- keyword=name** specifies the statistics to include in the output data set and gives names to the new variables. Specify a keyword for each desired statistic (see the following list), an equal sign, and the variable to contain the statistic.

The keywords allowed and the statistics they represent are as follows:

- LEVERAGE** specifies a variable to indicate leverage points. To include this variable in the OUTPUT data set, you must specify the LEVERAGE option in the MODEL statement. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for how to define LEVERAGE.
- MD** specifies a variable to contain the Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of Mahalanobis distance.
- OUTLIER** specifies a variable to indicate outliers. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for information about how to define OUTLIER.
- PMD** specifies a variable to contain the projected Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of projected Mahalanobis distance.
- POD** specifies a variable to contain the projected off-plane distances. See the section “[Robust Distance](#)” on page 6853 for the definition of off-plane distance.
- PRD** specifies a variable to contain the projected robust MCD Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of projected robust distance.
- PREDICTED | P** specifies a variable to contain the estimated responses
- $$\hat{y}_i = \mathbf{x}'_i \hat{\boldsymbol{\theta}}$$
- RD** specifies a variable to contain the robust MCD Mahalanobis distances. See the section “[Robust Distance](#)” on page 6853 for the definition of robust distance.
- RESIDUAL | R** specifies a variable to contain the unstandardized residuals
- $$y_i - \hat{y}_i \text{ or } y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}$$
- SRESIDUAL | SR** specifies a variable to contain the standardized residuals
- $$\frac{y_i - \hat{y}_i}{\hat{\sigma}} \text{ or } \frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}}{\hat{\sigma}}.$$
- By default, the LTS method uses Wscale as  $\hat{\sigma}$  for computing the standardized residuals.
- STDP** specifies a variable to contain the estimates of the standard errors of the estimated mean responses

$$\sqrt{\mathbf{x}'_i \boldsymbol{\Sigma} \mathbf{x}_i}$$

where  $\boldsymbol{\Sigma}$  denotes the covariance matrix of the parameter estimates. You can request the ODS table of this covariance matrix by using the COVB option of the MODEL statement. The STDP= option is applied to M, S, and MM estimation, but not to LTS estimation.

STDI specifies a variable to contain the estimates of the standard errors of the individual predicted values

$$\sqrt{\mathbf{x}'_i \boldsymbol{\Sigma} \mathbf{x}_i + \hat{\sigma}^2}.$$

The STDI= option is applied to M, S, and MM estimation, but not to LTS estimation.

WEIGHT specifies a variable to contain the computed final weights.

## PERFORMANCE Statement

The PERFORMANCE statement is used to specify options that affect the performance of PROC ROBUSTREG and to request tables that show the performance options in effect and timing details. See Chen (2002) for some empirical results.

**PERFORMANCE** < options > ;

The following *options* are available:

### CPUCOUNT=*n* | ACTUAL

specifies the number of processors to use for forming crossproduct matrices. You can specify any integer in the range 1–1024 for *n*. CPUCOUNT=ACTUAL sets CPUCOUNT to be the number of physical processors available. Note that this can be less than the physical number of CPUs if the SAS process has been restricted by system administration tools. Setting CPUCOUNT= to a number greater than the actual number of available CPUs might result in reduced performance. This option overrides the SAS system option CPUCOUNT=. If CPUCOUNT=1, then NOTHREADS is in effect, and PROC ROBUSTREG uses singly threaded code.

### DETAILS

requests the PerfSettings table that shows the performance settings in effect and the “Timing” table that provides a broad timing breakdown of the PROC ROBUSTREG step.

### THREADS

enables multithreaded computation. This option overrides the SAS system option NOTHREADS.

### NOTHREADS

disables multithreaded computation. This option overrides the SAS system option THREADS.

## TEST Statement

< label: > **TEST** effects ;

With M estimation and MM estimation, the TEST statement provides a means of obtaining a test for the canonical linear hypothesis concerning the parameters of the tested effects

$$\theta_j = 0, \quad j = i_1, \dots, i_q$$

where *q* is the total number of parameters of the tested effects.

PROC ROBUSTREG provides two kinds of robust tests: the  $\rho$  test and the  $R_n^2$  test. They are described in the section “[Details: ROBUSTREG Procedure](#)” on page 6838. No test is available for LTS and S estimation.

The optional *label*, which must be a valid SAS name, is used to label output from the corresponding TEST statement.

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement specifies a weight variable in the input data set.

If you want to use fixed weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. The values of the WEIGHT variable can be nonintegral and are not truncated. Observations with nonpositive or missing values for the weight variable do not contribute to the fit of the model.

## Details: ROBUSTREG Procedure

This section describes the statistical and computational aspects of the ROBUSTREG procedure. The following notation is used throughout this section.

Let  $\mathbf{X} = (x_{ij})$  denote an  $n \times p$  matrix,  $\mathbf{y} = (y_1, \dots, y_n)'$  denote a given  $n$ -vector of responses, and  $\boldsymbol{\theta} = (\theta_1, \dots, \theta_p)'$  denote an unknown  $p$ -vector of parameters or coefficients whose components are to be estimated. The matrix  $\mathbf{X}$  is called the design matrix. Consider the usual linear model

$$\mathbf{y} = \mathbf{X}\boldsymbol{\theta} + \mathbf{e}$$

where  $\mathbf{e} = (e_1, \dots, e_n)'$  is an  $n$ -vector of unknown errors. It is assumed that (for a given  $\mathbf{X}$ ) the components  $e_i$  of  $\mathbf{e}$  are independent and identically distributed according to a distribution  $L(\cdot/\sigma)$ , where  $\sigma$  is a scale parameter (usually unknown). Often  $L(\cdot) \approx \Phi(\cdot)$ , the standard normal distribution function. The vector of residuals for a given value of  $\hat{\boldsymbol{\theta}}$  is denoted by  $\mathbf{r} = (r_1, \dots, r_n)'$  and the  $i$ th row of the matrix  $\mathbf{X}$  is denoted by  $\mathbf{x}_i'$ .

## M Estimation

M estimation in the context of regression was first introduced by Huber (1973) as a result of making the least squares approach robust. Although M estimators are not robust with respect to leverage points, they are popular in applications where leverage points are not an issue.

Instead of minimizing a sum of squares of the residuals, a Huber-type M estimator  $\hat{\boldsymbol{\theta}}_M$  of  $\boldsymbol{\theta}$  minimizes a sum of less rapidly increasing functions of the residuals:

$$Q(\boldsymbol{\theta}) = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$$

where  $\mathbf{r} = \mathbf{y} - \mathbf{X}\boldsymbol{\theta}$ . For the ordinary least squares estimation,  $\rho$  is the square function,  $\rho(z) = z^2$ .

If  $\sigma$  is known, then by taking derivatives with respect to  $\boldsymbol{\theta}$ ,  $\hat{\boldsymbol{\theta}}_M$  is also a solution of the system of  $p$  equations:

$$\sum_{i=1}^n \psi\left(\frac{r_i}{\sigma}\right) x_{ij} = 0, \quad j = 1, \dots, p$$

where  $\psi = \frac{\partial \rho}{\partial z}$ . If  $\rho$  is convex,  $\hat{\boldsymbol{\theta}}_M$  is the unique solution.

The ROBUSTREG procedure solves this system by using iteratively reweighted least squares (IRLS). The weight function  $w(x)$  is defined as

$$w(z) = \frac{\psi(z)}{z}$$

The ROBUSTREG procedure provides 10 kinds of weight functions through the WEIGHTFUNCTION= option in the MODEL statement. Each weight function corresponds to a  $\rho$  function. See the section “Weight Functions” on page 6840 for a complete discussion. You can specify the scale parameter  $\sigma$  with the SCALE= option in the PROC ROBUSTREG statement.

If  $\sigma$  is unknown, both  $\boldsymbol{\theta}$  and  $\sigma$  are estimated by minimizing the function

$$Q(\boldsymbol{\theta}, \sigma) = \sum_{i=1}^n \left[ \rho\left(\frac{r_i}{\sigma}\right) + a \right] \sigma, \quad a > 0$$

The algorithm proceeds by alternately improving  $\hat{\boldsymbol{\theta}}$  in a location step and  $\hat{\sigma}$  in a scale step.

For the scale step, three methods are available to estimate  $\sigma$ , which you can select with the SCALE= option.

1. (SCALE=HUBER <(D=d)>) Compute  $\hat{\sigma}$  by the iteration

$$\left(\hat{\sigma}^{(m+1)}\right)^2 = \frac{1}{nh} \sum_{i=1}^n \chi_d\left(\frac{r_i}{\hat{\sigma}^{(m)}}\right) \left(\hat{\sigma}^{(m)}\right)^2$$

where

$$\chi_d(x) = \begin{cases} x^2/2 & \text{if } |x| < d \\ d^2/2 & \text{otherwise} \end{cases}$$

is the Huber function and  $h = \frac{n-p}{n} \left( d^2 + (1-d^2)\Phi(d) - 0.5 - d\sqrt{2\pi}e^{-\frac{1}{2}d^2} \right)$  is the Huber constant (Huber 1981, p. 179). You can specify  $d$  with the D=d option. By default, D=2.5.

2. (SCALE=TUKEY <(D=d)>) Compute  $\hat{\sigma}$  by solving the supplementary equation

$$\frac{1}{n-p} \sum_{i=1}^n \chi_d \left( \frac{r_i}{\sigma} \right) = \beta$$

where

$$\chi_d(x) = \begin{cases} \frac{3x^2}{d^2} - \frac{3x^4}{d^4} + \frac{x^6}{d^6} & \text{if } |x| < d \\ 1 & \text{otherwise} \end{cases}$$

Here  $\psi = \frac{1}{6}\chi_1'$  is Tukey's bisquare function, and  $\beta = \int \chi_d(s)d\Phi(s)$  is the constant such that the solution  $\hat{\sigma}$  is asymptotically consistent when  $L(\cdot/\sigma) = \Phi(\cdot)$  (Hampel et al. 1986, p. 149). You can specify  $d$  with the D=d option. By default, D=2.5.

3. (SCALE=MED) Compute  $\hat{\sigma}$  by the iteration

$$\hat{\sigma}^{(m+1)} = \text{median} \left\{ |y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}^{(m)}| / \beta_0, i = 1, \dots, n \right\}$$

where  $\beta_0 = \Phi^{-1}(.75)$  is the constant such that the solution  $\hat{\sigma}$  is asymptotically consistent when  $L(\cdot/\sigma) = \Phi(\cdot)$  (Hampel et al. 1986, p. 312).

SCALE=MED is the default.

## Algorithm

The basic algorithm for computing M estimates for regression is iteratively reweighted least squares (IRLS). As the name suggests, a weighted least squares fit is carried out inside an iteration loop. For each iteration, a set of weights for the observations is used in the least squares fit. The weights are constructed by applying a weight function to the current residuals. Initial weights are based on residuals from an initial fit. The ROBUSTREG procedure uses the unweighted least squares fit as a default initial fit. The iteration terminates when a convergence criterion is satisfied. The maximum number of iterations is set to 1,000. You can specify the weight function and the convergence criteria.

## Weight Functions

You can specify the weight function for M estimation with the WEIGHTFUNCTION= option. The ROBUSTREG procedure provides 10 weight functions. By default, the procedure uses the bisquare weight function. In most cases, M estimates are more sensitive to the parameters of these weight functions than to the type of the weight function. The median weight function is not stable and is seldom recommended in data analysis; it is included in the procedure for completeness. You can specify the parameters for these weight functions. Except for the Hampel and median weight functions, default values for these parameters are defined such that the corresponding M estimates have 95% asymptotic efficiency in the location model with the Gaussian distribution (Holland and Welsch 1977).

