covariance matrices. Each covariance matrix for variables is divided by the sample size  $n$  to create the covariance matrix for parameter estimates.
- If TYPE=CORR, the data set contains the sample means, sample sizes, standard errors, and correlation matrices. The covariance matrices are computed from the correlation matrices and associated standard errors. Each covariance matrix for variables is divided by the sample size  $n$  to create the covariance matrix for parameter estimates.

If you do not specify an input data set with the DATA= or PARMS= option, then the most recently created SAS data set is used as an input DATA= data set. See the section “[Input Data Sets](#)” on page 4840 for a detailed description of the input data sets.

**EDF=number**

specifies the complete-data degrees of freedom for the parameter estimates. This is used to compute an adjusted degrees of freedom for each parameter estimate. By default, EDF= $\infty$  and the degrees of freedom for each parameter estimate are not adjusted.

**MULT****MULTIVARIATE**

requests multivariate inference for the parameters. It is based on Wald tests and is a generalization of the univariate inference. See the section “[Multivariate Inferences](#)” on page 4845 for a detailed description of the multivariate inference.

**PARMINFO=SAS-data-set**

names an input SAS data set that contains parameter information associated with variables PRM1, PRM2, . . . , and so on. These variables are used as variables for parameters in a COVB= data set. See the section “[Input Data Sets](#)” on page 4840 for a detailed description of the PARMINFO= option.

**PARMS <(CLASSVAR= ctype)> =SAS-data-set**

names an input SAS data set that contains parameter estimates computed from imputed data sets. When a COVB= data set is not specified, the input PARMS= data set also contains standard errors associated with these parameter estimates. If multivariate inference is requested, you must also provide a COVB= or XPXI= data set.

When the effects contain classification variables, the option CLASSVAR= *ctype* can be used to identify the associated classification variables when reading the classification levels from observations. The available types are FULL, LEVEL, and CLASSVAL. The default is CLASSVAR= FULL. See the section “[Input Data Sets](#)” on page 4840 for a detailed description of the PARMS= option.

**TCOV**

displays the total covariance matrix derived by assuming that the population between-imputation and within-imputation covariance matrices are proportional to each other.

**THETA0=numbers****MU0=numbers**

specifies the parameter values  $\theta_0$  under the null hypothesis  $\theta = \theta_0$  in the  $t$  tests for location for the effects. If only one number  $\theta_0$  is specified, that number is used for all effects. If more than one number is specified, the specified numbers correspond to effects in the MODELEFFECTS statement in the order in which they appear in the statement. When an effect contains classification variables, the corresponding value is not used and the test is not performed.

**WCOV**

displays the within-imputation covariance matrices.

**XPXI=SAS-data-set**

names an input SAS data set that contains the  $(\mathbf{X}'\mathbf{X})^{-1}$  matrices associated with the parameter estimates computed from imputed data sets. If you provide an XPXI= data set, you must also provide a PARMS= data set. In this case, PROC MIANALYZE reads the standard errors of the estimates from the PARMS= data. The standard errors and  $(\mathbf{X}'\mathbf{X})^{-1}$  matrices are used to derive the covariance matrices.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC MIANALYZE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MIANALYZE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variables* ;

The CLASS statement specifies the classification variables in the MODELEFFECTS statement. Classification variables can be either character or numeric. Classification levels are determined from the formatted values of the classification variables. See “The FORMAT Procedure” in the *Base SAS Procedures Guide* for details.

---

## MODELEFFECTS Statement

**MODELEFFECTS** *effects* ;

The MODELEFFECTS statement lists the effects in the data set to be analyzed. Each effect is a variable or a combination of variables, and is specified with a special notation that uses variable names and operators.

Each variable is either a classification (or CLASS) variable or a continuous variable. If a variable is not declared in the CLASS statement, it is assumed to be continuous. Crossing and nesting operators can be used in an effect to create crossed and nested effects.

One general form of an effect involving several variables is

$$X1 * X2 * A * B * C ( D E )$$

where A, B, C, D, and E are classification variables and X1 and X2 are continuous variables.

When the input DATA= data set is not a specially structured SAS data set, you must also specify standard errors of the parameter estimates in an STDERR statement.

---

## STDERR Statement

**STDERR** *variables* ;

The STDERR statement lists standard errors associated with effects in the MODELEFFECTS statement, when the input DATA= data set contains both parameter estimates and standard errors as variables in the data set.

With the STDERR statement, only continuous effects are allowed in the MODELEFFECTS statement. The specified standard errors correspond to parameter estimates in the order in which they appear in the MODELEFFECTS statement.

For example, you can use the following MODELEFFECTS and STDERR statements to identify both the parameter estimates and associated standard errors in a SAS data set:

```
proc mianalyze;
 modeleffects y1-y3;
 stderr sy1-sy3;
run;
```

---

## TEST Statement

*< label: >* **TEST** *equation1 <, ..., < equationk >>* *</ options >* ;

The TEST statement tests linear hypotheses about the parameters  $\beta$ . An  $F$  test is used to jointly test the null hypotheses ( $H_0 : L\beta = c$ ) specified in a single TEST statement in which the MULT option is specified.

Each *equation* specifies a linear hypothesis (a row of the  $L$  matrix and the corresponding element of the  $c$  vector); multiple *equations* are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output. You can submit multiple TEST statements. When a label is not included in a TEST statement, a label of “Test  $j$ ” is used for the  $j$ th TEST statement.

The form of an *equation* is as follows:

$$term < \pm term \dots > < = \pm term < \pm term \dots > >$$

where *term* is a parameter of the model, or a constant, or a constant times a parameter. When no equal sign appears, the expression is set to 0. Only parameters for regressor effects (continuous variables by themselves) are allowed.

For each TEST statement, PROC MIANALYZE displays a “Test Specification” table of the  $L$  matrix and the  $c$  vector. The procedure also displays a “Variance Information” table of the between-imputation, within-imputation, and total variances for combining complete-data inferences, and a “Parameter Estimates” table of a combined estimate and standard error for each linear component. The linear components are labeled TestPrm1, TestPrm2, ... in the tables.

The following statements illustrate possible uses of the TEST statement:

```

proc mianalyze;
 modeleffects intercept a1 a2 a3;
 test1: test intercept + a2 = 0;
 test2: test intercept + a2;
 test3: test a1=a2=a3;
 test4: test a1=a2, a2=a3;
run;

```

The first and second TEST statements are equivalent and correspond to the specification in Figure 58.5.

**Figure 58.5** Test Specification for test1 and test2

| The MIANALYZE Procedure |           |    |          |    |   |

The ALPHA= and EDF options specified in the PROC MIANALYZE statement are also applied to the TEST statement. You can specify the following options in the TEST statement after a slash(/):

#### **BCOV**

displays the between-imputation covariance matrix.

#### **MULT**

displays the multivariate inference for parameters.

#### **TCOV**

displays the total covariance matrix.

**WCOV**

displays the within-imputation covariance matrix.

For more information, see the section “Testing Linear Hypotheses about the Parameters” on page 4847.

## Details: MIANALYZE Procedure

### Input Data Sets

You specify input data sets based on the type of inference you requested. For univariate inference, you can use one of the following options:

- a DATA= data set, which provides both parameter estimates and the associated standard errors
- a DATA=EST, COV, or CORR data set, which provides both parameter estimates and the associated standard errors either explicitly (type CORR) or through the covariance matrix (type EST, COV)
- PARMS= data set, which provides both parameter estimates and the associated standard errors

For multivariate inference, which includes the testing of linear hypotheses about parameters, you can use one of the following option combinations:

- a DATA=EST, COV, or CORR data set, which provides parameter estimates and the associated covariance matrix either explicitly (type EST, COV) or through the correlation matrix and standard errors (type CORR) in a single data set
- PARMS= and COVB= data sets, which provide parameter estimates in a PARMS= data set and the associated covariance matrix in a COVB= data set
- PARMS=, COVB=, and PARMINFO= data sets, which provide parameter estimates in a PARMS= data set, the associated covariance matrix in a COVB= data set with variables named PRM1, PRM2, . . . , and the effects associated with these variables in a PARMINFO= data set
- PARMS= and XPXI= data sets, which provide parameter estimates and the associated standard errors in a PARMS= data set and the associated  $(\mathbf{X}'\mathbf{X})^{-1}$  matrix in an XPXI= data set

The appropriate combination depends on the type of inference and the SAS procedure you used to create the data sets. For instance, if you used PROC REG to create an OUTEST= data set that contains the parameter estimates and covariance matrix, you would use the DATA= option to read the OUTEST= data set.

When the input DATA= data set is a specially structured SAS data set, the data set must contain the variable `_Imputation_` to identify the imputation by number. Otherwise, each observation corresponds to an imputation and contains both parameter estimates and associated standard errors.

If you do not specify an input data set with the DATA= or PARMS= option, then the most recently created SAS data set is used as an input DATA= data set. Note that with a DATA= data set, each effect represents a continuous variable; only regressor effects (continuous variables by themselves) are allowed in the MODELEFFECTS statement.

## DATA= SAS Data Set

The DATA= data set provides both parameter estimates and the associated standard errors computed from imputed data sets. Such data sets are typically created with an OUTPUT statement in procedures such as PROC MEANS and PROC UNIVARIATE.

The MIANALYZE procedure reads parameter estimates from observations with variables in the MODEL-EFFECTS statement, and standard errors for parameter estimates from observations with variables in the STDERR statement. The order of the variables for standard errors must match the order of the variables for parameter estimates.

## DATA=EST, COV, or CORR SAS Data Set

The specially structured DATA= data set provides both parameter estimates and the associated covariance matrix computed from imputed data sets. Such data sets are created by procedures such as PROC CORR (type COV, CORR) and PROC REG (type EST).

With TYPE=EST, the MIANALYZE procedure reads parameter estimates from observations with `_TYPE_='PARM'`, `_TYPE_='PARMS'`, `_TYPE_='OLS'`, or `_TYPE_='FINAL'`, and covariance matrices for parameter estimates from observations with `_TYPE_='COV'` or `_TYPE_='COVB'`.

With TYPE=COV, the procedure reads sample means from observations with `_TYPE_='MEAN'`, sample size  $n$  from observations with `_TYPE_='N'`, and covariance matrices for variables from observations with `_TYPE_='COV'`.

With TYPE=CORR, the procedure reads sample means from observations with `_TYPE_='MEAN'`, sample size  $n$  from observations with `_TYPE_='N'`, correlation matrices for variables from observations with `_TYPE_='CORR'`, and standard errors for variables from observations with `_TYPE_='STD'`. The standard errors and correlation matrix are used to generate a covariance matrix for the variables.

Note that with TYPE=COV or CORR, each covariance matrix for the variables is divided by  $n$  to create the covariance matrix for the sample means.

## PARMS <(CLASSVAR= *ctype*)> = Data Set

The PARMS= data set contains both parameter estimates and the associated standard errors computed from imputed data sets. Such data sets are typically created with an ODS OUTPUT statement in procedures such as PROC GENMOD, PROC GLM, PROC LOGISTIC, and PROC MIXED.

The MIANALYZE procedure reads effect names from observations with the variable Parameter, Effect, Variable, or Parm. It then reads parameter estimates from observations with the variable Estimate and standard errors for parameter estimates from observations with the variable StdErr.

When the effects contain classification variables, the option CLASSVAR= *ctype* can be used to identify associated classification variables when reading the classification levels from observations. The available types are FULL, LEVEL, and CLASSVAL. The default is CLASSVAR= FULL.

With CLASSVAR=FULL, the data set contains the classification variables explicitly. PROC MIANALYZE reads the classification levels from observations with their corresponding classification variables. PROC MIXED generates this type of table.

With CLASSVAR=LEVEL, PROC MIANALYZE reads the classification levels for the effect from observations with variables Level1, Level2, and so on, where the variable Level1 contains the classification level

for the first classification variable in the effect, and the variable `Level2` contains the classification level for the second classification variable in the effect. For each effect, the variables in the crossed list are displayed before the variables in the nested list. The variable order in the `CLASS` statement is used for variables inside each list. PROC GENMOD generates this type of table.

For example, with the following statements, the variable `Level1` has the classification level of the variable `c2` for the effect `c2`:

```
proc mianalyze parms(classvar=Level)= dataparm;
 class c1 c2 c3;
 modeleffects c2 c3(c2 c1);
run;
```

For the effect `c3(c2 c1)`, the variable `Level1` has the classification level of the variable `c3`, `Level2` has the level of `c1`, and `Level3` has the level of `c2`.

Similarly, with `CLASSVAR=CLASSVAL`, PROC MIANALYZE reads the classification levels for the effect from observations with variables `ClassVal0`, `ClassVal1`, and so on, where the variable `ClassVal0` contains the classification level for the first classification variable in the effect, and the variable `ClassVal1` contains the classification level for the second classification variable in the effect. For each effect, the variables in the crossed list are displayed before the variables in the nested list. The variable order in the `CLASS` statement is used for variables inside each list. PROC LOGISTIC generates this type of tables.

### PARMS <(CLASSVAR= *ctype*)> = and COVB= Data Sets

The `PARMS=` data set contains parameter estimates, and the `COVB=` data set contains associated covariance matrices computed from imputed data sets. Such data sets are typically created with an ODS OUTPUT statement in procedures such as PROC LOGISTIC, PROC MIXED, and PROC REG.

With a `PARMS=` data set, the MIANALYZE procedure reads effect names from observations with the variable `Parameter`, `Effect`, `Variable`, or `Parm`. It then reads parameter estimates from observations with the variable `Estimate`.

When the effects contain classification variables, the option `CLASSVAR= ctype` can be used to identify the associated classification variables when reading the classification levels from observations. The available types are `FULL`, `LEVEL`, and `CLASSVAL`, and they are described in the section “`PARMS <(CLASSVAR= ctype)> = Data Set`” on page 4841. The default is `CLASSVAR= FULL`.

The option `EFFECTVAR= etype` identifies the variables for parameters displayed in the covariance matrix. The available types are `STACKING` and `ROWCOL`. The default is `EFFECTVAR= STACKING`.

With `EFFECTVAR= STACKING`, each parameter is displayed by stacking variables in the effect. Begin with the variables in the crossed list, followed by the continuous list, then followed by the nested list. Each classification variable is displayed with its classification level attached. PROC LOGISTIC generates this type of table.

When each effect is a continuous variable by itself, each stacked parameter name reduces to the effect name. PROC REG generates this type of table.

With `EFFECTVAR= STACKING`, the MIANALYZE procedure reads parameter names from observations with the variable `Parameter`, `Effect`, `Variable`, `Parm`, or `RowName`. It then reads covariance matrices from observations with the stacked variables in a `COVB=` data set.

With `EFFECTVAR=ROWCOL`, parameters are displayed by the variables `Col1`, `Col2`, ... The parameter associated with the variable `Col1` is identified by the observation with value 1 for the variable `Row`. The parameter associated with the variable `Col2` is identified by the observation with value 2 for the variable `Row`. `PROC MIXED` generates this type of table.

With `EFFECTVAR=ROWCOL`, the `MIANALYZE` procedure reads the parameter indices from observations with the variable `Row` and the effect names from observations with the variable `Parameter`, `Effect`, `Variable`, `Parm`, or `RowName`. It then reads covariance matrices from observations with the variables `Col1`, `Col2`, and so on in a `COVB=` data set.

When the effects contain classification variables, the data set contains the classification variables explicitly and the `MIANALYZE` procedure also reads the classification levels from their corresponding classification variables.

### **PARMS <(CLASSVAR= *ctype*)> =, PARMINFO=, and COVB= Data Sets**

The input `PARMS=` data set contains parameter estimates and the input `COVB=` data set contains associated covariance matrices computed from imputed data sets. Such data sets are typically created with an `ODS OUTPUT` statement using procedure such as `PROC GENMOD`.

With a `PARMS=` data set, the `MIANALYZE` procedure reads effect names from observations with the variable `Parameter`, `Effect`, `Variable`, or `Parm`. It then reads parameter estimates from observations with the variable `Estimate`.

When the effects contain classification variables, the option `CLASSVAR= ctype` can be used to identify the associated classification variables when reading the classification levels from observations. The available types are `FULL`, `LEVEL`, and `CLASSVAL`, and they are described in the section “`PARMS <(CLASSVAR= ctype)> = Data Set`” on page 4841. The default is `CLASSVAR= FULL`.

With a `COVB=` data set, the `MIANALYZE` procedure reads parameter names from observations with the variable `Parameter`, `Effect`, `Variable`, `Parm`, or `RowName`. It then reads covariance matrices from observations with the variables `Prm1`, `Prm2`, and so on.

The parameters associated with the variables `Prm1`, `Prm2`, and so on are identified in the `PARMINFO=` data set. `PROC MIANALYZE` reads the parameter names from observations with the variable `Parameter` and the corresponding effect from observations with the variable `Effect`. When the effects contain classification variables, the data set contains the classification variables explicitly and the `MIANALYZE` procedure also reads the classification levels from observations with their corresponding classification variables.

### **PARMS= and XPXI= Data Sets**

The input `PARMS=` data set contains parameter estimates, and the input `XPXI=` data set contains associated  $(X'X)^{-1}$  matrices computed from imputed data sets. Such data sets are typically created with an `ODS OUTPUT` statement in a procedure such as `PROC GLM`.

With a `PARMS=` data set, the `MIANALYZE` procedure reads parameter names from observations with the variable `Parameter`, `Effect`, `Variable`, or `Parm`. It then reads parameter estimates from observations with the variable `Estimate` and standard errors for parameter estimates from observations with the variable `StdErr`.

With a `XPXI=` data set, the `MIANALYZE` procedure reads parameter names from observations with the variable `Parameter` and  $(X'X)^{-1}$  matrices from observations with the parameter variables in the data set.

Note that this combination can be used only when each effect is a continuous variable by itself.

## Combining Inferences from Imputed Data Sets

With  $m$  imputations,  $m$  different sets of the point and variance estimates for a parameter  $Q$  can be computed. Suppose that  $\hat{Q}_i$  and  $\hat{W}_i$  are the point and variance estimates, respectively, from the  $i$ th imputed data set,  $i = 1, 2, \dots, m$ . Then the combined point estimate for  $Q$  from multiple imputation is the average of the  $m$  complete-data estimates:

$$\bar{Q} = \frac{1}{m} \sum_{i=1}^m \hat{Q}_i$$

Suppose that  $\bar{W}$  is the within-imputation variance, which is the average of the  $m$  complete-data estimates:

$$\bar{W} = \frac{1}{m} \sum_{i=1}^m \hat{W}_i$$

And suppose that  $B$  is the between-imputation variance:

$$B = \frac{1}{m-1} \sum_{i=1}^m (\hat{Q}_i - \bar{Q})^2$$

Then the variance estimate associated with  $\bar{Q}$  is the total variance (Rubin 1987)

$$T = \bar{W} + \left(1 + \frac{1}{m}\right)B$$

The statistic  $(Q - \bar{Q})T^{-(1/2)}$  is approximately distributed as  $t$  with  $v_m$  degrees of freedom (Rubin 1987), where

$$v_m = (m-1) \left[ 1 + \frac{\bar{W}}{(1+m^{-1})B} \right]^2$$

The degrees of freedom  $v_m$  depend on  $m$  and the ratio

$$r = \frac{(1+m^{-1})B}{\bar{W}}$$

The ratio  $r$  is called the relative increase in variance due to nonresponse (Rubin 1987). When there is no missing information about  $Q$ , the values of  $r$  and  $B$  are both zero. With a large value of  $m$  or a small value of  $r$ , the degrees of freedom  $v_m$  will be large and the distribution of  $(Q - \bar{Q})T^{-(1/2)}$  will be approximately normal.

Another useful statistic is the fraction of missing information about  $Q$ :

$$\hat{\lambda} = \frac{r + 2/(v_m + 3)}{r + 1}$$

Both statistics  $r$  and  $\lambda$  are helpful diagnostics for assessing how the missing data contribute to the uncertainty about  $Q$ .

When the complete-data degrees of freedom  $v_0$  are small, and there is only a modest proportion of missing data, the computed degrees of freedom,  $v_m$ , can be much larger than  $v_0$ , which is inappropriate. For example, with  $m = 5$  and  $r = 10\%$ , the computed degrees of freedom  $v_m = 484$ , which is inappropriate for data sets with complete-data degrees of freedom less than 484.

Barnard and Rubin (1999) recommend the use of adjusted degrees of freedom

$$v_m^* = \left[ \frac{1}{v_m} + \frac{1}{\hat{v}_{obs}} \right]^{-1}$$

where  $\hat{v}_{obs} = (1 - \gamma)v_0(v_0 + 1)/(v_0 + 3)$  and  $\gamma = (1 + m^{-1})B/T$ .

If you specify the complete-data degrees of freedom  $v_0$  with the EDF= option, the MIANALYZE procedure uses the adjusted degrees of freedom,  $v_m^*$ , for inference. Otherwise, the degrees of freedom  $v_m$  are used.

---

## Multiple Imputation Efficiency

The relative efficiency (RE) of using the finite  $m$  imputation estimator, rather than using an infinite number for the fully efficient imputation, in units of variance, is approximately a function of  $m$  and  $\lambda$  (Rubin 1987, p. 114):

$$RE = \left(1 + \frac{\lambda}{m}\right)^{-1}$$

Table 58.2 shows relative efficiencies with different values of  $m$  and  $\lambda$ .

**Table 58.2** Relative Efficiencies

| m  | $\lambda$ |        |        |        |        |
|----|-----------|--------|--------|--------|--------|
|    | 10%       | 20%    | 30%    | 50%    | 70%    |
| 3  | 0.9677    | 0.9375 | 0.9091 | 0.8571 | 0.8108 |
| 5  | 0.9804    | 0.9615 | 0.9434 | 0.9091 | 0.8772 |
| 10 | 0.9901    | 0.9804 | 0.9709 | 0.9524 | 0.9346 |
| 20 | 0.9950    | 0.9901 | 0.9852 | 0.9756 | 0.9662 |

The table shows that for situations with little missing information, only a small number of imputations are necessary. In practice, the number of imputations needed can be informally verified by replicating sets of  $m$  imputations and checking whether the estimates are stable between sets (Horton and Lipsitz 2001, p. 246).

---

## Multivariate Inferences

Multivariate inference based on Wald tests can be done with  $m$  imputed data sets. The approach is a generalization of the approach taken in the univariate case (Rubin 1987, p. 137; Schafer 1997, p. 113). Suppose that  $\hat{Q}_i$  and  $\hat{W}_i$  are the point and covariance matrix estimates for a  $p$ -dimensional parameter  $Q$  (such as a

multivariate mean) from the  $i$ th imputed data set,  $i = 1, 2, \dots, m$ . Then the combined point estimate for  $\mathbf{Q}$  from the multiple imputation is the average of the  $m$  complete-data estimates:

$$\bar{\mathbf{Q}} = \frac{1}{m} \sum_{i=1}^m \hat{\mathbf{Q}}_i$$

Suppose that  $\bar{\mathbf{W}}$  is the within-imputation covariance matrix, which is the average of the  $m$  complete-data estimates:

$$\bar{\mathbf{W}} = \frac{1}{m} \sum_{i=1}^m \hat{\mathbf{W}}_i$$

And suppose that  $\mathbf{B}$  is the between-imputation covariance matrix:

$$\mathbf{B} = \frac{1}{m-1} \sum_{i=1}^m (\hat{\mathbf{Q}}_i - \bar{\mathbf{Q}})(\hat{\mathbf{Q}}_i - \bar{\mathbf{Q}})'$$

Then the covariance matrix associated with  $\bar{\mathbf{Q}}$  is the total covariance matrix

$$\mathbf{T}_0 = \bar{\mathbf{W}} + \left(1 + \frac{1}{m}\right)\mathbf{B}$$

The natural multivariate extension of the  $t$  statistic used in the univariate case is the  $F$  statistic

$$F_0 = (\mathbf{Q} - \bar{\mathbf{Q}})' \mathbf{T}_0^{-1} (\mathbf{Q} - \bar{\mathbf{Q}})$$

with degrees of freedom  $p$  and

$$v = (m-1)(1 + 1/r)^2$$

where

$$r = \left(1 + \frac{1}{m}\right) \text{trace}(\mathbf{B}\bar{\mathbf{W}}^{-1})/p$$

is an average relative increase in variance due to nonresponse (Rubin 1987, p. 137; Schafer 1997, p. 114).

However, the reference distribution of the statistic  $F_0$  is not easily derived. Especially for small  $m$ , the between-imputation covariance matrix  $\mathbf{B}$  is unstable and does not have full rank for  $m \leq p$  (Schafer 1997, p. 113).

One solution is to make an additional assumption that the population between-imputation and within-imputation covariance matrices are proportional to each other (Schafer 1997, p. 113). This assumption implies that the fractions of missing information for all components of  $\mathbf{Q}$  are equal. Under this assumption, a more stable estimate of the total covariance matrix is

$$\mathbf{T} = (1 + r)\bar{\mathbf{W}}$$

With the total covariance matrix  $\mathbf{T}$ , the  $F$  statistic (Rubin 1987, p. 137)

$$F = (\mathbf{Q} - \bar{\mathbf{Q}})' \mathbf{T}^{-1} (\mathbf{Q} - \bar{\mathbf{Q}})/p$$

has an  $F$  distribution with degrees of freedom  $p$  and  $v_1$ , where

$$v_1 = \frac{1}{2}(p+1)(m-1)\left(1 + \frac{1}{r}\right)^2$$

For  $t = p(m-1) \leq 4$ , PROC MIANALYZE uses the degrees of freedom  $v_1$  in the analysis. For  $t = p(m-1) > 4$ , PROC MIANALYZE uses  $v_2$ , a better approximation of the degrees of freedom given by Li, Raghunathan, and Rubin (1991):

$$v_2 = 4 + (t-4) \left[ 1 + \frac{1}{r} \left( 1 - \frac{2}{t} \right) \right]^2$$

## Testing Linear Hypotheses about the Parameters

Linear hypotheses for parameters  $\beta$  are expressed in matrix form as

$$H_0 : \mathbf{L}\beta = \mathbf{c}$$

where  $\mathbf{L}$  is a matrix of coefficients for the linear hypotheses and  $\mathbf{c}$  is a vector of constants.

Suppose that  $\hat{\mathbf{Q}}_i$  and  $\hat{\mathbf{U}}_i$  are the point and covariance matrix estimates, respectively, for a  $p$ -dimensional parameter  $\mathbf{Q}$  from the  $i$ th imputed data set,  $i=1, 2, \dots, m$ . Then for a given matrix  $\mathbf{L}$ , the point and covariance matrix estimates for the linear functions  $\mathbf{LQ}$  in the  $i$ th imputed data set are, respectively,

$$\mathbf{L}\hat{\mathbf{Q}}_i$$

$$\mathbf{L}\hat{\mathbf{U}}_i\mathbf{L}'$$

The inferences described in the section “Combining Inferences from Imputed Data Sets” on page 4844 and the section “Multivariate Inferences” on page 4845 are applied to these linear estimates for testing the null hypothesis  $H_0 : \mathbf{L}\beta = \mathbf{c}$ .

For each TEST statement, the “Test Specification” table displays the  $\mathbf{L}$  matrix and the  $\mathbf{c}$  vector, the “Variance Information” table displays the between-imputation, within-imputation, and total variances for combining complete-data inferences, and the “Parameter Estimates” table displays a combined estimate and standard error for each linear component.

With the WCOV and BCOV options in the TEST statement, the procedure displays the within-imputation and between-imputation covariance matrices, respectively.

With the TCOV option, the procedure displays the total covariance matrix derived under the assumption that the population between-imputation and within-imputation covariance matrices are proportional to each other.

With the MULT option in the TEST statement, the “Multivariate Inference” table displays an  $F$  test for the null hypothesis  $\mathbf{L}\beta = \mathbf{c}$  of the linear components.

## Examples of the Complete-Data Inferences

For a given parameter of interest, it is not always possible to compute the estimate and associated covariance matrix directly from a SAS procedure. This section describes examples of parameters with their estimates and associated covariance matrices, which provide the input to the MIANALYZE procedure. Some are straightforward, and others require special techniques.

### Means

For a population mean vector  $\mu$ , the usual estimate is the sample mean vector

$$\bar{y} = \frac{1}{n} \sum y_i$$

A variance estimate for  $\bar{y}$  is  $\frac{1}{n}S$ , where  $S$  is the sample covariance matrix

$$S = \frac{1}{n-1} \sum (y_i - \bar{y})(y_i - \bar{y})'$$

These statistics can be computed from a procedure such as PROC CORR. This approach is illustrated in [Example 58.2](#).

### Regression Coefficients

Many SAS procedures are available for regression analysis. Among them, PROC REG provides the most general analysis capabilities, and others like PROC LOGISTIC and PROC MIXED provide more specialized analyses.

Some regression procedures, such as REG and LOGISTIC, create an EST type data set that contains both the parameter estimates for the regression coefficients and their associated covariance matrix. You can read an EST type data set in the MIANALYZE procedure with the DATA= option. This approach is illustrated in [Example 58.3](#).

Other procedures, such as GLM, MIXED, and GENMOD, do not generate EST type data sets for regression coefficients. For PROC MIXED and PROC GENMOD, you can use ODS OUTPUT statement to save parameter estimates in a data set and the associated covariance matrix in a separate data set. These data sets are then read in the MIANALYZE procedure with the PARMS= and COVB= options, respectively. This approach is illustrated in [Example 58.4](#) for PROC MIXED and in [Example 58.5](#) for PROC GENMOD.

PROC GLM does not display tables for covariance matrices. However, you can use the ODS OUTPUT statement to save parameter estimates and associated standard errors in a data set and the associated  $(X'X)^{-1}$  matrix in a separate data set. These data sets are then read in the MIANALYZE procedure with the PARMS= and XPXI= options, respectively. This approach is illustrated in [Example 58.6](#).

For univariate inference, only parameter estimates and associated standard errors are needed. You can use the ODS OUTPUT statement to save parameter estimates and associated standard errors in a data set. This data set is then read in the MIANALYZE procedure with the PARMS= option. This approach is illustrated in [Example 58.4](#).

## Correlation Coefficients

For the population correlation coefficient  $\rho$ , a point estimate is the sample correlation coefficient  $r$ . However, for nonzero  $\rho$ , the distribution of  $r$  is skewed.

The distribution of  $r$  can be normalized through Fisher's  $z$  transformation

$$z(r) = \frac{1}{2} \log \left( \frac{1+r}{1-r} \right)$$

$z(r)$  is approximately normally distributed with mean  $z(\rho)$  and variance  $1/(n-3)$ .

With a point estimate  $\hat{z}$  and an approximate 95% confidence interval  $(z_1, z_2)$  for  $z(\rho)$ , a point estimate  $\hat{r}$  and a 95% confidence interval  $(r_1, r_2)$  for  $\rho$  can be obtained by applying the inverse transformation

$$r = \tanh(z) = \frac{e^{2z} - 1}{e^{2z} + 1}$$

to  $z = \hat{z}, z_1,$  and  $z_2$ .

This approach is illustrated in [Example 58.10](#).

## Ratios of Variable Means

For the ratio  $\mu_1/\mu_2$  of means for variables  $Y_1$  and  $Y_2$ , the point estimate is  $\bar{y}_1/\bar{y}_2$ , the ratio of the sample means. The Taylor expansion and delta method can be applied to the function  $y_1/y_2$  to obtain the variance estimate (Schafer 1997, p. 196)

$$\frac{1}{n} \left[ \left( \frac{\bar{y}_1}{\bar{y}_2} \right)^2 s_{22} - 2 \left( \frac{\bar{y}_1}{\bar{y}_2} \right) \left( \frac{1}{\bar{y}_2} \right) s_{12} + \left( \frac{1}{\bar{y}_2} \right)^2 s_{11} \right]$$

where  $s_{11}$  and  $s_{22}$  are the sample variances of  $Y_1$  and  $Y_2$ , respectively, and  $s_{12}$  is the sample covariance between  $Y_1$  and  $Y_2$ .

A ratio of sample means will be approximately unbiased and normally distributed if the coefficient of variation of the denominator (the standard error for the mean divided by the estimated mean) is 10% or less (Cochran 1977, p. 166; Schafer 1997, p. 196).

---

## ODS Table Names

PROC MIANALYZE assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in [Table 58.3](#). For more information about ODS, see Chapter 20, "Using the Output Delivery System."

**Table 58.3** ODS Tables Produced by PROC MIANALYZE

| ODS Table Name | Description                          | Statement | Option |
|----------------|--------------------------------------|-----------|--------|
| BCov           | Between-imputation covariance matrix |           | BCOV   |
| ModelInfo      | Model information                    |           |        |
| MultStat       | Multivariate inference               |           | MULT   |

Table 58.3 continued

| ODS Table Name         | Description                                       | Statement | Option |

## Examples: MIANALYZE Procedure

The following statements generate five imputed data sets to be used in this section. The data set Fitness1 was created in the section “Getting Started: MIANALYZE Procedure” on page 4831. See “The MI Procedure” chapter for details concerning the MI procedure.

```
proc mi data=Fitness1 seed=3237851 noprint out=outmi;
 var Oxygen RunTime RunPulse;
run;
```

The Fish data described in the STEPDISC procedure are measurements of 159 fish of seven species caught in Finland’s lake Laengelmavesi. For each fish, the length, height, and width are measured. See Chapter 89, “The STEPDISC Procedure,” for more information.

The Fish2 data set is constructed from the Fish data set and contains two species of fish. Some values have been set to missing, and the resulting data set has a monotone missing pattern in the variables Length, Height, Width, and Species.

The following statements create the Fish2 data set. It contains two species of fish in the Fish data set.

```
-----Fish2 Data-----
| The data set contains two species of the fish (Bream and Pike) |
| and three measurements: Length, Height, Width. |
| Some values have been set to missing, and the resulting data set |
| has a monotone missing pattern in the variables |
| Length, Height, Width, and Species. |

The following statements generate five imputed data sets to be used in this section. The default regression method is used to impute missing values in continuous variables Height and Width, and the discriminant function method is used to impute the variable Species.

```

proc mi data=Fish2 seed=1305417 out=outfish;
 class Species;
 monotone discrim(Species= Length Height Width);
 var Length Height Width Species;
run;

```

Example 58.1 through Example 58.6 use different input option combinations to combine parameter estimates computed from different procedures. Example 58.7 and Example 58.8 combine parameter estimates with classification variables. Example 58.9 shows the use of a TEST statement, and Example 58.10 combines statistics that are not directly derived from procedures.

---

## Example 58.1: Reading Means and Standard Errors from Variables in a DATA= Data Set

This example creates an ordinary SAS data set that contains sample means and standard errors computed from imputed data sets. These estimates are then combined to generate valid univariate inferences about the population means.

The following statements use the UNIVARIATE procedure to generate sample means and standard errors for the variables in each imputed data set:

```
proc univariate data=outmi noprint;
 var Oxygen RunTime RunPulse;
 output out=outuni mean=Oxygen RunTime RunPulse
 stderr=SOxygen SRunTime SRunPulse;
 by _Imputation_;
run;
```

The following statements display the output data set from PROC UNIVARIATE shown in [Output 58.1.1](#):

```
proc print data=outuni;
 title 'UNIVARIATE Means and Standard Errors';
run;
```

**Output 58.1.1** UNIVARIATE Output Data Set

| UNIVARIATE Means and Standard Errors |              |         |         |              |         |              |               |
|--------------------------------------|--------------|---------|---------|--------------|---------|--------------|---------------|
| Obs                                  | _Imputation_ | Oxygen  | RunTime | Run<br>Pulse | SOxygen | SRun<br>Time | SRun<br>Pulse |
| 1                                    | 1            | 47.0120 | 10.4441 | 171.216      | 0.95984 | 0.28520      | 1.59910       |
| 2                                    | 2            | 47.2407 | 10.5040 | 171.244      | 0.93540 | 0.26661      | 1.75638       |
| 3                                    | 3            | 47.4995 | 10.5922 | 171.909      | 1.00766 | 0.26302      | 1.85795       |
| 4                                    | 4            | 47.1485 | 10.5279 | 171.146      | 0.95439 | 0.26405      | 1.75011       |
| 5                                    | 5            | 47.0042 | 10.4913 | 172.072      | 0.96528 | 0.27275      | 1.84807       |

The following statements combine the means and standard errors from imputed data sets. The EDF= option requests that the adjusted degrees of freedom be used in the analysis. For sample means based on 31 observations, the complete-data error degrees of freedom is 30.

```
proc mianalyze data=outuni edf=30;
 modeleffects Oxygen RunTime RunPulse;
 stderr SOxygen SRunTime SRunPulse;
run;
```

The “Model Information” table in [Output 58.1.2](#) lists the input data set(s) and the number of imputations. The “Variance Information” table in [Output 58.1.2](#) displays the between-imputation variance, within-imputation variance, and total variance for each univariate inference. It also displays the degrees of freedom for the total variance. The relative increase in variance due to missing values, the fraction of missing information, and the relative efficiency for each imputed variable are also displayed. A detailed description of these statistics is provided in the section “Combining Inferences from Imputed Data Sets” on page 4844 and the section “Multiple Imputation Efficiency” on page 4845.

**Output 58.1.2** Variance Information

Note that the results in this example could also have been obtained with the MI procedure.

---

## Example 58.2: Reading Means and Covariance Matrices from a DATA= COV Data Set

This example creates a COV-type data set that contains sample means and covariance matrices computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the population means.

The following statements use the CORR procedure to generate sample means and a covariance matrix for the variables in each imputed data set:

```
proc corr data=outmi cov nocorr noprint out=outcov(type=cov);
 var Oxygen RunTime RunPulse;
 by _Imputation_;
run;
```

The following statements display (in [Output 58.2.1](#)) output sample means and covariance matrices from PROC CORR for the first two imputed data sets:

```
proc print data=outcov(obs=12);
 title 'CORR Means and Covariance Matrices'
 '(First Two Imputations)';
run;
```

## Output 58.2.1 COV Data Set

| CORR Means and Covariance Matrices (First Two Imputations) |              |        |          |          |         |          |

| 11                                                         | 2            | STD    |          | 5.2081   | 1.4844  | 9.779    |
| 12                                                         | 2            | N      |          | 31.0000  | 31.0000 | 31.000   |

Note that the covariance matrices in the data set outcov are estimated covariance matrices of variables,  $V(\mathbf{y})$ . The estimated covariance matrix of the sample means is  $V(\bar{\mathbf{y}}) = V(\mathbf{y})/n$ , where  $n$  is the sample size, and is not the same as an estimated covariance matrix for variables.

The following statements combine the results for the imputed data sets, and derive both univariate and multivariate inferences about the means. The EDF= option is specified to request that the adjusted degrees of freedom be used in the analysis. For sample means based on 31 observations, the complete-data error degrees of freedom is 30.

```
proc mianalyze data=outcov edf=30;
 modeleffects Oxygen RunTime RunPulse;
run;
```

The “Variance Information” and “Parameter Estimates” tables display the same results as in [Output 58.1.2](#) and [Output 58.1.3](#), respectively, in [Example 58.1](#).

With the WCOV, BCOV, and TCOV options, as in the following statements, the procedure displays the between-imputation covariance matrix, within-imputation covariance matrix, and total covariance matrix assuming that the between-imputation covariance matrix is proportional to the within-imputation covariance matrix in [Output 58.2.2](#).

```
proc mianalyze data=outcov edf=30 wcov bcov tcov mult;
 modeleffects Oxygen RunTime RunPulse;
run;
```

**Output 58.2.2** Covariance Matrices

| The MIANALYZE Procedure              |              |              |              |

|                                      | Oxygen       | RunTime      | RunPulse     |
| Oxygen                               | 0.0414778123 | 0.0099248946 | 0.0183701754 |
| RunTime                              | 0.0099248946 | 0.0029478891 | 0.0091684769 |
| RunPulse                             | 0.0183701754 | 0.0091684769 | 0.1910855259 |
| Total Covariance Matrix              |              |              |              |
|                                      | Oxygen       | RunTime      | RunPulse     |
| Oxygen                               | 1.202882661  | -0.292700068 | -0.595750001 |
| RunTime                              | -0.292700068 | 0.094516313  | 0.103787365  |
| RunPulse                             | -0.595750001 | 0.103787365  | 4.024598310  |

With the MULT option, the procedure assumes that the between-imputation covariance matrix is proportional to the within-imputation covariance matrix and displays a multivariate inference for all the parameters taken jointly.

**Output 58.2.3** Multivariate Inference

| Multivariate Inference                                         |        |        |                            |        |  |
|----------------------------------------------------------------|--------|--------|----------------------------|--------|--|
| Assuming Proportionality of Between/Within Covariance Matrices |        |        |                            |        |  |
| Avg Relative Increase in Variance                              | Num DF | Den DF | F for H0: Parameter=Theta0 | Pr > F |  |
| 0.292237                                                       | 3      | 122.68 | 12519.7                    | <.0001 |  |

The “Multivariate Inference” table in [Output 58.2.3](#) shows a significant  $p$ -value for the null hypothesis that the population means are all equal to zero.

## Example 58.3: Reading Regression Results from a DATA= EST Data Set

This example creates an EST-type data set that contains regression coefficients and their corresponding covariance matrices computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the regression model.

The following statements use the REG procedure to generate regression coefficients:

```
proc reg data=outmi outest=outreg covout noprint;
 model Oxygen= RunTime RunPulse;
 by _Imputation_;
run;
```

The following statements display (in [Output 58.3.1](#)) output regression coefficients and their covariance matrices from PROC REG for the first two imputed data sets:

```
proc print data=outreg(obs=8);
 var _Imputation_ _Type_ _Name_
 Intercept RunTime RunPulse;
 title 'REG Model Coefficients and Covariance Matrices'
 '(First Two Imputations)';
run;
```

**Output 58.3.1** EST-Type Data Set

| REG Model Coefficients and Covariance Matrices (First Two Imputations) |              |        |           |           |          |          |
|------------------------------------------------------------------------|--------------|--------|-----------|-----------|----------|----------|
| Obs                                                                    | _Imputation_ | _TYPE_ | _NAME_    | Intercept | RunTime  | RunPulse |
| 1                                                                      | 1            | PARMS  |           | 86.544    | -2.82231 | -0.05873 |
| 2                                                                      | 1            | COV    | Intercept | 100.145   | -0.53519 | -0.55077 |
| 3                                                                      | 1            | COV    | RunTime   | -0.535    | 0.10774  | -0.00345 |
| 4                                                                      | 1            | COV    | RunPulse  | -0.551    | -0.00345 | 0.00343  |
| 5                                                                      | 2            | PARMS  |           | 83.021    | -3.00023 | -0.02491 |
| 6                                                                      | 2            | COV    | Intercept | 79.032    | -0.66765 | -0.41918 |
| 7                                                                      | 2            | COV    | RunTime   | -0.668    | 0.11456  | -0.00313 |
| 8                                                                      | 2            | COV    | RunPulse  | -0.419    | -0.00313 | 0.00264  |

The following statements combine the results for the imputed data sets. The EDF= option is specified to request that the adjusted degrees of freedom be used in the analysis. For a regression model with three independent variables (including the Intercept) and 31 observations, the complete-data error degrees of freedom is 28.

```
proc mianalyze data=outreg edf=28;
 modeleffects Intercept RunTime RunPulse;
run;
```

**Output 58.3.2** Variance Information

| The MIANALYZE Procedure |                    |           |            |        |
|-------------------------|--------------------|-----------|------------|--------|

| Variance Information |                               |                              |                     |
|----------------------|-------------------------------|------------------------------|---------------------|
| Parameter            | Relative Increase in Variance | Fraction Missing Information | Relative Efficiency |
| Intercept            | 0.713777                      | 0.461277                     | 0.915537            |
| RunTime              | 0.219051                      | 0.192620                     | 0.962905            |
| RunPulse             | 0.476384                      | 0.355376                     | 0.933641            |

The “Variance Information” table in [Output 58.3.2](#) displays the between-imputation, within-imputation, and total variances for combining complete-data inferences.

The “Parameter Estimates” table in [Output 58.3.3](#) displays the estimated mean and standard error of the regression coefficients. The inferences are based on the  $t$  distribution. The table also displays a 95% mean confidence interval and a  $t$  test with the associated  $p$ -value for the hypothesis that the regression coefficient is equal to zero. Since the  $p$ -value for RunPulse is 0.1597, this variable can be removed from the regression model.

**Output 58.3.3** Parameter Estimates

| Parameter Estimates |           |           |                       |          |        |

**Example 58.4: Reading Mixed Model Results from PARMs= and COVB= Data Sets**

This example creates data sets that contains parameter estimates and covariance matrices computed by a mixed model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the parameters.

The following PROC MIXED statements generate the fixed-effect parameter estimates and covariance matrix for each imputed data set:

```
proc mixed data=outmi;
 model Oxygen= RunTime RunPulse RunTime*RunPulse/solution covb;
 by _Imputation_;
 ods output SolutionF=mixparms CovB=mixcovb;
run;
```

The following statements display (in Output 58.4.1) output parameter estimates from PROC MIXED for the first two imputed data sets:

```
proc print data=mixparms (obs=8);
 var _Imputation_ Effect Estimate StdErr;
 title 'MIXED Model Coefficients (First Two Imputations)';
run;
```

**Output 58.4.1** PROC MIXED Model Coefficients

| MIXED Model Coefficients (First Two Imputations) |              |                  |          |         |
|--------------------------------------------------|--------------|------------------|----------|---------|
| Obs                                              | _Imputation_ | Effect           | Estimate | StdErr  |
| 1                                                | 1            | Intercept        | 148.09   | 81.5231 |
| 2                                                | 1            | RunTime          | -8.8115  | 7.8794  |
| 3                                                | 1            | RunPulse         | -0.4123  | 0.4684  |
| 4                                                | 1            | RunTime*RunPulse | 0.03437  | 0.04517 |
| 5                                                | 2            | Intercept        | 64.3607  | 64.6034 |
| 6                                                | 2            | RunTime          | -1.1270  | 6.4307  |
| 7                                                | 2            | RunPulse         | 0.08160  | 0.3688  |
| 8                                                | 2            | RunTime*RunPulse | -0.01069 | 0.03664 |

The following statements display (in [Output 58.4.2](#)) the output covariance matrices associated with the parameter estimates from PROC MIXED for the first two imputed data sets:

```
proc print data=mixcovb (obs=8);
 var _Imputation_ Row Effect Col1 Col2 Col3 Col4;
 title 'Covariance Matrices (First Two Imputations)';
run;
```

**Output 58.4.2** PROC MIXED Covariance Matrices

| Covariance Matrices (First Two Imputations) |              |     |                  |          |         |          |          |
|---------------------------------------------|--------------|-----|------------------|----------|---------|----------|----------|
| Obs                                         | _Imputation_ | Row | Effect           | Col1     | Col2    | Col3     | Col4     |
| 1                                           | 1            | 1   | Intercept        | 6646.01  | -637.40 | -38.1515 | 3.6542   |
| 2                                           | 1            | 2   | RunTime          | -637.40  | 62.0842 | 3.6548   | -0.3556  |
| 3                                           | 1            | 3   | RunPulse         | -38.1515 | 3.6548  | 0.2194   | -0.02099 |
| 4                                           | 1            | 4   | RunTime*RunPulse | 3.6542   | -0.3556 | -0.02099 | 0.002040 |
| 5                                           | 2            | 1   | Intercept        | 4173.59  | -411.46 | -23.7889 | 2.3441   |
| 6                                           | 2            | 2   | RunTime          | -411.46  | 41.3545 | 2.3414   | -0.2353  |
| 7                                           | 2            | 3   | RunPulse         | -23.7889 | 2.3414  | 0.1360   | -0.01338 |
| 8                                           | 2            | 4   | RunTime*RunPulse | 2.3441   | -0.2353 | -0.01338 | 0.001343 |

Note that the variables Col1, Col2, Col3, and Col4 are used to identify the effects Intercept, RunTime, RunPulse, and RunTime\*RunPulse, respectively, through the variable Row.

For univariate inference, only parameter estimates and their associated standard errors are needed. The following statements use the MIANALYZE procedure with the input PARMs= data set to produce univariate results:

```
proc mianalyze parms=mixparms edf=28;
 modeleffects Intercept RunTime RunPulse RunTime*RunPulse;
run;
```

The “Variance Information” table in [Output 58.4.3](#) displays the between-imputation, within-imputation, and total variances for combining complete-data inferences.

**Output 58.4.3** Variance Information

| The MIANALYZE Procedure |                    |             |             |        |
|-------------------------|--------------------|-------------|-------------|--------|

| RunTime*RunPulse    | 0      | 0.56             | 0.5846  |  |

Since each covariance matrix contains variables Row, Col1, Col2, Col3, and Col4 for parameters, the EFFECTVAR=ROWCOL option is needed when you specify the COVB= option. The following statements illustrate the use of the MIANALYZE procedure with input PARMS= and COVB(EFFECTVAR=ROWCOL)= data sets:

```
proc mianalyze parms=mixparms edf=28
 covb(effectvar=rowcol)=mixcovb;
 modeleffects Intercept RunTime RunPulse RunTime*RunPulse;
run;
```

## Example 58.5: Reading Generalized Linear Model Results

This example creates data sets that contains parameter estimates and corresponding covariance matrices computed by a generalized linear model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC GENMOD to generate the parameter estimates and covariance matrix for each imputed data set:

```
proc genmod data=outmi;
 model Oxygen= RunTime RunPulse/covb;
 by _Imputation_;
 ods output ParameterEstimates=gmparms
 ParmInfo=gmpinfo
 CovB=gmcovb;
run;
```

The following statements print (in [Output 58.5.1](#)) the output parameter estimates and covariance matrix from PROC GENMOD for the first two imputed data sets:

```
proc print data=gmparms (obs=8);
 var _Imputation_ Parameter Estimate StdErr;
 title 'GENMOD Model Coefficients (First Two Imputations)';
run;
```

**Output 58.5.1** PROC GENMOD Model Coefficients

| GENMOD Model Coefficients (First Two Imputations) |              |           |          |        |
|---------------------------------------------------|--------------|-----------|----------|--------|
| Obs                                               | _Imputation_ | Parameter | Estimate | StdErr |
| 1                                                 | 1            | Intercept | 86.5440  | 9.5107 |
| 2                                                 | 1            | RunTime   | -2.8223  | 0.3120 |
| 3                                                 | 1            | RunPulse  | -0.0587  | 0.0556 |
| 4                                                 | 1            | Scale     | 2.6692   | 0.3390 |
| 5                                                 | 2            | Intercept | 83.0207  | 8.4489 |
| 6                                                 | 2            | RunTime   | -3.0002  | 0.3217 |
| 7                                                 | 2            | RunPulse  | -0.0249  | 0.0488 |
| 8                                                 | 2            | Scale     | 2.5727   | 0.3267 |

The following statements display the parameter information table in [Output 58.5.2](#). The table identifies parameter names used in the covariance matrices. The parameters Prm1, Prm2, and Prm3 are used for the effects Intercept, RunTime, and RunPulse, respectively, in each covariance matrix.

```
proc print data=gmpinfo (obs=6);
 title 'GENMOD Parameter Information (First Two Imputations)';
run;
```

**Output 58.5.2** PROC GENMOD Model Information

| GENMOD Parameter Information (First Two Imputations) |              |           |           |  |
|------------------------------------------------------|--------------|-----------|-----------|--|
| Obs                                                  | _Imputation_ | Parameter | Effect    |  |
| 1                                                    | 1            | Prm1      | Intercept |  |
| 2                                                    | 1            | Prm2      | RunTime   |  |
| 3                                                    | 1            | Prm3      | RunPulse  |  |
| 4                                                    | 2            | Prm1      | Intercept |  |
| 5                                                    | 2            | Prm2      | RunTime   |  |
| 6                                                    | 2            | Prm3      | RunPulse  |  |

The following statements display (in [Output 58.5.3](#)) the output covariance matrices from PROC GENMOD for the first two imputed data sets. Note that the GENMOD procedure computes maximum likelihood estimates for each covariance matrix.

```
proc print data=gmcovb (obs=8);
 var _Imputation_ RowName Prm1 Prm2 Prm3;
 title 'GENMOD Covariance Matrices (First Two Imputations)';
run;
```

**Output 58.5.3** PROC GENMOD Covariance Matrices

| GENMOD Covariance Matrices (First Two Imputations) |              |          |           |           |           |
|----------------------------------------------------|--------------|----------|-----------|-----------|-----------|
| Obs                                                | _Imputation_ | Row Name | Prm1      | Prm2      | Prm3      |
| 1                                                  | 1            | Prm1     | 90.453923 | -0.483394 | -0.497473 |
| 2                                                  | 1            | Prm2     | -0.483394 | 0.0973159 | -0.003113 |
| 3                                                  | 1            | Prm3     | -0.497473 | -0.003113 | 0.0030954 |
| 4                                                  | 1            | Scale    | 1.344E-15 | -1.09E-17 | -6.12E-18 |
| 5                                                  | 2            | Prm1     | 71.383332 | -0.603037 | -0.378616 |
| 6                                                  | 2            | Prm2     | -0.603037 | 0.1034766 | -0.002826 |
| 7                                                  | 2            | Prm3     | -0.378616 | -0.002826 | 0.0023843 |
| 8                                                  | 2            | Scale    | 1.602E-14 | 1.755E-16 | -1.02E-16 |

The following statements use the MIANALYZE procedure with input PARMS=, PARMINFO=, and COVB= data sets:

```
proc mianalyze parms=gmparms covb=gmcovb parminfo=gmpinfo;
 modeleffects Intercept RunTime RunPulse;
run;
```

Since the GENMOD procedure computes maximum likelihood estimates for the covariance matrix, the EDF= option is not used. The resulting model coefficients are identical to the estimates in [Output 58.3.3](#) in [Example 58.3](#). However, the standard errors are slightly different because in this example, maximum likelihood estimates for the standard errors are combined without the EDF= option, whereas in [Example 58.3](#), unbiased estimates for the standard errors are combined with the EDF= option.

## Example 58.6: Reading GLM Results from PARMs= and XPXI= Data Sets

This example creates data sets that contains parameter estimates and corresponding  $(X'X)^{-1}$  matrices computed by a general linear model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC GLM to generate the parameter estimates and  $(X'X)^{-1}$  matrix for each imputed data set:

```
proc glm data=outmi;
 model Oxygen= RunTime RunPulse/inverse;
 by _Imputation_;
 ods output ParameterEstimates=glmparms
 InvXPX=glmxpxi;
quit;
```

The following statements display (in [Output 58.6.1](#)) the output parameter estimates and standard errors from PROC GLM for the first two imputed data sets:

```
proc print data=glmparms (obs=6);
 var _Imputation_ Parameter Estimate StdErr;
 title 'GLM Model Coefficients (First Two Imputations)';
run;
```

**Output 58.6.1** PROC GLM Model Coefficients

| GLM Model Coefficients (First Two Imputations) |              |           |            |             |
|------------------------------------------------|--------------|-----------|------------|-------------|
| Obs                                            | _Imputation_ | Parameter | Estimate   | StdErr      |
| 1                                              | 1            | Intercept | 86.5440339 | 10.00726811 |
| 2                                              | 1            | RunTime   | -2.8223108 | 0.32824165  |
| 3                                              | 1            | RunPulse  | -0.0587292 | 0.05854109  |

| 5                                              | 2            | RunTime   | -3.0002288 | 0.33847204  |
| 6                                              | 2            | RunPulse  | -0.0249103 | 0.05137859  |

The following statements display (in [Output 58.6.2](#))  $(X'X)^{-1}$  matrices from PROC GLM for the first two imputed data sets:

```
proc print data=glmxpxi (obs=8);
 var _Imputation_ Parameter Intercept RunTime RunPulse;
 title 'GLM X'X Inverse Matrices (First Two Imputations)';
run;
```

**Output 58.6.2** PROC GLM  $(X'X)^{-1}$  Matrices

| GLM X'X Inverse Matrices (First Two Imputations) |              |           |              |              |              |
|--------------------------------------------------|--------------|-----------|--------------|--------------|--------------|
| Obs                                              | _Imputation_ | Parameter | Intercept    | RunTime      | RunPulse     |
| 1                                                | 1            | Intercept | 12.696250656 | -0.067849956 | -0.069826009 |
| 2                                                | 1            | RunTime   | -0.067849956 | 0.0136594055 | -0.000436938 |
| 3                                                | 1            | RunPulse  | -0.069826009 | -0.000436938 | 0.0004344762 |
| 4                                                | 1            | Oxygen    | 86.544033929 | -2.822310769 | -0.058729234 |
| 5                                                | 2            | Intercept | 10.784620785 | -0.091107072 | -0.057201387 |
| 6                                                | 2            | RunTime   | -0.091107072 | 0.0156332765 | -0.000426902 |
| 7                                                | 2            | RunPulse  | -0.057201387 | -0.000426902 | 0.0003602208 |
| 8                                                | 2            | Oxygen    | 83.020730343 | -3.000228818 | -0.024910305 |

The standard errors for the estimates in the output `glmparms` data set are needed to create the covariance matrix from the  $(X'X)^{-1}$  matrix. The following statements use the MIANALYZE procedure with input `PARMS=` and `XPXI=` data sets to produce the same results as displayed in [Output 58.3.2](#) and [Output 58.3.3](#) in [Example 58.3](#):

```
proc mianalyze parms=glmparms xpxi=glmxpxi edf=28;
 modeleffects Intercept RunTime RunPulse;
run;
```

---

### Example 58.7: Reading Logistic Model Results from `PARMS=` and `COVB=` Data Sets

This example creates data sets that contains parameter estimates and corresponding covariance matrices computed by a logistic regression analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC LOGISTIC to generate the parameter estimates and covariance matrix for each imputed data set:

```
proc logistic data=outfish;
 class Species;
 model Species= Height Width Height*Width/ covb;
 by _Imputation_;
 ods output ParameterEstimates=lgsparms
 CovB=lgscovb;
run;
```

The following statements display (in [Output 58.7.1](#)) the output logistic regression coefficients from PROC LOGISTIC for the first two imputed data sets:

```
proc print data=lgsparms (obs=8);
 title 'LOGISTIC Model Coefficients (First Two Imputations)';
run;
```

**Output 58.7.1** PROC LOGISTIC Model Coefficients

| LOGISTIC Model Coefficients (First Two Imputations) |              |              |    |          |         |           |               |           |

## Example 58.8: Reading Mixed Model Results with Classification Variables

This example creates data sets that contains parameter estimates and corresponding covariance matrices with classification variables computed by a mixed regression model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC MIXED to generate the parameter estimates and covariance matrix for each imputed data set:

```
proc mixed data=outfish;
 class Species;
 model Length= Species Height Width/ solution covb;
 by _Imputation_;
 ods output SolutionF=mxparms CovB=mxcovb;
run;
```

The following statements display (in [Output 58.8.1](#)) the output mixed model coefficients from PROC MIXED for the first two imputed data sets:

```
proc print data=mxparms (obs=10);
 var _Imputation_ Effect Species Estimate StdErr;
 title 'MIXED Model Coefficients (First Two Imputations)';
run;
```

**Output 58.8.1** PROC MIXED Model Coefficients

| MIXED Model Coefficients (First Two Imputations) |              |           |         |          |        |
|--------------------------------------------------|--------------|-----------|---------|----------|--------|
| Obs                                              | _Imputation_ | Effect    | Species | Estimate | StdErr |
| 1                                                | 1            | Intercept |         | 12.5356  | 2.7808 |
| 2                                                | 1            | Species   | Bream   | -11.9103 | 3.5386 |

### Example 58.9: Using a TEST statement

This example creates an EST-type data set that contains regression coefficients and their corresponding covariance matrices computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the regression model. A TEST statement is used to test linear hypotheses about the parameters.

The following statements use the REG procedure to generate regression coefficients:

```
proc reg data=outmi outest=outreg covout noprint;
 model Oxygen= RunTime RunPulse;
 by _Imputation_;
run;
```

The following statements combine the results for the imputed data sets. A TEST statement is used to test linear hypotheses of Intercept=0 and RunTime=RunPulse.

```
proc mianalyze data=outreg edf=28;
 modeleffects Intercept RunTime RunPulse;
 test Intercept, RunTime=RunPulse / mult;
run;
```

The “Test Specification” table in [Output 58.9.1](#) displays the L matrix and the c vector in a TEST statement. Since there is no label specified for the TEST statement, “Test 1” is used as the label.

**Output 58.9.1** Test Specification

| The MIANALYZE Procedure |           |          |           |   |
|-------------------------|-----------|----------|-----------|---|
| Test: Test 1            |           |          |           |   |
| Test Specification      |           |          |           |   |
| -----L Matrix-----      |           |          |           |   |
| Parameter               | Intercept | RunTime  | RunPulse  | C |
| TestPrm1                | 1.000000  | 0        | 0         | 0 |
| TestPrm2                | 0         | 1.000000 | -1.000000 | 0 |

The “Variance Information” table in [Output 58.9.2](#) displays the between-imputation variance, within-imputation variance, and total variance for each univariate inference. A detailed description of these statistics is provided in the section “[Combining Inferences from Imputed Data Sets](#)” on page 4844 and the section “[Multiple Imputation Efficiency](#)” on page 4845.

**Output 58.9.2** Variance Information

| Variance Information |           |           |            |        |
|----------------------|-----------|-----------|------------|--------|
| -----Variance-----   |           |           |            |        |
| Parameter            | Between   | Within    | Total      | DF     |
| TestPrm1             | 45.529229 | 76.543614 | 131.178689 | 9.1917 |
| TestPrm2             | 0.014715  | 0.114324  | 0.131983   | 20.598 |

| Variance Information |                               |                              |                     |
|----------------------|-------------------------------|------------------------------|---------------------|
| Parameter            | Relative Increase in Variance | Fraction Missing Information | Relative Efficiency |
| TestPrm1             | 0.713777                      | 0.461277                     | 0.915537            |
| TestPrm2             | 0.154459                      | 0.141444                     | 0.972490            |

The “Parameter Estimates” table in [Output 58.9.3](#) displays the estimated mean and standard error of the linear components. The inferences are based on the  $t$  distribution. The table also displays a 95% mean confidence interval and a  $t$  test with the associated  $p$ -value for the hypothesis that each linear component of  $L\beta$  is equal to zero.

**Output 58.9.3** Parameter Estimates

| Parameter Estimates |           |           |                       |          |        |
|---------------------|-----------|-----------|-----------------------|----------|--------|
| Parameter           | Estimate  | Std Error | 95% Confidence Limits |          | DF     |
| TestPrm1            | 90.837440 | 11.453327 | 65.01034              | 116.6645 | 9.1917 |

| Avg Relative Increase in Variance                              | Num DF | Den DF | F for H0:        |        |  |
|                                                                |        |        | Parameter=Theta0 | Pr > F |  |
| 0.419868                                                       | 2      | 35.053 | 60.34            | <.0001 |  |

### Example 58.10: Combining Correlation Coefficients

This example combines sample correlation coefficients computed from a set of imputed data sets by using Fisher’s  $z$  transformation.

Fisher’s  $z$  transformation of the sample correlation  $r$  is

$$z = \frac{1}{2} \log \left( \frac{1+r}{1-r} \right)$$

The statistic  $z$  is approximately normally distributed with mean

$$\log\left(\frac{1+\rho}{1-\rho}\right)$$

and variance  $1/(n-3)$ , where  $\rho$  is the population correlation coefficient and  $n$  is the number of observations.

The following statements use the CORR procedure to compute the correlation  $r$  and its associated Fisher's  $z$  statistic between variables Oxygen and RunTime for each imputed data set. The ODS statement is used to save Fisher's  $z$  statistic in an output data set.

```
proc corr data=outmi fisher(biasadj=no);
 var Oxygen RunTime;
 by _Imputation_;
 ods output FisherPearsonCorr= outz;
run;
```

The following statements display the number of observations and Fisher's  $z$  statistic for each imputed data set in [Output 58.10.1](#):

```
proc print data=outz;
 title 'Fisher's Correlation Statistics';
 var _Imputation_ NObs ZVal;
run;
```

**Output 58.10.1** Output  $z$  Statistics

| Fisher's Correlation Statistics |              |      |          |  |
|---------------------------------|--------------|------|----------|--|
| Obs                             | _Imputation_ | NObs | ZVal     |  |
| 1                               | 1            | 31   | -1.27869 |  |
| 2                               | 2            | 31   | -1.30715 |  |
| 3                               | 3            | 31   | -1.27922 |  |
| 4                               | 4            | 31   | -1.39243 |  |
| 5                               | 5            | 31   | -1.40146 |  |

The following statements generate the standard error associated with the  $z$  statistic,  $1/\sqrt{n-3}$ :

```
data outz;
 set outz;
 StdZ= 1. / sqrt(NObs-3);
run;
```

The following statements use the MIANALYZE procedure to generate a combined parameter estimate  $\hat{z}$  and its variance, as shown in [Output 58.10.2](#). The ODS statement is used to save the parameter estimates in an output data set.

```
proc mianalyze data=outz;
 ods output ParameterEstimates=parms;
 modeleffects ZVal;
 stderr StdZ;
run;
```

**Output 58.10.2** Combining Fisher's  $z$  Statistics

| The MIANALYZE Procedure |           |                               |                       |          |        |
|-------------------------|-----------|-------------------------------|-----------------------|----------|--------|
| Parameter Estimates     |           |                               |                       |          |        |
| Parameter               | Estimate  | Std Error                     | 95% Confidence Limits |          | DF     |
| ZVal                    | -1.331787 | 0.200327                      | -1.72587              | -0.93771 | 330.23 |
| Parameter Estimates     |           |                               |                       |          |        |
| Parameter               | Minimum   | Maximum                       |                       |          |        |
| ZVal                    | -1.401459 | -1.278686                     |                       |          |        |
| Parameter Estimates     |           |                               |                       |          |        |
| Parameter               | Theta0    | t for H0:<br>Parameter=Theta0 |                       | Pr >  t  |        |
| ZVal                    | 0         | -6.65                         |                       | <.0001   |        |

In addition to the estimate for  $z$ , PROC MIANALYZE also generates 95% confidence limits for  $z$ ,  $\hat{z}_{.025}$  and  $\hat{z}_{.975}$ . The following statements print the estimate and 95% confidence limits for  $z$  in [Output 58.10.3](#):

```
proc print data=parms;
 title 'Parameter Estimates with 95% Confidence Limits';
 var Estimate LCLMean UCLMean;
run;
```

**Output 58.10.3** Parameter Estimates with 95% Confidence Limits

| Parameter Estimates with 95% Confidence Limits |           |          |          |
|------------------------------------------------|-----------|----------|----------|
| Obs                                            | Estimate  | LCLMean  | UCLMean  |
| 1                                              | -1.331787 | -1.72587 | -0.93771 |

An estimate of the correlation coefficient with its corresponding 95% confidence limits is then generated from the following inverse transformation as described in the section “[Correlation Coefficients](#)” on page 4849:

$$r = \tanh(z) = \frac{e^{2z} - 1}{e^{2z} + 1}$$

for  $z = \hat{z}$ ,  $\hat{z}_{.025}$ , and  $\hat{z}_{.975}$ .

The following statements generate and display an estimate of the correlation coefficient and its 95% confidence limits, as shown in [Output 58.10.4](#):

```
data corr_ci;
 set parms;
 r= tanh(Estimate);
 r_lower= tanh(LCLMean);
 r_upper= tanh(UCLMean);
run;
proc print data=corr_ci;
 title 'Estimated Correlation Coefficient '
 ' with 95% Confidence Limits';
 var r r_lower r_upper;
run;
```

**Output 58.10.4** Estimated Correlation Coefficient

| Estimated Correlation Coefficient with 95% Confidence Limits |          |          |          |
|--------------------------------------------------------------|----------|----------|----------|
| Obs                                                          | r        | r_lower  | r_upper  |
| 1                                                            | -0.86969 | -0.93857 | -0.73417 |

## Overview: MIXED Procedure

The MIXED procedure fits a variety of mixed linear models to data and enables you to use these fitted models to make statistical inferences about the data. A *mixed linear model* is a generalization of the standard linear model used in the GLM procedure, the generalization being that the data are permitted to exhibit correlation and nonconstant variability. The mixed linear model, therefore, provides you with the flexibility of modeling not only the means of your data (as in the standard linear model) but their variances and covariances as well.

The primary assumptions underlying the analyses performed by PROC MIXED are as follows:

- The data are normally distributed (Gaussian).
- The means (expected values) of the data are linear in terms of a certain set of parameters.
- The variances and covariances of the data are in terms of a different set of parameters, and they exhibit a structure matching one of those available in PROC MIXED.

Since Gaussian data can be modeled entirely in terms of their means and variances/covariances, the two sets of parameters in a mixed linear model actually specify the complete probability distribution of the data. The parameters of the mean model are referred to as *fixed-effects parameters*, and the parameters of the variance-covariance model are referred to as *covariance parameters*.

The fixed-effects parameters are associated with known explanatory variables, as in the standard linear model. These variables can be either qualitative (as in the traditional analysis of variance) or quantitative (as in standard linear regression). However, the covariance parameters are what distinguishes the mixed linear model from the standard linear model.

The need for covariance parameters arises quite frequently in applications, the following being the two most typical scenarios:

- The experimental units on which the data are measured can be grouped into clusters, and the data from a common cluster are correlated.
- Repeated measurements are taken on the same experimental unit, and these repeated measurements are correlated or exhibit variability that changes.

The first scenario can be generalized to include one set of clusters nested within another. For example, if students are the experimental unit, they can be clustered into classes, which in turn can be clustered into schools. Each level of this hierarchy can introduce an additional source of variability and correlation. The second scenario occurs in longitudinal studies, where repeated measurements are taken over time. Alternatively, the repeated measures could be spatial or multivariate in nature.

PROC MIXED provides a variety of covariance structures to handle the previous two scenarios. The most common of these structures arises from the use of *random-effects parameters*, which are additional unknown random variables assumed to affect the variability of the data. The variances of the random-effects parameters, commonly known as *variance components*, become the covariance parameters for this particular structure. Traditional mixed linear models contain both fixed- and random-effects parameters, and, in fact, it is the combination of these two types of effects that led to the name *mixed model*. PROC MIXED fits not only these traditional variance component models but numerous other covariance structures as well.

PROC MIXED fits the structure you select to the data by using the method of *restricted maximum likelihood (REML)*, also known as *residual maximum likelihood*. It is here that the Gaussian assumption for the data is exploited. Other estimation methods are also available, including *maximum likelihood* and *MIVQUE0*. The details behind these estimation methods are discussed in subsequent sections.

After a model has been fit to your data, you can use it to draw statistical inferences via both the fixed-effects and covariance parameters. PROC MIXED computes several different statistics suitable for generating hypothesis tests and confidence intervals. The validity of these statistics depends upon the mean and variance-covariance model you select, so it is important to choose the model carefully. Some of the output from PROC MIXED helps you assess your model and compare it with others.

---

## Basic Features

PROC MIXED provides easy accessibility to numerous mixed linear models that are useful in many common statistical analyses. In the style of the GLM procedure, PROC MIXED fits the specified mixed linear model and produces appropriate statistics.

Here are some basic features of PROC MIXED:

- covariance structures, including variance components, compound symmetry, unstructured, AR(1), Toeplitz, spatial, general linear, and factor analytic
- GLM-type grammar, by using **MODEL**, **RANDOM**, and **REPEATED** statements for model specification and **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements for inferences
- appropriate standard errors for all specified estimable linear combinations of fixed and random effects, and corresponding *t* and *F* tests
- subject and group effects that enable blocking and heterogeneity, respectively
- REML and ML estimation methods implemented with a Newton-Raphson algorithm
- capacity to handle unbalanced data
- ability to create a SAS data set corresponding to any table

PROC MIXED uses the Output Delivery System (ODS), a SAS subsystem that provides capabilities for displaying and controlling the output from SAS procedures. ODS enables you to convert any of the output from PROC MIXED into a SAS data set. See the section “ODS Table Names” on page 4987.

The MIXED procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the statistical graphics available with the MIXED procedure, see the PLOTS= option in the PROC MIXED statement and the section “ODS Graphics” on page 4992.

---

## Notation for the Mixed Model

This section introduces the mathematical notation used throughout this chapter to describe the mixed linear model. You should be familiar with basic matrix algebra (see Searle 1982). A more detailed description of the mixed model is contained in the section “Mixed Models Theory” on page 4958.

A statistical model is a mathematical description of how data are generated. The standard linear model, as used by the GLM procedure, is one of the most common statistical models:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

In this expression,  $\mathbf{y}$  represents a vector of observed data,  $\boldsymbol{\beta}$  is an unknown vector of fixed-effects parameters with known design matrix  $\mathbf{X}$ , and  $\boldsymbol{\epsilon}$  is an unknown random error vector modeling the statistical noise around  $\mathbf{X}\boldsymbol{\beta}$ . The focus of the standard linear model is to model the mean of  $\mathbf{y}$  by using the fixed-effects parameters  $\boldsymbol{\beta}$ . The residual errors  $\boldsymbol{\epsilon}$  are assumed to be independent and identically distributed Gaussian random variables with mean 0 and variance  $\sigma^2$ .

The mixed model generalizes the standard linear model as follows:

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

Here,  $\boldsymbol{\gamma}$  is an unknown vector of random-effects parameters with known design matrix  $\mathbf{Z}$ , and  $\boldsymbol{\epsilon}$  is an unknown random error vector whose elements are no longer required to be independent and homogeneous.

To further develop this notion of variance modeling, assume that  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$  are Gaussian random variables that are uncorrelated and have expectations  $\mathbf{0}$  and variances  $\mathbf{G}$  and  $\mathbf{R}$ , respectively. The variance of  $\mathbf{y}$  is thus

$$\mathbf{V} = \mathbf{Z}\mathbf{G}\mathbf{Z}' + \mathbf{R}$$

Note that, when  $\mathbf{R} = \sigma^2\mathbf{I}$  and  $\mathbf{Z} = \mathbf{0}$ , the mixed model reduces to the standard linear model.

You can model the variance of the data,  $\mathbf{y}$ , by specifying the structure (or form) of  $\mathbf{Z}$ ,  $\mathbf{G}$ , and  $\mathbf{R}$ . The model matrix  $\mathbf{Z}$  is set up in the same fashion as  $\mathbf{X}$ , the model matrix for the fixed-effects parameters. For  $\mathbf{G}$  and  $\mathbf{R}$ , you must select some *covariance structure*. Possible covariance structures include the following:

- variance components
- compound symmetry (common covariance plus diagonal)
- unstructured (general covariance)
- autoregressive

- spatial
- general linear
- factor analytic

By appropriately defining the model matrices  $\mathbf{X}$  and  $\mathbf{Z}$ , as well as the covariance structure matrices  $\mathbf{G}$  and  $\mathbf{R}$ , you can perform numerous mixed model analyses.

---

## PROC MIXED Contrasted with Other SAS Procedures

PROC MIXED is a generalization of the GLM procedure in the sense that PROC GLM fits standard linear models, and PROC MIXED fits the wider class of mixed linear models. Both procedures have similar **CLASS**, **MODEL**, **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements, but their **RANDOM** and **REPEATED** statements differ (see the following paragraphs). Both procedures use the non-full-rank model parameterization, although the sorting of classification levels can differ between the two. PROC MIXED computes only Type I–Type III tests of fixed effects, while PROC GLM computes Types I–IV.

The **RANDOM** statement in PROC MIXED incorporates random effects constituting the  $\boldsymbol{\gamma}$  vector in the mixed model. However, in PROC GLM, effects specified in the **RANDOM** statement are still treated as fixed as far as the model fit is concerned, and they serve only to produce corresponding expected mean squares. These expected mean squares lead to the traditional ANOVA estimates of variance components. PROC MIXED computes REML and ML estimates of variance parameters, which are generally preferred to the ANOVA estimates (Searle 1988; Harville 1988; Searle, Casella, and McCulloch 1992). Optionally, PROC MIXED also computes MIVQUE0 estimates, which are similar to ANOVA estimates.

The **REPEATED** statement in PROC MIXED is used to specify covariance structures for repeated measurements on subjects, while the **REPEATED** statement in PROC GLM is used to specify various transformations with which to conduct the traditional univariate or multivariate tests. In repeated measures situations, the mixed model approach used in PROC MIXED is more flexible and more widely applicable than either the univariate or multivariate approach. In particular, the mixed model approach provides a larger class of covariance structures and a better mechanism for handling missing values (Wolfinger and Chang 1995).

PROC MIXED subsumes the VARCOMP procedure. PROC MIXED provides a wide variety of covariance structures, while PROC VARCOMP estimates only simple random effects. PROC MIXED carries out several analyses that are absent in PROC VARCOMP, including the estimation and testing of linear combinations of fixed and random effects.

The ARIMA and AUTOREG procedures provide more time series structures than PROC MIXED, although they do not fit variance component models. The CALIS procedure fits general covariance matrices, but the fixed effects structure of the model is formed differently than in PROC MIXED. The LATTICE and NESTED procedures fit special types of mixed linear models that can also be handled in PROC MIXED, although PROC MIXED might run slower because of its more general algorithm. The TSCSREG procedure analyzes time series cross-sectional data, and it fits some structures not available in PROC MIXED.

The GLIMMIX procedure fits generalized linear mixed models (GLMMs). Linear mixed models—where the data are normally distributed, given the random effects—are in the class of GLMMs. The MIXED procedure can estimate covariance parameters with ANOVA methods that are not available in the GLIMMIX procedure (see **METHOD=TYPE1**, **METHOD=TYPE2**, and **METHOD=TYPE3** in the **PROC MIXED**

statement). Also, PROC MIXED can perform a sampling-based Bayesian analysis through the **PRIOR** statement, and the procedure supports certain Kronecker-type covariance structures. These features are not available in the GLIMMIX procedure. The GLIMMIX procedure, on the other hand, accommodates nonnormal data and offers a broader array of post-processing features than the MIXED procedure.

---

## Getting Started: MIXED Procedure

---

### Clustered Data Example

Consider the following SAS data set as an introductory example:

```
data heights;
 input Family Gender$ Height @@;
 datalines;
1 F 67 1 F 66 1 F 64 1 M 71 1 M 72 2 F 63
2 F 63 2 F 67 2 M 69 2 M 68 2 M 70 3 F 63
3 M 64 4 F 67 4 F 66 4 M 67 4 M 67 4 M 69
;
```

The response variable Height measures the heights (in inches) of 18 individuals. The individuals are classified according to Family and Gender. You can perform a traditional two-way analysis of variance of these data with the following PROC MIXED statements:

```
proc mixed data=heights;
 class Family Gender;
 model Height = Gender Family Family*Gender;
run;
```

The **PROC MIXED** statement invokes the procedure. The **CLASS** statement instructs PROC MIXED to consider both Family and Gender as classification variables. Dummy (indicator) variables are, as a result, created corresponding to all of the distinct levels of Family and Gender. For these data, Family has four levels and Gender has two levels.

The **MODEL** statement first specifies the response (dependent) variable Height. The explanatory (independent) variables are then listed after the equal (=) sign. Here, the two explanatory variables are Gender and Family, and these are the main effects of the design. The third explanatory term, Family\*Gender, models an interaction between the two main effects.

PROC MIXED uses the dummy variables associated with Gender, Family, and Family\*Gender to construct the **X** matrix for the linear model. A column of 1s is also included as the first column of **X** to model a global intercept. There are no **Z** or **G** matrices for this model, and **R** is assumed to equal  $\sigma^2\mathbf{I}$ , where **I** is an  $18 \times 18$  identity matrix.

The **RUN** statement completes the specification. The coding is precisely the same as with the GLM procedure. However, much of the output from PROC MIXED is different from that produced by PROC GLM.

The output from PROC MIXED is shown in [Figure 59.1–Figure 59.7](#).

The “Model Information” table in [Figure 59.1](#) describes the model, some of the variables that it involves, and the method used in fitting it. This table also lists the method (profile, factor, parameter, or none) for handling the residual variance.

**Figure 59.1** Model Information

| The Mixed Procedure       |              |
|---------------------------|--------------|
| Model Information         |              |
| Data Set                  | WORK.HEIGHTS |
| Dependent Variable        | Height       |
| Covariance Structure      | Diagonal     |
| Estimation Method         | REML         |
| Residual Variance Method  | Profile      |
| Fixed Effects SE Method   | Model-Based  |
| Degrees of Freedom Method | Residual     |

The “Class Level Information” table in [Figure 59.2](#) lists the levels of all variables specified in the CLASS statement. You can check this table to make sure that the data are correct.

**Figure 59.2** Class Level Information

| Class Level Information |        |         |
|-------------------------|--------|---------|
| Class                   | Levels | Values  |
| Family                  | 4      | 1 2 3 4 |
| Gender                  | 2      | F M     |

The “Dimensions” table in [Figure 59.3](#) lists the sizes of relevant matrices. This table can be useful in determining CPU time and memory requirements.

**Figure 59.3** Dimensions

| Dimensions            |    |
|-----------------------|----|
| Covariance Parameters | 1  |
| Columns in X          | 15 |
| Columns in Z          | 0  |
| Subjects              | 1  |
| Max Obs Per Subject   | 18 |

The “Number of Observations” table in [Figure 59.4](#) displays information about the sample size being processed.

**Figure 59.4** Number of Observations

| Number of Observations          |    |
|---------------------------------|----|
| Number of Observations Read     | 18 |
| Number of Observations Used     | 18 |
| Number of Observations Not Used | 0  |

The “Covariance Parameter Estimates” table in Figure 59.5 displays the estimate of  $\sigma^2$  for the model.

**Figure 59.5** Covariance Parameter Estimates

| Covariance Parameter Estimates |          |
|--------------------------------|----------|
| Cov Parm                       | Estimate |
| Residual                       | 2.1000   |

The “Fit Statistics” table in Figure 59.6 lists several pieces of information about the fitted mixed model, including values derived from the computed value of the restricted/residual likelihood.

**Figure 59.6** Fit Statistics

| Fit Statistics           |      |
|--------------------------|------|
| -2 Res Log Likelihood    | 41.6 |
| AIC (smaller is better)  | 43.6 |
| AICC (smaller is better) | 44.1 |
| BIC (smaller is better)  | 43.9 |

The “Type 3 Tests of Fixed Effects” table in Figure 59.7 displays significance tests for the three effects listed in the MODEL statement. The Type 3  $F$  statistics and  $p$ -values are the same as those produced by the GLM procedure. However, because PROC MIXED uses a likelihood-based estimation scheme, it does not directly compute or display sums of squares for this analysis.

**Figure 59.7** Tests of Fixed Effects

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Gender                        | 1         | 10        | 17.63   | 0.0018 |
| Family                        | 3         | 10        | 5.90    | 0.0139 |
| Family*Gender                 | 3         | 10        | 2.89    | 0.0889 |

The Type 3 test for Family\*Gender effect is not significant at the 5% level, but the tests for both main effects are significant.

The important assumptions behind this analysis are that the data are normally distributed and that they are independent with constant variance. For these data, the normality assumption is probably realistic since the data are observed heights. However, since the data occur in clusters (families), it is very likely that observations from the same family are statistically correlated—that is, not independent.

The methods implemented in PROC MIXED are still based on the assumption of normally distributed data, but you can drop the assumption of independence by modeling statistical correlation in a variety of ways. You can also model variances that are heterogeneous—that is, nonconstant.

For the height data, one of the simplest ways of modeling correlation is through the use of *random effects*. Here the family effect is assumed to be normally distributed with zero mean and some unknown variance. This is in contrast to the previous model in which the family effects are just constants, or *fixed effects*. Declaring Family as a random effect sets up a common correlation among all observations having the same level of Family.

Declaring Family\*Gender as a random effect models an additional correlation between all observations that have the same level of both Family and Gender. One interpretation of this effect is that a female in a certain family exhibits more correlation with the other females in that family than with the other males, and likewise for a male. With the height data, this model seems reasonable.

The statements to fit this correlation model in PROC MIXED are as follows:

```
proc mixed;
 class Family Gender;
 model Height = Gender;
 random Family Family*Gender;
run;
```

Note that Family and Family\*Gender are now listed in the **RANDOM** statement. The dummy variables associated with them are used to construct the **Z** matrix in the mixed model. The **X** matrix now consists of a column of 1s and the dummy variables for Gender.

The **G** matrix for this model is diagonal, and it contains the variance components for both Family and Family\*Gender. The **R** matrix is still assumed to equal  $\sigma^2\mathbf{I}$ , where **I** is an identity matrix.

The output from this analysis is as follows.

**Figure 59.8** Model Information

| The Mixed Procedure       |                     |
|---------------------------|---------------------|
| Model Information         |                     |
| Data Set                  | WORK.HEIGHTS        |
| Dependent Variable        | Height              |
| Covariance Structure      | Variance Components |
| Estimation Method         | REML                |
| Residual Variance Method  | Profile             |
| Fixed Effects SE Method   | Model-Based         |
| Degrees of Freedom Method | Containment         |

The “Model Information” table in Figure 59.8 shows that the containment method is used to compute the degrees of freedom for this analysis. This is the default method when a **RANDOM** statement is used; see the description of the **DDFM=** option for more information.

**Figure 59.9** Class Level Information

| Class Level Information |        |        |       |
|-------------------------|--------|--------|-------|
| Class                   | Levels | Values |       |
| Family                  | 4      | 1      | 2 3 4 |
| Gender                  | 2      | F      | M     |

The “Class Level Information” table in Figure 59.9 is the same as before. The “Dimensions” table in Figure 59.10 displays the new sizes of the **X** and **Z** matrices.

**Figure 59.10** Dimensions and Number of Observations

| Dimensions                      |    |
|---------------------------------|----|
| Covariance Parameters           | 3  |
| Columns in X                    | 3  |
| Columns in Z                    | 12 |
| Subjects                        | 1  |
| Max Obs Per Subject             | 18 |
| Number of Observations          |    |
| Number of Observations Read     | 18 |
| Number of Observations Used     | 18 |
| Number of Observations Not Used | 0  |

The “Iteration History” table in Figure 59.11 displays the results of the numerical optimization of the restricted/residual likelihood. Six iterations are required to achieve the default convergence criterion of  $1E-8$ .

**Figure 59.11** REML Estimation Iteration History

| Iteration History |             |             |          |            |
|-------------------|-------------|-------------|----------|------------|
| Iteration         | Evaluations | -2 Res      | Log Like | Criterion  |
| 0                 | 1           | 74.11074833 |          |            |
| 1                 | 2           | 71.51614003 |          | 0.01441208 |
| 2                 | 1           | 71.13845990 |          | 0.00412226 |
| 3                 | 1           | 71.03613556 |          | 0.00058188 |
| 4                 | 1           | 71.02281757 |          | 0.00001689 |
| 5                 | 1           | 71.02245904 |          | 0.00000002 |
| 6                 | 1           | 71.02245869 |          | 0.00000000 |

| Convergence criteria met. |
|---------------------------|

The “Covariance Parameter Estimates” table in [Figure 59.12](#) displays the results of the REML fit. The Estimate column contains the estimates of the variance components for Family and Family\*Gender, as well as the estimate of  $\sigma^2$ .

**Figure 59.12** Covariance Parameter Estimates (REML)

| Covariance Parameter<br>Estimates |          |
|-----------------------------------|----------|
| Cov Parm                          | Estimate |
| Family                            | 2.4010   |
| Family*Gender                     | 1.7657   |
| Residual                          | 2.1668   |

The “Fit Statistics” table in [Figure 59.13](#) contains basic information about the REML fit.

**Figure 59.13** Fit Statistics

| Fit Statistics           |      |
|--------------------------|------|
| -2 Res Log Likelihood    | 71.0 |
| AIC (smaller is better)  | 77.0 |
| AICC (smaller is better) | 79.0 |
| BIC (smaller is better)  | 75.2 |

The “Type 3 Tests of Fixed Effects” table in [Figure 59.14](#) contains a significance test for the lone fixed effect, Gender. Note that the associated  $p$ -value is not nearly as significant as in the previous analysis. This illustrates the importance of correctly modeling correlation in your data.

**Figure 59.14** Type 3 Tests of Fixed Effects

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Gender                        | 1         | 3         | 7.95    | 0.0667 |

An additional benefit of the random effects analysis is that it enables you to make inferences about gender that apply to an entire population of families, whereas the inferences about gender from the analysis where Family and Family\*Gender are fixed effects apply only to the particular families in the data set.

PROC MIXED thus offers you the ability to model correlation directly and to make inferences about fixed effects that apply to entire populations of random effects.

## Syntax: MIXED Procedure

The following statements are available in the MIXED procedure:

```

PROC MIXED < options > ;
 BY variables ;
 CLASS variable < (REF= option) > ... < variable < (REF= option) > > < / global-options > ;
 CODE < options > ;
 ID variables ;
 MODEL dependent = < fixed-effects > < / options > ;
 RANDOM random-effects < / options > ;
 REPEATED < repeated-effect > < / options > ;
 PARMS (value-list) ... < / options > ;
 PERFORMANCE < options > ;
 PRIOR < distribution > < / options > ;
 CONTRAST 'label' < fixed-effect values ... >
 < | random-effect values ... >, ... < / options > ;
 ESTIMATE 'label' < fixed-effect values ... >
 < | random-effect values ... > < / options > ;
 LSMEANS fixed-effects < / options > ;
 LSMESTIMATE model-effect lsmestimate-specification < / options > ;
 SLICE model-effect < / options > ;
 STORE < OUT= > item-store-name < / LABEL='label' > ;
 WEIGHT variable ;

```

Items within angle brackets (<>) are optional. The **CONTRAST**, **ESTIMATE**, **LSMEANS**, and **RANDOM** statements can appear multiple times; all other statements can appear only once.

The **PROC MIXED** and **MODEL** statements are required, and the **MODEL** statement must appear after the **CLASS** statement if a **CLASS** statement is included. The **CONTRAST**, **ESTIMATE**, **LSMEANS**, **RANDOM**, and **REPEATED** statements must follow the **MODEL** statement. The **CONTRAST** and **ESTIMATE** statements must also follow any **RANDOM** statements. The **LSMESTIMATE**, **SLICE**, and **STORE** statements are shared with many procedures. Summary descriptions of functionality and syntax for these statements are also given after the **PROC MIXED** statement in alphabetical order, but you can find full documentation on them in Chapter 19, “Shared Concepts and Topics.”

Table 59.1 summarizes the basic functions and important options of each PROC MIXED statement. The syntax of each statement in Table 59.1 is described in the following sections in alphabetical order after the description of the **PROC MIXED** statement.

**Table 59.1** Summary of PROC MIXED Statements

| Statement         | Description           | Options                                                                           |
|-------------------|-----------------------|-----------------------------------------------------------------------------------|
| <b>PROC MIXED</b> | Invokes the procedure | <b>DATA=</b> specifies input data set, <b>METHOD=</b> specifies estimation method |

Table 59.1 *continued*

| Statement   | Description                                                                       | Options                                                                                                                                                                                                                                      |
|-------------|-----------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| BY          | Performs multiple PROC MIXED analyses in one invocation                           | None                                                                                                                                                                                                                                         |
| CLASS       | Declares qualitative variables that create indicator variables in design matrices | None                                                                                                                                                                                                                                         |
| CODE        | Requests that the procedure write SAS DATA step code to a file or catalog entry   | FILE= names the file where the generated code is saved, CATALOG= names the catalog entry where the generated code is saved, IMPUTE imputes predicted values for observations with missing or invalid covariates, RESIDUAL computes residuals |
| ID          | Lists additional variables to be included in predicted values tables              | None                                                                                                                                                                                                                                         |
| MODEL       | Specifies dependent variable and fixed effects, setting up X                      | S requests solution for fixed-effects parameters, DDFM= specifies denominator degrees of freedom method, OUTP= outputs predicted values to a data set, INFLUENCE computes influence diagnostics                                              |
| RANDOM      | Specifies random effects, setting up Z and G                                      | SUBJECT= creates block-diagonality, TYPE= specifies covariance structure, S requests solution for random-effects parameters, G displays estimated G                                                                                          |
| REPEATED    | Sets up R                                                                         | SUBJECT= creates block-diagonality, TYPE= specifies covariance structure, R displays estimated blocks of R, GROUP= enables between-subject heterogeneity, LOCAL adds a diagonal matrix to R                                                  |
| PARMS       | Specifies a grid of initial values for the covariance parameters                  | HOLD= and NOITER hold the covariance parameters or their ratios constant, PARMSDATA= reads the initial values from a SAS data set                                                                                                            |
| PERFORMANCE | Specifies the number of threads to use                                            | NTHREADS=                                                                                                                                                                                                                                    |
| PRIOR       | Performs a sampling-based Bayesian analysis for variance component models         | NSAMPLE= specifies the sample size, SEED= specifies the starting seed                                                                                                                                                                        |
| CONTRAST    | Constructs custom hypothesis tests                                                | E displays the L matrix coefficients                                                                                                                                                                                                         |
| ESTIMATE    | Constructs custom scalar estimates                                                | CL produces confidence limits                                                                                                                                                                                                                |

Table 59.1 *continued*

| Statement   | Description                                                    | Options                                                                                                                                                                                                                                                    |
|-------------|----------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LSMEANS     | Computes least squares means for classification fixed effects  | <b>DIFF</b> computes differences of the least squares means, <b>ADJUST=</b> performs multiple comparisons adjustments, <b>AT</b> changes covariates, <b>OM</b> changes weighting, <b>CL</b> produces confidence limits, <b>SLICE=</b> tests simple effects |
| LSMESTIMATE | Provides custom hypothesis tests among the least squares means | <b>ADJUST=</b> determines the method for multiple comparison adjustment of LS-mean differences, <b>JOINT</b> requests a joint <i>F</i> or chi-square test for the rows of the estimate                                                                     |
| SLICE       | Performs a partitioned analysis of LS-means for an interaction | <b>ADJUST=</b> determines the method for multiple comparison adjustment of LS-mean differences, <b>DIFF</b> requests differences of LS-means                                                                                                               |
| STORE       | Saves the context and results of the analysis                  | <b>LABEL=</b> adds a custom label                                                                                                                                                                                                                          |
| WEIGHT      | Specifies a variable by which to weight <b>R</b>               | None                                                                                                                                                                                                                                                       |

## PROC MIXED Statement

**PROC MIXED** < options > ;

The PROC MIXED statement invokes the MIXED procedure. Table 59.2 summarizes the options available in the PROC MIXED statement. These and other options in the PROC MIXED statement are then described fully in alphabetical order.

Table 59.2 PROC MIXED Statement Options

| Option                  | Description                                                                  |
|-------------------------|------------------------------------------------------------------------------|
| <b>Basic Options</b>    |                                                                              |
| <b>DATA=</b>            | Specifies input data set                                                     |
| <b>METHOD=</b>          | Specifies the estimation method                                              |
| <b>NOPROFILE</b>        | Includes scale parameter in optimization                                     |
| <b>ORDER=</b>           | Determines the sort order of <b>CLASS</b> variables                          |
| <b>Displayed Output</b> |                                                                              |
| <b>ASYCORR</b>          | Displays asymptotic correlation matrix of covariance parameter estimates     |
| <b>ASYCOV</b>           | Displays asymptotic covariance matrix of covariance parameter estimates      |
| <b>CL</b>               | Requests confidence limits for covariance parameter estimates                |
| <b>COVTEST</b>          | Displays asymptotic standard errors and Wald tests for covariance parameters |
| <b>IC</b>               | Displays a table of information criteria                                     |

Table 59.2 *continued*

| Option                       | Description                                                             |
|------------------------------|-------------------------------------------------------------------------|
| ITDETAILS                    | Displays estimates and gradients added to “Iteration History”           |
| LOGNOTE                      | Writes periodic status notes to the log                                 |
| MMEQ                         | Displays mixed model equations                                          |
| MMEQSOL                      | Displays the solution to the mixed model equations                      |
| NOCLPRINT                    | Suppresses “Class Level Information” completely or in parts             |
| NOITPRINT                    | Suppresses “Iteration History” table                                    |
| PLOTS=                       | Produces ODS statistical graphics                                       |
| RATIO                        | Produces ratio of covariance parameter estimates with residual variance |
| <b>Optimization Options</b>  |                                                                         |
| MAXFUNC=                     | Specifies the maximum number of likelihood evaluations                  |
| MAXITER=                     | Specifies the maximum number of iterations                              |
| <b>Computational Options</b> |                                                                         |
| CONVF                        | Requests and tunes the relative function convergence criterion          |
| CONVG                        | Requests and tunes the relative gradient convergence criterion          |
| CONVH                        | Requests and tunes the relative Hessian convergence criterion           |
| DFBW                         | Selects between-within degree of freedom method                         |
| EMPIRICAL                    | Computes empirical (“sandwich”) estimators                              |
| NOBOUND                      | Unbounds covariance parameter estimates                                 |
| RIDGE=                       | Specifies starting value for minimum ridge value                        |
| SCORING=                     | Applies Fisher scoring where applicable                                 |

You can specify the following *options*.

#### **ABSOLUTE**

makes the convergence criterion absolute. By default, it is relative (divided by the current objective function value). See the [CONVF](#), [CONVG](#), and [CONVH](#) options in this section for a description of various convergence criteria.

#### **ALPHA=*number***

requests that confidence limits be constructed for the covariance parameter estimates with confidence level  $1 - \textit{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

#### **ANOVAF**

The ANOVAF option computes *F* tests in models with REPEATED statement and without RANDOM statement by a method similar to that of Brunner, Domhof, and Langer (2002). The method consists of computing special *F* statistics and adjusting their degrees of freedom. The technique is a generalization of the Greenhouse-Geisser adjustment in MANOVA models (Greenhouse and Geisser 1959). For more details, see the section “[F Tests With the ANOVAF Option](#)” on page 4969.

#### **ASYCORR**

produces the asymptotic correlation matrix of the covariance parameter estimates. It is computed from the corresponding asymptotic covariance matrix (see the description of the [ASYCOV](#) option, which follows). The name of the “Asymptotic Correlation” table is AsyCorr.

**ASYCOV**

requests that the asymptotic covariance matrix of the covariance parameters be displayed. By default, this matrix is the observed inverse Fisher information matrix, which equals  $2\mathbf{H}^{-1}$ , where  $\mathbf{H}$  is the Hessian (second derivative) matrix of the objective function. See the section “Covariance Parameter Estimates” on page 4985 for more information about this matrix. When you use the **SCORING=** option and PROC MIXED converges without stopping the scoring algorithm, PROC MIXED uses the expected Hessian matrix to compute the covariance matrix instead of the observed Hessian. The ODS name of the “Asymptotic Covariance” table is AsyCov.

**CL<=WALD>**

requests confidence limits for the covariance parameter estimates. A Satterthwaite approximation is used to construct limits for all parameters that have a lower boundary constraint of zero. These limits take the form

$$\frac{\nu \hat{\sigma}^2}{\chi_{\nu, 1-\alpha/2}^2} \leq \sigma^2 \leq \frac{\nu \hat{\sigma}^2}{\chi_{\nu, \alpha/2}^2}$$

where  $\nu = 2Z^2$ ,  $Z$  is the Wald statistic  $\hat{\sigma}^2/\text{se}(\hat{\sigma}^2)$ , and the denominators are quantiles of the  $\chi^2$ -distribution with  $\nu$  degrees of freedom. See Milliken and Johnson (1992) and Burdick and Graybill (1992) for similar techniques.

For all other parameters, Wald Z-scores and normal quantiles are used to construct the limits. Wald limits are also provided for variance components if you specify the **NOBOUND** option. The optional **=WALD** specification requests Wald limits for all parameters.

The confidence limits are displayed as extra columns in the “Covariance Parameter Estimates” table. The confidence level is  $1 - \alpha = 0.95$  by default; this can be changed with the **ALPHA=** option.

**CONVF<=number>**

requests the relative function convergence criterion with tolerance *number*. The relative function convergence criterion is

$$\frac{|f_k - f_{k-1}|}{|f_k|} \leq \textit{number}$$

where  $f_k$  is the value of the objective function at iteration  $k$ . To prevent the division by  $|f_k|$ , use the **ABSOLUTE** option. The default convergence criterion is **CONVH**, and the default tolerance is 1E-8.

**CONVG <=number>**

requests the relative gradient convergence criterion with tolerance *number*. The relative gradient convergence criterion is

$$\frac{\max_j |g_{jk}|}{|f_k|} \leq \textit{number}$$

where  $f_k$  is the value of the objective function, and  $g_{jk}$  is the  $j$ th element of the gradient (first derivative) of the objective function, both at iteration  $k$ . To prevent division by  $|f_k|$ , use the **ABSOLUTE** option. The default convergence criterion is **CONVH**, and the default tolerance is 1E-8.

**CONVH**<=*number*>

requests the relative Hessian convergence criterion with tolerance *number*. The relative Hessian convergence criterion is

$$\frac{\mathbf{g}_k' \mathbf{H}_k^{-1} \mathbf{g}_k}{|f_k|} \leq \textit{number}$$

where  $f_k$  is the value of the objective function,  $\mathbf{g}_k$  is the gradient (first derivative) of the objective function, and  $\mathbf{H}_k$  is the Hessian (second derivative) of the objective function, all at iteration  $k$ .

If  $\mathbf{H}_k$  is singular, then PROC MIXED uses the following relative criterion:

$$\frac{\mathbf{g}_k' \mathbf{g}_k}{|f_k|} \leq \textit{number}$$

To prevent the division by  $|f_k|$ , use the **ABSOLUTE** option. The default convergence criterion is **CONVH**, and the default tolerance is 1E-8.

**COVTEST**

produces asymptotic standard errors and Wald Z-tests for the covariance parameter estimates.

**DATA**=SAS-*data-set*

names the SAS data set to be used by PROC MIXED. The default is the most recently created data set.

**DFBW**

has the same effect as the **DDFM**=BW option in the **MODEL** statement.

**EMPIRICAL**

computes the estimated variance-covariance matrix of the fixed-effects parameters by using the asymptotically consistent estimator described in Huber (1967); White (1980); Liang and Zeger (1986); Diggle, Liang, and Zeger (1994). This estimator is commonly referred to as the “sandwich” estimator, and it is computed as follows:

$$(\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-1} \left( \sum_{i=1}^S \mathbf{X}_i' \widehat{\mathbf{V}}_i^{-1} \widehat{\boldsymbol{\epsilon}}_i \widehat{\boldsymbol{\epsilon}}_i' \widehat{\mathbf{V}}_i^{-1} \mathbf{X}_i \right) (\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$$

Here,  $\widehat{\boldsymbol{\epsilon}}_i = y_i - \mathbf{X}_i \widehat{\boldsymbol{\beta}}$ ,  $S$  is the number of subjects, and matrices with an  $i$  subscript are those for the  $i$ th subject. You must include the **SUBJECT**= option in either a **RANDOM** or **REPEATED** statement for this option to take effect.

When you specify the **EMPIRICAL** option, PROC MIXED adjusts all standard errors and test statistics involving the fixed-effects parameters. This changes output in the following tables (listed in [Table 59.26](#)): Contrast, CorrB, CovB, Diffs, Estimates, InvCovB, LSMMeans, Slices, SolutionF, Tests1–Tests3. The **OUTP**= and **OUTPM**= data sets are also affected. Finally, the Satterthwaite and Kenward-Roger degrees of freedom methods are not available if you specify the **EMPIRICAL** option.

**IC**

displays a table of various information criteria. The criteria are all in smaller-is-better form, and are described in [Table 59.3](#).

**Table 59.3** Information Criteria

| Criterion | Formula                               | Reference                                              |
|-----------|---------------------------------------|--------------------------------------------------------|
| AIC       | $-2\ell + 2d$                         | Akaike (1974)                                          |
| AICC      | $-2\ell + 2dn^*/(n^* - d - 1)$        | Hurvich and Tsai (1989)<br>Burnham and Anderson (1998) |
| HQIC      | $-2\ell + 2d \log \log n$ for $n > 1$ | Hannan and Quinn (1979)                                |
| BIC       | $-2\ell + d \log n$ for $n > 0$       | Schwarz (1978)                                         |
| CAIC      | $-2\ell + d(\log n + 1)$ for $n > 0$  | Bozdogan (1987)                                        |

Here  $\ell$  denotes the maximum value of the (possibly restricted) log likelihood,  $d$  the dimension of the model, and  $n$  the number of observations. In SAS 6 of SAS/STAT software,  $n$  equals the number of valid observations for maximum likelihood estimation and  $n - p$  for restricted maximum likelihood estimation, where  $p$  equals the rank of  $\mathbf{X}$ . In later versions,  $n$  equals the number of effective subjects as displayed in the “Dimensions” table, unless this value equals 1, in which case  $n$  equals the number of levels of the first random effect you specify in a **RANDOM** statement. If the number of effective subjects equals 1 and you have no **RANDOM** statements, then  $n$  reverts to the SAS 6 values. For AICC (a finite-sample corrected version of AIC),  $n^*$  equals the SAS 6 values of  $n$ , unless this number is less than  $d + 2$ , in which case it equals  $d + 2$ . When  $n \leq 1$ , the value of the HQIC criterion is  $-2\ell$ . When  $n=0$ , the values of the BIC and CAIC criteria are  $-2\ell$  and  $-2\ell + d$ , respectively.

For restricted likelihood estimation,  $d$  equals  $q$ , the effective number of estimated covariance parameters. In SAS 6, when a parameter estimate lies on a boundary constraint, then it is still included in the calculation of  $d$ , but in later versions it is not. The most common example of this behavior is when a variance component is estimated to equal zero. For maximum likelihood estimation,  $d$  equals  $q + p$ . The value of  $d$  is displayed in the “Information Criteria” table as the value ofParms variable; see [Table 59.27](#).

The ODS name of the “Information Criteria” table is InfoCrit.

### INFO

is a default option. The creation of the “Model Information,” “Dimensions,” and “Number of Observations” tables can be suppressed by using the **NOINFO** option.

Note that in SAS 6 this option displays the “Model Information” and “Dimensions” tables.

### ITDETAILS

displays the parameter values at each iteration and enables the writing of notes to the SAS log pertaining to “infinite likelihood” and “singularities” during Newton-Raphson iterations.

### LOGNOTE

writes periodic notes to the log describing the current status of computations. It is designed for use with analyses requiring extensive CPU resources.

### MAXFUNC=*number*

specifies the maximum number of likelihood evaluations in the optimization process. The default is 150.

**MAXITER=*number***

specifies the maximum number of iterations. The default is 50.

**METHOD=REML | ML | MIVQUE0 | TYPE1 | TYPE2 | TYPE3**

specifies the estimation method for the covariance parameters. The REML specification performs residual (restricted) maximum likelihood, and it is the default method. The ML specification performs maximum likelihood, and the MIVQUE0 specification performs minimum variance quadratic unbiased estimation of the covariance parameters.

The METHOD=TYPE $n$  specifications apply only to variance component models with no **SUBJECT=** effects and no **REPEATED** statement. An analysis of variance table is included in the output, and the expected mean squares are used to estimate the variance components (see Chapter 42, “[The GLM Procedure](#),” for further explanation). The resulting method-of-moment variance component estimates are used in subsequent calculations, including standard errors computed from **ESTIMATE** and **LSMEANS** statements. The ODS table names are Type1, Type2, and Type3, respectively.

**MMEQ**

requests that the coefficient matrix and the right-hand side of the mixed model equations be displayed. If  $\hat{\mathbf{G}}$  is nonsingular, the coefficient matrix and the right-hand side have the following form:

$$\begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{y} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

If  $\hat{\mathbf{G}}$  is singular, the coefficient matrix and right-hand side have the following modified form:

$$\begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z}\hat{\mathbf{G}} \\ \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z}\hat{\mathbf{G}} + \mathbf{G} \end{bmatrix} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\tau}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{y} \\ \hat{\mathbf{G}}'\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

See the section “[Estimating Fixed and Random Effects in the Mixed Model](#)” on page 4965 for further information about these equations.

**MMEQSOL**

requests that a solution to the mixed model equations be produced, in addition to the inverted coefficients matrix. If  $\hat{\mathbf{G}}$  is nonsingular, the formula is the same as the preceding description of the **MMEQ** option. If  $\hat{\mathbf{G}}$  is singular,  $\hat{\boldsymbol{\beta}}$  and  $\mathbf{G}\hat{\boldsymbol{\tau}}$  are displayed in addition to the inverse of the modified coefficient matrix.

See the section “[Estimating Fixed and Random Effects in the Mixed Model](#)” on page 4965 for further information about these equations and solution transformation.

**NAMELEN<=*number*>**

specifies the length to which long effect names are shortened. The default and minimum value is 20.

**NOBOUND**

has the same effect as the **NOBOUND** option in the **PARMS** statement.

**NOCLPRINT<=*number*>**

suppresses the display of the “Class Level Information” table if you do not specify *number*. If you do specify *number*, only levels with totals that are less than *number* are listed in the table.

**NOINFO**

suppresses the display of the “Model Information,” “Dimensions,” and “Number of Observations” tables.

**NOITPRINT**

suppresses the display of the “Iteration History” table.

**NOPROFILE**

includes the residual variance as part of the Newton-Raphson iterations. This option applies only to models that have a residual variance parameter. By default, this parameter is profiled out of the likelihood calculations, except when you have specified the **HOLD=** option in the **PARMS** statement.

**ORD**

displays ordinates of the relevant distribution in addition to *p*-values. The ordinate can be viewed as an approximate odds ratio of hypothesis probabilities.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the **CLASS** statement). This option applies to the levels for all classification variables, except when you use the (default) **ORDER=FORMATTED** option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The **ORDER=** option can take the following values:

| Value of <b>ORDER=</b> | Levels Sorted By                                                                                                                       |
|------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>            | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>       | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>            | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>        | Unformatted value                                                                                                                      |

By default, **ORDER=FORMATTED**. For **ORDER=FORMATTED** and **ORDER=INTERNAL**, the sort order is machine-dependent. For more information about sort order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PLOTS** <(global-plot-options) > <=plot-request <(options) >>

**PLOTS** <(global-plot-options) > <= (plot-request<(options)><...plot-request<(options)> >>

requests that the MIXED procedure produce statistical graphics via the Output Delivery System, provided that ODS Graphics is enabled.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc mixed data=heights plots=all;
 class Family Gender;
 model Height = Gender / residual;
 random Family Family*Gender;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

For examples of the basic statistical graphics produced by the MIXED procedure and aspects of their computation and interpretation, see the section “[ODS Graphics](#)” on page 4992.

The *global-plot-options* apply to all relevant plots generated by the MIXED procedure. The *global-plot-options* supported by the MIXED procedure follow.

## Global Plot Options

### OBSNO

uses the data set observation number to identify observations in tooltips, provided that the observation number can be determined. Otherwise, the number displayed in tooltips is the index of the observation as it is used in the analysis within the BY group.

### ONLY

suppresses the default plots. Only the plots specifically requested are produced.

### UNPACKPANEL

### UNPACK

displays each graph separately. (By default, some graphs can appear together in a single panel.)

### MAXPOINTS=NONE | *number*

specifies that plots with elements that require processing more than *number* points be suppressed. The default is MAXPOINTS=5000. No plots are suppressed if you specify MAXPOINTS=NONE.

## Specific Plot Options

The following listing describes the specific plots and their options.

### ALL

requests that all plots appropriate for the particular analysis be produced.

### BOXPLOT <(boxplot-options)>

requests box plots for the effects in your model that consist of classification effects only. Note that these effects can involve more than one classification variable (interaction and nested effects), but they cannot contain any continuous variables. By default, the BOXPLOT request produces box plots based on (conditional) raw residuals for the qualifying effects in the **MODEL**,

**RANDOM**, and **REPEATED** statements. See the discussion of the *boxplot-options* in a later section for information about how to tune your box plot request.

**DISTANCE<(USEINDEX)>**

requests a plot of the likelihood or restricted likelihood distance. When influence diagnostics are requested with set selection according to an effect, the **USEINDEX** option enables you to replace the formatted tick values on the horizontal axis with integer indices of the effect levels in order to reduce the space taken up by the horizontal plot axis.

**INFLUENCEESTPLOT<(options)>**

requests panels of the deletion estimates in an influence analysis, provided that the **INFLUENCE** option is specified in the **MODEL** statement. No plots are produced for fixed-effects parameters associated with singular columns in the **X** matrix or for covariance parameters associated with singularities in the **ASYCOV** matrix. By default, separate panels are produced for the fixed-effects and covariance parameters delete estimates. The **FIXED** and **RANDOM** options enable you to select these specific panels. The **UNPACK** option produces separate plots for each of the parameter estimates. The **USEINDEX** option replaces formatted tick values for the horizontal axis with integer indices.

**INFLUENCESTATPANEL<(options)>**

requests panels of influence statistics. For iterative influence analysis (see the **INFLUENCE** option in the **MODEL** statement), the panel shows the Cook's *D* and CovRatio statistics for fixed-effects and covariance parameters, enabling you to gauge impact on estimates and precision for both types of estimates. In noniterative analysis, only statistics for the fixed effects are plotted. The **UNPACK** option produces separate plots from the elements in the panel. The **USEINDEX** option replaces formatted tick values for the horizontal axis with integer indices.

**RESIDUALPANEL <(residual-plot-options)>**

requests a panel of raw residuals. By default, the conditional residuals are produced. See the discussion of *residual-plot-options* in a later section for information about how to tune this panel.

**STUDENTPANEL <(residual-plot-options)>**

requests a panel of studentized residuals. By default, the conditional residuals are produced. See the discussion of *residual-plot-options* in a later section for information about how to tune this panel.

**PEARSONPANEL <(residual-plot-options)>**

requests a panel of Pearson residuals. By default, the conditional residuals are produced. See the discussion of *residual-plot-options* in a later section for information about how to tune this panel.

**PRESS<(USEINDEX)>**

requests a plot of PRESS residuals or PRESS statistics. These are based on “leave-one-out” or “leave-set-out” prediction of the marginal mean. When influence diagnostics are requested with set selection according to an effect, the **USEINDEX** option enables you to replace the formatted tick values on the horizontal axis with integer indices of the effect levels in order to reduce the space taken up by the horizontal plot axis.

**VCIRYPANEL** < (*residual-plot-options*) >

requests a panel of residual graphics based on the scaled residuals. See the **VCIRY** option in the **MODEL** statement for details about these scaled residuals. Only the **UNPACK** and **BOX** options of the *residual-plot-options* are available for this type of residual panel.

**NONE**

suppresses all plots.

**Residual Plot Options**

The *residual-plot-options* determine both the composition of the panels and the type of residuals being plotted.

**BOX****BOXPLOT**

replaces the inset of summary statistics in the lower-right corner of the panel with a box plot of the residual (the “PROC GLIMMIX look”).

**CONDITIONAL****BLUP**

constructs plots from conditional residuals.

**MARGINAL****NOBLUP**

constructs plots from marginal residuals.

**UNPACK**

produces separate plots from the elements of the panel. The inset statistics are not part of the unpack operation.

**Box Plot Options**

The *boxplot-options* determine whether box plots are produced for residuals or for residuals and observed values, and for which model effects the box plots are constructed. The available *boxplot-options* are as follows.

**CONDITIONAL****BLUP**

constructs box plots from conditional residuals—that is, residuals using the estimated BLUPs of random effects.

**FIXED**

produces box plots for all fixed effects (**MODEL** statement) consisting entirely of classification variables

**GROUP**

produces box plots for all GROUP= effects (**RANDOM** and **REPEATED** statement) consisting entirely of classification variables

**MARGINAL****NOBLUP**

constructs box plots from marginal residuals.

**NPANEL=number**

provides the ability to break a box plot into multiple graphics. If *number* is negative, no balancing of the number of boxes takes place and *number* is the maximum number of boxes per graphic. If *number* is positive, the number of boxes per graphic is balanced. For example, suppose variable A has 125 levels, and consider the following statements:

```
ods graphics on;
proc mixed plots=boxplot (npanel=20);
 class A;
 model y = A;
run;
```

The box balancing results in six plots with 18 boxes each and one plot with 17 boxes. If *number* is zero, and this is the default, all levels of the effect are displayed in a single plot.

**OBSERVED**

adds box plots of the observed data for the selected effects.

**RANDOM**

produces box plots for all random effects (**RANDOM** statement) consisting entirely of classification variables. This does not include effects specified in the **GROUP=** or **SUBJECT=** options of the **RANDOM** statement.

**REPEATED**

produces box plots for the repeated effects (**REPEATED** statement). This does not include effects specified in the **GROUP=** or **SUBJECT=** options of the **REPEATED** statement.

**STUDENT**

constructs box plots from studentized residuals rather than from raw residuals.

**SUBJECT**

produces box plots for all SUBJECT= effects (**RANDOM** and **REPEATED** statement) consisting entirely of classification variables.

**USEINDEX**

uses as the horizontal axis label the index of the effect level rather than the formatted value(s). For classification variables with many levels or model effects that involve multiple classification variables, the formatted values identifying the effect levels can take up too much space as axis tick values, leading to extensive thinning. The **USEINDEX** option replaces tick values constructed from formatted values with the internal level number.

## Multiple Plot Requests

You can list a plot request one or more times with different options. For example, the following statements request a panel of marginal raw residuals, individual plots generated from a panel of the conditional raw residuals, and a panel of marginal studentized residuals:

```
ods graphics on;
proc mixed plots(only)=(
 ResidualPanel(marginal)
 ResidualPanel(unpack conditional)
 StudentPanel(marginal box));
```

The inset of residual statistics is replaced in this last panel by a box plot of the studentized residuals. Similarly, if you specify the **INFLUENCE** option in the **MODEL** statement, then the following statements request statistical graphics of fixed-effects deletion estimates (in a panel), covariance parameter deletion estimates (unpacked in individual plots), and box plots for the **SUBJECT=** and fixed classification effects based on residuals and observed values:

```
ods graphics on / imagefmt=staticmap;
proc mixed plots(only)=(
 InfluenceEstPlot(fixed)
 InfluenceEstPlot(random unpack)
 BoxPlot(observed fixed subject);
```

The **STATICMAP** image format enables tooltips that show, for example, values of influence diagnostics associated with a particular delete estimate.

This concludes the syntax section for the **PLOTS=** option in the **PROC MIXED** statement.

## RATIO

produces the ratio of the covariance parameter estimates to the estimate of the residual variance when the latter exists in the model.

## RIDGE=*number*

specifies the starting value for the minimum ridge value used in the Newton-Raphson algorithm. The default is 0.3125.

## SCORING<=*number*>

requests that Fisher scoring be used in association with the estimation method up to iteration *number*, which is 0 by default. When you use the **SCORING=** option and **PROC MIXED** converges without stopping the scoring algorithm, **PROC MIXED** uses the expected Hessian matrix to compute approximate standard errors for the covariance parameters instead of the observed Hessian. The output from the **ASYCOV** and **ASYCORR** options is similarly adjusted.

## SIGITER

is an alias for the **NOPROFILE** option.

## UPDATE

is an alias for the **LOGNOTE** option.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC MIXED to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MIXED procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Because sorting the data changes the order in which PROC MIXED reads observations, the sort order for the levels of the CLASS variable might be affected if you have specified ORDER=DATA in the PROC MIXED statement. This, in turn, affects specifications in the CONTRAST or ESTIMATE statement.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

**CLASS** *variable* < (REF= *option*) > ... < *variable* < (REF= *option*) > > < / *global-options* > ;

The CLASS statement names the classification variables to be used in the model. Typical classification variables are Treatment, Sex, Race, Group, and Replication. If you use the CLASS statement, it must appear before the MODEL statement.

Classification variables can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variables.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior, you can use the TRUNCATE option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the ORDER= option in the PROC MIXED statement. You can specify the following REF= option to indicate how the levels of an individual classification variable are to be ordered by enclosing it in parentheses after the variable name:

**REF= 'level' | FIRST | LAST**

specifies a level of the classification variable to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC MIXED's singular parameterization. You can specify the *level* of the variable to use as the reference level; specify a value that corresponds to the formatted value of the variable if a format is assigned. Alternatively, you can specify REF=FIRST to designate that the first ordered level serve as the reference, or REF=LAST to designate that the last ordered level serve as the reference. To specify that REF=FIRST or REF=LAST be used for all classification variables, use the **REF= global-option** after the slash (/) in the CLASS statement.

You can specify the following *global-options* in the CLASS statement after a slash (/):

**REF=FIRST | LAST**

specifies a level of all classification variables to be put at the end of the list of levels. This level thus corresponds to the reference level in the usual interpretation of the estimates with PROC MIXED's singular parameterization. Specify REF=FIRST to designate that the first ordered level for each classification variable serve as the reference. Specify REF=LAST to designate that the last ordered level serve as the reference. This option applies to all the variables specified in the CLASS statement. To specify different reference levels for different classification variables, use **REF=** options for individual variables.

**TRUNCATE**

specifies that class levels be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

---

## CODE Statement

**CODE** < options > ;

The CODE statement enables you to write SAS DATA step code for computing predicted values of the fitted model either to a file or to a catalog entry. This code can then be included in a DATA step to score new data.

Table 59.4 summarizes the *options* available in the CODE statement.

**Table 59.4** CODE Statement Options

| Option    | Description                                                                  |
|-----------|------------------------------------------------------------------------------|
| CATALOG=  | Names the catalog entry where the generated code is saved                    |
| DUMMIES   | Retains the dummy variables in the data set                                  |
| ERROR     | Computes the error function                                                  |
| FILE=     | Names the file where the generated code is saved                             |
| FORMAT=   | Specifies the numeric format for the regression coefficients                 |
| GROUP=    | Specifies the group identifier for array names and statement labels          |
| IMPUTE    | Imputes predicted values for observations with missing or invalid covariates |
| LINESIZE= | Specifies the line size of the generated code                                |
| LOOKUP=   | Specifies the algorithm for looking up CLASS levels                          |
| RESIDUAL  | Computes residuals                                                           |

For details about the syntax of the CODE statement, see the section “CODE Statement” on page 390 in Chapter 19, “Shared Concepts and Topics.”

## CONTRAST Statement

```
CONTRAST 'label' <fixed-effect values ... >
 <| random-effect values ... >, ... </options>;
```

The CONTRAST statement provides a mechanism for obtaining custom hypothesis tests. It is patterned after the CONTRAST statement in PROC GLM, although it has been extended to include random effects. This enables you to select an appropriate inference space (McLean, Sanders, and Stroup 1991).

You can test the hypothesis  $L'\phi = 0$ , where  $L' = (K' M')$  and  $\phi' = (\beta' \gamma')$ , in several inference spaces. The inference space corresponds to the choice of  $M$ . When  $M = 0$ , your inferences apply to the entire population from which the random effects are sampled; this is known as the *broad* inference space. When all elements of  $M$  are nonzero, your inferences apply only to the observed levels of the random effects. This is known as the *narrow* inference space, and you can also choose it by specifying all of the random effects as fixed. The GLM procedure uses the narrow inference space. Finally, by setting to zero the portions of  $M$  corresponding to selected main effects and interactions, you can choose *intermediate* inference spaces. The broad inference space is usually the most appropriate, and it is used when you do not specify any random effects in the CONTRAST statement.

The CONTRAST statement has the following arguments:

|                      |                                                                                                                                                                                                                                          |
|----------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <i>label</i>         | identifies the contrast in the table. A label is required for every contrast specified. Labels can be up to 200 characters and must be enclosed in quotes.                                                                               |
| <i>fixed-effect</i>  | identifies an effect that appears in the <b>MODEL</b> statement. The keyword INTERCEPT can be used as an effect when an intercept is fitted in the model. You do not need to include all effects that are in the <b>MODEL</b> statement. |
| <i>random-effect</i> | identifies an effect that appears in the <b>RANDOM</b> statement. The first random effect must follow a vertical bar ( ); however, random effects do not have to be specified.                                                           |
| <i>values</i>        | are constants that are elements of the $L$ matrix associated with the fixed and random effects.                                                                                                                                          |

The rows of  $L'$  are specified in order and are separated by commas. The rows of the  $K'$  component of  $L'$  are specified on the left side of the vertical bars (|). These rows test the fixed effects and are, therefore, checked for estimability. The rows of the  $M'$  component of  $L'$  are specified on the right side of the vertical bars. They test the random effects, and no estimability checking is necessary.

If PROC MIXED finds the fixed-effects portion of the specified contrast to be nonestimable (see the **SINGULAR=** option), then it displays a message in the log.

The following CONTRAST statement reproduces the  $F$  test for the effect A in the split-plot example (see Example 59.1):

```
contrast 'A broad'
 A 1 -1 0 A*B .5 .5 -.5 -.5 0 0 ,
 A 1 0 -1 A*B .5 .5 0 0 -.5 -.5 / df=6;
```

Note that no random effects are specified in the preceding contrast; thus, the inference space is broad. The resulting  $F$  test has two numerator degrees of freedom because  $L'$  has two rows. The denominator degrees of freedom is, by default, the residual degrees of freedom (9), but the `DF=` option changes the denominator degrees of freedom to 6.

The following CONTRAST statement reproduces the  $F$  test for A when Block and A\*Block are considered fixed effects (the narrow inference space):

```
contrast 'A narrow'
 A 1 -1 0
 A*B .5 .5 -.5 -.5 0 0 |
 A*Block .25 .25 .25 .25
 -.25 -.25 -.25 -.25
 0 0 0 0 ,
 A 1 0 -1
 A*B .5 .5 0 0 -.5 -.5 |
 A*Block .25 .25 .25 .25
 0 0 0 0
 -.25 -.25 -.25 -.25 ;
```

The preceding contrast does not contain coefficients for B and Block, because they cancel out in estimated differences between levels of A. Coefficients for B and Block are necessary to estimate the mean of one of the levels of A in the narrow inference space (see [Example 59.1](#)).

If the elements of  $L$  are not specified for an effect that contains a specified effect, then the elements of the specified effect are automatically “filled in” over the levels of the higher-order effect. This feature is designed to preserve estimability for cases where there are complex higher-order effects. The coefficients for the higher-order effect are determined by equitably distributing the coefficients of the lower-level effect, as in the construction of least squares means. In addition, if the intercept is specified, it is distributed over all classification effects that are not contained by any other specified effect. If an effect is not specified and does not contain any specified effects, then all of its coefficients in  $L$  are set to 0. You can override this behavior by specifying coefficients for the higher-order effect.

If too many values are specified for an effect, the extra ones are ignored; if too few are specified, the remaining ones are set to 0. If no random effects are specified, the vertical bar can be omitted; otherwise, it must be present. If a `SUBJECT=` effect is used in the `RANDOM` statement, then the coefficients specified for the effects in the `RANDOM` statement are equitably distributed across the levels of the `SUBJECT` effect. You can use the `E` option to see exactly which  $L$  matrix is used.

The `SUBJECT` and `GROUP` options in the `CONTRAST` statement are useful for the case when a `SUBJECT=` or `GROUP=` variable appears in the `RANDOM` statement, and you want to contrast different subjects or groups. By default, `CONTRAST` statement coefficients on random effects are distributed equally across subjects and groups.

`PROC MIXED` handles missing level combinations of classification variables similarly to the way `PROC GLM` does. Both procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, `PROC MIXED` does not delete missing level combinations for random-effects parameters because linear combinations of the random-effects parameters are always estimable. These conventions can affect the way you specify your `CONTRAST` coefficients.

The CONTRAST statement computes the statistic

$$F = \frac{\begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}' \mathbf{L}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})^{-1}\mathbf{L}' \begin{bmatrix} \hat{\beta} \\ \hat{\gamma} \end{bmatrix}}{r}$$

where  $r = \text{rank}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})$ , and approximates its distribution with an  $F$  distribution. In this expression,  $\hat{\mathbf{C}}$  is an estimate of the generalized inverse of the coefficient matrix in the mixed model equations. See the section “Inference and Test Statistics” on page 4968 for more information about this  $F$  statistic.

The numerator degrees of freedom in the  $F$  approximation are  $r = \text{rank}(\mathbf{L}'\hat{\mathbf{C}}\mathbf{L})$ , and the denominator degrees of freedom are taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the CONTRAST statement. You can change the denominator degrees of freedom by using the **DF=** option.

You can specify the following *options* in the CONTRAST statement after a slash (/).

### CHISQ

requests that chi-square tests be performed in addition to any  $F$  tests. A chi-square statistic equals its corresponding  $F$  statistic times the associate numerator degrees of freedom, and the same degrees of freedom are used to compute the  $p$ -value for the chi-square test. This  $p$ -value is always less than that for the  $F$ -test, as it effectively corresponds to an  $F$  test with infinite denominator degrees of freedom.

### DF=*number*

specifies the denominator degrees of freedom for the  $F$  test. The default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the CONTRAST statement.

### E

requests that the  $\mathbf{L}$  matrix coefficients for the contrast be displayed. The ODS name of the “L Matrix Coefficients” table is Coef.

### GROUP *coeffs*

#### GRP *coeffs*

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, CONTRAST statement coefficients on random effects are distributed equally across groups.

### SINGULAR=*number*

tunes the estimability checking. If  $\mathbf{v}$  is a vector, define  $\text{ABS}(\mathbf{v})$  to be the absolute value of the element of  $\mathbf{v}$  with the largest absolute value. If  $\text{ABS}(\mathbf{K}' - \mathbf{K}'\mathbf{T})$  is greater than  $c*\text{number}$  for any row of  $\mathbf{K}'$  in the contrast, then  $\mathbf{K}$  is declared nonestimable. Here  $\mathbf{T}$  is the Hermite form matrix  $(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'\mathbf{X}$ , and  $c$  is  $\text{ABS}(\mathbf{K}')$  except when it equals 0, and then  $c$  is 1. The value for *number* must be between 0 and 1; the default is 1E-4.

### SUBJECT *coeffs*

#### SUB *coeffs*

sets up random-effect contrasts between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, CONTRAST statement coefficients on random effects are distributed equally across subjects.

## ESTIMATE Statement

```
ESTIMATE 'label' <fixed-effect values ... >
 <| random-effect values ... > </options>;
```

The ESTIMATE statement is exactly like a **CONTRAST** statement, except only one-row **L** matrices are permitted. The actual estimate,  $L'\hat{p}$ , is displayed along with its approximate standard error. An approximate *t* test that  $L'\hat{p} = 0$  is also produced.

PROC MIXED selects the degrees of freedom to match those displayed in the “Tests of Fixed Effects” table for the final effect you list in the ESTIMATE statement. You can modify the degrees of freedom by using the **DF=** option.

If PROC MIXED finds the fixed-effects portion of the specified estimate to be nonestimable, then it displays “Non-est” for the estimate entries.

The following examples of ESTIMATE statements compute the mean of the first level of A in the split-plot example (see [Example 59.1](#)) for various inference spaces:

```
estimate 'A1 mean narrow' intercept 1
 A 1 B .5 .5 A*B .5 .5 |
 block .25 .25 .25 .25
 A*Block .25 .25 .25 .25
 0 0 0 0
 0 0 0 0;

estimate 'A1 mean intermed' intercept 1
 A 1 B .5 .5 A*B .5 .5 |
 Block .25 .25 .25 .25;

estimate 'A1 mean broad' intercept 1
 A 1 B .5 .5 A*B .5 .5;
```

The construction of the **L** vector for an ESTIMATE statement follows the same rules as listed under the **CONTRAST** statement.

Table 59.5 summarizes the options available in the ESTIMATE statement.

**Table 59.5** ESTIMATE Statement Options

| Option    | Description                                                |
|-----------|------------------------------------------------------------|
| ALPHA=    | Specifies the confidence level                             |
| CL        | Constructs <i>t</i> -type confidence limits                |
| DF=       | Specifies the degrees of freedom                           |
| DIVISOR=  | Specifies a value by which to divide all coefficients      |
| E         | Displays the <b>L</b> matrix coefficients                  |
| GROUP     | Sets up random-effect contrasts between different groups   |
| LOWER     | Performs lower-tailed tests                                |
| SINGULAR= | Tunes the estimability checking                            |
| SUBJECT   | Sets up random-effect contrasts between different subjects |
| UPPER     | Performs upper-tailed tests                                |

You can specify the following *options* in the ESTIMATE statement after a slash (/).

**ALPHA=number**

requests that a  $t$ -type confidence interval be constructed with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**CL**

requests that  $t$ -type confidence limits be constructed. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

**DF=number**

specifies the degrees of freedom for the  $t$  test and confidence limits. The default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table and corresponds to the final effect you list in the ESTIMATE statement.

**DIVISOR=number**

specifies a value by which to divide all coefficients so that fractional coefficients can be entered as integer numerators.

**E**

requests that the **L** matrix coefficients be displayed. The ODS name of this “L Matrix Coefficients” table is “Coef.”

**GROUP coeffs****GRP coeffs**

sets up random-effect contrasts between different groups when a **GROUP=** variable appears in the **RANDOM** statement. By default, ESTIMATE statement coefficients on random effects are distributed equally across groups.

**LOWER****LOWERTAILED**

requests that the  $p$ -value for the  $t$  test be based only on values less than the  $t$  statistic. A two-tailed test is the default. A lower-tailed confidence limit is also produced if you specify the **CL** option.

**SINGULAR=number**

tunes the estimability checking as documented for the **SINGULAR=** option in the **CONTRAST** statement.

**SUBJECT coeffs****SUB coeffs**

sets up random-effect contrasts between different subjects when a **SUBJECT=** variable appears in the **RANDOM** statement. By default, ESTIMATE statement coefficients on random effects are distributed equally across subjects. For example, the ESTIMATE statement in the following code from [Example 59.5](#) constructs the difference between the random slopes of the first two batches.

```
proc mixed data=rc;
 class batch;
 model y = month / s;
 random int month / type=un sub=batch s;
 estimate 'slope b1 - slope b2' | month 1 / subject 1 -1;
run;
```

**UPPER****UPPERTAILED**

requests that the  $p$ -value for the  $t$  test be based only on values greater than the  $t$  statistic. A two-tailed test is the default. An upper-tailed confidence limit is also produced if you specify the **CL** option.

**ID Statement**

**ID** *variables* ;

The ID statement specifies which variables from the input data set are to be included in the **OUTP=** and **OUTPM=** data sets from the **MODEL** statement. If you do not specify an ID statement, then all variables are included in these data sets. Otherwise, only the variables you list in the ID statement are included. Specifying an ID statement with no variables prevents any variables from being included in these data sets.

**LSMEANS Statement**

**LSMEANS** *fixed-effects* < / *options* > ;

The LSMEANS statement computes least squares means (LS-means) of fixed effects. As in the GLM procedure, LS-means are *predicted population margins*—that is, they estimate the marginal means over a balanced population. In a sense, LS-means are to unbalanced designs as class and subclass arithmetic means are to balanced designs. The **L** matrix constructed to compute them is the same as the **L** matrix formed in PROC GLM; however, the standard errors are adjusted for the covariance parameters in the model.

Each LS-mean is computed as  $\mathbf{L}\hat{\boldsymbol{\beta}}$ , where **L** is the coefficient matrix associated with the least squares mean and  $\hat{\boldsymbol{\beta}}$  is the estimate of the fixed-effects parameter vector (see the section “Estimating Fixed and Random Effects in the Mixed Model” on page 4965). The approximate standard errors for the LS-mean is computed as the square root of  $\mathbf{L}(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{L}'$ .

LS-means can be computed for any effect in the **MODEL** statement that involves **CLASS** variables. You can specify multiple effects in one LSMEANS statement or in multiple LSMEANS statements, and all LSMEANS statements must appear after the **MODEL** statement. As in the **ESTIMATE** statement, the **L** matrix is tested for estimability, and if this test fails, PROC MIXED displays “Non-est” for the LS-means entries.

Assuming the LS-mean is estimable, PROC MIXED constructs an approximate  $t$  test to test the null hypothesis that the associated population quantity equals zero. By default, the denominator degrees of freedom for this test are the same as those displayed for the effect in the “Tests of Fixed Effects” table (see the section “Default Output” on page 4983).

Table 59.6 summarizes the options available in the LSMEANS statement. All LSMEANS options are subsequently discussed in alphabetical order.

**Table 59.6** Summary of LSMEANS Statement Options

| Option                                          | Description                                    |
|-------------------------------------------------|------------------------------------------------|
| <b>Construction and Computation of LS-Means</b> |                                                |
| <b>AT</b>                                       | Modifies covariate value in computing LS-means |

Table 59.6 continued

| Option                                              | Description                                                                                                                                  |
|-----------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| BYLEVEL                                             | Computes separate margins                                                                                                                    |
| DIFF                                                | Requests differences of LS-means                                                                                                             |
| OM                                                  | Specifies weighting scheme for LS-mean computation                                                                                           |
| SINGULAR=                                           | Tunes estimability checking                                                                                                                  |
| SLICE=                                              | Partitions $F$ tests (simple effects)                                                                                                        |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                                                                              |
| ADJDFE=                                             | Determines whether to compute row-wise denominator degrees of freedom with <code>DDFM=SATTERTHWAITE</code> or <code>DDFM=KENWARDROGER</code> |
| ADJUST=                                             | Determines the method for multiple comparison adjustment of LS-mean differences                                                              |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                                                                             |
| DF=                                                 | Assigns specific value to degrees of freedom for tests and confidence limits                                                                 |
| <b>Statistical Output</b>                           |                                                                                                                                              |
| CL                                                  | Constructs confidence limits for means and or mean differences                                                                               |
| CORR                                                | Displays correlation matrix of LS-means                                                                                                      |
| COV                                                 | Displays covariance matrix of LS-means                                                                                                       |
| E                                                   | Prints the $L$ matrix                                                                                                                        |

You can specify the following *options* in the LSMEANS statement after a slash (/).

**ADJDFE=SOURCE****ADJDFE=ROW**

specifies how denominator degrees of freedom are determined when  $p$ -values and confidence limits are adjusted for multiple comparisons with the `ADJUST=` option. When you do not specify the `ADJDFE=` option, or when you specify `ADJDFE=SOURCE`, the denominator degrees of freedom for multiplicity-adjusted results are the denominator degrees of freedom for the LS-mean effect in the “Type 3 Tests of Fixed Effects” table. When you specify `ADJDFE=ROW`, the denominator degrees of freedom for multiplicity-adjusted results correspond to the degrees of freedom displayed in the DF column of the “Differences of Least Squares Means” table.

The `ADJDFE=ROW` setting is particularly useful if you want multiplicity adjustments to take into account that denominator degrees of freedom are not constant across LS-mean differences. This can be the case, for example, when the `DDFM=SATTERTHWAITE` or `DDFM=KENWARDROGER` degrees-of-freedom method is in effect.

In one-way models with heterogeneous variance, combining certain `ADJUST=` options with the `ADJDFE=ROW` option corresponds to particular methods of performing multiplicity adjustments in the presence of heteroscedasticity. For example, the following statements fit a heteroscedastic one-way model and perform Dunnett’s T3 method (Dunnett 1980), which is based on the studentized maximum modulus (`ADJUST=SMM`):

```

proc mixed;
 class A;
 model y = A / ddfm=satterth;
 repeated / group=A;
 lsmeans A / adjust=smm adjdfe=row;
run;

```

If you combine the ADJDFE=ROW option with ADJUST=SIDAK, the multiplicity adjustment corresponds to the T2 method of Tamhane (1979), while ADJUST=TUKEY corresponds to the method of Games-Howell (Games and Howell 1976). Note that ADJUST=TUKEY gives the exact results for the case of fractional degrees of freedom in the one-way model, but it does not take into account that the degrees of freedom are subject to variability. A more conservative method, such as ADJUST=SMM, might protect the overall error rate better.

Unless the ADJUST= option of the LSMEANS statement is specified, the ADJDFE= option has no effect.

#### ADJUST=BON

#### ADJUST=DUNNETT

#### ADJUST=SCHEFFE

#### ADJUST=SIDAK

#### ADJUST=SIMULATE<(sim-options)>

#### ADJUST=SMM | GT2

#### ADJUST=TUKEY

requests a multiple comparison adjustment for the  $p$ -values and confidence limits for the differences of LS-means. By default, PROC MIXED adjusts all pairwise differences unless you specify ADJUST=DUNNETT, in which case PROC MIXED analyzes all differences with a control level. The ADJUST= option implies the DIFF option.

The BON (Bonferroni) and SIDAK adjustments involve correction factors described in Chapter 42, “The GLM Procedure,” and Chapter 61, “The MULTTEST Procedure;” also see Westfall and Young (1993) and Westfall et al. (1999). When you specify ADJUST=TUKEY and your data are unbalanced, PROC MIXED uses the approximation described in Kramer (1956). Similarly, when you specify ADJUST=DUNNETT and the LS-means are correlated, PROC MIXED uses the factor-analytic covariance approximation described in Hsu (1992). The preceding references also describe the SCHEFFE and SMM adjustments.

The SIMULATE adjustment computes adjusted  $p$ -values and confidence limits from the simulated distribution of the maximum or maximum absolute value of a multivariate  $t$  random vector. All covariance parameters except the residual variance are fixed at their estimated values throughout the simulation, potentially resulting in some underdispersion. The simulation estimates  $q$ , the true  $(1 - \alpha)$  quantile, where  $1 - \alpha$  is the confidence coefficient. The default  $\alpha$  is 0.05, and you can change this value with the ALPHA= option in the LSMEANS statement.

The number of samples is set so that the tail area for the simulated  $q$  is within  $\gamma$  of  $1 - \alpha$  with  $100(1 - \epsilon)\%$  confidence. In equation form,

$$P(|F(\hat{q}) - (1 - \alpha)| \leq \gamma) = 1 - \epsilon$$

where  $\hat{q}$  is the simulated  $q$  and  $F$  is the true distribution function of the maximum; see Edwards and Berry (1987) for details. By default,  $\gamma = 0.005$  and  $\epsilon = 0.01$ , placing the tail area of  $\hat{q}$  within 0.005 of 0.95 with 99% confidence. The `ACC=` and `EPS=` *sim-options* reset  $\gamma$  and  $\epsilon$ , respectively; the `NSAMP=` *sim-option* sets the sample size directly; and the `SEED=` *sim-option* specifies an integer used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is generated from reading the time of day from the computer clock. For additional descriptions of these and other simulation options, see the section “[LSMEANS Statement](#)” on page 3293 in Chapter 42, “[The GLM Procedure](#).”

**ALPHA=number**

requests that a  $t$ -type confidence interval be constructed for each of the LS-means with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**AT variable = value****AT (variable-list) = (value-list)****AT MEANS**

enables you to modify the values of the covariates used in computing LS-means. By default, all covariate effects are set equal to their mean values for computation of standard LS-means. The AT option enables you to assign arbitrary values to the covariates. Additional columns in the output table indicate the values of the covariates.

If there is an effect containing two or more covariates, the AT option sets the effect equal to the product of the individual means rather than the mean of the product (as with standard LS-means calculations). The AT MEANS option sets covariates equal to their mean values (as with standard LS-means) and incorporates this adjustment to crossproducts of covariates.

As an example, consider the following invocation of PROC MIXED:

```
proc mixed;
 class A;
 model Y = A X1 X2 X1*X2;
 lsmeans A;
 lsmeans A / at means;
 lsmeans A / at X1=1.2;
 lsmeans A / at (X1 X2)=(1.2 0.3);
run;
```

For the first two LSMEANS statements, the LS-means coefficient for X1 is  $\bar{x}_1$  (the mean of X1) and for X2 is  $\bar{x}_2$  (the mean of X2). However, for the first LSMEANS statement, the coefficient for X1\*X2 is  $\bar{x}_1\bar{x}_2$ , but for the second LSMEANS statement, the coefficient is  $\bar{x}_1 \cdot \bar{x}_2$ . The third LSMEANS statement sets the coefficient for X1 equal to 1.2 and leaves it at  $\bar{x}_2$  for X2, and the final LSMEANS statement sets these values to 1.2 and 0.3, respectively.

If a WEIGHT variable is present, it is used in processing AT variables. Also, observations with missing dependent variables are included in computing the covariate means, unless these observations form a missing cell and the `FULLX` option in the `MODEL` statement is not in effect. You can use the `E` option in conjunction with the AT option to check that the modified LS-means coefficients are the ones you want.

The AT option is disabled if you specify the `BYLEVEL` option.

**BYLEVEL**

requests PROC MIXED to process the OM data set by each level of the LS-mean effect (LSMEANS effect) in question. For more details, see the **OM** option later in this section.

**CL**

requests that *t*-type confidence limits be constructed for each of the LS-means. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

**CORR**

displays the estimated correlation matrix of the least squares means as part of the “Least Squares Means” table.

**COV**

displays the estimated covariance matrix of the least squares means as part of the “Least Squares Means” table.

**DF=number**

specifies the degrees of freedom for the *t* test and confidence limits. The default is the denominator degrees of freedom taken from the “Tests of Fixed Effects” table corresponding to the LS-means effect unless the **DDFM=SATTERTHWAITE** or **DDFM=KENWARDROGER** option is in effect in the **MODEL** statement. For these **DDFM=** methods, degrees of freedom are determined separately for each test; see the **DDFM=** option for more information.

**DIFF<=difftype>****PDIFF<=difftype>**

requests that differences of the LS-means be displayed. The optional *difftype* specifies which differences to produce, with possible values being **ALL**, **CONTROL**, **CONTROLL**, and **CONTROLU**. The *difftype* **ALL** requests all pairwise differences, and it is the default. The *difftype* **CONTROL** requests the differences with a control, which, by default, is the first level of each of the specified LSMEANS effects.

To specify which levels of the effects are the controls, list the quoted formatted values in parentheses after the keyword **CONTROL**. For example, if the effects **A**, **B**, and **C** are classification variables, each having two levels, 1 and 2, the following LSMEANS statement specifies the (1,2) level of **A\*B** and the (2,1) level of **B\*C** as controls:

```
lsmeans A*B B*C / diff=control('1' '2' '2' '1');
```

For multiple effects, the results depend upon the order of the list, and so you should check the output to make sure that the controls are correct.

Two-tailed tests and confidence limits are associated with the **CONTROL** *difftype*. For one-tailed results, use either the **CONTROLL** or **CONTROLU** *difftype*. The **CONTROLL** *difftype* tests whether the noncontrol levels are significantly smaller than the control; the upper confidence limits for the control minus the noncontrol levels are considered to be infinity and are displayed as missing. Conversely, the **CONTROLU** *difftype* tests whether the noncontrol levels are significantly larger than the control; the upper confidence limits for the noncontrol levels minus the control are considered to be infinity and are displayed as missing.

If you want to perform multiple comparison adjustments on the differences of LS-means, you must specify the **ADJUST=** option.

The differences of the LS-means are displayed in a table titled “Differences of Least Squares Means.” The ODS table name is `Diff`s.

**E**

requests that the **L** matrix coefficients for all LSMEANS effects be displayed. The ODS name of this “L Matrix Coefficients” table is `Coef`.

**OM**<=*OM-data-set*>

**OBSMARGINS**<=*OM-data-set*>

specifies a potentially different weighting scheme for the computation of LS-means coefficients. The standard LS-means have equal coefficients across classification effects; however, the **OM** option changes these coefficients to be proportional to those found in *OM-data-set*. This adjustment is reasonable when you want your inferences to apply to a population that is not necessarily balanced but has the margins observed in *OM-data-set*.

By default, *OM-data-set* is the same as the analysis data set. You can optionally specify another data set that describes the population for which you want to make inferences. This data set must contain all model variables except for the dependent variable (which is ignored if it is present). In addition, the levels of all **CLASS** variables must be the same as those occurring in the analysis data set. Specifying an *OM-data-set* enables you to construct arbitrarily weighted LS-means.

In computing the observed margins, PROC MIXED uses all observations for which there are no missing or invalid independent variables, including those for which there are missing dependent variables. Also, if *OM-data-set* has a **WEIGHT** variable, PROC MIXED uses weighted margins to construct the LS-means coefficients. If *OM-data-set* is balanced, the LS-means are unchanged by the **OM** option.

The **BYLEVEL** option modifies the observed-margins LS-means. Instead of computing the margins across all of the *OM-data-set*, PROC MIXED computes separate margins for each level of the LSMEANS effect in question. In this case the resulting LS-means are actually equal to raw means for fixed-effects models and certain balanced random-effects models, but their estimated standard errors account for the covariance structure that you have specified. If the **AT** option is specified, the **BYLEVEL** option disables it.

You can use the **E** option in conjunction with either the **OM** or **BYLEVEL** option to check that the modified LS-means coefficients are the ones you want. It is possible that the modified LS-means are not estimable when the standard ones are, or vice versa. Nonestimable LS-means are noted as “Non-est” in the output.

**PDIF**

is the same as the **DIFF** option.

**SINGULAR**=*number*

tunes the estimability checking as documented for the **SINGULAR**= option in the **CONTRAST** statement.

**SLICE**= *fixed-effect*

**SLICE**= (*fixed-effects*)

specifies effects by which to partition interaction LSMEANS effects. This can produce what are known as tests of simple effects (Winer 1971). For example, suppose that **A\*B** is significant, and you want to test the effect of **A** for each level of **B**. The appropriate LSMEANS statement is as follows:

```
lsmeans A*B / slice=B;
```

This code tests for the simple main effects of A for B, which are calculated by extracting the appropriate rows from the coefficient matrix for the A\*B LS-means and by using them to form an  $F$  test. See the section “[Inference and Test Statistics](#)” for more information about this  $F$  test.

The SLICE option produces a table titled “Tests of Effect Slices.” The ODS table name is Slices.

---

## LSMESTIMATE Statement

```
LSMESTIMATE model-effect <'label'> values <divisor=n>
 < , ... <'label'> values <divisor=n> >
 </ options > ;
```

The LSMESTIMATE statement provides a mechanism for obtaining custom hypothesis tests among least squares means.

Table 59.7 summarizes the options available in the LSMESTIMATE statement.

**Table 59.7** LSMESTIMATE Statement Options

| Option                                              | Description                                                                         |
|-----------------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Construction and Computation of LS-Means</b>     |                                                                                     |
| AT                                                  | Modifies covariate values in computing LS-means                                     |
| BYLEVEL                                             | Computes separate margins                                                           |
| DIVISOR=                                            | Specifies a list of values to divide the coefficients                               |
| OM=                                                 | Specifies the weighting scheme for LS-means computation as determined by a data set |
| SINGULAR=                                           | Tunes estimability checking                                                         |
| <b>Degrees of Freedom and <math>p</math>-values</b> |                                                                                     |
| ADJUST=                                             | Determines the method for multiple-comparison adjustment of LS-means differences    |
| ALPHA= $\alpha$                                     | Determines the confidence level ( $1 - \alpha$ )                                    |
| LOWER                                               | Performs one-sided, lower-tailed inference                                          |
| STEPDOWN                                            | Adjusts multiple-comparison $p$ -values further in a step-down fashion              |
| TESTVALUE=                                          | Specifies values under the null hypothesis for tests                                |
| UPPER                                               | Performs one-sided, upper-tailed inference                                          |

---

Table 59.7 continued

| Option                    | Description                                                                            |
|---------------------------|----------------------------------------------------------------------------------------|
| <b>Statistical Output</b> |                                                                                        |
| CL                        | Constructs confidence limits for means and mean differences                            |
| CORR                      | Displays the correlation matrix of LS-means                                            |
| COV                       | Displays the covariance matrix of LS-means                                             |
| E                         | Prints the <b>L</b> matrix                                                             |
| ELSM                      | Prints the <b>K</b> matrix                                                             |
| JOINT                     | Produces a joint <i>F</i> or chi-square test for the LS-means and LS-means differences |
| SEED=                     | Specifies the seed for computations that depend on random numbers                      |

For details about the syntax of the LSMESTIMATE statement, see the section “LSMESTIMATE Statement” on page 470 in Chapter 19, “Shared Concepts and Topics.”

## MODEL Statement

**MODEL** *dependent* = < fixed-effects > < / options > ;

The MODEL statement names a single dependent variable and the fixed effects, which determine the **X** matrix of the mixed model (see the section “Parameterization of Mixed Models” on page 4971 for details). The specification of effects is the same as in the GLM procedure; however, unlike PROC GLM, you do not specify random effects in the MODEL statement. The MODEL statement is required.

An intercept is included in the fixed-effects model by default. If no fixed effects are specified, only this intercept term is fit. The intercept can be removed by using the NOINT option.

Table 59.8 summarizes the options available in the MODEL statement. These are subsequently discussed in detail in alphabetical order.

Table 59.8 Summary of MODEL Statement Options

| Option                          | Description                                                         |
|---------------------------------|---------------------------------------------------------------------|
| <b>Model Building</b>           |                                                                     |
| NOINT                           | Excludes fixed-effect intercept from model                          |
| <b>Statistical Computations</b> |                                                                     |
| ALPHA= $\alpha$                 | Determines the confidence level $(1 - \alpha)$ for fixed effects    |
| ALPHAP= $\alpha$                | Determines the confidence level $(1 - \alpha)$ for predicted values |
| CHISQ                           | Requests chi-square tests                                           |
| DDF=                            | Specifies denominator degrees of freedom (list)                     |
| DDFM=                           | Specifies the method for computing denominator degrees of freedom   |
| HTYPE=                          | Selects the type of hypothesis test                                 |
| INFLUENCE                       | Requests influence and case-deletion diagnostics                    |

Table 59.8 *continued*

| Option                        | Description                                                                    |
|-------------------------------|--------------------------------------------------------------------------------|
| NOTESET                       | Suppresses hypothesis tests for the fixed effects                              |
| OUTP=                         | Specifies output data set for predicted values and related quantities          |
| OUTPM=                        | Specifies output data set for predicted means and related quantities           |
| RESIDUAL                      | Adds Pearson-type and studentized residuals to output data sets                |
| VCIRY                         | Adds scaled marginal residual to output data sets                              |
| <b>Statistical Output</b>     |                                                                                |
| CL                            | Displays confidence limits for fixed-effects parameter estimates               |
| CORRB                         | Displays correlation matrix of fixed-effects parameter estimates               |
| COVB                          | Displays covariance matrix of fixed-effects parameter estimates                |
| COVBI                         | Displays inverse covariance matrix of fixed-effects parameter estimates        |
| E, E1, E2, E3                 | Displays <b>L</b> matrix coefficients                                          |
| INTERCEPT                     | Adds a row for the intercept to test tables                                    |

| SINGRES=                      | Tunes singularity criterion for residual variance                              |
| SINGULAR=                     | Tunes the sensitivity in sweeping                                              |
| ZETA=                         | Tunes the sensitivity in forming Type 3 functions                              |

You can specify the following *options* in the MODEL statement after a slash (/).

**ALPHA=number**

requests that a *t*-type confidence interval be constructed for each of the fixed-effects parameters with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**ALPHAP=number**

requests that a *t*-type confidence interval be constructed for the predicted values with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**CHISQ**

requests that chi-square tests be performed for all specified effects in addition to the *F* tests. Type 3 tests are the default; you can produce the Type 1 and Type 2 tests by using the **HTYPE=** option.

**CL**

requests that *t*-type confidence limits be constructed for each of the fixed-effects parameter estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

**CONTAIN**

has the same effect as the **DDFM=CONTAIN** option.

**CORRB**

produces the approximate correlation matrix of the fixed-effects parameter estimates. The ODS name of this table is CorrB.

**COVB**

produces the approximate variance-covariance matrix of the fixed-effects parameter estimates  $\hat{\beta}$ . By default, this matrix equals  $(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$  and results from sweeping  $(\mathbf{X} \ \mathbf{y})'\hat{\mathbf{V}}^{-1}(\mathbf{X} \ \mathbf{y})$  on all but its last pivot and removing the  $y$  border. The **EMPIRICAL** option in the **PROC MIXED** statement changes this matrix into “empirical sandwich” form. The ODS name of this table is CovB. If the degrees-of-freedom method of Kenward and Roger (1997) is in effect (**DDFM=KENWARDROGER**), the COVB matrix changes because the method entails an adjustment of the variance-covariance matrix of the fixed effects by the method proposed by Prasad and Rao (1990); Harville and Jeske (1992). See also Kackar and Harville (1984).

**COVBI**

produces the inverse of the approximate variance-covariance matrix of the fixed-effects parameter estimates. The ODS name of this table is InvCovB.

**DDF=***value-list*

enables you to specify your own denominator degrees of freedom for the fixed effects. The *value-list* specification is a list of numbers or missing values (.) separated by commas. The degrees of freedom should be listed in the order in which the effects appear in the “Tests of Fixed Effects” table. If you want to retain the default degrees of freedom for a particular effect, use a missing value for its location in the list. For example, the following statement assigns 3 denominator degrees of freedom to A and 4.7 to A\*B, while those for B remain the same:

```
model Y = A B A*B / ddf=3, ., 4.7;
```

If you specify **DDFM=SATTERTHWAITE** or **DDFM=KENWARDROGER**, the DDF= option has no effect.

**DDFM=****DDFM=CONTAIN****DDFM=BETWITHIN****DDFM=RESIDUAL****DDFM=SATTERTHWAITE****DDFM=KENWARDROGER<(FIRSTORDER)>****DDFM=KENWARDROGER<(LINEAR)>**

specifies the method for computing the denominator degrees of freedom for the tests of fixed effects resulting from the **MODEL**, **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements.

Table 59.9 lists syntax aliases for the degrees-of-freedom methods.

**Table 59.9** Aliases for DDFM= Option

| DDFM= Option | Alias |
|--------------|-------|
| BETWITHIN    | BW    |
| CONTAIN      | CON   |

Table 59.9 *continued*

| DDFM= Option  | Alias         |
|---------------|---------------|
| KENWARDROGER  | KENROG, KR    |
| RESIDUAL      | RES           |
| SATTERTHWAITE | SATTERTH, SAT |

The DDFM=CONTAIN option invokes the *containment method* to compute denominator degrees of freedom, and it is the default when you specify a **RANDOM** statement. The containment method is carried out as follows: Denote the fixed effect in question **A**, and search the **RANDOM** effect list for the effects that *syntactically* contain **A**. For example, the random effect **B(A)** contains **A**, but the random effect **C** does not, even if it has the same levels as **B(A)**.

Among the random effects that contain **A**, compute their rank contribution to the  $(\mathbf{X} \mathbf{Z})$  matrix. The DDF assigned to **A** is the smallest of these rank contributions. If no effects are found, the DDF for **A** is set equal to the residual degrees of freedom,  $N - \text{rank}(\mathbf{X} \mathbf{Z})$ . This choice of DDF matches the tests performed for balanced split-plot designs and should be adequate for moderately unbalanced designs.

**CAUTION:** If you have a **Z** matrix with a large number of columns, the overall memory requirements and the computing time after convergence can be substantial for the containment method. If it is too large, you might want to use the DDFM=BETWITHIN option.

The DDFM=BETWITHIN option is the default for **REPEATED** statement specifications (with no **RANDOM** statements). It is computed by dividing the residual degrees of freedom into between-subject and within-subject portions. PROC MIXED then checks whether a fixed effect changes within any subject. If so, it assigns within-subject degrees of freedom to the effect; otherwise, it assigns the between-subject degrees of freedom to the effect (see Schluchter and Elashoff 1990). If there are multiple within-subject effects containing classification variables, the within-subject degrees of freedom are partitioned into components corresponding to the subject-by-effect interactions.

One exception to the preceding method is the case where you have specified no **RANDOM** statements and a **REPEATED** statement with the **TYPE=UN** option. In this case, all effects are assigned the between-subject degrees of freedom to provide for better small-sample approximations to the relevant sampling distributions. DDFM=KENWARDROGER might be a better option to try for this case.

The DDFM=RESIDUAL option performs all tests by using the residual degrees of freedom,  $n - \text{rank}(\mathbf{X})$ , where  $n$  is the number of observations.

The DDFM=SATTERTHWAITE option performs a general Satterthwaite approximation for the denominator degrees of freedom, computed as follows. Suppose  $\boldsymbol{\theta}$  is the vector of unknown parameters in **V**, and suppose  $\mathbf{C} = (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}$ , where  $^{-}$  denotes a generalized inverse. Let  $\hat{\mathbf{C}}$  and  $\hat{\boldsymbol{\theta}}$  be the corresponding estimates.

Consider the one-dimensional case, and consider  $\ell$  to be a vector defining an estimable linear combination of  $\boldsymbol{\beta}$ . The Satterthwaite degrees of freedom for the  $t$  statistic

$$t = \frac{\ell \hat{\boldsymbol{\beta}}}{\sqrt{\ell \hat{\mathbf{C}} \ell'}}$$

is computed as

$$v = \frac{2(\ell \hat{\mathbf{C}} \ell')^2}{\mathbf{g}' \mathbf{A} \mathbf{g}}$$

where  $\mathbf{g}$  is the gradient of  $\ell\mathbf{C}\ell'$  with respect to  $\boldsymbol{\theta}$ , evaluated at  $\widehat{\boldsymbol{\theta}}$ , and  $\mathbf{A}$  is the asymptotic variance-covariance matrix of  $\widehat{\boldsymbol{\theta}}$  obtained from the second derivative matrix of the likelihood equations.

For the multidimensional case, let  $\mathbf{L}$  be an estimable contrast matrix and denote the rank of  $\mathbf{L}\widehat{\mathbf{C}}\mathbf{L}'$  as  $q > 1$ . The Satterthwaite denominator degrees of freedom for the  $F$  statistic

$$F = \frac{\widehat{\boldsymbol{\beta}}'\mathbf{L}'(\mathbf{L}\widehat{\mathbf{C}}\mathbf{L}')^{-1}\mathbf{L}\widehat{\boldsymbol{\beta}}}{q}$$

are computed by first performing the spectral decomposition  $\mathbf{L}\widehat{\mathbf{C}}\mathbf{L}' = \mathbf{P}'\mathbf{D}\mathbf{P}$ , where  $\mathbf{P}$  is an orthogonal matrix of eigenvectors and  $\mathbf{D}$  is a diagonal matrix of eigenvalues, both of dimension  $q \times q$ . Define  $\ell_m$  to be the  $m$ th row of  $\mathbf{P}\mathbf{L}$ , and let

$$v_m = \frac{2(D_m)^2}{\mathbf{g}_m'\mathbf{A}\mathbf{g}_m}$$

where  $D_m$  is the  $m$ th diagonal element of  $\mathbf{D}$  and  $\mathbf{g}_m$  is the gradient of  $\ell_m\mathbf{C}\ell'_m$  with respect to  $\boldsymbol{\theta}$ , evaluated at  $\widehat{\boldsymbol{\theta}}$ . Then let

$$E = \sum_{m=1}^q \frac{v_m}{v_m - 2} I(v_m > 2)$$

where the indicator function eliminates terms for which  $v_m \leq 2$ . The degrees of freedom for  $F$  are then computed as

$$v = \frac{2E}{E - q}$$

provided  $E > q$ ; otherwise  $v$  is set to zero.

This method is a generalization of the techniques described in Giesbrecht and Burns (1985); McLean and Sanders (1988); Fai and Cornelius (1996). The method can also include estimated random effects. In this case, append  $\widehat{\boldsymbol{\gamma}}$  to  $\widehat{\boldsymbol{\beta}}$  and change  $\widehat{\mathbf{C}}$  to be the inverse of the coefficient matrix in the mixed model equations. The calculations require extra memory to hold  $c$  matrices that are the size of the mixed model equations, where  $c$  is the number of covariance parameters. In the notation of Table 59.29, this is approximately  $8q(p + g)(p + g)/2$  bytes. Extra computing time is also required to process these matrices. The Satterthwaite method implemented here is intended to produce an accurate  $F$  approximation; however, the results can differ from those produced by PROC GLM. Also, the small sample properties of this approximation have not been extensively investigated for the various models available with PROC MIXED.

The DDFM=KENWARDROGER option performs the degrees of freedom calculations detailed by Kenward and Roger (1997). This approximation involves inflating the estimated variance-covariance matrix of the fixed and random effects by the method proposed by Prasad and Rao (1990) and Harville and Jeske (1992), see also Kackar and Harville (1984). Satterthwaite-type degrees of freedom are then computed based on this adjustment. By default, the observed information matrix of the covariance parameter estimates is used in the calculations. For covariance structures that have nonzero second derivatives with respect to the covariance parameters, the Kenward-Roger covariance matrix adjustment includes a second-order term. This term can result in standard error shrinkage. Also, the resulting adjusted covariance matrix can then be indefinite and is not invariant under reparameterization. The FIRSTORDER or LINEAR suboption of the DDFM=KENWARDROGER option

eliminates the second derivatives from the calculation of the covariance matrix adjustment. The `LINEAR` suboption is an alias for `FIRSTORDER`. For the case of scalar estimable functions, the resulting estimator is referred to as the Prasad-Rao estimator  $\tilde{m}^{\circledast}$  in Harville and Jeske (1992). The following are examples of covariance structures that generally lead to nonzero second derivatives: `TYPE=ANTE(1)`, `TYPE=AR(1)`, `TYPE=ARH(1)`, `TYPE=ARMA(1,1)`, `TYPE=CSH`, `TYPE=FA`, `TYPE=FA0(q)`, `TYPE=TOEPH`, `TYPE=UNR`, and all `TYPE=SP()` structures.

When the asymptotic variance matrix of the covariance parameters is found to be singular, a generalized inverse is used. Covariance parameters with zero variance then do not contribute to the degrees-of-freedom adjustment for `DDFM=SATTERTHWAITE` and `DDFM=KENWARDROGER`, and a message is written to the log.

This method changes output in the following tables (listed in [Table 59.26](#)): `Contrast`, `CorrB`, `CovB`, `DiffS`, `Estimates`, `InvCovB`, `LSMeans`, `Slices`, `SolutionF`, `SolutionR`, `Tests1–Tests3`. The `OUTP=` and `OUTPM=` data sets are also affected.

**E**

requests that Type 1, Type 2, and Type 3 `L` matrix coefficients be displayed for all specified effects. The ODS name of the table is `Coef`.

**E1**

requests that Type 1 `L` matrix coefficients be displayed for all specified effects. The ODS name of the table is `Coef`.

**E2**

requests that Type 2 `L` matrix coefficients be displayed for all specified effects. The ODS name of the table is `Coef`.

**E3**

requests that Type 3 `L` matrix coefficients be displayed for all specified effects. The ODS name of the table is `Coef`.

**FULLX**

requests that columns of the `X` matrix that consist entirely of zeros not be eliminated from `X`; otherwise, they are eliminated by default. For a column corresponding to a missing cell to be added to `X`, its particular levels must be present in at least one observation in the analysis data set along with a missing dependent variable. The use of the `FULLX` option can affect coefficient specifications in the `CONTRAST` and `ESTIMATE` statements, as well as covariate coefficients from `LSMEANS` statements specified with the `AT MEANS` option.

**HTYPE=value-list**

indicates the type of hypothesis test to perform on the fixed effects. Valid entries for *values* in the list are 1, 2, and 3; the default value is 3. You can specify several types by separating the values with a comma or a space. The ODS table names are “Tests1” for the Type 1 tests, “Tests2” for the Type 2 tests, and “Tests3” for the Type 3 tests.

**INFLUENCE<(influence-options)>**

specifies that influence and case deletion diagnostics are to be computed.

The `INFLUENCE` option computes influence diagnostics by noniterative or iterative methods. The noniterative diagnostics rely on recomputation formulas under the assumption that covariance parameters or their ratios remain fixed. With the possible exception of a profiled residual variance, no

covariance parameters are updated. This is the default behavior because of its computational efficiency. However, the impact of an observation on the overall analysis can be underestimated if its effect on covariance parameters is not assessed. Toward this end, iterative methods can be applied to gauge the overall impact of observations and to obtain influence diagnostics for the covariance parameter estimates.

If you specify the INFLUENCE option without further suboptions, PROC MIXED computes single-case deletion diagnostics and influence statistics for each observation in the data set by updating estimates for the fixed-effects parameter estimates, and also the residual variance, if it is profiled. The **EFFECT=**, **SELECT=**, **ITER=**, **SIZE=**, and **KEEP=** suboptions provide additional flexibility in the computation and reporting of influence statistics. Table 59.10 briefly describes important suboptions and their effect on the influence analysis.

**Table 59.10** Summary of INFLUENCE Default and Suboptions

| Description                                                                                                                                                    | Suboption                         |
|----------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------------------------------|
| Compute influence diagnostics for individual observations                                                                                                      | Default                           |
| Measure influence of sets of observations chosen according to a classification variable or effect                                                              | <b>EFFECT=</b>                    |
| Remove pairs of observations and report the results sorted by degree of influence                                                                              | <b>SIZE=2</b>                     |
| Remove triples, quadruples of observations, etc.                                                                                                               | <b>SIZE=</b>                      |
| Allow selection of individual observations, observations sharing specific levels of effects, and construction of tuples from specified subsets of observations | <b>SELECT=</b>                    |
| Update fixed effects and covariance parameters by refitting the mixed model, adding up to $n$ iterations                                                       | <b>ITER=<math>n &gt; 0</math></b> |
| Compute influence diagnostics for the covariance parameters                                                                                                    | <b>ITER=<math>n &gt; 0</math></b> |
| Update only fixed effects and the residual variance, if it is profiled                                                                                         | <b>ITER=0</b>                     |
| Add the reduced-data estimates to the data set created with ODS OUTPUT                                                                                         | <b>ESTIMATES</b>                  |

The modifiers and their default values are discussed in the following paragraphs. The set of computed influence diagnostics varies with the suboptions. The most extensive set of influence diagnostics is obtained when **ITER= $n$**  with  $n > 0$ .

You can produce statistical graphics of influence diagnostics when ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the MIXED procedure, see the section “ODS Graphics” on page 4992.

You can specify the following *influence-options* in parentheses:

**EFFECT=***effect*

specifies an effect according to which observations are grouped. Observations sharing the same level of the *effect* are removed from the analysis as a group. The *effect* must contain only classification variables, but they need not be contained in the model.

Removing observations can change the rank of the  $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$  matrix. This is particularly likely to happen when multiple observations are eliminated from the analysis. If the rank of the estimated variance-covariance matrix of  $\hat{\boldsymbol{\beta}}$  changes or its singularity pattern is altered, no influence diagnostics are computed.

## ESTIMATES

### EST

specifies that the updated parameter estimates should be written to the ODS output data set. The values are not displayed in the “Influence” table, but if you use ODS OUTPUT to create a data set from the listing, the estimates are added to the data set. If `ITER=0`, only the fixed-effects estimates are saved. In iterative influence analyses, fixed-effects and covariance parameters are stored. The  $p$  fixed-effects parameter estimates are named `Parm1–Parm $p$` , and the  $q$  covariance parameter estimates are named `CovP1–CovP $q$` . The order corresponds to that in the “Solution for Fixed Effects” and “Covariance Parameter Estimates” tables. If parameter updates fail—for example, because of a loss of rank or a nonpositive definite Hessian—missing values are reported.

### ITER= $n$

controls the maximum number of additional iterations PROC MIXED performs to update the fixed-effects and covariance parameter estimates following data point removal. If you specify  $n > 0$ , then statistics such as DFFITS, MDFFITS, and the likelihood distances measure the impact of observation(s) on all aspects of the analysis. Typically, the influence will grow compared to values at `ITER=0`. In models without `RANDOM` or `REPEATED` effects, the `ITER=` option has no effect.

This documentation refers to analyses when  $n > 0$  simply as iterative influence analysis, even if final covariance parameter estimates can be updated in a single step (for example, when `METHOD=MIVQUE0` or `METHOD=TYPE3`). This nomenclature reflects the fact that only if  $n > 0$  are all model parameters updated, which can require additional iterations. If  $n > 0$  and `METHOD=REML` (default) or `METHOD=ML`, the procedure updates fixed effects *and* variance-covariance parameters after removing the selected observations with additional Newton-Raphson iterations, starting from the converged estimates for the entire data. The process stops for each observation or set of observations if the convergence criterion is satisfied or the number of further iterations exceeds  $n$ . If  $n > 0$  and `METHOD=TYPE1`, `TYPE2`, or `TYPE3`, ANOVA estimates of the covariance parameters are recomputed in a single step.

Compared to noniterative updates, the computations are more involved. In particular for large data sets or a large number of random effects (or both), iterative updates require considerably more resources. A one-step (`ITER=1`) or two-step update might be a good compromise. The output includes the number of iterations performed, which is less than  $n$  if the iteration converges. If the process does not converge in  $n$  iterations, you should be careful in interpreting the results, especially if  $n$  is fairly large.

Bounds and other restrictions on the covariance parameters carry over from the full-data model. Covariance parameters that are not iterated in the model fit to the full data (the `NOITER` or `HOLD=` option in the `PARMS` statement) are likewise not updated in the refit. In certain models, such as random-effects models, the ratios between the covariance parameters and the residual variance are maintained rather than the actual value of the covariance parameter estimate (see the section “Influence Diagnostics” on page 4977).

**KEEP=*n***

determines how many observations are retained for display and in the output data set or how many tuples if you specify **SIZE=**. The output is sorted by an influence statistic as discussed for the **SIZE=** suboption.

**SELECT=*value-list***

specifies which observations or effect levels are chosen for influence calculations. If the **SELECT=** suboption is not specified, diagnostics are computed as follows:

- for all observations, if **EFFECT=** or **SIZE=** are not given
- for all levels of the specified effect, if **EFFECT=** is specified
- for all tuples of size *k* formed from the observations in *value-list*, if **SIZE=*k*** is specified

When you specify an effect with the **EFFECT=** option, the values in *value-list* represent indices of the levels in the order in which PROC MIXED builds classification effects. Which observations in the data set correspond to this index depends on the order of the variables in the **CLASS** statement, not the order in which the variables appear in the interaction effect. See the section “Parameterization of Mixed Models” on page 4971 to understand precisely how the procedure indexes nested and crossed effects and how levels of classification variables are ordered. The actual values of the classification variables involved in the effect are shown in the output so you can determine which observations were removed.

If the **EFFECT=** suboption is not specified, the **SELECT=** value list refers to the sequence in which observations are read from the input data set or from the current BY group if there is a **BY** statement. This indexing is not necessarily the same as the observation numbers in the input data set, for example, if a **WHERE** clause is specified or during BY processing.

**SIZE=*n***

instructs PROC MIXED to remove groups of observations formed as tuples of size *n*. For example, **SIZE=2** specifies all  $n \times (n - 1) / 2$  unique pairs of observations. The number of tuples for **SIZE=*k*** is  $n! / (k!(n - k)!)$  and grows quickly with *n* and *k*. Using the **SIZE=** option can result in considerable computing time. The MIXED procedure displays by default only the 50 tuples with the greatest influence. Use the **KEEP=** option to override this default and to retain a different number of tuples in the listing or ODS output data set. Regardless of the **KEEP=** specification, all tuples are evaluated and the results are ordered according to an influence statistic. This statistic is the (restricted) likelihood distance as a measure of overall influence if **ITER=*n* > 0** or when a residual variance is profiled. When likelihood distances are unavailable, the results are ordered by the PRESS statistic.

To reduce computational burden, the **SIZE=** option can be combined with the **SELECT=*value-list*** modifier. For example, the following statements evaluate all  $15 = 6 \times 5 / 2$  pairs formed from observations 13, 14, 18, 30, 31, and 33 and display the five pairs with the greatest influence:

```
proc mixed;
 class a m f;
 model penetration = a m /
 influence(size=2 keep=5
 select=13,14,18,30,31,33);
 random f(m);
run;
```

If any observation in a tuple contains missing values or has otherwise not contributed to the analysis, the tuple is not evaluated. This guarantees that the displayed results refer to the same number of observations, so that meaningful statistics are available by which to order the results. If computations fail for a particular tuple—for example, because the  $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$  matrix changes rank or the  $\mathbf{G}$  matrix is not positive definite—no results are produced. Results are retained when the maximum number of iterative updates is exceeded in iterative influence analyses.

The `SIZE=` suboption cannot be combined with the `EFFECT=` suboption. As in the case of the `EFFECT=` suboption, the statistics being computed are those appropriate for removal of multiple data points, even if `SIZE=1`.

The ODS name of the “Influence Diagnostics” table is `Influence`. The variables in this table depend on whether you specify the `EFFECT=`, `SIZE=`, or `KEEP=` suboption and whether covariance parameters are iteratively updated. When `ITER=0` (the default), certain influence diagnostics are meaningful only if the residual variance is profiled. [Table 59.11](#) and [Table 59.12](#) summarize the statistics obtained depending on the model and modifiers. The last column in these tables gives the variable name in the ODS `OUTPUT INFLUENCE=` data set. Restricted likelihood distances are reported instead of the likelihood distance unless `METHOD=ML`. See the section “[Influence Diagnostics](#)” on page 4977 for details about the individual statistics.

**Table 59.11** Statistics Computed with `INFLUENCE` Option, Noniterative Analysis (`ITER=0`)

| Suboption                                                               | $\sigma^2$<br>Profiled | Statistic                                    | Variable<br>Name    |
|-------------------------------------------------------------------------|------------------------|----------------------------------------------|---------------------|

**INTERCEPT**

adds a row to the tables for Type 1, 2, and 3 tests corresponding to the overall intercept.

**LCOMPONENTS**

requests an estimate for each row of the **L** matrix used to form tests of fixed effects. Components corresponding to Type 3 tests are the default; you can produce the Type 1 and Type 2 component estimates with the **HTYPE=** option.

Tests of fixed effects involve testing of linear hypotheses of the form  $\mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ . The matrix **L** is constructed from Type 1, 2, or 3 estimable functions. By default the MIXED procedure constructs Type 3 tests. In many situations, the individual rows of the matrix **L** represent contrasts of interest. For example, in a one-way classification model, the Type 3 estimable functions define differences of factor-level means. In a balanced two-way layout, the rows of **L** correspond to differences of cell means.

For example, suppose factors **A** and **B** have *a* and *b* levels, respectively. The following statements produce (*a* – 1) one degree of freedom tests for the rows of **L** associated with the Type 1 and Type 3 estimable functions for factor **A**, (*b* – 1) tests for the rows of **L** associated with factor **B**, and a single test for the Type 1 and Type 3 coefficients associated with regressor **X**:

```
class A B;
model y = A B x / htype=1,3 lcomponents;
```

The denominator degrees of freedom associated with a row of **L** are the same as those in the corresponding “Tests of Fixed Effects” table, except for **DDFM=KENWARDROGER** and **DDFM=SATTERTHWAITE**. For these degree of freedom methods, the denominator degrees of freedom are computed separately for each row of **L**.

The ODS name of the table containing all requested component tests is **LComponents**. See [Example 59.9](#) for applications of the **LCOMPONENTS** option.

**NOCONTAIN**

has the same effect as the **DDFM=RESIDUAL** option.

**NOINT**

requests that no intercept be included in the model. An intercept is included by default.

**NOTEST**

specifies that no hypothesis tests be performed for the fixed effects.

**OUTP=SAS-data-set****OUTPRED=SAS-data-set**

specifies an output data set containing predicted values and related quantities. This option replaces the **P** option from SAS 6.

Predicted values are formed by using the rows from  $(\mathbf{X} \ \mathbf{Z})$  as **L** matrices. Thus, predicted values from the original data are  $\mathbf{X}\hat{\boldsymbol{\beta}} + \mathbf{Z}\hat{\boldsymbol{\gamma}}$ . Their approximate standard errors of prediction are formed from the quadratic form of **L** with  $\hat{\mathbf{C}}$  defined in the section “Statistical Properties” on page 4967. The **L95** and **U95** variables provide a *t*-type confidence interval for the predicted values, and they correspond to the **L95M** and **U95M** variables from the GLM and REG procedures for fixed-effects models. The residuals are the observed minus the predicted values. Predicted values for data points other than those observed can be obtained by using missing dependent variables in your input data set.

Specifications that have a **REPEATED** statement with the **SUBJECT=** option and missing dependent variables compute predicted values by using empirical best linear unbiased prediction (EBLUP). Using hats ( $\hat{\cdot}$ ) to denote estimates, the EBLUP formula is

$$\hat{\mathbf{m}} = \mathbf{X}_m \hat{\boldsymbol{\beta}} + \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} (\mathbf{y} - \mathbf{X} \hat{\boldsymbol{\beta}})$$

where  $\mathbf{m}$  represents a hypothetical realization of a missing data vector with associated design matrix  $\mathbf{X}_m$ . The matrix  $\mathbf{C}_m$  is the model-based covariance matrix between  $\mathbf{m}$  and the observed data  $\mathbf{y}$ , and other notation is as presented in the section “**Mixed Models Theory**” on page 4958.

The estimated prediction variance is as follows:

$$\widehat{\text{Var}}(\hat{\mathbf{m}} - \mathbf{m}) = \hat{\mathbf{V}}_m - \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} \hat{\mathbf{C}}_m' + [\mathbf{X}_m - \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} \mathbf{X}] (\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} [\mathbf{X}_m - \hat{\mathbf{C}}_m \hat{\mathbf{V}}^{-1} \mathbf{X}]'$$

where  $\mathbf{V}_m$  is the model-based variance matrix of  $\mathbf{m}$ . For further details, see Henderson (1984) and Harville (1990). This feature can be useful for forecasting time series or for computing spatial predictions.

By default, all variables from the input data set are included in the **OUTP=** data set. You can select a subset of these variables by using the **ID** statement.

#### **OUTPM=SAS-data-set**

#### **OUTPREDM=SAS-data-set**

specifies an output data set containing predicted means and related quantities. This option replaces the **PM** option from SAS 6.

The output data set is of the same form as that resulting from the **OUTP=** option, except that the predicted values do not incorporate the EBLUP values  $\mathbf{Z}\hat{\boldsymbol{\gamma}}$ . They also do not use the EBLUPs for specifications that have a **REPEATED** statement with the **SUBJECT=** option and missing dependent variables. The predicted values are formed as  $\mathbf{X}\hat{\boldsymbol{\beta}}$  in the **OUTPM=** data set, and standard errors are quadratic forms in the approximate variance-covariance matrix of  $\hat{\boldsymbol{\beta}}$  as displayed by the **COVB** option.

By default, all variables from the input data set are included in the **OUTPM=** data set. You can select a subset of these variables by using the **ID** statement.

### **RESIDUAL**

#### **RESIDUALS**

requests that Pearson-type and (internally) studentized residuals be added to the **OUTP=** and **OUTPM=** data sets. Studentized residuals are raw residuals standardized by their estimated standard error. When residuals are internally studentized, the data point in question has contributed to the estimation of the covariance parameter estimates on which the standard error of the residual is based. Externally studentized marginal residuals can be computed with the **INFLUENCE** option. Pearson-type residuals scale the residual by the standard deviation of the response.

The option has no effect unless the **OUTP=** or **OUTPM=** option is specified or unless **ODS Graphics** is enabled. For general information about **ODS Graphics**, see Chapter 21, “**Statistical Graphics Using ODS.**” For specific information about the graphics available in the **MIXED** procedure, see the section “**ODS Graphics**” on page 4992. For computational details about studentized and Pearson residuals in **MIXED**, see the section “**Residual Diagnostics**” on page 4976.

**SINGCHOL=number**

tunes the sensitivity in computing Cholesky roots. If a diagonal pivot element is less than  $D \times \text{number}$  as PROC MIXED performs the Cholesky decomposition on a matrix, the associated column is declared to be linearly dependent upon previous columns and is set to 0. The value  $D$  is the original diagonal element of the matrix. The default for *number* is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**SINGRES=number**

sets the tolerance for which the residual variance is considered to be zero. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**SINGULAR=number**

tunes the sensitivity in sweeping. If a diagonal pivot element is less than  $D \times \text{number}$  as PROC MIXED sweeps a matrix, the associated column is declared to be linearly dependent upon previous columns, and the associated parameter is set to 0. The value  $D$  is the original diagonal element of the matrix. The default is 1E4 times the machine epsilon; this product is approximately 1E–12 on most computers.

**SOLUTION****S**

requests that a solution for the fixed-effects parameters be produced. Using notation from the section “Mixed Models Theory” on page 4958, the fixed-effects parameter estimates are  $\hat{\beta}$  and their approximate standard errors are the square roots of the diagonal elements of  $(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}$ . You can output this approximate variance matrix with the **COVB** option or modify it with the **EMPIRICAL** option in the PROC MIXED statement or the **DDFM=KENWARDROGER** option in the **MODEL** statement.

Along with the estimates and their approximate standard errors, a  $t$  statistic is computed as the estimate divided by its standard error. The degrees of freedom for this  $t$  statistic matches the one appearing in the “Tests of Fixed Effects” table under the effect containing the parameter. The “Pr > |t|” column contains the two-tailed  $p$ -value corresponding to the  $t$  statistic and associated degrees of freedom. You can use the **CL** option to request confidence intervals for all of the parameters; they are constructed around the estimate by using a radius of the standard error times a percentage point from the  $t$  distribution.

**VCIRY**

requests that responses and marginal residuals be scaled by the inverse Cholesky root of the marginal variance-covariance matrix. The variables **ScaledDep** and **ScaledResid** are added to the **OUTPM=** data set. These quantities can be important in bootstrapping of data or residuals. Examination of the scaled residuals is also helpful in diagnosing departures from normality. Notice that the results of this scaling operation can depend on the order in which the MIXED procedure processes the data.

The **VCIRY** option has no effect unless you also use the **OUTPM=** option or unless ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.” For specific information about the graphics available in the MIXED procedure, see the section “ODS Graphics” on page 4992.

**XPVIX**

is an alias for the **COVBI** option.

**XPVIXI**

is an alias for the **COVB** option.

**ZETA=number**

tunes the sensitivity in forming Type 3 functions. Any element in the estimable function basis with an absolute value less than *number* is set to 0. The default is 1E–8.

## PARMS Statement

**PARMS** (*value-list*)...</ options > ;

The **PARMS** statement specifies initial values for the covariance parameters, or it requests a grid search over several values of these parameters. You must specify the values in the order in which they appear in the “Covariance Parameter Estimates” table.

The *value-list* specification can take any of several forms:

|                                  |                                                                                                                          |
|----------------------------------|--------------------------------------------------------------------------------------------------------------------------|
| <i>m</i>                         | a single value                                                                                                           |
| $m_1, m_2, \dots, m_n$           | several values                                                                                                           |
| <i>m</i> to <i>n</i>             | a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals 1        |
| <i>m</i> to <i>n</i> by <i>i</i> | a sequence where <i>m</i> equals the starting value, <i>n</i> equals the ending value, and the increment equals <i>i</i> |
| $m_1, m_2$ to $m_3$              | mixed values and sequences                                                                                               |

You can use the **PARMS** statement to input known parameters. Referring to the split-plot example ([Example 59.1](#)), suppose the three variance components are known to be 60, 20, and 6. The SAS statements to fix the variance components at these values are as follows:

```
proc mixed data=sp noprofile;
 class Block A B;
 model Y = A B A*B;
 random Block A*Block;
 parms (60) (20) (6) / noiter;
run;
```

The **NOPROFILE** option requests PROC MIXED to refrain from profiling the residual variance parameter during its calculations, thereby enabling its value to be held at 6 as specified in the **PARMS** statement. The **NOITER** option prevents any Newton-Raphson iterations so that the subsequent results are based on the given variance components. You can also specify known parameters of **G** by using the **GDATA=** option in the **RANDOM** statement.

If you specify more than one set of initial values, PROC MIXED performs a grid search of the likelihood surface and uses the best point on the grid for subsequent analysis. Specifying a large number of grid points can result in long computing times. The grid search feature is also useful for exploring the likelihood surface. (See [Example 59.3](#).)

The results from the **PARMS** statement are the values of the parameters on the specified grid (denoted by CovP1–CovP*n*), the residual variance (possibly estimated) for models with a residual variance parameter, and various functions of the likelihood.

The ODS name of the “Parameter Search” table is ParmSearch.

Table 59.13 summarizes the options available in the PARMS statement.

**Table 59.13** PARMS Statement Options

| Option            | Description                                                              |
|-------------------|--------------------------------------------------------------------------|
| <b>HOLD=</b>      | Holds parameter values equal to the specified values                     |
| <b>LOGDETH</b>    | Evaluates the log determinant of the Hessian matrix                      |
| <b>LOWERB=</b>    | Specifies lower boundary constraints                                     |
| <b>NOBOUND</b>    | Removes boundary constraints on covariance parameters                    |
| <b>NOITER</b>     | Performs inferences using the best value from the grid search            |
| <b>NOPRINT</b>    | Suppresses the “Parameter Search” table                                  |
| <b>NOPROFILE</b>  | Specifies a different computational method for the residual variance     |
| <b>OLS</b>        | Requests starting values corresponding to the usual general linear model |
| <b>PARMSDATA=</b> | Reads in covariance parameter values from a SAS data set                 |
| <b>RATIOS</b>     | Indicates that ratios with the residual variance are specified           |
| <b>UPPERB=</b>    | Specifies upper boundary constraints                                     |

You can specify the following *options* in the PARMS statement after a slash (/).

**HOLD=***value-list*

**EQCONS=***value-list*

specifies which parameter values PROC MIXED should hold to equal the specified values. For example, the following statement constrains the first and third covariance parameters to equal 5 and 2, respectively:

```
parms (5) (3) (2) (3) / hold=1,3;
```

**LOGDETH**

evaluates the log determinant of the Hessian matrix for each point specified in the PARMS statement. A Log Det H column is added to the “Parameter Search” table.

**LOWERB=***value-list*

enables you to specify lower boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC MIXED uses for the covariance parameters, and each number corresponds to the lower boundary constraint. A missing value instructs PROC MIXED to use its default constraint, and if you do not specify numbers for all of the covariance parameters, PROC MIXED assumes the remaining ones are missing.

An example for which this option is useful is when you want to constrain the **G** matrix to be positive definite in order to avoid the more computationally intensive algorithms required when **G** becomes singular. The corresponding statements for a random coefficients model are as follows:

```
proc mixed;
 class person;
 model y = time;
```

```

 random int time / type=fa0(2) sub=person;
 parms / lowerb=1e-4, ., 1e-4;
run;

```

Here the `TYPE=FA0(2)` structure is used in order to specify a Cholesky root parameterization for the  $2 \times 2$  unstructured blocks in **G**. This parameterization ensures that the **G** matrix is nonnegative definite, and the `PARMS` statement then ensures that it is positive definite by constraining the two diagonal terms to be greater than or equal to  $1E-4$ .

#### **NOBOUND**

requests the removal of boundary constraints on covariance parameters. For example, variance components have a default lower boundary constraint of 0, and the `NOBOUND` option allows their estimates to be negative.

#### **NOITER**

requests that no Newton-Raphson iterations be performed and that PROC MIXED use the best value from the grid search to perform inferences. By default, iterations begin at the best value from the `PARMS` grid search.

#### **NOPRINT**

suppresses the display of the “Parameter Search” table.

#### **NOPROFILE**

specifies a different computational method for the residual variance during the grid search. By default, PROC MIXED estimates this parameter by using the profile likelihood when appropriate. This estimate is displayed in the Variance column of the “Parameter Search” table. The `NOPROFILE` option suppresses the profiling and uses the actual value of the specified variance in the likelihood calculations.

#### **OLS**

requests starting values corresponding to the usual general linear model. Specifically, all variances and covariances are set to zero except for the residual variance, which is set equal to its ordinary least squares (OLS) estimate. This option is useful when the default `MIVQUE0` procedure produces poor starting values for the optimization process.

#### **PARMSDATA=SAS-data-set**

#### **PDATA=SAS-data-set**

reads in covariance parameter values from a SAS data set. The data set should contain the `Est` or `Covp1–Covpn` variables.

#### **RATIOS**

indicates that ratios with the residual variance are specified instead of the covariance parameters themselves. The default is to use the individual covariance parameters.

#### **UPPERB=value-list**

enables you to specify upper boundary constraints on the covariance parameters. The *value-list* specification is a list of numbers or missing values (.) separated by commas. You must list the numbers in the order that PROC MIXED uses for the covariance parameters, and each number corresponds to the upper boundary constraint. A missing value instructs PROC MIXED to use its default constraint, and if you do not specify numbers for all of the covariance parameters, PROC MIXED assumes that the remaining ones are missing.

---

## PERFORMANCE Statement

**PERFORMANCE** < *performance-options* > ;

The PERFORMANCE statement defines performance parameters for multithreaded computing in solving large mixed model equations and other large matrix sweep operations.

You can specify the following *performance-options* in the PERFORMANCE statement:

**CPUCOUNT=ACTUAL** | *num*

specifies how many processors the procedure assumes to be available on the machine. You can specify any integer from 1 to 256 for *num*. CPUCOUNT=ACTUAL is equivalent to setting *num* to be the number of physical processors available. This number can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available CPUs might result in reduced performance. This option overrides the CPUCOUNT= SAS system option.

**NTHREADS**=*n*

specifies the number of threads for analytic computations and overrides the SAS system option THREADS | NOTHEADS. If you do not specify the NTHREADS= option, the number of threads are determined based on the number of CPUs on the machine by creating one thread per CPU for the analytic computations. The largest number that can be specified for *n* is 256.

By default, PROC MIXED executes in multiple concurrent threads unless you specify the NOTHEADS system option or you force single-threaded execution with NTHREADS=1 or the NOTHEADS options in the PERFORMANCE statement.

**THREADS=YES** | **NO**

specifies whether PROC MIXED executes in multiple concurrent threads. The default is YES.

**NOTHEAD**

turns off the multithreaded computation.

---

## PRIOR Statement

**PRIOR** < *distribution* > < / *options* > ;

The PRIOR statement enables you to carry out a sampling-based Bayesian analysis in PROC MIXED. It currently operates only with variance component models. Other TYPE= structures are not supported. The analysis produces a SAS data set containing a pseudo-random sample from the joint posterior density of the variance components and other parameters in the mixed model.

The posterior analysis is performed after all other PROC MIXED computations. It begins with the “Posterior Sampling Information” table, which provides basic information about the posterior sampling analysis, including the prior densities, sampling algorithm, sample size, and random number seed. The ODS name of this table is Posterior.

By default, PROC MIXED uses an independence chain algorithm in order to generate the posterior sample (Tierney 1994). This algorithm works by generating a pseudo-random proposal from a convenient base distribution, chosen to be as close as possible to the posterior. The proposal is then retained in the sample

with probability proportional to the ratio of weights constructed by taking the ratio of the true posterior to the base density. If a proposal is not accepted, then a duplicate of the previous observation is added to the chain.

In selecting the base distribution, PROC MIXED makes use of the fact that the fixed-effects parameters can be analytically integrated out of the joint posterior, leaving the marginal posterior density of the variance components. In order to better approximate the marginal posterior density of the variance components, PROC MIXED transforms them by using the MIVQUE(0) equations. You can display the selected transformation with the PTRANS option or specify your own with the TDATA= option. The density of the transformed parameters is then approximated by a product of inverted gamma densities (see Gelfand et al. 1990).

To determine the parameters for the inverted gamma densities, PROC MIXED evaluates the logarithm of the posterior density over a grid of points in each of the transformed parameters, and you can display the results of this search with the PSEARCH option. PROC MIXED then performs a linear regression of these values on the logarithm of the inverted gamma density. The resulting base densities are displayed in the “Base Densities” table; for ODS purposes, the name of this table is “Base.” You can input different base densities with the BDATA= option.

At the end of the sampling, the “Acceptance Rates” table displays the acceptance rate computed as the number of accepted samples divided by the total number of samples generated. The ODS name of the “Acceptance Rates” table is AccRates.

The OUT= option specifies the output data set containing the posterior sample. PROC MIXED automatically includes all variance component parameters in this data set (labeled COVP1–COVP $n$ ), the Type 3  $F$  statistics constructed as in Ghosh (1992) discussing Schervish (1992) (labeled T3F $n$ ), the log values of the posterior (labeled LOGF), the log of the base sampling density (labeled LOGG), and the log of their ratio (labeled LOGRATIO). If you specify the SOLUTION option in the MODEL statement, the data set also contains a random sample from the posterior density of the fixed-effects parameters (labeled BETAn); and if you specify the SOLUTION option in the RANDOM statement, the table contains a random sample from the posterior density of the random-effects parameters (labeled GAM $n$ ). PROC MIXED also generates additional variables corresponding to any CONTRAST, ESTIMATE, or LSMEANS statement that you specify.

Subsequently, you can use SAS/INSIGHT or the UNIVARIATE, CAPABILITY, or KDE procedure to analyze the posterior sample.

The prior density of the variance components is, by default, a noninformative version of Jeffreys’ prior (Box and Tiao 1973). You can also specify informative priors with the DATA= option or a flat (equal to 1) prior for the variance components. The prior density of the fixed-effects parameters is assumed to be flat (equal to 1), and the resulting posterior is conditionally multivariate normal (conditioning on the variance component parameters) with mean  $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}^{-1}\mathbf{y}$  and variance  $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-1}$ .

Table 59.14 summarizes the options available in the PRIOR statement.

**Table 59.14** PRIOR Statement Options

| Option   | Description                                                     |
|----------|-----------------------------------------------------------------|
| DATA=    | Inputs the prior densities of the variance components           |
| JEFFREYS | Specifies a noninformative reference version of Jeffreys’ prior |
| FLAT     | Specifies a prior density equal to 1 everywhere                 |

Table 59.14 *continued*

| Option     | Description                                                                             |
|------------|-----------------------------------------------------------------------------------------|
| ALG=       | Specifies the algorithm used for generating the posterior sample                        |
| BDATA=     | Inputs the base densities used by the sampling algorithm                                |
| GRID=      | Specifies a grid of values over which to evaluate the posterior density                 |
| GRIDT=     | Specifies a transformed grid of values over which to evaluate the posterior density     |
| IFACTOR=   | An alias for the SFACTOR= option                                                        |
| LOGNOTE=   | Writes a note to the log after generating the sample                                    |
| LOGRBOUND= | Specifies the bounding constant for rejection sampling                                  |
| NSAMPLE=   | Specifies the number of posterior samples to generate                                   |
| NSEARCH=   | Specifies the number of posterior evaluations                                           |
| OUT=       | Creates an output data set containing the sample from the posterior density             |
| OUTG=      | Creates an output data set from the grid evaluations                                    |
| OUTGT=     | Creates an output data set from the transformed grid evaluations                        |
| PSEARCH    | Displays the search used to determine the parameters for the inverted gamma densities   |
| PTRANS     | Displays the transformation of the variance components                                  |
| SEED=      | Specifies an integer used to start the pseudo-random number generator                   |
| SFACTOR=   | Adjusts the search range of the transformed parameters                                  |
| TDATA=     | Inputs the transformation used by the sampling algorithm                                |
| TRANS=     | Specifies the algorithm that determines the transformation of the covariance parameters |
| UPDATE=    | An alias for the LOGNOTE= option                                                        |

The *distribution* argument in the PRIOR statement determines the prior density for the variance component parameters of your mixed model. Valid values are as follows.

#### DATA=

enables you to input the prior densities of the variance components used by the sampling algorithm. This data set must contain the Type and Parm1–Parm*n* variables, where *n* is the largest number of parameters among each of the base densities. The format of the DATA= data set matches that created by PROC MIXED in the “Base Densities” table, so you can output the densities from one run and use them as input for a subsequent run.

#### JEFFREYS

specifies a noninformative reference version of Jeffreys’ prior constructed by using the square root of the determinant of the expected information matrix as in (1.3.92) of Box and Tiao (1973). This is the default prior.

#### FLAT

specifies a prior density equal to 1 everywhere, making the likelihood function the posterior.

You can specify the following *options* in the PRIOR statement after a slash (/).

**ALG=IC | INDCHAIN****ALG=IS | IMPSAMP****ALG=RS | REJSAMP****ALG=RWC | RWCHAIN**

specifies the algorithm used for generating the posterior sample. The ALG=IC option requests an independence chain algorithm, and it is the default. The option ALG=IS requests importance sampling, ALG=RS requests rejection sampling, and ALG=RWC requests a random walk chain. For more information about these techniques, see Ripley (1987); Smith and Gelfand (1992); Tierney (1994).

**BDATA=**

enables you to input the base densities used by the sampling algorithm. This data set must contain the Type and Parm1–Parm $n$  variables, where  $n$  is the largest number of parameters among each of the base densities. The format of the BDATA= data set matches that created by PROC MIXED in the “Base Densities” table, so you can output the densities from one run and use them as input for a subsequent run.

**GRID=(value-list)**

specifies a grid of values over which to evaluate the posterior density. The *value-list* syntax is the same as in the PARMs statement, and you must specify an output data set name with the OUTG= option.

**GRIDT=(value-list)**

specifies a transformed grid of values over which to evaluate the posterior density. The *value-list* syntax is the same as in the PARMs statement, and you must specify an output data set name with the OUTGT= option.

**IFACTOR=number**

is an alias for the SFACTOR= option.

**LOGNOTE=number**

instructs PROC MIXED to write a note to the SAS log after it generates the sample corresponding to each multiple of *number*. This is useful for monitoring the progress of CPU-intensive runs.

**LOGRBOUND=number**

specifies the bounding constant for rejection sampling. The value of *number* equals the maximum of  $\log\{f/g\}$  over the variance component parameter space, where  $f$  is the posterior density and  $g$  is the product inverted gamma densities used to perform rejection sampling.

When performing the rejection sampling, you might encounter the following message:

```
WARNING: The log ratio bound of LL was violated at sample XX.
```

When this occurs, PROC MIXED reruns an optimization algorithm to determine a new log upper bound and then restarts the rejection sampling. The resulting OUT= data set contains all observations that have been generated; therefore, assuming that you have requested  $N$  samples, you should retain only the final  $N$  observations in this data set for analysis purposes.

**NSAMPLE=***number*

specifies the number of posterior samples to generate. The default is 1000, but more accurate results are obtained with larger samples such as 10000.

**NSEARCH=***number*

specifies the number of posterior evaluations PROC MIXED makes for each transformed parameter in determining the parameters for the inverted gamma densities. The default is 20.

**OUT=***SAS-data-set*

creates an output data set containing the sample from the posterior density.

**OUTG=***SAS-data-set*

creates an output data set from the grid evaluations specified in the **GRID=** option.

**OUTGT=***SAS-data-set*

creates an output data set from the transformed grid evaluations specified in the **GRIDT=** option.

**PSEARCH**

displays the search used to determine the parameters for the inverted gamma densities. The ODS name of the table is Search.

**PTRANS**

displays the transformation of the variance components. For ODS purposes, the name of the table is “Trans.”

**SEED=***number*

specifies an integer used to start the pseudo-random number generator for the simulation. If you do not specify a seed, or if you specify a value less than or equal to zero, the seed is by default generated from reading the time of day from the computer clock. You should use a positive seed (less than  $2^{31} - 1$ ) whenever you want to duplicate the sample in another run of PROC MIXED.

**SFACTOR=***number*

enables you to adjust the range over which PROC MIXED searches the transformed parameters in order to determine the parameters for the inverted gamma densities. PROC MIXED determines the range by first transforming the estimates from the standard PROC MIXED analysis (REML, ML, or MIVQUE0, depending upon which estimation method you select). It then multiplies and divides the transformed estimates by  $2 * \textit{number}$  to obtain upper and lower bounds, respectively. Transformed values that produce negative variance components in the original scale are not included in the search. The default value is 1; *number* must be greater than 0.5.

**TDATA=**

enables you to input the transformation of the covariance parameters used by the sampling algorithm. This data set should contain the CovP1–CovP*n* variables. The format of the TDATA= data set matches that created by PROC MIXED in the “Trans” table, so you can output the transformation from one run and use it as input for a subsequent run.

**TRANS=**EXPECTED | MIVQUE0 | OBSERVED

specifies the particular algorithm used to determine the transformation of the covariance parameters. The default is MIVQUE0, indicating a transformation based on the MIVQUE(0) equations. The other two options indicate the type of Hessian matrix used in constructing the transformation via a Cholesky root.

**UPDATE=number**

is an alias for the **LOGNOTE=** option.

---

## RANDOM Statement

**RANDOM** *random-effects* </ options > ;

The **RANDOM** statement defines the random effects constituting the  $\boldsymbol{\gamma}$  vector in the mixed model. It can be used to specify traditional variance component models (as in the **VARCOMP** procedure) and to specify random coefficients. The random effects can be classification or continuous, and multiple **RANDOM** statements are possible.

Using notation from the section “**Mixed Models Theory**” on page 4958, the purpose of the **RANDOM** statement is to define the **Z** matrix of the mixed model, the random effects in the  $\boldsymbol{\gamma}$  vector, and the structure of **G**. The **Z** matrix is constructed exactly as the **X** matrix for the fixed effects, and the **G** matrix is constructed to correspond with the effects constituting **Z**. The structure of **G** is defined by using the **TYPE=** option.

You can specify **INTERCEPT** (or **INT**) as a random effect to indicate the intercept. **PROC MIXED** does not include the intercept in the **RANDOM** statement by default as it does in the **MODEL** statement.

Table 59.15 summarizes the options available in the **RANDOM** statement. All options are subsequently discussed in alphabetical order.

**Table 59.15** Summary of **RANDOM** Statement Options

| Option                                      | Description                                                                            |
|---------------------------------------------|----------------------------------------------------------------------------------------|
| <b>Construction of Covariance Structure</b> |                                                                                        |
| <b>GDATA=</b>                               | Requests that the <b>G</b> matrix be read from a SAS data set                          |
| <b>GROUP=</b>                               | Varies covariance parameters by groups                                                 |
| <b>LDATA=</b>                               | Specifies data set with coefficient matrices for <b>TYPE=LIN</b>                       |
| <b>NOFULLZ</b>                              | Eliminates columns in <b>Z</b> corresponding to missing values                         |
| <b>RATIOS</b>                               | Indicates that ratios are specified in the <b>GDATA=</b> data set                      |
| <b>SUBJECT=</b>                             | Identifies the subjects in the model                                                   |
| <b>TYPE=</b>                                | Specifies the covariance structure                                                     |
| <b>Statistical Output</b>                   |                                                                                        |
| <b>ALPHA=<math>\alpha</math></b>            | Determines the confidence level ( $1 - \alpha$ )                                       |
| <b>CL</b>                                   | Requests confidence limits for predictors of random effects                            |
| <b>G</b>                                    | Displays the estimated <b>G</b> matrix                                                 |
| <b>GC</b>                                   | Displays the Cholesky root (lower) of estimated <b>G</b> matrix                        |
| <b>GCI</b>                                  | Displays the inverse Cholesky root (lower) of estimated <b>G</b> matrix                |
| <b>GCORR</b>                                | Displays the correlation matrix corresponding to estimated <b>G</b> matrix             |
| <b>GI</b>                                   | Displays the inverse of the estimated <b>G</b> matrix                                  |
| <b>SOLUTION</b>                             | Displays solutions $\hat{\boldsymbol{\gamma}}$ of the G-side random effects            |
| <b>V</b>                                    | Displays blocks of the estimated <b>V</b> matrix                                       |
| <b>VC</b>                                   | Displays the lower-triangular Cholesky root of blocks of the estimated <b>V</b> matrix |

Table 59.15 *continued*

| Option | Description                                                                              |
|--------|------------------------------------------------------------------------------------------|
| VCI    | Displays the inverse Cholesky root of blocks of the estimated <b>V</b> matrix            |
| VCORR  | Displays the correlation matrix corresponding to blocks of the estimated <b>V</b> matrix |
| VI     | Displays the inverse of the blocks of the estimated <b>V</b> matrix                      |

You can specify the following *options* in the RANDOM statement after a slash (/).

**ALPHA=number**

requests that a *t*-type confidence interval be constructed for each of the random-effect estimates with confidence level  $1 - \text{number}$ . The value of *number* must be between 0 and 1; the default is 0.05.

**CL**

requests that *t*-type confidence limits be constructed for each of the random-effect estimates. The confidence level is 0.95 by default; this can be changed with the **ALPHA=** option.

**G**

requests that the estimated **G** matrix be displayed. PROC MIXED displays blanks for values that are 0. If you specify the **SUBJECT=** option, then the block of the **G** matrix corresponding to the first subject is displayed. For ODS purposes, the name of the table is “G.”

**GC**

displays the lower-triangular Cholesky root of the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is CholG.

**GCI**

displays the inverse Cholesky root of the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is InvCholG.

**GCORR**

displays the correlation matrix corresponding to the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is GCorr.

**GDATA=SAS-data-set**

requests that the **G** matrix be read in from a SAS data set. This **G** matrix is assumed to be known; therefore, only **R**-side parameters from effects in the **REPEATED** statement are included in the Newton-Raphson iterations. If no **REPEATED** statement is specified, then only a residual variance is estimated.

The information in the **GDATA=** data set can appear in one of two ways. The first is a sparse representation for which you include **Row**, **Col**, and **Value** variables to indicate the row, column, and value of **G**, respectively. All unspecified locations are assumed to be 0. The second representation is for dense matrices. In it you include **Row** and **Col1–Coln** variables to indicate, respectively, the row and columns of **G**, which is a symmetric matrix of order *n*. For both representations, you must specify effects in the RANDOM statement that generate a **Z** matrix that contains *n* columns. (See Example 59.4.)

If you have more than one RANDOM statement, only one GDATA= option is required in any one of them, and the data set you specify must contain the entire **G** matrix defined by all of the RANDOM statements.

If the GDATA= data set contains variance ratios instead of the variances themselves, then use the **RATIOS** option.

Known parameters of **G** can also be input by using the PARMS statement with the **HOLD=** option.

## GI

displays the inverse of the estimated **G** matrix according to the rules listed under the **G** option. The ODS name of the table is InvG.

## GROUP=effect

### GRP=effect

defines an effect specifying heterogeneity in the covariance structure of **G**. All observations having the same level of the group effect have the same covariance parameters. Each new level of the group effect produces a new set of covariance parameters with the same structure as the original group. You should exercise caution in defining the group effect, because strange covariance patterns can result from its misuse. Also, the group effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

Continuous variables are permitted as arguments to the GROUP= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

## LDATA=SAS-data-set

reads the coefficient matrices associated with the **TYPE=LIN(number)** option. The data set must contain the variables Parm, Row, Col1–Col $n$  or Parm, Row, Col, Value. The Parm variable denotes which of the *number* coefficient matrices is currently being constructed, and the Row, Col1–Col $n$ , or Row, Col, Value variables specify the matrix values, as they do with the GDATA= option. Unspecified values of these matrices are set equal to 0.

## NOFULLZ

eliminates the columns in **Z** corresponding to missing levels of random effects involving **CLASS** variables. By default, these columns are included in **Z**.

## RATIOS

indicates that ratios with the residual variance are specified in the GDATA= data set instead of the covariance parameters themselves. The default GDATA= data set contains the individual covariance parameters.

## SOLUTION

### S

requests that the solution for the random-effects parameters be produced. Using notation from the section “Mixed Models Theory” on page 4958, these estimates are the empirical best linear unbiased predictors (EBLUPs)  $\hat{\boldsymbol{y}} = \hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})$ . They can be useful for comparing the random effects from different experimental units and can also be treated as residuals in performing diagnostics for your mixed model.

The numbers displayed in the SE Pred column of the “Solution for Random Effects” table are not the standard errors of the  $\hat{\boldsymbol{\gamma}}$  displayed in the Estimate column; rather, they are the standard errors of predictions  $\hat{\boldsymbol{\gamma}}_i - \boldsymbol{\gamma}_i$ , where  $\hat{\boldsymbol{\gamma}}_i$  is the  $i$ th EBLUP and  $\boldsymbol{\gamma}_i$  is the  $i$ th random-effect parameter.

**SUBJECT=effect**

**SUB=effect**

identifies the subjects in your mixed model. Complete independence is assumed across subjects; thus, for the RANDOM statement, the SUBJECT= option produces a block-diagonal structure in  $\mathbf{G}$  with identical blocks. The  $\mathbf{Z}$  matrix is modified to accommodate this block diagonality. In fact, specifying a subject effect is equivalent to nesting all other effects in the RANDOM statement within the subject effect.

Continuous variables are permitted as arguments to the SUBJECT= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

When you specify the SUBJECT= option and a classification random effect, computations are usually much quicker if the levels of the random effect are duplicated within each level of the SUBJECT= effect.

**TYPE=covariance-structure**

specifies the covariance structure of  $\mathbf{G}$ . Valid values for *covariance-structure* and their descriptions are listed in Table 59.17 and Table 59.18. Although a variety of structures are available, most applications call for either TYPE=VC or TYPE=UN. The TYPE=VC (variance components) option is the default structure, and it models a different variance component for each random effect.

The TYPE=UN (unstructured) option is useful for correlated random coefficient models. For example, the following statement specifies a random intercept-slope model that has different variances for the intercept and slope and a covariance between them:

```
random intercept age / type=un subject=person;
```

You can also use TYPE=FA0(2) here to request a  $\mathbf{G}$  estimate that is constrained to be nonnegative definite.

If you are constructing your own columns of  $\mathbf{Z}$  with continuous variables, you can use the TYPE=TOEP(1) structure to group them together to have a common variance component. If you want to have different covariance structures in different parts of  $\mathbf{G}$ , you must use multiple RANDOM statements with different TYPE= options.

**V<=value-list>**

requests that blocks of the estimated  $\mathbf{V}$  matrix be displayed. The first block determined by the SUBJECT= effect is the default displayed block. PROC MIXED displays entries that are 0 as blanks in the table.

You can optionally use the *value-list* specification, which indicates the subjects for which blocks of  $\mathbf{V}$  are to be displayed. For example, the following statement displays block matrices for the first, third, and seventh persons:

```
random int time / type=un subject=person v=1,3,7;
```

The ODS table name is V.

**VC**<=*value-list*>

displays the Cholesky root of the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The ODS table name is CholV.

**VCI**<=*value-list*>

displays the inverse of the Cholesky root of the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The table name for ODS purposes is “InvCholV.”

**VCORR**<=*value-list*>

displays the correlation matrix corresponding to the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The table name for ODS purposes is “VCorr.”

**VI**<=*value-list*>

displays the inverse of the blocks of the estimated **V** matrix. The *value-list* specification is the same as in the **V** option. The ODS table name is InvV.

---

## REPEATED Statement

**REPEATED** < *repeated-effect* > < / *options* > ;

The REPEATED statement is used to specify the **R** matrix in the mixed model. Its syntax is different from that of the REPEATED statement in PROC GLM. If no REPEATED statement is specified, **R** is assumed to be equal to  $\sigma^2\mathbf{I}$ .

For many repeated measures models, no repeated effect is required in the REPEATED statement. Simply use the **SUBJECT=** option to define the blocks of **R** and the **TYPE=** option to define their covariance structure. In this case, the repeated measures data must be similarly ordered for each subject, and you must indicate all missing response variables with periods in the input data set unless they all fall at the end of a subject’s repeated response profile. These requirements are necessary in order to inform PROC MIXED of the proper location of the observed repeated responses.

Specifying a repeated effect is useful when you do not want to indicate missing values with periods in the input data set. The repeated effect must contain only classification variables. Make sure that the levels of the repeated effect are different for each observation within a subject; otherwise, PROC MIXED constructs identical rows in **R** corresponding to the observations with the same level. This results in a singular **R** and an infinite likelihood.

Whether you specify a REPEATED effect or not, the rows of **R** for each subject are constructed in the order in which they appear in the input data set.

Table 59.16 summarizes the options available in the REPEATED statement. All options are subsequently discussed in alphabetical order.

**Table 59.16** Summary of REPEATED Statement Options

| Option                                      | Description                                                                              |
|---------------------------------------------|------------------------------------------------------------------------------------------|
| <b>Construction of Covariance Structure</b> |                                                                                          |
| GROUP=                                      | Defines an effect specifying heterogeneity in the R-side covariance structure            |
| LDATA=                                      | Specifies data set with coefficient matrices for TYPE=LIN                                |
| LOCAL                                       | Requests that a diagonal matrix be added to <b>R</b>                                     |
| LOCALW                                      | Specifies that only the local effects are weighted                                       |
| NONLOCALW                                   | Specifies that only the nonlocal effects are weighted                                    |
| SUBJECT=                                    | Identifies the subjects in the R-side model                                              |
| TYPE=                                       | Specifies the R-side covariance structure                                                |
| <b>Statistical Output</b>                   |                                                                                          |
| HLM                                         | Produces a table of Hotelling-Lawley-McKeon statistics (McKeon 1974)                     |
| HLPS                                        | Produces a table of Hotelling-Lawley-Pillai-Samson statistics (Pillai and Samson 1959)   |
| R                                           | Displays blocks of the estimated <b>R</b> matrix                                         |
| RC                                          | Display the Cholesky root (lower) of blocks of the estimated <b>R</b> matrix             |
| RCI                                         | Displays the inverse Cholesky root (lower) of blocks of the estimated <b>R</b> matrix    |
| RCORR                                       | Displays the correlation matrix corresponding to blocks of the estimated <b>R</b> matrix |
| RI                                          | Displays the inverse of blocks of the estimated <b>R</b> matrix                          |

You can specify the following *options* in the REPEATED statement after a slash (/).

**GROUP=effect****GRP=effect**

defines an effect that specifies heterogeneity in the covariance structure of **R**. All observations that have the same level of the GROUP effect have the same covariance parameters. Each new level of the GROUP effect produces a new set of covariance parameters with the same structure as the original group. You should exercise caution in properly defining the GROUP effect, because strange covariance patterns can result with its misuse. Also, the GROUP effect can greatly increase the number of estimated covariance parameters, which can adversely affect the optimization process.

Continuous variables are permitted as arguments to the GROUP= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

**HLM**

produces a table of Hotelling-Lawley-McKeon statistics (McKeon 1974) for all fixed effects whose levels change across data having the same level of the SUBJECT= effect (the *within-subject* fixed effects). This option applies only when you specify a REPEATED statement with the TYPE=UN

option and no **RANDOM** statements. For balanced data, this model is equivalent to the multivariate model for repeated measures in PROC GLM.

The Hotelling-Lawley-McKeon statistic has a slightly better  $F$  approximation than the Hotelling-Lawley-Pillai-Samson statistic (see the description of the **HLPS** option, which follows). Both of the Hotelling-Lawley statistics can perform much better in small samples than the default  $F$  statistic (Wright 1994).

Separate tables are produced for Type 1, 2, and 3 tests, according to the ones you select. The ODS table names are HLM1, HLM2, and HLM3, respectively.

## HLPS

produces a table of Hotelling-Lawley-Pillai-Samson statistics (Pillai and Samson 1959) for all fixed effects whose levels change across data having the same level of the **SUBJECT=** effect (the *within-subject* fixed effects). This option applies only when you specify a **REPEATED** statement with the **TYPE=UN** option and no **RANDOM** statements. For balanced data, this model is equivalent to the multivariate model for repeated measures in PROC GLM, and this statistic is the same as the Hotelling-Lawley Trace statistic produced by PROC GLM.

Separate tables are produced for Type 1, 2, and 3 tests, according to the ones you select. The ODS table names are HLPS1, HLPS2, and HLPS3, respectively.

## **LDATA=SAS-data-set**

reads the coefficient matrices associated with the **TYPE=LIN(number)** option. The data set must contain the variables **Parm, Row, Col1–Col $n$**  or **Parm, Row, Col, Value**. The **Parm** variable denotes which of the *number* coefficient matrices is currently being constructed, and the **Row, Col1–Col $n$** , or **Row, Col, Value** variables specify the matrix values, as they do with the **RANDOM** statement option **GDATA=**. Unspecified values of these matrices are set equal to 0.

## LOCAL

### **LOCAL=POM(POM-data-set)**

requests that a diagonal matrix be added to **R**. With just the **LOCAL** option, this diagonal matrix equals  $\sigma^2\mathbf{I}$ , and  $\sigma^2$  becomes an additional variance parameter that PROC MIXED profiles out of the likelihood provided that you do not specify the **NOPROFILE** option in the **PROC MIXED** statement. The **LOCAL** option is useful if you want to add an observational error to a time series structure (Jones and Boadi-Boateng 1991) or a nugget effect to a spatial structure Cressie (1993).

The **LOCAL=EXP(<effects>)** option produces exponential local effects, also known as dispersion effects, in a log-linear variance model. These local effects have the form

$$\sigma^2 \text{diag}[\exp(\mathbf{U}\boldsymbol{\delta})]$$

where **U** is the full-rank design matrix corresponding to the effects that you specify and  $\boldsymbol{\delta}$  are the parameters that PROC MIXED estimates. An intercept is not included in **U** because it is accounted for by  $\sigma^2$ . PROC MIXED constructs the full-rank **U** in terms of 1s and –1s for classification effects. Be sure to scale continuous effects in **U** sensibly.

The **LOCAL=POM(POM-data-set)** option specifies the power-of-the-mean structure. This structure possesses a variance of the form  $\sigma^2|\mathbf{x}'_i\boldsymbol{\beta}^*|^\theta$  for the *i*th observation, where  $\mathbf{x}_i$  is the *i*th row of **X** (the design matrix of the fixed effects) and  $\boldsymbol{\beta}^*$  is an estimate of the fixed-effects parameters that you specify in **POM-data-set**.

The SAS data set specified by *POM-data-set* contains the numeric variable Estimate (in previous releases, the variable name was required to be EST), and it has at least as many observations as there are fixed-effects parameters. The first  $p$  observations of the Estimate variable in *POM-data-set* are taken to be the elements of  $\beta^*$ , where  $p$  is the number of columns of  $\mathbf{X}$ . You must order these observations according to the non-full-rank parameterization of the MIXED procedure. One easy way to set up *POM-data-set* for a  $\beta^*$  corresponding to ordinary least squares is illustrated by the following statements:

```
ods output SolutionF=sf;
proc mixed;
 class a;
 model y = a x / s;
run;

proc mixed;
 class a;
 model y = a x;
 repeated / local=pom(sf);
run;
```

Note that the generalized least squares estimate of the fixed-effects parameters from the second PROC MIXED step usually is not the same as your specified  $\beta^*$ . However, you can iterate the POM fitting until the two estimates agree. Continuing from the previous example, the statements for performing one step of this iteration are as follows:

```
ods output SolutionF=sf1;
proc mixed;
 class a;
 model y = a x / s;
 repeated / local=pom(sf);
run;

proc compare brief data=sf compare=sf1;
 var estimate;
run;

data sf;
 set sf1;
run;
```

Unfortunately, this iterative process does not always converge. For further details, see the description of pseudo-likelihood in Chapter 3 of Carroll and Ruppert (1988).

### LOCALW

specifies that only the local effects and no others be weighted. By default, all effects are weighted. The LOCALW option is used in connection with the WEIGHT statement and the LOCAL option in the REPEATED statement.

**NONLOCALW**

specifies that only the nonlocal effects and no others be weighted. By default, all effects are weighted. The NONLOCALW option is used in connection with the WEIGHT statement and the LOCAL option in the REPEATED statement.

**R<=value-list>**

requests that blocks of the estimated **R** matrix be displayed. The first block determined by the SUBJECT= effect is the default displayed block. PROC MIXED displays blanks for value-lists that are 0.

The *value-list* indicates the subjects for which blocks of **R** are to be displayed. For example, the following statement displays block matrices for the first, third, and fifth persons:

```
repeated / type=cs subject=person r=1,3,5;
```

See the PARMs statement for the possible forms of *value-list*. The ODS table name is R.

**RC<=value-list>**

produces the Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as with the R option. The ODS table name is CholR.

**RCI<=value-list>**

produces the inverse Cholesky root of blocks of the estimated **R** matrix. The *value-list* specification is the same as with the R option. The ODS table name is InvCholR.

**RCORR<=value-list>**

produces the correlation matrix corresponding to blocks of the estimated **R** matrix. The *value-list* specification is the same as with the R option. The table name for ODS purposes is "RCorr."

**RI<=value-list>**

produces the inverse of blocks of the estimated **R** matrix. The *value-list* specification is the same as with the R option. The ODS table name is InvR.

**SSCP**

requests that an unstructured **R** matrix be estimated from the sum-of-squares-and-crossproducts matrix of the residuals. It applies only when you specify TYPE=UN and have no RANDOM statements. Also, you must have a sufficient number of subjects for the estimate to be positive definite.

This option is useful when the size of the blocks of **R** is large (for example, greater than 10) and you want to use or inspect an unstructured estimate that is much quicker to compute than the default REML estimate. The two estimates will agree for certain balanced data sets when you have a classification fixed effect defined across all time points within a subject.

**SUBJECT=effect****SUB=effect**

identifies the subjects in your mixed model. Complete independence is assumed across subjects; therefore, the SUBJECT= option produces a block-diagonal structure in **R** with identical blocks. When the SUBJECT= effect consists entirely of classification variables, the blocks of **R** correspond to observations sharing the same level of that effect. These blocks are sorted according to this effect as well.

Continuous variables are permitted as arguments to the SUBJECT= option. PROC MIXED does not sort by the values of the continuous variable; rather, it considers the data to be from a new subject or group whenever the value of the continuous variable changes from the previous observation. Using a continuous variable decreases execution time for models with a large number of subjects or groups and also prevents the production of a large “Class Level Information” table.

If you want to model nonzero covariance among all of the observations in your SAS data set, specify SUBJECT=INTERCEPT to treat the data as if they are all from one subject. However, be aware that in this case PROC MIXED manipulates an **R** matrix with dimensions equal to the number of observations. If no SUBJECT= effect is specified, then every observation is assumed to be from a different subject and **R** is assumed to be diagonal. For this reason, you usually want to use the SUBJECT= option in the REPEATED statement.

**TYPE=covariance-structure**

specifies the covariance structure of the **R** matrix. The SUBJECT= option defines the blocks of **R**, and the TYPE= option specifies the structure of these blocks. Valid values for *covariance-structure* and their descriptions are provided in Table 59.17 and Table 59.18. The default structure is VC.

**Table 59.17** Covariance Structures

| Structure | Description          | Parms                         | (i, j) element                                                             |
|-----------|----------------------|-------------------------------|----------------------------------------------------------------------------|
| ANTE(1)   | Antedependence       | $2t - 1$                      | $\sigma_i \sigma_j \prod_{k=i}^{j-1} \rho_k$                               |

**Table 59.17** continued

| Structure | Description         | Parms                                 | (i, j) element                                                                                                                 |
|-----------|---------------------|---------------------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| UN@CS     | Direct product CS   | $t_1(t_1 + 1)/2 + 1$                  | $\begin{cases} \sigma_{i_1 j_1} & i_2 = j_2 \\ \sigma^2 \sigma_{i_1 j_1} & i_2 \neq j_2 \\ 0 \leq \sigma^2 \leq 1 \end{cases}$ |
| UN@UN     | Direct product UN   | $t_1(t_1 + 1)/2 + t_2(t_2 + 1)/2 - 1$ | $\sigma_{1,i_1 j_1} \sigma_{2,i_2 j_2}$                                                                                        |
| VC        | Variance components | $q$                                   | $\sigma_k^2 1(i = j)$<br>and $i$ corresponds to $k$ th effect                                                                  |

In Table 59.17, “Parms” is the number of covariance parameters in the structure,  $t$  is the overall dimension of the covariance matrix, and  $1(A)$  equals 1 when  $A$  is true and 0 otherwise. For example,  $1(i = j)$  equals 1 when  $i = j$  and 0 otherwise, and  $1(|i - j| < q)$  equals 1 when  $|i - j| < q$  and 0 otherwise. For the TYPE=TOEPH structures,  $\rho_0 = 1$ , and for the TYPE=UNR structures,  $\rho_{ii} = 1$  for all  $i$ . For the direct product structures, the subscripts “1” and “2” see the first and second structure in the direct product, respectively, and  $i_1 = \text{int}((i + t_2 - 1)/t_2)$ ,  $j_1 = \text{int}((j + t_2 - 1)/t_2)$ ,  $i_2 = \text{mod}(i - 1, t_2) + 1$ , and  $j_2 = \text{mod}(j - 1, t_2) + 1$ .

| SP(SPH)(c-list)                           | Spherical                                 | 2        | $\sigma^2 [1 - (\frac{3d_{ij}}{2\rho}) + (\frac{d_{ij}^3}{2\rho^3})] 1(d_{ij} \leq \rho)$                                                           |
| SP(SPHGA)(c <sub>1</sub> c <sub>2</sub> ) | 2D Spherical, geometrically anisotropic   | 4        | $\sigma^2 [1 - (\frac{3d_{ij}(\theta, \lambda)}{2\rho}) + (\frac{d_{ij}(\theta, \lambda)^3}{2\rho^3})] \times 1(d_{ij}(\theta, \lambda) \leq \rho)$ |

In Table 59.18, *c-list* contains the names of the numeric variables used as coordinates of the location of the observation in space, and  $d_{ij}$  is the Euclidean distance between the  $i$ th and  $j$ th vectors of these coordinates, which correspond to the  $i$ th and  $j$ th observations in the input data set. For SP(POWA) and SP(EXPA),  $c$  is the number of coordinates, and  $d(i, j, k)$  is the absolute distance between the  $k$ th coordinate,  $k = 1, \dots, c$ , of the  $i$ th and  $j$ th observations in the input data set. For the geometrically anisotropic structures SP(EXPGA), SP(GAUGA), and SP(SPHGA), exactly two spatial coordinate variables must be specified as  $c_1$  and  $c_2$ . Geometric anisotropy is corrected by applying a rotation  $\theta$  and scaling  $\lambda$  to the coordinate system, and  $d_{ij}(\theta, \lambda)$  represents the Euclidean distance between two points in the transformed space. SP(MATERN) and SP(MATHSW) represent covariance structures in a class defined by Matérn (see Matérn 1986; Handcock and Stein 1993; Handcock and Wallis 1994). The function  $K_\nu$  is the modified Bessel function of the second kind of (real) order  $\nu > 0$ ; the parameter  $\nu$  governs the smoothness of the process (see below for more details).

Table 59.19 lists some examples of the structures in Table 59.17 and Table 59.18.

**Table 59.19** Covariance Structure Examples

| Description                | Structure    | Example                                                                                                                                                                                                                                                      |

**Table 59.19** *continued*

| Description | Structure | Example                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------|-----------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|             |           | $\begin{bmatrix} \sigma_1^2 & \sigma_1^2\rho & \sigma_1^2\rho^2 & \sigma_{21} & \sigma_{21}\rho & \sigma_{21}\rho^2 \\ \sigma_1^2\rho & \sigma_1^2 & \sigma_1^2\rho & \sigma_{21}\rho & \sigma_{21} & \sigma_{21}\rho \\ \sigma_1^2\rho^2 & \sigma_1^2\rho & \sigma_1^2 & \sigma_{21}\rho^2 & \sigma_{21}\rho & \sigma_{21} \\ \sigma_{21} & \sigma_{21}\rho & \sigma_{21}\rho^2 & \sigma_2^2 & \sigma_2^2\rho & \sigma_2^2\rho^2 \\ \sigma_{21}\rho & \sigma_{21} & \sigma_{21}\rho & \sigma_2^2\rho & \sigma_2^2 & \sigma_2^2\rho \\ \sigma_{21}\rho^2 & \sigma_{21}\rho & \sigma_{21} & \sigma_2^2\rho^2 & \sigma_2^2\rho & \sigma_2^2 \end{bmatrix}$ |

The following provides some further information about these covariance structures:

TYPE=ANTE(1) specifies the first-order antedependence structure (see Kenward 1987; Patel 1991; Macchiavelli and Arnold 1994). In Table 59.17,  $\sigma_i^2$  is the  $i$ th variance parameter, and  $\rho_k$  is the  $k$ th autocorrelation parameter satisfying  $|\rho_k| < 1$ .

TYPE=AR(1) specifies a first-order autoregressive structure. PROC MIXED imposes the constraint  $|\rho| < 1$  for stationarity.

TYPE=ARH(1) specifies a heterogeneous first-order autoregressive structure. As with TYPE=AR(1), PROC MIXED imposes the constraint  $|\rho| < 1$  for stationarity.

TYPE=ARMA(1,1) specifies the first-order autoregressive moving-average structure. In Table 59.17,  $\rho$  is the autoregressive parameter,  $\gamma$  models a moving-average component, and  $\sigma^2$  is the residual variance. In the notation of Fuller (1976, p. 68),  $\rho = \theta_1$  and

$$\gamma = \frac{(1 + b_1\theta_1)(\theta_1 + b_1)}{1 + b_1^2 + 2b_1\theta_1}$$

The example in Table 59.19 and  $|b_1| < 1$  imply that

$$b_1 = \frac{\beta - \sqrt{\beta^2 - 4\alpha^2}}{2\alpha}$$

where  $\alpha = \gamma - \rho$  and  $\beta = 1 + \rho^2 - 2\gamma\rho$ . PROC MIXED imposes the constraints  $|\rho| < 1$  and  $|\gamma| < 1$  for stationarity, although for some values of  $\rho$  and  $\gamma$  in this region the resulting covariance matrix is not positive definite. When the estimated value of  $\rho$  becomes negative, the computed covariance is multiplied by  $\cos(\pi d_{ij})$  to account for the negativity.

TYPE=CS specifies the compound-symmetry structure, which has constant variance and constant covariance.

TYPE=CSH specifies the heterogeneous compound-symmetry structure. This structure has a different variance parameter for each diagonal element, and it uses the square roots of these parameters in the off-diagonal entries. In Table 59.17,  $\sigma_i^2$  is the  $i$ th variance parameter, and  $\rho$  is the correlation parameter satisfying  $|\rho| < 1$ .

TYPE=FA( $q$ ) specifies the factor-analytic structure with  $q$  factors (Jennrich and Schluchter 1986). This structure is of the form  $\mathbf{\Lambda}\mathbf{\Lambda}' + \mathbf{D}$ , where  $\mathbf{\Lambda}$  is a  $t \times q$  rectangular matrix and  $\mathbf{D}$  is a  $t \times t$  diagonal matrix with  $t$  different parameters. When  $q > 1$ , the elements of  $\mathbf{\Lambda}$  in its upper-right corner (that is, the elements in the  $i$ th row and  $j$ th column for  $j > i$ ) are set to zero to fix the rotation of the structure.

- TYPE=FA0(*q*)** is similar to the **FA(*q*)** structure except that no diagonal matrix **D** is included. When  $q < t$ —that is, when the number of factors is less than the dimension of the matrix—this structure is nonnegative definite but not of full rank. In this situation, you can use it for approximating an unstructured **G** matrix in the **RANDOM** statement or for combining with the **LOCAL** option in the **REPEATED** statement. When  $q = t$ , you can use this structure to constrain **G** to be nonnegative definite in the **RANDOM** statement.
- TYPE=FA1(*q*)** is similar to the **TYPE=FA(*q*)** structure except that all of the elements in **D** are constrained to be equal. This offers a useful and more parsimonious alternative to the full factor-analytic structure.
- TYPE=HF** specifies the Huynh-Feldt covariance structure (Huynh and Feldt 1970). This structure is similar to the **TYPE=CSH** structure in that it has the same number of parameters and heterogeneity along the main diagonal. However, it constructs the off-diagonal elements by taking arithmetic rather than geometric means.
- You can perform a likelihood ratio test of the Huynh-Feldt conditions by running PROC MIXED twice, once with **TYPE=HF** and once with **TYPE=UN**, and then subtracting their respective values of  $-2$  times the maximized likelihood.
- If PROC MIXED does not converge under your Huynh-Feldt model, you can specify your own starting values with the **PARMS** statement. The default **MIVQUE(0)** starting values can sometimes be poor for this structure. A good choice for starting values is often the parameter estimates corresponding to an initial fit that uses **TYPE=CS**.
- TYPE=LIN(*q*)** specifies the general linear covariance structure with  $q$  parameters. This structure consists of a linear combination of known matrices that are input with the **LDATA=** option. This structure is very general, and you need to make sure that the variance matrix is positive definite. By default, PROC MIXED sets the initial values of the parameters to 1. You can use the **PARMS** statement to specify other initial values.
- TYPE=LINEAR(*q*)** is an alias for **TYPE=LIN(*q*)**.
- TYPE=SIMPLE** is an alias for **TYPE=VC**.
- TYPE=SP(EXPA)(*c-list*)** specifies the spatial anisotropic exponential structure, where *c-list* is a list of variables indicating the coordinates. This structure has (*i, j*) element equal to

$$\sigma^2 \prod_{k=1}^c \exp\{-\theta_k d(i, j, k)^{p_k}\}$$

where  $c$  is the number of coordinates and  $d(i, j, k)$  is the absolute distance between the  $k$ th coordinate ( $k = 1, \dots, c$ ) of the  $i$ th and  $j$ th observations in the input data set. There are  $2c + 1$  parameters to be estimated:  $\theta_k$ ,  $p_k$  ( $k = 1, \dots, c$ ), and  $\sigma^2$ .

You might want to constrain some of the EXPA parameters to known values. For example, suppose you have three coordinate variables **C1**, **C2**, and **C3** and you want to constrain the powers  $p_k$  to equal 2, as in Sacks et al. (1989). Suppose further that you want to model covariance across the entire input data set and you suspect the  $\theta_k$  and  $\sigma^2$  estimates are close to 3, 4, 5, and 1, respectively. Then specify the following statements:

```

repeated / type=sp(expa) (c1 c2 c3)
 subject=intercept;
parms (3) (4) (5) (2) (2) (2) (1) /
 hold=4, 5, 6;

```

TYPE=SP(EXPGA)(c<sub>1</sub> c<sub>2</sub>) specify modification of the isotropic SP(EXP) covariance structure.

TYPE=SP(GAUGA)(c<sub>1</sub> c<sub>2</sub>) specify modification of the isotropic SP(GAU) covariance structure.

TYPE=SP(SPHGA)(c<sub>1</sub> c<sub>2</sub>) specify modification of the isotropic SP(SPH) covariance structure.

These are structures that allow for geometric anisotropy in two dimensions. The coordinates are specified by the variables c<sub>1</sub> and c<sub>2</sub>.

If the spatial process is geometrically anisotropic in  $\mathbf{c} = [c_{i1}, c_{i2}]$ , then it is isotropic in the coordinate system

$$\mathbf{Ac} = \begin{bmatrix} 1 & 0 \\ 0 & \lambda \end{bmatrix} \begin{bmatrix} \cos \theta & -\sin \theta \\ \sin \theta & \cos \theta \end{bmatrix} \mathbf{c} = \mathbf{c}^*$$

for a properly chosen angle  $\theta$  and scaling factor  $\lambda$ . Elliptical isocorrelation contours are thereby transformed to spherical contours, adding two parameters to the respective isotropic covariance structures. Euclidean distances (see Table 59.18) are expressed in terms of  $\mathbf{c}^*$ .

The angle  $\theta$  of the clockwise rotation is reported in radians,  $0 \leq \theta \leq 2\pi$ . The scaling parameter  $\lambda$  represents the ratio of the range parameters in the direction of the major and minor axis of the correlation contours. In other words, following a rotation of the coordinate system by angle  $\theta$ , isotropy is achieved by compressing or magnifying distances in one coordinate by the factor  $\lambda$ .

Fixing  $\lambda = 1.0$  reduces the models to isotropic ones for any angle of rotation. If the scaling parameter is held constant at 1.0, you should also hold constant the angle of rotation, as in the following statements:

```

repeated / type=sp(expga) (gxc gyc)
 subject=intercept;
parms (6) (1.0) (0.0) (1) / hold=2, 3;

```

If  $\lambda$  is fixed at any other value than 1.0, the angle of rotation can be estimated. Specifying a starting grid of angles and scaling factors can considerably improve the convergence properties of the optimization algorithm for these models. Only a single random effect with geometrically anisotropic structure is permitted.

TYPE=SP(MATERN)(c-list) | TYPE=SP(MATHSW)(c-list) specifies covariance structures in the Matérn class of covariance functions (Matérn 1986). Two observations for the same subject (block of  $\mathbf{R}$ ) that are Euclidean distance  $d_{ij}$  apart have covariance

$$\sigma^2 \frac{1}{\Gamma(\nu)} \left( \frac{d_{ij}}{2\rho} \right)^\nu 2K_\nu(d_{ij}/\rho) \quad \nu > 0, \rho > 0$$

where  $K_\nu$  is the modified Bessel function of the second kind of (real) order  $\nu > 0$ . The smoothness (continuity) of a stochastic process with covariance function in this class increases with  $\nu$ . The Matérn class thus enables data-driven estimation

of the smoothness properties. The covariance is identical to the exponential model for  $\nu = 0.5$  (TYPE=SP(EXP)(*c-list*)), while for  $\nu = 1$  the model advocated by Whittle (1954) results. As  $\nu \rightarrow \infty$  the model approaches the gaussian covariance structure (TYPE=SP(GAU)(*c-list*)).

The MATHSW structure represents the Matérn class in the parameterization of Handcock and Stein (1993) and Handcock and Wallis (1994),

$$\sigma^2 \frac{1}{\Gamma(\nu)} \left( \frac{d_{ij} \sqrt{\nu}}{\rho} \right)^\nu 2K_\nu \left( \frac{2d_{ij} \sqrt{\nu}}{\rho} \right)$$

Since computation of the function  $K_\nu$  and its derivatives is numerically very intensive, fitting models with Matérn covariance structures can be more time-consuming than with other spatial covariance structures. Good starting values are essential.

TYPE=SP(POW)(*c-list*) | TYPE=SP(POWA)(*c-list*) specifies the spatial power structures. When the estimated value of  $\rho$  becomes negative, the computed covariance is multiplied by  $\cos(\pi d_{ij})$  to account for the negativity.

TYPE=TOEP(*q*) specifies a banded Toeplitz structure. This can be viewed as a moving-average structure with order equal to  $q - 1$ . The TYPE=TOEP option is a full Toeplitz matrix, which can be viewed as an autoregressive structure with order equal to the dimension of the matrix. The specification TYPE=TOEP(1) is the same as  $\sigma^2 I$ , where  $I$  is an identity matrix, and it can be useful for specifying the same variance component for several effects.

TYPE=TOEPH(*q*) specifies a heterogeneous banded Toeplitz structure. In Table 59.17,  $\sigma_i^2$  is the  $i$ th variance parameter and  $\rho_j$  is the  $j$ th correlation parameter satisfying  $|\rho_j| < 1$ . If you specify the order parameter  $q$ , then PROC MIXED estimates only the first  $q$  bands of the matrix, setting all higher bands equal to 0. The option TOEPH(1) is equivalent to both the TYPE=UN(1) and TYPE=UNR(1) options.

TYPE=UN(*q*) specifies a completely general (unstructured) covariance matrix parameterized directly in terms of variances and covariances. The variances are constrained to be nonnegative, and the covariances are unconstrained. This structure is not constrained to be nonnegative definite in order to avoid nonlinear constraints; however, you can use the TYPE=FA0 structure if you want this constraint to be imposed by a Cholesky factorization. If you specify the order parameter  $q$ , then PROC MIXED estimates only the first  $q$  bands of the matrix, setting all higher bands equal to 0.

TYPE=UNR(*q*) specifies a completely general (unstructured) covariance matrix parameterized in terms of variances and correlations. This structure fits the same model as the TYPE=UN(*q*) option but with a different parameterization. The  $i$ th variance parameter is  $\sigma_i^2$ . The parameter  $\rho_{jk}$  is the correlation between the  $j$ th and  $k$ th measurements; it satisfies  $|\rho_{jk}| < 1$ . If you specify the order parameter  $r$ , then PROC MIXED estimates only the first  $q$  bands of the matrix, setting all higher bands equal to zero.

TYPE=UN@AR(1) | TYPE=UN@CS | TYPE=UN@UN specify direct (Kronecker) product structures designed for multivariate repeated measures (see Galecki 1994). These structures are constructed by taking the Kronecker product of an unstructured matrix

(modeling covariance across the multivariate observations) with an additional covariance matrix (modeling covariance across time or another factor). The upper-left value in the second matrix is constrained to equal 1 to identify the model. See the *SAS/IML User's Guide* for more details about direct products.

To use these structures in the REPEATED statement, you must specify two distinct REPEATED effects, both of which must be included in the CLASS statement. The first effect indicates the multivariate observations, and the second identifies the levels of time or some additional factor. Note that the input data set must still be constructed in “univariate” format; that is, all dependent observations are still listed observation-wise in one single variable. Although this construction provides for general modeling possibilities, it forces you to construct variables indicating both dimensions of the Kronecker product.

For example, suppose your observed data consist of heights and weights of several children measured over several successive years. Your input data set should then contain variables similar to the following:

- Y, all of the heights and weights, with a separate observation for each
- Var, indicating whether the measurement is a height or a weight
- Year, indicating the year of measurement
- Child, indicating the child on which the measurement was taken

Your PROC MIXED statements for a Kronecker AR(1) structure across years would then be as follows:

```
proc mixed;
 class Var Year Child;
 model Y = Var Year Var*Year;
 repeated Var Year / type=un@ar(1)
 subject=Child;
run;
```

You should nearly always want to model different means for the multivariate observations; hence the inclusion of Var in the MODEL statement. The preceding mean model consists of cell means for all combinations of VAR and YEAR.

TYPE=VC specifies standard variance components and is the default structure for both the RANDOM and REPEATED statements. In the RANDOM statement, a distinct variance component is assigned to each effect. In the REPEATED statement, this structure is usually used only with the GROUP= option to specify a heterogeneous variance model.

Jennrich and Schluchter (1986) provide general information about the use of covariance structures, and Wolfinger (1996) presents details about many of the heterogeneous structures. Modeling with spatial covariance structures is discussed in many sources (Marx and Thompson 1987; Zimmerman and Harville 1991; Cressie 1993; Brownie, Bowman, and Burton 1993; Stroup, Baenziger, and Moltipz 1994; Brownie and Gumpertz 1997; Gotway and Stroup 1997; Chilès and Delfiner 1999; Schabenberger and Gotway 2005; Littell et al. 2006).

---

## SLICE Statement

**SLICE** *model-effect* </ options > ;

The SLICE statement provides a general mechanism for performing a partitioned analysis of the LS-means for an interaction. This analysis is also known as an analysis of simple effects.

The SLICE statement uses the same options as the LSMEANS statement, which are summarized in Table 19.21. For details about the syntax of the SLICE statement, see the section “SLICE Statement” on page 498 in Chapter 19, “Shared Concepts and Topics.”

**NOTE:** Use the section “LSMEANS Statement” on page 453 of Chapter 19, “Shared Concepts and Topics.” only for definitions of the options that you can use with the SLICE statement. PROC MIXED uses a slightly different syntax for the LSMEANS, which is described in the section “LSMEANS Statement” on page 491.

---

## STORE Statement

**STORE** < OUT= > *item-store-name* </ LABEL= 'label' > ;

The STORE statement requests that the procedure save the context and results of the statistical analysis. The resulting item store has a binary file format that cannot be modified. The contents of the item store can be processed with the PLM procedure.

For details about the syntax of the STORE statement, see the section “STORE Statement” on page 501 in Chapter 19, “Shared Concepts and Topics.”

---

## WEIGHT Statement

**WEIGHT** *variable* ;

If you do not specify a REPEATED statement, the WEIGHT statement operates exactly like the one in PROC GLM. In this case PROC MIXED replaces  $X'X$  and  $Z'Z$  with  $X'WX$  and  $Z'WZ$ , where  $W$  is the diagonal weight matrix. If you specify a REPEATED statement, then the WEIGHT statement replaces  $R$  with  $LRL$ , where  $L$  is a diagonal matrix with elements  $W^{-1/2}$ . Observations with nonpositive or missing weights are not included in the PROC MIXED analysis.

If a computation in PROC MIXED involves  $R$ , then the WEIGHT statement replaces  $R$  with  $W^{-1/2}RW^{-1/2}$ . For example, the covariance matrix  $V$  for the observations usually have the form  $V = ZGZ' + R$ , which with the WEIGHT statement becomes  $V = ZGZ' + W^{-1/2}RW^{-1/2}$ .

## Details: MIXED Procedure

---

### Mixed Models Theory

This section provides an overview of a likelihood-based approach to general linear mixed models. This approach simplifies and unifies many common statistical analyses, including those involving repeated mea-

tures, random effects, and random coefficients. The basic assumption is that the data are linearly related to unobserved multivariate normal random variables. For extensions to nonlinear and nonnormal situations see the documentation of the GLIMMIX and NLMIXED procedures. Additional theory and examples are provided in Littell et al. (2006); Verbeke and Molenberghs (1997, 2000); Brown and Prescott (1999).

## Matrix Notation

Suppose that you observe  $n$  data points  $y_1, \dots, y_n$  and that you want to explain them by using  $n$  values for each of  $p$  explanatory variables  $x_{11}, \dots, x_{1p}, x_{21}, \dots, x_{2p}, \dots, x_{n1}, \dots, x_{np}$ . The  $x_{ij}$  values can be either regression-type continuous variables or dummy variables indicating class membership. The standard linear model for this setup is

$$y_i = \sum_{j=1}^p x_{ij} \beta_j + \epsilon_i \quad i = 1, \dots, n$$

where  $\beta_1, \dots, \beta_p$  are unknown *fixed-effects* parameters to be estimated and  $\epsilon_1, \dots, \epsilon_n$  are unknown independent and identically distributed normal (Gaussian) random variables with mean 0 and variance  $\sigma^2$ .

The preceding equations can be written simultaneously by using vectors and a matrix, as follows:

$$\begin{bmatrix} y_1 \\ y_2 \\ \vdots \\ y_n \end{bmatrix} = \begin{bmatrix} x_{11} & x_{12} & \dots & x_{1p} \\ x_{21} & x_{22} & \dots & x_{2p} \\ \vdots & \vdots & & \vdots \\ x_{n1} & x_{n2} & \dots & x_{np} \end{bmatrix} \begin{bmatrix} \beta_1 \\ \beta_2 \\ \vdots \\ \beta_p \end{bmatrix} + \begin{bmatrix} \epsilon_1 \\ \epsilon_2 \\ \vdots \\ \epsilon_n \end{bmatrix}$$

For convenience, simplicity, and extendability, this entire system is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \boldsymbol{\epsilon}$$

where  $\mathbf{y}$  denotes the vector of observed  $y_i$ 's,  $\mathbf{X}$  is the known matrix of  $x_{ij}$ 's,  $\boldsymbol{\beta}$  is the unknown fixed-effects parameter vector, and  $\boldsymbol{\epsilon}$  is the unobserved vector of independent and identically distributed Gaussian random errors.

In addition to denoting data, random variables, and explanatory variables in the preceding fashion, the subsequent development makes use of basic matrix operators such as transpose ( $'$ ), inverse ( $^{-1}$ ), generalized inverse ( $^{-}$ ), determinant ( $|\cdot|$ ), and matrix multiplication. See Searle (1982) for details about these and other matrix techniques.

## Formulation of the Mixed Model

The previous general linear model is certainly a useful one (Searle 1971), and it is the one fitted by the GLM procedure. However, many times the distributional assumption about  $\boldsymbol{\epsilon}$  is too restrictive. The mixed model extends the general linear model by allowing a more flexible specification of the covariance matrix of  $\boldsymbol{\epsilon}$ . In other words, it allows for both correlation and heterogeneous variances, although you still assume normality.

The mixed model is written as

$$\mathbf{y} = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma} + \boldsymbol{\epsilon}$$

where everything is the same as in the general linear model except for the addition of the known design matrix,  $\mathbf{Z}$ , and the vector of unknown *random-effects parameters*,  $\boldsymbol{\gamma}$ . The matrix  $\mathbf{Z}$  can contain either continuous or dummy variables, just like  $\mathbf{X}$ . The name *mixed model* comes from the fact that the model contains both fixed-effects parameters,  $\boldsymbol{\beta}$ , and random-effects parameters,  $\boldsymbol{\gamma}$ . See Henderson (1990) and Searle, Casella, and McCulloch (1992) for historical developments of the mixed model.

A key assumption in the foregoing analysis is that  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$  are normally distributed with

$$\begin{aligned} \text{E} \begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} &= \begin{bmatrix} \mathbf{0} \\ \mathbf{0} \end{bmatrix} \\ \text{Var} \begin{bmatrix} \boldsymbol{\gamma} \\ \boldsymbol{\epsilon} \end{bmatrix} &= \begin{bmatrix} \mathbf{G} & \mathbf{0} \\ \mathbf{0} & \mathbf{R} \end{bmatrix} \end{aligned}$$

The variance of  $\mathbf{y}$  is, therefore,  $\mathbf{V} = \mathbf{ZGZ}' + \mathbf{R}$ . You can model  $\mathbf{V}$  by setting up the random-effects design matrix  $\mathbf{Z}$  and by specifying covariance structures for  $\mathbf{G}$  and  $\mathbf{R}$ .

Note that this is a general specification of the mixed model, in contrast to many texts and articles that discuss only simple random effects. Simple random effects are a special case of the general specification with  $\mathbf{Z}$  containing dummy variables,  $\mathbf{G}$  containing variance components in a diagonal structure, and  $\mathbf{R} = \sigma^2\mathbf{I}_n$ , where  $\mathbf{I}_n$  denotes the  $n \times n$  identity matrix. The general linear model is a further special case with  $\mathbf{Z} = \mathbf{0}$  and  $\mathbf{R} = \sigma^2\mathbf{I}_n$ .

The following two examples illustrate the most common formulations of the general linear mixed model.

**Example: Growth Curve with Compound Symmetry**

Suppose that you have three growth curve measurements for  $s$  individuals and that you want to fit an overall linear trend in time. Your  $\mathbf{X}$  matrix is as follows:

$$\mathbf{X} = \begin{bmatrix} 1 & 1 \\ 1 & 2 \\ 1 & 3 \\ \vdots & \vdots \\ 1 & 1 \\ 1 & 2 \\ 1 & 3 \end{bmatrix}$$

The first column (coded entirely with 1s) fits an intercept, and the second column (coded with times of 1, 2, 3) fits a slope. Here,  $n = 3s$  and  $p = 2$ .

Suppose further that you want to introduce a common correlation among the observations from a single individual, with correlation being the same for all individuals. One way of setting this up in the general mixed model is to eliminate the  $\mathbf{Z}$  and  $\mathbf{G}$  matrices and let the  $\mathbf{R}$  matrix be block diagonal with blocks corresponding to the individuals and with each block having the *compound-symmetry* structure. This structure has two unknown parameters, one modeling a common covariance and the other modeling a residual variance. The

In many situations, the best approach is to use *likelihood-based* methods, exploiting the assumption that  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$  are normally distributed (Hartley and Rao 1967; Patterson and Thompson 1971; Harville 1977; Laird and Ware 1982; Jennrich and Schluchter 1986). PROC MIXED implements two likelihood-based methods: *maximum likelihood* (ML) and *restricted/residual maximum likelihood* (REML). A favorable theoretical property of ML and REML is that they accommodate data that are missing at random (Rubin 1976; Little 1995).

PROC MIXED constructs an objective function associated with ML or REML and maximizes it over all unknown parameters. Using calculus, it is possible to reduce this maximization problem to one over only the parameters in  $\mathbf{G}$  and  $\mathbf{R}$ . The corresponding log-likelihood functions are as follows:

$$\begin{aligned} \text{ML : } \quad l(\mathbf{G}, \mathbf{R}) &= -\frac{1}{2} \log |\mathbf{V}| - \frac{1}{2} \mathbf{r}' \mathbf{V}^{-1} \mathbf{r} - \frac{n}{2} \log(2\pi) \\ \text{REML : } \quad l_R(\mathbf{G}, \mathbf{R}) &= -\frac{1}{2} \log |\mathbf{V}| - \frac{1}{2} \log |\mathbf{X}' \mathbf{V}^{-1} \mathbf{X}| - \frac{1}{2} \mathbf{r}' \mathbf{V}^{-1} \mathbf{r} - \frac{n-p}{2} \log(2\pi) \end{aligned}$$

where  $\mathbf{r} = \mathbf{y} - \mathbf{X}(\mathbf{X}' \mathbf{V}^{-1} \mathbf{X})^{-1} \mathbf{X}' \mathbf{V}^{-1} \mathbf{y}$  and  $p$  is the rank of  $\mathbf{X}$ . PROC MIXED actually minimizes  $-2$  times these functions by using a ridge-stabilized Newton-Raphson algorithm. Lindstrom and Bates (1988) provide reasons for preferring Newton-Raphson to the Expectation-Maximum (EM) algorithm (Dempster, Laird, and Rubin 1977; Laird, Lange, and Stram 1987), as well as analytical details for implementing a QR-decomposition approach to the problem. Wolfinger, Tobias, and Sall (1994) present the sweep-based algorithms that are implemented in PROC MIXED.

One advantage of using the Newton-Raphson algorithm is that the second derivative matrix of the objective function evaluated at the optima is available upon completion. Denoting this matrix  $\mathbf{H}$ , the asymptotic theory of maximum likelihood (see Serfling 1980) shows that  $2\mathbf{H}^{-1}$  is an asymptotic variance-covariance matrix of the estimated parameters of  $\mathbf{G}$  and  $\mathbf{R}$ . Thus, tests and confidence intervals based on asymptotic normality can be obtained. However, these can be unreliable in small samples, especially for parameters such as variance components that have sampling distributions that tend to be skewed to the right.

If a residual variance  $\sigma^2$  is a part of your mixed model, it can usually be *profiled* out of the likelihood. This means solving analytically for the optimal  $\sigma^2$  and plugging this expression back into the likelihood formula (see Wolfinger, Tobias, and Sall 1994). This reduces the number of optimization parameters by one and can improve convergence properties. PROC MIXED profiles the residual variance out of the log likelihood whenever it appears reasonable to do so. This includes the case when  $\mathbf{R}$  equals  $\sigma^2 \mathbf{I}$  and when it has blocks with a compound symmetry, time series, or spatial structure. PROC MIXED does not profile the log likelihood when  $\mathbf{R}$  has unstructured blocks, when you use the **HOLD=** or **NOITER** option in the **PARMS** statement, or when you use the **NOPROFILE** option in the **PROC MIXED** statement.

Instead of ML or REML, you can use the noniterative MIVQUE0 method to estimate  $\mathbf{G}$  and  $\mathbf{R}$  (Rao 1972; LaMotte 1973; Wolfinger, Tobias, and Sall 1994). In fact, by default PROC MIXED uses MIVQUE0 estimates as starting values for the ML and REML procedures. For variance component models, another estimation method involves equating Type 1, 2, or 3 expected mean squares to their observed values and solving the resulting system. However, Swallow and Monahan (1984) present simulation evidence favoring REML and ML over MIVQUE0 and other method-of-moment estimators.

## Estimating Fixed and Random Effects in the Mixed Model

ML, REML, MIVQUE0, or Type1–Type3 provide estimates of  $\mathbf{G}$  and  $\mathbf{R}$ , which are denoted  $\hat{\mathbf{G}}$  and  $\hat{\mathbf{R}}$ , respectively. To obtain estimates of  $\boldsymbol{\beta}$  and  $\boldsymbol{\gamma}$ , the standard method is to solve the *mixed model equations* (Henderson 1984):

$$\begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z} + \widehat{\mathbf{G}}^{-1} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\boldsymbol{\gamma}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \\ \mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

The solutions can also be written as

$$\begin{aligned} \widehat{\boldsymbol{\beta}} &= (\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{y} \\ \widehat{\boldsymbol{\gamma}} &= \widehat{\mathbf{G}}\mathbf{Z}'\widehat{\mathbf{V}}^{-1}(\mathbf{y} - \mathbf{X}\widehat{\boldsymbol{\beta}}) \end{aligned}$$

and have connections with empirical Bayes estimators (Laird and Ware 1982; Carlin and Louis 1996).

Note that the mixed model equations are extended normal equations and that the preceding expression assumes that  $\widehat{\mathbf{G}}$  is nonsingular. For the extreme case where the eigenvalues of  $\widehat{\mathbf{G}}$  are very large,  $\widehat{\mathbf{G}}^{-1}$  contributes very little to the equations and  $\widehat{\boldsymbol{\gamma}}$  is close to what it would be if  $\boldsymbol{\gamma}$  actually contained fixed-effects parameters. On the other hand, when the eigenvalues of  $\widehat{\mathbf{G}}$  are very small,  $\widehat{\mathbf{G}}^{-1}$  dominates the equations and  $\widehat{\boldsymbol{\gamma}}$  is close to 0. For intermediate cases,  $\widehat{\mathbf{G}}^{-1}$  can be viewed as shrinking the fixed-effects estimates of  $\boldsymbol{\gamma}$  toward 0 (Robinson 1991).

If  $\widehat{\mathbf{G}}$  is singular, then the mixed model equations are modified (Henderson 1984) as follows:

$$\begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{Z}\widehat{\mathbf{G}} \\ \widehat{\mathbf{G}}'\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{X} & \widehat{\mathbf{G}}'\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{Z}\widehat{\mathbf{G}} + \mathbf{G} \end{bmatrix} \begin{bmatrix} \widehat{\boldsymbol{\beta}} \\ \widehat{\boldsymbol{\tau}} \end{bmatrix} = \begin{bmatrix} \mathbf{X}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \\ \widehat{\mathbf{G}}'\mathbf{Z}'\widehat{\mathbf{R}}^{-1}\mathbf{y} \end{bmatrix}$$

Denote the generalized inverses of the nonsingular  $\widehat{\mathbf{G}}$  and singular  $\widehat{\mathbf{G}}$  forms of the mixed model equations by  $\mathbf{C}$  and  $\mathbf{M}$ , respectively. In the nonsingular case, the solution  $\widehat{\boldsymbol{\gamma}}$  estimates the random effects directly, but in the singular case the estimates of random effects are achieved through a back-transformation  $\widehat{\boldsymbol{\gamma}} = \widehat{\mathbf{G}}\widehat{\boldsymbol{\tau}}$  where  $\widehat{\boldsymbol{\tau}}$  is the solution to the modified mixed model equations. Similarly, while in the nonsingular case  $\mathbf{C}$  itself is the estimated covariance matrix for  $(\widehat{\boldsymbol{\beta}}, \widehat{\boldsymbol{\gamma}})$ , in the singular case the covariance estimate for  $(\widehat{\boldsymbol{\beta}}, \widehat{\mathbf{G}}\widehat{\boldsymbol{\tau}})$  is given by  $\mathbf{PMP}$  where

$$\mathbf{P} = \begin{bmatrix} \mathbf{I} & \\ & \widehat{\mathbf{G}} \end{bmatrix}$$

An example of when the singular form of the equations is necessary is when a variance component estimate falls on the boundary constraint of 0.

## Model Selection

The previous section on estimation assumes the specification of a mixed model in terms of  $\mathbf{X}$ ,  $\mathbf{Z}$ ,  $\mathbf{G}$ , and  $\mathbf{R}$ . Even though  $\mathbf{X}$  and  $\mathbf{Z}$  have known elements, their specific form and construction are flexible, and several possibilities can present themselves for a particular data set. Likewise, several different covariance structures for  $\mathbf{G}$  and  $\mathbf{R}$  might be reasonable.

Space does not permit a thorough discussion of model selection, but a few brief comments and references are in order. First, subject matter considerations and objectives are of great importance when selecting a model; see Diggle (1988) and Lindsey (1993).

Second, when the data themselves are looked to for guidance, many of the graphical methods and diagnostics appropriate for the general linear model extend to the mixed model setting as well (Christensen, Pearson, and Johnson 1992).

Finally, a likelihood-based approach to the mixed model provides several statistical measures for model adequacy as well. The most common of these are the likelihood ratio test and Akaike's and Schwarz's criteria (Bozdogan 1987; Wolfinger 1993; Keselman et al. 1998, 1999).

### Statistical Properties

If  $\mathbf{G}$  and  $\mathbf{R}$  are known,  $\hat{\boldsymbol{\beta}}$  is the *best linear unbiased estimator* (BLUE) of  $\boldsymbol{\beta}$ , and  $\hat{\boldsymbol{\gamma}}$  is the *best linear unbiased predictor* (BLUP) of  $\boldsymbol{\gamma}$  (Searle 1971; Harville 1988, 1990; Robinson 1991; McLean, Sanders, and Stroup 1991). Here, "best" means minimum mean squared error. The covariance matrix of  $(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}, \hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})$  is

$$\mathbf{C} = \begin{bmatrix} \mathbf{X}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{X}'\mathbf{R}^{-1}\mathbf{Z} \\ \mathbf{Z}'\mathbf{R}^{-1}\mathbf{X} & \mathbf{Z}'\mathbf{R}^{-1}\mathbf{Z} + \mathbf{G}^{-1} \end{bmatrix}^{-}$$

where  $^{-}$  denotes a generalized inverse (see Searle 1971).

However,  $\mathbf{G}$  and  $\mathbf{R}$  are usually unknown and are estimated by using one of the aforementioned methods. These estimates,  $\hat{\mathbf{G}}$  and  $\hat{\mathbf{R}}$ , are therefore simply substituted into the preceding expression to obtain

$$\hat{\mathbf{C}} = \begin{bmatrix} \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{X}'\hat{\mathbf{R}}^{-1}\mathbf{Z} \\ \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{X} & \mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1} \end{bmatrix}^{-}$$

as the approximate variance-covariance matrix of  $(\hat{\boldsymbol{\beta}} - \boldsymbol{\beta}, \hat{\boldsymbol{\gamma}} - \boldsymbol{\gamma})$ . In this case, the BLUE and BLUP acronyms no longer apply, but the word *empirical* is often added to indicate such an approximation. The appropriate acronyms thus become EBLUE and EBLUP.

McLean and Sanders (1988) show that  $\hat{\mathbf{C}}$  can also be written as

$$\hat{\mathbf{C}} = \begin{bmatrix} \hat{\mathbf{C}}_{11} & \hat{\mathbf{C}}'_{21} \\ \hat{\mathbf{C}}_{21} & \hat{\mathbf{C}}_{22} \end{bmatrix}$$

where

$$\hat{\mathbf{C}}_{11} = (\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-}$$

$$\hat{\mathbf{C}}_{21} = -\hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}\mathbf{X}\hat{\mathbf{C}}_{11}$$

$$\hat{\mathbf{C}}_{22} = (\mathbf{Z}'\hat{\mathbf{R}}^{-1}\mathbf{Z} + \hat{\mathbf{G}}^{-1})^{-1} - \hat{\mathbf{C}}_{21}\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{Z}\hat{\mathbf{G}}$$

Note that  $\hat{\mathbf{C}}_{11}$  is the familiar estimated generalized least squares formula for the variance-covariance matrix of  $\hat{\boldsymbol{\beta}}$ .

As a cautionary note,  $\hat{\mathbf{C}}$  tends to underestimate the true sampling variability of  $(\hat{\boldsymbol{\beta}}, \hat{\boldsymbol{\gamma}})$  because no account is made for the uncertainty in estimating  $\mathbf{G}$  and  $\mathbf{R}$ . Although inflation factors have been proposed (Kackar and Harville 1984; Kass and Steffey 1989; Prasad and Rao 1990), they tend to be small for data sets that are fairly well balanced. PROC MIXED does not compute any inflation factors by default, but rather accounts for the downward bias by using the approximate  $t$  and  $F$  statistics described subsequently. The `DDFM=KENWARDROGER` option in the `MODEL` statement prompts PROC MIXED to compute a specific inflation factor along with Satterthwaite-based degrees of freedom.

## Inference and Test Statistics

For inferences concerning the covariance parameters in your model, you can use likelihood-based statistics. One common likelihood-based statistic is the *Wald Z*, which is computed as the parameter estimate divided by its asymptotic standard error. The asymptotic standard errors are computed from the inverse of the second derivative matrix of the likelihood with respect to each of the covariance parameters. The *Wald Z* is valid for large samples, but it can be unreliable for small data sets and for parameters such as variance components, which are known to have a skewed or bounded sampling distribution.

A better alternative is the likelihood ratio  $\chi^2$  statistic. This statistic compares two covariance models, one a special case of the other. To compute it, you must run PROC MIXED twice, once for each of the two models, and then subtract the corresponding values of  $-2$  times the log likelihoods. You can use either ML or REML to construct this statistic, which tests whether the full model is necessary beyond the reduced model.

As long as the reduced model does not occur on the boundary of the covariance parameter space, the  $\chi^2$  statistic computed in this fashion has a large-sample  $\chi^2$  distribution that is  $\chi^2$  with degrees of freedom equal to the difference in the number of covariance parameters between the two models. If the reduced model does occur on the boundary of the covariance parameter space, the asymptotic distribution becomes a mixture of  $\chi^2$  distributions (Self and Liang 1987). A common example of this is when you are testing that a variance component equals its lower boundary constraint of 0.

A final possibility for obtaining inferences concerning the covariance parameters is to simulate or resample data from your model and construct empirical sampling distributions of the parameters. The SAS macro language and the ODS system are useful tools in this regard.

### *F* and *t* Tests for Fixed- and Random-Effects Parameters

For inferences concerning the fixed- and random-effects parameters in the mixed model, consider estimable linear combinations of the following form:

$$\mathbf{L} \begin{bmatrix} \boldsymbol{\beta} \\ \boldsymbol{\gamma} \end{bmatrix}$$

The estimability requirement (Searle 1971) applies only to the  $\boldsymbol{\beta}$  portion of  $\mathbf{L}$ , because any linear combination of  $\boldsymbol{\gamma}$  is estimable. Such a formulation in terms of a general  $\mathbf{L}$  matrix encompasses a wide variety of common inferential procedures such as those employed with Type 1–Type 3 tests and LS-means. The **CONTRAST** and **ESTIMATE** statements in PROC MIXED enable you to specify your own  $\mathbf{L}$  matrices. Typically, inference on fixed effects is the focus, and, in this case, the  $\boldsymbol{\gamma}$  portion of  $\mathbf{L}$  is assumed to contain all 0s.

Statistical inferences are obtained by testing the hypothesis

$$H : \mathbf{L} \begin{bmatrix} \boldsymbol{\beta} \\ \boldsymbol{\gamma} \end{bmatrix} = 0$$

or by constructing point and interval estimates.

When  $\mathbf{L}$  consists of a single row, a general *t* statistic can be constructed as follows (see McLean and Sanders 1988; Stroup 1989a):

$$t = \frac{\mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}}{\sqrt{\mathbf{L}\widehat{\mathbf{C}}\mathbf{L}'}}$$

Under the assumed normality of  $\boldsymbol{\gamma}$  and  $\boldsymbol{\epsilon}$ ,  $t$  has an exact  $t$  distribution only for data exhibiting certain types of balance and for some special unbalanced cases. In general,  $t$  is only approximately  $t$ -distributed, and its degrees of freedom must be estimated. See the `DDFM=` option for a description of the various degrees-of-freedom methods available in PROC MIXED.

With  $\hat{\nu}$  being the approximate degrees of freedom, the associated confidence interval is

$$\mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix} \pm t_{\hat{\nu}, \alpha/2} \sqrt{\mathbf{L}\hat{\mathbf{C}}\mathbf{L}'}$$

where  $t_{\hat{\nu}, \alpha/2}$  is the  $(1 - \alpha/2)100$  percentile of the  $t_{\hat{\nu}}$  distribution.

When the rank of  $\mathbf{L}$  is greater than 1, PROC MIXED constructs the following general  $F$  statistic:

$$F = \frac{\begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}' \mathbf{L}'(\mathbf{L}\hat{\mathbf{C}}\mathbf{L}')^{-1} \mathbf{L} \begin{bmatrix} \hat{\boldsymbol{\beta}} \\ \hat{\boldsymbol{\gamma}} \end{bmatrix}}{r}$$

where  $r = \text{rank}(\mathbf{L}\hat{\mathbf{C}}\mathbf{L}')$ . Analogous to  $t$ ,  $F$  in general has an approximate  $F$  distribution with  $r$  numerator degrees of freedom and  $\hat{\nu}$  denominator degrees of freedom.

The  $t$  and  $F$  statistics enable you to make inferences about your fixed effects, which account for the variance-covariance model you select. An alternative is the  $\chi^2$  statistic associated with the likelihood ratio test. This statistic compares two fixed-effects models, one a special case of the other. It is computed just as when comparing different covariance models, although you should use ML and not REML here because the penalty term associated with restricted likelihoods depends upon the fixed-effects specification.

### ***F Tests With the ANOVAF Option***

The ANOVAF option computes  $F$  tests by the following method in models with `REPEATED` statement and without `RANDOM` statement. Let  $\mathbf{L}$  denote the matrix of estimable functions for the hypothesis  $H: \mathbf{L}\boldsymbol{\beta} = \mathbf{0}$ , where  $\boldsymbol{\beta}$  are the fixed-effects parameters. Let  $\mathbf{M} = \mathbf{L}'(\mathbf{L}\mathbf{L}')^{-1}\mathbf{L}$ , and suppose that  $\hat{\mathbf{C}}$  denotes the estimated variance-covariance matrix of  $\hat{\boldsymbol{\beta}}$  (see the section “Statistical Properties” for the construction of  $\hat{\mathbf{C}}$ ).

The ANOVAF  $F$  statistics are computed as

$$F_A = \hat{\boldsymbol{\beta}}' \mathbf{L}' (\mathbf{L}\mathbf{L}')^{-1} \mathbf{L} \hat{\boldsymbol{\beta}} / t_1 = \hat{\boldsymbol{\beta}}' \mathbf{M} \hat{\boldsymbol{\beta}} / t_1$$

Notice that this is a modification of the usual  $F$  statistic where  $(\mathbf{L}\hat{\mathbf{C}}\mathbf{L}')^{-1}$  is replaced with  $(\mathbf{L}\mathbf{L}')^{-1}$  and  $\text{rank}(\mathbf{L})$  is replaced with  $t_1 = \text{trace}(\mathbf{M}\hat{\mathbf{C}})$ ; see, for example, Brunner, Domhof, and Langer (2002, Sec. 5.4). The  $p$ -values for this statistic are computed from either an  $F_{v_1, v_2}$  or an  $F_{v_1, \infty}$  distribution. The respective degrees of freedom are determined by the MIXED procedure as follows:

$$v_1 = \frac{t_1^2}{\text{trace}(\mathbf{M}\hat{\mathbf{C}}\mathbf{M})}$$

$$v_2^* = \frac{2t_1^2}{\mathbf{g}'\mathbf{A}\mathbf{g}}$$

$$v_2 = \begin{cases} \max\{\min\{v_2^*, df_e\}, 1\} & \mathbf{g}'\mathbf{A}\mathbf{g} > 1\text{E}3 \times \text{MACEPS} \\ 1 & \text{otherwise} \end{cases}$$

The term  $\mathbf{g}'\mathbf{A}\mathbf{g}$  in the term  $\nu_2^*$  for the denominator degrees of freedom is based on approximating  $\text{Var}[\text{trace}(\widehat{\mathbf{M}\mathbf{C}})]$  based on a first-order Taylor series about the true covariance parameters. This generalizes results in the appendix of Brunner, Dette, and Munk (1997) to a broader class of models. The vector  $\mathbf{g} = [g_1, \dots, g_q]$  contains the partial derivatives

$$\text{trace} \left( \mathbf{L}' (\mathbf{L}\mathbf{L}')^{-1} \mathbf{L} \frac{\partial \widehat{\mathbf{C}}}{\partial \theta_i} \right)$$

and  $\mathbf{A}$  is the asymptotic variance-covariance matrix of the covariance parameter estimates (`ASYCOV` option).

PROC MIXED reports  $\nu_1$  and  $\nu_2$  as “NumDF” and “DenDF” under the “ANOVA F” heading in the output. The corresponding  $p$ -values are denoted as “Pr > F(DDF)” for  $F_{\nu_1, \nu_2}$  and “Pr > F(infty)” for  $F_{\nu_1, \infty}$ , respectively.

$P$ -values computed with the ANOVAF option can be identical to the nonparametric tests in Akritas, Arnold, and Brunner (1997) and in Brunner, Domhof, and Langer (2002), provided that the response data consist of properly created (and sorted) ranks and that the covariance parameters are estimated by MIVQUE0 in models with `REPEATED` statement and properly chosen `SUBJECT=` and/or `GROUP=` effects.

If you model an unstructured covariance matrix in a longitudinal model with one or more repeated factors, the ANOVAF results are identical to a multivariate MANOVA where degrees of freedom are corrected with the Greenhouse-Geisser adjustment (Greenhouse and Geisser 1959). For example, suppose that factor A has 2 levels and factor B has 4 levels. The following two sets of statements produce the same  $p$ -values:

```
proc mixed data=Mydata anovaf method=mivque0;
 class id A B;
 model score = A | B / chisq;
 repeated / type=un subject=id;
 ods select Tests3;
run;

proc transpose data=MyData out=tdata;
 by id;
 var score;
run;
proc glm data=tdata;
 model col: = / nouni;
 repeated A 2, B 4;
 ods output ModelANOVA=maov epsilons=eps;
run;
proc transpose data=eps(where=(substr(statistic,1,3)='Gre')) out=teps;
 var cvalue1;
run;

data aov; set maov;
 if (_n_ = 1) then merge teps;
 if (Source='A') then do;
 pFddf = ProbF;
 pFinf = 1 - probchi(df*Fvalue,df);
 output;
 end; else if (Source='B') then do;
 pFddf = ProbFGG;
```

```

 pFinf = 1 - probchi(df*col1*Fvalue,df*col1);
 output;
 end; else if (Source='A*B') then do;
 pfddf = ProbFGG;
 pFinf = 1 - probchi(df*col2*Fvalue,df*col2);
 output;
 end;
run;
proc print data=aov label noobs;
 label Source = 'Effect'
 df = 'NumDF'
 Fvalue = 'Value'
 pFddf = 'Pr > F(DDF)'
 pFinf = 'Pr > F(infty)';
 var Source df Fvalue pFddf pFinf;
 format pF: pvalue6.;
run;

```

The PROC GLM code produces  $p$ -values that correspond to the ANOVA  $p$ -values shown as Pr > F(DDF) in the MIXED output. The subsequent DATA step computes the  $p$ -values that correspond to Pr > F(infty) in the PROC MIXED output.

---

## Parameterization of Mixed Models

Recall that a mixed model is of the form

$$y = X\beta + Z\gamma + \epsilon$$

where  $y$  represents univariate data,  $\beta$  is an unknown vector of fixed effects with known model matrix  $X$ ,  $\gamma$  is an unknown vector of random effects with known model matrix  $Z$ , and  $\epsilon$  is an unknown random error vector.

PROC MIXED constructs a mixed model according to the specifications in the **MODEL**, **RANDOM**, and **REPEATED** statements. Each effect in the **MODEL** statement generates one or more columns in the model matrix  $X$ , and each effect in the **RANDOM** statement generates one or more columns in the model matrix  $Z$ . Effects in the **REPEATED** statement do not generate model matrices; they serve only to index observations within subjects. This section shows precisely how PROC MIXED builds  $X$  and  $Z$ .

### Intercept

By default, all models automatically include a column of 1s in  $X$  to estimate a fixed-effect intercept parameter  $\mu$ . You can use the **NOINT** option in the **MODEL** statement to suppress this intercept. The **NOINT** option is useful when you are specifying a classification effect in the **MODEL** statement and you want the parameter estimate to be in terms of the mean response for each level of that effect, rather than in terms of a deviation from an overall mean.

By contrast, the intercept is not included by default in  $Z$ . To obtain a column of 1s in  $Z$ , you must specify in the **RANDOM** statement either the **INTERCEPT** effect or some effect that has only one level.

## Regression Effects

Numeric variables, or polynomial terms involving them, can be included in the model as regression effects (covariates). The actual values of such terms are included as columns of the model matrices **X** and **Z**. You can use the bar operator with a regression effect to generate polynomial effects. For instance,  $X|X|X$  expands to  $X$   $X*X$   $X*X*X$ , a cubic model.

## Main Effects

If a classification variable has  $m$  levels, PROC MIXED generates  $m$  columns in the model matrix for its main effect. Each column is an indicator variable for a given level. The order of the columns is the sort order of the values of their levels and can be controlled with the **ORDER=** option in the PROC MIXED statement. Table 59.20 is an example.

**Table 59.20** Example of Main Effects

| Data |   | I     | A  |    | B  |    |    |
|------|---|-------|----|----|----|----|----|
| A    | B | $\mu$ | A1 | A2 | B1 | B2 | B3 |
| 1    | 1 | 1     | 1  | 0  | 1  | 0  | 0  |
| 1    | 2 | 1     | 1  | 0  | 0  | 1  | 0  |
| 1    | 3 | 1     | 1  | 0  | 0  | 0  | 1  |
| 2    | 1 | 1     | 0  | 1  | 1  | 0  | 0  |
| 2    | 2 | 1     | 0  | 1  | 0  | 1  | 0  |
| 2    | 3 | 1     | 0  | 1  | 0  | 0  | 1  |

Typically, there are more columns for these effects than there are degrees of freedom for them. In other words, PROC MIXED uses an overparameterized model.

## Interaction Effects

Often a model includes interaction (crossed) effects. With an interaction, PROC MIXED first reorders the terms to correspond to the order of the variables in the **CLASS** statement. Thus,  $B*A$  becomes  $A*B$  if **A** precedes **B** in the **CLASS** statement. Then, PROC MIXED generates columns for all combinations of levels that occur in the data. The order of the columns is such that the rightmost variables in the cross index faster than the leftmost variables (Table 59.21). Empty columns (that would contain all 0s) are not generated for **X**, but they are for **Z**.

**Table 59.21** Example of Interaction Effects

| Data |   | I     | A  |    | B  |    |    | A*B  |      |      |      |      |      |
|------|---|-------|----|----|----|----|----|------|------|------|------|------|------|
| A    | B | $\mu$ | A1 | A2 | B1 | B2 | B3 | A1B1 | A1B2 | A1B3 | A2B1 | A2B2 | A2B3 |
| 1    | 1 | 1     | 1  | 0  | 1  | 0  | 0  | 1    | 0    | 0    | 0    | 0    | 0    |
| 1    | 2 | 1     | 1  | 0  | 0  | 1  | 0  | 0    | 1    | 0    | 0    | 0    | 0    |
| 1    | 3 | 1     | 1  | 0  | 0  | 0  | 1  | 0    | 0    | 1    | 0    | 0    | 0    |
| 2    | 1 | 1     | 0  | 1  | 1  | 0  | 0  | 0    | 0    | 0    | 1    | 0    | 0    |
| 2    | 2 | 1     | 0  | 1  | 0  | 1  | 0  | 0    | 0    | 0    | 0    | 1    | 0    |
| 2    | 3 | 1     | 0  | 1  | 0  | 0  | 1  | 0    | 0    | 0    | 0    | 0    | 1    |

In the preceding matrix, main-effects columns are not linearly independent of crossed-effects columns; in fact, the column space for the crossed effects contains the space of the main effect.

When your model contains many interaction effects, you might be able to code them more parsimoniously by using the bar operator ( | ). The bar operator generates all possible interaction effects. For example, A|B|C expands to A B A\*B C A\*C B\*C A\*B\*C. To eliminate higher-order interaction effects, use the at sign (@) in conjunction with the bar operator. For instance, A|B|C|D @2 expands to A B A\*B C A\*C B\*C D A\*D B\*D C\*D.

### Nested Effects

Nested effects are generated in the same manner as crossed effects. Hence, the design columns generated by the following two statements are the same (but the ordering of the columns is different):

```
model Y=A B(A);
```

```
model Y=A A*B;
```

The nesting operator in PROC MIXED is more a notational convenience than an operation distinct from crossing. Nested effects are typically characterized by the property that the nested variables never appear as main effects. The order of the variables within nesting parentheses is made to correspond to the order of these variables in the CLASS statement. The order of the columns is such that variables outside the parentheses index faster than those inside the parentheses, and the rightmost nested variables index faster than the leftmost variables (Table 59.22).

**Table 59.22** Example of Nested Effects

| Data |   | I     | A  |    | B(A) |      |      |      |      |      |
|------|---|-------|----|----|------|------|------|------|------|------|
| A    | B | $\mu$ | A1 | A2 | B1A1 | B2A1 | B3A1 | B1A2 | B2A2 | B3A2 |
| 1    | 1 | 1     | 1  | 0  | 1    | 0    | 0    | 0    | 0    | 0    |
| 1    | 2 | 1     | 1  | 0  | 0    | 1    | 0    | 0    | 0    | 0    |
| 1    | 3 | 1     | 1  | 0  | 0    | 0    | 1    | 0    | 0    | 0    |
| 2    | 1 | 1     | 0  | 1  | 0    | 0    | 0    | 1    | 0    | 0    |
| 2    | 2 | 1     | 0  | 1  | 0    | 0    | 0    | 0    | 1    | 0    |
| 2    | 3 | 1     | 0  | 1  | 0    | 0    | 0    | 0    | 0    | 1    |

Note that nested effects are often distinguished from interaction effects by the implied randomization structure of the design. That is, they usually indicate random effects within a fixed-effects framework. The fact that random effects can be modeled directly in the RANDOM statement might make the specification of nested effects in the MODEL statement unnecessary.

### Continuous-Nesting-Class Effects

When a continuous variable nests with a classification variable, the design columns are constructed by multiplying the continuous values into the design columns for the class effect (Table 59.23).

**Table 59.23** Example of Continuous-Nesting-Class Effects

| Data |   | I     | A  |    | X(A)  |       |
|------|---|-------|----|----|-------|-------|
| X    | A | $\mu$ | A1 | A2 | X(A1) | X(A2) |
| 21   | 1 | 1     | 1  | 0  | 21    | 0     |
| 24   | 1 | 1     | 1  | 0  | 24    | 0     |
| 22   | 1 | 1     | 1  | 0  | 22    | 0     |
| 28   | 2 | 1     | 0  | 1  | 0     | 28    |
| 19   | 2 | 1     | 0  | 1  | 0     | 19    |
| 23   | 2 | 1     | 0  | 1  | 0     | 23    |

This model estimates a separate slope for X within each level of A.

### Continuous-by-Class Effects

Continuous-by-class effects generate the same design columns as continuous-nesting-class effects. The two models are made different by the presence of the continuous variable as a regressor by itself, as well as a contributor to a compound effect. Table 59.24 shows an example.

**Table 59.24** Example of Continuous-by-Class Effects

| Data |   | I     | X  | A  |    | X*A  |      |
|------|---|-------|----|----|----|------|------|
| X    | A | $\mu$ | X  | A1 | A2 | X*A1 | X*A2 |
| 21   | 1 | 1     | 21 | 1  | 0  | 21   | 0    |
| 24   | 1 | 1     | 24 | 1  | 0  | 24   | 0    |
| 22   | 1 | 1     | 22 | 1  | 0  | 22   | 0    |
| 28   | 2 | 1     | 28 | 0  | 1  | 0    | 28   |
| 19   | 2 | 1     | 19 | 0  | 1  | 0    | 19   |
| 23   | 2 | 1     | 23 | 0  | 1  | 0    | 23   |

You can use continuous-by-class effects to test for homogeneity of slopes.

### General Effects

An example that combines all the effects is  $X1*X2*A*B*C$  (D E). The continuous list comes first, followed by the crossed list, followed by the nested list in parentheses. You should be aware of the sequencing of parameters when you use the **CONTRAST** or **ESTIMATE** statement to compute some function of the parameter estimates.

Effects might be renamed by PROC MIXED to correspond to ordering rules. For example,  $B*A(E D)$  might be renamed  $A*B(D E)$  to satisfy the following:

- Classification variables that occur outside parentheses (crossed effects) are sorted in the order in which they appear in the **CLASS** statement.
- Variables within parentheses (nested effects) are sorted in the order in which they appear in the **CLASS** statement.

The sequencing of the parameters generated by an effect can be described by which variables have their levels indexed faster:

- Variables in the crossed list index faster than variables in the nested list.
- Within a crossed or nested list, variables to the right index faster than variables to the left.

For example, suppose a model includes four effects—A, B, C, and D—each having two levels, 1 and 2. Suppose the **CLASS** statement is as follows:

```
class A B C D;
```

Then the order of the parameters for the effect B\*A(C D), which is renamed A\*B (C D), is

$$\begin{aligned} A_1 B_1 C_1 D_1 &\rightarrow A_1 B_2 C_1 D_1 \rightarrow A_2 B_1 C_1 D_1 \rightarrow A_2 B_2 C_1 D_1 \rightarrow \\ A_1 B_1 C_1 D_2 &\rightarrow A_1 B_2 C_1 D_2 \rightarrow A_2 B_1 C_1 D_2 \rightarrow A_2 B_2 C_1 D_2 \rightarrow \\ A_1 B_1 C_2 D_1 &\rightarrow A_1 B_2 C_2 D_1 \rightarrow A_2 B_1 C_2 D_1 \rightarrow A_2 B_2 C_2 D_1 \rightarrow \\ A_1 B_1 C_2 D_2 &\rightarrow A_1 B_2 C_2 D_2 \rightarrow A_2 B_1 C_2 D_2 \rightarrow A_2 B_2 C_2 D_2 \end{aligned}$$

Note that first the crossed effects B and A are sorted in the order in which they appear in the **CLASS** statement so that A precedes B in the parameter list. Then, for each combination of the nested effects in turn, combinations of A and B appear. The B effect moves fastest because it is rightmost in the cross list. Then A moves next fastest, and D moves next fastest. The C effect is the slowest since it is leftmost in the nested list.

When numeric levels are used, levels are sorted by their character format, which might not correspond to their numeric sort sequence (for example, noninteger levels). Therefore, it is advisable to include a desired format for numeric levels or to use the **ORDER=INTERNAL** option in the **PROC MIXED** statement to ensure that levels are sorted by their internal values.

### Implications of the Non-Full-Rank Parameterization

For models with fixed effects involving classification variables, there are more design columns in **X** constructed than there are degrees of freedom for the effect. Thus, there are linear dependencies among the columns of **X**. In this event, all of the parameters are not estimable; there is an infinite number of solutions to the mixed model equations. **PROC MIXED** uses a generalized inverse (a  $g_2$ -inverse, Pringle and Rayner 1971) to obtain values for the estimates (Searle 1971). The solution values are not displayed unless you specify the **SOLUTION** option in the **MODEL** statement. The solution has the characteristic that estimates are 0 whenever the design column for that parameter is a linear combination of previous columns. With this parameterization, hypothesis tests are constructed to test linear functions of the parameters that are estimable.

Some procedures (such as the **CATMOD** procedure) reparameterize models to full rank by using restrictions on the parameters. **PROC GLM** and **PROC MIXED** do not reparameterize, making the hypotheses that are commonly tested more understandable. See Goodnight (1978) for additional reasons for not reparameterizing.

## Missing Level Combinations

PROC MIXED handles missing level combinations of classification variables similarly to the way PROC GLM does. Both procedures delete fixed-effects parameters corresponding to missing levels in order to preserve estimability. However, PROC MIXED does not delete missing level combinations for random-effects parameters because linear combinations of the random-effects parameters are always estimable. These conventions can affect the way you specify your **CONTRAST** and **ESTIMATE** coefficients.

---

## Residuals and Influence Diagnostics

### Residual Diagnostics

Consider a residual vector of the form  $\tilde{\mathbf{e}} = \mathbf{P}\mathbf{Y}$ , where  $\mathbf{P}$  is a projection matrix, possibly an oblique projector. A typical element  $\tilde{e}_i$  with variance  $v_i$  and estimated variance  $\hat{v}_i$  is said to be *standardized* as

$$\frac{\tilde{e}_i}{\sqrt{\text{Var}[\tilde{e}_i]}} = \frac{\tilde{e}_i}{\sqrt{v_i}}$$

and *studentized* as

$$\frac{\tilde{e}_i}{\sqrt{\hat{v}_i}}$$

External studentization uses an estimate of  $\text{Var}[\tilde{e}_i]$  that does not involve the  $i$ th observation. Externally studentized residuals are often preferred over internally studentized residuals because they have well-known distributional properties in standard linear models for independent data.

Residuals that are scaled by the estimated variance of the response, i.e.,  $\tilde{e}_i / \sqrt{\widehat{\text{Var}}[Y_i]}$ , are referred to as Pearson-type residuals.

### Marginal and Conditional Residuals

The marginal and conditional means in the linear mixed model are  $E[\mathbf{Y}] = \mathbf{X}\boldsymbol{\beta}$  and  $E[\mathbf{Y}|\boldsymbol{\gamma}] = \mathbf{X}\boldsymbol{\beta} + \mathbf{Z}\boldsymbol{\gamma}$ , respectively. Accordingly, the vector  $\mathbf{r}_m$  of marginal residuals is defined as

$$\mathbf{r}_m = \mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}}$$

and the vector  $\mathbf{r}_c$  of conditional residuals is

$$\mathbf{r}_c = \mathbf{Y} - \mathbf{X}\hat{\boldsymbol{\beta}} - \mathbf{Z}\hat{\boldsymbol{\gamma}} = \mathbf{r}_m - \mathbf{Z}\hat{\boldsymbol{\gamma}}$$

Following Gregoire, Schabenberger, and Barrett (1995), let  $\mathbf{Q} = \mathbf{X}(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{X}'$  and  $\mathbf{K} = \mathbf{I} - \mathbf{Z}\hat{\mathbf{G}}\mathbf{Z}'\hat{\mathbf{V}}^{-1}$ . Then

$$\widehat{\text{Var}}[\mathbf{r}_m] = \hat{\mathbf{V}} - \mathbf{Q}$$

$$\widehat{\text{Var}}[\mathbf{r}_c] = \mathbf{K}(\hat{\mathbf{V}} - \mathbf{Q})\mathbf{K}'$$

For an individual observation the raw, studentized, and Pearson-type residuals computed by the MIXED procedure are given in Table 59.25.

**Table 59.25** Residual Types Computed by the MIXED Procedure

| Type of Residual | Marginal                                                                | Conditional                                                                                |
|------------------|-------------------------------------------------------------------------|--------------------------------------------------------------------------------------------|
| Raw              | $r_{mi} = Y_i - \mathbf{x}'_i \hat{\boldsymbol{\beta}}$                 | $r_{ci} = r_{mi} - \mathbf{z}'_i \hat{\boldsymbol{\gamma}}$                                |
| Studentized      | $r_{mi}^{student} = \frac{r_{mi}}{\sqrt{\widehat{\text{Var}}[r_{mi}]}}$ | $r_{ci}^{student} = \frac{r_{ci}}{\sqrt{\widehat{\text{Var}}[r_{ci}]}}$                    |
| Pearson          | $r_{mi}^{pearson} = \frac{r_{mi}}{\sqrt{\widehat{\text{Var}}[Y_i]}}$    | $r_{ci}^{pearson} = \frac{r_{ci}}{\sqrt{\widehat{\text{Var}}[Y_i   \boldsymbol{\gamma}]}}$ |

When the **OUTPM=** option is specified in addition to the **RESIDUAL** option in the **MODEL** statement,  $r_{mi}^{student}$  and  $r_{mi}^{pearson}$  are added to the data set as variables **Resid**, **StudentResid**, and **PearsonResid**, respectively. When the **OUTP=** option is specified,  $r_{ci}^{student}$  and  $r_{ci}^{pearson}$  are added to the data set. Raw residuals are part of the **OUTPM=** and **OUTP=** data sets without the **RESIDUAL** option.

### Scaled Residuals

For correlated data, a set of scaled quantities can be defined through the Cholesky decomposition of the variance-covariance matrix. Since fitted residuals in linear models are rank-deficient, it is customary to draw on the variance-covariance matrix of the data. If  $\text{Var}[\mathbf{Y}] = \mathbf{V}$  and  $\mathbf{C}'\mathbf{C} = \mathbf{V}$ , then  $\mathbf{C}'^{-1}\mathbf{Y}$  has uniform dispersion and its elements are uncorrelated.

Scaled residuals in a mixed model are meaningful for quantities based on the marginal distribution of the data. Let  $\hat{\mathbf{C}}$  denote the Cholesky root of  $\hat{\mathbf{V}}$ , so that  $\hat{\mathbf{C}}'\hat{\mathbf{C}} = \hat{\mathbf{V}}$ , and define

$$\mathbf{Y}_c = \hat{\mathbf{C}}'^{-1}\mathbf{Y}$$

$$\mathbf{r}_{m(c)} = \hat{\mathbf{C}}'^{-1}\mathbf{r}_m$$

By analogy with other scalings, the inverse Cholesky decomposition can also be applied to the residual vector,  $\hat{\mathbf{C}}'^{-1}\mathbf{r}_m$ , although  $\mathbf{V}$  is not the variance-covariance matrix of  $\mathbf{r}_m$ .

To diagnose whether the covariance structure of the model has been specified correctly can be difficult based on  $\mathbf{Y}_c$ , since the inverse Cholesky transformation affects the expected value of  $\mathbf{Y}_c$ . You can draw on  $\mathbf{r}_{m(c)}$  as a vector of (approximately) uncorrelated data with constant mean.

When the **OUTPM=** option in the **MODEL** statement is specified in addition to the **VCIRY** option,  $\mathbf{Y}_c$  is added as variable **ScaledDep** and  $\mathbf{r}_{m(c)}$  is added as **ScaledResid** to the data set.

## Influence Diagnostics

### Basic Idea and Statistics

The general idea of quantifying the influence of one or more observations relies on computing parameter estimates based on all data points, removing the cases in question from the data, refitting the model, and computing statistics based on the change between full-data and reduced-data estimation. Influence statistics can be coarsely grouped by the aspect of estimation that is their primary target:

- overall measures compare changes in objective functions: (restricted) likelihood distance (Cook and Weisberg 1982, Ch. 5.2)
- influence on parameter estimates: Cook's  $D$  (Cook 1977, 1979), MDFFITS (Belsley, Kuh, and Welsch 1980, p. 32)

- influence on precision of estimates: CovRatio and CovTrace
- influence on fitted and predicted values: PRESS residual, PRESS statistic (Allen 1974), DFFITS (Belsley, Kuh, and Welsch 1980, p. 15)
- outlier properties: internally and externally studentized residuals, leverage

For linear models for uncorrelated data, it is not necessary to refit the model after removing a data point in order to measure the impact of an observation on the model. The change in fixed effect estimates, residuals, residual sums of squares, and the variance-covariance matrix of the fixed effects can be computed based on the fit to the full data alone. By contrast, in mixed models several important complications arise. Data points can affect not only the fixed effects but also the covariance parameter estimates on which the fixed-effects estimates depend. Furthermore, closed-form expressions for computing the change in important model quantities might not be available.

This section provides background material for the various influence diagnostics available with the MIXED procedure. See the section “[Mixed Models Theory](#)” on page 4958 for relevant expressions and definitions. The parameter vector  $\theta$  denotes all unknown parameters in the  $\mathbf{R}$  and  $\mathbf{G}$  matrix.

The observations whose influence is being ascertained are represented by the set  $U$  and referred to simply as “the observations in  $U$ .” The estimate of a parameter vector, such as  $\beta$ , obtained from all observations except those in the set  $U$  is denoted  $\hat{\beta}_{(U)}$ . In case of a matrix  $\mathbf{A}$ , the notation  $\mathbf{A}_{(U)}$  represents the matrix with the rows in  $U$  removed; these rows are collected in  $\mathbf{A}_U$ . If  $\mathbf{A}$  is symmetric, then notation  $\mathbf{A}_{(U)}$  implies removal of rows and columns. The vector  $Y_U$  comprises the responses of the data points being removed, and  $\mathbf{V}_{(U)}$  is the variance-covariance matrix of the remaining observations. When  $k = 1$ , lowercase notation emphasizes that single points are removed, such as  $\mathbf{A}_{(u)}$ .

### Managing the Covariance Parameters

An important component of influence diagnostics in the mixed model is the estimated variance-covariance matrix  $\mathbf{V} = \mathbf{ZGZ}' + \mathbf{R}$ . To make the dependence on the vector of covariance parameters explicit, write it as  $\mathbf{V}(\theta)$ . If one parameter,  $\sigma^2$ , is profiled or factored out of  $\mathbf{V}$ , the remaining parameters are denoted as  $\theta^*$ . Notice that in a model where  $\mathbf{G}$  is diagonal and  $\mathbf{R} = \sigma^2\mathbf{I}$ , the parameter vector  $\theta^*$  contains the ratios of each variance component and  $\sigma^2$  (see Wolfinger, Tobias, and Sall 1994). When ITER=0, two scenarios are distinguished:

1. If the residual variance is not profiled, either because the model does not contain a residual variance or because it is part of the Newton-Raphson iterations, then  $\hat{\theta}_{(U)} \equiv \hat{\theta}$ .
2. If the residual variance is profiled, then  $\hat{\theta}_{(U)}^* \equiv \hat{\theta}^*$  and  $\hat{\sigma}_{(U)}^2 \neq \hat{\sigma}^2$ . Influence statistics such as Cook’s  $D$  and internally studentized residuals are based on  $\mathbf{V}(\hat{\theta})$ , whereas externally studentized residuals and the DFFITS statistic are based on  $\mathbf{V}(\hat{\theta}_{(U)}) = \sigma_{(U)}^2 \mathbf{V}(\hat{\theta}^*)$ . In a random components model with uncorrelated errors, for example, the computation of  $\mathbf{V}(\hat{\theta}_{(U)})$  involves scaling of  $\hat{\mathbf{G}}$  and  $\hat{\mathbf{R}}$  by the full-data estimate  $\hat{\sigma}^2$  and multiplying the result with the reduced-data estimate  $\hat{\sigma}_{(U)}^2$ .

Certain statistics, such as MDFFITS, CovRatio, and CovTrace, require an estimate of the variance of the fixed effects that is based on the reduced number of observations. For example,  $\mathbf{V}(\hat{\theta}_{(U)})$  is evaluated at the reduced-data parameter estimates but computed for the entire data set. The matrix  $\mathbf{V}_{(U)}(\hat{\theta}_{(U)})$ , on the other hand, has rows and columns corresponding to the points in  $U$  removed. The resulting matrix is evaluated at the delete-case estimates.

When influence analysis is iterative, the entire vector  $\boldsymbol{\theta}$  is updated, whether the residual variance is profiled or not. The matrices to be distinguished here are  $\mathbf{V}(\hat{\boldsymbol{\theta}})$ ,  $\mathbf{V}(\hat{\boldsymbol{\theta}}_{(U)})$ , and  $\mathbf{V}_{(U)}(\hat{\boldsymbol{\theta}}_{(U)})$ , with unambiguous notation.

### **Predicted Values, PRESS Residual, and PRESS Statistic**

An unconditional predicted value is  $\hat{y}_i = \mathbf{x}_i' \hat{\boldsymbol{\beta}}$ , where the vector  $\mathbf{x}_i$  is the  $i$ th row of  $\mathbf{X}$ . The (raw) residual is given as  $\hat{\epsilon}_i = y_i - \hat{y}_i$ , and the PRESS residual is

$$\hat{\epsilon}_{i(U)} = y_i - \mathbf{x}_i' \hat{\boldsymbol{\beta}}_{(U)}$$

The PRESS statistic is the sum of the squared PRESS residuals,

$$PRESS = \sum_{i \in U} \hat{\epsilon}_{i(U)}^2$$

where the sum is over the observations in  $U$ .

If **EFFECT=**, **SIZE=**, or **KEEP=** is not specified, PROC MIXED computes the PRESS residual for each observation selected through **SELECT=** (or all observations if **SELECT=** is not given). If **EFFECT=**, **SIZE=**, or **KEEP=** is specified, the procedure computes PRESS.

### **Leverage**

For the general mixed model, leverage can be defined through the projection matrix that results from a transformation of the model with the inverse of the Cholesky decomposition of  $\mathbf{V}$ , or through an oblique projector. The MIXED procedure follows the latter path in the computation of influence diagnostics. The leverage value reported for the  $i$ th observation is the  $i$ th diagonal entry of the matrix

$$\mathbf{H} = \mathbf{X}(\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-1}\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}$$

which is the weight of the observation in contributing to its own predicted value,  $\mathbf{H} = d\hat{\mathbf{Y}}/d\mathbf{Y}$ .

While  $\mathbf{H}$  is idempotent, it is generally not symmetric and thus not a projection matrix in the narrow sense.

The properties of these leverages are generalizations of the properties in models with diagonal variance-covariance matrices. For example,  $\hat{\mathbf{Y}} = \mathbf{H}\mathbf{Y}$ , and in a model with intercept and  $\mathbf{V} = \sigma^2\mathbf{I}$ , the leverage values

$$h_{ii} = \mathbf{x}_i'(\mathbf{X}'\mathbf{X})^{-1}\mathbf{x}_i$$

are  $h_{ii}^l = 1/n \leq h_{ii} \leq 1 = h_{ii}^u$  and  $\sum_{i=1}^n h_{ii} = \text{rank}(\mathbf{X})$ . The lower bound for  $h_{ii}$  is achieved in an intercept-only model, and the upper bound is achieved in a saturated model. The trace of  $\mathbf{H}$  equals the rank of  $\mathbf{X}$ .

If  $v_{ij}$  denotes the element in row  $i$ , column  $j$  of  $\mathbf{V}^{-1}$ , then for a model containing only an intercept the diagonal elements of  $\mathbf{H}$  are

$$h_{ii} = \frac{\sum_{j=1}^n v_{ij}}{\sum_{i=1}^n \sum_{j=1}^n v_{ij}}$$

Because  $\sum_{j=1}^n v_{ij}$  is a sum of elements in the  $i$ th row of the inverse variance-covariance matrix,  $h_{ii}$  can be negative, even if the correlations among data points are nonnegative. In case of a saturated model with  $\mathbf{X} = \mathbf{I}$ ,  $h_{ii} = 1.0$ .

### Internally and Externally Studentized Residuals

See the section “Residual Diagnostics” on page 4976 for the distinction between standardization, studentization, and scaling of residuals. Internally studentized marginal and conditional residuals are computed with the **RESIDUAL** option of the **MODEL** statement. The **INFLUENCE** option computes internally and externally studentized marginal residuals.

The computation of internally studentized residuals relies on the diagonal entries of  $\mathbf{V}(\hat{\boldsymbol{\theta}}) - \mathbf{Q}(\hat{\boldsymbol{\theta}})$ , where  $\mathbf{Q}(\hat{\boldsymbol{\theta}}) = \mathbf{X}(\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-1}\mathbf{X}'$ . Externally studentized residuals require iterative influence analysis or a profiled residual variance. In the former case the studentization is based on  $\mathbf{V}(\hat{\boldsymbol{\theta}}_U)$ ; in the latter case it is based on  $\sigma_{(U)}^2 \mathbf{V}(\hat{\boldsymbol{\theta}}^*)$ .

### Cook's *D*

Cook's *D* statistic is an invariant norm that measures the influence of observations in  $U$  on a vector of parameter estimates (Cook 1977). In case of the fixed-effects coefficients, let

$$\boldsymbol{\delta}_{(U)} = \hat{\boldsymbol{\beta}} - \hat{\boldsymbol{\beta}}_{(U)}$$

Then the MIXED procedure computes

$$D(\boldsymbol{\beta}) = \boldsymbol{\delta}'_{(U)} \widehat{\text{Var}}[\hat{\boldsymbol{\beta}}]^{-} \boldsymbol{\delta}_{(U)} / \text{rank}(\mathbf{X})$$

where  $\widehat{\text{Var}}[\hat{\boldsymbol{\beta}}]^{-}$  is the matrix that results from sweeping  $(\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}})^{-1}\mathbf{X})^{-}$ .

If  $\mathbf{V}$  is known, Cook's *D* can be calibrated according to a chi-square distribution with degrees of freedom equal to the rank of  $\mathbf{X}$  (Christensen, Pearson, and Johnson 1992). For estimated  $\mathbf{V}$  the calibration can be carried out according to an  $F(\text{rank}(\mathbf{X}), n - \text{rank}(\mathbf{X}))$  distribution. To interpret *D* on a familiar scale, Cook (1979) and Cook and Weisberg (1982, p. 116) refer to the 50th percentile of the reference distribution. If *D* is equal to that percentile, then removing the points in  $U$  moves the fixed-effects coefficient vector from the center of the confidence region to the 50% confidence ellipsoid (Myers 1990, p. 262).

In the case of iterative influence analysis, the MIXED procedure also computes a *D*-type statistic for the covariance parameters. If  $\boldsymbol{\Gamma}$  is the asymptotic variance-covariance matrix of  $\hat{\boldsymbol{\theta}}$ , then MIXED computes

$$D_{\boldsymbol{\theta}} = (\hat{\boldsymbol{\theta}} - \hat{\boldsymbol{\theta}}_{(U)})' \hat{\boldsymbol{\Gamma}}^{-1} (\hat{\boldsymbol{\theta}} - \hat{\boldsymbol{\theta}}_{(U)})$$

### DFFITS and MDFFITS

A DFFIT measures the change in predicted values due to removal of data points. If this change is standardized by the externally estimated standard error of the predicted value in the full data, the DFFITS statistic of Belsley, Kuh, and Welsch (1980, p. 15) results:

$$\text{DFFITS}_i = (\hat{y}_i - \hat{y}_{i(u)}) / \text{ese}(\hat{y}_i)$$

The MIXED procedure computes DFFITS when the **EFFECT=** or **SIZE=** modifier of the **INFLUENCE** option is not in effect. In general, an external estimate of the estimated standard error is used. When **ITER** > 0, the estimate is

$$\text{ese}(\hat{y}_i) = \sqrt{\mathbf{x}'_i (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}}_{(u)})^{-1}\mathbf{X})^{-1} \mathbf{x}_i}$$

When **ITER=0** and  $\sigma^2$  is profiled, then

$$\text{ese}(\hat{y}_i) = \hat{\sigma}_{(u)} \sqrt{\mathbf{x}'_i (\mathbf{X}'\mathbf{V}(\hat{\boldsymbol{\theta}}^*)^{-1}\mathbf{X})^{-1} \mathbf{x}_i}$$

When the **EFFECT=**, **SIZE=**, or **KEEP=** modifier is specified, the MIXED procedure computes a multivariate version suitable for the deletion of multiple data points. The statistic, termed MDFFITS after the MDFFIT statistic of Belsley, Kuh, and Welsch (1980, p. 32), is closely related to Cook's  $D$ . Consider the case  $\mathbf{V} = \sigma^2 \mathbf{V}(\boldsymbol{\theta}^*)$  so that

$$\text{Var}[\widehat{\boldsymbol{\beta}}] = \sigma^2 (\mathbf{X}' \mathbf{V}(\boldsymbol{\theta}^*)^{-1} \mathbf{X})^{-1}$$

and let  $\widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}_{(U)}]$  be an estimate of  $\text{Var}[\widehat{\boldsymbol{\beta}}_{(U)}]$  that does not use the observations in  $U$ . The MDFFITS statistic is then computed as

$$\text{MDFFITS}(\boldsymbol{\beta}) = \boldsymbol{\delta}'_{(U)} \widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}_{(U)}]^{-1} \boldsymbol{\delta}_{(U)} / \text{rank}(\mathbf{X})$$

If **ITER=0** and  $\sigma^2$  is profiled, then  $\widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}_{(U)}]^{-1}$  is obtained by sweeping

$$\widehat{\sigma}^2_{(U)} (\mathbf{X}'_{(U)} \mathbf{V}_{(U)}(\widehat{\boldsymbol{\theta}}^*)^{-1} \mathbf{X}_{(U)})^{-1}$$

The underlying idea is that if  $\boldsymbol{\theta}^*$  were known, then

$$(\mathbf{X}'_{(U)} \mathbf{V}_{(U)}(\boldsymbol{\theta}^*)^{-1} \mathbf{X}_{(U)})^{-1}$$

would be  $\text{Var}[\widehat{\boldsymbol{\beta}}]/\sigma^2$  in a generalized least squares regression with all but the data in  $U$ .

In the case of iterative influence analysis,  $\widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}_{(U)}]$  is evaluated at  $\widehat{\boldsymbol{\theta}}_{(U)}$ . Furthermore, a MDFFITS-type statistic is then computed for the covariance parameters:

$$\text{MDFFITS}(\boldsymbol{\theta}) = (\widehat{\boldsymbol{\theta}} - \widehat{\boldsymbol{\theta}}_{(U)})' \widetilde{\text{Var}}[\widehat{\boldsymbol{\theta}}_{(U)}]^{-1} (\widehat{\boldsymbol{\theta}} - \widehat{\boldsymbol{\theta}}_{(U)})$$

### Covariance Ratio and Trace

These statistics depend on the availability of an external estimate of  $\mathbf{V}$ , or at least of  $\sigma^2$ . Whereas Cook's  $D$  and MDFFITS measure the impact of data points on a vector of parameter estimates, the covariance-based statistics measure impact on their precision. Following Christensen, Pearson, and Johnson (1992), the MIXED procedure computes

$$\text{CovTrace}(\boldsymbol{\beta}) = |\text{trace}(\widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}]^{-1} \widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}_{(U)}]) - \text{rank}(\mathbf{X})|$$

$$\text{CovRatio}(\boldsymbol{\beta}) = \frac{\det_{ns}(\widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}_{(U)}])}{\det_{ns}(\widetilde{\text{Var}}[\widehat{\boldsymbol{\beta}}])}$$

where  $\det_{ns}(\mathbf{M})$  denotes the determinant of the nonsingular part of matrix  $\mathbf{M}$ .

In the case of iterative influence analysis these statistics are also computed for the covariance parameter estimates. If  $q$  denotes the rank of  $\text{Var}[\widehat{\boldsymbol{\theta}}]$ , then

$$\text{CovTrace}(\boldsymbol{\theta}) = |\text{trace}(\widetilde{\text{Var}}[\widehat{\boldsymbol{\theta}}]^{-1} \widetilde{\text{Var}}[\widehat{\boldsymbol{\theta}}_{(U)}]) - q|$$

$$\text{CovRatio}(\boldsymbol{\theta}) = \frac{\det_{ns}(\widetilde{\text{Var}}[\widehat{\boldsymbol{\theta}}_{(U)}])}{\det_{ns}(\widetilde{\text{Var}}[\widehat{\boldsymbol{\theta}}])}$$

### Likelihood Distances

The log-likelihood function  $l$  and restricted log-likelihood function  $l_R$  of the linear mixed model are given in the section “Estimating Covariance Parameters in the Mixed Model” on page 4964. Denote as  $\psi$  the collection of all parameters, i.e., the fixed effects  $\beta$  and the covariance parameters  $\theta$ . Twice the difference between the (restricted) log-likelihood evaluated at the full-data estimates  $\hat{\psi}$  and at the reduced-data estimates  $\hat{\psi}_{(U)}$  is known as the (restricted) likelihood distance:

$$\begin{aligned} \text{RLD}_{(U)} &= 2\{l_R(\hat{\psi}) - l_R(\hat{\psi}_{(U)})\} \\ \text{LD}_{(U)} &= 2\{l(\hat{\psi}) - l(\hat{\psi}_{(U)})\} \end{aligned}$$

Cook and Weisberg (1982, Ch. 5.2) refer to these differences as *likelihood distances*, Beckman, Nachtsheim, and Cook (1987) call the measures *likelihood displacements*. If the number of elements in  $\psi$  that are subject to updating following point removal is  $q$ , then likelihood displacements can be compared against cutoffs from a chi-square distribution with  $q$  degrees of freedom. Notice that this reference distribution does not depend on the number of observations removed from the analysis, but rather on the number of model parameters that are updated. The likelihood displacement gives twice the amount by which the log likelihood of the full data changes if one were to use an estimate based on fewer data points. It is thus a global, summary measure of the influence of the observations in  $U$  jointly on all parameters.

Unless `METHOD=ML`, the MIXED procedure computes the likelihood displacement based on the residual (=restricted) log likelihood, even if `METHOD=MIVQUE0` or `METHOD=TYPE1`, `TYPE2`, or `TYPE3`.

### Noniterative Update Formulas

Update formulas that do not require refitting of the model are available for the cases where  $\mathbf{V} = \sigma^2\mathbf{I}$ ,  $\mathbf{V}$  is known, or  $\mathbf{V}^*$  is known. When `ITER=0` and these update formulas can be invoked, the MIXED procedure uses the computational devices that are outlined in the following paragraphs. It is then assumed that the variance-covariance matrix of the fixed effects has the form  $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}$ . When `DDFM=KENWARDROGER`, this is not the case; the estimated variance-covariance matrix is then inflated to better represent the uncertainty in the estimated covariance parameters. Influence statistics when `DDFM=KENWARDROGER` should iteratively update the covariance parameters (`ITER > 0`). The dependence of  $\mathbf{V}$  on  $\theta$  is suppressed in the sequel for brevity.

**Updating the Fixed Effects** Denote by  $\mathbf{U}$  the  $(n \times k)$  matrix that is assembled from  $k$  columns of the identity matrix. Each column of  $\mathbf{U}$  corresponds to the removal of one data point. The point being targeted by the  $i$ th column of  $\mathbf{U}$  corresponds to the row in which a 1 appears. Furthermore, define

$$\begin{aligned} \mathbf{\Omega} &= (\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-} \\ \mathbf{Q} &= \mathbf{X}\mathbf{\Omega}\mathbf{X}' \\ \mathbf{P} &= \mathbf{V}^{-1}(\mathbf{V} - \mathbf{Q})\mathbf{V}^{-1} \end{aligned}$$

The change in the fixed-effects estimates following removal of the observations in  $U$  is

$$\hat{\beta} - \hat{\beta}_{(U)} = \mathbf{\Omega}\mathbf{X}'\mathbf{V}^{-1}\mathbf{U}(\mathbf{U}'\mathbf{P}\mathbf{U})^{-1}\mathbf{U}'\mathbf{V}^{-1}(\mathbf{y} - \mathbf{X}\hat{\beta})$$

Using results in Cook and Weisberg (1982, A2) you can further compute

$$\tilde{\mathbf{\Omega}} = (\mathbf{X}'_{(U)}\mathbf{V}_{(U)}^{-1}\mathbf{X}_{(U)})^{-} = \mathbf{\Omega} + \mathbf{\Omega}\mathbf{X}'\mathbf{V}^{-1}\mathbf{U}(\mathbf{U}'\mathbf{P}\mathbf{U})^{-1}\mathbf{U}'\mathbf{V}^{-1}\mathbf{X}\mathbf{\Omega}$$

If  $\mathbf{X}$  is  $(n \times p)$  of rank  $m < p$ , then  $\mathbf{\Omega}$  is deficient in rank and the MIXED procedure computes needed quantities in  $\tilde{\mathbf{\Omega}}$  by sweeping (Goodnight 1979). If the rank of the  $(k \times k)$  matrix  $\mathbf{U}'\mathbf{P}\mathbf{U}$  is less than  $k$ , the removal

of the observations introduces a new singularity, whether  $\mathbf{X}$  is of full rank or not. The solution vectors  $\hat{\boldsymbol{\beta}}$  and  $\hat{\boldsymbol{\beta}}_{(U)}$  then do not have the same expected values and should not be compared. When the MIXED procedure encounters this situation, influence diagnostics that depend on the choice of generalized inverse are not computed. The procedure also monitors the singularity criteria when sweeping the rows of  $(\mathbf{X}'\mathbf{V}^{-1}\mathbf{X})^{-}$  and of  $(\mathbf{X}'_{(U)}\mathbf{V}_{(U)}^{-1}\mathbf{X}_{(U)})^{-}$ . If a new singularity is encountered or a former singularity disappears, no influence statistics are computed.

**Residual Variance** When  $\sigma^2$  is profiled out of the marginal variance-covariance matrix, a closed-form estimate of  $\sigma^2$  that is based on only the remaining observations can be computed provided  $\mathbf{V}^* = \mathbf{V}(\hat{\boldsymbol{\theta}}^*)$  is known. Hurtado (1993, Thm. 5.2) shows that

$$(n - q - r)\hat{\sigma}_{(U)}^2 = (n - q)\hat{\sigma}^2 - \hat{\boldsymbol{\epsilon}}'_U(\hat{\sigma}^2\mathbf{U}'\mathbf{P}\mathbf{U})^{-1}\hat{\boldsymbol{\epsilon}}_U$$

and  $\hat{\boldsymbol{\epsilon}}_U = \mathbf{U}'\mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})$ . In the case of maximum likelihood estimation  $q = 0$  and for REML estimation  $q = \text{rank}(\mathbf{X})$ . The constant  $r$  equals the rank of  $(\mathbf{U}'\mathbf{P}\mathbf{U})$  for REML estimation and the number of effective observations that are removed if `METHOD=ML`.

**Likelihood Distances** For noniterative methods the following computational devices are used to compute (restricted) likelihood distances provided that the residual variance  $\sigma^2$  is profiled.

The log likelihood function  $l(\hat{\boldsymbol{\theta}})$  evaluated at the full-data and reduced-data estimates can be written as

$$\begin{aligned} l(\hat{\boldsymbol{\psi}}) &= -\frac{n}{2}\log(\hat{\sigma}^2) - \frac{1}{2}\log|\mathbf{V}^*| - \frac{1}{2}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})'\mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}})/\hat{\sigma}^2 - \frac{n}{2}\log(2\pi) \\ l(\hat{\boldsymbol{\psi}}_{(U)}) &= -\frac{n}{2}\log(\hat{\sigma}_{(U)}^2) - \frac{1}{2}\log|\mathbf{V}^*| - \frac{1}{2}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})'\mathbf{V}^{*-1}(\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})/\hat{\sigma}_{(U)}^2 - \frac{n}{2}\log(2\pi) \end{aligned}$$

Notice that  $l(\hat{\boldsymbol{\theta}}_{(U)})$  evaluates the log likelihood for  $n$  data points at the reduced-data estimates. It is not the log likelihood obtained by fitting the model to the reduced data. The likelihood distance is then

$$\text{LD}_{(U)} = n \log \left\{ \frac{\hat{\sigma}_{(U)}^2}{\hat{\sigma}^2} \right\} - n + (\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)})' \mathbf{V}^{*-1} (\mathbf{y} - \mathbf{X}\hat{\boldsymbol{\beta}}_{(U)}) / \hat{\sigma}_{(U)}^2$$

Expressions for  $\text{RLD}_{(U)}$  in noniterative influence analysis are derived along the same lines.

## Default Output

The following sections describe the output PROC MIXED produces by default. This output is organized into various tables, and they are discussed in order of appearance.

## Model Information

The “Model Information” table describes the model, some of the variables it involves, and the method used in fitting it. It also lists the method (profile, factor, parameter, or none) for handling the residual variance in the model. The *profile* method concentrates the residual variance out of the optimization problem, whereas the *parameter* method retains it as a parameter in the optimization. The *factor* method keeps the residual fixed, and *none* is displayed when a residual variance is not part of the model.

The “Model Information” table also has a row labeled Fixed Effects SE Method. This row describes the method used to compute the approximate standard errors for the fixed-effects parameter estimates and related functions of them. The two possibilities for this row are Model-Based, which is the default method, and Empirical, which results from using the **EMPIRICAL** option in the **PROC MIXED** statement.

The ODS name of the “Model Information” table is ModelInfo.

### Class Level Information

The “Class Level Information” table lists the levels of every variable specified in the **CLASS** statement. You should check this information to make sure the data are correct. You can adjust the order of the **CLASS** variable levels with the **ORDER=** option in the **PROC MIXED** statement. The ODS name of the “Class Level Information” table is ClassLevels.

### Dimensions

The “Dimensions” table lists the sizes of relevant matrices. This table can be useful in determining CPU time and memory requirements. The ODS name of the “Dimensions” table is Dimensions.

### Number of Observations

The “Number of Observations” table shows the number of observations read from the data set and the number of observations used in fitting the model.

### Iteration History

The “Iteration History” table describes the optimization of the **residual log likelihood** or **log likelihood**. The function to be minimized (the *objective function*) is  $-2l$  for ML and  $-2l_R$  for REML; the column name of the objective function in the “Iteration History” table is “-2 Log Like” for ML and “-2 Res Log Like” for REML. The minimization is performed by using a ridge-stabilized Newton-Raphson algorithm, and the rows of this table describe the iterations that this algorithm takes in order to minimize the objective function.

The Evaluations column of the “Iteration History” table tells how many times the objective function is evaluated during each iteration.

The Criterion column of the “Iteration History” table is, by default, a relative Hessian convergence quantity given by

$$\frac{\mathbf{g}'_k \mathbf{H}_k^{-1} \mathbf{g}_k}{|f_k|}$$

where  $f_k$  is the value of the objective function at iteration  $k$ ,  $\mathbf{g}_k$  is the gradient (first derivative) of  $f_k$ , and  $\mathbf{H}_k$  is the Hessian (second derivative) of  $f_k$ . If  $\mathbf{H}_k$  is singular, then **PROC MIXED** uses the following relative quantity:

$$\frac{\mathbf{g}'_k \mathbf{g}_k}{|f_k|}$$

To prevent the division by  $|f_k|$ , use the **ABSOLUTE** option in the **PROC MIXED** statement. To use a relative function or gradient criterion, use the **CONVF** or **CONVG** option, respectively.

The Hessian criterion is considered superior to function and gradient criteria because it measures orthogonality rather than lack of progress (Bates and Watts 1988). Provided the initial estimate is feasible and the maximum number of iterations is not exceeded, the Newton-Raphson algorithm is considered to have converged when the criterion is less than the tolerance specified with the `CONVF`, `CONVG`, or `CONVH` option in the `PROC MIXED` statement. The default tolerance is  $1E-8$ . If convergence is not achieved, `PROC MIXED` displays the estimates of the parameters at the last iteration.

A convergence criterion that is missing indicates that a boundary constraint has been dropped; it is usually not a cause for concern.

If you specify the `ITDETAILS` option in the `PROC MIXED` statement, then the covariance parameter estimates at each iteration are included as additional columns in the “Iteration History” table.

The ODS name of the “Iteration History” table is `IterHistory`.

## Convergence Status

The “Convergence Status” table informs about the status of the iterative estimation process at the end of the Newton-Raphson optimization. It appears as a message in the listing, and this message is repeated in the log. The ODS object “ConvergenceStatus” also contains several nonprinting columns that can be helpful in checking the success of the iterative process, in particular during batch processing or when analyzing BY groups. The `Status` variable takes on the value 0 for a successful convergence (even if the Hessian matrix might not be positive definite). The values 1 and 2 of the `Status` variable indicate lack of convergence and infeasible initial parameter values, respectively. The variables `pdG` and `pdH` can be used to check whether the `G` and `H` (Hessian) matrices are positive definite.

For models that are not fit iteratively, such as models without random effects or when the `NOITER` option is in effect, the “Convergence Status” is not produced.

## Covariance Parameter Estimates

The “Covariance Parameter Estimates” table contains the estimates of the parameters in `G` and `R` (see the section “Estimating Covariance Parameters in the Mixed Model” on page 4964). Their values are labeled in the table along with Subject and Group information if applicable. The estimates are displayed in the `Estimate` column and are the results of one of the following estimation methods: `REML`, `ML`, `MIVQUE0`, `SSCP`, `Type1`, `Type2`, or `Type3`.

If you specify the `RATIO` option in the `PROC MIXED` statement, the `Ratio` column is added to the table listing the ratio of each parameter estimate to that of the residual variance.

Specifying the `COVTEST` option in the `PROC MIXED` statement produces the “Std Error,” “Z Value,” and “Pr Z” columns. The “Std Error” column contains the approximate standard errors of the covariance parameter estimates. These are the square roots of the diagonal elements of the observed inverse Fisher information matrix, which equals  $2\mathbf{H}^{-1}$ , where `H` is the Hessian matrix. The `H` matrix consists of the second derivatives of the objective function with respect to the covariance parameters; see Wolfinger, Tobias, and Sall (1994) for formulas. When you use the `SCORING=` option and `PROC MIXED` converges without stopping the scoring algorithm, `PROC MIXED` uses the expected Hessian matrix to compute the covariance matrix instead of the observed Hessian. The observed or expected inverse Fisher information matrix can be viewed as an asymptotic covariance matrix of the estimates.

The “Z Value” column is the estimate divided by its approximate standard error, and the “Pr Z” column is the one- or two-tailed area of the standard Gaussian density outside of the Z-value. The `MIXED` procedure

computes one-sided  $p$ -values for the residual variance and for covariance parameters with a lower bound of 0. The procedure computes two-sided  $p$ -values otherwise. These statistics constitute Wald tests of the covariance parameters, and they are valid only asymptotically.

**CAUTION:** Wald tests can be unreliable in small samples.

The ODS name of the “Covariance Parameter Estimates” table is CovParms.

## Fit Statistics

The “Fit Statistics” table provides some statistics about the estimated mixed model. Expressions for the  $-2$  times the log likelihood are provided in the section “[Estimating Covariance Parameters in the Mixed Model](#)” on page 4964. If the log likelihood is an extremely large number, then PROC MIXED has deemed the estimated  $\mathbf{V}$  matrix to be singular. In this case, all subsequent results should be viewed with caution.

In addition, the “Fit Statistics” table lists three information criteria: AIC, AICC, and BIC, all in smaller-is-better form. Expressions for these criteria are described under the **IC** option.

The ODS name of the “Model Fitting Information” table is FitStatistics.

## Null Model Likelihood Ratio Test

If one covariance model is a submodel of another, you can carry out a likelihood ratio test for the significance of the more general model by computing  $-2$  times the difference between their log likelihoods. Then compare this statistic to the  $\chi^2$  distribution with degrees of freedom equal to the difference in the number of parameters for the two models.

This test is reported in the “Null Model Likelihood Ratio Test” table to determine whether it is necessary to model the covariance structure of the data at all. The “Chi-Square” value is  $-2$  times the log likelihood from the null model minus  $-2$  times the log likelihood from the fitted model, where the null model is the one with only the fixed effects listed in the **MODEL** statement and  $\mathbf{R} = \sigma^2\mathbf{I}$ . This statistic has an asymptotic  $\chi^2$  distribution with  $q - 1$  degrees of freedom, where  $q$  is the effective number of covariance parameters (those not estimated to be on a boundary constraint). The “Pr > ChiSq” column contains the upper-tail area from this distribution. This  $p$ -value can be used to assess the significance of the model fit.

This test is not produced for cases where the null hypothesis lies on the boundary of the parameter space, which is typically for variance component models. This is because the standard asymptotic theory does not apply in this case (Self and Liang 1987, Case 5).

If you specify a **PARMS** statement, PROC MIXED constructs a likelihood ratio test between the best model from the grid search and the final fitted model and reports the results in the “Parameter Search” table.

The ODS name of the “Null Model Likelihood Ratio Test” table is LRT.

## Type 3 Tests of Fixed Effects

The “Type 3 Tests of Fixed Effects” table contains hypothesis tests for the significance of each of the fixed effects—that is, those effects you specify in the **MODEL** statement. By default, PROC MIXED computes these tests by first constructing a Type 3 **L** matrix (see Chapter 15, “[The Four Types of Estimable Functions](#)”) for each effect. This **L** matrix is then used to compute the following  $F$  statistic:

$$F = \frac{\hat{\boldsymbol{\beta}}' \mathbf{L}' [\mathbf{L}(\mathbf{X}' \hat{\mathbf{V}}^{-1} \mathbf{X})^{-1} \mathbf{L}]^{-1} \mathbf{L} \hat{\boldsymbol{\beta}}}{r}$$

where  $r = \text{rank}(\mathbf{L}(\mathbf{X}'\hat{\mathbf{V}}^{-1}\mathbf{X})^{-1}\mathbf{L}')$ . A  $p$ -value for the test is computed as the tail area beyond this statistic from an  $F$  distribution with NDF and DDF degrees of freedom. The numerator degrees of freedom (NDF) are the row rank of  $\mathbf{L}$ , and the denominator degrees of freedom are computed by using one of the methods described under the `DDFM=` option. Small values of the  $p$ -value (typically less than 0.05 or 0.01) indicate a significant effect.

You can use the `HTYPE=` option in the `MODEL` statement to obtain tables of Type 1 (sequential) tests and Type 2 (adjusted) tests in addition to or instead of the table of Type 3 (partial) tests.

You can use the `CHISQ` option in the `MODEL` statement to obtain Wald  $\chi^2$  tests of the fixed effects. These are carried out by using the numerator of the  $F$  statistic and comparing it with the  $\chi^2$  distribution with NDF degrees of freedom. It is more liberal than the  $F$  test because it effectively assumes infinite denominator degrees of freedom.

The ODS names of the “Type 1 Tests of Fixed Effects” through the “Type 3 Tests of Fixed Effects” tables are Tests1 through Tests3, respectively.

## ODS Table Names

Each table created by PROC MIXED has a name associated with it, and you must use this name to reference the table when using ODS statements. These names are listed in Table 59.26.

**Table 59.26** ODS Tables Produced by PROC MIXED

| Table Name  | Description                                                  | Required Statement / Option                                                                                    |
|-------------|--------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| AccRates    | Acceptance rates for posterior sampling                      | PRIOR                                                                                                          |
| AsyCorr     | Asymptotic correlation matrix of covariance parameters       | PROC MIXED ASYCORR                                                                                             |
| AsyCov      | Asymptotic covariance matrix of covariance parameters        | PROC MIXED ASYCOV                                                                                              |
| Base        | Base densities used for posterior sampling                   | PRIOR                                                                                                          |
| Bound       | Computed bound for posterior rejection sampling              | PRIOR                                                                                                          |
| CholG       | Cholesky root of the estimated $\mathbf{G}$ matrix           | RANDOM / GC                                                                                                    |
| CholR       | Cholesky root of blocks of the estimated $\mathbf{R}$ matrix | REPEATED / RC                                                                                                  |
| CholV       | Cholesky root of blocks of the estimated $\mathbf{V}$ matrix | RANDOM / VC                                                                                                    |

| SolutionF   | Fixed-effects solution vector                                                                       | MODEL / S                   |
| SolutionR   | Random-effects solution vector                                                                      | RANDOM / S                  |
| Tests1      | Type 1 tests of fixed effects                                                                       | MODEL / HTYPE=1             |
| Tests2      | Type 2 tests of fixed effects                                                                       | MODEL / HTYPE=2             |
| Tests3      | Type 3 tests of fixed effects                                                                       | Default output              |
| Type1       | Type 1 analysis of variance                                                                         | PROC MIXED METHOD=TYPE1     |
| Type2       | Type 2 analysis of variance                                                                         | PROC MIXED METHOD=TYPE2     |
| Type3       | Type 3 analysis of variance                                                                         | PROC MIXED METHOD=TYPE3     |
| Trans       | Transformation of covariance parameters                                                             | PRIOR / PTRANS              |
| V           | Blocks of the estimated <b>V</b> matrix                                                             | RANDOM / V                  |
| VCorr       | Correlation matrix from blocks of the estimated <b>V</b> matrix                                     | RANDOM / VCORR              |

In Table 59.26, “Coef” refers to multiple tables produced by the **E**, **E1**, **E2**, or **E3** option in the **MODEL** statement and the **E** option in the **CONTRAST**, **ESTIMATE**, and **LSMEANS** statements. You can create one large data set of these tables with a statement similar to the following:

```
ods output Coef=c;
```

To create separate data sets, use the following statement:

```
ods output Coef(match_all)=c;
```

Here the resulting data sets are named **C**, **C1**, **C2**, etc. The same principles apply to data sets created from the “**R**,” “**CholR**,” “**InvCholR**,” “**RCorr**,” “**InvR**,” “**V**,” “**CholV**,” “**InvCholV**,” “**VCorr**,” and “**InvV**” tables.

In Table 59.26, the following changes have occurred from SAS 6. The “**Predicted**,” “**PredMeans**,” and “**Sample**” tables from SAS 6 no longer exist and have been replaced by output data sets; see descriptions

of the **MODEL** statement options **OUTP=** and **OUTPM=** and the **PRIOR** statement option **OUT=** for more details. The “ML” and “REML” tables from SAS 6 have been replaced by the “IterHistory” table. The “Tests,” “HLM,” and “HLPS” tables from SAS 6 have been renamed “Tests3,” “HLM3,” and “HLPS3,” respectively.

Table 59.27 lists the variable names associated with the data sets created when you use the ODS OUTPUT option in conjunction with the preceding tables. In Table 59.27, *n* is used to denote a generic number that depends on the particular data set and model you select, and it can assume a different value each time it is used (even within the same table). The phrase *model specific* appears in rows of the affected tables to indicate that columns in these tables depend on the variables you specify in the model.

**CAUTION:** There is a danger of name collisions with the variables in the *model specific* tables in Table 59.27 and variables in your input data set. You should avoid using input variables with the same names as the variables in these tables.

**Table 59.27** Variable Names for the ODS Tables Produced in PROC MIXED

| Table Name    | Variables                                                                                                                                                           |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| AsyCorr       | Row, CovParm, CovP1–CovPn                                                                                                                                           |
| AsyCov        | Row, CovParm, CovP1–CovPn                                                                                                                                           |

Some of the variables listed in [Table 59.27](#) are created only when you specify certain options in the relevant PROC MIXED statements.

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Some graphs are produced by default; other graphs are produced by using statements and options.

## ODS Graph Names

You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC MIXED generates are listed in [Table 59.28](#), along with the required statements and options.

**Table 59.28** Graphs Produced by PROC MIXED

| ODS Graph Name | Plot Description                                               | Statement or Option                                    |
|----------------|----------------------------------------------------------------|--------------------------------------------------------|
| Boxplot        | Box plots                                                      | PLOTS=BOXPLOT                                          |
| CovRatioPlot   | CovRatio statistics for fixed effects or covariance parameters | PLOTS=INFLUENCESTATPANEL(UNPACK) and MODEL / INFLUENCE |
| CooksDPlot     | Cook’s <i>D</i> for fixed effects or covariance parameters     | PLOTS=INFLUENCESTATPANEL(UNPACK) and MODEL / INFLUENCE |
| DistancePlot   | Likelihood or restricted likelihood distance                   | MODEL / INFLUENCE                                      |

Table 59.28 *continued*

| ODS Graph Name      | Plot Description                                                       | Statement or Option                                                          |
|---------------------|------------------------------------------------------------------------|------------------------------------------------------------------------------|
| InfluenceEstPlot    | Panel of deletion estimates                                            | MODEL / INFLUENCE(EST)<br>or PLOTS=INFLUENCEESTPLOT and<br>MODEL / INFLUENCE |
| InfluenceEstPlot    | Parameter estimates after removing observation or sets of observations | PLOTS=INFLUENCEESTPLOT(UNPACK)<br>and MODEL / INFLUENCE                      |
| InfluenceStatPanel  | Panel of influence statistics                                          | MODEL / INFLUENCE                                                            |

| StudentBoxplot      | Box plot of studentized residuals                                      | PLOTS=STUDENTPANEL(UNPACK BOX)                                               |
| StudentByPredicted  | Studentized residuals vs. predicted                                    | PLOTS=STUDENTPANEL(UNPACK)                                                   |
| StudentHistogram    | Histogram of studentized residuals                                     | PLOTS=STUDENTPANEL(UNPACK)                                                   |
| StudentPanel        | Panel of studentized residuals                                         | MODEL / RESIDUAL                                                             |
| StudentQQplot       | $Q-Q$ plot of studentized residuals                                    | PLOTS=STUDENTPANEL(UNPACK)                                                   |
| VCIRYPanel          | Panel of scaled residuals                                              | MODEL / VCIRY                                                                |

## Residual Plots

The MIXED procedure can generate panels of residual diagnostics. Each panel consists of a plot of residuals versus predicted values, a histogram with normal density overlaid, a Q-Q plot, and summary residual and fit statistics (Figure 59.15). The plots are produced even if the `OUTP=` and `OUTPM=` options in the `MODEL` statement are not specified. Residual panels can be generated for marginal and conditional raw, studentized, and Pearson residuals as well as for scaled residuals (see the section “Residual Diagnostics” on page 4976).

Recall the example in the section “Getting Started: MIXED Procedure” on page 4884. The following statements generate several  $2 \times 2$  panels of residual graphs:

```
ods graphics on;
proc mixed data=heights plots=studentpanel(marginal conditional);
 class Family Gender;
 model Height = Gender / residual;
 random Family Family*Gender;
run;
ods graphics off;
```

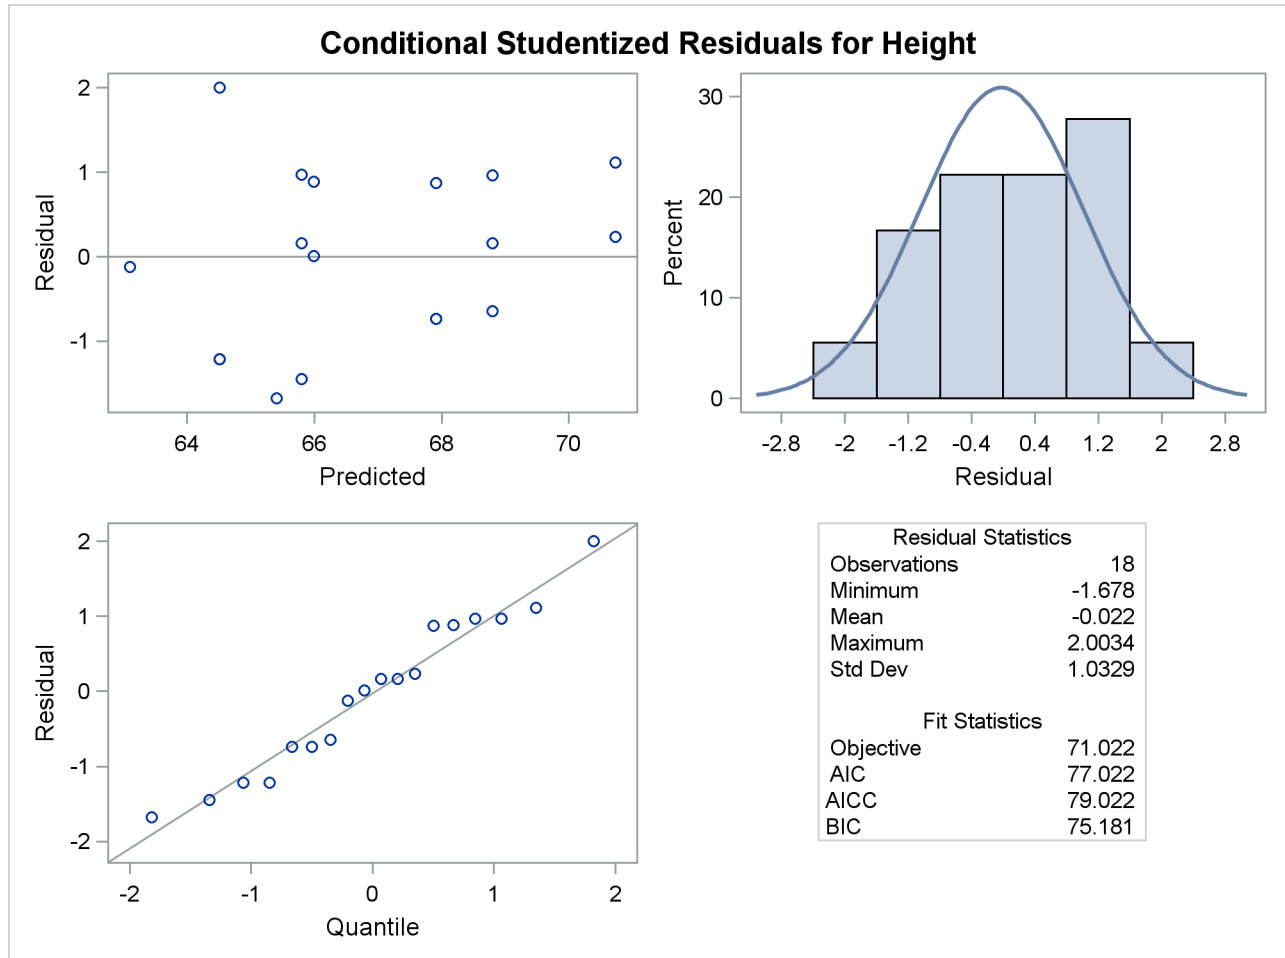

The graphs are created when ODS Graphics is enabled. The panel of the studentized marginal residuals is shown in Figure 59.15, and the panel of the studentized conditional residuals is shown in Figure 59.16.

**Figure 59.15** Panel of the Studentized (Marginal) Residuals

Since the fixed-effects part of the model comprises only an intercept and the gender effect, the marginal mean takes on only two values, one for each gender. The “Residual Statistics” inset in the lower-right corner provides descriptive statistics for the set of residuals that is displayed. Note that residuals in a mixed model do not necessarily sum to zero, even if the model contains an intercept.

**Figure 59.16** Panel of the Conditional Studentized Residuals

### Influence Plots

The graphical features of the MIXED procedure enable you to generate plots of influence diagnostics and of deletion estimates. The type and number of plots produced depend on your modifiers of the **INFLUENCE** option in the **MODEL** statement and on the **PLOTS=** option in the **PROC MIXED** statement. Plots related to covariance parameters are produced only when diagnostics are computed by iterative methods (**ITER=**). The estimates of the fixed effects—and covariance parameters when updates are iterative—are plotted when you specify the **ESTIMATES** modifier or when you request **PLOTS=INFLUENCEESTPLOT**.

Two basic types of influence panels are shown in [Figure 59.17](#) and [Figure 59.18](#). The diagnostics panel shows Cook’s *D* and CovRatio statistics for the fixed effects and the covariance parameters. For the SAS statements that produce these influence panels, see [Example 59.8](#). In this example, the impact of subjects (Person) on the analysis is assessed. The Cook’s *D* statistic measures a subject’s impact on the estimates,

and the CovRatio statistic measures a subject's impact on the precision of the estimates. Separate statistics are computed for the fixed effects and the covariance parameters. The CovRatio statistic has a threshold of 1.0. Values larger than 1.0 indicate that precision of the estimates is lost by exclusion of the observations in question. Values smaller than 1.0 indicate that precision is gained by exclusion of the observations from the analysis. For example, it is evident from [Output 59.17](#) that person 20 has considerable impact on the covariance parameter estimates and moderate influence on the fixed-effects estimates. Furthermore, exclusion of this subject from the analysis increases the precision of the covariance parameters, whereas the effect on the precision of the fixed effects is minor.

[Output 59.18](#) shows another type of influence plot, a panel of the deletion estimates. Each plot within the panel corresponds to one of the model parameters. A reference line is drawn at the estimate based on the full data.

## Computational Issues

### Computational Method

In addition to numerous matrix-multiplication routines, PROC MIXED frequently uses the sweep operator (Goodnight 1979) and the Cholesky root (Golub and Van Loan 1989). The routines perform a modified W transformation (Goodnight and Hemmerle 1979) for **G**-side likelihood calculations and a direct method for **R**-side likelihood calculations. For the Type 3 *F* tests, PROC MIXED uses the algorithm described in Chapter 42, “The GLM Procedure.”

PROC MIXED uses a ridge-stabilized Newton-Raphson algorithm to optimize either a full (ML) or residual (REML) likelihood function. The Newton-Raphson algorithm is preferred to the EM algorithm (Lindstrom and Bates 1988). PROC MIXED profiles the likelihood with respect to the fixed effects and also with respect to the residual variance whenever it appears reasonable to do so. The residual profiling can be avoided by using the NOPROFILE option of the PROC MIXED statement. PROC MIXED uses the MIVQUE0 method (Rao 1972; Giesbrecht 1989) to compute initial values.

The likelihoods that PROC MIXED optimizes are usually well-defined continuous functions with a single optimum. The Newton-Raphson algorithm typically performs well and finds the optimum in a few iterations. It is a quadratically converging algorithm, meaning that the error of the approximation near the optimum is squared at each iteration. The quadratic convergence property is evident when the convergence criterion drops to zero by factors of 10 or more.

**Table 59.29** Notation for Order Calculations

| Symbol | Number                           |
|--------|----------------------------------|
| $p$    | Columns of $\mathbf{X}$          |
| $g$    | Columns of $\mathbf{Z}$          |
| $N$    | Observations                     |
| $q$    | Covariance parameters            |
| $t$    | Maximum observations per subject |
| $S$    | Subjects                         |

Using the notation from Table 59.29, the following are estimates of the computational speed of the algorithms used in PROC MIXED. For likelihood calculations, the crossproducts matrix construction is of order  $N(p + g)^2$  and the sweep operations are of order  $(p + g)^3$ . The first derivative calculations for parameters in  $\mathbf{G}$  are of order  $qg^3$  for ML and  $q(g^3 + pg^2 + p^2g)$  for REML. If you specify a subject effect in the **RANDOM** statement and if you are not using the **REPEATED** statement, then replace  $g$  with  $g/S$  and  $q$  with  $qS$  in these calculations. The first derivative calculations for parameters in  $\mathbf{R}$  are of order  $qS(t^3 + gt^2 + g^2t)$  for ML and  $qS(t^3 + (p + g)t^2 + (p^2 + g^2)t)$  for REML. For the second derivatives, replace  $q$  with  $q(q + 1)/2$  in the first derivative expressions. When you specify both **G**- and **R**-side parameters (that is, when you use both the **RANDOM** and **REPEATED** statements), then additional calculations are required of an order equal to the sum of the orders for **G** and **R**. Considerable execution times can result in this case.

For further details about the computational techniques used in PROC MIXED, see Wolfinger, Tobias, and Sall (1994).

## Parameter Constraints

By default, some covariance parameters are assumed to satisfy certain boundary constraints during the Newton-Raphson algorithm. For example, variance components are constrained to be nonnegative, and autoregressive parameters are constrained to be between  $-1$  and  $1$ . You can remove these constraints with the **NOBOUND** option in the **PARMS** statement (or with the **NOBOUND** option in the **PROC MIXED** statement), but this can lead to estimates that produce an infinite likelihood. You can also introduce or change boundary constraints with the **LOWERB=** and **UPPERB=** options in the **PARMS** statement.

During the Newton-Raphson algorithm, a parameter might be set equal to one of its boundary constraints for a few iterations and then it might move away from the boundary. You see a missing value in the Criterion column of the “Iteration History” table whenever a boundary constraint is dropped.

For some data sets the final estimate of a parameter might equal one of its boundary constraints. This is usually not a cause for concern, but it might lead you to consider a different model. For instance, a variance component estimate can equal zero; in this case, you might want to drop the corresponding random effect from the model. However, be aware that changing the model in this fashion can affect degrees-of-freedom calculations.

## Convergence Problems

For some data sets, the Newton-Raphson algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data.

It is also possible for PROC MIXED to converge to a point that is not the global optimum of the likelihood, although this usually occurs only with the spatial covariance structures.

If you experience convergence problems, the following points might be helpful:

- One useful tool is the **PARMS** statement, which lets you input initial values for the covariance parameters and performs a grid search over the likelihood surface.
- Sometimes the Newton-Raphson algorithm does not perform well when two of the covariance parameters are on a different scale—that is, when they are several orders of magnitude apart. This is because the Hessian matrix is processed jointly for the two parameters, and elements of it corresponding to one of the parameters can become close to internal tolerances in PROC MIXED. In this case, you can improve stability by rescaling the effects in the model so that the covariance parameters are on the same scale.
- Data that are extremely large or extremely small can adversely affect results because of the internal tolerances in PROC MIXED. Rescaling it can improve stability.
- For stubborn problems, you might want to specify **ODS OUTPUT COVPARMS=*data-set-name*** to output the “Covariance Parameter Estimates” table as a precautionary measure. That way, if the problem does not converge, you can read the final parameter values back into a new run with the **PARMSDATA=** option in the **PARMS** statement.
- Fisher scoring can be more robust than Newton-Raphson with poor **MIVQUE(0)** starting values. Specifying a **SCORING=** value of 5 or so might help to recover from poor starting values.
- Tuning the singularity options **SINGULAR=**, **SINGCHOL=**, and **SINGRES=** in the **MODEL** statement can improve the stability of the optimization process.
- Tuning the **MAXITER=** and **MAXFUNC=** options in the **PROC MIXED** statement can save resources. Also, the **ITDETAILS** option displays the values of all the parameters at each iteration.
- Using the **NOPROFILE** and **NOBOUND** options in the **PROC MIXED** statement might help convergence, although they can produce unusual results.
- Although the **CONVH** convergence criterion usually gives the best results, you might want to try **CONVF** or **CONVG**, possibly along with the **ABSOLUTE** option.
- If the convergence criterion reaches a relatively small value such as  $1E-7$  but never gets lower than  $1E-8$ , you might want to specify **CONVH=1E-6** in the **PROC MIXED** statement to get results; however, interpret the results with caution.
- An infinite likelihood during the iteration process means that the Newton-Raphson algorithm has stepped into a region where either the **R** or **V** matrix is nonpositive definite. This is usually no cause for concern as long as iterations continue. If PROC MIXED stops because of an infinite likelihood, recheck your model to make sure that no observations from the same subject are producing identical rows in **R** or **V** and that you have enough data to estimate the particular covariance structure you have selected. Any time that the final estimated likelihood is infinite, subsequent results should be interpreted with caution.

- A nonpositive definite Hessian matrix can indicate a surface saddlepoint or linear dependencies among the parameters.
- A warning message about the singularities of  $\mathbf{X}$  changing indicates that there is some linear dependency in the estimate of  $\mathbf{X}'\widehat{\mathbf{V}}^{-1}\mathbf{X}$  that is not found in  $\mathbf{X}'\mathbf{X}$ . This can adversely affect the likelihood calculations and optimization process. If you encounter this problem, make sure that your model specification is reasonable and that you have enough data to estimate the particular covariance structure you have selected. Rearranging effects in the **MODEL** statement so that the most significant ones are first can help, because PROC MIXED sweeps the estimate of  $\mathbf{X}'\mathbf{V}^{-1}\mathbf{X}$  in the order of the **MODEL** effects and the sweep is more stable if larger pivots are dealt with first. If this does not help, specifying starting values with the **PARMS** statement can place the optimization on a different and possibly more stable path.
- Lack of convergence can indicate model misspecification or a violation of the normality assumption.

## Memory

Let  $p$  be the number of columns in  $\mathbf{X}$ , and let  $g$  be the number of columns in  $\mathbf{Z}$ . For large models, most of the memory resources are required for holding symmetric matrices of order  $p$ ,  $g$ , and  $p + g$ . The approximate memory requirement in bytes is

$$40(p^2 + g^2) + 32(p + g)^2$$

If you have a large model that exceeds the memory capacity of your computer, see the suggestions listed under “Computing Time.”

## Computing Time

PROC MIXED is computationally intensive, and execution times can be long. In addition to the CPU time used in collecting sums and crossproducts and in solving the mixed model equations (as in PROC GLM), considerable CPU time is often required to compute the likelihood function and its derivatives. These latter computations are performed for every Newton-Raphson iteration.

If you have a model that takes too long to run, the following suggestions can be helpful:

- Examine the “Model Information” table to find out the number of columns in the  $\mathbf{X}$  and  $\mathbf{Z}$  matrices. A large number of columns in either matrix can greatly increase computing time. You might want to eliminate some higher-order effects if they are too large.
- If you have a  $\mathbf{Z}$  matrix with a lot of columns, use the **DDFM=BW** option in the **MODEL** statement to eliminate the time required for the containment method.
- If possible, “factor out” a common effect from the effects in the **RANDOM** statement and make it the **SUBJECT=** effect. This creates a block-diagonal  $\mathbf{G}$  matrix and can often speed calculations.
- If possible, use the same or nested **SUBJECT=** effects in all **RANDOM** and **REPEATED** statements.
- If your data set is very large, you might want to analyze it in pieces. The **BY** statement can help implement this strategy.

- In general, specify random effects with a lot of levels in the **REPEATED** statement and those with a few levels in the **RANDOM** statement.
- The **METHOD=MIVQUE0** option runs faster than either the **METHOD=REML** or **METHOD=ML** option because it is noniterative.
- You can specify known values for the covariance parameters by using the **HOLD=** or **NOITER** option in the **PARMS** statement or the **GDATA=** option in the **RANDOM** statement. This eliminates the need for iteration.
- The **LOGNOTE** option in the **PROC MIXED** statement writes periodic messages to the SAS log concerning the status of the calculations. It can help you diagnose where the slowdown is occurring.

---

## Examples: MIXED Procedure

The following are basic examples of the use of PROC MIXED. More examples and details can be found in Littell et al. (2006); Wolfinger (1997); Verbeke and Molenberghs (1997, 2000); Murray (1998); Singer (1998); Sullivan, Dukes, and Losina (1999), and Brown and Prescott (1999).

---

### Example 59.1: Split-Plot Design

PROC MIXED can fit a variety of mixed models. One of the most common mixed models is the split-plot design. The split-plot design involves two experimental factors, A and B. Levels of A are randomly assigned to whole plots (main plots), and levels of B are randomly assigned to split plots (subplots) within each whole plot. The design provides more precise information about B than about A, and it often arises when A can be applied only to large experimental units. An example is where A represents irrigation levels for large plots of land and B represents different crop varieties planted in each large plot.

Consider the following data from Stroup (1989a), which arise from a balanced split-plot design with the whole plots arranged in a randomized complete-block design. The variable A is the whole-plot factor, and the variable B is the subplot factor. A traditional analysis of these data involves the construction of the whole-plot error (A\*Block) to test A and the pooled residual error (B\*Block and A\*B\*Block) to test B and A\*B. To carry out this analysis with PROC GLM, you must use a TEST statement to obtain the correct *F* test for A.

Performing a mixed model analysis with PROC MIXED eliminates the need for the error term construction. PROC MIXED estimates variance components for Block, A\*Block, and the residual, and it automatically incorporates the correct error terms into test statistics.

The following statements create a DATA set for a split-plot design with four blocks, three whole-plot levels, and two subplot levels:

```
data sp;
 input Block A B Y @@;
 datalines;
1 1 1 56 1 1 2 41
1 2 1 50 1 2 2 36
```

```

1 3 1 39 1 3 2 35
2 1 1 30 2 1 2 25
2 2 1 36 2 2 2 28
2 3 1 33 2 3 2 30
3 1 1 32 3 1 2 24
3 2 1 31 3 2 2 27
3 3 1 15 3 3 2 19
4 1 1 30 4 1 2 25
4 2 1 35 4 2 2 30
4 3 1 17 4 3 2 18
;

```

The following statements fit the split-plot model assuming random block effects:

```

proc mixed;
 class A B Block;
 model Y = A B A*B;
 random Block A*Block;
run;

```

The variables A, B, and Block are listed as classification variables in the **CLASS** statement. The columns of model matrix **X** consist of indicator variables corresponding to the levels of the fixed effects A, B, and A\*B listed on the right side of the **MODEL** statement. The dependent variable Y is listed on the left side of the **MODEL** statement.

The columns of the model matrix **Z** consist of indicator variables corresponding to the levels of the random effects Block and A\*Block. The **G** matrix is diagonal and contains the variance components of Block and A\*Block. The **R** matrix is also diagonal and contains the residual variance.

The SAS statements produce [Output 59.1.1–Output 59.1.8](#).

The “Model Information” table in [Output 59.1.1](#) lists basic information about the split-plot model. REML is used to estimate the variance components, and the residual variance is profiled from the optimization.

### Output 59.1.1 Results for Split-Plot Analysis

| The Mixed Procedure       |                     |
|---------------------------|---------------------|
| Model Information         |                     |
| Data Set                  | WORK.SP             |
| Dependent Variable        | Y                   |
| Covariance Structure      | Variance Components |
| Estimation Method         | REML                |
| Residual Variance Method  | Profile             |
| Fixed Effects SE Method   | Model-Based         |
| Degrees of Freedom Method | Containment         |

The “Class Level Information” table in [Output 59.1.2](#) lists the levels of all variables specified in the **CLASS** statement. You can check this table to make sure that the data are correct.

**Output 59.1.2** Split-Plot Example (*continued*)

| Class Level Information |        |         |
|-------------------------|--------|---------|
| Class                   | Levels | Values  |
| A                       | 3      | 1 2 3   |
| B                       | 2      | 1 2     |
| Block                   | 4      | 1 2 3 4 |

The “Dimensions” table in [Output 59.1.3](#) lists the magnitudes of various vectors and matrices. The **X** matrix is seen to be  $24 \times 12$ , and the **Z** matrix is  $24 \times 16$ .

**Output 59.1.3** Split-Plot Example (*continued*)

| Dimensions            |    |
|-----------------------|----|
| Covariance Parameters | 3  |
| Columns in X          | 12 |
| Columns in Z          | 16 |
| Subjects              | 1  |
| Max Obs Per Subject   | 24 |

The “Number of Observations” table in [Output 59.1.4](#) shows that all observations read from the data set are used in the analysis.

**Output 59.1.4** Split-Plot Example (*continued*)

| Number of Observations          |    |
|---------------------------------|----|
| Number of Observations Read     | 24 |
| Number of Observations Used     | 24 |
| Number of Observations Not Used | 0  |

PROC MIXED estimates the variance components for Block, A\*Block, and the residual by REML. The REML estimates are the values that maximize the likelihood of a set of linearly independent error contrasts, and they provide a correction for the downward bias found in the usual maximum likelihood estimates. The objective function is  $-2$  times the logarithm of the restricted likelihood, and PROC MIXED minimizes this objective function to obtain the estimates.

The minimization method is the Newton-Raphson algorithm, which uses the first and second derivatives of the objective function to iteratively find its minimum. The “Iteration History” table in [Output 59.1.5](#) records the steps of that optimization process. For this example, only one iteration is required to obtain the estimates. The Evaluations column reveals that the restricted likelihood is evaluated once for each of the iterations. A criterion of 0 indicates that the Newton-Raphson algorithm has converged.

**Output 59.1.5** Split-Plot Analysis (*continued*)

| Iteration History |             |                 |            |
|-------------------|-------------|-----------------|------------|
| Iteration         | Evaluations | -2 Res Log Like | Criterion  |
| 0                 | 1           | 139.81461222    |            |
| 1                 | 1           | 119.76184570    | 0.00000000 |

Convergence criteria met.

The REML estimates for the variance components of Block, A\*Block, and the residual are 62.40, 15.38, and 9.36, respectively, as listed in the Estimate column of the “Covariance Parameter Estimates” table in Output 59.1.6.

**Output 59.1.6** Split-Plot Analysis (*continued*)

| Covariance Parameter Estimates |          |
|--------------------------------|----------|
| Cov Parm                       | Estimate |
| Block                          | 62.3958  |
| A*Block                        | 15.3819  |
| Residual                       | 9.3611   |

The “Fit Statistics” table in Output 59.1.7 lists several pieces of information about the fitted mixed model, including the residual log likelihood. The Akaike (AIC) and Bayesian (BIC) information criteria can be used to compare different models; the ones with smaller values are preferred. The AICC information criteria is a small-sample bias-adjusted form of the Akaike criterion (Hurvich and Tsai 1989).

**Output 59.1.7** Split-Plot Analysis (*continued*)

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Res Log Likelihood    | 119.8 |
| AIC (smaller is better)  | 125.8 |
| AICC (smaller is better) | 127.5 |
| BIC (smaller is better)  | 123.9 |

Finally, the fixed effects are tested by using Type 3 estimable functions (Output 59.1.8).

**Output 59.1.8** Split-Plot Analysis (*continued*)

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| A                             | 2         | 6         | 4.07    | 0.0764 |
| B                             | 1         | 9         | 19.39   | 0.0017 |
| A*B                           | 2         | 9         | 4.02    | 0.0566 |

The tests match the one obtained from the following PROC GLM statements:

```
proc glm data=sp;
 class A B Block;
 model Y = A B A*B Block A*Block;
 test h=A e=A*Block;
run;
```

You can continue this analysis by producing solutions for the fixed and random effects and then testing various linear combinations of them by using the **CONTRAST** and **ESTIMATE** statements. If you use the same **CONTRAST** and **ESTIMATE** statements with PROC GLM, the test statistics correspond to the fixed-effects-only model. The test statistics from PROC MIXED incorporate the random effects.

The various “inference space” contrasts given by Stroup (1989a) can be implemented via the **ESTIMATE** statement. Consider the following examples:

```
proc mixed data=sp;
 class A B Block;
 model Y = A B A*B;
 random Block A*Block;
 estimate 'a1 mean narrow'
 intercept 1 A 1 B .5 .5 A*B .5 .5 |
 Block .25 .25 .25 .25
 A*Block .25 .25 .25 .25 0 0 0 0 0 0 0 0;

 estimate 'a1 mean intermed'
 intercept 1 A 1 B .5 .5 A*B .5 .5 |
 Block .25 .25 .25 .25;

 estimate 'a1 mean broad'
 intercept 1 a 1 b .5 .5 A*B .5 .5;
run;
```

These statements result in **Output 59.1.9**.

## Output 59.1.9 Inference Space Results

| The Mixed Procedure |          |                |    |         |         |
|---------------------|----------|----------------|----|---------|---------|
| Estimates           |          |                |    |         |         |
| Label               | Estimate | Standard Error | DF | t Value | Pr >  t |
| a1 mean narrow      | 32.8750  | 1.0817         | 9  | 30.39   | <.0001  |
| a1 mean intermed    | 32.8750  | 2.2396         | 9  | 14.68   | <.0001  |
| a1 mean broad       | 32.8750  | 4.5403         | 9  | 7.24    | <.0001  |

Note that all the estimates are equal, but their standard errors increase with the size of the inference space. The narrow inference space consists of the observed levels of Block and A\*Block, and the  $t$ -statistic value of 30.39 applies only to these levels. This is the same  $t$  statistic computed by PROC GLM, because it computes standard errors from the narrow inference space. The intermediate inference space consists of the observed levels of Block and the entire population of levels from which A\*Block are sampled. The  $t$ -statistic value of 14.68 applies to this intermediate space. The broad inference space consists of arbitrary random levels of both Block and A\*Block, and the  $t$ -statistic value of 7.24 is appropriate. Note that the larger the inference space, the weaker the conclusion. However, the broad inference space is usually the one of interest, and even in this space conclusive results are common. The highly significant  $p$ -value for 'a1 mean broad' is an example. You can also obtain the 'a1 mean broad' result by specifying A in an LSMEANS statement. For more discussion of the inference space concept, see McLean, Sanders, and Stroup (1991).

The following statements illustrate another feature of the RANDOM statement. Recall that the basic statements for a split-plot design with whole plots arranged in randomized blocks are as follows.

```
proc mixed;
 class A B Block;
 model Y = A B A*B;
 random Block A*Block;
run;
```

An equivalent way of specifying this model is as follows:

```
proc mixed data=sp;
 class A B Block;
 model Y = A B A*B;
 random intercept A / subject=Block;
run;
```

In general, if all of the effects in the RANDOM statement can be nested within one effect, you can specify that one effect by using the SUBJECT= option. The subject effect is, in a sense, “factored out” of the random effects. The specification that uses the SUBJECT= effect can result in faster execution times for large problems because PROC MIXED is able to perform the likelihood calculations separately for each subject.

## Example 59.2: Repeated Measures

The following data are from Pothoff and Roy (1964) and consist of growth measurements for 11 girls and 16 boys at ages 8, 10, 12, and 14. Some of the observations are suspect (for example, the third observation for person 20); however, all of the data are used here for comparison purposes.

The analysis strategy employs a linear growth curve model for the boys and girls as well as a variance-covariance model that incorporates correlations for all of the observations arising from the same person. The data are assumed to be Gaussian, and their likelihood is maximized to estimate the model parameters. For overviews of this approach to repeated measures, see Jennrich and Schluchter (1986); Louis (1988); Crowder and Hand (1990); Diggle, Liang, and Zeger (1994); Everitt (1995). Jennrich and Schluchter present results for the Pothoff and Roy data from various covariance structures. The PROC MIXED statements to fit an unstructured variance matrix (their Model 2) are as follows:

```
data pr;
 input Person Gender $ y1 y2 y3 y4;
 y=y1; Age=8; output;
 y=y2; Age=10; output;
 y=y3; Age=12; output;
 y=y4; Age=14; output;
 drop y1-y4;
 datalines;
 1 F 21.0 20.0 21.5 23.0
 2 F 21.0 21.5 24.0 25.5
 3 F 20.5 24.0 24.5 26.0
 4 F 23.5 24.5 25.0 26.5

 24 M 17.0 24.5 26.0 29.5
 25 M 22.5 25.5 25.5 26.0
 26 M 23.0 24.5 26.0 30.0
 27 M 22.0 21.5 23.5 25.0
 ;
```

```

proc mixed data=pr method=ml covtest;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 repeated / type=un subject=Person r;
run;

```

To follow Jennrich and Schluchter, this example uses maximum likelihood (**METHOD=ML**) instead of the default REML to estimate the unknown covariance parameters. The **COVTEST** option requests asymptotic tests of all the covariance parameters.

The **MODEL** statement first lists the dependent variable *Y*. The fixed effects are then listed after the equal sign. The variable *Gender* requests a different intercept for the girls and boys, *Age* models an overall linear growth trend, and *Gender\*Age* makes the slopes different over time. It is actually not necessary to specify *Age* separately, but doing so enables PROC MIXED to carry out a test for heterogeneous slopes. The **SOLUTION** option requests the display of the fixed-effects solution vector.

The **REPEATED** statement contains no effects, taking advantage of the default assumption that the observations are ordered similarly for each subject. The **TYPE=UN** option requests an unstructured block for each **SUBJECT=Person**. The **R** matrix is, therefore, block diagonal with 27 blocks, each block consisting of identical 4×4 unstructured matrices. The 10 parameters of these unstructured blocks make up the covariance parameters estimated by maximum likelihood. The **R** option requests that the first block of **R** be displayed.

The results from this analysis are shown in [Output 59.2.1–Output 59.2.9](#).

#### Output 59.2.1 Repeated Measures Analysis with Unstructured Covariance Matrix

| The Mixed Procedure       |                |
|---------------------------|----------------|
| Model Information         |                |
| Data Set                  | WORK.PR        |
| Dependent Variable        | y              |
| Covariance Structure      | Unstructured   |
| Subject Effect            | Person         |
| Estimation Method         | ML             |
| Residual Variance Method  | None           |
| Fixed Effects SE Method   | Model-Based    |
| Degrees of Freedom Method | Between-Within |

In [Output 59.2.1](#), the covariance structure is listed as “Unstructured,” and no residual variance is used with this structure. The default degrees-of-freedom method here is “Between-Within.”

**Output 59.2.2** Repeated Measures Analysis (*continued*)

| Class Level Information |        |                                                                               |
|-------------------------|--------|-------------------------------------------------------------------------------|
| Class                   | Levels | Values                                                                        |
| Person                  | 27     | 1 2 3 4 5 6 7 8 9 10 11 12 13<br>14 15 16 17 18 19 20 21 22 23<br>24 25 26 27 |
| Gender                  | 2      | F M                                                                           |

In [Output 59.2.2](#), note that Person has 27 levels and Gender has 2.

**Output 59.2.3** Repeated Measures Analysis (*continued*)

| Dimensions            |    |
|-----------------------|----|
| Covariance Parameters | 10 |
| Columns in X          | 6  |
| Columns in Z          | 0  |
| Subjects              | 27 |
| Max Obs Per Subject   | 4  |

In [Output 59.2.3](#), the 10 covariance parameters result from the  $4 \times 4$  unstructured blocks of **R**. There is no **Z** matrix for this model, and each of the 27 subjects has a maximum of 4 observations.

**Output 59.2.4** Repeated Measures Analysis (*continued*)

| Number of Observations          |     |
|---------------------------------|-----|
| Number of Observations Read     | 108 |
| Number of Observations Used     | 108 |
| Number of Observations Not Used | 0   |

| Iteration History |             |              |            |
|-------------------|-------------|--------------|------------|
| Iteration         | Evaluations | -2 Log Like  | Criterion  |
| 0                 | 1           | 478.24175986 |            |
| 1                 | 2           | 419.47721707 | 0.00000152 |
| 2                 | 1           | 419.47704812 | 0.00000000 |

Convergence criteria met.

Three Newton-Raphson iterations are required to find the maximum likelihood estimates ([Output 59.2.4](#)). The default relative Hessian criterion has a final value less than  $1E-8$ , indicating the convergence of the Newton-Raphson algorithm and the attainment of an optimum.

**Output 59.2.5** Repeated Measures Analysis (*continued*)

| Estimated R Matrix for Person 1 |        |        |        |        |
|---------------------------------|--------|--------|--------|--------|
| Row                             | Col1   | Col2   | Col3   | Col4   |
| 1                               | 5.1192 | 2.4409 | 3.6105 | 2.5222 |
| 2                               | 2.4409 | 3.9279 | 2.7175 | 3.0624 |
| 3                               | 3.6105 | 2.7175 | 5.9798 | 3.8235 |
| 4                               | 2.5222 | 3.0624 | 3.8235 | 4.6180 |

The 4×4 matrix in [Output 59.2.5](#) is the estimated unstructured covariance matrix. It is the estimate of the first block of **R**, and the other 26 blocks all have the same estimate.

**Output 59.2.6** Repeated Measures Analysis (*continued*)

| Covariance Parameter Estimates |         |          |                |         |        |
|--------------------------------|---------|----------|----------------|---------|--------|
| Cov Parm                       | Subject | Estimate | Standard Error | Z Value | Pr Z   |
| UN(1,1)                        | Person  | 5.1192   | 1.4169         | 3.61    | 0.0002 |
| UN(2,1)                        | Person  | 2.4409   | 0.9835         | 2.48    | 0.0131 |
| UN(2,2)                        | Person  | 3.9279   | 1.0824         | 3.63    | 0.0001 |
| UN(3,1)                        | Person  | 3.6105   | 1.2767         | 2.83    | 0.0047 |
| UN(3,2)                        | Person  | 2.7175   | 1.0740         | 2.53    | 0.0114 |
| UN(3,3)                        | Person  | 5.9798   | 1.6279         | 3.67    | 0.0001 |
| UN(4,1)                        | Person  | 2.5222   | 1.0649         | 2.37    | 0.0179 |
| UN(4,2)                        | Person  | 3.0624   | 1.0135         | 3.02    | 0.0025 |
| UN(4,3)                        | Person  | 3.8235   | 1.2508         | 3.06    | 0.0022 |
| UN(4,4)                        | Person  | 4.6180   | 1.2573         | 3.67    | 0.0001 |

The “Covariance Parameter Estimates” table in [Output 59.2.6](#) lists the 10 estimated covariance parameters in order; note their correspondence to the first block of **R** displayed in [Output 59.2.5](#). The parameter estimates are labeled according to their location in the block in the Cov Parm column, and all of these estimates are associated with Person as the subject effect. The Std Error column lists approximate standard errors of the covariance parameters obtained from the inverse Hessian matrix. These standard errors lead to approximate Wald Z statistics, which are compared with the standard normal distribution. The results of these tests indicate that all the parameters are significantly different from 0; however, the Wald test can be unreliable in small samples.

To carry out Wald tests of various linear combinations of these parameters, use the following procedure. First, run the statements again, adding the **ASYCOV** option and an ODS statement:

```
ods output CovParms=cp AsyCov=asy;
proc mixed data=pr method=ml covtest asycov;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 repeated / type=un subject=Person r;
run;
```

This creates two data sets, `cp` and `asy`, which contain the covariance parameter estimates and their asymptotic variance covariance matrix, respectively. Then read these data sets into the SAS/IML matrix programming language as follows:

```
proc iml;
 use cp;
 read all var {Estimate} into est;
 use asy;
 read all var ('CovP1':'CovP10') into asy;
```

You can then construct your desired linear combinations and corresponding quadratic forms with the `asy` matrix.

### Output 59.2.7 Repeated Measures Analysis (*continued*)

| Fit Statistics                   |            |            |
|----------------------------------|------------|------------|
| -2 Log Likelihood                |            | 419.5      |
| AIC (smaller is better)          |            | 447.5      |
| AICC (smaller is better)         |            | 452.0      |
| BIC (smaller is better)          |            | 465.6      |
| Null Model Likelihood Ratio Test |            |            |
| DF                               | Chi-Square | Pr > ChiSq |
| 9                                | 58.76      | <.0001     |

The null model likelihood ratio test (LRT) in [Output 59.2.7](#) is highly significant for this model, indicating that the unstructured covariance matrix is preferred to the diagonal matrix of the ordinary least squares null model. The degrees of freedom for this test is 9, which is the difference between 10 and the 1 parameter for the null model's diagonal matrix.

### Output 59.2.8 Repeated Measures Analysis (*continued*)

| Solution for Fixed Effects |        |          |                |    |         |         |
|----------------------------|--------|----------|----------------|----|---------|---------|
| Effect                     | Gender | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                  |        | 15.8423  | 0.9356         | 25 | 16.93   | <.0001  |
| Gender                     | F      | 1.5831   | 1.4658         | 25 | 1.08    | 0.2904  |
| Gender                     | M      | 0        | .              | .  | .       | .       |
| Age                        |        | 0.8268   | 0.07911        | 25 | 10.45   | <.0001  |
| Age*Gender                 | F      | -0.3504  | 0.1239         | 25 | -2.83   | 0.0091  |
| Age*Gender                 | M      | 0        | .              | .  | .       | .       |

The “Solution for Fixed Effects” table in [Output 59.2.8](#) lists the solution vector for the fixed effects. The estimate of the boys' intercept is 15.8423, while that for the girls is  $15.8423 + 1.5831 = 17.0654$ . Similarly, the estimate for the boys' slope is 0.8268, while that for the girls is  $0.8268 - 0.3504 = 0.4764$ . Thus the

girls' starting point is larger than that for the boys, but their growth rate is about half that of the boys.

Note that two of the estimates equal 0; this is a result of the overparameterized model used by PROC MIXED. You can obtain a full-rank parameterization by using the following **MODEL** statement:

```
model y = Gender Gender*Age / noint s;
```

Here, the **NOINT** option causes the different intercepts to be fit directly as the two levels of Gender. However, this alternative specification results in different tests for these effects.

**Output 59.2.9** Repeated Measures Analysis (*continued*)

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Gender                        | 1         | 25        | 1.17    | 0.2904 |
| Age                           | 1         | 25        | 110.54  | <.0001 |
| Age*Gender                    | 1         | 25        | 7.99    | 0.0091 |

The “Type 3 Tests of Fixed Effects” table in **Output 59.2.9** displays Type 3 tests for all of the fixed effects. These tests are partial in the sense that they account for all of the other fixed effects in the model. In addition, you can use the **HTYPE=** option in the **MODEL** statement to obtain Type 1 (sequential) or Type 2 (also partial) tests of effects.

It is usually best to consider higher-order terms first, and in this case the **Age\*Gender** test reveals a difference between the slopes that is statistically significant at the 1% level. Note that the  $p$ -value for this test (0.0091) is the same as the  $p$ -value in the “Age\*Gender F” row in the “Solution for Fixed Effects” table (**Output 59.2.8**) and that the  $F$  statistic (7.99) is the square of the  $t$  statistic (−2.83), ignoring rounding error. Similar connections are evident among the other rows in these two tables.

The **Age** test is one for an overall growth curve accounting for possible heterogeneous slopes, and it is highly significant. Finally, the **Gender** row tests the null hypothesis of a common intercept, and this hypothesis cannot be rejected from these data.

As an alternative to the  $F$  tests shown here, you can carry out likelihood ratio tests of various hypotheses by fitting the reduced models, subtracting  $-2 \log$  likelihoods, and comparing the resulting statistics with  $\chi^2$  distributions.

Since the different levels of the repeated effect represent different years, it is natural to try fitting a time series model to the data within each subject. To obtain time series structures in **R**, you can replace **TYPE=UN** with **TYPE=AR(1)** or **TYPE=TOEP** to obtain the first- or  $n$ th-order autoregressive covariance matrices, respectively. For example, the statements to fit an **AR(1)** structure are as follows:

```
/* first-order autoregressive */
proc mixed data=pr method=ml;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 repeated / type=ar(1) sub=Person r;
run;
```

To fit a random coefficients model, use the following statements:

```
/* random coefficients model */
proc mixed data=pr method=ml;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 random intercept Age / type=un sub=Person g;
run;
```

This specifies an unstructured covariance matrix for the random intercept and slope. In mixed model notation, **G** is block diagonal with identical 2×2 unstructured blocks for each person. By default, **R** becomes  $\sigma^2\mathbf{I}$ . See [Example 59.5](#) for further information about this model.

Finally, you can fit a compound symmetry structure by using **TYPE=CS**, as follows:

```
proc mixed data=pr method=ml covtest;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 repeated / type=cs subject=Person r;
run;
```

The results from this analysis are shown in [Output 59.2.10–Output 59.2.17](#).

The “Model Information” table in [Output 59.2.10](#) is the same as before except for the change in “Covariance Structure.”

**Output 59.2.10** Repeated Measures Analysis with Compound Symmetry Structure

| The Mixed Procedure       |                   |
|---------------------------|-------------------|
| Model Information         |                   |
| Data Set                  | WORK.PR           |
| Dependent Variable        | y                 |
| Covariance Structure      | Compound Symmetry |
| Subject Effect            | Person            |
| Estimation Method         | ML                |
| Residual Variance Method  | Profile           |
| Fixed Effects SE Method   | Model-Based       |
| Degrees of Freedom Method | Between-Within    |

The “Dimensions” table in [Output 59.2.11](#) shows that there are only two covariance parameters in the compound symmetry model; this covariance structure has common variance and common covariance.

**Output 59.2.11** Analysis with Compound Symmetry (*continued*)

[Output 59.2.13](#) displays the estimated **R** matrix for the first subject. Note the compound symmetry structure here, which consists of a common covariance with a diagonal enhancement.

**Output 59.2.13** Analysis with Compound Symmetry (*continued*)

| Estimated R Matrix for Person 1 |        |        |        |        |
|---------------------------------|--------|--------|--------|--------|
| Row                             | Col1   | Col2   | Col3   | Col4   |
| 1                               | 4.9052 | 3.0306 | 3.0306 | 3.0306 |
| 2                               | 3.0306 | 4.9052 | 3.0306 | 3.0306 |
| 3                               | 3.0306 | 3.0306 | 4.9052 | 3.0306 |
| 4                               | 3.0306 | 3.0306 | 3.0306 | 4.9052 |

The common covariance is estimated to be 3.0306, as listed in the CS row of the “Covariance Parameter Estimates” table in [Output 59.2.14](#), and the residual variance is estimated to be 1.8746, as listed in the Residual row. You can use these two numbers to estimate the intraclass correlation coefficient (ICC) for this model. Here, the ICC estimate equals  $3.0306 / (3.0306 + 1.8746) = 0.6178$ . You can also obtain this

number by adding the `RCORR` option to the `REPEATED` statement.

**Output 59.2.14** Analysis with Compound Symmetry (*continued*)

| Covariance Parameter Estimates |         |          |                |         |        |
|--------------------------------|---------|----------|----------------|---------|--------|
| Cov Parm                       | Subject | Estimate | Standard Error | Z Value | Pr Z   |
| CS                             | Person  | 3.0306   | 0.9552         | 3.17    | 0.0015 |
| Residual                       |         | 1.8746   | 0.2946         | 6.36    | <.0001 |

In the case shown in [Output 59.2.15](#), the null model LRT has only one degree of freedom, corresponding to the common covariance parameter. The test indicates that modeling this extra covariance is superior to fitting the simple null model.

**Output 59.2.15** Analysis with Compound Symmetry (*continued*)

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Log Likelihood        | 428.6 |
| AIC (smaller is better)  | 440.6 |
| AICC (smaller is better) | 441.5 |
| BIC (smaller is better)  | 448.4 |

| Null Model Likelihood Ratio Test |            |            |
|----------------------------------|------------|------------|
| DF                               | Chi-Square | Pr > ChiSq |
| 1                                | 49.60      | <.0001     |

Note that the fixed-effects estimates and their standard errors ([Output 59.2.16](#)) are not very different from those in the preceding unstructured example ([Output 59.2.8](#)).

**Output 59.2.16** Analysis with Compound Symmetry (*continued*)

| Solution for Fixed Effects |        |          |                |    |         |         |
|----------------------------|--------|----------|----------------|----|---------|---------|
| Effect                     | Gender | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                  |        | 16.3406  | 0.9631         | 25 | 16.97   | <.0001  |
| Gender                     | F      | 1.0321   | 1.5089         | 25 | 0.68    | 0.5003  |
| Gender                     | M      | 0        | .              | .  | .       | .       |
| Age                        |        | 0.7844   | 0.07654        | 79 | 10.25   | <.0001  |
| Age*Gender                 | F      | -0.3048  | 0.1199         | 79 | -2.54   | 0.0130  |
| Age*Gender                 | M      | 0        | .              | .  | .       | .       |

The  $F$  tests shown in [Output 59.2.17](#) are also similar to those from the preceding unstructured example ([Output 59.2.9](#)). Again, the slopes are significantly different but the intercepts are not.

**Output 59.2.17** Analysis with Compound Symmetry (*continued*)

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|

| Age                           | 1         | 79        | 111.10  | <.0001 |
| Age*Gender                    | 1         | 79        | 6.46    | 0.0130 |

You can fit the same compound symmetry model with the following specification by using the [RANDOM](#) statement:

```
proc mixed data=pr method=ml;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 random Person;
run;
```

Compound symmetry is the structure that Jennrich and Schluchter deemed best among the ones they fit. To carry the analysis one step further, you can use the [GROUP=](#) option as follows to specify heterogeneity of this structure across girls and boys:

```
proc mixed data=pr method=ml;
 class Person Gender;
 model y = Gender Age Gender*Age / s;
 repeated / type=cs subject=Person group=Gender;
run;
```

The results from this analysis are shown in [Output 59.2.18–Output 59.2.24](#). Note that in [Output 59.2.18](#) Gender is listed as a “Group Effect.”

**Output 59.2.18** Repeated Measures Analysis with Heterogeneous Structures

| The Mixed Procedure       |                   |
|---------------------------|-------------------|
| Model Information         |                   |

| Subjects                        |        | 27                                                                            |
| Max Obs Per Subject             |        | 4                                                                             |
| Number of Observations          |        |                                                                               |
| Number of Observations Read     |        | 108                                                                           |
| Number of Observations Used     |        | 108                                                                           |
| Number of Observations Not Used |        | 0                                                                             |

As [Output 59.2.20](#) shows, even with the heterogeneity, only one iteration is required for convergence.

**Output 59.2.20** Analysis with Heterogeneous Structures (*continued*)

| Iteration History         |             |              |            |
|---------------------------|-------------|--------------|------------|
| Iteration                 | Evaluations | -2 Log Like  | Criterion  |
| 0                         | 1           | 478.24175986 |            |
| 1                         | 1           | 408.81297228 | 0.00000000 |
| Convergence criteria met. |             |              |            |

The “Covariance Parameter Estimates” table in [Output 59.2.21](#) lists the heterogeneous estimates. Note that both the common covariance and the diagonal enhancement differ between girls and boys.

**Output 59.2.21** Analysis with Heterogeneous Structures (*continued*)

| Covariance Parameter Estimates |         |          |          |
|--------------------------------|---------|----------|----------|
| Cov Parm                       | Subject | Group    | Estimate |
| Variance                       | Person  | Gender F | 0.5900   |
| CS                             | Person  | Gender F | 3.8804   |
| Variance                       | Person  | Gender M | 2.7577   |
| CS                             | Person  | Gender M | 2.4463   |

As [Output 59.2.22](#) shows, both Akaike's information criterion (424.8) and Schwarz's Bayesian information criterion (435.2) are smaller for this model than for the homogeneous compound symmetry model (440.6 and 448.4, respectively). This indicates that the heterogeneous model is more appropriate. To construct the likelihood ratio test between the two models, subtract the  $-2 \log$  likelihood values:  $428.6 - 408.8 = 19.8$ . Comparing this value with the  $\chi^2$  distribution with two degrees of freedom yields a  $p$ -value less than 0.0001, again favoring the heterogeneous model.

**Output 59.2.22** Analysis with Heterogeneous Structures (*continued*)

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Log Likelihood        | 408.8 |
| AIC (smaller is better)  | 424.8 |
| AICC (smaller is better) | 426.3 |
| BIC (smaller is better)  | 435.2 |

| Null Model Likelihood Ratio Test |            |            |
|----------------------------------|------------|------------|
| DF                               | Chi-Square | Pr > ChiSq |
| 3                                | 69.43      | <.0001     |

Note that the fixed-effects estimates shown in [Output 59.2.23](#) are the same as in the homogeneous case, but the standard errors are different.

**Output 59.2.23** Analysis with Heterogeneous Structures (*continued*)

| Solution for Fixed Effects |        |          |                |    |         |         |
|----------------------------|--------|----------|----------------|----|---------|---------|
| Effect                     | Gender | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                  |        | 16.3406  | 1.1130         | 25 | 14.68   | <.0001  |
| Gender                     | F      | 1.0321   | 1.3890         | 25 | 0.74    | 0.4644  |
| Gender                     | M      | 0        | .              | .  | .       | .       |
| Age                        |        | 0.7844   | 0.09283        | 79 | 8.45    | <.0001  |
| Age*Gender                 | F      | -0.3048  | 0.1063         | 79 | -2.87   | 0.0053  |
| Age*Gender                 | M      | 0        | .              | .  | .       | .       |

The fixed-effects tests shown in [Output 59.2.24](#) are similar to those from previous models, although the  $p$ -values do change as a result of specifying a different covariance structure. It is important for you to select a reasonable covariance structure in order to obtain valid inferences for your fixed effects.

**Output 59.2.24** Analysis with Heterogeneous Structures (*continued*)

| Type 3 Tests of Fixed Effects |           |           |         |        |

## Example 59.3: Plotting the Likelihood

The data for this example are from Hemmerle and Hartley (1973) and are also used for an example in the VARCOMP procedure. The response variable consists of measurements from an oven experiment, and the model contains a fixed effect A and random effects B and A\*B.

The SAS statements are as follows:

```
data hh;
 input a b y @@;
 datalines;
1 1 237 1 1 254 1 1 246
1 2 178 1 2 179
2 1 208 2 1 178 2 1 187
2 2 146 2 2 145 2 2 141
3 1 186 3 1 183
3 2 142 3 2 125 3 2 136
;

ods output ParmSearch=parms;
proc mixed data=hh asycov mmeq mmeqsol covtest;
 class a b;
 model y = a / outp=predicted;
 random b a*b;
 lsmeans a;
 parms (17 to 20 by .1) (.3 to .4 by .005) (1.0);
run;
proc print data=predicted;
run;
```

The **ASYCOV** option in the **PROC MIXED** statement requests the asymptotic variance matrix of the covariance parameter estimates. This matrix is the observed inverse Fisher information matrix, which equals  $2\mathbf{H}^{-1}$ , where  $\mathbf{H}$  is the Hessian matrix of the objective function evaluated at the final covariance parameter estimates. The **MMEQ** and **MMEQSOL** options in the **PROC MIXED** statement request that the mixed model equations and their solution be displayed.

The `OUTP=` option in the `MODEL` statement produces the data set predicted, containing the predicted values. Least squares means (LSMEANS) are requested for A. The `PARMS` and `ODS` statements are used to construct a data set containing the likelihood surface.

The results from this analysis are shown in [Output 59.3.1–Output 59.3.13](#).

The “Model Information” table in [Output 59.3.1](#) lists details about this variance components model.

**Output 59.3.1** Model Information

| The Mixed Procedure       |                     |
|---------------------------|---------------------|
| Model Information         |                     |
| Data Set                  | WORK.HH             |
| Dependent Variable        | y                   |
| Covariance Structure      | Variance Components |
| Estimation Method         | REML                |
| Residual Variance Method  | Profile             |
| Fixed Effects SE Method   | Model-Based         |
| Degrees of Freedom Method | Containment         |

The “Class Level Information” table in [Output 59.3.2](#) lists the levels for A and B.

**Output 59.3.2** Class Level Information

| Class Level Information |        |        |
|-------------------------|--------|--------|
| Class                   | Levels | Values |
| a                       | 3      | 1 2 3  |
| b                       | 2      | 1 2    |

The “Dimensions” table in [Output 59.3.3](#) reveals that  $\mathbf{X}$  is  $16 \times 4$  and  $\mathbf{Z}$  is  $16 \times 8$ . Since there are no `SUBJECT=` effects, PROC MIXED considers the data to be effectively from one subject with 16 observations.

**Output 59.3.3** Model Dimensions and Number of Observations

| Dimensions            |    |
|-----------------------|----|
| Covariance Parameters | 3  |
| Columns in X          | 4  |
| Columns in Z          | 8  |
| Subjects              | 1  |
| Max Obs Per Subject   | 16 |

**Output 59.3.3** *continued*

| Number of Observations          |    |
|---------------------------------|----|
| Number of Observations Read     | 16 |
| Number of Observations Used     | 16 |
| Number of Observations Not Used | 0  |

Only a portion of the “Parameter Search” table is shown in [Output 59.3.4](#) because the full listing has 651 rows.

**Output 59.3.4** Selected Results of Parameter Search

| The Mixed Procedure |        |        |          |              |                 |
|---------------------|--------|--------|----------|--------------|-----------------|

As [Output 59.3.5](#) shows, convergence occurs quickly because PROC MIXED starts from the best value from the grid search.

**Output 59.3.5** Iteration History and Convergence Status

| Iteration History         |             |                 |            |  |
|---------------------------|-------------|-----------------|------------|--|
| Iteration                 | Evaluations | -2 Res Log Like | Criterion  |  |
| 1                         | 2           | 104.93416367    | 0.00000000 |  |
| Convergence criteria met. |             |                 |            |  |

The “Covariance Parameter Estimates” table in [Output 59.3.6](#) lists the variance components estimates. Note that B is much more variable than A\*B.

**Output 59.3.6** Estimated Covariance Parameters

| Covariance Parameter Estimates |          |                |         |        |
|--------------------------------|----------|----------------|---------|--------|
| Cov Parm                       | Estimate | Standard Error | Z Value | Pr > Z |
| b                              | 1464.36  | 2098.01        | 0.70    | 0.2426 |
| a*b                            | 26.9581  | 59.6570        | 0.45    | 0.3257 |
| Residual                       | 78.8426  | 35.3512        | 2.23    | 0.0129 |

The asymptotic covariance matrix in [Output 59.3.7](#) also reflects the large variability of B relative to A\*B.

**Output 59.3.7** Asymptotic Covariance Matrix of Covariance Parameters

| Asymptotic Covariance Matrix of Estimates |          |         |         |         |
|-------------------------------------------|----------|---------|---------|---------|
| Row                                       | Cov Parm | CovP1   | CovP2   | CovP3   |
| 1                                         | b        | 4401640 | 1.2831  | -273.32 |
| 2                                         | a*b      | 1.2831  | 3558.96 | -502.84 |
| 3                                         | Residual | -273.32 | -502.84 | 1249.71 |

As [Output 59.3.8](#) shows, the PARMS likelihood ratio test (LRT) compares the best model from the grid search with the final fitted model. Since these models are nearly the same, the LRT is not significant.

**Output 59.3.8** Fit Statistics and Likelihood Ratio Test

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Res Log Likelihood    | 104.9 |
| AIC (smaller is better)  | 110.9 |
| AICC (smaller is better) | 113.6 |
| BIC (smaller is better)  | 107.0 |

**Output 59.3.8** *continued*

| PARMS Model Likelihood Ratio Test |            |            |
|-----------------------------------|------------|------------|
| DF                                | Chi-Square | Pr > ChiSq |
| 2                                 | 0.00       | 1.0000     |

The mixed model equations are analogous to the normal equations in the standard linear model. As [Output 59.3.9](#) shows, for this example, rows 1–4 correspond to the fixed effects, rows 5–12 correspond to the random effects, and Col13 corresponds to the dependent variable.

**Output 59.3.9** Mixed Model Equations

| Mixed Model Equations |           |   |   |         |         |         |         |         |         |         |

| 12                             | 1.9200   | -2.1570  | 2.1570   | 4.1555   | 22.8027  | 0.8115   |

The A factor is significant at the 5% level (Output 59.3.11).

**Output 59.3.11** Tests of Fixed Effects

| Type 3 Tests of Fixed Effects |        |        |         |        |
|-------------------------------|--------|--------|---------|--------|
| Effect                        | Num DF | Den DF | F Value | Pr > F |
| a                             | 2      | 2      | 28.00   | 0.0345 |

Output 59.3.12 shows that the significance of A appears to be from the difference between its first level and its other two levels.

**Output 59.3.12** Least Squares Means for A Effect

| Least Squares Means |   |          |                |    |         |         |
|---------------------|---|----------|----------------|----|---------|---------|
| Effect              | a | Estimate | Standard Error | DF | t Value | Pr >  t |
| a                   | 1 | 212.82   | 27.6014        | 2  | 7.71    | 0.0164  |
| a                   | 2 | 167.50   | 27.5463        | 2  | 6.08    | 0.0260  |
| a                   | 3 | 159.61   | 27.6014        | 2  | 5.78    | 0.0286  |

Output 59.3.13 lists the predicted values from the model. These values are the sum of the fixed-effects estimates and the empirical best linear unbiased predictors (EBLUPs) of the random effects.

**Output 59.3.13** Predicted Values

| Obs | a | b | y   | Pred    | StdErr  |    | DF   | Alpha   | Lower   | Upper    | Resid |

| 15  | 3 | 2 | 125 | 133.542 | 4.72563 | 10 | 0.05 | 123.013 | 144.072 | -8.5422  |       |
| 16  | 3 | 2 | 136 | 133.542 | 4.72563 | 10 | 0.05 | 123.013 | 144.072 | 2.4578   |       |

To plot the likelihood surface by using ODS Graphics, use the following statements:

```
proc template;
 define statgraph surface;
 begingraph;
 layout overlay3d;
 surfaceplotparm x=CovP1 y=CovP2 z=ResLogLike;
 endlayout;
 endgraph;
 end;
run;
proc sgrender data=parms template=surface;
run;
```

The results from this plot are shown in Output 59.3.14. The peak of the surface is the REML estimates for the B and A\*B variance components.

**Output 59.3.14** Plot of Likelihood Surface

---

### Example 59.4: Known G and R

This animal breeding example from Henderson (1984, p. 48) considers multiple traits. The data are artificial and consist of measurements of two traits on three animals, but the second trait of the third animal is missing. Assuming an additive genetic model, you can use PROC MIXED to predict the breeding value of both traits on all three animals and also to predict the second trait of the third animal. The data are as follows:

```
data h;
 input Trait Animal Y;
 datalines;
1 1 6
1 2 8
1 3 7
2 1 9
2 2 5
2 3 .
;
```

Both **G** and **R** are known.

$$\mathbf{G} = \begin{bmatrix} 2 & 1 & 1 & 2 & 1 & 1 \\ 1 & 2 & .5 & 1 & 2 & .5 \\ 1 & .5 & 2 & 1 & .5 & 2 \\ 2 & 1 & 1 & 3 & 1.5 & 1.5 \\ 1 & 2 & .5 & 1.5 & 3 & .75 \\ 1 & .5 & 2 & 1.5 & .75 & 3 \end{bmatrix}$$

$$\mathbf{R} = \begin{bmatrix} 4 & 0 & 0 & 1 & 0 & 0 \\ 0 & 4 & 0 & 0 & 1 & 0 \\ 0 & 0 & 4 & 0 & 0 & 1 \\ 1 & 0 & 0 & 5 & 0 & 0 \\ 0 & 1 & 0 & 0 & 5 & 0 \\ 0 & 0 & 1 & 0 & 0 & 5 \end{bmatrix}$$

In order to read **G** into PROC MIXED by using the **GDATA=** option in the **RANDOM** statement, perform the following DATA step:

```
data g;
 input Row Col1-Col6;
 datalines;
1 2 1 1 2 1 1
2 1 2 .5 1 2 .5
3 1 .5 2 1 .5 2
4 2 1 1 3 1.5 1.5
5 1 2 .5 1.5 3 .75
6 1 .5 2 1.5 .75 3
;
```

The preceding data are in the dense representation for a **GDATA=** data set. You can also construct a data set with the sparse representation by using **Row**, **Col**, and **Value** variables, although this would require 21 observations instead of 6 for this example.

The PROC MIXED statements are as follows:

```
proc mixed data=h mmeq mmeqsol;
 class Trait Animal;
 model Y = Trait / noint s outp=predicted;
 random Trait*Animal / type=un gdata=g g gi s;
 repeated / type=un sub=Animal r ri;
 parms (4) (1) (5) / noiter;
run;
proc print data=predicted;
run;
```

The **MMEQ** and **MMEQSOL** options request the mixed model equations and their solution. The variables **Trait** and **Animal** are classification variables, and **Trait** defines the entire **X** matrix for the fixed-effects portion of the model, since the intercept is omitted with the **NOINT** option. The fixed-effects solution vector and predicted values are also requested by using the **S** and **OUTP=** options, respectively.

The random effect **Trait\*Animal** leads to a **Z** matrix with six columns, the first five corresponding to the identity matrix and the last consisting of 0s. An unstructured **G** matrix is specified by using the **TYPE=UN**

option, and it is read into PROC MIXED from a SAS data set by using the `GDATA=G` specification. The `G` and `GI` options request the display of  $G$  and  $G^{-1}$ , respectively. The `S` option requests that the random-effects solution vector be displayed.

Note that the preceding  $R$  matrix is block diagonal if the data are sorted by animals. The `REPEATED` statement exploits this fact by requesting  $R$  to have unstructured  $2 \times 2$  blocks corresponding to animals, which are the subjects. The `R` and `RI` options request that the estimated  $2 \times 2$  blocks for the first animal and its inverse be displayed. The `PARMS` statement lists the parameters of this  $2 \times 2$  matrix. Note that the parameters from  $G$  are not specified in the `PARMS` statement because they have already been assigned by using the `GDATA=` option in the `RANDOM` statement. The `NOITER` option prevents PROC MIXED from computing residual (restricted) maximum likelihood estimates; instead, the known values are used for inferences.

The results from this analysis are shown in [Output 59.4.1–Output 59.4.12](#).

The “Unstructured” covariance structure ([Output 59.4.1](#)) applies to both  $G$  and  $R$  here. The levels of Trait and Animal have been specified correctly.

**Output 59.4.1** Model and Class Level Information

| The Mixed Procedure       |        |              |
|---------------------------|--------|--------------|
| Model Information         |        |              |
| Data Set                  |        | WORK.H       |
| Dependent Variable        |        | Y            |
| Covariance Structure      |        | Unstructured |
| Subject Effect            |        | Animal       |
| Estimation Method         |        | REML         |
| Residual Variance Method  |        | None         |
| Fixed Effects SE Method   |        | Model-Based  |
| Degrees of Freedom Method |        | Containment  |
| Class Level Information   |        |              |
| Class                     | Levels | Values       |
| Trait                     | 2      | 1 2          |
| Animal                    | 3      | 1 2 3        |

The three covariance parameters indicated in [Output 59.4.2](#) correspond to those from the  $R$  matrix. Those from  $G$  are considered fixed and known because of the `GDATA=` option.

**Output 59.4.2** Model Dimensions and Number of Observations

| Dimensions                      |   |
|---------------------------------|---|
| Covariance Parameters           | 3 |
| Columns in X                    | 2 |
| Columns in Z                    | 6 |
| Subjects                        | 1 |
| Max Obs Per Subject             | 6 |
| Number of Observations          |   |
| Number of Observations Read     | 6 |
| Number of Observations Used     | 5 |
| Number of Observations Not Used | 1 |

Because starting values for the covariance parameters are specified in the **PARMS** statement, the MIXED procedure prints the residual (restricted) log likelihood at the starting values. Because of the **NOITER** option in the **PARMS** statement, this is also the final log likelihood in this analysis (Output 59.4.3).

**Output 59.4.3** REML Log Likelihood

| Parameter Search |        |        |              |                 |
|------------------|--------|--------|--------------|-----------------|
| CovP1            | CovP2  | CovP3  | Res Log Like | -2 Res Log Like |
| 4.0000           | 1.0000 | 5.0000 | -7.3731      | 14.7463         |

The block of **R** corresponding to the first animal and the inverse of this block are shown in Output 59.4.4.

**Output 59.4.4** Inverse R Matrix

| Estimated R Matrix<br>for Animal 1      |          |          |
|-----------------------------------------|----------|----------|
| Row                                     | Col1     | Col2     |
| 1                                       | 4.0000   | 1.0000   |
| 2                                       | 1.0000   | 5.0000   |
| Estimated Inv(R) Matrix<br>for Animal 1 |          |          |
| Row                                     | Col1     | Col2     |
| 1                                       | 0.2632   | -0.05263 |
| 2                                       | -0.05263 | 0.2105   |

The G matrix as specified in the `GDATA=` data set and its inverse are shown in [Output 59.4.5](#) and [Output 59.4.6](#).

**Output 59.4.5** G Matrix

| Estimated G Matrix |              |       |        |        |        |        |        |
|--------------------|--------------|-------|--------|--------|--------|--------|--------|
| Row                | Effect       | Trait | Animal | Col1   | Col2   | Col3   | Col4   |

The table of covariance parameter estimates in [Output 59.4.7](#) displays only the parameters in **R**. Because of the `GDATA=` option in the `RANDOM` statement, the G-side parameters do not participate in the pa-

parameter estimation process. Because of the **NOITER** option in the **PARMS** statement, however, the R-side parameters in this output are identical to their starting values.

**Output 59.4.7** R-Side Covariance Parameters

| Covariance Parameter Estimates |         |          |
|--------------------------------|---------|----------|
| Cov Parm                       | Subject | Estimate |
| UN(1,1)                        | Animal  | 4.0000   |
| UN(2,1)                        | Animal  | 1.0000   |
| UN(2,2)                        | Animal  | 5.0000   |

The coefficients of the mixed model equations in **Output 59.4.8** agree with Henderson (1984, p. 55). Recall from **Output 59.4.1** that there are 2 columns in **X** and 6 columns in **Z**. The first 8 columns of the mixed model equations correspond to the **X** and **Z** components. Column 9 represents the Y border.

**Output 59.4.8** Mixed Model Equations with Y Border

|                             |       |        |          |         | Pred   |    |         |         |
| Trait*Animal                | 1     | 1      | 0.05450  |         | 1.3521 | 0  | 0.04    | .       |
| Trait*Animal                | 1     | 2      | -0.04955 |         | 1.3262 | 0  | -0.04   | .       |
| Trait*Animal                | 1     | 3      | 0.02230  |         | 1.3346 | 0  | 0.02    | .       |
| Trait*Animal                | 2     | 1      | 0.2651   |         | 1.6589 | 0  | 0.16    | .       |
| Trait*Animal                | 2     | 2      | -0.2601  |         | 1.6393 | 0  | -0.16   | .       |
| Trait*Animal                | 2     | 3      | 0.1276   |         | 1.6627 | 0  | 0.08    | .       |

The estimates for the two traits are nearly identical, but the standard error of the second trait is larger because of the missing observation.

The Estimate column in the “Solution for Random Effects” table lists the best linear unbiased predictions (BLUPs) of the breeding values of both traits for all three animals. The *p*-values are missing because the default containment method for computing degrees of freedom results in zero degrees of freedom for the random effects parameter tests.

**Output 59.4.11** Significance Test Comparing Traits

| Type 3 Tests of Fixed Effects |     |     |         |        |
|-------------------------------|-----|-----|---------|--------|
| Effect                        | Num | Den | F Value | Pr > F |
|                               | DF  | DF  |         |        |
| Trait                         | 2   | 3   | 10.59   | 0.0437 |

The two estimated traits are significantly different from zero at the 5% level (Output 59.4.11).

Output 59.4.12 displays the predicted values of the observations based on the trait and breeding value estimates—that is, the fixed and random effects.

**Output 59.4.12** Predicted Observations

| Obs | Trait | Animal | Y | Pred    | StdErr  |    | Alpha | Lower | Upper | Resid    |
|-----|-------|--------|---|---------|---------|----|-------|-------|-------|----------|
|     |       |        |   |         | Pred    | DF |       |       |       |          |
| 1   | 1     | 1      | 6 | 7.04542 | 1.33027 | 0  | 0.05  | .     | .     | -1.04542 |
| 2   | 1     | 2      | 8 | 6.94137 | 1.39806 | 0  | 0.05  | .     | .     | 1.05863  |
| 3   | 1     | 3      | 7 | 7.01321 | 1.41129 | 0  | 0.05  | .     | .     | -0.01321 |
| 4   | 2     | 1      | 9 | 7.26094 | 1.72839 | 0  | 0.05  | .     | .     | 1.73906  |
| 5   | 2     | 2      | 5 | 6.73576 | 1.74077 | 0  | 0.05  | .     | .     | -1.73576 |
| 6   | 2     | 3      | . | 7.12015 | 2.99088 | 0  | 0.05  | .     | .     | .        |

The predicted values are not the predictions of future records in the sense that they do not contain a component corresponding to a new observational error. See Henderson (1984) for information about predicting future records. The Lower and Upper columns usually contain confidence limits for the predicted values; they are missing here because the random-effects parameter degrees of freedom equals 0.

## Example 59.5: Random Coefficients

This example comes from a pharmaceutical stability data simulation performed by Obenchain (1990). The observed responses are replicate assay results, expressed in percent of label claim, at various shelf ages, expressed in months. The desired mixed model involves three batches of product that differ randomly in intercept (initial potency) and slope (degradation rate). This type of model is also known as a hierarchical or multilevel model (Singer 1998; Sullivan, Dukes, and Losina 1999).

The SAS statements are as follows:

```

data rc;
 input Batch Month @@;
 Monthc = Month;
 do i = 1 to 6;
 input Y @@;
 output;
 end;
 datalines;
1 0 101.2 103.3 103.3 102.1 104.4 102.4
1 1 98.8 99.4 99.7 99.5 . .

3 9 100.9 99.5 102.2 100.8 . .
3 12 97.8 98.3 96.9 98.4 96.9 96.5
;

proc mixed data=rc;
 class Batch;
 model Y = Month / s;
 random Int Month / type=un sub=Batch s;
run;

```

In the DATA step, Monthc is created as a duplicate of Month in order to enable both a continuous and a classification version of the same variable. The variable Monthc is used in a subsequent [analysis](#)

In the PROC MIXED statements, Batch is listed as the only classification variable. The fixed effect Month in the MODEL statement is not declared as a classification variable; thus it models a linear trend in time. An intercept is included as a fixed effect by default, and the S option requests that the fixed-effects parameter estimates be produced.

The two random effects are Int and Month, modeling random intercepts and slopes, respectively. Note that Intercept and Month are used as both fixed and random effects. The TYPE=UN option in the RANDOM statement specifies an unstructured covariance matrix for the random intercept and slope effects. In mixed model notation, G is block diagonal with unstructured 2x2 blocks. Each block corresponds to a different level of Batch, which is the SUBJECT= effect. The unstructured type provides a mechanism for estimating the correlation between the random coefficients. The S option requests the production of the random-effects parameter estimates.

The results from this analysis are shown in Output 59.5.1–Output 59.5.9. The “Unstructured” covariance structure in Output 59.5.1 applies to G here.

**Output 59.5.1** Model Information in Random Coefficients Analysis

| The Mixed Procedure       |              |
|---------------------------|--------------|
| Model Information         |              |

Batch is the only classification variable in this analysis, and it has three levels (Output 59.5.2).

**Output 59.5.2** Random Coefficients Analysis (continued)

| Class Level Information |        |        |
|-------------------------|--------|--------|
| Class                   | Levels | Values |
| Batch                   | 3      | 1 2 3  |

The “Dimensions” table in Output 59.5.3 indicates that there are three subjects (corresponding to batches). The 24 observations not used correspond to the missing values of Y in the input data set.

**Output 59.5.3** Random Coefficients Analysis (*continued*)

| Dimensions                      |     |
|---------------------------------|-----|
| Covariance Parameters           | 4   |
| Columns in X                    | 2   |
| Columns in Z Per Subject        | 2   |
| Subjects                        | 3   |
| Max Obs Per Subject             | 36  |
| Number of Observations          |     |
| Number of Observations Read     | 108 |
| Number of Observations Used     | 84  |
| Number of Observations Not Used | 24  |

As [Output 59.5.4](#) shows, only one iteration is required for convergence.

**Output 59.5.4** Random Coefficients Analysis (*continued*)

| Iteration History         |             |                 |            |
|---------------------------|-------------|-----------------|------------|
| Iteration                 | Evaluations | -2 Res Log Like | Criterion  |
| 0                         | 1           | 367.02768461    |            |
| 1                         | 1           | 350.32813577    | 0.00000000 |
| Convergence criteria met. |             |                 |            |

The Estimate column in [Output 59.5.5](#) lists the estimated elements of the unstructured  $2 \times 2$  matrix comprising the blocks of  $G$ . Note that the random coefficients are negatively correlated.

**Output 59.5.5** Random Coefficients Analysis (*continued*)

| Covariance Parameter Estimates |         |          |
|--------------------------------|---------|----------|
| Cov Parm                       | Subject | Estimate |
| UN(1,1)                        | Batch   | 0.9768   |
| UN(2,1)                        | Batch   | -0.1045  |
| UN(2,2)                        | Batch   | 0.03717  |
| Residual                       |         | 3.2932   |

The null model likelihood ratio test indicates a significant improvement over the null model consisting of no random effects and a homogeneous residual error ([Output 59.5.6](#)).

**Output 59.5.6** Random Coefficients Analysis (*continued*)

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Res Log Likelihood    | 350.3 |
| AIC (smaller is better)  | 358.3 |
| AICC (smaller is better) | 358.8 |
| BIC (smaller is better)  | 354.7 |

| Null Model Likelihood Ratio Test |            |            |
|----------------------------------|------------|------------|
| DF                               | Chi-Square | Pr > ChiSq |
| 3                                | 16.70      | 0.0008     |

The fixed-effects estimates represent the estimated means for the random intercept and slope, respectively ([Output 59.5.7](#)).

**Output 59.5.7** Random Coefficients Analysis (*continued*)

| Solution for Fixed Effects |          |                |    |         |         |
|----------------------------|----------|----------------|----|---------|---------|
| Effect                     | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                  | 102.70   | 0.6456         | 2  | 159.08  | <.0001  |
| Month                      | -0.5259  | 0.1194         | 2  | -4.41   | 0.0478  |

The random-effects estimates represent the estimated deviation from the mean intercept and slope for each batch ([Output 59.5.8](#)). Therefore, the intercept for the first batch is close to  $102.7 - 1 = 101.7$ , while the intercepts for the other two batches are greater than 102.7. The second batch has a slope less than the mean slope of  $-0.526$ , while the other two batches have slopes greater than  $-0.526$ .

**Output 59.5.8** Random Coefficients Analysis (*continued*)

| Solution for Random Effects |       |          |              |    |         |         |
|-----------------------------|-------|----------|--------------|----|---------|---------|
| Effect                      | Batch | Estimate | Std Err Pred | DF | t Value | Pr >  t |
| Intercept                   | 1     | -1.0010  | 0.6842       | 78 | -1.46   | 0.1474  |
| Month                       | 1     | 0.1287   | 0.1245       | 78 | 1.03    | 0.3047  |
| Intercept                   | 2     | 0.3934   | 0.6842       | 78 | 0.58    | 0.5669  |
| Month                       | 2     | -0.2060  | 0.1245       | 78 | -1.65   | 0.1021  |
| Intercept                   | 3     | 0.6076   | 0.6842       | 78 | 0.89    | 0.3772  |
| Month                       | 3     | 0.07731  | 0.1245       | 78 | 0.62    | 0.5365  |

The  $F$  statistic in the “Type 3 Tests of Fixed Effects” table in [Output 59.5.9](#) is the square of the  $t$  statistic

used in the test of Month in the preceding “Solution for Fixed Effects” table (compare [Output 59.5.7](#) and [Output 59.5.9](#)). Both statistics test the null hypothesis that the slope assigned to Month equals 0, and this hypothesis can barely be rejected at the 5% level.

**Output 59.5.9** Random Coefficients Analysis (*continued*)

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Month                         | 1         | 2         | 19.41   | 0.0478 |

It is also possible to fit a random coefficients model with error terms that follow a nested structure (Fuller and Battese 1973). The following SAS statements represent one way of doing this:

```
proc mixed data=rc;
 class Batch Monthc;
 model Y = Month / s;
 random Int Month Monthc / sub=Batch s;
run;
```

The variable Monthc is added to the **CLASS** and **RANDOM** statements, and it models the nested errors. Note that Month and Monthc are continuous and classification versions of the same variable. Also, the **TYPE=UN** option is dropped from the **RANDOM** statement, resulting in the default variance components model instead of correlated random coefficients. The results from this analysis are shown in [Output 59.5.10](#).

**Output 59.5.10** Random Coefficients with Nested Errors Analysis

| Residual                        |             | 0.7969          |            |

For this analysis, the Newton-Raphson algorithm requires five iterations and nine likelihood evaluations to achieve convergence. The missing value in the Criterion column in iteration 1 indicates that a boundary constraint has been dropped.

The estimate for the Intercept variance component equals 0. This occurs frequently in practice and indicates that the restricted likelihood is maximized by setting this variance component equal to 0. Whenever a zero variance component estimate occurs, the following note appears in the SAS log:

**NOTE: Estimated G matrix is not positive definite.**

The remaining variance component estimates are positive, and the estimate corresponding to the nested errors (MONTHC) is much larger than the other two.

A comparison of AIC and BIC for this model with those of the previous model favors the nested error model

(compare [Output 59.5.11](#) and [Output 59.5.6](#)). Strictly speaking, a likelihood ratio test cannot be carried out between the two models because one is not contained in the other; however, a cautious comparison of likelihoods can be informative.

**Output 59.5.11** Random Coefficients with Nested Errors Analysis (*continued*)

| Fit Statistics           |       |
|--------------------------|-------|
| -2 Res Log Likelihood    | 276.9 |
| AIC (smaller is better)  | 282.9 |
| AICC (smaller is better) | 283.2 |
| BIC (smaller is better)  | 280.2 |

The better-fitting covariance model affects the standard errors of the fixed-effects parameter estimates more than the estimates themselves ([Output 59.5.12](#)).

**Output 59.5.12** Random Coefficients with Nested Errors Analysis (*continued*)

| Solution for Fixed Effects |          |                |    |         |         |
|----------------------------|----------|----------------|----|---------|---------|
| Effect                     | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                  | 102.56   | 0.7287         | 2  | 140.74  | <.0001  |
| Month                      | -0.5003  | 0.1259         | 2  | -3.97   | 0.0579  |

The random-effects solution provides the empirical best linear unbiased predictions (EBLUPs) for the realizations of the random intercept, slope, and nested errors ([Output 59.5.13](#)). You can use these values to compare batches and months.

**Output 59.5.13** Random Coefficients with Nested Errors Analysis (*continued*)

| Solution for Random Effects |       |        |          |                 |    |         |         |

**Output 59.5.14** Random Coefficients with Nested Errors Analysis (*continued*)

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| Month                         | 1         | 2         | 15.78   | 0.0579 |

The test of Month is similar to that from the previous model, although it is no longer significant at the 5% level (Output 59.5.14).

## Example 59.6: Line-Source Sprinkler Irrigation

These data appear in Hanks et al. (1980); Johnson, Chaudhuri, and Kanemasu (1983); Stroup (1989b). Three cultivars (Cult) of winter wheat are randomly assigned to rectangular plots within each of three blocks (Block). The nine plots are located side by side, and a line-source sprinkler is placed through the middle. Each plot is subdivided into twelve subplots—six to the north of the line source, six to the south (Dir). The

two plots closest to the line source represent the maximum irrigation level (Irrig=6), the two next-closest plots represent the next-highest level (Irrig=5), and so forth.

This example is a case where both **G** and **R** can be modeled. One of Stroup's models specifies a diagonal **G** containing the variance components for Block, Block\*Dir, and Block\*Irrig, and a Toeplitz **R** with four bands. The SAS statements to fit this model and carry out some further analyses follow.

**CAUTION:** This analysis can require considerable CPU time.

```

The preceding statements use the bar operator (|) and the at sign (@) to specify all two-factor interactions between Cult, Dir, and Irrig as fixed effects.

The **RANDOM** statement sets up the **Z** and **G** matrices corresponding to the random effects Block, Block\*Dir, and Block\*Irrig.

In the **REPEATED** statement, the **TYPE=TOEP(4)** option sets up the blocks of the **R** matrix to be Toeplitz with four bands below and including the main diagonal. The subject effect is Block\*Cult, and it produces

nine 12×12 blocks. The **R** option requests that the first block of **R** be displayed.

Least squares means (**LSMEANS**) are requested for **Cult**, **Irrig**, and **Cult\*Irrig**, and a few **ESTIMATE** statements are specified to illustrate some linear combinations of the fixed effects.

The results from this analysis are shown in **Output 59.6.1**.

The “Covariance Structures” row in **Output 59.6.1** reveals the two different structures assumed for **G** and **R**.

**Output 59.6.1** Model Information in Line-Source Sprinkler Analysis

| The Mixed Procedure       |                                  |
|---------------------------|----------------------------------|
| Model Information         |                                  |
| Data Set                  | WORK.LINE                        |
| Dependent Variable        | Y                                |
| Covariance Structures     | Variance Components,<br>Toeplitz |
| Subject Effect            | Block*Cult                       |
| Estimation Method         | REML                             |
| Residual Variance Method  | Profile                          |
| Fixed Effects SE Method   | Model-Based                      |
| Degrees of Freedom Method | Containment                      |

The levels of each classification variable are listed as a single string in the **Values** column, regardless of whether the levels are numeric or character (**Output 59.6.2**).

**Output 59.6.2** Class Level Information

| Class Level Information |        |                       |
|-------------------------|--------|-----------------------|
| Class                   | Levels | Values                |
| Block                   | 3      | 1 2 3                 |
| Cult                    | 3      | Bridger Luke Nugaines |
| Dir                     | 2      | North South           |
| Irrig                   | 6      | 1 2 3 4 5 6           |

Even though there is a **SUBJECT=** effect in the **REPEATED** statement, the analysis considers all of the data to be from one subject because there is no corresponding **SUBJECT=** effect in the **RANDOM** statement (**Output 59.6.3**).

**Output 59.6.3** Model Dimensions and Number of Observations

Output 59.6.6 lists the estimated covariance parameters from both **G** and **R**. The first three are the variance components making up the diagonal **G**, and the final four make up the Toeplitz structure in the blocks of **R**. The Residual row corresponds to the variance of the Toeplitz structure, and it represents the parameter profiled out during the optimization process.

**Output 59.6.6** Estimated Covariance Parameters

| Covariance Parameter Estimates |            |          |

The “Estimates” table lists the results from the various linear combinations of fixed effects specified in the **ESTIMATE** statements ([Output 59.6.9](#)). Bridger is not significantly different from Luke, and Irrig possesses a strong linear component. This strength appears to be influencing the significance of the interaction.

**Output 59.6.9** Estimates

| Estimates             |          |                   |    |         |         |
|-----------------------|----------|-------------------|----|---------|---------|
| Label                 | Estimate | Standard<br>Error | DF | t Value | Pr >  t |
| Bridger vs Luke       | –0.03889 | 0.09524           | 68 | –0.41   | 0.6843  |
| Linear Irrig          | 30.6444  | 1.4412            | 10 | 21.26   | <.0001  |
| B vs L x Linear Irrig | –9.8667  | 2.7400            | 68 | –3.60   | 0.0006  |

The least squares means shown in [Output 59.6.10](#) are useful in comparing the levels of the various fixed effects. For example, it appears that irrigation levels 5 and 6 have virtually the same effect.

**Output 59.6.10** Least Squares Means for Cult, Irrig, and Their Interaction

| Least Squares Means |          |       |          |                |    |         |         |

An interesting exercise is to fit other variance-covariance models to these data and to compare them to this one by using likelihood ratio tests, Akaike's information criterion, or Schwarz's Bayesian information criterion. In particular, some spatial models are worth investigating (Marx and Thompson 1987; Zimmerman and Harville 1991). The following is one example of spatial model statements:

```
proc mixed;
 class Block Cult Dir Irrig;
 model Y = Cult|Dir|Irrig@2;
 repeated / type=sp(pow)(Row Sbplt) sub=intercept;
run;
```

The `TYPE=SP(POW)(Row Sbplt)` option in the `REPEATED` statement requests the spatial power structure, with the two defining coordinate variables being `Row` and `Sbplt`. The `SUBJECT=INTERCEPT` option indicates that the entire data set is to be considered as one subject, thereby modeling **R** as a dense 108×108 covariance matrix. See Wolfinger (1993) for further discussion of this example and additional analyses.

## Example 59.7: Influence in Heterogeneous Variance Model

In this example from Snedecor and Cochran (1976, p. 256), a one-way classification model with heterogeneous variances is fit. The data, shown in the following DATA step, represent amounts of different types of fat absorbed by batches of doughnuts during cooking, measured in grams.

```
data absorb;
 input FatType Absorbed @@;
 datalines;
 1 164 1 172 1 168 1 177 1 156 1 195
 2 178 2 191 2 197 2 182 2 185 2 177
 3 175 3 193 3 178 3 171 3 163 3 176
 4 155 4 166 4 149 4 164 4 170 4 168
 ;
```

The statistical model for these data can be written as

$$Y_{ij} = \mu + \tau_i + \epsilon_{ij}$$

$$i = 1, \dots, t = 4$$

$$j = 1, \dots, r = 6$$

$$\epsilon_{ij} = N(0, \sigma_i^2)$$

where  $Y_{ij}$  is the amount of fat absorbed by the  $j$ th batch of the  $i$ th fat type, and  $\tau_i$  denotes the fat-type effects. A quick glance at the data suggests that observations 6, 9, 14, and 21 might be influential on the analysis, because these are extreme observations for the respective fat types.

The following SAS statements fit this model and request influence diagnostics for the fixed effects and covariance parameters. ODS Graphics is used to create plots of the influence diagnostics in addition to the tabular output. The `ESTIMATES` suboption requests plots of “leave-one-out” estimates for the fixed effects and group variances.

```
ods graphics on;

proc mixed data=absorb asycov;
 class FatType;
 model Absorbed = FatType / s
 influence(iter=10 estimates);
 repeated / group=FatType;
 ods output Influence=inf;
run;

ods graphics off;
```

The “Influence” table is output to the SAS data set `inf` so that parameter estimates can be printed subsequently. Results from this analysis are shown in [Output 59.7.1](#).

| FatType                        | 3                   | 14.0000   | 5.2472         | 20 | 2.67    | 0.0148  |
| FatType                        | 4                   | 0         | .              | .  | .       | .       |

The fixed-effects solutions correspond to estimates of the following parameters:

$$\text{Intercept} : \mu + \tau_4$$

$$\text{FatType1} : \tau_1 - \tau_4$$

$$\text{FatType2} : \tau_2 - \tau_4$$

$$\text{FatType3} : \tau_3 - \tau_4$$

$$\text{FatType4} : 0$$

You can easily verify that these estimates are simple functions of the arithmetic means  $\bar{y}_i$  in the groups. For example,  $\widehat{\mu + \tau_4} = \bar{y}_4 = 162.0$ ,  $\widehat{\tau_1 - \tau_4} = \bar{y}_1 - \bar{y}_4 = 10.0$ , and so forth. The covariance parameter estimates are the sample variances in the groups and are uncorrelated.

The variances in the four groups are shown in the “Covariance Parameter Estimates” table (Output 59.7.1). The estimated variance in the first group is two to three times larger than the variance in the other groups.

**Output 59.7.2** Asymptotic Variances of Group Variance Estimates

| Asymptotic Covariance Matrix of Estimates |          |       |         |         |         |
|-------------------------------------------|----------|-------|---------|---------|---------|
| Row                                       | Cov Parm | CovP1 | CovP2   | CovP3   | CovP4   |
| 1                                         | Residual | 12674 |         |         |         |
| 2                                         | Residual |       | 1459.26 |         |         |
| 3                                         | Residual |       |         | 3810.30 |         |
| 4                                         | Residual |       |         |         | 1827.90 |

In groups where the residual variance estimate is large, the precision of the estimate is also small (Output 59.7.2).

The following statements print the “leave-one-out” estimates for fixed effects and covariance parameters that were written to the inf data set with the **ESTIMATES** suboption (Output 59.7.3):

```
proc print data=inf label;
 var parm1-parm5 covp1-covp4;
run;
```

**Output 59.7.3** Leave-One-Out Estimates

| Obs | Intercept | Fat    |        |        |        | Residual  | Residual  | Residual  | Residual  |

The graphical displays in [Output 59.7.4](#) and [Output 59.7.5](#) are created when ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the MIXED procedure, see the section “[ODS Graphics](#)” on page 4992.

**Output 59.7.4** Fixed-Effects Deletion Estimates

**Output 59.7.5** Covariance Parameter Deletion Estimates

The estimate of the intercept is affected only when observations from the last group are removed. The estimate of the “FatType 1” effect reacts to removal of observations in the first and last group (Output 59.7.4).

While observations can affect one or more fixed-effects solutions in this model, they can affect only one covariance parameter, the variance in their group (Output 59.7.5). Observations 6, 9, 14, and 21, which are extreme in their group, reduce the group variance considerably.

Diagnostics related to residuals and predicted values are printed with the following statements:

```
proc print data=inf label;
 var observed predicted residual pressres
 student Rstudent;
run;
```

**Output 59.7.6** Residual Diagnostics

Observations 6, 9, 14, and 21 have large studentized residuals (Output 59.7.6). That the externally studentized residuals are much larger than the internally studentized residuals for these observations indicates that the variance estimate in the group shrinks when the observation is removed. Also important to note is that comparisons based on raw residuals in models with heterogeneous variance can be misleading. Observation 5, for example, has a larger residual but a smaller studentized residual than observation 21. The variance for the first fat type is much larger than the variance in the fourth group. A “large” residual is more “surprising” in the groups with small variance.

A measure of the overall influence on the analysis is the (restricted) likelihood distance, shown in Output 59.7.7. Observations 6, 9, 14, and 21 clearly displace the REML solution more than any other observations.

**Output 59.7.7** Restricted Likelihood Distance

The following statements list the restricted likelihood distance and various diagnostics related to the fixed-effects estimates (Output 59.7.8):

```
proc print data=inf label;
 var leverage observed CookD DFFITS CovRatio RLD;
run;
```

**Output 59.7.8** Restricted Likelihood Distance and Fixed-Effects Diagnostics

In this example, observations with large likelihood distances also have large values for Cook's  $D$  and values of CovRatio far less than one ([Output 59.7.8](#)). The latter indicates that the fixed effects are estimated more precisely when these observations are removed from the analysis.

The following statements print the values of the  $D$  statistic and the CovRatio for the covariance parameters:

```
proc print data=inf label;
 var iter CookDCP CovRatioCP;
run;
```

The same conclusions as for the fixed-effects estimates hold for the covariance parameter estimates. Observations 6, 9, 14, and 21 change the estimates and their precision considerably ([Output 59.7.9](#), [Output 59.7.10](#)). All iterative updates converged within at most four iterations.

**Output 59.7.9** Covariance Parameter Diagnostics

Output 59.7.10 displays the standard panel of influence diagnostics that is obtained when influence analysis is iterative. The Cook's  $D$  and CovRatio statistics are displayed for each deletion set for both fixed-effects and covariance parameter estimates. This provides a convenient summary of the impact on the analysis for each deletion set, since Cook's  $D$  statistic measures impact on the estimates and the CovRatio statistic measures impact on the precision of the estimates.

**Output 59.7.10** Influence Diagnostics

Observations 6, 9, 14, and 21 have considerable impact on estimates and precision of fixed effects and covariance parameters. This is not necessarily the case. Observations can be influential on only some aspects of the analysis, as shown in the next example.

**Example 59.8: Influence Analysis for Repeated Measures Data**

This example revisits the repeated measures data of Pothoff and Roy (1964) that were analyzed in [Example 59.2](#). Recall that the data consist of growth measurements at ages 8, 10, 12, and 14 for 11 girls and 16 boys. The model being fit contains fixed effects for Gender and Age and their interaction.

The earlier analysis of these data indicated some unusual observations in this data set. Because of the clustered data structure, it is of interest to study the influence of clusters (children) on the analysis rather than the influence of individual observations. A cluster comprises the repeated measurements for each child.

The repeated measures are first modeled with an unstructured within-child variance-covariance matrix. A residual variance is not profiled in this model. A noniterative influence analysis will update the fixed effects only. The following statements request this noniterative maximum likelihood analysis and produce [Output 59.8.1](#):

```

proc mixed data=pr method=ml;
 class person gender;
 model y = gender age gender*age /
 influence(effect=person);
 repeated / type=un subject=person;
 ods select influence;
run;

```

| 27                                         | 4                                     | 20.2913            | 0.02523     |  |

Each observation in the “Influence Diagnostics for Levels of Person” table in [Output 59.8.1](#) represents the removal of four observations. The subjects 10, 15, and 24 have the greatest impact on the fixed effects (Cook’s  $D$ ), and subject 10 and 21 have large PRESS statistics. The 21st child has a large PRESS statistic, and its  $D$  statistic is not that extreme. This is an indication that the model fits rather poorly for this child, whether it is part of the data or not.

The previous analysis does not take into account the effect on the covariance parameters when a subject is removed from the analysis. If you also update the covariance parameters, the impact of observations on

these can amplify or allay their effect on the fixed effects. To assess the overall influence of subjects on the analysis and to compute separate statistics for the fixed effects and covariance parameters, an iterative analysis is obtained by adding the **INFLUENCE** suboption **ITER=**, as follows:

```
ods graphics on;

proc mixed data=pr method=ml;
 class person gender;
 model y = gender age gender*age /
 influence(effect=person iter=5);
 repeated / type=un subject=person;
run;
```

The number of additional iterations following removal of the observations for a particular subject is limited to five. Graphical displays of influence diagnostics are created when ODS Graphics is enabled. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the graphics available in the MIXED procedure, see the section “[ODS Graphics](#)” on page 4992.

The MIXED procedure produces a plot of the restricted likelihood distance ([Output 59.8.2](#)) and a panel of diagnostics for fixed effects and covariance parameters ([Output 59.8.3](#)).

**Output 59.8.2** Restricted Likelihood Distance

**Output 59.8.3** Influence Diagnostics Panel

As judged by the restricted likelihood distance, subjects 20 and 24 clearly have the most influence on the overall analysis (Output 59.8.2).

Output 59.8.3 displays Cook's  $D$  and CovRatio statistics for the fixed effects and covariance parameters. Clearly, subject 20 has a dramatic effect on the estimates of variances and covariances. This subject also affects the precision of the covariance parameter estimates more than any other subject in Output 59.8.3 (CovRatio near 0).

The child who exerts the greatest influence on the fixed effects is subject 24. Maybe surprisingly, this subject affects the variance-covariance matrix of the fixed effects more than subject 20 (small CovRatio in Output 59.8.3).

The final model investigated for these data is a random coefficient model as in Stram and Lee (1994) with random effects for the intercept and age effect. The following statements examine the estimates for fixed effects and the entries of the unstructured  $2 \times 2$  variance matrix of the random coefficients graphically:

```
proc mixed data=pr method=ml
 plots (only)=InfluenceEstPlot;
 class person gender;
 model y = gender age gender*age /
```

```
influence(iter=5 effect=person est);
random intercept age / type=un subject=person;
run;
```

The `PLOTS(ONLY)=INFLUENCEESTPLOT` option restricts the graphical output from this PROC MIXED run to only the panels of deletion estimates (Output 59.8.4 and Output 59.8.5).

**Output 59.8.4** Fixed-Effects Deletion Estimates

In Output 59.8.4 the graphs on the left side of the panel represent the intercept and slope estimate for boys; the graphs on the right side represent the difference in intercept and slope between boys and girls. Removing any one of the first eleven children, who are girls, does not alter the intercept or slope in the group of boys. The difference in these parameters between boys and girls is altered by the removal of any child. Subject 24 changes the fixed effects considerably, subject 20 much less so.

**Output 59.8.5** Covariance Parameter Deletion Estimates

The covariance parameter deletion estimates in [Output 59.8.5](#) show several important features.

- The panels do not contain information about subject 24. Estimation of the  $G$  matrix following removal of that child did not yield a positive definite matrix. As a consequence, covariance parameter diagnostics are not produced for this subject.
- Subject 20 has great impact on the four covariance parameters. Removing this child from the analysis increases the variance of the random intercept and random slope and reduces the residual variance by almost 80%. The repeated measurements of this child exhibit an up-and-down behavior.
- The variance of the random intercept and slope are reduced when child 15 is removed from the analysis. This child's growth measurements oscillate about 27.0 from age 10 on.

Examining observed and residual values by levels of classification variables is also a useful tool to diagnose the adequacy of the model and unusual observations. Box plots for effects in the model that consist of only classification variables can be requested with the `BOXPLOT` option of the `PLOTS=` option in the `PROC MIXED` statement. For example, the following statements produce box plots for the `SUBJECT=` effects in the model:

```
ods graphics on;
proc mixed data=pr method=ml
 plot=boxplot(observed marginal conditional subject);
 class person gender;
 model y = gender age gender*age;
 random intercept age / type=un subject=person;
run;
```

The specific boxplot options request a plot of the observed data (Output 59.8.6), the marginal residuals (Output 59.8.7), and the conditional residuals (Output 59.8.8). Box plots of the observed values show the variation within and between children clearly. The group of girls (subjects 1–11) is distinguishable from the group of boys by somewhat lesser average growth and lesser within-child variation (Output 59.8.6). After adjusting for overall (population-averaged) gender and age effects, the residual within-child variation is reduced but substantial differences in the means remain (Output 59.8.7). If child-specific inferences are desired, a model accounting for only Gender, Age, and Gender\*Age effects is not adequate for these data.

**Output 59.8.6** Distribution of Observed Values

**Output 59.8.7** Distribution of Marginal Residuals

The conditional residuals incorporate the EBLUPs for each child and enable you to examine whether the subject-specific model is adequate (Output 59.8.8). By using each child “as its own control,” the residuals are now centered near zero. Subjects 20 and 24 stand out as unusual in all three sets of box plots.

**Output 59.8.8** Distribution of Conditional Residuals

## Example 59.9: Examining Individual Test Components

The `LCOMPONENTS` option in the `MODEL` statement enables you to perform single-degree-of-freedom tests for individual rows of the `L` matrix. Such tests are useful to identify interaction patterns. In a balanced layout, Type 3 components of `L` associated with `A*B` interactions correspond to simple contrasts of cell mean differences.

The first example revisits the data from the split-plot design by Stroup (1989a) that was analyzed in [Example 59.1](#). Recall that variables `A` and `B` in the following statements represent the whole-plot and subplot factors, respectively:

```
proc mixed data=sp;
 class a b block;
 model y = a b a*b / LComponents e3;
 random block a*block;
run;
```

The `MIXED` procedure constructs a separate `L` matrix for each of the three fixed-effects components. The matrices are displayed in [Output 59.9.1](#). The tests for fixed effects are shown in [Output 59.9.2](#).

## Output 59.9.1 Coefficients of Type 3 Estimable Functions

| The Mixed Procedure         |   |   |        |      |
|-----------------------------|---|---|--------|------|
| Type 3 Coefficients for A   |   |   |        |      |
| Effect                      | A | B | Row1   | Row2 |
| Intercept                   |   |   |        |      |
| A                           | 1 |   | 1      |      |
| A                           | 2 |   |        | 1    |
| A                           | 3 |   | -1     | -1   |
| B                           |   | 1 |        |      |
| B                           |   | 2 |        |      |
| A*B                         | 1 | 1 | 0.5    |      |
| A*B                         | 1 | 2 | 0.5    |      |
| A*B                         | 2 | 1 |        | 0.5  |
| A*B                         | 2 | 2 |        | 0.5  |

**Output 59.9.2** Type 3 Tests in Split-Plot Example

| Type 3 Tests of Fixed Effects |           |           |         |        |
|-------------------------------|-----------|-----------|---------|--------|
| Effect                        | Num<br>DF | Den<br>DF | F Value | Pr > F |
| A                             | 2         | 6         | 4.07    | 0.0764 |
| B                             | 1         | 9         | 19.39   | 0.0017 |
| A*B                           | 2         | 9         | 4.02    | 0.0566 |

If  $\mu_{i.}$  denotes a whole-plot main effect mean,  $\mu_{.j}$  denotes a subplot main effect mean, and  $\mu_{ij}$  denotes a cell mean, the five components shown in [Output 59.9.3](#) correspond to tests of the following:

- $H_0 : \mu_{1.} = \mu_{3.}$
- $H_0 : \mu_{2.} = \mu_{3.}$
- $H_0 : \mu_{.1} = \mu_{.2}$
- $H_0 : \mu_{11} - \mu_{12} = \mu_{31} - \mu_{32}$
- $H_0 : \mu_{21} - \mu_{22} = \mu_{31} - \mu_{32}$

**Output 59.9.3** Type 3 L Components Table

| L Components of Type 3 Tests of Fixed Effects |            |          |                   |    |         |         |

| Effect                                        | L<br>Index | Estimate | Standard<br>Error | DF | t Value | Pr >  t |
| A                                             | 1          | 7.1250   | 3.1672            | 6  | 2.25    | 0.0655  |
| A                                             | 2          | 8.3750   | 3.1672            | 6  | 2.64    | 0.0383  |
| B                                             | 1          | 5.5000   | 1.2491            | 9  | 4.40    | 0.0017  |
| A*B                                           | 1          | 7.7500   | 3.0596            | 9  | 2.53    | 0.0321  |
| A*B                                           | 2          | 7.2500   | 3.0596            | 9  | 2.37    | 0.0419  |

The first three components are comparisons of marginal means. The fourth component compares the effect of factor B at the first whole-plot level against the effect of B at the third whole-plot level. Finally, the last component tests whether the factor B effect changes between the second and third whole-plot level.

The Type 3 component tests can also be produced with these corresponding `ESTIMATE` statements:

```
proc mixed data=sp;
 class a b block ;
 model y = a b a*b;
 random block a*block;
 estimate 'a' 1' a 1 0 -1;
 estimate 'a' 2' a 0 1 -1;
 estimate 'b' 1' b 1 -1;
```

```

estimate 'a*b 1' a*b 1 -1 0 0 -1 1;
estimate 'a*b 2' a*b 0 0 1 -1 -1 1;
ods select Estimates;
run;

```

The results are shown in [Output 59.9.4](#).

**Output 59.9.4** Results from ESTIMATE Statements

| The Mixed Procedure |   |          |                |    |         |         |
|---------------------|---|----------|----------------|----|---------|---------|
| Estimates           |   |          |                |    |         |         |
| Label               |   | Estimate | Standard Error | DF | t Value | Pr >  t |
| a                   | 1 | 7.1250   | 3.1672         | 6  | 2.25    | 0.0655  |
| a                   | 2 | 8.3750   | 3.1672         | 6  | 2.64    | 0.0383  |
| b                   | 1 | 5.5000   | 1.2491         | 9  | 4.40    | 0.0017  |
| a*b                 | 1 | 7.7500   | 3.0596         | 9  | 2.53    | 0.0321  |
| a*b                 | 2 | 7.2500   | 3.0596         | 9  | 2.37    | 0.0419  |

A second useful application of the **LCOMPONENTS** option is in polynomial models, where Type 1 tests are often used to test the entry of model terms sequentially. The **SOLUTION** option in the **MODEL** statement displays the regression coefficients that correspond to a Type 3 analysis. That is, the coefficients represent the partial coefficients you would get by adding the regressor variable last in a model containing all other effects, and the tests are identical to those in the “Type 3 Tests of Fixed Effects” table.

Consider the following **DATA** step and the fit of a third-order polynomial regression model.

```

data polynomial;
 do x=1 to 20; input y@@; output; end;
 datalines;
1.092 1.758 1.997 3.154 3.880
3.810 4.921 4.573 6.029 6.032
6.291 7.151 7.154 6.469 7.137
6.374 5.860 4.866 4.155 2.711
;

proc mixed data=polynomial;
 model y = x x*x x*x*x / s lcomponents htype=1,3;
run;

```

The *t* tests displayed in the “Solution for Fixed Effects” table are Type 3 tests, sometimes referred to as partial tests. They measure the contribution of a regressor in the presence of all other regressor variables in the model.

**Output 59.9.5** Parameter Estimates in Polynomial Model

| The Mixed Procedure        |          |                |    |         |         |
|----------------------------|----------|----------------|----|---------|---------|
| Solution for Fixed Effects |          |                |    |         |         |
| Effect                     | Estimate | Standard Error | DF | t Value | Pr >  t |
| Intercept                  | 0.7837   | 0.3545         | 16 | 2.21    | 0.0420  |
| x                          | 0.3726   | 0.1426         | 16 | 2.61    | 0.0189  |
| x*x                        | 0.04756  | 0.01558        | 16 | 3.05    | 0.0076  |
| x*x*x                      | -0.00306 | 0.000489       | 16 | -6.27   | <.0001  |

The Type 3 L components are identical to the tests in the “Solutions for Fixed Effects” table shown in Output 59.9.5. The Type 1 table yields the following:

- sequential (Type 1) tests of regression variables that test the significance of a regressor given all other variables preceding it in the model list
- the regression coefficients for sequential submodels

**Output 59.9.6** Type 1 and Type 3 L Components

| L Components of Type 1 Tests of Fixed Effects |         |          |                |    |         |         |
|-----------------------------------------------|---------|----------|----------------|----|---------|---------|
| Effect                                        | L Index | Estimate | Standard Error | DF | t Value | Pr >  t |
| x                                             | 1       | 0.1763   | 0.01259        | 16 | 14.01   | <.0001  |
| x*x                                           | 1       | -0.04886 | 0.002449       | 16 | -19.95  | <.0001  |
| x*x*x                                         | 1       | -0.00306 | 0.000489       | 16 | -6.27   | <.0001  |

| L Components of Type 3 Tests of Fixed Effects |         |          |                |    |         |         |
|-----------------------------------------------|---------|----------|----------------|----|---------|---------|
| Effect                                        | L Index | Estimate | Standard Error | DF | t Value | Pr >  t |
| x                                             | 1       | 0.3726   | 0.1426         | 16 | 2.61    | 0.0189  |
| x*x                                           | 1       | 0.04756  | 0.01558        | 16 | 3.05    | 0.0076  |
| x*x*x                                         | 1       | -0.00306 | 0.000489       | 16 | -6.27   | <.0001  |

The estimate of 0.1763 is the regression coefficient in a simple linear regression of Y on X. The estimate of -0.04886 is the partial coefficient for the quadratic term when it is added to a model containing only a linear component. Similarly, the value -0.00306 is the partial coefficient for the cubic term when it is added to a model containing a linear and quadratic component. The last Type 1 component is always identical to the corresponding Type 3 component.

## Example 59.10: Isotonic Contrasts for Ordered Mean Values

It is often of interest to test whether the mean values of the dependent variable increases or decreases monotonically with certain factors. Hirotsu and Srivastava (2000) demonstrate one approach by using data (Moriguchi 1976). The data consist of ferrite cores subjected to four increasing temperatures. The response variable is the magnetic force of each core.

```
data FerriteCores;
 do Temp = 1 to 4;
 do rep = 1 to 5; drop rep;
 input MagneticForce @@;
 output;
 end;
 end;
 datalines;
10.8 9.9 10.7 10.4 9.7
10.7 10.6 11.0 10.8 10.9
11.9 11.2 11.0 11.1 11.3
11.4 10.7 10.9 11.3 11.7
;
```

The method presented by Hirotsu and Srivastava (2000) to test whether the magnetic force of the cores rises monotonically with temperature depends on the lower confidence limits of the *isotonic contrasts* of the force means at each temperature, adjusted for multiplicity. The corresponding isotonic contrast compares the average of a particular group and the preceding groups with the average of the succeeding groups. You can compute adjusted confidence intervals for isotonic contrasts by using the `LSMESTIMATE` statement.

The following statements analyze the `FerriteCores` data as a one-way design and multiplicity-adjusted lower confidence limits for the isotonic contrasts. For the multiplicity adjustment, the `LSMESTIMATE` statement employs simulation, which provides adjusted  $p$ -values and lower confidence limits that are exact up to Monte Carlo error.

```
proc mixed data=FerriteCores;
 class Temp;
 model MagneticForce = Temp;
 lsestimate Temp
 'avg(1:1)<avg(2:4)' -3 1 1 1 divisor=3,
 'avg(1:2)<avg(3:4)' -1 -1 1 1 divisor=2,
 'avg(1:3)<avg(4:4)' -1 -1 -1 3 divisor=3
 / adjust=simulate(seed=1) cl upper;
 ods select LSMestimates;
run;
```

The results are shown in [Output 59.10.1](#).

### Output 59.10.1 Analysis of LS-Means with Isotonic Contrasts

|----------------------------------------|---------------------|-----------|-----------|--|--|
| Adjustment for Multiplicity: Simulated |                     |           |           |  |  |
| Effect                                 | Label               | Adj Lower | Adj Upper |  |  |
| Temp                                   | avg(1:1) < avg(2:4) | 0.3771    | Infty     |  |  |
| Temp                                   | avg(1:2) < avg(3:4) | 0.3337    | Infty     |  |  |
| Temp                                   | avg(1:3) < avg(4:4) | -0.02291  | Infty     |  |  |

With an adjusted  $p$ -value of 0.001, the magnetic force at the first temperature is significantly less than the average of the other temperatures. Likewise, the average of the first two temperatures is significantly less than the average of the last two ( $p = 0.0009$ ). However, the magnetic force at the last temperature is not significantly greater than the average magnetic force of the others ( $p = 0.0625$ ). These results indicate a significant monotone increase over the first three temperatures, but not across all four temperatures.

### Overview: MODECLUS Procedure

The MODECLUS procedure clusters observations in a SAS data set by using any of several algorithms based on nonparametric density estimates. The data can be numeric coordinates or distances. PROC MODECLUS can perform approximate significance tests for the number of clusters and can hierarchically join nonsignificant clusters. The significance tests are empirically validated by simulations with sample sizes ranging from 20 to 2000.

PROC MODECLUS produces output data sets containing density estimates and cluster membership, various cluster statistics including approximate  $p$ -values, and a summary of the number of clusters generated by various algorithms, smoothing parameters, and significance levels.

Most clustering methods are biased toward finding clusters possessing certain characteristics related to size (number of members), shape, or dispersion. Methods based on the least squares criterion (Sarle 1982), such as  $k$ -means and Ward's minimum variance method, tend to find clusters with roughly the same number of observations in each cluster. Average linkage (see Chapter 31, "The CLUSTER Procedure") is somewhat biased toward finding clusters of equal variance. Many clustering methods tend to produce compact, roughly hyperspherical clusters and are incapable of detecting clusters with highly elongated or irregular shapes. The methods with the least bias are those based on nonparametric density estimation (Silverman 1986, pp. 130–146; Scott 1992, pp. 125–190) such as density linkage (see Chapter 31, "The CLUSTER Procedure"), Wong and Lane (1983); Wong and Schaack (1982). The biases of many commonly used clustering methods are discussed in Chapter 11, "Introduction to Clustering Procedures."

PROC MODECLUS implements several clustering methods by using nonparametric density estimation. Such clustering methods are referred to hereafter as *nonparametric clustering methods*. The methods in PROC MODECLUS are related to, but not identical to, methods developed by Gitman (1973); Huizinga (1978); Koontz and Fukunaga (1972a, b); Koontz, Narendra, and Fukunaga (1976); Mizoguchi and Shimura (1980); Wong and Lane (1983).

Details of the algorithms are provided in the section "Clustering Methods" on page 5099.

For nonparametric clustering methods, a cluster is loosely defined as a region surrounding a local maximum of the probability density function (see the section "Significance Tests" on page 5101 for a more rigorous definition). Given a sufficiently large sample, nonparametric clustering methods are capable of detecting clusters of unequal size and dispersion and with highly irregular shapes. Nonparametric methods can also obtain good results for compact clusters of equal size and dispersion, but they naturally require larger sample sizes for good recovery than clustering methods that are biased toward finding such "nice" clusters.

For coordinate data, nonparametric clustering methods are less sensitive to changes in scale of the variables or to affine transformations of the variables than are most other commonly used clustering methods. Nevertheless, it is necessary to consider questions of scaling and transformation, since variables with large variances tend to have more of an effect on the resulting clusters than those with small variances. If two or more variables are not measured in comparable units, some type of standardization or scaling is necessary; otherwise, the distances used by the procedure might be based on inappropriate apples-and-oranges computations. For variables with comparable units of measurement, standardization or scaling might still be desirable if the scale estimates of the variables are not related to their expected importance for defining clusters. If you want two variables to have equal importance in the analysis, they should have roughly equal scale estimates. If you want one variable to have more of an effect than another, the former should be scaled to have a greater scale estimate than the latter. The STD option in the PROC MODECLUS statement scales all variables to equal variance. However, the variance is not necessarily the most appropriate scale estimate for cluster analysis. In particular, outliers should be removed before using PROC MODECLUS with the STD option. A variety of scale estimators including robust estimators are provided in the STDIZE procedure (for detailed information, see Chapter 87, "The STDIZE Procedure"). Additionally, the ACECLUS procedure provides another way to transform the variables to try to improve the separation of clusters.

Since clusters are defined in terms of local maxima of the probability density function, nonlinear transformations of the data can change the number of population clusters. The variables should be transformed so that equal differences are of equal practical importance. An interval scale of measurement is required. Or-

dinal or ranked data are generally inappropriate, since monotone transformations can produce any arbitrary number of modes.

Unlike the methods in the CLUSTER procedure, the methods in the MODECLUS procedure are not inherently hierarchical. However, PROC MODECLUS can do approximate nonparametric significance tests for the number of clusters by obtaining an approximate  $p$ -value for each cluster, and it can hierarchically join nonsignificant clusters.

Another important difference between the MODECLUS procedure and many other clustering methods is that you do not tell PROC MODECLUS how many clusters you want. Instead, you specify a *smoothing parameter* (see the section “Density Estimation” on page 5096) and, optionally, a significance level, and PROC MODECLUS determines the number of clusters. You can specify a list of smoothing parameters, and PROC MODECLUS performs a separate cluster analysis for each value in the list.

---

## Getting Started: MODECLUS Procedure

This section illustrates how PROC MODECLUS can be used to examine the clusters of data in the following artificial data set.

```
data example;
 input x y @@;
 datalines;
18 18 20 22 21 20 12 23 17 12 23 25 25 20 16 27
20 13 28 22 80 20 75 19 77 23 81 26 55 21 64 24
72 26 70 35 75 30 78 42 18 52 27 57 41 61 48 64
59 72 69 72 80 80 31 53 51 69 72 81
;
```

It is a good practice to plot the data to check for obvious clusters or pathologies prior to the analysis. In this example, with only two variables and a small sample size, the SGPLOT procedure in the following statements produces a scatter plot:

```
proc sgplot;
 scatter y=y x=x;
run;
```

Figure 60.1 suggests three clusters. Of these clusters, the one in the lower-left corner is the most compact, while the lower-right cluster is more dispersed.

The upper cluster is elongated and would be difficult for most clustering algorithms to identify as a single cluster. The plot also suggests that a Euclidean distance of 10 or 20 is a good initial guess for the neighborhood size in density estimation and clustering.

**Figure 60.1** Scatter Plot of Data

To obtain a cluster analysis in PROC MODECLUS, you must specify the METHOD= option; for most purposes, METHOD=1 is recommended. The cluster analysis can be performed with a list of radii (R=10 15 35), as shown in the following PROC MODECLUS statement. An output data set containing the cluster membership is created with the OUT= option. The following statements produce Figure 60.2 through Figure 60.5:

```
proc modeclus data=example method=1 r=10 15 35 out=out;
run;
```

For each cluster solution, PROC MODECLUS produces a table of cluster statistics including the cluster number, the number of observations in the cluster, the maximum estimated density within the cluster, the number of observations in the cluster having a neighbor that belongs to a different cluster, and the estimated saddle density of the cluster. The results are displayed in Figure 60.2, Figure 60.3, and Figure 60.4 for three different radii. A smaller radius (R=10) yields a larger number of clusters (6), as displayed in Figure 60.2; a larger radius (R=35) includes all observations in a single cluster, as displayed in Figure 60.4. Note that all clusters in these three figures are “isolated” since their corresponding boundary frequencies are all zeros. Consequently, all the estimated saddle densities are missing. A table summarizing each cluster solution is then produced at the end, as displayed in Figure 60.5.

The OUT= data set contains a complete copy of the input data set for each cluster solution. By using a BY statement in the following PROC SGLOT statement, you can examine the differences in cluster memberships for each radius as shown in Figure 60.6 through Figure 60.8:

```
proc sgplot data=out noautolegend;
 scatter y=y x=x / group=cluster markerchar=cluster;
 by _r_;
run;
```

**Figure 60.6** Scatter Plots of Cluster Memberships with \_R\_=10

**Figure 60.7** Scatter Plots of Cluster Memberships with  $_R_=15$

**Figure 60.8** Scatter Plots of Cluster Memberships with  $_R_=35$

## Syntax: MODECLUS Procedure

The following statements are available in the MODECLUS procedure:

```
PROC MODECLUS < options > ;
 BY variables ;
 FREQ variable ;
 ID variable ;
 VAR variables ;
```

The PROC MODECLUS statement is required. All other statements are optional.

## PROC MODECLUS Statement

```
PROC MODECLUS < options > ;
```

The PROC MODECLUS statement invokes the MODECLUS procedure. [Table 60.1](#) summarizes the options available in the PROC MODECLUS statement. These options are discussed in the following sections.

**Table 60.1** Summary of PROC MODECLUS Statement Options

| Option                                                         | Description                                                                                                     |
|----------------------------------------------------------------|-----------------------------------------------------------------------------------------------------------------|
| <b>Specify input and output data sets</b>                      |                                                                                                                 |
| DATA=                                                          | Specifies input data set name                                                                                   |
| OUT=                                                           | Specifies output data set name for observations                                                                 |
| OUTCLUS=                                                       | Specifies output data set name for clusters                                                                     |
| OUTSUM=                                                        | Specifies output data set name for cluster solutions                                                            |
| <b>Specify variables in output data sets</b>                   |                                                                                                                 |
| CLUSTER=                                                       | Specifies variable in the OUT= and OUTCLUS= data sets identifying clusters                                      |
| DENSITY=                                                       | Specifies variable in the OUT= data set containing density estimates                                            |
| OUTLENGTH=                                                     | Specifies length of variables in the output data sets                                                           |
| <b>Summarize and process coordinate data before clustering</b> |                                                                                                                 |
| SIMPLE                                                         | Requests simple statistics                                                                                      |
| STANDARD                                                       | Standardizes the variables to mean 0 and standard deviation 1                                                   |
| <b>Specify smoothing parameters</b>                            |                                                                                                                 |
| DK=                                                            | Specifies number of neighbors to use for <i>k</i> th-nearest-neighbor density estimation                        |

| K=                                                             | Specifies number of neighbors to use for <i>k</i> th-nearest-neighbor density estimation and clustering         |
| DR=                                                            | Specifies radius of the sphere of support for uniform-kernel density estimation                                 |
| CR=                                                            | Specifies radius of the neighborhood for clustering                                                             |
| R=                                                             | Specifies radius of the sphere of support for uniform-kernel density estimation and the neighborhood clustering |
| <b>Specify density estimation options</b>                      |                                                                                                                 |
| CASCADE=                                                       | Specifies number of times the density estimates are to be cascaded                                              |

Table 60.1 continued

| Option                                        | Description                                                                                                                                  |
|-----------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| DIMENSION=                                    | Specifies dimensionality to be used when computing density estimates                                                                         |
| AM                                            | Uses arithmetic means for cascading density estimates                                                                                        |
| HM                                            | Uses harmonic means for cascading density estimates                                                                                          |
| SUM                                           | Uses sums for cascading density estimates                                                                                                    |
| <b>Specify clustering methods and options</b> |                                                                                                                                              |
| DOCK=                                         | Dissolves clusters with $n$ or fewer members                                                                                                 |
| EARLY                                         | Stops the analysis after obtaining a solution with either no cluster or a single cluster                                                     |
| JOIN=                                         | Requests that nonsignificant clusters be hierarchically joined                                                                               |
| MAXCLUSTERS=                                  | Specifies maximum number of clusters to be obtained with METHOD=6                                                                            |
| METHOD=                                       | Specifies clustering method to use                                                                                                           |
| MODE=                                         | Specifies minimum members for either cluster to be designated a modal cluster when two clusters are joined using METHOD=5                    |
| POWER=                                        | Specifies power of the density used with METHOD=6                                                                                            |
| TEST                                          | Specifies approximate significance tests for the number of clusters                                                                          |
| THRESHOLD=                                    | Specifies assignment threshold used with METHOD=6                                                                                            |
| <b>Specify the output display options</b>     |                                                                                                                                              |
| ALL                                           | Produces all optional output                                                                                                                 |
| BOUNDARY                                      | Displays the density and cluster membership of observations with neighbors belonging to a different cluster                                  |
| CORE                                          | Retains the neighbor lists for each observation in memory                                                                                    |
| CROSS                                         | Displays the estimated cross validated log density of each observation                                                                       |
| CROSSLIST                                     | Displays the estimated density and cluster membership of each observation                                                                    |
| LOCAL                                         | Displays estimates of local dimensionality and writes them to the OUT=data set                                                               |
| NEIGHBOR                                      | Displays the neighbors of each observation                                                                                                   |
| NOPRINT                                       | Suppresses the display of the output                                                                                                         |
| NOSUMMARY                                     | Suppresses the display of the summary of the number of clusters, number of unassigned observations, and maximum $p$ -value for each analysis |
| SHORT                                         | Suppresses the display of statistics for each cluster                                                                                        |
| TRACE                                         | Traces the cluster assignments when METHOD=6                                                                                                 |

You can specify at least one of the following options for smoothing parameters for density estimation: DK=, K=, DR=, or R=. To obtain a cluster analysis, you can specify the METHOD= option and at least one of the following smoothing parameters for clustering: CK=, K=, CR=, or R=. If you want significance tests for the number of clusters, you should specify either the DR= or R= option. If none of the smoothing parameters is specified, the MODECLUS procedure provides a default value for the R= option. See the section “Density Estimation” on page 5096 for the formula of a reasonable first guess for R= and a discussion of smoothing parameters.

You can specify lists of values for the DK=, CK=, K=, DR=, CR=, and R= options. Numbers in the lists can be separated by blanks or commas. You can include in the lists one or more items of the form *start TO stop BY increment*. Each list can contain either one value or the same number of values as in every other list that contains more than one value. If a list has only one value, that value is used in combination with all

the values in longer lists. If two or more lists have more than one value, then one analysis is done by using the first value in each list, another analysis is done by using the second value in each list, and so on.

You can specify the following options in the PROC MODECLUS statement.

**ALL**

produces all optional output.

**AM**

specifies arithmetic means for cascading density estimates. See the description of the CASCADE= option.

**BOUNDARY**

displays the density and cluster membership of observations with neighbors belonging to a different cluster.

**CASCADE=*n*****CASC=*n***

specifies the number of times the density estimates are to be cascaded (see the section “[Density Estimation](#)” on page 5096). The default value 0 performs no cascading.

You can specify a list of values for the CASCADE= option. Each value in the list is combined with each combination of smoothing parameters to produce a separate analysis.

**CK=*n***

specifies the number of neighbors to use for clustering. The number of neighbors should be at least two but less than the number of observations. See the section “[Density Estimation](#)” on page 5096 for details.

**CLUSTER=*name***

provides a name for the variable in the OUT= and OUTCLUS= data sets identifying clusters. The default name is CLUSTER.

**CORE**

keeps the neighbor lists for each observation in the computer memory to make small problems run faster.

**CR=*n***

specifies the radius of the neighborhood for clustering. See the section “[Density Estimation](#)” on page 5096 for details.