The following list shows the weight functions available. See Table 80.5 for the default values of the constants in these weight functions.

Andrews 
$$W(x, c) = \begin{cases} \frac{\sin(x/c)}{x/c} & \text{if } |x| \leq \pi c \\ 0 & \text{otherwise} \end{cases}$$

Bisquare 
$$W(x, c) = \begin{cases} (1 - (x/c)^2)^2 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$$

Cauchy 
$$W(x, c) = \frac{1}{1 + (|x|/c)^2}$$

Fair 
$$W(x, c) = \frac{1}{(1 + |x|/c)}$$

Hampel 
$$W(x, a, b, c) = \begin{cases} 1 & |x| < a \\ \frac{a}{|x|} & a < |x| \leq b \\ \frac{a}{|x|} \frac{c-|x|}{c-b} & b < |x| \leq c \\ 0 & \text{otherwise} \end{cases}$$

Huber  $W(x, c) = \begin{cases} 1 & \text{if } |x| < c \\ \frac{c}{|x|} & \text{otherwise} \end{cases}$

Logistic  $W(x, c) = \frac{\tanh(x/c)}{x/c}$

Median  $W(x, c) = \begin{cases} \frac{1}{c} & \text{if } x = 0 \\ \frac{1}{|x|} & \text{otherwise} \end{cases}$

Talworth  $W(x, c) = \begin{cases} 1 & \text{if } |x| < c \\ 0 & \text{otherwise} \end{cases}$

Welsch  $W(x, c) = \exp\left(-\frac{(x/c)^2}{2}\right)$

## Convergence Criteria

The following convergence criteria are available in PROC ROBUSTREG:

- relative change in the coefficients (CONVERGENCE= COEF)

- relative change in the scaled residuals (CONVERGENCE= RESID)
- relative change in weights (CONVERGENCE= WEIGHT)

You can specify the criteria with the CONVERGENCE= option in the PROC ROBUSTREG statement. The default is CONVERGENCE= COEF.

You can specify the precision of the convergence criterion with the EPS= suboption. The default is EPS=1E-8.

In addition to these convergence criteria, a convergence criterion based on scale-independent measure of the gradient is always checked. See Coleman et al. (1980) for more details. A warning is issued if this criterion is not satisfied.

### Asymptotic Covariance and Confidence Intervals

The following three estimators of the asymptotic covariance of the robust estimator are available in PROC ROBUSTREG:

$$\text{H1: } K^2 \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]^2} (\mathbf{X}'\mathbf{X})^{-1}$$

$$\text{H2: } K \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]} \mathbf{W}^{-1}$$

$$\text{H3: } K^{-1} \frac{1}{(n-p)} \sum (\psi(r_i))^2 \mathbf{W}^{-1} (\mathbf{X}'\mathbf{X}) \mathbf{W}^{-1}$$

where  $K = 1 + \frac{p}{n} \frac{\text{Var}(\psi')}{(E\psi')^2}$  is a correction factor and  $W_{jk} = \sum \psi'(r_i) x_{ij} x_{ik}$ . See Huber (1981, p. 173) for more details.

You can specify the asymptotic covariance estimate with the option ASYMPCOV= option. The ROBUSTREG procedure uses H1 as the default because of its simplicity and stability. Confidence intervals are computed from the diagonal elements of the estimated asymptotic covariance matrix.

### R Square and Deviance

The robust version of R-square is defined as

$$R^2 = \frac{\sum \rho \left( \frac{y_i - \hat{\mu}}{\hat{s}} \right) - \sum \rho \left( \frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}}{\hat{s}} \right)}{\sum \rho \left( \frac{y_i - \hat{\mu}}{\hat{s}} \right)}$$

and the robust deviance is defined as the optimal value of the objective function on the  $\sigma^2$  scale

$$D = 2\hat{s}^2 \sum \rho \left( \frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}}{\hat{s}} \right)$$

where  $\rho' = \psi$ ,  $\hat{\boldsymbol{\theta}}$  is the M estimator of  $\boldsymbol{\theta}$ ,  $\hat{\mu}$  is the M estimator of location, and  $\hat{s}$  is the M estimator of the scale parameter in the full model.

## Linear Tests

Two tests are available in PROC ROBUSTREG for the canonical linear hypothesis

$$H_0 : \theta_j = 0, \quad j = i_1, \dots, i_q$$

where  $q$  is the total number of parameters of the tested effects. The first test is a robust version of the  $F$  test, which is referred to as the  $\rho$  test. Denote the M estimators in the full and reduced models as  $\hat{\boldsymbol{\theta}}(0) \in \Omega_0$  and  $\hat{\boldsymbol{\theta}}(1) \in \Omega_1$ , respectively. Let

$$\begin{aligned} Q_0 &= Q(\hat{\boldsymbol{\theta}}(0)) = \min\{Q(\boldsymbol{\theta}) \mid \boldsymbol{\theta} \in \Omega_0\} \\ Q_1 &= Q(\hat{\boldsymbol{\theta}}(1)) = \min\{Q(\boldsymbol{\theta}) \mid \boldsymbol{\theta} \in \Omega_1\} \end{aligned}$$

with

$$Q = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$$

The robust  $F$  test is based on the test statistic

$$S_n^2 = \frac{2}{q}[Q_1 - Q_0]$$

Asymptotically  $S_n^2 \sim \lambda \chi_q^2$  under  $H_0$ , where the standardization factor is  $\lambda = \int \psi^2(s) d\Phi(s) / \int \psi'(s) d\Phi(s)$  and  $\Phi$  is the cumulative distribution function of the standard normal distribution. Large values of  $S_n^2$  are significant. This test is a special case of the general  $\tau$  test of Hampel et al. (1986, Section 7.2).

The second test is a robust version of the Wald test, which is referred to as  $R_n^2$  test. The test uses a test statistic

$$R_n^2 = n(\hat{\theta}_{i_1}, \dots, \hat{\theta}_{i_q}) \mathbf{H}_{22}^{-1}(\hat{\theta}_{i_1}, \dots, \hat{\theta}_{i_q})'$$

where  $\frac{1}{n} \mathbf{H}_{22}$  is the  $q \times q$  block (corresponding to  $\theta_{i_1}, \dots, \theta_{i_q}$ ) of the asymptotic covariance matrix of the M estimate  $\hat{\boldsymbol{\theta}}_M$  of  $\boldsymbol{\theta}$  in a  $p$ -parameter linear model.

Under  $H_0$ , the statistic  $R_n^2$  has an asymptotic  $\chi^2$  distribution with  $q$  degrees of freedom. Large values of  $R_n^2$  are significant. See Hampel et al. (1986, Chapter 7) for more details.

## Model Selection

When M estimation is used, two criteria are available in PROC ROBUSTREG for model selection. The first criterion is a counterpart of the Akaike (1974) information criterion for robust regression (AICR); it is defined as

$$\text{AICR} = 2 \sum_{i=1}^n \rho(r_{i:p}) + \alpha p$$

where  $r_{i:p} = (y_i - \mathbf{x}_i' \hat{\boldsymbol{\theta}}) / \hat{\sigma}$ ,  $\hat{\sigma}$  is a robust estimate of  $\sigma$  and  $\hat{\boldsymbol{\theta}}$  is the M estimator with  $p$ -dimensional design matrix.

As with AIC,  $\alpha$  is the weight of the penalty for dimensions. The ROBUSTREG procedure uses  $\alpha = 2E\psi^2/E\psi'$  (Ronchetti 1985) and estimates it by using the final robust residuals.

The second criterion is a robust version of the Schwarz information criteria (BICR); it is defined as

$$\text{BICR} = 2 \sum_{i=1}^n \rho(r_{i;p}) + p \log(n)$$

## High-Breakdown-Value Estimation

The *breakdown value* of an estimator is defined as the smallest fraction of contamination that can cause the estimator to take on values that are arbitrarily far from its value on the uncontaminated data. The breakdown value of an estimator can be used as a measure of the robustness of the estimator. Rousseeuw and Leroy (1987) and others introduced the following high-breakdown-value estimators for linear regression.

### LTS Estimate

The least trimmed squares (LTS) estimate proposed by Rousseeuw (1984) is defined as the  $p$ -vector

$$\hat{\theta}_{LTS} = \arg \min_{\theta} Q_{LTS}(\theta) \text{ with } Q_{LTS}(\theta) = \sum_{i=1}^h r_i^2$$

where  $r_{(1)}^2 \leq r_{(2)}^2 \leq \dots \leq r_{(n)}^2$  are the ordered squared residuals  $r_i^2 = (y_i - \mathbf{x}_i' \theta)^2$ ,  $i = 1, \dots, n$ , and  $h$  is defined in the range  $\frac{n}{2} + 1 \leq h \leq \frac{3n+p+1}{4}$ .

You can specify the parameter  $h$  with the H= option in the PROC ROBUSTREG statement. By default,  $h = \lceil \frac{3n+p+1}{4} \rceil$ . The breakdown value is  $\frac{n-h}{n}$  for the LTS estimate.

The ROBUSTREG procedure computes LTS estimates by using the FAST-LTS algorithm of Rousseeuw and Van Driessen (2000). The estimates are often used to detect outliers in the data, which are then down-weighted in the resulting weighted LS regression.

### Algorithm

Least trimmed squares (LTS) regression is based on the subset of  $h$  observations (out of a total of  $n$  observations) whose least squares fit possesses the smallest sum of squared residuals. The coverage  $h$  can be set between  $\frac{n}{2}$  and  $n$ . The LTS method was proposed by Rousseeuw (1984, p. 876) as a highly robust regression estimator with breakdown value  $\frac{n-h}{n}$ . The ROBUSTREG procedure uses the FAST-LTS algorithm given by Rousseeuw and Van Driessen (2000). The intercept adjustment technique is also used in this implementation. However, because this adjustment is expensive to compute, it is optional. You can use the IADJUST= option in the PROC ROBUSTREG statement to request or suppress the intercept adjustment. By default, PROC ROBUSTREG does intercept adjustment for data sets with fewer than 10,000 observations. The steps of the algorithm are described briefly as follows. See Rousseeuw and Van Driessen (2000) for details.

1. The default  $h$  is  $\lceil \frac{3n+p+1}{4} \rceil$ , where  $p$  is the number of independent variables. You can specify any integer  $h$  with  $\lceil \frac{n}{2} \rceil + 1 \leq h \leq \lceil \frac{3n+p+1}{4} \rceil$  with the H= option in the MODEL statement. The breakdown value for LTS,  $\frac{n-h}{n}$ , is reported. The default  $h$  is a good compromise between breakdown value and statistical efficiency.
2. If  $p = 1$  (single regressor), the procedure uses the exact algorithm of Rousseeuw and Leroy (1987, p. 172).

3. If  $p \geq 2$ , PROC ROBUSTREG uses the following algorithm. If  $n < 2 \textit{ssubs}$ , where  $\textit{ssubs}$  is the size of the subgroups (you can specify  $\textit{ssubs}$  by using the SUBGROUPSIZE= option in the PROC ROBUSTREG statement; by default,  $\textit{ssubs} = 300$ ), PROC ROBUSTREG draws a random  $p$ -subset and computes the regression coefficients by using these  $p$  points (if the regression is degenerate, another  $p$ -subset is drawn). The absolute residuals for all observations in the data set are computed, and the first  $h$  points with smallest absolute residuals are selected. From this selected  $h$ -subset, PROC ROBUSTREG carries out  $\textit{nsteps}$  C-steps (concentration steps; see Rousseeuw and Van Driessen (2000) for details). You can specify  $\textit{nsteps}$  with the CSTEP= option in the PROC ROBUSTREG statement; by default,  $\textit{nsteps} = 2$ . PROC ROBUSTREG redraws  $p$ -subsets and repeats the preceding computation  $\textit{nrep}$  times, and then finds the  $\textit{nbsol}$  (at most) solutions with the lowest sums of  $h$  squared residuals. You can specify  $\textit{nrep}$  with the NREP= option in the PROC ROBUSTREG statement; by default,  $\textit{NREP} = \min\{500, \binom{n}{p}\}$ . For small  $n$  and  $p$ , all  $\binom{n}{p}$  subsets are used and the NREP= option is ignored (Rousseeuw and Hubert 1996). You can specify  $\textit{nbsol}$  with the NBEST= option in the PROC ROBUSTREG statement; by default,  $\textit{NBEST} = 10$ . For each of these  $\textit{nbsol}$  best solutions, C-steps are taken until convergence and the best final solution is found.
4. If  $n \geq 5\textit{ssubs}$ , construct five disjoint random subgroups with size  $\textit{ssubs}$ . If  $2\textit{ssubs} < n < 5\textit{ssubs}$ , the data are split into at most four subgroups with  $\textit{ssubs}$  or more observations in each subgroup, so that each observation belongs to a subgroup and the subgroups have roughly the same size. Let  $\textit{nsubs}$  denote the number of subgroups. Inside each subgroup, PROC ROBUSTREG repeats the step 3 algorithm  $\textit{nrep} / \textit{nsubs}$  times, keeps the  $\textit{nbsol}$  best solutions, and pools the subgroups, yielding the merged set of size  $\textit{nmerged}$ . In the merged set, for each of the  $\textit{nsubs} \times \textit{nbsol}$  best solutions,  $\textit{nsteps}$  C-steps are carried out by using  $\textit{nmerged}$  and  $\textit{hmerged} = \lceil \textit{nmerged} \frac{h}{n} \rceil$  and the  $\textit{nbsol}$  best solutions are kept. In the full data set, for each of these  $\textit{nbsol}$  best solutions, C-steps are taken by using  $n$  and  $h$  until convergence and the best final solution is found.

**NOTE:** At step 3 in the algorithm, a randomly selected  $p$ -subset might be degenerate (that is, its design matrix might be singular). If the total number of  $p$ -subsets from any subgroup is more than 4,000 and the ratio of degenerate  $p$ -subsets is more than the threshold specified in FAILRATIO= option, the algorithm is terminated with an error message.

### R-Square

The robust version of R-square for the LTS estimate is defined as

$$R_{LTS}^2 = 1 - \frac{s_{LTS}^2(\mathbf{X}, \mathbf{y})}{s_{LTS}^2(\mathbf{1}, \mathbf{y})}$$

for models with the intercept term and as

$$R_{LTS}^2 = 1 - \frac{s_{LTS}^2(\mathbf{X}, \mathbf{y})}{s_{LTS}^2(\mathbf{0}, \mathbf{y})}$$

for models without the intercept term, where

$$s_{LTS}(\mathbf{X}, \mathbf{y}) = d_{h,n} \sqrt{\frac{1}{h} \sum_{i=1}^h r_{(i)}^2}$$

Note that  $s_{LTS}$  is a preliminary estimate of the parameter  $\sigma$  in the distribution function  $L(\cdot/\sigma)$ .

Here  $d_{h,n}$  is chosen to make  $s_{LTS}$  consistent, assuming a Gaussian model. Specifically,

$$d_{h,n} = 1/\sqrt{1 - \frac{2n}{hc_{h,n}}\phi(1/c_{h,n})}$$

$$c_{h,n} = 1/\Phi^{-1}\left(\frac{h+n}{2n}\right)$$

with  $\Phi$  and  $\phi$  being the distribution function and the density function of the standard normal distribution, respectively.

### Final Weighted Scale Estimator

The ROBUSTREG procedure displays two scale estimators,  $s_{LTS}$  and Wscale. The estimator Wscale is a more efficient scale estimator based on the preliminary estimate  $s_{LTS}$ ; it is defined as

$$\text{Wscale} = \sqrt{\frac{\sum_i w_i r_i^2}{\sum_i w_i - p}}$$

where

$$w_i = \begin{cases} 0 & \text{if } |r_i|/s_{LTS} > k \\ 1 & \text{otherwise} \end{cases}$$

You can specify  $k$  with the CUTOFF= option in the MODEL statement. By default,  $k = 3$ .

## S Estimate

The S estimate proposed by Rousseeuw and Yohai (1984) is defined as the  $p$ -vector

$$\hat{\theta}_S = \arg \min_{\theta} S(\theta)$$

where the dispersion  $S(\theta)$  is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi\left(\frac{y_i - \mathbf{x}_i' \theta}{S}\right) = \beta$$

Here  $\beta$  is set to  $\int \chi(s) d\Phi(s)$  such that  $\hat{\theta}_S$  and  $S(\hat{\theta}_S)$  are asymptotically consistent estimates of  $\theta$  and  $\sigma$  for the Gaussian regression model. The breakdown value of the S estimate is

$$\frac{\beta}{\max_s \chi(s)}$$

The ROBUSTREG procedure provides two choices for  $\chi$ : Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3\left(\frac{s}{k_0}\right)^2 - 3\left(\frac{s}{k_0}\right)^4 + \left(\frac{s}{k_0}\right)^6, & \text{if } |s| \leq k_0 \\ 1 & \text{otherwise} \end{cases}$$

The constant  $k_0$  controls the breakdown value and efficiency of the S estimate. If you specify the efficiency by using the EFF= option, you can determine the corresponding  $k_0$ . The default  $k_0$  is 2.9366 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 75.9%.

The Yohai function, which you can specify with the option CHIF=YOHAI, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_0 \\ k_0^2 [b_0 + b_1(\frac{s}{k_0})^2 + b_2(\frac{s}{k_0})^4 + b_3(\frac{s}{k_0})^6 + b_4(\frac{s}{k_0})^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where  $b_0 = 1.792$ ,  $b_1 = -0.972$ ,  $b_2 = 0.432$ ,  $b_3 = -0.052$ , and  $b_4 = 0.002$ . If you specify the efficiency by using the EFF= option, you can determine the corresponding  $k_0$ . By default,  $k_0$  is set to 0.7405 such that the breakdown value of the S estimate is 0.25 with a corresponding asymptotic efficiency for the Gaussian model of 72.7%.

### Algorithm

The ROBUSTREG procedure implements the algorithm by Marazzi (1993) for the S estimate, which is a refined version of the algorithm proposed by Ruppert (1992). The refined algorithm is briefly described as follows.

Initialize  $iter = 1$ .

1. Draw a random  $q$ -subset of the total  $n$  observations and compute the regression coefficients by using these  $q$  observations (if the regression is degenerate, draw another  $q$ -subset), where  $q \geq p$  can be specified with the SUBSIZE= option. By default,  $q = p$ .
2. Compute the residuals:  $r_i = y_i - \sum_{j=1}^p x_{ij}\theta_j$  for  $i = 1, \dots, n$ . If  $iter = 1$ , set  $s^* = 2\text{median}\{|r_i|, i = 1, \dots, n\}$ ; if  $s^* = 0$ , set  $s^* = \min\{|r_i|, i = 1, \dots, n\}$ ; else while  $\sum_{i=1}^n \chi(r_i/s^*) > (n-p)\beta$ , set  $s^* = 1.5s^*$ ; go to step 3. If  $iter > 1$  and  $\sum_{i=1}^n \chi(r_i/s^*) \leq (n-p)\beta$ , go to step 3; otherwise, go to step 5.

3. Solve for  $s$  the equation

$$\frac{1}{n-p} \sum_{i=1}^n \chi(r_i/s) = \beta$$

using an iterative algorithm.

4. If  $iter > 1$  and  $s > s^*$ , go to step 5. Otherwise, set  $s^* = s$  and  $\theta^* = \theta$ . If  $s^* < \text{TOLS}$ , return  $s^*$  and  $\theta^*$ ; otherwise, go to step 5.
5. If  $iter < \text{NREP}$ , set  $iter = iter + 1$  and return to step 1; otherwise, return  $s^*$  and  $\theta^*$ .

The ROBUSTREG procedure does the following refinement step by default. You can request that this refinement not be done by using the NOREFINE option in the PROC ROBUSTREG statement.

6. Let  $\psi = \chi'$ . Using the values  $s^*$  and  $\theta^*$  from the previous steps, compute M estimates  $\theta_M$  and  $\sigma_M$  of  $\theta$  and  $\sigma$  with the setup for M estimation that is described in the section “M Estimation” on page 6838. If  $\sigma_M > s^*$ , give a warning and return  $s^*$  and  $\theta^*$ ; otherwise, return  $\sigma_M$  and  $\theta_M$ .

You can specify TOLS with the TOLERANCE= option; by default, TOLERANCE=0.001. Alternately, you can specify NREP with the NREP= option. You can also use the options NREP=NREP0 or NREP=NREP1 to determine NREP according to the following table. NREP=NREP0 is set as the default.

**Table 80.11** Default NREP

| <b>P</b> | <b>NREP0</b> | <b>NREP1</b> |
|----------|--------------|--------------|
| 1        | 150          | 500          |
| 2        | 300          | 1000         |
| 3        | 400          | 1500         |
| 4        | 500          | 2000         |
| 5        | 600          | 2500         |
| 6        | 700          | 3000         |
| 7        | 850          | 3000         |
| 8        | 1250         | 3000         |
| 9        | 1500         | 3000         |
| >9       | 1500         | 3000         |

**NOTE:** At step 1 in the algorithm, a randomly selected  $q$ -subset might be degenerate. If the total number of  $q$ -subsets from any subgroup is more than 4,000 and the ratio of degenerate  $q$ -subsets is more than the threshold specified in FAILRATIO= option, the algorithm is terminated with an error message.

### ***R-Square and Deviance***

The robust version of R-square for the S estimate is defined as

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{(n-1)S_\mu^2}$$

for the model with the intercept term and

$$R_S^2 = 1 - \frac{(n-p)S_p^2}{nS_0^2}$$

for the model without the intercept term, where  $S_p$  is the S estimate of the scale in the full model,  $S_\mu$  is the S estimate of the scale in the regression model with only the intercept term, and  $S_0$  is the S estimate of the scale without any regressor. The deviance  $D$  is defined as the optimal value of the objective function on the  $\sigma^2$  scale:

$$D = S_p^2$$

### ***Asymptotic Covariance and Confidence Intervals***

Since the S estimate satisfies the first-order necessary conditions as the M estimate, it has the same asymptotic covariance as that of the M estimate. All three estimators of the asymptotic covariance for the M estimate in the section “Asymptotic Covariance and Confidence Intervals” on page 6843 can be used for the S estimate. Besides, the weighted covariance estimator H4 described in the section “Asymptotic Covariance and Confidence Intervals” on page 6852 is also available and is set as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

## MM Estimation

MM estimation is a combination of high-breakdown-value estimation and efficient estimation, which was introduced by Yohai (1987). It has the following three steps:

1. Compute an initial (consistent) high-breakdown-value estimate  $\hat{\theta}'$ . The ROBUSTREG procedure provides two kinds of estimates as the initial estimate: the LTS estimate and the S estimate. By default, the LTS estimate is used because of its speed and high breakdown value. The breakdown value of the final MM estimate is decided by the breakdown value of the initial LTS estimate and the constant  $k_0$  in the  $\chi$  function. To use the S estimate as the initial estimate, you specify the INITEST=S option in the PROC ROBUSTREG statement. In this case, the breakdown value of the final MM estimate is decided only by the constant  $k_0$ . Instead of computing the LTS estimate or the S estimate as the initial estimate, you can also specify the initial estimate explicitly by using the INEST= option in the PROC ROBUSTREG statement. See the section “[INEST= Data Set](#)” on page 6861 for details.