**CROSS**

computes the likelihood cross validation criterion (Silverman 1986, pp. 52–55). This option appears to be of limited usefulness. See the section “[Density Estimation](#)” on page 5096 for details.

**CROSSLIST**

displays the cross validated log density of each observation.

**DATA=*SAS-data-set***

specifies the input data set containing observations to be clustered. If you omit the DATA= option, the most recently created SAS data set is used.

If the data set is TYPE=DISTANCE, the data are interpreted as a distance matrix. The number of variables must equal the number of observations in the data set or in each BY group. The distances are assumed to be Euclidean, but the procedure accepts other types of distances or dissimilarities. Unlike the CLUSTER procedure, PROC MODECLUS uses the entire distance matrix, not just the lower triangle; the distances are not required to be symmetric. The neighbors of a given observation are determined solely from the distances in that observation. Missing values are considered infinite. Various distance measures can be computed from coordinate data by using the DISTANCE procedure (for detailed information, see Chapter 34, “[The DISTANCE Procedure](#)”).

If the data set is not TYPE=DISTANCE, the data are interpreted as coordinates in a Euclidean space, and Euclidean distances are computed. The variables can be discrete or continuous and should be at the interval level of measurement.

Data set types such as TYPE=DISTANCE do not persist when you copy or modify a data set. You must specify the TYPE= data set option for the new data set, as in the following example:

```
data dist2(type=distance);
 set dist;
run;
```

If you do not specify the TYPE=DISTANCE data set option, the new data set is the default TYPE=DATA. If you use the new data set in a procedure that accepts both TYPE=DATA or TYPE=DISTANCE data sets (such as PROC CLUSTER or PROC MODECLUS), the results will be incorrect.

**DENSITY=*name***

provides a name for the variable in the OUT= data set containing density estimates. The default name is DENSITY.

**DIMENSION=*n***

**DIM=*n***

specifies the dimensionality to be used when computing density estimates. The default is the number of variables if the data are coordinates; the default is 1 if the data are distances.

**DK=*n***

specifies the number of neighbors to use for *k*th-nearest-neighbor density estimation. The number of neighbors should be at least two but less than the number of observations. See the section “[Density Estimation](#)” on page 5096 for details.

**DOCK=*n***

dissolves clusters with *n* or fewer members by making the members unassigned.

**DR=*n***

specifies the radius of the sphere of support for uniform-kernel density estimation. See the section “[Density Estimation](#)” on page 5096 for details.

**EARLY**

stops the cluster analysis after obtaining either a solution with no cluster or a solution with one cluster to which all observations are assigned. The smoothing parameters should be specified in increasing order. This can reduce the computer time required for the analysis but might occasionally miss some multiple-cluster solutions.

**HM**

uses harmonic means for cascading density estimates. See the description of the `CASCADE=` option for details.

**JOIN<=*p*>**

requests that nonsignificant clusters be hierarchically joined. The JOIN option implies the TEST option. After each solution is obtained, the cluster with the largest approximate  $p$ -value is either joined to a neighboring cluster or, if there is no neighboring cluster, dissolved by making all of its members unassigned. After two clusters are joined, an analysis of the remaining clusters is displayed.

If you do not specify a  $p$ -value with the JOIN= option, joining continues until only one cluster remains, and the results are written to the output data sets after each analysis. If you specify a  $p$ -value with the JOIN= option, joining continues until the greatest approximate  $p$ -value is less than the value given in the JOIN= option, and only if there is more than one cluster are the results for that analysis written to the output data sets.

Any value of  $p$  less than 1E-8 is set to 1E-8.

**K=*n***

specifies the number of neighbors to use for  $k$ th-nearest-neighbor density estimation and clustering. The number of neighbors should be at least two but less than the number of observations. Specifying `K=n` is equivalent to specifying both `DK=n` and `CK=n`. See the section “Density Estimation” on page 5096 for details.

**LIST**

displays the estimated density and cluster membership of each observation.

**LOCAL**

requests estimates of local dimensionality (Tukey and Tukey 1981, pp. 236–237).

**MAXCLUSTERS=*n*****MAXC=*n***

specifies the maximum number of clusters to be obtained with the `METHOD=6` option. By default, there is no fixed limit.

**METHOD=*n*****MET=*n*****M=*n***

specifies what clustering method to use. Since these methods do not have widely recognized names, the methods are indicated by numbers from 0 to 6. The methods are described in the section “Clustering Methods” on page 5099. For most purposes, `METHOD=1` is recommended, although `METHOD=6` might occasionally produce better results in return for considerably greater computer time and space requirements. `METHOD=1` is not good for discrete coordinate data with only a few equally spaced values. In this case, `METHOD=6` or `METHOD=3` works better. `METHOD=4` or `METHOD=5` is less desirable than other methods when there are ties, since a general characteristic of agglomerative hierarchical clustering methods is that the results are indeterminate in the presence of ties.

You must specify the `METHOD=` option to obtain a cluster analysis.

You can specify a list of values for the `METHOD=` option. Each value in the list is combined with each combination of smoothing and cascading parameters to produce a separate cluster analysis.

**MODE=*n***

specifies that when two clusters are joined using the METHOD=5 option (no other methods are affected by the MODE= option), each must have at least *n* members for either cluster to be designated a modal cluster. In any case, each cluster must also have a maximum density greater than the fusion density for either cluster to be designated a modal cluster. If you specify the K= option, the default value of the MODE= option is the same as the value of the K= option because the use of *k*th-nearest-neighbor density estimation limits the resolution that can be obtained for clusters with fewer than *k* members. If you do not specify the K= option, the default is MODE=2. If you specify MODE=0, the default value is used instead of 0. If you specify a FREQ statement, the MODE= value is compared to the number of observations in each cluster, not to the sum of the frequencies.

**NEIGHBOR**

displays the neighbors of each observation in a table called “Nearest Neighbor List.” See [Nearest Neighbor List](#) for information displayed in the table.

**NOPRINT**

suppresses the display of the output. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

**NOSUMMARY**

suppresses the display of the summary of the number of clusters, number of unassigned observations, and maximum *p*-value for each analysis.

**OUT=*SAS-data-set***

specifies the output data set containing the input data plus density estimates, cluster membership, and variables identifying the type of solution. There is an output observation corresponding to each input observation for each solution. Therefore, the OUT= data set can be very large.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUT= data sets, see the section “[Output Data Sets](#)” on page 5107.

**OUTCLUS=*SAS-data-set*****OUTC=*SAS-data-set***

specifies the output data set containing an observation corresponding to each cluster in each solution. The variables identify the solution and contain statistics describing the clusters.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUTCLUS= data sets, see the section “[Output Data Sets](#)” on page 5107.

**OUTSUM=*SAS-data-set*****OUTS=*SAS-data-set***

specifies the output data set containing an observation corresponding to each cluster solution, giving the number of clusters and the number of unclassified observations for that solution.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For details about OUTSUM= data sets, see the section “[Output Data Sets](#)” on page 5107.

**OUTLENGTH=*n*****OUTL=*n***

specifies the length of those output variables that are not copied from the input data set but are created by PROC MODECLUS.

The OUTLENGTH= option applies only to the following variables that appear in all of the output data sets: `_K_`, `_DK_`, `_CK_`, `_R_`, `_DR_`, `_CR_`, `_CASCAD_`, `_METHOD_`, `_NJOIN_`, and `_LOCAL_`.

The minimum value is 2 or 3, depending on the operating system. The maximum value is 8. The default value is 8.

**POWER=*n*****POW=*n***

specifies the power of the density used with the METHOD=6 option. The default value is 2.

**R=*n***

specifies the radius of the sphere of support for uniform-kernel density estimation and the neighborhood for clustering. Specifying R=*n* is equivalent to specifying both DR=*n* and CR=*n*. See the section “Density Estimation” on page 5096 for details.

**SHORT**

suppresses the display of statistics for each cluster.

**SIMPLE****S**

displays means, standard deviations, skewness, kurtosis, and a coefficient of bimodality. The SIMPLE option applies only to coordinate data.

**STANDARD****STD**

standardizes the variables to mean 0 and standard deviation 1. The STANDARD option applies only to coordinate data.

**SUM**

uses sums for cascading density estimates. See the description of the CASCADE= option for details.

**TEST**

performs approximate significance tests for the number of clusters. The R= or DR= option must also be specified with a nonzero value to obtain significance tests.

The significance tests performed by PROC MODECLUS are valid only for simple random samples, and they require at least 20 observations per cluster to have enough power to be of any use. See the section “Significance Tests” on page 5101 for details.

**THRESHOLD=*n*****THR=*n***

specifies the assignment threshold used with the METHOD=6 option. The default is 0.5.

**TRACE**

traces the process of cluster assignments when METHOD=6 is specified.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC MODECLUS to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MODECLUS procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## FREQ Statement

**FREQ variable ;**

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable's name in a FREQ statement. PROC MODECLUS then treats the data set as if each observation appeared  $n$  times, where  $n$  is the value of the FREQ variable for the observation. Nonintegral values of the FREQ variable are truncated to the largest integer less than the FREQ value.

---

## ID Statement

**ID variable ;**

The values of the ID variable identify observations in the displayed results and in the OUT= data set. If you omit the ID statement, each observation is identified by its observation number, and a variable called `_OBS_` is written to the OUT= data set containing the original observation numbers.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement specifies numeric variables to be used in the cluster analysis. If you omit the VAR statement, all numeric variables not specified in other statements are used.

---

## Details: MODECLUS Procedure

---

### Density Estimation

See Silverman (1986) or Scott (1992) for an introduction to nonparametric density estimation.

PROC MODECLUS uses hyperspherical uniform kernels of fixed or variable radius. The density estimate at a point is computed by dividing the number of observations within a sphere centered at the point by the product of the sample size and the volume of the sphere. The size of the sphere is determined by the smoothing parameters that you are required to specify.

For fixed-radius kernels, specify the radius as a Euclidean distance with either the DR= or R= option. For variable-radius kernels, specify the number of neighbors desired within the sphere with either the DK= or K= option; the radius is then the smallest radius that contains at least the specified number of observations including the observation at which the density is being estimated. If you specify both the DR= or R= option and the DK= or K= option, the radius used is the maximum of the two indicated radii; this is useful for dealing with outliers.

It is convenient to refer to the sphere of support of the kernel at observation  $x_i$  as the *neighborhood* of  $x_i$ . The observations within the neighborhood of  $x_i$  are the *neighbors* of  $x_i$ . In some contexts,  $x_i$  is considered a neighbor of itself, but in other contexts it is not. The following notation is used in this chapter:

|          |                                                                                          |
|----------|------------------------------------------------------------------------------------------|
| $x_i$    | the $i$ th observation                                                                   |
| $d(x,y)$ | the distance between points $x$ and $y$                                                  |
| $n$      | the total number of observations in the sample                                           |
| $n_i$    | the number of observations within the neighborhood of $x_i$ , including $x_i$ itself     |
| $n_i^-$  | the number of observations within the neighborhood of $x_i$ , not including $x_i$ itself |
| $N_i$    | the set of indices of neighbors of $x_i$ , including $i$                                 |
| $N_i^-$  | the set of indices of neighbors of $x_i$ , not including $i$                             |
| $v_i$    | the volume of the neighborhood of $x_i$                                                  |
| $r_i$    | the radius of the neighborhood of $x_i$                                                  |

|               |                                                            |
|---------------|------------------------------------------------------------|
| $\hat{f}_i$   | the estimated density at $x_i$                             |
| $\hat{f}_i^-$ | the cross validated density estimate at $x_i$              |
| $C_k$         | the set of indices of observations assigned to cluster $k$ |
| $v$           | the number of variables or the dimensionality              |
| $s_l$         | standard deviation of the $l$ th variable                  |

The estimated density at  $x_i$  is

$$\hat{f}_i = \frac{n_i}{nv_i}$$

which indicates the number of neighbors of  $x_i$  divided by the product of the sample size and the volume of the neighborhood at  $x_i$ , where

$$v_i = \frac{\pi^{\frac{v}{2}} r_i^v}{\Gamma(\frac{v}{2} + 1)}$$

and  $\Gamma$  can be computed in a DATA step by using the GAMMA function. Note that  $v = 1$  for distance data.

The density estimates provided by uniform kernels are not quite as good as those provided by some other types of kernels, but they are quite satisfactory for clustering. The significance tests for the number of clusters require the use of fixed-size uniform kernels.

There is no simple answer to the question of which smoothing parameter to use (Silverman 1986, pp. 43–61, 84–88, 98–99). It is usually necessary to try several different smoothing parameters. A reasonable first guess for the K= option is in the range of 0.1 to 1 times  $n^{4/(v+4)}$ , smaller values being suitable for higher dimensionalities. A reasonable first guess for the R= option in many coordinate data sets is given by

$$\left[ \frac{2^{v+2}(v+2)\Gamma(\frac{v}{2}+1)}{nv^2} \right]^{1/(v+4)} \sqrt{\sum_{l=1}^v s_l^2}$$

which can be computed in a DATA step by using the GAMMA function for  $\Gamma$ . The MODECLUS procedure also provides this first guess as a default smoothing parameter if none of the options (DR=, CR=, R=, DK=, CK=, and K=) is specified. This formula is derived under the assumption that the data are sampled from a multivariate normal distribution and, therefore, tend to be too large (oversmooth) if the true distribution is multimodal. Robust estimates of the standard deviations might be preferable if there are outliers. If the data are distances, the factor  $\sqrt{\sum s_l^2}$  can be replaced by an average root-mean-squared Euclidean distance divided by  $\sqrt{2}$ . To prevent outliers from appearing as separate clusters, you can also specify K=2 or CK=2 or, more generally, K= $m$  or CK= $m$ ,  $m \geq 2$ , which in most cases forces clusters to have at least  $m$  members.

If the variables all have unit variance (for example, if you specify the STD option), you can use [Table 60.2](#) to obtain an initial guess for the R= option.

**Table 60.2** Reasonable First Guess for R= for Standardized Data

| Number<br>of Obs | Number of Variables |      |      |      |      |      |      |      |      |      |
|------------------|---------------------|------|------|------|------|------|------|------|------|------|
|                  | 1                   | 2    | 3    | 4    | 5    | 6    | 7    | 8    | 9    | 10   |
| 20               | 1.01                | 1.36 | 1.77 | 2.23 | 2.73 | 3.25 | 3.81 | 4.38 | 4.98 | 5.60 |
| 35               | 0.91                | 1.24 | 1.64 | 2.08 | 2.56 | 3.08 | 3.62 | 4.18 | 4.77 | 5.38 |
| 50               | 0.84                | 1.17 | 1.56 | 1.99 | 2.46 | 2.97 | 3.50 | 4.06 | 4.64 | 5.24 |
| 75               | 0.78                | 1.09 | 1.47 | 1.89 | 2.35 | 2.85 | 3.38 | 3.93 | 4.50 | 5.09 |
| 100              | 0.73                | 1.04 | 1.41 | 1.82 | 2.28 | 2.77 | 3.29 | 3.83 | 4.40 | 4.99 |
| 150              | 0.68                | 0.97 | 1.33 | 1.73 | 2.18 | 2.66 | 3.17 | 3.71 | 4.27 | 4.85 |
| 200              | 0.64                | 0.93 | 1.28 | 1.67 | 2.11 | 2.58 | 3.09 | 3.62 | 4.17 | 4.75 |
| 350              | 0.57                | 0.85 | 1.18 | 1.56 | 1.98 | 2.44 | 2.93 | 3.45 | 4.00 | 4.56 |
| 500              | 0.53                | 0.80 | 1.12 | 1.49 | 1.91 | 2.36 | 2.84 | 3.35 | 3.89 | 4.45 |
| 750              | 0.49                | 0.74 | 1.06 | 1.42 | 1.82 | 2.26 | 2.74 | 3.24 | 3.77 | 4.32 |
| 1000             | 0.46                | 0.71 | 1.01 | 1.37 | 1.77 | 2.20 | 2.67 | 3.16 | 3.69 | 4.23 |
| 1500             | 0.43                | 0.66 | 0.96 | 1.30 | 1.69 | 2.11 | 2.57 | 3.06 | 3.57 | 4.11 |
| 2000             | 0.40                | 0.63 | 0.92 | 1.25 | 1.63 | 2.05 | 2.50 | 2.99 | 3.49 | 4.03 |

One data-based method for choosing the smoothing parameter is likelihood cross validation (Silverman 1986, pp. 52–55). The cross validated density estimate at an observation is obtained by omitting the observation from the computations:

$$\hat{f}_i^- = \frac{n_i^-}{nv_i}$$

The (log) likelihood cross validation criterion is then computed as

$$\sum_{i=1}^n \log \hat{f}_i^-$$

The suggested smoothing parameter is the one that maximizes this criterion. With fixed-radius kernels, likelihood cross validation oversmooths long-tailed distributions; for purposes of clustering, it tends to undersmooth short-tailed distributions. With  $k$ -nearest-neighbor density estimation, likelihood cross validation is useless because it almost always indicates  $k=2$ .

Cascaded density estimates are obtained by computing initial kernel density estimates and then, at each observation, taking the arithmetic mean, harmonic mean, or sum of the initial density estimates of the observations within the neighborhood. The cascaded density estimates can, in turn, be cascaded, and so on. Let  ${}_k \hat{f}_i$  be the density estimate at  $x_i$  cascaded  $k$  times. For all types of cascading,  ${}_0 \hat{f}_i = \hat{f}_i$ . If the cascading is done by arithmetic means, then, for  $k \geq 0$ ,

$${}_{k+1} \hat{f}_i = \sum_{j \in N_i} {}_k \hat{f}_j / n_i$$

For harmonic means,

$${}_{k+1} \hat{f}_i = \left( \sum_{j \in N_i} {}_k \hat{f}_j^{-1} / n_i \right)^{-1}$$

and for sums,

$${}_{k+1}\hat{f}_i = \left( \sum_{j \in N_i} {}_k\hat{f}_j^{k+1} \right)^{\frac{1}{k+2}}$$

To avoid cluttering formulas, the symbol  $\hat{f}_i$  is used in the rest of the chapter to denote the density estimate at  $x_i$  whether cascaded or not, since the clustering methods and significance tests do not depend on the degree of cascading.

Cascading increases the smoothness of the estimates with less computation than would be required by increasing the smoothing parameters to yield a comparable degree of smoothness. For population densities with bounded support and discontinuities at the boundaries, cascading improves estimates near the boundaries. Cascaded estimates, especially using sums, might be more sensitive to the local covariance structure of the distribution than are the uncascaded kernel estimates. Cascading seems to be useful for detecting very nonspherical clusters. Cascading was suggested by Tukey and Tukey (1981, p. 237). Additional research into the properties of cascaded density estimates is needed.

---

## Clustering Methods

The number of clusters is a function of the smoothing parameters. The number of clusters tends to decrease as the smoothing parameters increase, but the relationship is not strictly monotonic. Generally, you should specify several different values of the smoothing parameters to see how the number of clusters varies.

The clustering methods used by PROC MODECLUS use spherical clustering neighborhoods of fixed or variable radius that are similar to the spherical kernels used for density estimation. For fixed-radius neighborhoods, specify the radius as a Euclidean distance with either the CR= or R= option. For variable-radius neighborhoods, specify the number of neighbors desired within the sphere with either the CK= or K= option; the radius is then the smallest radius that contains at least the specified number of observations including the observation for which the neighborhood is being determined. However, in the following descriptions of clustering methods, an observation is not considered to be one of its own neighbors. If you specify both the CR= or R= option and the CK= or K= option, the radius used is the maximum of the two indicated radii; this is useful for dealing with outliers. In this section, the symbols  $N_i$ ,  $N_i^-$ ,  $n_i$ , and  $n_i^-$  refer to clustering neighborhoods, not density estimation neighborhoods.

### METHOD=0

Begin with each observation in a separate cluster. For each observation and each of its neighbors, join the cluster to which the observation belongs with the cluster to which the neighbor belongs. This method does not use density estimates. With a fixed clustering radius, the clusters are those obtained by cutting the single linkage tree at the specified radius (see Chapter 31, “The CLUSTER Procedure”).

### METHOD=1

Begin with each observation in a separate cluster. For each observation, find the nearest neighbor with a greater estimated density. If such a neighbor exists, join the cluster to which the observation belongs with the cluster to which the specified neighbor belongs.

Next, consider each observation with density estimates equal to that of one or more neighbors but not less than the estimate at any neighbor. Join the cluster containing the observation with (1) each cluster containing a neighbor of the observation such that the maximum density estimate in the cluster equals the density estimate at the observation and (2) the cluster containing the nearest neighbor of the observation such that the maximum density estimate in the cluster exceeds the density estimate at the observation.

This method is similar to the classification or assignment stage of algorithms described by Gitman (1973) and Huizinga (1978).

## METHOD=2

Begin with each observation in a separate cluster. For each observation, find the neighbor with the greatest estimated density exceeding the estimated density of the observation. If such a neighbor exists, join the cluster to which the observation belongs with the cluster to which the specified neighbor belongs.

Observations with density estimates equal to that of one or more neighbors but not less than the estimate at any neighbor are treated the same way as they are in METHOD=1.

This method is similar to the first stage of an algorithm proposed by Mizoguchi and Shimura (1980).

## METHOD=3

Begin with each observation in a separate cluster. For each observation, find the neighbor with greater estimated density such that the slope of the line connecting the point on the estimated density surface at the observation with the point on the estimated density surface at the neighbor is a maximum. That is, for observation  $x_i$ , find a neighbor  $x_j$  such that  $(\hat{f}_j - \hat{f}_i)/d(x_j, x_i)$  is a maximum. If this slope is positive, join the cluster to which observation  $x_i$  belongs with the cluster to which the specified neighbor  $x_j$  belongs. This method was invented by Koontz, Narendra, and Fukunaga (1976).

Observations with density estimates equal to that of one or more neighbors but not less than the estimate at any neighbor are treated the same way as they are in METHOD=1. The algorithm suggested for this situation by Koontz, Narendra, and Fukunaga (1976) might fail for flat areas in the estimated density that contain four or more observations.

## METHOD=4

This method is equivalent to the first stage of two-stage density linkage (see Chapter 31, “The CLUSTER Procedure”) without the use of the MODE=option.

## METHOD=5

This method is equivalent to the first stage of two-stage density linkage (see Chapter 31, “The CLUSTER Procedure”) with the use of the MODE=option.

## METHOD=6

Begin with all observations unassigned.

**Step 1:** Form a list of seeds, each seed being a single observation such that the estimated density of the observation is not less than the estimated density of any of its neighbors. If you specify the MAXCLUSTERS= $n$  option, retain only the  $n$  seeds with the greatest estimated densities.

**Step 2:** Consider each seed in decreasing order of estimated density, as follows:

1. If the current seed has already been assigned, proceed to the next seed. Otherwise, form a new cluster consisting of the current seed.
2. Add to the cluster any unassigned seed that is a neighbor of a member of the cluster or that shares a neighbor with a member of the cluster; repeat until no unassigned seed satisfies these conditions.
3. Add to the cluster all neighbors of seeds that belong to the cluster.
4. Consider each unassigned observation. Compute the ratio of the sum of the  $p - 1$  powers of the estimated density of the neighbors that belong to the current cluster to the sum of the  $p - 1$  powers of the estimated density of all of its neighbors, where  $p$  is specified by the POWER= option and is 2 by default. Let  $x_i$  be the current observation, and let  $k$  be the index of the current cluster. Then this ratio is

$$r_{ik} = \frac{\sum_{j \in N_i \cap C_k} \hat{f}_j^{p-1}}{\sum_{j \in N_i} \hat{f}_j^{p-1}}$$

(The sum of the  $p - 1$  powers of the estimated density of the neighbors of an observation is an estimate of the integral of the  $p$ th power of the density over the neighborhood.) If  $r_{ik}$  exceeds the maximum of 0.5 and the value of the THRESHOLD= option, add the observation  $x_i$  to the current cluster  $k$ . Repeat until no more observations can be added to the current cluster.

**Step 3:** (This step is performed only if the value of the THRESHOLD= option is less than 0.5.) Form a list of unassigned observations in decreasing order of estimated density. Repeat the following actions until the list is empty:

1. Remove the first observation from the list, such as observation  $x_i$ .
2. For each cluster  $k$ , compute  $r_{ik}$ .
3. If the maximum over clusters of  $r_{ik}$  exceeds the value of the THRESHOLD= option, assign observation  $x_i$  to the corresponding cluster and insert all observations of which the current observation is a neighbor into the list, keeping the list in decreasing order of estimated density.

METHOD=6 is related to a method invented by Koontz and Fukunaga (1972a) and discussed by Koontz and Fukunaga (1972b).

---

## Significance Tests

Significance tests require that a fixed-radius kernel be specified for density estimation via the DR= or R= option. You can also specify the DK= or K= option, but only the fixed radius is used for the significance tests.

The purpose of the significance tests is as follows: given a simple random sample of objects from a population, obtain an estimate of the number of clusters in the population such that the probability in repeated sampling that the estimate exceeds the true number of clusters is not much greater than  $\alpha$ ,  $1\% \leq \alpha \leq 10\%$ . In other words, a sequence of null hypotheses of the form

$H_0^{(i)}$ : The number of population clusters is  $i$  or less

where  $i = 1, 2, \dots, n$ , is tested against the alternatives such as

$H_a^{(i)}$ : The number of population clusters exceeds  $i$

with a maximum experimentwise error rate of approximately  $\alpha$ . The tests protect you from overestimating the number of population clusters. It is impossible to protect against underestimating the number of population clusters without introducing much stronger assumptions than are used here, since the number of population clusters could conceivably exceed the sample size.

The method for conducting significance tests is as follows:

1. Estimate densities by using fixed-radius uniform kernels.
2. Obtain preliminary clusters by a “valley-seeking” method. Other clustering methods could be used but would yield less power.
3. Compute an approximate  $p$ -value for each cluster by comparing the estimated maximum density in the cluster with the estimated maximum density on the cluster boundary.
4. Repeatedly join the least significant cluster with a neighboring cluster until all remaining clusters are significant.
5. Estimate the number of population clusters as the number of significant sample clusters.
6. The preceding steps can be repeated for any number of different radii, and the estimate of the number of population clusters can be taken to be the maximum number of significant sample clusters for any radius.

This method has the following useful features:

- No distributional assumptions are required.
- The choice of smoothing parameter is not critical since you can try any number of different values.
- The data can be coordinates or distances.
- Time and space requirements for the significance tests are no worse than those for obtaining the clusters.
- The power is high enough to be useful for practical purposes.

The method for computing the  $p$ -values is based on a series of plausible approximations. There are as yet no rigorous proofs that the method is infallible. Neither are there any asymptotic results. However, simulations for sample sizes ranging from 20 to 2000 indicate that the  $p$ -values are almost always conservative. The only case discovered so far in which the  $p$ -values are liberal is a uniform distribution in one dimension for

which the simulated error rates exceed the nominal significance level only slightly for a limited range of sample sizes.

To make inferences regarding population clusters, it is first necessary to define what is meant by a cluster. For clustering methods that use nonparametric density estimation, a cluster is usually loosely defined as a region surrounding a local maximum of the probability density function or a maximal connected set of local maxima. This definition might not be satisfactory for very rough densities with many local maxima. It is not applicable at all to discrete distributions for which the density does not exist. As another example in which this definition is not intuitively reasonable, consider a uniform distribution in two dimensions with support in the shape of a figure eight (including the interior). This density might be considered to contain two clusters even though it does not have two distinct modes.

These difficulties can be avoided by defining clusters in terms of the local maxima of a smoothed probability density or mass function. For example, define the neighborhood distribution function (NDF) with radius  $r$  at a point  $x$  as the probability that a randomly selected point will lie within a radius  $r$  of  $x$ —that is, the probability integral over a hypersphere of radius  $r$  centered at  $x$ :

$$s(x) = P(d(x, X) \leq r)$$

where  $X$  is the random variable being sampled,  $r$  is a user-specified radius, and  $d(x,y)$  is the distance between points  $x$  and  $y$ .

The NDF exists for all probability distributions. You can select the radius according to the degree of resolution required. The minimum-variance unbiased estimate of the NDF at a point  $x$  is proportional to the uniform-kernel density estimate with corresponding support.

You can define a *modal region* as a maximal connected set of local maxima of the NDF. A cluster is a connected set containing exactly one modal region. This definition seems to give intuitively reasonable results in most cases. An exception is a uniform density on the perimeter of a square. The NDF has four local maxima. There are eight local maxima along the perimeter, but running PROC MODECLUS with the R= option would yield four clusters since the two local maxima at each corner are separated by a distance equal to the radius. While this density does indeed have four distinctive features (the corners), it is not obvious that each corner should be considered a cluster.

The number of population clusters depends on the radius of the NDF. The significance tests in PROC MODECLUS protect against overestimating the number of clusters at any specified radius. It is often useful to look at the clustering results across a range of radii. A plot of the number of sample clusters as a function of the radius is a useful descriptive display, especially for high-dimensional data (Wong and Schaack 1982).

If a population has two clusters, it must have two modal regions. If there are two modal regions, there must be a “valley” between them. It seems intuitively desirable that the boundary between the two clusters should follow the bottom of this valley. All the clustering methods in PROC MODECLUS are designed to locate the estimated cluster boundaries in this way, although methods 1 and 6 seem to be much more successful at this than the others. Regardless of the precise location of the cluster boundary, it is clear that the maximum of the NDF along the boundary between two clusters must be strictly less than the value of the NDF in either modal region; otherwise, there would be only a single modal region; according to Hartigan and Hartigan (1985), there must be a “dip” between the two modes. PROC MODECLUS assesses the significance of a sample cluster by comparing the NDF in the modal region with the maximum of the NDF along the cluster boundary. If the NDF has second-order derivatives in the region of interest and if the boundary between the two clusters is indeed at the bottom of the valley, then the maximum value of the NDF along the boundary

occurs at a saddle point. Hence, this test is called a *saddle test*. This term is intended to describe any test for clusters that compares modal densities with saddle densities, not just the test currently implemented in the MODECLUS procedure.

The obvious estimate of the maximum NDF in a sample cluster is the maximum estimated NDF at an observation in the cluster. Let  $m(k)$  be the index of the observation for which the maximum is attained in cluster  $k$ .

Estimating the maximum NDF on the cluster boundary is more complicated. One approach is to take the maximum NDF estimate at an observation in the cluster that has a neighbor belonging to another cluster. This method yields excessively large estimates when the neighborhood is large. Another approach is to try to choose an object closer to the boundary by taking the observation with the maximum sum of estimated densities of neighbors belonging to a different cluster. After some experimentation, it is found that a combination of these two methods works well. Let  $B_k$  be the set of indices of observations in cluster  $k$  that have neighbors belonging to a different cluster, and compute

$$\max_{i \in B_k} \left( 0.2 \hat{f}_i n_i + \sum_{j \in N_i - C_k} \hat{f}_j \right)$$

Let  $s(k)$  be the index of the observation for which the maximum is attained.

Using the notation  $\#(S)$  for the cardinality of set  $S$ , let

$$\begin{aligned} n_{ij}^- &= \#(N_i^- \cap N_j^-) \\ c_m(k) &= n_{m(k)}^- - n_{m(k)s(k)}^- \\ c_s(k) &= n_{s(k)}^- - n_{m(k)s(k)}^- \text{ if } B_k \neq \emptyset, \\ &= 0 \text{ otherwise} \\ q_k &= 1/2 \text{ if } B_k \neq \emptyset, \\ &= 2/3 \text{ otherwise} \\ z_k &= \frac{c_m(k) - q_k(c_m(k) + c_s(k)) - 1/2}{\sqrt{q_k(1 - q_k)(c_m(k) + c_s(k))}} \\ u &= \left\lceil (0.2 + 0.05\sqrt{n}) \sum_{i: n_i > 1} \frac{1}{n_i + 1} \right\rceil \end{aligned}$$

Let  $R(u)$  be a random variable distributed as the range of a random sample of  $u$  observations from a standard normal distribution. Then the approximate  $p$ -value  $p_k$  for cluster  $k$  is

$$p_k = \Pr(z_k > R(u)/\sqrt{2})$$

If points  $m(k)$  and  $s(k)$  are fixed a priori,  $z_k$  would be the usual approximately normal test statistic for comparing two binomial random variables. In fact,  $m(k)$  and  $s(k)$  are selected in such a way that  $c_m(k)$  tends to be large and  $c_s(k)$  tends to be small. For this reason, and because there might be a large number of clusters, each with its own  $z_k$  to be tested, each  $z_k$  is referred to the distribution of  $R(u)$  instead of a

standard normal distribution. If the tests are conducted for only one radius and if  $u$  is chosen equal to  $n$ , then the  $p$ -values are very conservative because (1) you are not making all possible pairwise comparisons of observations in the sample and (2)  $n_i^-$  and  $n_j^-$  are positively correlated if the neighborhoods overlap. In the formula for  $u$ , the summation overcorrects somewhat for the conservativeness due to correlated  $n_i^-$ 's. The factor  $0.2 + 0.05\sqrt{n}$  is empirically estimated from simulation results to adjust for the use of more than one radius.

If the JOIN option is specified, the least significant cluster (the cluster with the smallest  $z_k$ ) is either dissolved or joined with a neighboring cluster. If no members of the cluster have neighbors belonging to a different cluster, all members of the cluster are unassigned. Otherwise, the cluster is joined to the neighboring cluster such that the sum of density estimates of neighbors of the estimated saddle point belonging to it is a maximum. Joining clusters increases the power of the saddle test. For example, consider a population with two well-separated clusters. Suppose that, for a certain radius, each population cluster is divided into two sample clusters. None of the four sample clusters is likely to be significant, but after the two sample clusters corresponding to each population cluster are joined, the remaining two clusters can be highly significant.

The saddle test implemented in PROC MODECLUS has been evaluated by simulation from known distributions. Some results are given in the following three tables. In Table 60.3, samples of 20 to 2000 observations are generated from a one-dimensional uniform distribution. For sample sizes of 1000 or less, 2000 samples are generated and analyzed by PROC MODECLUS. For a sample size of 2000, only 1000 samples are generated. The analysis is done with at least 20 different values of the R= option spread across the range of radii most likely to yield significant results. The six central columns of the table give the observed error rates at the nominal error rates ( $\alpha$ ) at the head of each column. The standard errors of the observed error rates are given at the bottom of the table. The observed error rates are conservative for  $\alpha \leq 5\%$ , but they increase with  $\alpha$  and become slightly liberal for sample sizes in the middle of the range tested.

**Table 60.3** Observed Error Rates (%) for Uniform Distribution

| Sample Size     | Nominal Type 1 Error Rate |      |      |       |       |       | Number of Simulations |
|-----------------|---------------------------|------|------|-------|-------|-------|-----------------------|
|                 | 1                         | 2    | 5    | 10    | 15    | 20    |                       |
| 20              | 0.00                      | 0.00 | 0.00 | 0.60  | 11.65 | 27.05 | 2000                  |
| 50              | 0.35                      | 0.70 | 4.50 | 10.95 | 20.55 | 29.80 | 2000                  |
| 100             | 0.35                      | 0.85 | 3.90 | 11.05 | 18.95 | 28.05 | 2000                  |
| 200             | 0.30                      | 1.35 | 4.00 | 10.50 | 18.60 | 27.05 | 2000                  |
| 500             | 0.45                      | 1.05 | 4.35 | 9.80  | 16.55 | 23.55 | 2000                  |
| 1000            | 0.70                      | 1.30 | 4.65 | 9.55  | 15.45 | 19.95 | 2000                  |
| 2000            | 0.40                      | 1.10 | 3.00 | 7.40  | 11.50 | 16.70 | 1000                  |
| <b>Standard</b> | 0.22                      | 0.31 | 0.49 | 0.67  | 0.80  | 0.89  | 2000                  |
| <b>Error</b>    | 0.31                      | 0.44 | 0.69 | 0.95  | 1.13  | 1.26  | 1000                  |

All unimodal distributions other than the uniform that have been tested, including normal, Cauchy, and exponential distributions and uniform mixtures, have produced much more conservative results. Table 60.4 displays results from a unimodal mixture of two normal distributions with equal variances and equal sampling probabilities and with means separated by two standard deviations. Any greater separation would produce a bimodal distribution. The observed error rates are quite conservative.

**Table 60.4** Observed Error Rates (%) for Normal Mixture with  $2\sigma$  Separation

| Sample Size | Nominal Type 1 Error Rate |     |     |     |     |     | Number of Simulations |
|-------------|---------------------------|-----|-----|-----|-----|-----|-----------------------|
|             | 1                         | 2   | 5   | 10  | 15  | 20  |                       |
| 100         | 0.0                       | 0.0 | 0.0 | 1.0 | 2.0 | 4.0 | 200                   |
| 200         | 0.0                       | 0.0 | 0.0 | 2.0 | 3.0 | 3.0 | 200                   |
| 500         | 0.0                       | 0.0 | 0.5 | 0.5 | 0.5 | 0.5 | 200                   |

All distributions in two or more dimensions that have been tested yield extremely conservative results. For example, a uniform distribution on a circle yields observed error rates that are never more than one-tenth of the nominal error rates for sample sizes up to 1000. This conservatism is due to the fact that, as the dimensionality increases, more and more of the probability lies in the tails of the distribution (Silverman 1986, p. 92), and the saddle test used by PROC MODECLUS is more conservative for distributions with pronounced tails. This applies even to a uniform distribution on a hypersphere because, although the density does not have tails, the NDF does.

Since the formulas for the significance tests do not involve the dimensionality, no problems are created when the data are linearly dependent. Simulations of data in nonlinear subspaces (the circumference of a circle or surface of a sphere) have also yielded conservative results.

Table 60.5 displays results in terms of power for identifying two clusters in samples from a bimodal mixture of two normal distributions with equal variances and equal sampling probabilities separated by four standard deviations. In this simulation, PROC MODECLUS never indicated more than two significant clusters.

**Table 60.5** Power (%) for Normal Mixture with  $4\sigma$  Separation

| Sample Size | Nominal Type 1 Error Rate |      |      |       |       |       | Number of Simulations |
|-------------|---------------------------|------|------|-------|-------|-------|-----------------------|
|             | 1                         | 2    | 5    | 10    | 15    | 20    |                       |
| 20          | 0.0                       | 0.0  | 0.0  | 2.0   | 37.5  | 68.5  | 200                   |
| 35          | 0.0                       | 13.5 | 38.5 | 48.5  | 64.0  | 75.5  | 200                   |
| 50          | 17.5                      | 26.0 | 51.5 | 67.0  | 78.5  | 84.0  | 200                   |
| 75          | 25.5                      | 36.0 | 58.5 | 77.5  | 85.5  | 89.5  | 200                   |
| 100         | 40.0                      | 54.5 | 72.5 | 84.5  | 91.5  | 92.5  | 200                   |
| 150         | 70.5                      | 80.0 | 92.0 | 97.0  | 100.0 | 100.0 | 200                   |
| 200         | 89.0                      | 96.0 | 99.5 | 100.0 | 100.0 | 100.0 | 200                   |

The saddle test is not as efficient as excess-mass tests for multimodality (Müller and Sawitzki 1991; Polonik 1993). However, there is not yet a general approximation for the distribution of excess-mass statistics to circumvent the need for simulations to do significance tests. See Minnotte (1992) for a review of tests for multimodality.

---

## Computational Resources

The MODECLUS procedure stores coordinate data in memory if there is enough space. For distance data, only one observation at a time is in memory.

PROC MODECLUS constructs lists of the neighbors of each observation. The total space required is  $12 \sum n_i$  bytes, where  $n_i$  is based on the largest neighborhood required by any analysis. The lists are stored

in a SAS utility data set unless you specify the CORE option. You might get an error message from the SAS System or from the operating system if there is not enough disk space for the utility data set. Clustering method 6 requires a second list that is always stored in memory.

For coordinate data, the time required to construct the neighbor lists is roughly proportional to  $v(\log n)(\sum n_i) \log(\sum n_i/n)$ . For distance data, the time is roughly proportional to  $n^2 \log(\sum n_i/n)$ .

The time required for density estimation is proportional to  $\sum n_i$  and is usually small compared to the time required for constructing the neighbor lists.

Clustering methods 0 through 3 are quite efficient, requiring time proportional to  $\sum n_i$ . Methods 4 and 5 are slower, requiring time roughly proportional to  $(\sum n_i) \log(\sum n_i)$ . Method 6 can also be slow, but the time requirements depend very much on the data and the particular options specified. Methods 4, 5, and 6 also require more memory than the other methods.

The time required for significance tests is roughly proportional to  $g \sum n_i$ , where  $g$  is the number of clusters.

PROC MODECLUS can process data sets of several thousand observations if you specify reasonable smoothing parameters. Very small smoothing values produce many clusters, whereas very large values produce many neighbors; either case can require excessive time or space.

## Missing Values

If the data are coordinates, observations with missing values are excluded from the analysis.

If the data are distances, missing values are treated as infinite. The neighbors of each observation are determined solely by the distances in that observation. The distances are not required to be symmetric, and there is no check for symmetry; the neighbors of each observation are determined only from the distances in that observation. This treatment of missing values is quite different from that of the CLUSTER procedure, which ignores the upper triangle of the distance matrix.

## Output Data Sets

The OUT= data set contains one complete copy of the input data set for each cluster solution. There are additional variables identifying each solution and giving information about individual observations. Solutions with only one remaining cluster when JOIN= $p$  is specified are omitted from the OUT= data set (see the description of the JOIN= option). The OUT= data set can be extremely large, so it is advisable to specify the DROP= data set option to exclude unnecessary variables.

The OUTCLUS= or OUTC= data set contains one observation for each cluster in each cluster solution. The variables identify the solution and provide statistics describing the cluster.

The OUTSUM= or OUTS= data set contains one observation for each cluster solution. The variables identify the solution and provide information about the solution as a whole.

The following variables can appear in all of the output data sets:

- `_K_`, which is the value of the K= option for the current solution. This variable appears only if you specify the K= option.

- `_DK_`, which is the value of the `DK=` option for the current solution. This variable appears only if you specify the `DK=` option.
- `_CK_`, which is the value of the `CK=` option for the current solution. This variable appears only if you specify the `CK=` option.
- `_R_`, which is the value of the `R=` option for the current solution. This variable appears only if you specify the `R=` option.
- `_DR_`, which is the value of the `DR=` option for the current solution. This variable appears only if you specify the `DR=` option.
- `_CR_`, which is the value of the `CR=` option for the current solution. This variable appears only if you specify the `CR=` option.
- `_CASCAD_`, which is the number of times the density estimates have been cascaded for the current solution. This variable appears only if you specify the `CASCADE=` option.
- `_METHOD_`, which is the value of the `METHOD=` option for the current solution. This variable appears only if you specify the `METHOD=` option.
- `_NJOIN_`, which is the number of clusters that are joined or dissolved in the current solution. This variable appears only if you specify the `JOIN` option.
- `_LOCAL_`, which is the local dimensionality estimate of the observation. This variable appears only if you specify the `LOCAL` option.

The `OUT=` data set contains the following variables:

- the variables from the input data set
- `_OBS_`, which is the observation number from the input data set. This variable appears only if you omit the `ID` statement.
- `DENSITY`, which is the estimated density at the observation. This variable can be renamed by the `DENSITY=` option.
- `CLUSTER`, which is the number of the cluster to which the observation is assigned. This variable can be renamed by the `CLUSTER=` option.

The `OUTCLUS=` data set contains the following variables:

- the `BY` variables, if any
- `_NCLUS_`, which is the number of clusters in the solution
- `CLUSTER`, which is the number of the current cluster
- `_FREQ_`, which is the number of observations in the cluster
- `_MODE_`, which is the maximum estimated density in the cluster
- `_BFREQ_`, which is the number of observations in the cluster with neighbors belonging to a different cluster

- `_SADDLE_`, which is the estimated saddle density for the cluster
- `_MC_`, which is the number of observations within the fixed-radius density-estimation neighborhood of the modal observation. This variable appears only if you specify the TEST or JOIN option.
- `_SC_`, which is the number of observations within the fixed-radius density-estimation neighborhood of the saddle observation. This variable appears only if you specify the TEST or JOIN option.
- `_OC_`, which is the number of observations within the overlap of the two previous neighborhoods. This variable appears only if you specify the TEST or JOIN option.
- `_Z_`, which is the approximate  $z$  statistic for the cluster. This variable appears only if you specify the TEST or JOIN option.
- `_P_`, which is the approximate  $p$ -value for the cluster. This variable appears only if you specify the TEST or JOIN option.

The OUTSUM= data set contains the following variables:

- the BY variables, if any
- `_NCLUS_`, which is the number of clusters in the solution
- `_UNCL_`, which is the number of unclassified observations
- `_CROSS_`, which is the likelihood cross validation criterion if you specify the CROSS or CROSSLIST option

---

## Displayed Output

If you specify the SIMPLE option and the data are coordinates, PROC MODECLUS displays the following simple descriptive statistics for each variable:

- the mean
- the standard deviation
- the skewness
- the kurtosis
- a coefficient of bimodality (see Chapter 31, “The CLUSTER Procedure”)

If you specify the NEIGHBOR option, PROC MODECLUS displays a list of neighbors for each observation. The table contains the following items:

- the observation number or ID value of the observation
- the observation number or ID value of each of its neighbors
- the distance to each neighbor

If you specify the CROSSLIST option, PROC MODECLUS produces a table of information regarding cross validation of the density estimates. Each table has a row for each observation. For each observation, the following are displayed:

- the observation number or ID value of the observation
- the radius of the neighborhood
- the number of neighbors
- the estimated log density
- the estimated cross validated log density

If you specify the LOCAL option, PROC MODECLUS produces a table of information regarding estimates of local dimensionality. Each table has a row for each observation. For each observation, the following are displayed:

- the observation number or ID value of the observation
- the radius of the neighborhood
- the estimated local dimensionality

If you specify the LIST option, PROC MODECLUS produces a table listing the observations within each cluster. The table includes the following items:

- the cluster number
- the observation number or ID value of the observation
- the estimated density
- the sum of the density estimates of observations within the neighborhood that belong to the same cluster
- the sum of the density estimates of observations within the neighborhood that belong to a different cluster
- the sum of the density estimates of all the observations within the neighborhood
- the ratio of the sum of the density estimates for the same cluster to the sum of all the density estimates in the neighborhood

If you specify the LIST option and there are unassigned objects, PROC MODECLUS produces a table listing those observations. The table includes the following items:

- the observation number or ID value of the observation
- the estimated density
- the ratio of the sum of the density estimates for the same cluster to the sum of the density estimates in the neighborhood for all other clusters

If you specify the BOUNDARY option, PROC MODECLUS produces a table listing the observations in each cluster that have a neighbor belonging to a different cluster. The table includes the following items:

- the observation number or ID value of the observation
- the estimated density

- the cluster number
- the ratio of the sum of the density estimates for the same cluster to the sum of the density estimates in the neighborhood for all other clusters

If you do not specify the SHORT option, PROC MODECLUS produces a table of cluster statistics including the following items:

- the cluster number
- the cluster frequency (the number of observations in the cluster)
- the maximum estimated density within the cluster
- the number of observations in the cluster having a neighbor that belongs to a different cluster
- the estimated saddle density of the cluster

If you specify the TEST or JOIN option, the table of cluster statistics includes the following items pertaining to the saddle test:

- the number of observations within the fixed-radius density-estimation neighborhood of the modal observation
- the number of observations within the fixed-radius density-estimation neighborhood of the saddle observation
- the number of observations within the overlap of the two preceding neighborhoods
- the  $z$  statistic for comparing the preceding counts
- the approximate  $p$ -value

If you do not specify the NOSUMMARY option, PROC MODECLUS produces a table summarizing each cluster solution containing the following items:

- the smoothing parameters and cascade value
- the number of clusters
- the frequency of unclassified objects
- the likelihood cross validation criterion if you specify the CROSS or CROSSLIST option

If you specify the JOIN option, the summary table also includes the following items:

- the number of clusters joined
- the maximum  $p$ -value of any cluster in the solution

If you specify the TRACE option, PROC MODECLUS produces a table for each cluster solution that lists each observation along with its cluster membership as it is reassigned from the “Old” cluster to the “New” cluster. This reassignment is described in **Step 1** through **Step 3** of the section “METHOD=6” on page 5100. Each table has a row for each observation. For each observation, the following are displayed:

- the observation number or ID value of the observation

- the estimated density
- the “Old” cluster membership. 0 represents an unassigned observation and –1 represents a seed.
- the “New” cluster membership
- “Ratio,” which is documented in the section “METHOD=6” on page 5100. The following character values can also be displayed:

“M” means the observation is a mode

“S” means the observation is a seed

“N” means the neighbor of a mode or seed, for which the ratio is not computed

---

## ODS Table Names

PROC MODECLUS assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 60.6.

For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

All of the ODS tables in Table 60.6 are created by specifying the PROC MODECLUS statement.

**Table 60.6** ODS Tables Produced by PROC MODECLUS

| ODS Table Name   | Description                                                                                                   | Option                                            |
|------------------|---------------------------------------------------------------------------------------------------------------|---------------------------------------------------|
| BoundaryFreq     | Boundary objects information                                                                                  | BOUNDARY or ALL                                   |
| ClusterList      | Cluster listing, cluster ID, frequency, density etc.                                                          | LIST or ALL                                       |
| ClusterStats     | Cluster statistics<br>Cluster statistics, significance test statistics                                        | default<br>TEST, JOIN, or ALL                     |
| ClusterSummary   | Cluster summary<br>Cluster summary, crossvalidation criterion<br>Cluster summary, clusters joined information | default<br>CROSS, CROSSLIS, or ALL<br>JOIN or ALL |
| CrossList        | Cross validated log density                                                                                   | CROSSLIST                                         |
| ListLocal        | Local dimensionality estimates                                                                                | LOCAL                                             |
| Neighbor         | Nearest neighbor list                                                                                         | NEIGHBOR or ALL                                   |
| SimpleStatistics | Simple statistics                                                                                             | SIMPLE or ALL                                     |
| Trace            | Trace of clustering algorithm (METHOD=6 only)                                                                 | TRACE or ALL when METHOD=6                        |
| UnassignObjects  | Information about unassigned objects                                                                          | LIST or ALL                                       |

## Examples: MODECLUS Procedure

---

### Example 60.1: Cluster Analysis of Samples from Univariate Distributions

This example uses pseudo-random samples from a uniform distribution, an exponential distribution, and a bimodal mixture of two normal distributions. Results are presented in [Output 60.1.1](#) through [Output 60.1.18](#) as plots displaying both the true density and the estimated density, as well as cluster membership.

The following statements produce [Output 60.1.1](#) through [Output 60.1.4](#):

```
title 'Modeclus Example with Univariate Distributions';
title2 'Uniform Distribution';

data uniform;
 drop n;
 true=1;
 do n=1 to 100;
 x=ranuni(123);
 output;
 end;
run;

proc modeclus data=uniform m=1 k=10 20 40 60 out=out short;
 var x;
run;

proc sgplot data=out noautolegend;
 y2axis label='True' values=(0 to 2 by 1.);
 yaxis values=(0 to 3 by 0.5);
 scatter y=density x=x / markerchar=cluster group=cluster;
 pbspline y=true x=x / y2axis nomarkers lineattrs=(thickness= 1);
 by _K_;
run;

proc modeclus data=uniform m=1 r=.05 .10 .20 .30 out=out short;
 var x;
run;

proc sgplot data=out noautolegend;

## Example 60.2: Cluster Analysis of Flying Mileages between Ten American Cities

This example uses distance data and illustrates the use of the TRANSPOSE procedure and the DATA step to fill in the upper triangle of the distance matrix. A data set containing a table of flying mileages between 10 U.S. cities is available in the Sashelp library. The results are displayed in [Output 60.2.1](#) through [Output 60.2.3](#).

The following statements produce [Output 60.2.1](#):

```
title 'Modeclus Analysis of 10 American Cities';
title2 'Based on Flying Mileages';

*-----Fill in Upper Triangle of Distance Matrix-----;
proc transpose data=sashelp.mileages out=tran;
 copy city;
run;

data mileages(type=distance drop=col: _: i);
 merge sashelp.mileages tran;
 array var[10] atlanta--washingtondc;
 array col[10];
 do i = 1 to 10;
 var[i] = sum(var[i], col[i]);
 end;
run;

*-----Clustering with K-Nearest-Neighbor Density Estimates-----;
proc modeclus data=mileages all m=1 k=3;
 id CITY;
run;
```

**Example 60.3: Cluster Analysis with Significance Tests**

This example uses artificial data containing two clusters. One cluster is from a circular bivariate normal distribution. The other is a ring-shaped cluster that completely surrounds the first cluster. Without significance tests, the ring is divided into several sample clusters for any degree of smoothing that yields reasonable density estimates. The JOIN= option puts the ring back together. [Output 60.3.1](#) displays a short summary generated from the first PROC MODECLUS statement. [Output 60.3.2](#) contains a series of tables produced from the second PROC MODECLUS statement. The lack of  $p$ -value in the JOIN= option makes joining continue until only one cluster remains (see the description of the JOIN= option). The cluster memberships are then plotted as displayed in [Output 60.3.1](#) through [Output 60.3.8](#).

The following statements produce [Output 60.3.1](#) through [Output 60.3.8](#):

```

title 'Modeclus Analysis with the JOIN= option';
title2 'A Normal Cluster Surrounded by a Ring Cluster';

data circle; keep x y;
 c=1;
 do n=1 to 30;
 x=rannor(5);
 y=rannor(5);
 output;
 end;

 c=2;
 do n=1 to 300;
 x=rannor(5);
 y=rannor(5);
 z=rannor(5)+8;
 l=z/sqrt(x**2+y**2);
 x=x*l;
 y=y*l;
 output;
 end;
run;

```

```

proc modeclus data=circle m=1 r=1 to 3.5 by .25 join=20 short;
run;

proc modeclus data=circle m=1 r=2.5 join out=out;
run;

proc sgplot data=out noautolegend;
 yaxis values=(-10 to 10 by 5);
 xaxis values=(-15 to 15 by 5);
 scatter y=y x=x / group=cluster Markerchar=cluster;
 by _NJOIN_;
run;

```

**Output 60.3.7** Cluster Memberships When Number of Clusters Joined=4

**Output 60.3.8** Cluster Memberships When Number of Clusters Joined=5**Example 60.4: Cluster Analysis: Hertzsprung-Russell Plot**

This example uses computer-generated data to mimic a Hertzsprung-Russell plot (Struve and Zeberg's 1962, p. 259) of the temperature and luminosity of stars. The data are plotted and displayed in [Output 60.4.1](#). It appears that there are two main groups of stars and a collection of isolated stars. The long straggling group of points appearing diagonally across the figure represents the main group of stars; the more compact group in the top-right corner contains giant stars. The JOIN= option is specified at a 0.05 significance level with various smoothing parameters. The CK=5 option is specified in order to prevent the numerous outliers from forming separate clusters. The results from PROC MODECLUS is displayed in [Output 60.4.2](#). The cluster memberships are then plotted by PROC SGPLOT, as displayed in [Output 60.4.3](#) through [Output 60.4.5](#).

Note that the graphic output from PROC SGPLOT in [Output 60.4.3](#) is not available when `_R_ = 2.5` because only one cluster remains after joining at a 5% significance level, and the results are not written to the OUT= data set. See the description of the JOIN= option). for more information.

**Output 60.4.4** Scatter Plots of Cluster Memberships by  $\_R\_ = 1.5$

**Output 60.4.5** Scatter Plots of Cluster Memberships by `_R_=2`**Example 60.5: Using the TRACE Option When METHOD=6**

To illustrate how the TRACE option can help you to understand the clustering process when METHOD=6 is specified, the following data set is created with 12 observations:

```
data test;
 input x @@;
 datalines;
 1 2 3 4 5 7.5 9 11.5 13 14.5 15 16
 ;
```

The first five observations seem to be close to each other, and the last five observations seem to be close to each other. Observation 6 is separated from the first five observations with a (Euclidean) distance of 2.5, and the same distance separates observation 7 from the last five observations. Observations 6 and 7 differ by 1.5.

Suppose METHOD=6 with a radius of 2.5 is chosen for the cluster analysis. You can specify the TRACE option to understand how each observation is assigned.

The following statements produce [Output 60.5.1](#) and [Output 60.5.2](#):

```
/*-- METHOD=6 with TRACE and THRESHOLD=0.5 (default) --*/
title 'METHOD=6 with TRACE and THRESHOLD=0.5 (default)';

proc modeclus data=test method=6 r=2.5 trace short out=out;
 var x;
run;
```

```

title2 'Plot of DENSITY*X=CLUSTER';

proc sgplot data=out;
 scatter y=density x=x / group=cluster datalabel=_obs_;
run;

```

**Output 60.5.1** Partial Output of METHOD=6 with TRACE and Default THRESHOLD=

```

 2.5 2 0

```

**Output 60.5.2** Density Plot

Note that in [Output 60.5.1](#), observation 7 is originally a seed (indicated by a value of -1 in the “Old” column) and then assigned to cluster 1. This is because the ratio of observation 7 to cluster 1 is 0.5 and is not less than the default value of the THRESHOLD= option (0.5).

If the value of the THRESHOLD= option is increased to 0.55, observation 7 should be excluded from cluster 1 and the cluster membership of observation 7 is changed.

The following statements produce [Output 60.5.3](#) and [Output 60.5.4](#):

```

/*-- METHOD=6 with TRACE and THRESHOLD=0.55 --*/
title 'METHOD=6 with TRACE and THRESHOLD=0.55';

proc modeclus data=test method=6 r=2.5 trace threshold=0.55 short out=out;

Output 60.5.4 Density Plot

In [Output 60.5.3](#), observation 7 is a seed that is excluded by cluster 1 because its ratio to cluster 1 is less than 0.55. Being a neighbor of a member (observation 8) of cluster 2, observation 7 eventually joins cluster 2 even though it remains a “SEED.” (See [Step 2.2](#) in the section “[METHOD=6](#)” on page 5100.)

## Overview: MULTTEST Procedure

The MULTTEST procedure addresses the multiple testing problem. This problem arises when you perform many hypothesis tests on the same data set. Carrying out multiple tests is often reasonable because of the cost of obtaining data, the discovery of new aspects of the data, and the many alternative statistical methods. However, a disadvantage of multiple testing is the greatly increased probability of declaring false significances.

For example, suppose you carry out 10 hypothesis tests at the 5% level, and you assume that the distributions of the  $p$ -values from these tests are uniform and independent. Then, the probability of declaring a particular test significant under its null hypothesis is 0.05, but the probability of declaring at least 1 of the 10 tests significant is 0.401. If you perform 20 hypothesis tests, the latter probability increases to 0.642. These high chances illustrate the danger of multiple testing.

PROC MULTTEST approaches the multiple testing problem by adjusting the  $p$ -values from a family of hypothesis tests. An adjusted  $p$ -value is defined as the smallest significance level for which the given hypothesis would be rejected, when the entire family of tests is considered. The decision rule is to reject the null hypothesis when the adjusted  $p$ -value is less than  $\alpha$ . For most methods, this decision rule controls the *familywise error rate* at or below the  $\alpha$  level. However, the *false discovery rate* controlling procedures control the false discovery rate at or below the  $\alpha$  level.

PROC MULTTEST provides the following  $p$ -value adjustments:

- Bonferroni
- Šidák
- step-down methods
- Hochberg
- Hommel
- Fisher and Stouffer combination
- bootstrap
- permutation
- adaptive methods
- false discovery rate
- positive FDR

The Bonferroni and Šidák adjustments are simple functions of the raw  $p$ -values. They are computationally quick, but they can be too conservative. Step-down methods remove some conservativeness, as do the step-up methods of Hochberg (1988), and the adaptive methods. The bootstrap and permutation adjustments resample the data with and without replacement, respectively, to approximate the distribution of the minimum  $p$ -value of all tests. This distribution is then used to adjust the individual raw  $p$ -values. The bootstrap and permutation methods are computationally intensive but appealing in that, unlike the other methods, correlations and distributional characteristics are incorporated into the adjustments (Westfall and Young 1989; Westfall et al. 1999).

PROC MULTTEST handles data arising from a multivariate one-way ANOVA model, possibly stratified, with continuous and discrete response variables; it can also accept raw  $p$ -values as input data. You can perform a  $t$  test for the mean for continuous data with or without a homogeneity assumption, and the following statistical tests for discrete data:

- Cochran-Armitage linear trend test
- Freeman-Tukey double arcsine test
- Peto mortality-prevalence (log-rank) test
- Fisher exact test

The Cochran-Armitage and Peto tests have exact versions that use permutation distributions and asymptotic versions that use an optional continuity correction. Also, with the exception of the Fisher exact test, you can use a stratification variable to construct Mantel-Haenszel-type tests. All of the previously mentioned tests can be one- or two-sided.

As in the GLM procedure, you can specify linear contrasts that compare means or proportions of the treated groups. The output contains summary statistics and regular and multiplicity-adjusted  $p$ -values. You can create output data sets containing raw and adjusted  $p$ -values, test statistics and other intermediate calculations, permutation distributions, and resampling information.

The MULTTEST procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

The GLIMMIX, GLM, MIXED, and LIFETEST procedures, and other procedures that implement the ESTIMATE, LSMEANS, LSMESTIMATE, and SLICE statements, also adjust their results for multiple tests. For more information, see the documentation for these procedures and statements, and Westfall et al. (1999).

## Getting Started: MULTTEST Procedure

### Drug Example

Suppose you conduct a small study to test the effect of a drug on 15 subjects. You randomly divide the subjects into three balanced groups receiving 0 mg, 1 mg, and 2 mg of the drug, respectively. You carry out the experiment and record the presence or absence of 10 side effects for each subject. Your data set is as follows:

```
data Drug;
 input Dose$ SideEff1-SideEff10;
 datalines;
0MG 0 0 1 0 0 1 0 0 0 0
0MG 0 0 0 0 0 0 0 0 0 1
0MG 0 0 0 0 0 0 0 0 0 0
0MG 0 0 0 0 0 0 0 0 0 0
0MG 0 1 0 0 0 0 0 0 0 0
1MG 1 0 0 1 0 1 0 0 1 0
1MG 0 0 0 1 1 0 0 1 0 1
1MG 0 1 0 0 0 0 1 0 0 0
1MG 0 0 1 0 0 0 0 0 0 1
1MG 1 0 1 0 0 0 0 1 0 0
2MG 0 1 1 1 0 1 1 1 0 1
2MG 1 1 1 1 1 1 0 1 1 0
2MG 1 0 0 1 0 1 1 0 1 0
2MG 0 1 1 1 1 0 1 1 1 1
```

```

2MG 1 0 1 0 1 1 1 0 0 1
;

```

The increasing incidence of 1s for higher dosages in the preceding data set provides an initial visual indication that the drug has an effect. To explore this statistically, you perform an analysis in which the possibility of side effects increases linearly with drug level. You can analyze the data for each side effect separately, but you are concerned that, with so many tests, there might be a high probability of incorrectly declaring some drug effects significant. You want to correct for this multiplicity problem in a way that accounts for the discreteness of the data and for the correlations between observations on the same unit.

PROC MULTTEST addresses these concerns by processing all of the data simultaneously and adjusting the  $p$ -values. The following statements perform a typical analysis:

```

ods graphics on;
proc multtest bootstrap nsample=20000 seed=41287 notables
 plots=PByTest(vref=0.05 0.1);
 class Dose;
 test ca(SideEff1-SideEff10);
 contrast 'Trend' 0 1 2;
run;
ods graphics off;

```

This analysis uses the **BOOTSTRAP** option to adjust the  $p$ -values. The **NSAMPLE=** option requests 20,000 samples for the bootstrap analysis, and the starting seed for the random number generator is 41287. The **NOTABLES** option suppresses the display of summary statistics for each side effect and drug level combination. The **PLOTS=** option displays a visual summary of the unadjusted and adjusted  $p$ -values against each test, and the **VREF=** option adds reference lines to the display.

The **CLASS** statement is used to specify the grouping variable, **Dose**. The **ca(sideeff1-sideeff10)** specification in the **TEST** statement requests a Cochran-Armitage linear trend test for all 10 characteristics. The **CONTRAST** statement gives the coefficients for the linear trend test.

The “Model Information” table in Figure 61.1 describes the statistical tests performed by PROC MULTTEST. For this example, PROC MULTTEST carries out a two-tailed Cochran-Armitage linear trend test with no continuity correction or strata adjustment. This test is performed on the raw data and on 20,000 bootstrap samples.

**Figure 61.1** Output Summary for the MULTTEST Procedure

| The Multtest Procedure      |                  |
|-----------------------------|------------------|
| Model Information           |                  |
| Test for discrete variables | Cochran-Armitage |
| Z-score approximation used  | Everywhere       |
| Continuity correction       | 0                |
| Tails for discrete tests    | Two-tailed       |
| Strata weights              | None             |
| P-value adjustment          | Bootstrap        |
| Number of resamples         | 20000            |
| Seed                        | 41287            |

The “Contrast Coefficients” table in [Figure 61.2](#) displays the coefficients for the Cochran-Armitage test. They are 0, 1, and 2, as specified in the `CONTRAST` statement.

**Figure 61.2** Coefficients Used in the MULTTEST Procedure

| Contrast Coefficients |      |     |     |
|-----------------------|------|-----|-----|
| Contrast              | Dose |     |     |
|                       | 0MG  | 1MG | 2MG |
| Trend                 | 0    | 1   | 2   |

The “p-Values” table in [Figure 61.3](#) lists the  $p$ -values for the drug example. The Raw column lists the  $p$ -values for the Cochran-Armitage test on the original data, and the Bootstrap column provides the bootstrap adjustment of the raw  $p$ -values.

Note that the raw  $p$ -values lead you to reject the null hypothesis of no linear trend for 3 of the 10 characteristics at the 5% level and 7 of the 10 characteristics at the 10% level. The bootstrap  $p$ -values, however, lead to this conclusion for 0 of the 10 characteristics at the 5% level and only 2 of the 10 characteristics at the 10% level; you can also see this in [Figure 61.4](#).

**Figure 61.3** Summary of  $p$ -Values for the MULTTEST Procedure

| p-Values  |          |        |           |
|-----------|----------|--------|-----------|
| Variable  | Contrast | Raw    | Bootstrap |
| SideEff1  | Trend    | 0.0519 | 0.3388    |
| SideEff2  | Trend    | 0.1949 | 0.8403    |
| SideEff3  | Trend    | 0.0662 | 0.5190    |
| SideEff4  | Trend    | 0.0126 | 0.0884    |
| SideEff5  | Trend    | 0.0382 | 0.2408    |
| SideEff6  | Trend    | 0.0614 | 0.4383    |
| SideEff7  | Trend    | 0.0095 | 0.0514    |
| SideEff8  | Trend    | 0.0519 | 0.3388    |
| SideEff9  | Trend    | 0.1949 | 0.8403    |
| SideEff10 | Trend    | 0.2123 | 0.9030    |

Figure 61.4 Adjusted  $p$ -Values

The bootstrap adjustment gives the probability of observing a  $p$ -value as extreme as each given  $p$ -value, considering all 10 tests simultaneously. This adjustment incorporates the correlation of the raw  $p$ -values, the discreteness of the data, and the multiple testing problem. Failure to account for these issues can certainly lead to misleading inferences for these data.

## Syntax: MULTTEST Procedure

The following statements are available in the MULTTEST procedure:

```

PROC MULTTEST < options > ;
 BY variables ;
 CLASS variable ;
 CONTRAST 'label' values ;
 FREQ variable ;
 ID variables ;
 STRATA variable ;
 TEST name (variables < / options >) ;

```

Statements that follow the PROC MULTTEST statement can appear in any order. The CLASS and TEST statements are required unless the INPVALUES= option is specified in the PROC MULTTEST statement.

The following sections describe the PROC MULTTEST statement and then describe the other statements in alphabetical order.

## PROC MULTTEST Statement

**PROC MULTTEST** < options > ;

The PROC MULTTEST statement invokes the MULTTEST procedure. It also specifies the  $p$ -value adjustments. Table 61.1 summarizes the options available in the PROC MULTTEST statement. These options are described in alphabetical order following the table.

**Table 61.1** PROC MULTTEST Statement Options by Function

| Option                                                  | Description                                                 |
|---------------------------------------------------------|-------------------------------------------------------------|
| <b>FWE-Controlling <math>p</math>-Value Adjustments</b> |                                                             |
| ADAPTIVEHOLM                                            | Computes the adaptive step-down Bonferroni adjustment       |
| ADAPTIVEHOCHBERG                                        | Computes the adaptive step-up Bonferroni adjustment         |
| BONFERRONI                                              | Computes the Bonferroni adjustment                          |
| BOOTSTRAP                                               | Computes the bootstrap min- $p$ adjustment                  |
| FISHER_C                                                | Computes Fisher's combination adjustment                    |
| HOCHBERG                                                | Computes the step-up Bonferroni adjustment                  |
| HOMMEL                                                  | Computes Hommel's adjustment                                |
| HOLM                                                    | Computes the step-down Bonferroni adjustment                |
| PERMUTATION                                             | Computes the permutation min- $p$ adjustment                |
| SIDAK                                                   | Computes Šidák's adjustment                                 |
| STEPBON                                                 | Computes the step-down Bonferroni adjustment                |
| STEPBOOT                                                | Computes the step-down bootstrap adjustment                 |
| STEPPERM                                                | Computes the step-down permutation adjustment               |
| STEPSID                                                 | Computes the step-down Šidák adjustment                     |
| STOUFFER                                                | Computes the Stouffer-Liptak combination adjustment         |
| <b>FDR-Controlling <math>p</math>-Value Adjustments</b> |                                                             |
| ADAPTIVEFDR                                             | Computes the adaptive linear step-up adjustment             |
| DEPENDENTFDR                                            | Computes the linear step-up adjustment under dependence     |
| FDR                                                     | Computes the linear step-up adjustment                      |
| FDRBOOT                                                 | Computes the linear step-up bootstrap min- $p$ adjustment   |
| FDRPERM                                                 | Computes the linear step-up permutation min- $p$ adjustment |
| PFDR                                                    | Computes the positive FDR adjustment                        |
| <b>Input/Output Data Sets</b>                           |                                                             |
| DATA=                                                   | Names the input data set                                    |
| INPVALUES=                                              | Names the input data set of raw $p$ -values                 |
| OUT=                                                    | Names the output data set                                   |
| OUTPERM=                                                | Names the output permutation data set                       |
| OUTSAMP=                                                | Names the output resample data set                          |

Table 61.1 continued

| Option                          | Description                                                      |
|---------------------------------|------------------------------------------------------------------|
| <b>Displayed Output Options</b> |                                                                  |
| NOPRINT                         | Suppresses all tables                                            |
| NOTABLES                        | Suppresses variable tables                                       |
| NOZEROS                         | Suppresses zero tables for CLASS variables                       |
| NOPVALUE                        | Suppresses the “p-Values” table                                  |
| PLOTS                           | Requests ODS Graphics                                            |
| <b>Resampling Options</b>       |                                                                  |
| CENTER                          | Mean-centers continuous variables before resampling              |
| NOCENTER                        | Does not mean-center continuous variables before resampling      |
| NSAMPLE=                        | Specifies the number of resamples                                |
| RANUNI                          | Specifies a different random number generator                    |
| SEED=                           | Specifies the seed for resampling                                |
| <b>CLASS Variable Options</b>   |                                                                  |
| NOZEROS                         | Suppresses zero tables for CLASS variables                       |
| ORDER=                          | Specifies CLASS variable order                                   |
| <b>Computational Options</b>    |                                                                  |
| EPSILON=                        | Specifies the comparison value                                   |
| NTRUENULL=                      | Specifies the estimation method for the number of true nulls     |
| PTRUENULL=                      | Specifies the estimation method for the proportion of true nulls |

You can specify the following options in the PROC MULTTEST statement.

**ADAPTIVEHOCHBERG****AHOC**

requests adjusted  $p$ -values by using the Hochberg and Benjamini (1990) adaptive step-up Bonferroni method. See the section “Adaptive Adjustments” on page 5200 for more details.

**ADAPTIVEHOLM****AHOLM**

requests adjusted  $p$ -values by using the Hochberg and Benjamini (1990) adaptive step-down Bonferroni method. See the section “Adaptive Adjustments” on page 5200 for more details.

**ADAPTIVEFDR<(UNRESTRICT)>****AFDR<(UNRESTRICT)>**

requests adjusted  $p$ -values by using the Benjamini and Hochberg (2000) adaptive linear step-up method (AFDR). The UNRESTRICT option estimates the AFDR as defined in Benjamini and Hochberg (2000), which allows the adjustment to reduce the raw  $p$ -value. By default, the AFDR is constrained to be greater than or equal to the raw  $p$ -value. See the section “Adaptive False Discovery Rate” on page 5202 for more details.

**BONFERRONI****BON**

specifies that the Bonferroni adjustments (number of tests  $\times p$ -value) be computed for each test. These adjustments can be extremely conservative and should be viewed with caution. When exact tests are specified via the PERMUTATION= option in the TEST statement, the actual permutation

distributions are used, resulting in a much less conservative version of this procedure (Westfall and Wolfinger 1997). See the section “[Bonferroni](#)” on page 5197 for more details.

## BOOTSTRAP

### BOOT

specifies that the  $p$ -values be adjusted by using the bootstrap method to resample vectors (Westfall and Young 1993). Resampling is performed with replacement and independently within levels of the [STRATA](#) variable. Continuous variables are mean-centered by default prior to resampling; specify the [NOCENTER](#) option to change this. See the section “[Bootstrap](#)” on page 5197 for more details. The [BOOTSTRAP](#) option is not allowed with the Peto test.

If the [PERMUTATION=](#) suboption is used with the [CA](#) test in the [TEST](#) statement, the exact permutation distribution is recomputed for each bootstrap sample. **CAUTION:** This can be very time-consuming. It is preferable to use permutation resampling when permutation base tests are used.

### CENTER

requests that continuous variables be mean-centered prior to resampling. The default action is to mean-center for bootstrap resampling and not to mean-center for permutation resampling.

### DATA=*SAS-data-set*

names the input SAS data set to be used by PROC MULTTEST. The default is to use the most recently created data set. The [DATA=](#) and [INPVALUES=](#) options cannot both be specified.

## DEPENDENTFDR

### DFDR

requests adjusted  $p$ -values by using the method of Benjamini and Yekateuli (2001). See the section “[Dependent False Discovery Rate](#)” on page 5201 for more details.

### EPSILON=*number*

specifies the amount by which two  $p$ -values must differ to be declared unequal. The value *number* must be between 0 and 1; the default value is 1000 times the machine epsilon, which is approximately  $1\text{E}-12$ . For SAS 9.1 and earlier releases the default value was  $1\text{E}-8$ . See Westfall and Young (1993, pp. 165–166) for more information.

## FDR

### LSU

requests adjusted  $p$ -values by using the linear step-up method of Benjamini and Hochberg (1995). These  $p$ -values do not control the familywise error rate, but they do control the false discovery rate in some cases. See the section “[False Discovery Rate Controlling Adjustments](#)” on page 5200 for more details.

### FDRBOOT< ( $\beta$ ) >

A bootstrap-resampling false discovery rate controlling method due to Yekateuli and Benjamini (1999). This method uses the same resampling algorithm as the [BOOTSTRAP](#) option. Every resample is saved in order to compute a quantile of the resampled  $p$ -values; therefore, this method can use a lot of memory. The parameter  $\beta$  designates that a  $100(1 - \beta)$  quantile is used in the computations for determining the adjustments; by default,  $\beta = 0.05$ . See the section “[False Discovery Rate Resampling Adjustments](#)” on page 5201 for details.

**FDRPERM**< ( $\beta$ ) >

A permutation-resampling false discovery rate controlling method due to Yekateuli and Benjamini (1999). This method uses the same resampling algorithm as the **PERMUTATION** option. Every resample is saved in order to compute a quantile of the resampled  $p$ -values; therefore, this method can use a lot of memory. The parameter  $\beta$  designates that a  $100(1 - \beta)$  quantile is used in the computations for determining the adjustments; by default,  $\beta = 0.05$ . See the section “[False Discovery Rate Resampling Adjustments](#)” on page 5201 for details.

**FISHER\_C****FIC**

requests adjusted  $p$ -values by using Fisher’s combination method. See the section “[Fisher Combination](#)” on page 5199 for more details.

**HOCHBERG****HOC**

requests adjusted  $p$ -values by using the step-up Bonferroni method due to Hochberg (1988). See the section “[Hochberg](#)” on page 5199 for more details.

**HOMMEL****HOM**

requests adjusted  $p$ -values by using the method of Hommel (1988). See the section “[Hommel](#)” on page 5199 for more details.

**HOLM**

is an alias for the [STEPBON](#) adjustment.

**INPVALUES**< (*pvalue-name*) >=*SAS-data-set*

names an input SAS data set that includes a variable containing raw  $p$ -values. The MULTTEST procedure adjusts the collection of raw  $p$ -values for multiplicity. Resampling-based adjustments are not permitted with this type of data input. The **CLASS**, **CONTRAST**, **FREQ**, **STRATA**, and **TEST** statements are ignored when an INPVALUES= data set is specified. The INPVALUES= and **DATA=** options cannot both be specified. The *pvalue-name* enables you to specify the name of the  $p$ -value column from your data set. By default, *pvalue-name*=’raw\_p’. The INPVALUES= data set can contain variables in addition to the raw  $p$ -values variable; see [Example 61.5](#) for an example.