2. Find  $\hat{\sigma}'$  such that

$$\frac{1}{n-p} \sum_{i=1}^n \chi \left( \frac{y_i - \mathbf{x}'_i \hat{\theta}'}{\hat{\sigma}'} \right) = \beta$$

where  $\beta = \int \chi(s) d\Phi(s)$ .

The ROBUSTREG procedure provides two choices for  $\chi$ : Tukey’s bisquare function and Yohai’s optimal function.

Tukey’s bisquare function, which you can specify with the option CHIF=TUKEY, is

$$\chi_{k_0}(s) = \begin{cases} 3\left(\frac{s}{k_0}\right)^2 - 3\left(\frac{s}{k_0}\right)^4 + \left(\frac{s}{k_0}\right)^6 & \text{if } |s| \leq k_0 \\ 1 & \text{otherwise} \end{cases}$$

where  $k_0$  can be specified with the K0= option. The default  $k_0$  is 2.9366 such that the asymptotically consistent scale estimate  $\hat{\sigma}'$  has the breakdown value of 25%.

Yohai’s optimal function, which you can specify with the option CHIF=YOHAI, is

$$\chi_{k_0}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_0 \\ k_0^2 [b_0 + b_1 \left(\frac{s}{k_0}\right)^2 + b_2 \left(\frac{s}{k_0}\right)^4 + b_3 \left(\frac{s}{k_0}\right)^6 + b_4 \left(\frac{s}{k_0}\right)^8] & \text{if } 2k_0 < |s| \leq 3k_0 \\ 3.25k_0^2 & \text{if } |s| > 3k_0 \end{cases}$$

where  $b_0 = 1.792$ ,  $b_1 = -0.972$ ,  $b_2 = 0.432$ ,  $b_3 = -0.052$ , and  $b_4 = 0.002$ . You can specify  $k_0$  with the K0= option. The default  $k_0$  is 0.7405 such that the asymptotically consistent scale estimate  $\hat{\sigma}'$  has the breakdown value of 25%.

3. Find a local minimum  $\hat{\theta}_{MM}$  of

$$Q_{MM} = \sum_{i=1}^n \rho \left( \frac{y_i - \mathbf{x}'_i \theta}{\hat{\sigma}'} \right)$$

such that  $Q_{MM}(\hat{\theta}_{MM}) \leq Q_{MM}(\hat{\theta}')$ . The algorithm for M estimation is used here.

The ROBUSTREG procedure provides two choices for  $\rho$ : Tukey's bisquare function and Yohai's optimal function.

Tukey's bisquare function, which you can specify with the option CHIF=DUKEY, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} 3\left(\frac{s}{k_1}\right)^2 - 3\left(\frac{s}{k_1}\right)^4 + \left(\frac{s}{k_1}\right)^6 & \text{if } |s| \leq k_1 \\ 1 & \text{otherwise} \end{cases}$$

where  $k_1$  can be specified with the K1= option. The default  $k_1$  is 3.440 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

Yohai's optimal function, which you can specify with the option CHIF=YOHA, is

$$\rho(s) = \chi_{k_1}(s) = \begin{cases} \frac{s^2}{2} & \text{if } |s| \leq 2k_1 \\ k_1^2 [b_0 + b_1\left(\frac{s}{k_1}\right)^2 + b_2\left(\frac{s}{k_1}\right)^4 + b_3\left(\frac{s}{k_1}\right)^6 + b_4\left(\frac{s}{k_1}\right)^8] & \text{if } 2k_1 < |s| \leq 3k_1 \\ 3.25k_1^2 & \text{if } |s| > 3k_1 \end{cases}$$

where  $k_1$  can be specified with the K1= option. The default  $k_1$  is 0.868 such that the MM estimate has 85% asymptotic efficiency with the Gaussian distribution.

## Algorithm

The initial LTS estimate is computed using the algorithm described in the section "LTS Estimate" on page 6845. You can control the quantile of the LTS estimate with the option INITH= $h$ , where  $h$  is an integer between  $\lfloor \frac{n}{2} \rfloor + 1$  and  $\lfloor \frac{3n+p+1}{4} \rfloor$ . By default,  $h = \lfloor \frac{3n+p+1}{4} \rfloor$ , which corresponds to a breakdown value of around 25%.

The initial S estimate is computed using the algorithm described in the section "S Estimate" on page 6847. You can control the breakdown value and efficiency of this initial S estimate by the constant  $k_0$ , which can be specified with the K0 option.

The scale parameter  $\sigma$  is solved by an iterative algorithm

$$(\sigma^{(m+1)})^2 = \frac{1}{(n-p)\beta} \sum_{i=1}^n \chi_{k_0} \left( \frac{r_i}{\sigma^{(m)}} \right) (\sigma^{(m)})^2$$

where  $\beta = \int \chi_{k_0}(s) d\Phi(s)$ .

Once the scale parameter is computed, the iteratively reweighted least squares (IRLS) algorithm with fixed scale parameter is used to compute the final MM estimate.

## Convergence Criteria

In the iterative algorithm for the scale parameter, the relative change of the scale parameter controls the convergence.

In the iteratively reweighted least squares algorithm, the same convergence criteria for the M estimate used before are used here.

## Bias Test

Although the final MM estimate inherits the high-breakdown-value property, its bias due to the distortion of the outliers can be high. Yohai, Stahel, and Zamar (1991) introduced a bias test. The ROBUSTREG procedure implements this test when you specify the BIASTEST= option in the PROC ROBUSTREG statement. This test is based on the initial scale estimate  $\hat{\sigma}'$  and the final scale estimate  $\hat{\sigma}'_1$ , which is the solution of

$$\frac{1}{n-p} \sum_{i=1}^n \chi \left( \frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}_{MM}}{\hat{\sigma}'_1} \right) = \beta$$

Let  $\psi_{k_0}(z) = \frac{\partial \chi_{k_0}(z)}{\partial z}$  and  $\psi_{k_1}(z) = \frac{\partial \chi_{k_1}(z)}{\partial z}$ . Compute

$$\tilde{r}_i = (y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}') / \hat{\sigma}' \quad \text{for } i = 1, \dots, n$$

$$v_0 = \frac{(1/n) \sum \psi'_{k_0}(\tilde{r}_i)}{(\hat{\sigma}'_1/n) \sum \psi_{k_0}(\tilde{r}_i) \tilde{r}_i}$$

$$p_i^{(0)} = \frac{\psi_{k_0}(\tilde{r}_i)}{(1/n) \sum \psi'_{k_0}(\tilde{r}_i)} \quad \text{for } i = 1, \dots, n$$

$$p_i^{(1)} = \frac{\psi_{k_1}(\tilde{r}_i)}{(1/n) \sum \psi'_{k_1}(\tilde{r}_i)} \quad \text{for } i = 1, \dots, n$$

$$d^2 = \frac{1}{n} \sum (p_i^{(1)} - p_i^{(0)})^2$$

Let

$$T = \frac{2n(\hat{\sigma}'_1 - \hat{\sigma}')}{v_0 d^2 (\hat{\sigma}')^2}$$

Standard asymptotic theory shows that  $T$  approximately follows a  $\chi^2$  distribution with  $p$  degrees of freedom. If  $T$  exceeds the  $\alpha$  quantile  $\chi^2_\alpha$  of the  $\chi^2$  distribution with  $p$  degrees of freedom, then the ROBUSTREG procedure gives a warning and recommends that you use other methods. Otherwise, the final MM estimate and the initial scale estimate are reported. You can specify  $\alpha$  with the ALPHA= option following the BIASTEST= option. By default, ALPHA=0.99.

## Asymptotic Covariance and Confidence Intervals

Since the MM estimate is computed as a M estimate with a known scale in the last step, the asymptotic covariance for the M estimate can be used here for the asymptotic covariance of the MM estimate. Besides the three estimators H1, H2, and H3 as described in the section “Asymptotic Covariance and Confidence Intervals” on page 6843, a weighted covariance estimator H4 is available. H4 is calculated as

$$K^2 \frac{[1/(n-p)] \sum (\psi(r_i))^2}{[(1/n) \sum (\psi'(r_i))]^2} \mathbf{W}^{-1}$$

where  $K = 1 + \frac{p}{n} \frac{\text{Var}(\psi')}{(E\psi')^2}$  is the correction factor and  $W_{jk} = \frac{1}{\bar{w}} \sum w_i x_{ij} x_{ik}$ ,  $\bar{w} = \frac{1}{n} \sum w_i$ .

You can specify these estimators with the option ASYMPCOV= [H1 | H2 | H3 | H4]. The ROBUSTREG procedure uses H4 as the default. Confidence intervals for estimated parameters are computed from the diagonal elements of the estimated asymptotic covariance matrix.

## R Square and Deviance

The robust version of R-square for the MM estimate is defined as

$$R^2 = \frac{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right) - \sum \rho\left(\frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}}{\hat{s}}\right)}{\sum \rho\left(\frac{y_i - \hat{\mu}}{\hat{s}}\right)}$$

and the robust deviance is defined as the optimal value of the objective function on the  $\sigma^2$  scale,

$$D = 2\hat{s}^2 \sum \rho\left(\frac{y_i - \mathbf{x}'_i \hat{\boldsymbol{\theta}}}{\hat{s}}\right)$$

where  $\rho' = \psi$ ,  $\hat{\boldsymbol{\theta}}$  is the MM estimator of  $\boldsymbol{\theta}$ ,  $\hat{\mu}$  is the MM estimator of location, and  $\hat{s}$  is the MM estimator of the scale parameter in the full model.

## Linear Tests

For MM estimation, the same  $\rho$  test and  $R_n^2$  test used for M estimation can be used. See the section “Linear Tests” on page 6844 for details.

## Model Selection

For MM estimation, the same two model selection methods used for M estimation can be used. See the section “Model Selection” on page 6844 for details.

## Robust Distance

The ROBUSTREG procedure uses the robust multivariate location and scatter estimates for leverage-point detection. The procedure computes a robust version of the Mahalanobis distance by using a generalized minimum covariance determinant (MCD) method. The original MCD method was proposed by Rousseeuw (1984).

## Algorithm

PROC ROBUSTREG implements a generalized MCD algorithm based on the fast-MCD algorithm formulated by Rousseeuw and Van Driessen (1999), which is similar to the algorithm for least trimmed squares (LTS).

## Mahalanobis Distance versus Robust Distance

The canonical Mahalanobis distance is defined as

$$\text{MD}(\mathbf{x}_i) = [(\mathbf{x}_i - \bar{\mathbf{x}})' \bar{\mathbf{C}}(\mathbf{X})^{-1} (\mathbf{x}_i - \bar{\mathbf{x}})]^{1/2}$$

where  $\bar{\mathbf{x}} = \frac{1}{n} \sum_{i=1}^n \mathbf{x}_i$  and  $\bar{\mathbf{C}}(\mathbf{X}) = \frac{1}{n-1} \sum_{i=1}^n (\mathbf{x}_i - \bar{\mathbf{x}})' (\mathbf{x}_i - \bar{\mathbf{x}})$  are the empirical multivariate location and scatter, respectively. Here  $\mathbf{x}_i = (x_{i1}, \dots, x_{ip})'$  excludes the intercept. The relation between the Mahalanobis distance  $\text{MD}(\mathbf{x}_i)$  and the hat matrix  $\mathbf{H} = (h_{ij}) = \mathbf{X}(\mathbf{X}'\mathbf{X})^{-1}\mathbf{X}'$  is

$$h_{ii} = \frac{1}{n-1} \text{MD}_i^2 + \frac{1}{n}$$

The canonical robust distance is defined as

$$RD(\mathbf{x}_i) = [(\mathbf{x}_i - \mathbf{T}(\mathbf{X}))' \mathbf{C}(\mathbf{X})^{-1} (\mathbf{x}_i - \mathbf{T}(\mathbf{X}))]^{1/2}$$

where  $\mathbf{T}(\mathbf{X})$  and  $\mathbf{C}(\mathbf{X})$  are the robust multivariate location and scatter, respectively, obtained by MCD.

To achieve robustness, the MCD algorithm estimates the covariance of a multivariate data set mainly through an MCD  $h$ -point subset of the data set. This subset has the smallest sample-covariance determinant among all the possible  $h$ -subsets. Accordingly, the breakdown value for the MCD algorithm equals  $\frac{(n-h)}{n}$ . This means the MCD estimate is reliable, even if up to  $\frac{100(n-h)}{n}\%$  observations in the data set are contaminated.

## Low-Dimensional Structure

It is possible that the original data are in  $p$  dimensional space, but the  $h$ -point subset that yields the minimum covariance determinant lies in a lower-dimensional hyperplane. Applying the canonical MCD algorithm to such a data set would result in a singular covariance problem (called exact fit in Rousseeuw and Van Driessen (1999)), so that the relevant robust distances cannot be computed. To deal with the singularity problem and provide further leverage point analysis, PROC ROBUSTREG implements a generalized MCD algorithm. See the section “Generalized MCD Algorithm” on page 6857 for details. The algorithm distinguishes in-(hyper)plane points from off-(hyper)plane points, and performs MCD leverage point analysis in the dimension-reduced space by projecting all points onto the hyperplane.

Low-dimensional structure is often induced by classification covariates. Suppose, in a study with 25 female subjects and 5 male subjects, that *gender* is the only classification effect. If the breakdown setting is larger than  $\frac{5}{(25+5)}$ , the canonical MCD algorithm fails, and so does the relevant leverage point analysis. In this case, the MCD  $h$ -subset would contain only female observations and the constant gender in the  $h$ -subset would cause the relevant MCD estimate to be singular. The generalized MCD algorithm solves that problem by identifying all male observations as off-plane leverage points, and then carries out the leverage point analysis with all the other covariates being centered separately for female and male groups against their group means.

In general, low-dimensional structure is not necessarily due to classification covariates. Imagine that 80 children are supposed to play on a straight trail (denoted by  $y = x$ ), but some adventurous children go off the trail. The following statements generate the children data and the relevant scatter plot.

```
data children;
 do i=1 to 80;
 off_trail=ranuni(321)>.9;
 x=rannor(111)*ranuni(321);
 trail_x=(i-40)/80*3;
 trail_y=trail_x;
 if off_trail=1 then y=x-1+rannor(321);
 else y=x;
 output;
 end;
run;

proc sgplot data=children;
 series x=trail_x y=trail_y/lineattrs=(color="red" pattern=4);
 scatter x=x y=y/group=off_trail;
 ellipse x=x y=y/alpha=.05 lineattrs=(color="green" pattern=34);
run;
```

Figure 80.17 shows the positions of all the 80 children, the trail (as a red dashed line), and a contour curve of regular Mahalanobis distance centered at the mean position (as a green dotted ellipse). In terms of regular Mahalanobis distance, the associated covariance estimate is not singular, but its relevant leverage point analysis completely ignores the trail (which is the entity of the low-dimensional structure). The children outside of the ellipse are defined as leverage points, but the children off the trail would not be viewed as leverage points unless they have large Mahalanobis distances. As mentioned in Rousseeuw and Van Driessen (1999), the canonical MCD method can find the low-dimensional structure, but it does not provide further robust covariance estimation because the MCD covariance estimate is singular. As an improved version of the canonical MCD method, the generalized MCD method can find the trail, identify the children off the trail as off-plane leverage points, and further execute in-plane leverage analysis. The following statements apply the generalized MCD algorithm on the children data set.

```
ods graphics on;
proc robustreg data=children plots=ddplot(label=none);
 model i = x y/leverage(mcdinfo opc);
run;
ods graphics off;
```

**Figure 80.17** Scatter Plot for Children Data

Figure 80.18 exactly identifies the equation underlying the trail. The analysis projects off-plane points onto the trail and computes their projected robust distances and projected Mahalanobis distances the same way as is done for the in-plane points.

**Figure 80.18** Robust Dependence Equations

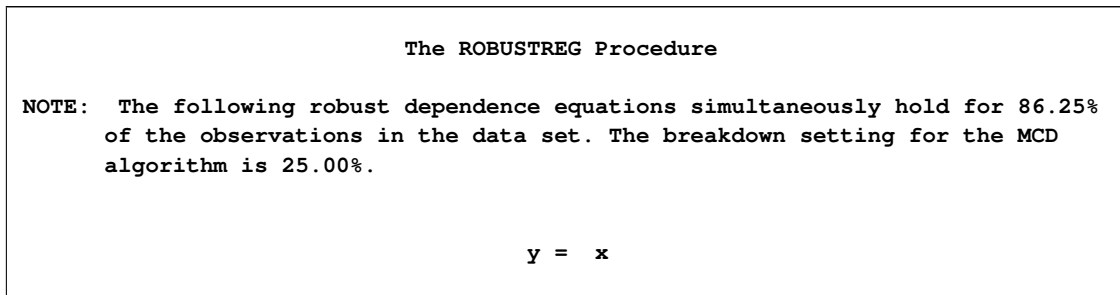

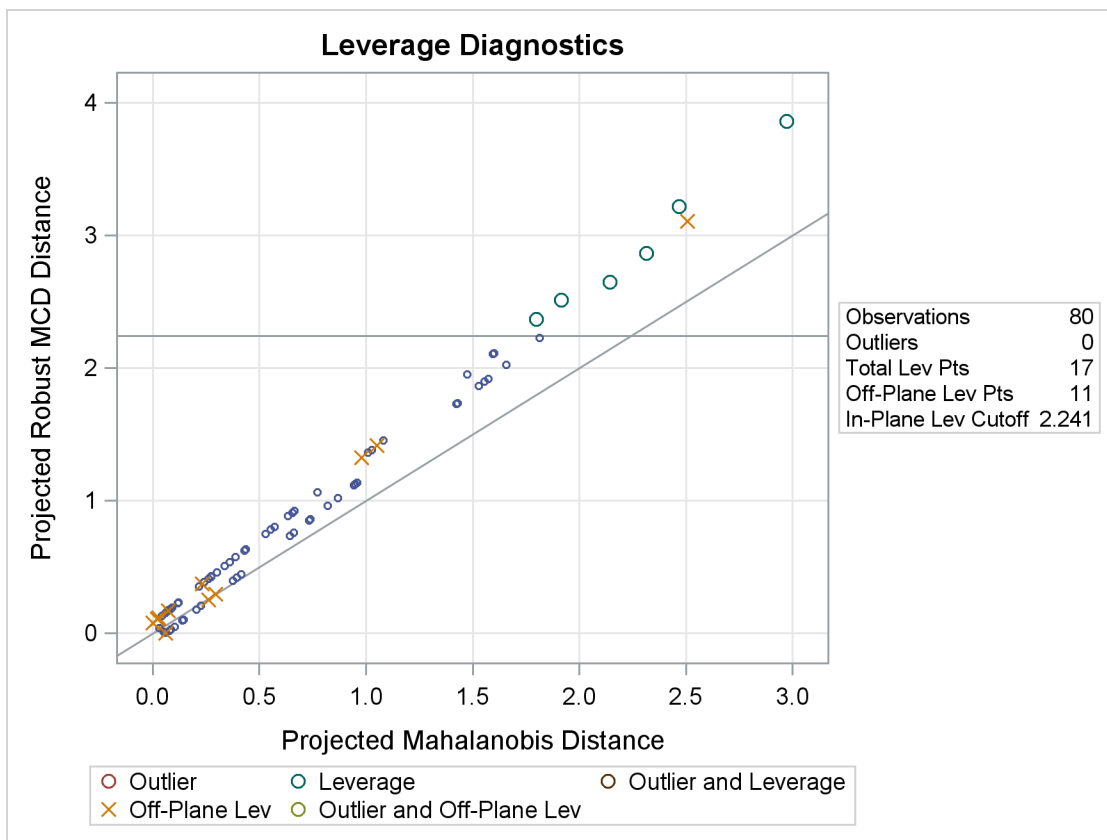

Figure 80.19 shows the relevant distance-distance plot. Robust distance is typically larger than Mahalanobis distance because the sample covariance can be strongly influenced by unusual points that cause the sample covariance to be larger than the MCD covariance.

**Figure 80.19** DDPlot for Children Data

**NOTE:** The PROC ROBUSTREG step in this example is used to obtain the leverage diagnostics; the response is not relevant for this analysis.

Through the off-plane and in-plane symbols and the horizontal cutoff line in Figure 80.19, you can separate all the children into four groups:

- on-trail and close to the MCD center

- on-trail but far away from the MCD center
- off-trail but close to the MCD center
- off-trail and far away from the MCD center

The children in the latter three groups are defined as leverage points in PROC ROBUSTREG.

### Generalized MCD Algorithm

The generalized MCD algorithm follows the same resampling strategy as the canonical MCD algorithm by Rousseeuw and Van Driessen (1999) but with modifications in the following aspects.

1. Data are orthonormalized before further processing. The orthonormalized covariates,  $\mathbf{x}_i^*$ , are defined by  $\mathbf{x}_i^* = (\mathbf{x}_i - \bar{\mathbf{x}})\mathbf{P}\mathbf{\Lambda}^{-1/2}$ , where  $\mathbf{P}$  and  $\mathbf{\Lambda}$  are the eigenvector and eigenvalue matrices of  $\bar{\mathbf{C}}(\mathbf{X})$  (that is,  $\bar{\mathbf{C}}(\mathbf{X}) = \mathbf{P}\mathbf{\Lambda}\mathbf{P}'$ ).
2. Let

$$S_h(\mathbf{X}^*) = \frac{1}{h-1} \sum_{j=1}^h (\mathbf{x}_{i_j}^* - \bar{\mathbf{x}}^*)' (\mathbf{x}_{i_j}^* - \bar{\mathbf{x}}^*) = \sum_{j=1}^{p-1} \lambda_j \mathbf{p}_j \mathbf{p}_j'$$

denote the covariance and eigendecomposition for a low-dimensional  $h$ -subset  $\{\mathbf{x}_{i_1}^*, \dots, \mathbf{x}_{i_h}^*\}$ , where  $\bar{\mathbf{x}}^* = \frac{1}{h} \sum_{j=1}^h \mathbf{x}_{i_j}^*$  and the eigenvalues satisfy

$$\lambda_1 \geq \dots \geq \lambda_q > 0 = \lambda_{q+1} = \dots = \lambda_p$$

Then, the rank of  $S_h(\mathbf{X}^*)$  equals  $q$ , and the pseudo-determinant of  $S_h(\mathbf{X}^*)$  is defined as  $\prod_{j=1}^q \lambda_j$ .

In finite precision arithmetic,  $q$  is defined as the number of  $\lambda$ 's with  $\frac{\lambda_i}{\lambda_1}$  being larger than a certain tolerance value. You can specify this tolerance with the PTOL suboption of the LEVERAGE option.