**LIPTAK**

is an alias for the [STOUFFER](#) adjustment.

**NOCENTER**

requests that continuous variables not be mean-centered prior to resampling. The default action is to mean-center for bootstrap resampling and not to mean-center for permutation resampling.

**NOPRINT**

suppresses the normal display of results. Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

**NOPVALUE**

suppresses the display of the “ $p$ -Values” table of raw and adjusted  $p$ -values. This option is most useful when you are adjusting many tests and need to create only an **OUT=** data set or display graphics.

**NOTABLES**

suppresses display of the “Discrete Variable Tabulations” and “Continuous Variable Tabulations” tables.

**NOZEROS**

suppresses display of tables having zero occurrences for all **CLASS** levels.

**NSAMPLE=*number*****N=*number***

specifies the number of resamples for use with the resampling methods. The value *number* must be a positive integer; by default, 20,000 resamples are used. Large values of *number* (20,000 or more) are usually recommended for accuracy, but long execution times can result, particularly with large data sets.

**NTRUENULL=*keyword* | *value*****M0=*keyword* | *value***

Controls the method used to estimate the number of true NULL hypotheses ( $m_0$ ) for the adaptive methods. This option is ignored unless one of the adaptive methods is specified. By default, PROC MULTTEST uses the **DECREASESLOPE** method for the **ADAPTIVEHOLM** and **ADAPTIVEHOCHBERG** adjustments, and the **LOWESTSLOPE** method for **ADAPTIVEFDR** adjustment. For the **PFDR** adjustment, the **SPLINE** method is attempted first. If the estimate is nonpositive or if the slope of the spline at the last  $\lambda$  is greater than 0.1 times the range of the fitted spline values, then the **BOOTSTRAP** method is used.

You can specify a positive integer as the *value*, or you can specify one of the *keywords* in the following list. Alternatively, you can specify the proportion of true NULL hypotheses by using the **PTRUENULL=** option. Suppose you have  $m$  tests with ordered  $p$ -values  $p_{(1)} \leq \dots \leq p_{(m)}$ , and define  $q_{(i)} = 1 - p_{(i)}$ .

**BOOTSTRAP<(bootstrap-options)>**

uses the bootstrap method of Storey and Tibshirani (2003). Compute the proportion of true null hypotheses  $\hat{\pi}_0(\lambda) = \frac{m - N(\lambda) + f}{(1 - \lambda)m}$  for  $\lambda \in L = \{0, 0.05, \dots, 0.95\}$ , where  $N(\lambda)$  is the number of  $p$ -values less than or equal to  $\lambda$ , and  $f = 1$  for the finite-sample case; otherwise  $f = 0$ . For each  $\lambda$ , bootstrap on the  $p$ -values to form  $B$  bootstrap versions  $\hat{\pi}_0^b(\lambda)$ ,  $b = 1, \dots, B$ , and choose the  $\lambda$  that yields the minimum  $\widehat{\text{MSE}}(\lambda) = \frac{1}{B} \sum_{b=1}^B (\hat{\pi}_0^b(\lambda) - \min_{\lambda' \in L} \hat{\pi}_0(\lambda'))^2$ . The available *bootstrap-options* are as follows:

**FINITE**

the finite-sample case of the **PFDR** option, described on page 5178.

**NBOOT=*B***

bootstrap resamples of the raw  $p$ -values for the  $\lambda$  computations. **NBOOT=10,000** by default;  $B$  must be a positive integer.

**NLAMBDA=*n***

“optimal”  $\lambda$  is the value in  $\{0, \frac{1}{n}, \dots, \frac{n-1}{n}\}$  that minimizes the MSE. **NLAMBDA=20** by default;  $n$  must be an integer greater than 1.

**DECREASESLOPE**

Schweder and Spjøtvoll (1982) as modified by Hochberg and Benjamini (1990). Let  $b_i$  be the slope of the least squares line fit to  $\{q_{(m)}, \dots, q_{(m-i+1)}\}$  and through the origin, for  $i = 1, \dots, m$ . Find the first  $i = m-1, m-2, \dots, 1$  such that  $b_i < b_{i+1}$ . Then  $\hat{m}_0 = \text{ceil}(\frac{1}{b_{i+1}} - 1)$ .

**KSTEST<( $\beta$ )>**

uses the Kolmogorov-Smirnov uniformity test method of Turkheimer, Smith, and Schmidt (2001). Let  $k_{min} = 1, k_{max} = m$ , and the Kolmogorov-Smirnov statistic  $D = \max(q_{(i)} - i/(m+1)(\sqrt{k} + 0.12 + 0.11/\sqrt{k}))$ . If  $D$  is greater than the upper-tail probability (Press et al. 1992), then  $k_{max} = k, k = \text{floor}((k_{min} + k)/2)$ ; otherwise, let  $k_{min} = k, k = \text{floor}((k + k_{max})/2)$ . Repeat until  $k = k_{min}$ . Next compute the slope  $b$  of the weighted least squares regression line on the  $k$  smallest  $q_{(i)}$  by using weights  $w_i = i(k - i + 1)/((k + 1)^2(k + 2))$ . Then  $\hat{m}_0 = \text{ceil}(\frac{1}{b} - 1)$ .

**LEASTSQUARES**

uses a linear least squares method to search for the correct cutpoint. For each  $i = 0, \dots, m$  compute the SSE of the least squares line through the origin fitting  $\{q_{(m)}, \dots, q_{(m-i+1)}\}$ , let  $b_i$  be the slope of this line, and add the SSE of the unconstrained least squares line through the rest of the  $q$ s. For  $i = 0$  compute the SSE for the unconstrained line. The argument  $i$  that minimizes the SSE is the cutpoint: if  $i = 0$  then  $\hat{m}_0 = 0$ ; if  $i = m$  then  $\hat{m}_0 = m$ ; otherwise  $\hat{m}_0 = \text{ceil}(\frac{1}{b_i} - 1)$ .

**LOWESTSLOPE**

uses the lowest slope method of Benjamini and Hochberg (2000). Find the first  $i = 1, \dots, m$  such that  $b_i = q_{(i)}/(m - i + 1)$  decreases. Then  $\hat{m}_0 = \text{floor}(\min(\frac{1}{b_i} + 1, m))$ .

**MEANDIFF**

uses the mean of differences method of Hsueh, Chen, and Kodell (2003). Let  $\bar{d}_i = \frac{q_{(m-i+1)}}{i}$  and estimate  $\hat{m}_0^i = \frac{1}{\bar{d}_i} - 1$ . Start from  $i = m$  and proceed downward until the first time  $\hat{m}_0^{i-1} \geq \hat{m}_0^i$  occurs.

**SPLINE<(spline-options)>**

uses the cubic spline method of Storey and Tibshirani (2003). For each  $\lambda \in \{0, \frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}\}$  compute  $\hat{\pi}_0(\lambda) = \frac{\#\{p_i > \lambda\}}{m(1-\lambda)}$ . Let  $\hat{f}(\lambda)$  be the natural cubic spline with 3 degrees of freedom of  $\hat{\pi}_0(\lambda)$  versus  $\lambda$ . Estimate  $\hat{\pi}_0$  by taking the spline value at the last  $\lambda$ :  $\hat{\pi}_0 = \hat{\pi}_0(\frac{n-1}{n})$ , so that  $\hat{m}_0 = m\hat{\pi}_0$ . The available *spline-options* are as follows:

**DF=df**

sets the degrees of freedom of the spline, where *df* is a nonnegative integer. The default is DF=3.

**DFCONV=number**

specifies the absolute change in spline degrees of freedom value for concluding convergence. If  $|df_i - df_{i+1}| < \text{number}$  (or if the **SPCONV=** criterion is satisfied), then convergence is declared. *number* must be between 0 and 1; by default, *number* is 1000 times the square root of machine epsilon, which is about 1E-5.

**FINITE**

computations for the finite-sample case of the [PFDR](#) option, described on page 5178.

**MAXITER=*n***

specifies the maximum number of golden-search iterations used to find a spline with  $DF=df$  degrees of freedom. By default, `MAXITER=100`; *number* must be a nonnegative integer.

**NLAMBDA=*n***

$\hat{\pi}_0(\lambda)$  for  $\lambda \in \{0, \frac{1}{n}, \frac{2}{n}, \dots, \frac{n-1}{n}\}$  for the spline fit. By default, `NLAMBDA=20`; *number* must be an integer greater than 1.

**SPCONV=*number***

specifies the absolute change in smoothing parameter value for concluding convergence of the spline. If  $|sp_i - sp_{i+1}| < number$  (or if the `DFCONV=` criterion is satisfied), then convergence is declared. By default, *number* equals the square root of the machine epsilon, which is about  $1E-8$ .

In all cases  $\hat{m}_0$  is constrained to lie between 0 and  $m$ ; if the computed  $\hat{m}_0 = 0$ , then the adaptive adjustments do not produce results. If you specify  $\hat{m}_0 > m$ , then it is reduced to  $m$ . Values of  $\hat{m}_0$  are displayed in the “Estimated Number of True Null Hypotheses” table.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the sort order for the levels of the classification variables (which are specified in the `CLASS` statement). This option applies to the levels for all classification variables, except when you use the (default) `ORDER=FORMATTED` option with numeric classification variables that have no explicit format. With this option, the levels of such variables are ordered by their internal value.

The `ORDER=` option can take the following values:

| Value of <code>ORDER=</code> | Levels Sorted By                                                                                                                       |
|------------------------------|----------------------------------------------------------------------------------------------------------------------------------------|
| <b>DATA</b>                  | Order of appearance in the input data set                                                                                              |
| <b>FORMATTED</b>             | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| <b>FREQ</b>                  | Descending frequency count; levels with the most observations come first in the order                                                  |
| <b>INTERNAL</b>              | Unformatted value                                                                                                                      |

By default, `ORDER=FORMATTED`. For `ORDER=FORMATTED` and `ORDER=INTERNAL`, the sort order is machine-dependent. For more information about sort order, see the chapter on the `SORT` procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**OUT=*SAS-data-set***

names the output SAS data set containing variable names, contrast names, intermediate calculations, and all associated  $p$ -values. See “[OUT= Data Set](#)” on page 5204 for more information.

**OUTPERM=SAS-data-set**

names the output SAS data set containing entire permutation distributions (upper-tail probabilities) for all tests when the **PERMUTATION=** option is specified. See “**OUTPERM= Data Set**” on page 5205 for more information. **CAUTION:** This data set can be very large.

**OUTSAMP=SAS-data-set**

names the output SAS data set containing information from the resampled data sets when resampling is performed. See “**OUTSAMP= Data Set**” on page 5205 for more information. **CAUTION:** This data set can be very large.

**PDATA=SAS-data-set**

is an alias for the **INPVALUES=** option.

**PERMUTATION****PERM**

computes adjusted  $p$ -values in identical fashion as the **BOOTSTRAP** option, with the exception that PROC MULTTEST resamples without replacement rather than with replacement. Resampling is performed independently within levels of the **STRATA** variable. Continuous variables are not mean-centered prior to resampling; specify the **CENTER** to change this. See the section “**Bootstrap**” on page 5197 for more details. The **PERMUTATION** option is not allowed with the Peto test.

**PFDR<(options)>**

computes the “ $q$ -values”  $\hat{q}_\lambda(p_i)$  of Storey (2002) and Storey, Taylor, and Siegmund (2004). PROC MULTTEST treats these “ $q$ -values” as adjusted  $p$ -values. The computations depend on selecting a parameter  $\lambda$  and an estimation method for the false discovery rate; see the section “**Positive False Discovery Rate**” on page 5202 for computational details. The available *options* for choosing the method are as follows:

**FINITE**

estimates the false discovery rate with  $\widehat{pFDR}$  or  $\widehat{FDR}$  for the finite-sample case with independent null  $p$ -values.

**POSITIVE**

estimates the false discovery rate with  $\widehat{pFDR}$  instead of the default  $\widehat{FDR}$ .

**UNRESTRICT**

estimates the false discovery rate as defined in Storey (2002), which allows the adjustment to reduce the raw  $p$ -value. By default, the PFDR is constrained to be greater than or equal to the raw  $p$ -value.

The available options for controlling the  $\lambda$  search are the *bootstrap-options* (page 5175), the *spline-options* (page 5176), and the following options:

**LAMBDA=number**

specifies a  $\lambda \in [0, 1)$  and does not perform the bootstrap or spline searches for an “optimal”  $\lambda$ .

**MAXLAMBDA=number**

stops the NLAMBDA= search sequence for the **bootstrap** and **spline** searches when this *number* is reached. The *number* must be in  $[0, 1]$ . This option is ignored if the **LAMBDA=** option is specified.

**PLOTS**< (*global-plot-options*) >=*plot-request*< (*options*) >

**PLOTS**< (*global-plot-options*) >=*(plot-request*< (*options*) >< . . . *plot-request*< (*options*) >> )

controls the plots produced through ODS Graphics. If you specify only one *plot-request*, you can omit the parentheses. For example, the following statements are valid specifications of the PLOTS= option:

```
plots = all
plots = (rawprob adjusted)
plots(sigonly) = (rawprob adjusted(unpack))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc multtest plots=adjusted invalues=a pfdr;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, no graphs are created; you must specify the PLOTS= option to make graphs. You need at least two tests to produce a graph. If you are not using an INPVALUES= data set, then each test is given a name constructed as “variable-name contrast-label”. If you specify a MEAN test in the TEST statement, the *t*-test names are prefixed with “Mean:”. See [Example 61.6](#) for examples of the ODS graphical displays.

The following *global-plot-options* are available:

#### **UNPACKPANELS | UNPACK**

suppresses paneling. By default, the plots produced with the ADJUSTED and RAWPROB options are grouped in a single display, called a *panel*. Specify UNPACK to display each plot separately.

#### **SIGONLY**< =*number* >

displays only those tests with adjusted *p*-values  $\leq$  *number*, where  $0 \leq$  *number*  $\leq$  1. By default, *number* = 0.05.

The following *plot-requests* are available:

#### **ADJUSTED**< (**UNPACK**) >

displays a 2×2 panel of adjusted *p*-value plots similar to those Storey and Tibshirani (2003) developed for use with the PFDR *p*-value adjustment method. The plots of the adjusted *p*-values by the raw *p*-values and the adjusted *p*-values by their rank show the effect of the adjustments. The plot of the proportion of adjusted *p*-values  $\leq$  each adjusted *p*-value and the plot of the expected number of false positives (the proportion significant multiplied by the adjusted *p*-value) versus the proportion significant show the effect of choosing different significance levels. The UNPACK option unpanels the display.

**ALL**

produces all appropriate plots. You can specify other options with ALL; for example, to display all plots and unpack the RAWPROB plots you can specify `plots=(all rawprob(unpack))`.

**LAMBDA**

displays plots of the MSE and the estimated number of true nulls against the  $\lambda$  parameter when the `NTRUENULL=SPLINE` or `NTRUENULL=BOOTSTRAP` option is in effect.

**MANHATTAN**< (options) >

displays the Manhattan plot (a plot of  $-\log_{10}$  of the adjusted  $p$ -values versus the tests). You can specify the following options:

**GROUP**=variable

specifies a variable to group the adjusted  $p$ -values in the display.

**LABEL** < =OBS >

labels the observations that have adjusted  $p$ -values that are less than the value specified in the `VREF=` option. By default, labels are created as follows: if an `INPVALUES=` data set and an `ID` statement are specified, then the observations are labeled with the ID values; if a `DATA=` data set is specified, then the observations are labeled with their constructed test name; otherwise, the observation or test number is displayed.

**NOTESTNAME**

displays the number of the test instead of the test name on the X-axis, which is useful when you have many tests.

**UNPACK**

suppresses paneling. By default, Manhattan plots are created for each requested  $p$ -value adjustment, and the results are grouped in a single display, called a *panel*. Specify UNPACK to display each plot separately.

**VREF**=number | NONE

displays a reference line at  $-\log_{10}(\text{number})$ . The *number* must be between 0 and 1. By default, a reference line at  $-\log_{10}(0.05)$  is displayed; it can be suppressed by specifying `VREF=0` or `VREF=NONE`. If the LABEL option is also specified, then observations above this line are labeled with their ID variables, their observation number, their test name, or their test number.

**NONE**

suppresses all plots.

**PBYTEST**< (options) >

displays the adjusted  $p$ -values for each test. The available options are as follows:

**NOTESTNAME**

displays the number of the test instead of the test name on the axis, which is useful when you have many tests.

**VREF=**

*number-list* displays reference lines at the  $p$ -values specified in the *number-list*. The values in the *number-list* must be between 0 and 1; otherwise they are ignored. You can specify a single value or a list of values; for example, **vref=0.1 0 to 0.05 by 0.01** displays reference lines at each of the values {0.01, 0.02, 0.03, 0.04, 0.05, and 0.1}.

**RAWPROB<(UNPACK)>**

displays a uniform probability plot of 1 minus the raw  $p$ -values (Schweder and Spjøtvoll 1982) along with a histogram. If  $m_0$  is the number of true null hypotheses among the  $m$  tests, the points on the left side of the plot should be approximately linear with slope  $\frac{1}{m_0+1}$ . This graphic is displayed when an adaptive  $p$ -value adjustment method is requested in order to see if the **NTRUENULL=** estimate is appropriate. The UNPACK option unpanels the display.

**PTRUENULL=***keyword* | *value*

**PIO=***keyword* | *value*

is alias for the **NTRUENULL=** option, except that you can specify the proportion of true null hypotheses as a *value* between 0 and 1, instead of specifying the number of true null hypotheses. The available *keywords* are also the **NTRUENULL=** options described on page 5175.

**RANUNI**

requests the random number generator used in releases prior to SAS 9.2. Beginning with SAS 9.2, the random number generator is the Mersenne Twister, which has better performance when bootstrapping. Changes in the **bootstrap-** or **permutation-**adjusted  $p$ -values from prior releases are due to unimportant sampling differences.

**SEED=***number*

**S=***number*

specifies the initial seed for the random number generator used for resampling. The value for *number* must be an integer. If you do not specify a seed, or if you specify a value less than or equal to zero, then PROC MULTTEST uses the time of day from the computer's clock to generate an initial seed. For more details about seed values, see *SAS Language Reference: Concepts*.

**SIDAK****SID**

computes the Šidák adjustment for each test. These adjustments take the form

$$1 - (1 - p)^m$$

where  $p$  is the raw  $p$ -value and  $m$  is the number of tests. These are slightly less conservative than the Bonferroni adjustments, but they still should be viewed with caution. When exact tests are specified via the **PERMUTATION=** option in the **TEST** statement, the actual permutation distributions are used, resulting in a much less conservative version of this procedure (Westfall and Wolfinger 1997). See the section “Šidák” on page 5197 for more details.

**STEPBON****HOLM**

requests adjusted  $p$ -values by using the step-down Bonferroni method of Holm (1979). See the section “Step-Down Methods” on page 5198 for more details.

**STEPBOOT**

requests that adjusted  $p$ -values be computed by using bootstrap resampling as described under the **BOOTSTRAP** option, but in step-down fashion. See the section “[Step-Down Methods](#)” on page 5198 for more details.

**STEPPERM**

requests that adjusted  $p$ -values be computed by using permutation resampling as described under the **PERMUTATION** option, but in step-down fashion. See the section “[Step-Down Methods](#)” on page 5198 for more details.

**STEPSID**

requests adjusted  $p$ -values by using the Šidák method as described in the **SIDAK** option, but in step-down fashion. See the section “[Step-Down Methods](#)” on page 5198 for more details.

**STOUFFER****LIPTAK**

requests adjusted  $p$ -values by using the Stouffer-Liptak combination method. See the section “[Stouffer-Liptak Combination](#)” on page 5199 for more details.

---

## BY Statement

**BY** *variables* ;

You can specify a **BY** statement with PROC MULTTEST to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar **BY** statement.
- Specify the **NOTSORTED** or **DESCENDING** option in the **BY** statement for the MULTTEST procedure. The **NOTSORTED** option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the **BY** variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the **BY** variables by using the DATASETS procedure (in Base SAS software).

You can specify one or more *variables* in the input data set on the **BY** statement.

Since sorting the data changes the order in which PROC MULTTEST reads observations, this can affect the sort order for the levels of the **CLASS** variable if you have specified **ORDER=DATA** in the PROC MULTTEST statement. This, in turn, affects specifications in the **CONTRAST** statements.

For more information about **BY**-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLASS Statement

```
CLASS variable </ TRUNCATE > ;
```

The CLASS statement is required unless the `INPVALUES=` option is specified. The CLASS statement specifies a single variable (character or numeric) used to identify the groups for the analysis. For example, if the variable `Treatment` defines different levels of a treatment that you want to compare, then you would specify the following statements:

```
class Treatment;
```

The CLASS variable can be either character or numeric. By default, class levels are determined from the entire set of formatted values of the CLASS variable. The order of the class levels used by PROC MULTTEST corresponds to the order of their formatted values; this order can be changed with the `ORDER=` option in the PROC MULTTEST statement.

**NOTE:** Prior to SAS 9, class levels were determined by using no more than the first 16 characters of the formatted values. To revert to this previous behavior you can specify the `TRUNCATE` option in the CLASS statement.

In any case, you can use formats to group values into levels. See the discussion of the `FORMAT` procedure in the *Base SAS Procedures Guide* and the discussions of the `FORMAT` statement and SAS formats in *SAS Formats and Informats: Reference*. You can adjust the order of CLASS variable levels with the `ORDER=` option in the PROC MULTTEST statement. You need to be aware of the order when using the `CONTRAST` statement, and you should check the “Contrast Coefficients” table to verify that it is suitable.

You can specify the following option in the CLASS statement after a slash (/):

### TRUNCATE

specifies that class levels should be determined by using only up to the first 16 characters of the formatted values of CLASS variables. When formatted values are longer than 16 characters, you can use this option to revert to the levels as determined in releases prior to SAS 9.

---

## CONTRAST Statement

```
CONTRAST 'label' values ;
```

This statement is used to identify tests between the levels of the CLASS variable; in particular, it is used to specify the coefficients for the trend tests. The *label* is a string naming the contrast; it contains a maximum of 21 characters. The *values* are scoring coefficients across the CLASS variable levels.

You can specify multiple CONTRAST statements, thereby specifying multiple contrasts for each variable. Multiplicity adjustments are computed for all contrasts and all variables simultaneously. The coefficients are applied to the ordered CLASS variables; this order can be changed with the `ORDER=` option in the PROC MULTTEST statement. For example, consider a four-group experiment with CLASS variable levels A1, A2, B1, and B2 denoting two levels of two treatments. The following statements produce three linear trend tests for each variable identified in the TEST statement. PROC MULTTEST computes the multiplicity adjustments over the entire collection of tests, which is three times the number of variables.

```
contrast 'a vs b' -1 -1 1 1;
contrast 'a linear' -1 1 0 0;
contrast 'b linear' 0 0 -1 1;
```

As another example, consider an animal carcinogenicity experiment with dose levels 0, 4, 8, 16, and 50. You can specify a trend test with the indicated scoring coefficients by using the following statement:

```
contrast 'arithmetic trend' 0 4 8 16 50;
```

Multiplicity-adjusted  $p$ -values are then computed over the collection of variables identified in the **TEST** statement. See Lagakos and Louis (1985) for guidelines on the selection of contrast-scoring values.

When a Fisher test is specified in the **TEST** statement, the **CONTRAST** statement coefficients are used to group the **CLASS** variable's levels. Groups with a  $-1$  contrast coefficient are combined and compared with groups with a  $1$  contrast coefficient for each test, and groups with a  $0$  coefficient are not included in the contrast. For example, the following statements compute Fisher exact tests for (a) control versus the combined treatment groups, (b) control versus the first treatment group, and (c) control versus the third treatment group:

```
contrast 'c vs all' 1 -1 -1 -1;
contrast 'c vs t1' 1 -1 0 0;
contrast 'c vs t3' 1 0 0 -1;
```

Multiplicity adjustments are then computed over the entire collection of tests and variables. Only  $-1$ ,  $1$ , and  $0$  are acceptable **CONTRAST** coefficients when the Fisher test is specified; PROC MULTTEST ignores the **CONTRAST** statement if any other coefficients appear.

If you specify the **FISHER** test and no **CONTRAST** statements, then all contrasts of control versus treatment are automatically generated, with the first level of the **CLASS** variable deemed to be the control. In this case, the control level is assigned the value  $1$  in each contrast and the other treatment levels are assigned  $-1$ . You should therefore use the **LOWERTAILED** option to test for higher success rates in the treatment groups.

For tests other than **FISHER**, **CONTRAST** values are  $0, 1, 2, \dots$  by default. If you specify the **CA** or **PETO** test with the **PERMUTATION=** option, then your **CONTRAST** coefficients must be integer valued.

For  $t$  tests for the mean of continuous data (and for the **FT** tests), the contrast coefficients are centered to have mean  $= 0$ . The resulting centered scoring coefficients are then applied to the sample means (or to the double-arcsine-transformed proportions in the case of the **FT** tests).

## FREQ Statement

**FREQ** *variable* ;

The **FREQ** statement names a variable that provides frequencies for each observation in the **DATA=** data set. Specifically, if  $n$  is the value of the **FREQ** variable for a given observation, then that observation is used  $n$  times.

If the value of the **FREQ** variable is missing or is less than  $1$ , the observation is not used in the analysis. If the value is not an integer, only the integer portion is used.

---

## ID Statement

**ID** *variables* ;

The ID statement names one or more variables for identifying observations in the output and in the plots. The statement requires an **INPVALUES=** data set. All ID variables are displayed in the “pValues” table. The ID variables are used as the X axis for the plots requested by the **PLOTS=PBYTEST** and **PLOTS=MANHATTAN** options in the PROC MULTTEST statement; they are also used to label points on the Manhattan plots. This option has no effect on the **OUT=** data set.

---

## STRATA Statement

**STRATA** *variable* ;

The STRATA statement identifies a single variable to use as a stratification variable in the analysis. This yields tests similar to those discussed in Mantel and Haenszel (1959) and Hoel and Walburg (1972) for binary data and pooled-means tests for continuous data. For example, when you test for prevalence in a carcinogenicity study, it is common to stratify on intervals of the time of death; the first level of the stratification variable might represent weeks 0–52, the second might represent weeks 53–80, and so on. In multicenter clinical studies, each level of the stratification variable might represent a particular center.

The following option is available in the STRATA statement after a slash (/):

**WEIGHT=***keyword*

specifies the type of strata weighting to use when computing the Freeman-Tukey and *t* tests. Valid *keywords* are SAMPLESIZE, HARMONIC, and EQUAL. SAMPLESIZE requests weights proportional to the within-stratum sample sizes, and is the default method even if the WEIGHT= option is not specified. HARMONIC sets up weights equal to the harmonic mean of the nonmissing within-stratum CLASS sizes, and is similar to a Type 2 analysis in PROC GLM. EQUAL specifies equal weights, and is similar to a Type 3 analysis in PROC GLM.

---

## TEST Statement

**TEST** *name (variables </ options>)* ;

The TEST statement is required unless the **INPVALUES=** option is specified. The TEST statement identifies statistical tests to be performed and the discrete and continuous variables to be tested. [Table 61.2](#) summarizes the names and options available in the TEST statement.

**Table 61.2** TEST Statement Names and Options

| Option              | Description                                                                                  |
|---------------------|----------------------------------------------------------------------------------------------|
| <b>TEST Names</b>   |                                                                                              |
| CA                  | Requests the Cochran-Armitage linear trend tests for group comparisons                       |
| FISHER              | Requests Fisher exact tests                                                                  |
| FT                  | Requests Z-score CA tests based upon the Freeman-Tukey double arcsine transformation         |
| MEAN                | Requests the <i>t</i> test for the mean                                                      |
| PETO                | Requests the Peto mortality-prevalence test                                                  |
| <b>TEST Options</b> |                                                                                              |
| BINOMIAL            | Uses the binomial variance estimate for CA and Peto tests                                    |
| CONTINUITY=         | Specifies a continuity correction                                                            |
| DDFM=               | Specifies whether to use homogeneous or heterogeneous variances                              |
| LOWERTAILED         | Makes all tests lower-tailed                                                                 |
| PERMUTATION=        | Computes <i>p</i> -values for the CA and Peto tests by using exact permutation distributions |
| TIME=               | Identifies the Peto test variable containing the age at death                                |
| UPPERTAILED         | Makes all tests upper-tailed                                                                 |

The following tests are permitted as *name* in the TEST statement.

**CA**

requests the Cochran-Armitage linear trend tests for group comparisons. The test variables should take the value 0 for a failure and 1 for a success. **PERMUTATION=** option can be used to request an exact permutation test; otherwise, a Z-score approximation is used. The **CONTINUITY=** option can be used to specify a continuity correction for the Z-score approximation.

**FISHER**

requests Fisher exact tests for comparing two treatment groups. The test variables should take the value 0 for a failure and 1 for a success.

**FT**

requests Z-score CA tests based upon the Freeman-Tukey double arcsine transformation of the frequencies. The test variables should take the value 0 for a failure and 1 for a success.

**MEAN**

requests the *t* test for the mean. The test variables can take on any numeric values.

**PETO**

requests the Peto mortality-prevalence test. The test variables should take the value 0 for a nonoccurrence, 1 for an incidental occurrence, and 2 for a fatal occurrence. The **TIME=** option should be used with the Peto test to specify an integer-valued variable giving the age at death. The **CONTINUITY=** option can be used to specify a continuity correction for the test.

If the value of a TEST variable is invalid, the observation is not used in the analysis. You can specify two tests only if one of them is **MEAN**. For example, the following statement is valid:

```
test ca (d1-d2) mean (c1-c2);
```

But specifying both CA and FT, as shown in the following statement, is invalid:

```
test ca (d1-d2) ft (d1-d2);
```

You can specify the following options in the TEST statement (some apply to only one test).

#### **BINOMIAL**

uses the binomial variance estimate for CA and Peto tests in their asymptotic normal approximations. The default is to use the hypergeometric variance.

#### **CONTINUITY=number**

##### **C=number**

specifies *number* as a particular continuity correction for the Z-score approximation in the CA and Peto tests. The default is 0.

#### **LOWERTAILED**

##### **LOWER**

is used to make all tests lower-tailed. All tests are two-tailed by default.

#### **PERMUTATION=number**

##### **PERM=number**

computes *p*-values for the CA and Peto tests by using exact permutation distributions when marginal success or failure totals within a stratum are *number* or less. You can specify *number* as a nonnegative integer. For totals greater than *number* (or when the PERMUTATION= option is omitted), PROC MULTTEST uses standard normal approximations with a continuity correction chosen to approximate the permutation distribution. PROC MULTTEST computes the appropriate convolution distributions when you use the [STRATA](#) statement along with the PERMUTATION= option.

#### **DDFM= POOLED | SATTERTHWAITE**

specifies whether the [MEAN](#) test uses a homogeneity assumption (DDFM=POOLED, the default) or deals with heterogeneous variances (DDFM=SATTERTHWAITE). See “[t Test for the Mean](#)” on page 5194 for more information.

#### **TIME=variable**

identifies the Peto test variable containing the age at death, which must be integer valued. If the TIME= option is omitted, all ages are assumed to equal 1.

#### **UPPERTAILED**

##### **UPPER**

is used to make all tests upper-tailed. All tests are two-tailed by default.

---

## Details: MULTTEST Procedure

---

### Statistical Tests

The following section discusses the statistical tests performed in the MULTTEST procedure. For continuous data, a  $t$  test for the mean (**MEAN**) is available. For discrete variables, available tests are the Cochran-Armitage linear trend test (**CA**), the Freeman-Tukey double arcsine test (**FT**), the Peto mortality-prevalence test (**PETO**), and the Fisher exact test (**FISHER**).

Throughout this section, the discrete and continuous variables are denoted by  $S_{vgsr}$  and  $X_{vgsr}$ , respectively, where  $v$  is the variable,  $g$  is the treatment group,  $s$  is the stratum, and  $r$  is the replication. Let  $m_{vgs}$  denote the sample size for a binary variable  $v$  within group  $g$  and stratum  $s$ . A plus sign (+) subscript denotes summation over an index. Note that the tests are invariant to the location and scale of the contrast coefficients  $t_g$ .

### Cochran-Armitage Linear Trend Test

The Cochran-Armitage linear trend test (Cochran 1954; Armitage 1955; Agresti 2002) is implemented by using a  $Z$ -score approximation, an exact permutation distribution, or a combination of both.

#### Z-Score Approximation

The pooled probability estimate for variable  $v$  and stratum  $s$  is

$$p_{vs} = \frac{S_{v+s+}}{m_{v+s}}$$

The expected value (under constant within-stratum treatment probabilities) for variable  $v$ , group  $g$ , and stratum  $s$  is

$$E_{vgs} = m_{vgs} p_{vs}$$

Letting  $t_g$  denote the contrast trend coefficients specified by the **CONTRAST** statement, the test statistic for variable  $v$  has numerator

$$N_v = \sum_s \sum_g t_g (S_{vgs+} - E_{vgs})$$

The binomial variance estimate for this statistic is

$$V_v = \sum_s p_{vs}(1 - p_{vs}) \sum_g m_{vgs} (t_g - \bar{t}_{vs})^2$$

where

$$\bar{t}_{vs} = \sum_g \frac{m_{vgs} t_g}{m_{v+s}}$$

The hypergeometric variance estimate (the default) is

$$V_v = \sum_s \{m_{v+s}/(m_{v+s} - 1)\} p_{vs}(1 - p_{vs}) \sum_g m_{vgs} (t_g - \bar{t}_{vs})^2$$

For any strata  $s$  with  $m_{v+s} \leq 1$ , the contribution to the variance is taken to be zero.

PROC MULTTEST computes the  $Z$ -score statistic

$$Z_v = \frac{N_v}{\sqrt{V_v}}$$

The  $p$ -value for this statistic comes from the standard normal distribution. Whenever a 0 is computed for the denominator, the  $p$ -value is set to 1. This  $p$ -value approximates the probability obtained from the exact permutation distribution, discussed in the following text.

The  $Z$ -score statistic can be continuity-corrected to better approximate the permutation distribution. With continuity correction  $c$ , the upper-tailed  $p$ -value is computed from

$$Z_v = \frac{N_v - c}{\sqrt{V_v}}$$

For two-tailed, noncontinuity-corrected tests, PROC MULTTEST reports the  $p$ -value as  $2 \min(p, 1 - p)$ , where  $p$  is the upper-tailed  $p$ -value. The same formula holds for the continuity-corrected test, with the exception that when the noncontinuity-corrected  $Z$  and the continuity-corrected  $Z$  have opposite signs, the two-tailed  $p$ -value is 1.

When the `PERMUTATION=` option is specified and no `STRATA` variable is specified, PROC MULTTEST uses a continuity correction selected to optimally approximate the upper-tail probability of permutation distributions with smaller marginal totals (Westfall and Lin 1988). Otherwise, the continuity correction is specified by the `CONTINUITY=` option in the `TEST` statement.

The `CA`  $Z$ -score statistic is the Hoel-Walburg (Mantel-Haenszel) statistic reported by Dinse (1985).

### Exact Permutation Test

When you use the `PERMUTATION=` option for `CA` in the `TEST` statement, PROC MULTTEST computes the exact permutation distribution of the trend score

$$T_v = \sum_s \sum_g t_g S_{vgs+}$$

where the contrast trend coefficients  $t_g$  must be integer valued. The observed value of this trend is compared to the permutation distribution to obtain the  $p$ -value

$$p_v = \Pr(X \geq \text{observed } T_v)$$

where  $X$  is a random variable from the permutation distribution and where upper-tailed tests are requested. This probability can be viewed as a binomial probability, where the within-stratum probabilities are constant and where the probability is conditional with respect to the marginal totals  $S_{v+s+}$ . It also can be considered a rerandomization probability.

Because the computations can be quite time-consuming with large data sets, specifying the `PERMUTATION=number` option in the `TEST` statement limits the situations where PROC MULTTEST computes the exact permutation distribution. When marginal total success or total failure frequencies exceed `number` for a particular stratum, the permutation distribution is approximated by a continuity-corrected normal distribution. You should be cautious when using the `PERMUTATION=` option in conjunction with bootstrap resampling because the permutation distribution is recomputed for each bootstrap sample. This recomputation is not necessary with permutation resampling.

The permutation distribution is computed in two steps:

1. The permutation distributions of the trend scores are computed within each stratum.
2. The distributions are convolved to obtain the distribution of the total trend.

As long as the total success or failure frequency does not exceed *number* for any stratum, the computed distributions are exact. In other words, if  $S_{v+s+} \leq \text{number}$  or  $(m_{v+s} - S_{v+s+}) \leq \text{number}$  for all  $s$ , then the permutation trend distribution for variable  $v$  is computed exactly.

In step 1, the distribution of the within-stratum trend

$$\sum_g t_g S_{vg s+}$$

is computed by using the multivariate hypergeometric distribution of the  $S_{vg s+}$ , provided *number* is not exceeded. This distribution can be written as

$$\Pr(S_{v1s+}, S_{v2s+}, \dots, S_{vGs+}) = \prod_{g=1}^G \frac{\binom{m_{vgs}}{S_{vgs+}}}{\binom{m_{v+s}}{S_{v+s+}}}$$

The distribution of the within-stratum trend is then computed by summing these probabilities over appropriate configurations. For further information about this technique, see Bickis and Krewski (1986) and Westfall and Lin (1988). In step 2, the exact convolution distribution is obtained for the trend statistic summed over all strata having totals that meet the threshold criterion. This distribution is obtained by applying the fast Fourier transform to the exact within-stratum distributions. A description of this general method can be found in Pagano and Tritchler (1983) and Good (1987).

The convolution distribution of the overall trend is then computed by convolving the exact distribution with the distribution of the continuity-corrected standard normal approximation. To be more specific, let  $S_1$  denote the subset of stratum indices that satisfy the threshold criterion, and let  $S_2$  denote the subset of indices that do not satisfy the criterion. Let  $T_{v1}$  denote the combined trend statistic from the set  $S_1$ , which has an exact distribution obtained from Fourier analysis as previously outlined, and let  $T_{v2}$  denote the combined trend statistic from the set  $S_2$ . Then the distribution of the overall trend  $T_v = T_{v1} + T_{v2}$  is obtained by convolving the analytic distribution of  $T_{v1}$  with the continuity-corrected normal approximation for  $T_{v2}$ . Using the notation from the section “Z-Score Approximation” on page 5188, this convolution can be written as

$$\begin{aligned} \Pr(T_{v1} + T_{v2} \geq u) &= \sum_{u1} \Pr(T_{v1} + T_{v2} \geq u \mid T_{v1} = u1) \Pr(T_{v1} = u1) \\ &\approx \sum_{u1} \Pr(Z \geq z) \Pr(T_{v1} = u1) \end{aligned}$$

where  $Z$  is a standard normal random variable, and

$$z = \frac{1}{\sqrt{V_v}} \left( u - u1 - \sum_{S_2} p_{vs} \sum_g t_g m_{vgs} - c \right)$$

In this expression, the summation of  $s$  in  $V_v$  is over  $S_2$ , and  $c$  is the continuity correction discussed under the  $Z$ -score approximation.

When a two-tailed test is requested, the expected trend is computed

$$E_v = \sum_s \sum_g t_g E_{vgs}$$

The two-tailed  $p$ -value is reported as the permutation tail probability for the observed trend  $T_v$  plus the permutation tail probability for  $2E_v - T_v$ , the reflected trend.

### Freeman-Tukey Double Arcsine Test

For this test, the contrast trend coefficients  $t_1, \dots, t_G$  are centered to the values  $c_1, \dots, c_G$ , where  $c_g = t_g - \bar{t}$ ,  $\bar{t} = \sum_g t_g / G$ , and  $G$  is the number of groups. The numerator of this test statistic is

$$N_v = \sum_s w_{vs} \sum_g c_g f(S_{vgs+}, m_{vgs})$$

where the weights  $w_{vs}$  take on three different types of values depending upon your specification of the **WEIGHT=** option in the **STRATA** statement. The default value is the within-strata sample size  $m_{v+s}$ , ensuring comparability with the ordinary CA trend statistic. **WEIGHT=HARMONIC** sets  $w_{vs}$  equal to the harmonic mean

$$\left[ \left( \sum_g \frac{1}{m_{vgs}} \right) / G^* \right]^{-1}$$

where  $G^*$  is the number of nonmissing groups and the summation is over only the nonmissing elements. The harmonic means analysis places more weight on the smaller sample sizes than does the default sample size method, and is similar to a Type 2 analysis in PROC GLM. **WEIGHT=EQUAL** sets  $w_{vs} = 1$  for all  $v$  and  $s$ , and is similar to a Type 3 analysis in PROC GLM.

The function  $f(r, n)$  is the double arcsine transformation:

$$f(r, n) = \arcsin \left( \sqrt{\frac{r}{n+1}} \right) + \arcsin \left( \sqrt{\frac{r+1}{n+1}} \right)$$

The variance estimate is

$$V_v = \sum_s w_{vs}^2 \sum_g \frac{c_g^2}{m_{vgs} + \frac{1}{2}}$$

The test statistic is

$$Z_v = \frac{N_v}{\sqrt{V_v}}$$

The Freeman-Tukey transformation and its variance are described by Freeman and Tukey (1950) and Miller (1978). Since its variance is not weighted by the pooled probabilities, as is the CA test, the **FT** test can be more useful than the CA test for tests involving only a subset of the groups.

### Peto Mortality-Prevalence Trend Test

The Peto test is a modified Cochran-Armitage procedure incorporating mortality and prevalence information. The Peto test is computed like two Cochran-Armitage Z-score approximations, one for prevalence and one for mortality (Peto, Pike, and Day 1980). It represents a special case in PROC MULTTEST because the data structure requirements are different, and the resampling methods used for adjusting  $p$ -values are not valid. The `TIME=` option variable is required to specify “death” times or, more generally, times of occurrence. In addition, the test variables must assume one of the following three values:

- 0 = no occurrence
- 1 = incidental occurrence
- 2 = fatal occurrence

Use the `TIME=` option variable to define the mortality strata, and use the `STRATA` statement variable to define the prevalence strata.

In the following notation, the subscript  $v$  represents the variable,  $g$  represents the treatment group,  $s$  represents the stratum, and  $t$  represents the time. Recall that a plus sign (+) in a subscript location denotes summation over that subscript.

Let  $S_{vgs}^P$  be the number of incidental occurrences, and let  $m_{vgs}^P$  be the total sample size for variable  $v$  in group  $g$ , stratum  $s$ , excluding fatal tumors.

Let  $S_{vgt}^F$  be the number of fatal occurrences in time period  $t$ , and let  $m_{vgt}^F$  be the number of patients alive at the end of time  $t - 1$ .

The pooled probability estimates are given by

$$p_{vs}^P = \frac{S_{v+s}^P}{m_{v+s}^P}$$

$$p_{vt}^F = \frac{S_{v+t}^F}{m_{v+t}^F}$$

The expected values are

$$E_{vgs}^P = m_{vgs}^P p_{vs}^P$$

$$E_{vgt}^F = m_{vgt}^F p_{vt}^F$$

Let  $t_g$  denote a contrast trend coefficient, and define the numerator terms as follows:

$$N_v^P = \sum_s \sum_g t_g (S_{vgs}^P - E_{vgs}^P)$$

$$N_v^F = \sum_t \sum_g t_g (S_{vgt}^F - E_{vgt}^F)$$

Define the denominator variance terms by using the binomial variance:

$$V_v^P = \sum_s p_{vs}^P (1 - p_{vs}^P) \left[ \left( \sum_g m_{vgs}^P t_g^2 \right) - \frac{1}{m_{v+s}^P} \left( \sum_g m_{vgs}^P t_g \right)^2 \right]$$

$$V_v^F = \sum_s p_{vt}^F (1 - p_{vt}^F) \left[ \left( \sum_g m_{vgt}^F t_g^2 \right) - \frac{1}{m_{v+t}^F} \left( \sum_g m_{vgt}^F t_g \right)^2 \right]$$

The hypergeometric variances (the default) are calculated by weighting the within-strata variances as discussed in the section “Z-Score Approximation” on page 5188.

The Peto statistic is computed as

$$Z_v = \frac{N_v^P + N_v^F - c}{\sqrt{V_v^P + V_v^F}}$$

where  $c$  is a continuity correction. The  $p$ -value is determined from the standard normal distribution unless the `PERMUTATION=number` option is used. When you use the `PERMUTATION=` option for `PETO` in the `TEST` statement, PROC MULTTEST computes the “discrete approximation” permutation distribution described by Mantel (1980) and Soper and Tonkonoh (1993). Specifically, the permutation distribution of  $\sum_s \sum_g t_g S_{vgs}^P + \sum_t \sum_g t_g S_{vgt}^F$  is computed, assuming that  $\{\sum_g t_g S_{vgs}^P\}$  and  $\{\sum_g t_g S_{vgt}^F\}$  are independent over all  $s$  and  $t$ . Note that the contrast trend coefficients  $t_g$  must be integer valued. The  $p$ -values are exact under this independence assumption. However, the independence assumption is valid only asymptotically, which is why these  $p$ -values are called “approximate.”

An exact permutation distribution is available only under the assumption of equal risk of censoring in all treatment groups; even then, computing this distribution can be cumbersome. Soper and Tonkonoh (1993) describe situations where the discrete approximation distribution closely fits the exact permutation distribution.

### Fisher Exact Test

The `CONTRAST` statement in PROC MULTTEST enables you to compute Fisher exact tests for two-group comparisons. No stratification variable is allowed for this test. Note, however, that the `FISHER` exact test is a special case of the exact permutation tests performed by PROC MULTTEST and that these permutation tests allow a stratification variable. Recall that contrast coefficients can be  $-1$ ,  $0$ , or  $1$  for the Fisher test. The frequencies and sample sizes of the groups scored as  $-1$  are combined, as are the frequencies and sample sizes of the groups scored as  $1$ . Groups scored as  $0$  are excluded. The  $-1$  group is then compared with the  $1$  group by using the Fisher exact test.

Letting  $x$  and  $m$  denote the frequency and sample size of the  $1$  group, and letting  $y$  and  $n$  denote those of the  $-1$  group, the  $p$ -value is calculated as

$$\Pr(X \geq x \mid X + Y = x + y) = \sum_{i=x}^m \frac{\binom{m}{i} \binom{n}{x+y-i}}{\binom{m+n}{x+y}}$$

where  $X$  and  $Y$  are independent binomially distributed random variables with sample sizes  $m$  and  $n$  and common probability parameters. The hypergeometric distribution is used to determine the stated probability; Yates (1984) discusses this technique. PROC MULTTEST computes the two-tailed  $p$ -values by adding probabilities from both tails of the hypergeometric distribution. The first tail is from the observed  $x$  and  $y$ , and the other tail is chosen so that the resulting probability is as large as possible without exceeding the probability from the first tail. If the variable being tested has only one level, then the  $p$ -value is set to 1.

### ***t* Test for the Mean**

For continuous variables, PROC MULTTEST automatically centers the contrast trend coefficients, as in the Freeman-Tukey test. These centered coefficients  $c_g$  are then used to form a  $t$  statistic contrasting the within-group means. Let  $n_{vgs}$  denote the sample size within group  $g$  and stratum  $s$ ; it depends on variable  $v$  only when there are missing values. Determine the weights  $w_{vs}$  as in the Freeman-Tukey test with  $n_{vgs}$  replacing  $m_{vgs}$ . Define

$$\bar{X}_{vgs+} = \frac{1}{n_{vgs}} \sum_r X_{vgsr}$$

as the sample mean within a group-and-stratum combination, and let  $\mu_{vgs}$  denote the treatment means. Write the null hypothesis as

$$\sum_s w_{vs} \sum_g c_g \mu_{vgs} = 0$$

Also define

$$s_v^2 = \frac{\sum_s \sum_g \sum_r (X_{vgsr} - \bar{X}_{vgs+})^2}{\sum_s \sum_g (n_{vgs} - 1)}$$

as the pooled sample variance.

### ***Homogeneous Variance***

Assuming constant variance for all group-and-stratum combinations, the  $t$  statistic for the mean is

$$M_v = \frac{\sum_s w_{vs} \sum_g c_g \bar{X}_{vgs+}}{\sqrt{s_v^2 \left( \sum_s w_{vs}^2 \sum_g \frac{c_g^2}{n_{vgs}} \right)}}$$

Then under the null hypothesis and assuming normality, independence, and homoscedasticity,  $M_v$  follows a  $t$  distribution with  $df_p = \sum_s \sum_g (n_{vgs} - 1)$  degrees of freedom.

Whenever a denominator of 0 is computed, the  $p$ -value is set to 1. When missing data force  $n_{vgs} = 0$ , the contribution to the denominator of the pooled variance is 0 and not  $-1$ . This is also true for the degrees of freedom.

### Heterogeneous Variance

If you do not assume constant variance for all group-and-stratum combinations, then the approximate  $t$  test is

$$M_v = \frac{\sum_s w_{vs} \sum_g c_g \bar{X}_{vgs} +}{\sqrt{\sum_s w_{vs}^2 \sum_g c_g^2 \frac{s_{vgs}^2}{n_{vgs}}}}$$

Under the null hypothesis and assuming normality and independence, the Satterthwaite (1946) approximation for the degrees of freedom of the  $t$  test is given by

$$df_s = \frac{\left(\sum_s w_{vs}^2 \sum_g c_g^2 \frac{s_{vgs}^2}{n_{vgs}}\right)^2}{\sum_s \sum_g \frac{\left(w_{vs}^2 c_g^2 \frac{s_{vgs}^2}{n_{vgs}}\right)^2}{n_{vgs} - 1}}$$

under the restriction  $1 \leq df_s \leq \sum_s \sum_g n_{vgs}$ .

Whenever a denominator of 0 for  $M_v$  is computed, the  $p$ -value is set to 1. If the denominator for  $df_s$  is computed as 0, then set  $df_s = df_p$ . When missing data force  $n_{vgs} \leq 1$ , that group-and-stratum combination does not contribute to the  $df_s$  computation.

## p-Value Adjustments

Suppose you test  $m$  null hypotheses,  $H_{01}, \dots, H_{0m}$ , and obtain the  $p$ -values  $p_1, \dots, p_m$ . Denote the ordered  $p$ -values as  $p_{(1)} \leq \dots \leq p_{(m)}$  and order the tests appropriately:  $H_{0(1)}, \dots, H_{0(m)}$ . Suppose you know  $m_0$  of the null hypotheses are true and  $m_1 = m - m_0$  are false. Let  $R$  indicate the number of null hypotheses rejected by the tests, where  $V$  of these are incorrectly rejected (that is,  $V$  tests are Type I errors) and  $R - V$  are correctly rejected (so  $m_1 - R + V$  tests are Type II errors). This information is summarized in the following table:

|               | Null is Rejected | Null is Not Rejected | Total |
|---------------|------------------|----------------------|-------|
| Null is True  | $V$              | $m_0 - V$            | $m_0$ |
| Null is False | $R - V$          | $m_1 - R + V$        | $m_1$ |
| Total         | $R$              | $m - R$              | $m$   |

The *familywise error rate* (FWE) is the overall Type I error rate for all the comparisons (possibly under some restrictions); that is, it is the maximum probability of incorrectly rejecting one or more null hypotheses:

$$\text{FWE} = \Pr(V > 0)$$

The FWE is also known as the *maximum experimentwise error rate* (MEER), as discussed in the section “Pairwise Comparisons” on page 3351 of Chapter 42, “The GLM Procedure.”

The *false discovery rate* (FDR) is the expected proportion of incorrectly rejected hypotheses among all rejected hypotheses:

$$\begin{aligned} \text{FDR} &= E\left(\frac{V}{R}\right) \quad \text{where } \frac{V}{R} = 0 \text{ when } V = R = 0 \\ &= E\left(\frac{V}{R} \mid R > 0\right) \Pr(R > 0) \end{aligned}$$

Under the overall null hypothesis (all the null hypotheses are true), the FDR=FWE since  $V = R$  gives  $E\left(\frac{V}{R}\right) = 1 \times \Pr\left(\frac{V}{R} = 1\right) = \Pr(V > 0)$ . Otherwise, FDR is always less than FWE, and an FDR-controlling adjustment also controls the FWE. Another definition used is the *positive* false discovery rate:

$$\text{pFDR} = E\left(\frac{V}{R} \mid R > 0\right)$$

The  $p$ -value adjustment methods discussed in the following sections attempt to correct the raw  $p$ -values while controlling either the FWE or the FDR. Note that the methods might impose some restrictions in order to achieve this; restrictions are discussed along with the methods in the following sections. Discussions and comparisons of some of these methods are given in Dmitrienko et al. (2005), Dudoit, Shaffer, and Boldrick (2003), Westfall et al. (1999), and Brown and Russell (1997).

## Familywise Error Rate Controlling Adjustments

PROC MULTTEST provides several  $p$ -value adjustments to control the familywise error rate. *Single-step* adjustment methods are computed without reference to the other hypothesis tests under consideration. The available single-step methods are the Bonferroni and Šidák adjustments, which are simple functions of the raw  $p$ -values that try to distribute the significance level  $\alpha$  across all the tests, and the bootstrap and permutation resampling adjustments, which require the raw data. The Bonferroni and Šidák methods are calculated from the permutation distributions when exact permutation tests are used with the **CA** or **Peto** test.

*Stepwise* tests, or *sequentially rejective* tests, order the hypotheses in *step-up* (least significant to most significant) or *step-down* fashion, then sequentially determine acceptance or rejection of the nulls. These tests are more powerful than the single-step tests, and they do not always require you to perform every test. However, PROC MULTTEST still adjusts every  $p$ -value. PROC MULTTEST provides the following stepwise  $p$ -value adjustments: step-down Bonferroni (Holm), step-down Šidák, step-down bootstrap and permutation resampling, Hochberg's (1988) step-up, Hommel's (1988), Fisher's combination method, and the Stouffer-Liptak combination method. Adaptive versions of Holm's step-down Bonferroni and Hochberg's step-up Bonferroni methods, which require an estimate of the number of true null hypotheses, are also available.

Liu (1996) shows that all single-step and stepwise tests based on marginal  $p$ -values can be used to construct a *closed* test (Marcus, Peritz, and Gabriel 1976; Dmitrienko et al. 2005). Closed testing methods not only control the familywise error rate at size  $\alpha$ , but are also more powerful than the tests on which they are based. Westfall and Wolfinger (2000) note that several of the methods available in PROC MULTTEST are closed—namely, the **step-down methods**, **Hommel's method**, and **Fisher's combination**; see that reference for conditions and exceptions.

All methods except the resampling methods are calculated by simple functions of the raw  $p$ -values or marginal permutation distributions; the permutation and bootstrap adjustments require the raw data. Because the resampling techniques incorporate distributional and correlational structures, they tend to be less conservative than the other methods.

When a resampling (bootstrap or permutation) method is used with only one test, the adjusted  $p$ -value is the bootstrap or permutation  $p$ -value for that test, with no adjustment for multiplicity, as described by Westfall and Soper (1994).

### **Bonferroni**

The Bonferroni  $p$ -value for test  $i$ ,  $i = 1, \dots, m$  is simply  $\tilde{p}_i = mp_i$ . If the adjusted  $p$ -value exceeds 1, it is set to 1. The Bonferroni test is conservative but always controls the familywise error rate.

If the unadjusted  $p$ -values are computed by using exact permutation distributions, then the Bonferroni adjustment for  $p_i$  is  $\tilde{p}_i = p_1^* + \dots + p_m^*$ , where  $p_j^*$  is the largest  $p$ -value from the permutation distribution of test  $j$  satisfying  $p_j^* \leq p_i$ , or 0 if all permutational  $p$ -values of test  $j$  are greater than  $p_i$ . These adjustments are much less conservative than the ordinary Bonferroni adjustments because they incorporate the discrete distributional characteristics. However, they remain conservative in that they do not incorporate correlation structures between multiple contrasts and multiple variables (Westfall and Wolfinger 1997).

### **Šidák**

A technique slightly less conservative than Bonferroni is the Šidák  $p$ -value (Šidák 1967), which is  $\tilde{p}_i = 1 - (1 - p_i)^m$ . It is exact when all of the  $p$ -values are uniformly distributed and independent, and it is conservative when the test statistics satisfy the positive orthant dependence condition (Holland and Copenhaver 1987).

If the unadjusted  $p$ -values are computed by using exact permutation distributions, then the Šidák adjustment for  $p_i$  is  $\tilde{p}_i = 1 - (1 - p_1^*) \dots (1 - p_m^*)$ , where the  $p_j^*$  are as described previously. These adjustments are less conservative than the corresponding Bonferroni adjustments, but they do not incorporate correlation structures between multiple contrasts and multiple variables (Westfall and Wolfinger 1997).

### **Bootstrap**

The bootstrap method creates pseudo-data sets by sampling observations with replacement from each within-stratum pool of observations. An entire data set is thus created, and  $p$ -values for all tests are computed on this pseudo-data set. A counter records whether the minimum  $p$ -value from the pseudo-data set is less than or equal to the actual  $p$ -value for each base test. (If there are  $m$  tests, then there are  $m$  such counters.) This process is repeated a large number of times, and the proportion of resampled data sets where the minimum pseudo- $p$ -value is less than or equal to an actual  $p$ -value is the adjusted  $p$ -value reported by PROC MULTTEST. The algorithms are described in Westfall and Young (1993).

In the case of continuous data, the pooling of the groups is not likely to re-create the shape of the null hypothesis distribution, since the pooled data are likely to be multimodal. For this reason, PROC MULTTEST automatically mean-centers all continuous variables prior to resampling. Such mean-centering is akin to resampling residuals in a regression analysis, as discussed by Freedman (1981). You can specify the **NO-CENTER** option if you do not want to center the data.

The bootstrap method implicitly incorporates all sources of correlation, from both the multiple contrasts and the multivariate structure. The adjusted  $p$ -values incorporate all correlations and distributional characteristics. This method always provides weak control of the familywise error rate, and it provides strong control when the *subset pivotality* condition holds; that is, for any subset of the null hypotheses, the joint distribution of the  $p$ -values for the subset is identical to that under the complete null (Westfall and Young 1993).

### Permutation

The permutation-style-adjusted  $p$ -values are computed in identical fashion as the **bootstrap**-adjusted  $p$ -values, with the exception that the within-stratum resampling is performed without replacement instead of with replacement. This produces a rerandomization analysis such as in Brown and Fears (1981) and Heyse and Rom (1988). In the spirit of rerandomization analyses, the continuous variables are not centered prior to resampling. This default can be overridden by using the **CENTER** option.

The permutation method implicitly incorporates all sources of correlation, from both the multiple contrasts and the multivariate structure. The adjusted  $p$ -values incorporate all correlations and distributional characteristics. This method always provides weak control of the familywise error rate, and it provides strong control of the familywise error rate under the *subset pivotality* condition, as described in the preceding section.

### Step-Down Methods

Step-down testing is available for the Bonferroni, Šidák, bootstrap, and permutation methods. The benefit of using step-down methods is that the tests are made more powerful (smaller adjusted  $p$ -values) while, in most cases, maintaining strong control of the familywise error rate. The step-down method was pioneered by Holm (1979) and further developed by Shaffer (1986), Holland and Copenhaver (1987), and Hochberg and Tamhane (1987).

The Bonferroni step-down (Holm)  $p$ -values  $\tilde{p}_{(1)}, \dots, \tilde{p}_{(m)}$  are obtained from

$$\tilde{p}_{(i)} = \begin{cases} mp_{(1)} & \text{for } i = 1 \\ \max(\tilde{p}_{(i-1)}, (m - i + 1)p_{(i)}) & \text{for } i = 2, \dots, m \end{cases}$$

As always, if any adjusted  $p$ -value exceeds 1, it is set to 1.

The Šidák step-down  $p$ -values are determined similarly:

$$\tilde{p}_{(i)} = \begin{cases} 1 - (1 - p_{(1)})^m & \text{for } i = 1 \\ \max(\tilde{p}_{(i-1)}, 1 - (1 - p_{(i)})^{m-i+1}) & \text{for } i = 2, \dots, m \end{cases}$$

Step-down Bonferroni adjustments that use exact tests are defined as

$$\tilde{p}_{(i)} = \begin{cases} p_{(1)}^* + \dots + p_{(m)}^* & \text{for } i = 1 \\ \max(\tilde{p}_{(i-1)}, p_{(i)}^* + \dots + p_{(m)}^*) & \text{for } i = 2, \dots, m \end{cases}$$

where the  $p_j^*$  are defined as before. Note that  $p_j^*$  is taken from the permutation distribution corresponding to the  $j$ th-smallest unadjusted  $p$ -value. Also, any  $\tilde{p}_j$  greater than 1.0 is reduced to 1.0.

Step-down Šidák adjustments for exact tests are defined analogously by substituting  $1 - (1 - p_{(j)}^*) \cdots (1 - p_{(m)}^*)$  for  $p_{(j)}^* + \dots + p_{(m)}^*$ .

The resampling-style step-down methods are analogous to the preceding step-down methods; the most extreme  $p$ -value is adjusted according to all  $m$  tests, the second-most extreme  $p$ -value is adjusted according to  $(m - 1)$  tests, and so on. The difference is that all correlational and distributional characteristics are incorporated when you use resampling methods. More specifically, assuming the same ordering of  $p$ -values as discussed previously, the resampling-style step-down-adjusted  $p$ -value for test  $i$  is the probability that the minimum pseudo- $p$ -value of tests  $i, \dots, m$  is less than or equal to  $p_i$ .

This probability is evaluated by using Monte Carlo simulation, as are the previously described resampling-style-adjusted *p*-values. In fact, the computations for step-down-adjusted *p*-values are essentially no more time-consuming than the computations for the non-step-down-adjusted *p*-values. After Monte Carlo, the step-down-adjusted *p*-values are corrected to ensure monotonicity; this correction leaves the first adjusted *p*-values alone, then corrects the remaining ones as needed. The step-down method approximately controls the familywise error rate, and it is described in more detail by Westfall and Young (1993), Westfall et al. (1999), and Westfall and Wolfinger (2000).

**Hommel**

Hommel’s (1988) method is a closed testing procedure based on Simes’ test (Simes 1986). The Simes *p*-value for a joint test of any set of *S* hypotheses with *p*-values  $p_{(1)} \leq p_{(2)} \leq \dots \leq p_{(S)}$  is  $\min((S/1)p_{(1)}, (S/2)p_{(2)}, \dots, (S/S)p_{(S)})$ . The Hommel-adjusted *p*-value for test *j* is the maximum of all such Simes *p*-values, taken over all joint tests that include *j* as one of their components.

Hochberg-adjusted *p*-values are always as large or larger than Hommel-adjusted *p*-values. Sarkar and Chang (1997) shows that Simes’ method is valid under independent or positively dependent *p*-values, so Hommel’s and Hochberg’s methods are also valid in such cases by the closure principle.

**Hochberg**

Assuming *p*-values are independent and uniformly distributed under their respective null hypotheses, Hochberg (1988) demonstrates that Holm’s step-down adjustments control the familywise error rate even when calculated in *step-up* fashion. Since the adjusted *p*-values are uniformly smaller for Hochberg’s method than for Holm’s method, the Hochberg method is more powerful. However, this improved power comes at the cost of having to make the assumption of independence. Hochberg’s method can be derived from Hommel’s (Liu 1996), and is thus also derived from Simes’ test (Simes 1986).

Hochberg-adjusted *p*-values are always as large or larger than Hommel-adjusted *p*-values. Sarkar and Chang (1997) showed that Simes’ method is valid under independent or positively dependent *p*-values, so Hommel’s and Hochberg’s methods are also valid in such cases by the closure principle.

The Hochberg-adjusted *p*-values are defined in reverse order of the step-down Bonferroni:

$$\tilde{p}_{(i)} = \begin{cases} p_{(m)} & \text{for } i = m \\ \min(\tilde{p}_{(i+1)}, (m - i + 1)p_{(i)}) & \text{for } i = m - 1, \dots, 1 \end{cases}$$

**Fisher Combination**

The FISHER\_C option requests adjusted *p*-values by using closed tests, based on the idea of Fisher’s combination test. The Fisher combination test for a joint test of any set of *S* hypotheses with *p*-values uses the chi-square statistic  $\chi^2 = -2 \sum \log(p_i)$ , with  $2S$  degrees of freedom. The FISHER\_C adjusted *p*-value for test *j* is the maximum of all *p*-values for the combination tests, taken over all joint tests that include *j* as one of their components. Independence of *p*-values is required for the validity of this method.

**Stouffer-Liptak Combination**

The STOUFFER option requests adjusted *p*-values by using closed tests, based on the Stouffer-Liptak combination test. The Stouffer combination joint test of any set of *S* one-sided hypotheses with *p*-values,  $p_1, \dots, p_S$ , yields the *p*-value,  $1 - \Phi\left(\frac{1}{\sqrt{S}} \sum_i \Phi^{-1}(1 - p_i)\right)$ . The STOUFFER adjusted *p*-value for test *j* is the maximum of all *p*-values for the combination tests, taken over all joint tests that include *j* as one of their components.

Independence of the one-sided  $p$ -values is required for the validity of this method. Westfall (2005) shows that the Stouffer-Liptak adjustment might have more power than the Fisher combination and Simes' adjustments when the test results reinforce each other.

### Adaptive Adjustments

*Adaptive* adjustments modify the FWE- and FDR-controlling procedures by taking an estimate of the number  $m_0$  or proportion  $\pi_0$  of true null hypotheses into account. The adjusted  $p$ -values for Holm's and Hochberg's methods involve the number of unadjusted  $p$ -values larger than ( $i$ ),  $m - i + 1$ . So the minimal significance level at which the  $i$ th ordered  $p$ -value is rejected implies that the number of true null hypotheses is  $m - i + 1$ . However, if you know  $m_0$ , then you can replace  $m - i + 1$  with  $\min(m_0, m - i + 1)$ , thereby obtaining more power while maintaining the original  $\alpha$ -level significance.

Since  $m_0$  is unknown, there are several methods used to estimate the value—see the `NTRUENULL=` option for more information. The estimation method described by Hochberg and Benjamini (1990) considers the graph of  $1 - p_{(i)}$  versus  $i$ , where the  $p_{(i)}$  are the ordered  $p$ -values of your tests. See [Output 61.6.4](#) for an example. If all null hypotheses are actually true ( $m_0 = m$ ), then the  $p$ -values behave like a sample from a uniform distribution and this graph should be a straight line through the origin. However, if points in the upper-right corner of this plot do not follow the initial trend, then some of these null hypotheses are probably false and  $0 < m_0 < m$ .

The `ADAPTIVEHOLM` option uses this estimate of  $m_0$  to adjust the step-up Bonferroni method while the `ADAPTIVEHOCHBERG` option adjusts the step-down Bonferroni method. Both of these methods are due to Hochberg and Benjamini (1990). When  $m_0$  is known, these procedures control the familywise error rate in the same manner as their nonadaptive versions but with more power; however, since  $m_0$  must be estimated, the FWE control is only approximate. The `ADAPTIVEFDR` and `PFDR` options also use  $\hat{m}_0$ , and are described in the following section.

The adjusted  $p$ -values for the `ADAPTIVEHOLM` method are computed by

$$\tilde{p}_{(i)} = \begin{cases} \min(m, \hat{m}_0) p_{(1)} & \text{for } i = 1 \\ \max[\tilde{p}_{(i-1)}, \min(m - i + 1, \hat{m}_0) p_{(i)}] & \text{for } i = 2, \dots, m \end{cases}$$

The adjusted  $p$ -values for the `ADAPTIVEHOCHBERG` method are computed by

$$\tilde{p}_{(i)} = \begin{cases} \min(1, \hat{m}_0) p_{(m)} & \text{for } i = m \\ \min[\tilde{p}_{(i+1)}, \min(m - i + 1, \hat{m}_0) p_{(i)}] & \text{for } i = m - 1, \dots, 1 \end{cases}$$

### False Discovery Rate Controlling Adjustments

Methods that control the *false discovery rate* (FDR) were described by Benjamini and Hochberg (1995). These adjustments do not necessarily control the familywise error rate (FWE). However, FDR-controlling methods are more powerful and more liberal, and hence reject more null hypotheses, than adjustments protecting the FWE. FDR-controlling methods are often used when you have a large number of null hypotheses. To control the FDR, Benjamini and Hochberg's (1995) linear step-up method is provided, as well as an adaptive version, a dependence version, and bootstrap and permutation resampling versions. Storey's (2002) pFDR methods are also provided.

The `FDR` option requests  $p$ -values that control the "false discovery rate" described by Benjamini and Hochberg (1995). These *linear step-up* adjustments are potentially much less conservative than the `Hochberg` adjustments.

The FDR-adjusted *p*-values are defined in step-up fashion, like the Hochberg adjustments, but with less conservative multipliers:

$$\tilde{p}^{(i)} = \begin{cases} p^{(m)} & \text{for } i = m \\ \min(\tilde{p}^{(i+1)}, \frac{m}{i} p^{(i)}) & \text{for } i = m - 1, \dots, 1 \end{cases}$$

The FDR method is guaranteed to control the false discovery rate at level  $\leq \frac{m_0}{m} \alpha \leq \alpha$  when you have independent *p*-values that are uniformly distributed under their respective null hypotheses. Benjamini and Yekateuli (2001) show that the false discovery rate is also controlled at level  $\leq \frac{m_0}{m} \alpha$  when the *positive regression dependent* condition holds on the set of the true null hypotheses, and they provide several examples where this condition is true.

**NOTE:** The positive regression dependent condition on the set of the true null hypotheses holds if the joint distribution of the test statistics  $\mathbf{X} = (X_1, \dots, X_m)$  for the null hypotheses  $H_{01}, \dots, H_{0m}$  satisfies:  $\Pr(\mathbf{X} \in A | X_i = x)$  is nondecreasing in *x* for each  $X_i$  where  $H_{0i}$  is true, for any increasing set *A*. The set *A* is increasing if  $\mathbf{x} \in A$  and  $\mathbf{y} \geq \mathbf{x}$  implies  $\mathbf{y} \in A$ .

**Dependent False Discovery Rate**

The DEPENDENTFDR option requests a false discovery rate controlling method that is always valid for *p*-values under any kind of dependency (Benjamini and Yekateuli 2001), but is thus quite conservative. Let  $\gamma = \sum_{i=1}^m \frac{1}{i}$ . The DEPENDENTFDR procedure always controls the false discovery rate at level  $\leq \frac{m_0}{m} \alpha \gamma$ . The adjusted *p*-values are computed as

$$\tilde{p}^{(i)} = \begin{cases} \gamma p^{(m)} & \text{for } i = m \\ \min(\tilde{p}^{(i+1)}, \gamma \frac{m}{i} p^{(i)}) & \text{for } i = m - 1, \dots, 1 \end{cases}$$

**False Discovery Rate Resampling Adjustments**

Bootstrap and permutation resampling methods to control the false discovery rate are available with the FDRBOOT and FDRPERM options (Yekateuli and Benjamini 1999). These methods approximately control the false discovery rate when the *subset pivotality* condition holds, as discussed in the section “Bootstrap” on page 5197, and when the *p*-values corresponding to the true null hypotheses are independent of those for the false null hypotheses.

The resampling methodology for the BOOTSTRAP and PERMUTATION methods is used to create *B* resamples. For the *b*th resample, let  $R^b(p)$  denote the number of *p*-values that are less than or equal to the observed *p*-value *p*. Let  $r_\beta(p)$  be the  $100(1 - \beta)$  quantile of  $\{R^1(p) \dots R^b(p) \dots R^B(p)\}$ , and let  $r(p)$  be the number of observed *p*-values less than or equal to *p*. Compute one of the following estimators:

$$\begin{aligned} \text{local estimator} \quad Q_1(p) &= \begin{cases} \frac{1}{B} \sum_{b=1}^B \frac{R^b(p)}{R^b(p) + r(p) - pm} & \text{if } r(p) - r_\beta(p) \geq pm \\ \#\{R^b(p) \geq 1\} / B & \text{otherwise} \end{cases} \\ \text{upper limit estimator} \quad Q_\beta(p) &= \begin{cases} \sup_{x \in [0, p]} \left( \frac{1}{B} \sum_{b=1}^B \frac{R^b(x)}{R^b(x) + r(x) - r_\beta(x)} \right) & \text{if } r(x) - r_\beta(x) \geq 0 \\ \#\{R^b(p) \geq 1\} / B & \text{otherwise} \end{cases} \end{aligned}$$

where  $m$  is the number of tests and  $B$  is the number of resamples. Then for  $Q = Q_1$  or  $Q_\beta$ , the adjusted  $p$ -values are computed as

$$\tilde{p}^{(i)} = \begin{cases} Q(p^{(m)}) & \text{for } i = m \\ \min(\tilde{p}^{(i+1)}, Q(p^{(i)})) & \text{for } i = m - 1, \dots, 1 \end{cases}$$

### Adaptive False Discovery Rate

Since the FDR method controls the false discovery rate at  $\leq \frac{m_0}{m}\alpha \leq \alpha$ , knowledge of  $m_0$  allows improvement of the power of the adjustment while still maintaining control of the false discovery rate. The ADAPTIVEFDR option requests adaptive adjusted  $p$ -values for approximate control of the false discovery rate, as discussed in Benjamini and Hochberg (2000). See the section “Adaptive Adjustments” on page 5200 for more details. These adaptive adjustments are also defined in step-up fashion but use an estimate  $\hat{m}_0$  of the number of true null hypotheses:

$$\tilde{p}^{(i)} = \begin{cases} \frac{\hat{m}_0}{m} p^{(m)} & \text{for } i = m \\ \min(\tilde{p}^{(i+1)}, \frac{\hat{m}_0}{i} p^{(i)}) & \text{for } i = m - 1, \dots, 1 \end{cases}$$

Since  $\hat{m}_0 \leq m$ , the larger  $p$ -values are adjusted down. This means that, as defined, controlling the false discovery rate enables you to reject these tests at a level less than the observed  $p$ -value. However, by default, this reduction is prevented with an additional restriction:  $\tilde{p}^{(i)} = \max\{\tilde{p}^{(i)}, p^{(i)}\}$ .

To use this adjustment, Benjamini and Hochberg (2000) suggest first specifying the FDR option—if at least one test is rejected at your level, then apply the ADAPTIVEFDR adjustment. Alternatively, Benjamini, Krieger, and Yekutieli (2006) apply the FDR adjustment at level  $\frac{\alpha}{\alpha+1}$ , then specify the resulting number of true hypotheses with the NTRUENULL= option and apply the ADAPTIVEFDR adjustment; they show that this *two-stage linear step-up* procedure controls the false discovery rate at level  $\alpha$  for independent test statistics.

### Positive False Discovery Rate

The PFDR option computes the “ $q$ -values”  $\hat{q}_\lambda(p_i)$  (Storey 2002; Storey, Taylor, and Siegmund 2004), which are adaptive adjusted  $p$ -values for strong control of the false discovery rate when the  $p$ -values corresponding to the true null hypotheses are independent and uniformly distributed. There are four versions of the PFDR available. Let  $N(\lambda)$  be the number of observed  $p$ -values that are less than or equal to  $\lambda$ ; let  $m$  be the number of tests; let  $f = 1$  if the FINITE option is specified, and otherwise set  $f = 0$ ; and denote the estimated proportion of true null hypotheses by

$$\hat{\pi}_0(\lambda) = \frac{m - N(\lambda) + f}{(1 - \lambda)m}$$

The default estimate of FDR is

$$\widehat{\text{FDR}}_\lambda(p) = \frac{\hat{\pi}_0(\lambda)p}{\max(N(p), 1)/m}$$

If you set  $\lambda = 0$ , then this is identical to the FDR adjustment.

The positive FDR is estimated by

$$\widehat{\text{pFDR}}_\lambda(p) = \frac{\widehat{\text{FDR}}_\lambda(p)}{1 - (1 - p)^m}$$

The finite-sample versions of these two estimators for independent null  $p$ -values are given by

$$\widehat{\text{FDR}}_{\lambda}^*(p) = \begin{cases} \frac{\hat{\pi}_0^*(\lambda)p}{\max(N(p), 1)/m} & \text{if } p \leq \lambda \\ 1 & \text{if } p > \lambda \end{cases}$$

$$\widehat{\text{pFDR}}_{\lambda}^*(p) = \frac{\widehat{\text{FDR}}_{\lambda}^*(p)}{1 - (1 - p)^m}$$

Finally, the adjusted  $p$ -values are computed as

$$\tilde{p}_i = \hat{q}_{\lambda}(p_i) = \inf_{p \geq p_i} \widehat{\text{FDR}}_{\lambda}(p) \quad i = 1, \dots, m$$

This method can produce adjusted  $p$ -values that are smaller than the raw  $p$ -values. This means that, as defined, controlling the false discovery rate enables you to reject these tests at a level less than the observed  $p$ -value. However, by default, this reduction is prevented with an additional restriction:  $\tilde{p}_i = \max\{\tilde{p}_i, p_i\}$ .

## Missing Values

If a **CLASS** or **STRATA** variable has a missing value, then PROC MULTTEST removes that observation from the analysis.