3. Given  $S_h(\mathbf{X}^*)$  and  $\bar{\mathbf{x}}^*$  as the covariance and center estimates, the projected Mahalanobis distance for  $\mathbf{x}_i$  is defined as

$$\left[ \sum_{j=1}^q \frac{((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2}{\lambda_j} \right]^{1/2}$$

The generalized algorithm also computes off-plane distance for each  $\mathbf{x}_i$  as

$$\left[ \sum_{j=q+1}^p ((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2 \right]^{1/2}$$

In finite precision arithmetic,  $((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2$  in the previous off-plane formula are truncated to zero if they satisfy

$$\frac{((\mathbf{x}_i^* - \bar{\mathbf{x}}^*)\mathbf{p}_j)^2}{\lambda_j} \leq \text{cutoff}$$

You can tune this cutoff by using either the PCUTOFF or the PALPHA suboption of the LEVERAGE option. The points with zero off-plane distances are called in-plane points; otherwise, they are called off-plane points. Analogous to ordering all points in terms of their canonical Mahalanobis distances, with the generalized MCD algorithm the points are first sorted by their off-plane distances, and the points with the same off-plane distance values are further sorted by their projected Mahalanobis distances.

4. Instead of comparing the determinants of  $h$ -subset covariance matrices, the generalized algorithm compares both the ranks and pseudo-determinants of the  $h$ -subset covariance matrices. If the ranks of two matrices are different, the matrix with smaller rank is treated as if its determinant were smaller. If two matrices are of the same rank, they are compared in terms of their pseudo-determinants.
5. Suppose that the  $S_h(\mathbf{X}^*)$  of the minimum determinant is singular. Then the relevant low-dimensional structure or hyperplane can be identified by using the eigendecomposition of  $S_h(\mathbf{X}^*)$ . The eigenvectors that correspond to the nonzero eigenvalues form a basis for the low-dimensional hyperplane. The projected off-plane distance (POD) for  $\mathbf{x}_i$  is defined as the off-plane distance associated with the  $S_h(\mathbf{X}^*)$ . To provide further leverage analysis on the low-dimensional hyperplane, every  $\mathbf{x}_i^*$  is transformed into  $(\mathbf{x}_i^* \mathbf{p}_1, \dots, \mathbf{x}_i^* \mathbf{p}_q)$ , where  $\mathbf{p}_j$  are the eigenvectors of the  $S_h(\mathbf{X}^*)$ . The projected robust distance (PRD) is then computed as the reweighted Mahalanobis distance on all the transformed in-plane points. The off-plane points are assigned zero weights at the reweighting stage, because they are leverage points by definition. The in-plane points are classified into two groups, the normal group and the in-plane leverage group. This classification is made by comparing their projected robust distances with a leverage cutoff value. See the section “Leverage Point and Outlier Detection” on page 6860 for details. This reweighting process mirrors the one proposed by Rousseeuw and Van Driessen (1999). However, the degrees of freedom  $p$  for the reweighting critical  $\chi^2$  value is replaced by  $q$ . You can control the  $\chi^2$  critical value with the MDCUTOFF= or the MCDALPHA= option.

If the data set under investigation has a low-dimensional structure, you can use two ODS objects, DependenceEquations and MCDDependenceEquations, to identify the regressors that are linear combinations of other regressors plus certain constants. The equations in DependenceEquations hold for the entire data set, while the equations in MCDDependenceEquations apply only to the majority of the observations.

By using the OPC suboption of the LEVERAGE option, you can request an ODS table called DroppedComponents. Figure 80.20 shows the DroppedComponents table for the children data example. This table contains a set of coefficient vectors for regressors, which form a basis of the complementary space for the relevant low-dimensional structure.

**Figure 80.20** MCD Dropped Components

| Coefficients for<br>MCD-Dropped<br>Components |                 |
|-----------------------------------------------|-----------------|
| Parameter                                     | Robust<br>Drop1 |
| x                                             | -1.000          |
| y                                             | 1.0000          |

By using the MCDINFO suboption of the LEVERAGE option, you can request that detailed information about the MCD covariance estimate be displayed in four ODS tables: MCDProfile, MCDCenter, MCD Cov, and MCDCorr. Figure 80.21 shows an example of the MCD information tables for the children data. The number of dimensions in the table MCDProfile equals the number of nonintercept regressors minus the number of design dropped components. The specified value of H is the same as  $h$  for the  $h$ -subset that you can specify with the QUANTILE= suboption of the LEVERAGE option in the MODEL statement, and the reweighted H is the number of observations that are actually used to compute the MCD center and MCD covariance after the reweighting step of the MCD algorithm.

**Figure 80.21** MCD Information

| MCD Profile                         |  |  |        |
|-------------------------------------|--|--|--------|
| Number of Dimensions                |  |  | 2      |
| Number of Robust Dropped Components |  |  | 1      |
| Number of Observations              |  |  | 80     |
| Number of Off-Plane Observations    |  |  | 11     |
| Specified Value of H                |  |  | 60     |
| Reweighted Value of H               |  |  | 63     |
| Breakdown Value                     |  |  | 0.2500 |

| MCD Center     |           |        |  |
|----------------|-----------|--------|--|
| Parameter Name | Parameter | Center |  |
| x              | x         | 0.0307 |  |
| y              | y         | 0.0307 |  |

| MCD Covariance |  |          |          |
|----------------|--|----------|----------|
|                |  | x        | y        |
| x              |  | 0.207713 | 0.207713 |
| y              |  | 0.207713 | 0.207713 |

| MCD Correlation |  |   |   |
|-----------------|--|---|---|
|                 |  | x | y |
| x               |  | 1 | 1 |
| y               |  | 1 | 1 |

## Leverage Point and Outlier Detection

The regular variable LEVERAGE is defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } \text{RD}(\mathbf{x}_i) \leq C(p) \\ 1 & \text{otherwise} \end{cases}$$

where  $C(p) = \sqrt{\chi_{p;1-\alpha}^2}$  is the cutoff value.  $C(p)$  can be set with the leverage CUTOFF= option, and  $\alpha$  can be set with the leverage CUTOFFALPHA= option.

If projected robust distances are computed for a data set that has a low-dimensional structure, the default cutoff value is  $C(q) = \sqrt{\chi_{q;1-\alpha}^2}$  where  $q$  is the dimensionality of the low-dimensional space. The LEVERAGE is then defined as

$$\text{LEVERAGE} = \begin{cases} 0 & \text{if } \text{POD}(\mathbf{x}_i) = 0 \text{ and } \text{PRD}(\mathbf{x}_i) \leq C(q) \\ 1 & \text{if } \text{POD}(\mathbf{x}_i) = 0 \text{ and } \text{PRD}(\mathbf{x}_i) > C(q) \text{ (called in-plane leverage)} \\ 1 & \text{if } \text{POD}(\mathbf{x}_i) > 0 \text{ (called off-plane leverage)} \end{cases}$$

where POD is the projected off-plane distance and PRD denotes the projected robust distance. You can specify a cutoff value with the CUTOFF or the CUTOFFALPHA suboptions of the LEVERAGE option in the MODEL statement.

Residuals  $r_i, i = 1, \dots, n$ , based on robust regression estimates are used to detect vertical outliers. The variable OUTLIER is defined as

$$\text{OUTLIER} = \begin{cases} 0 & \text{if } |r_i| \leq k\hat{\sigma} \\ 1 & \text{otherwise} \end{cases}$$

where  $\hat{\sigma}$  is the estimated scale in the model and the multiplier  $k$  of the cutoff value is specified by the CUTOFF= option in the MODEL statement. By default,  $k = 3$ .

An ODS table called Diagnostics contains the LEVERAGE and OUTLIER variables.

## Implementation of the WEIGHT Statement

You can use the WEIGHT statement to specify a weight variable in the input data set. See the section “WEIGHT Statement” on page 6838 for more information. This section describes how PROC ROBUSTREG implements the WEIGHT statement for each of the estimation methods and for leverage detection.

### M Estimation

If you use M estimation with a known scale, instead of minimizing  $Q(\boldsymbol{\theta}) = \sum_{i=1}^n \rho\left(\frac{r_i}{\sigma}\right)$ , the weighted M estimation minimizes the weighted Huber-type objective function

$$Q(\boldsymbol{\theta}) = \sum_{i=1}^n v_i \rho\left(\frac{r_i}{\sigma}\right),$$

where  $v$  is the weight variable specified by the WEIGHT statement. If you use M estimation with an unknown scale, the weight variable is used in the location steps but not in the scale steps. See the section “M Estimation” on page 6838 and the SCALE= option for more details. For estimating the covariance of the weighted M estimation,  $\psi(r_i)$  and  $\psi'(r_i)$  are obtained from the final iteration of the weighted M estimation, and  $\mathbf{X}'\mathbf{X}$  and  $\mathbf{W}$  are respectively replaced by  $\mathbf{X}'\mathbf{V}\mathbf{X}$  and  $W_{jk} = \sum v_i \psi'(r_i) x_{ij} x_{ik}$ , where  $\mathbf{V}$  is a diagonal matrix with its diagonal elements being  $v_i$ 's. See the section “Asymptotic Covariance and Confidence Intervals” on page 6843 for more information. The weight variable does not affect the model degrees of freedom  $p$  and the error degrees of freedom  $n - p$ .

## LTS Estimation

LTS estimation ignores the weight variable.

## S Estimation

S estimation applies the weight variable only in its M-refinement step. Except for the initial estimates, the M-refinement step of S estimation is the same as the weighted M estimation with unknown scale. If you use the NOREFINE suboption, S estimation ignores the weight variable along with the M-refinement step.

## MM Estimation

By default, the initial step of MM estimation is the initial LTS estimation. Unlike the regular LTS estimation, the initial LTS estimation is applied on the weighted data  $(y_i^*, \mathbf{x}_i^*)$ 's, where  $y_i^* = \sqrt{v_i} y_i$  and  $\mathbf{x}_i^* = \sqrt{v_i} \mathbf{x}_i$ . After the initial LTS estimation, the weight variable is ignored for the subsequent scale adjustment.

You can use INITEST=S to specify the initial S estimation as the initial step of the MM estimation. Similarly to the regular S estimation, the weight variable is used only in the M-refinement step of the initial S estimation. There is no subsequent scale adjustment step if the initial S estimation is applied.

Except for the initial estimates, the final M estimation of the MM estimation is the same as the weighted M estimation with known scale.

## Final Weighted Least Squares Estimation

Final weighted least squares estimation is always applied on the weighted data  $(y_i^*, \mathbf{x}_i^*)$  no matter how the weight variable is applied in the preceding estimation. For example, if the option METHOD=LTS is specified along with the option FWLS, although the outliers identified by LTS estimation do not depend on the weight variable, final weighted least squares estimation applies the weight variable on all the points that are not outliers.

## Robust Distances and Leverage Detection

Robust distance computation ignores the weight variable. Because leverage detection depends on robust distance, it also ignores the weight variable.

---

## INEST= Data Set

When you use M or MM estimation, you can use the INEST= data set to specify initial estimates for all the parameters in the model. The INEST= option is ignored if you specify LTS or S estimation by using the

METHOD=LTS or METHOD=S option or if you specify the INITEST= option after the METHOD=MM option in the PROC ROBUSTREG statement. The INEST= data set must contain the intercept variable (named Intercept) and all independent variables in the MODEL statement.

If BY processing is used, the INEST= data set should also include the BY variables, and there must be at least one observation for each BY group. If there is more than one observation in a BY group, the first one read is used for that BY group.

If the INEST= data set also contains the \_TYPE\_ variable, only observations with \_TYPE\_ value “PARMS” are used as starting values.

You can specify starting values for the iteratively reweighted least squares algorithm in the INEST= data set. The INEST= data set has the same structure as the OUTEST= data set but is not required to have all the variables or observations that appear in the OUTEST= data set. One simple use of the INEST= option is passing the previous OUTEST= data set directly to the next model as an INEST= data set, assuming that the two models have the same parameterization.

## OUTEST= Data Set

The OUTEST= data set contains parameter estimates for the model. You can specify a label in the MODEL statement to distinguish between the estimates for different models used by the ROBUSTREG procedure. If the COVOUT option is specified, the OUTEST= data set also contains the estimated covariance matrix of the parameter estimates. If the ROBUSTREG procedure does not converge, the parameter estimates are set to missing in the OUTEST data set.

The OUTEST= data set contains all variables specified in the MODEL statement and the BY statement. One observation consists of parameter values for the model with the dependent variable having the value  $-1$ . If the COVOUT option is specified, there are additional observations that contain the rows of the estimated covariance matrix. For these observations, the dependent variable contains the parameter estimate for the corresponding row variable. The following variables are also added to the data set:

|                        |                                                                                                                                                                  |
|------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_MODEL_</code>   | is a character variable that contains the label of the MODEL statement, if present. Otherwise, the variable's value is blank.                                    |
| <code>_NAME_</code>    | is a character variable that contains the name of the dependent variable for the parameter estimates or the name of the row for the covariance matrix estimates. |
| <code>_TYPE_</code>    | is a character variable that contains the type of the observation, either PARMS for parameter estimates or COV for covariance estimates.                         |
| <code>_METHOD_</code>  | is a character variable that contains the type of estimation method: either M estimation, LTS estimation, S estimation, or MM estimation.                        |
| <code>_STATUS_</code>  | is a character variable that contains the status of model fitting: either Converged, Warning, or Failed.                                                         |
| <code>INTERCEPT</code> | is a numeric variable that contains the intercept parameter estimates and covariances.                                                                           |
| <code>_SCALE_</code>   | is a numeric variable that contains the scale parameter estimates.                                                                                               |

Any BY variables specified are also added to the OUTEST= data set.

## Computational Resources

The algorithms for the various estimation methods need a different amount of memory for working space. Let  $p$  be the number of parameters estimated and  $n$  be the number of observations used in the model estimation.

For M estimation, the minimum working space (in bytes) needed is

$$3n + 2p^2 + 30p$$

If sufficient space is available, the input data set is also kept in memory; otherwise, the input data set is read again for computing the iteratively reweighted least squares estimates and the execution time of the procedure increases substantially. For each reweighted least squares,  $O(np^2 + p^3)$  multiplications and additions are required for computing the crossproduct matrix and its inverse. The  $O(v)$  notation means that, for large values of the argument,  $v$ ,  $O(v)$  is approximately a constant times  $v$ .

Since the iteratively reweighted least squares algorithm converges very quickly (normally within fewer than 20 iterations), the computation of M estimates is fast.

LTS estimation is more expensive in computation. The minimum working space (in bytes) needed is

$$np + 12n + 4p^2 + 60p$$

The memory is mainly used to store the current data used by LTS for modeling. The LTS algorithm uses subsampling and spends much of its computing time on resampling and computing estimates for subsamples. Since it resamples if singularity is detected, it might take more time if the data set has serious singularities.

The MCD algorithm for leverage-point diagnostics is similar to the LTS algorithm.

## ODS Table Names

The ROBUSTREG procedure assigns a name to each table it creates. You can specify these names when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in the following table.

**Table 80.12** ODS Tables Produced by PROC ROBUSTREG

| ODS Table Name      | Description                           | Statement | Option      |
|---------------------|---------------------------------------|-----------|-------------|
| BestEstimates       | Best final estimates for LTS          | PROC      | SUBANALYSIS |
| BestSubEstimates    | Best estimates for each subgroup      | PROC      | SUBANALYSIS |
| BiasTest            | Bias test for MM estimation           | PROC      | BIATEST     |
| ClassLevels         | Classification variable levels        | CLASS     | Default     |
| CorrB               | Parameter estimate correlation matrix | MODEL     | CORRB       |
| CovB                | Parameter estimate covariance matrix  | MODEL     | COVB        |
| CStep               | C-step for LTS fitting                | PROC      | SUBANALYSIS |
| DependenceEquations | Design dependence equations           | MODEL     | LEVERAGE    |
| Diagnostics         | Outlier diagnostics                   | MODEL     | DIAGNOSTICS |

Table 80.12 (continued)

| ODS Table Name         | Description                             | Statement | Option             |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

If the model includes a single continuous independent variable, a plot of robust fit against this variable (FITPLOT) is provided by default. Two plots are particularly useful in revealing outliers and leverage points. The first is a scatter plot of the standardized robust residuals against the robust distances (RDPLOT). The second is a scatter plot of the robust distances against the classical Mahalanobis distances (DDPLOT). In addition to these two plots, a histogram and a quantile-quantile plot of the standardized robust residuals are also helpful.

PROC ROBUSTREG assigns a name to each graph it creates using ODS. You can use these names to refer to the graphs when using ODS. The names and PLOTS= options are listed in [Table 80.13](#).

**Table 80.13** Graphs Produced by PROC ROBUSTREG

| ODS Graph Name | Plot Description                                                                                                 | Statement | PLOTS= Option |
|----------------|------------------------------------------------------------------------------------------------------------------|-----------|---------------|
| DDPlot         | Robust distance versus Mahalanobis distance (or projected robust distance versus Projected Mahalanobis distance) | PROC      | DDPLOT        |
| FitPlot        | Robust fit versus independent variable                                                                           | PROC      | FITPLOT       |
| Histogram      | Histogram of standardized robust residuals                                                                       | PROC      | HISTOGRAM     |

## Fit Plot

When the model has a single independent continuous variable (with or without the intercept), the ROBUSTREG procedure automatically creates a plot of robust fit against this independent variable.

The following simple example shows the fit plot. The data, from Rousseeuw and Leroy (1987, Table 3), include the logarithm of surface temperature and the logarithm of light intensity for 47 stars in the direction of the constellation Cygnus.

```
data star;
 input index x y @@;
 label x = 'Log Temperature'
 y = 'Log Light Intensity';
 datalines;
 1 4.37 5.23 2 4.56 5.74 3 4.26 4.93 4 4.56 5.74
 5 4.30 5.19 6 4.46 5.46 7 3.84 4.65 8 4.57 5.27
 9 4.26 5.57 10 4.37 5.12 11 3.49 5.73 12 4.43 5.45
 13 4.48 5.42 14 4.01 4.05 15 4.29 4.26 16 4.42 4.58
 17 4.23 3.94 18 4.42 4.18 19 4.23 4.18 20 3.49 5.89
 21 4.29 4.38 22 4.29 4.22 23 4.42 4.42 24 4.49 4.85
 25 4.38 5.02 26 4.42 4.66 27 4.29 4.66 28 4.38 4.90
 29 4.22 4.39 30 3.48 6.05 31 4.38 4.42 32 4.56 5.10
 33 4.45 5.22 34 3.49 6.29 35 4.23 4.34 36 4.62 5.62
 37 4.53 5.10 38 4.45 5.22 39 4.53 5.18 40 4.43 5.57
 41 4.38 4.62 42 4.45 5.06 43 4.50 5.34 44 4.45 5.34
 45 4.55 5.54 46 4.45 4.98 47 4.42 4.50
 ;
```

The following statements plot the robust fit of the logarithm of light intensity with the MM method against the logarithm of the surface temperature.

```
ods graphics on;

proc robustreg data=star method=mm;
 model y = x;
run;
```

Figure 80.22 shows the fit plot. Confidence limits are added on the plot by default.

Figure 80.22 Robust Fit

You can suppress the confidence limits with the NOLIMITS option, as shown in the following statements:

```
proc robustreg data=star method=mm plot=fitplot(nolimits);
 model y = x;
run;
```

### Distance-Distance Plot

The distance-distance plot (DDPLOT) is mainly used for leverage-point diagnostics. It is a scatter plot of the robust distances (or projected robust distances) against the classical Mahalanobis distances (or projected classical Mahalanobis distances) for the independent variables. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details about the robust distance.

You can use the PLOT=DDPLOT option to request this plot. The following statements use the stack data set in the section “[M Estimation](#)” on page 6811 to create the single plot shown in [Figure 80.5](#).

```
proc robustreg data=stack plot=ddplot;
 model y = x1 x2 x3;
run;
```

The reference lines represent the cutoff values. The diagonal line is also drawn to show the distribution of the distances. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in [Table 80.2](#).

If you specify ID variables in the ID statement, the values of the first ID variable instead of observation numbers are used as labels.

## Residual-Distance Plot

The residual-distance plot (RDPLOT) is used for both outlier and leverage-point diagnostics. It is a scatter plot of the standardized robust residuals against the robust distances. See the section “[Leverage Point and Outlier Detection](#)” on page 6860 for details about the robust distance.

You can use the PLOT=RDPLOT option to request this plot. The following statements use the stack data set in the section “[M Estimation](#)” on page 6811 to create the plot shown in [Figure 80.4](#).

```
proc robustreg data=stack plot=rdplot;
 model y = x1 x2 x3;
run;
```

The reference lines represent the cutoff values. By default, all outliers and leverage points are labeled with observation numbers. To change the default, you can use the LABEL= option as described in [Table 80.2](#).

If you specify ID variables in the ID statement, the values of the first ID variable instead of observation numbers are used as labels.

## Histogram and Q-Q Plot

PROC ROBUSTREG produces a histogram and a Q-Q plot for the standardized robust residuals. The histogram is superimposed with a normal density curve and a kernel density curve. Using the stack data set in the section “[M Estimation](#)” on page 6811, the following statements create the plots in [Figure 80.6](#) and [Figure 80.7](#).

```
proc robustreg data=stack plots=(histogram qqplot);
 model y = x1 x2 x3;
run;
```

---

## Examples: ROBUSTREG Procedure

---

### Example 80.1: Comparison of Robust Estimates

This example contrasts several of the robust methods available in the ROBUSTREG procedure.

The following statements generate 1,000 random observations. The first 900 observations are from a linear model, and the last 100 observations are significantly biased in the  $y$ -direction. In other words, 10% of the observations are contaminated with outliers.

```
data a (drop=i);
 do i=1 to 1000;
 x1=rannor(1234);
 x2=rannor(1234);
 e=rannor(1234);
 if i > 900 then y=100 + e;
 else y=10 + 5*x1 + 3*x2 + .5 * e;
 output;
 end;
run;
```

The following statements invoke PROC REG and PROC ROBUSTREG with the data set a.

```
proc reg data=a;
 model y = x1 x2;
run;

proc robustreg data=a method=m;
 model y = x1 x2;
run;

proc robustreg data=a method=mm seed=100;
 model y = x1 x2;
run;

proc robustreg data=a method=s seed=100;
 model y = x1 x2;
run;

proc robustreg data=a method=lts seed=100;
 model y = x1 x2;
run;
```

The tables of parameter estimates generated by using M estimation, MM estimation, S estimation, and LTS estimation in the ROBUSTREG procedure are shown in [Output 80.1.2](#), [Output 80.1.3](#), [Output 80.1.4](#), and [Output 80.1.5](#), respectively. For comparison, the ordinary least squares (OLS) estimates produced by the REG procedure (Chapter 79, “The REG Procedure”) are shown in [Output 80.1.1](#). The four robust methods, M, MM, S, and LTS, correctly estimate the regression coefficients for the underlying model (10, 5, and 3), but the OLS estimate does not.

The next statements demonstrate that if the percentage of contamination is increased to 40%, the M method and the MM method with default options fail to estimate the underlying model. [Output 80.1.6](#) and [Output 80.1.7](#) display these estimates. However, by tuning the constant  $c$  for the M method and the constants INITH and K0 for the MM method, you can increase the breakdown values of the estimates and capture the right model. [Output 80.1.8](#) and [Output 80.1.9](#) display these estimates. Similarly, you can tune the constant EFF for the S method and the constant H for the LTS method and correctly estimate the underlying model with these methods. Results are not presented.

When there are bad leverage points, the M method fails to estimate the underlying model no matter what constant  $c$  you use. In this case, other methods (LTS, S, and MM) in PROC ROBUSTREG, which are robust to bad leverage points, correctly estimate the underlying model.

The following statements generate and analyze 1,000 observations with 1% bad high leverage points.

```
data c (drop=i);
 do i=1 to 1000;
 x1=rannor(1234);
 x2=rannor(1234);
 e=rannor(1234);
 if i > 600 then y=100 + e;
 else y=10 + 5*x1 + 3*x2 + .5 * e;
 if i < 11 then x1=200 * rannor(1234);
 if i < 11 then x2=200 * rannor(1234);
 if i < 11 then y= 100*e;
 output;
 end;
run;

proc robustreg data=c method=mm(inith=502 k0=1.8) seed=100;
 model y = x1 x2;
run;

proc robustreg data=c method=s(k0=1.8) seed=100;
 model y = x1 x2;
run;
```

```
proc robustreg data=c method=lts(h=502) seed=100;
 model y = x1 x2;
run;
```

Output 80.1.10 displays the MM estimates with initial LTS estimates, Output 80.1.11 displays the S estimates, and Output 80.1.12 displays the LTS estimates.

**Example 80.2: Robust ANOVA**

The classical analysis of variance (ANOVA) technique based on least squares assumes that the underlying experimental errors are normally distributed. However, data often contain outliers due to recording or other errors. In other cases, extreme responses occur when control variables in the experiments are set to extremes. It is important to distinguish these extreme points and determine whether they are outliers or important extreme cases. You can use the ROBUSTREG procedure for robust analysis of variance based on M estimation. Typically, there are no high leverage points in a well-designed experiment, so M estimation is appropriate.

The following example shows how to use the ROBUSTREG procedure for robust ANOVA.

An experiment was carried out to study the effects of two successive treatments (T1, T2) on the recovery time of mice with certain diseases. Sixteen mice were randomly assigned into four groups for the four different combinations of the treatments. The recovery times (time) were recorded (in hours) as shown in the following data set recover.

```
data recover;
 input T1 $ T2 $ time @@;
 datalines;
0 0 20.2 0 0 23.9 0 0 21.9 0 0 42.4
1 0 27.2 1 0 34.0 1 0 27.4 1 0 28.5
0 1 25.9 0 1 34.5 0 1 25.1 0 1 34.2
1 1 35.0 1 1 33.9 1 1 38.3 1 1 39.9
;
```

The following statements invoke the GLM procedure (Chapter 42, “The GLM Procedure”) for a standard ANOVA:

```
proc glm data=recover;
 class T1 T2;
 model time = T1 T2 T1*T2;
run;
```

**Output 80.2.1** Overall ANOVA

| The GLM Procedure        |          |                |             |           |        |

| Dependent Variable: time |          |                |             |           |        |
| Source                   | DF       | Sum of Squares | Mean Square | F Value   | Pr > F |
| Model                    | 3        | 209.9118750    | 69.9706250  | 1.86      | 0.1905 |
| Error                    | 12       | 451.9225000    | 37.6602083  |           |        |
| Corrected Total          | 15       | 661.8343750    |             |           |        |
|                          | R-Square | Coeff Var      | Root MSE    | time Mean |        |
|                          | 0.317167 | 19.94488       | 6.136791    | 30.76875  |        |

**Output 80.2.2** Model ANOVA

| Source | DF | Type I SS   | Mean Square | F Value | Pr > F |
|--------|----|-------------|-------------|---------|--------|
| T1     | 1  | 81.4506250  | 81.4506250  | 2.16    | 0.1671 |
| T2     | 1  | 106.6056250 | 106.6056250 | 2.83    | 0.1183 |
| T1*T2  | 1  | 21.8556250  | 21.8556250  | 0.58    | 0.4609 |

Output 80.2.1 indicates that the overall model effect is not significant at the 10% level, and Output 80.2.2 indicates that neither treatment is significant at the 10% level.

The following statements invoke the ROBUSTREG procedure with the same model:

```
proc robustreg data=recover;
 class T1 T2;
 model time = T1 T2 T1*T2 / diagnostics;
 T1_T2: test T1*T2;

The reason for the difference between the traditional ANOVA and the robust ANOVA is explained by [Output 80.2.5](#), which shows that the fourth observation is an outlier. Further investigation shows that the original value of 24.4 for the fourth observation was recorded incorrectly.

[Output 80.2.6](#) displays the robust test results. The interaction between the two treatments is not significant. [Output 80.2.7](#) displays the robust residuals and standardized robust residuals.

**Example 80.3: Growth Study of De Long and Summers**

Robust regression and outlier detection techniques have considerable applications to econometrics. The following example from Zaman, Rousseeuw, and Orhan (2001) shows how these techniques substantially improve the ordinary least squares (OLS) results for the growth study of De Long and Summers.

De Long and Summers (1991) studied the national growth of 61 countries from 1960 to 1985 by using OLS with the following data set growth.

```
data growth;
 input country $ GDP LFG EQP NEQ GAP @@;
 datalines;
Argentin 0.0089 0.0118 0.0214 0.2286 0.6079
Austria 0.0332 0.0014 0.0991 0.1349 0.5809
Belgium 0.0256 0.0061 0.0684 0.1653 0.4109
Bolivia 0.0124 0.0209 0.0167 0.1133 0.8634
Botswana 0.0676 0.0239 0.1310 0.1490 0.9474

... more lines ...

Venezuel 0.0120 0.0378 0.0340 0.0760 0.4974
Zambia -0.0110 0.0275 0.0702 0.2012 0.8695
Zimbabwe 0.0110 0.0309 0.0843 0.1257 0.8875
;
```

The regression equation they used is

$$\text{GDP} = \beta_0 + \beta_1\text{LFG} + \beta_2\text{GAP} + \beta_3\text{EQP} + \beta_4\text{NEQ} + \epsilon$$

where the response variable is the growth in gross domestic product per worker (GDP) and the regressors are labor force growth (LFG), relative GDP gap (GAP), equipment investment (EQP), and nonequipment investment (NEQ).

The following statements invoke the REG procedure (Chapter 79, “The REG Procedure”) for the OLS analysis:

```
proc reg data=growth;
 model GDP = LFG GAP EQP NEQ;
run;
```

The OLS analysis shown in [Output 80.3.1](#) indicates that GAP and EQP have a significant influence on GDP at the 5% level.

**Output 80.3.1** OLS Estimates

Output 80.3.3 displays the M estimates. Besides GAP and EQP, the robust analysis also indicates that NEQ is significant. This new finding is explained by Output 80.3.4, which shows that Zambia, the 60th country in the data, is an outlier. Output 80.3.4 also identifies leverage points based on the robust MCD distances; however, there are no serious high-leverage points in this data set.

Output 80.3.5 displays robust versions of goodness-of-fit statistics for the model.

**Output 80.3.5** Goodness-of-Fit Statistics

| Goodness-of-Fit |         |
|-----------------|---------|
| Statistic       | Value   |
| R-Square        | 0.3178  |
| AICR            | 80.2134 |
| BICR            | 91.5095 |
| Deviance        | 0.0070  |

The PLOTS=ALL option generates four diagnostic plots. Output 80.3.6 and Output 80.3.7 are for outlier and leverage-point diagnostics. Output 80.3.8 and Output 80.3.9 are a histogram and a Q-Q plot of the standardized robust residuals, respectively.

**Output 80.3.6** RDPLLOT for growth Data

**Output 80.3.7** DDLOT for growth Data

**Output 80.3.8** Histogram

**Output 80.3.9** Q-Q Plot

The following statements invoke the ROBUSTREG procedure with LTS estimation, which was used by Zaman, Rousseeuw, and Orhan (2001). The results are consistent with those of M estimation.

```
proc robustreg method=lts(h=33) fwls data=growth seed=100;
 model GDP = LFG GAP EQP NEQ / diagnostics leverage;
 id country;
run;
```

**Output 80.3.10** LTS Estimates and LTS R Square

| The ROBUSTREG Procedure |    |          |

| Scale                                                    | 0  | 0.0116   |                   |                          |         |                |            |

Output 80.3.12 displays the final weighted least squares estimates, which are identical to those reported in Zaman, Rousseeuw, and Orhan (2001).

## Example 80.4: Constructed Effects

The algorithms of PROC ROBUSTREG assume that a response variable is linearly dependent on the regressors. However, in practice, a response often depends on some factors in a nonlinear manner. This example demonstrates how a nonlinear response-factor relationship can be modeled by using constructed effects. (See the section “EFFECT Statement” on page 393 of Chapter 19, “Shared Concepts and Topics,” for details.)

The following data set contains 526 female observations and 474 male observations sampled from 2003 National Health and Nutrition Examination Survey (NHANES). Each observation is composed of three values: BMI (body mass index), Age, and Gender, measured for subjects whose ages are between 20 and 60.

```
data BMI;

;
```

The goal of this analysis is to evaluate whether the BMI by Age curves are different between women and men at a 5% significance level. In order to provide sufficient flexibility to model the effect of Age on BMI, you can use regression splines that you define with an EFFECT statement. In this example, a regression spline of degree 2 with three knots is used for variable Age. The knots are placed at the 25, 50, and 75 percentiles of Age. This analysis assume that there is no interaction between Gender and Age, so that the BMI by Age curves for women and men are the same up to a constant. The following statements produce the BMI by Age scatter plot shown in Output 80.4.1:

```
proc sort data=bmi;
 by age;
run;

ods graphics on;
proc sgplot data=bmi;
 scatter x=age y=bmi/group=gender;
run;
```

**Output 80.4.1** Scatter Plot for BMI Data

The observations with large BMI values (for example, BMI > 40) are outliers that can substantially influence an ordinary least squares (OLS) analysis. [Output 80.4.1](#) shows that the distributions of BMI conditional on Age are skewed toward the side of large BMI, and there are more observations with large BMI values (outliers) in the female group. Hence you can expect a significant Gender difference in the BMI by Age OLS regression analysis. This expectation is confirmed by the OLS Gender  $p$ -value = 0.0059 in [Output 80.4.2](#), which is produced by the following statements:

```
proc glmselect data=bmi;
 class gender;
 effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
 model bmi = gender age_sp /selection=none showpvalues;
 output out=out_ols P=pred R=res;
run;
```

## Output 80.4.2 OLS Estimates

A robust regression method can reduce the outlier influence by automatically assigning smaller or even zero weights to outliers. For the BMI data, a robust regression method is likely to set less weight on observations with large BMI, so more female observations would receive smaller weights than male observations. The following statements invoke PROC ROBUSTREG with the BMI data set:

```
proc robustreg data=bmi method=s seed=100;
 class gender;
 effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
 model bmi = gender age_sp;
 output out=out_s P=pred R=res;
run;
```

Output 80.4.3 shows the parameter estimates and the diagnostics summary produced by PROC ROBUSTREG with the S method. In contrast to OLS, the robust  $p$ -value=0.5573 of the Gender coefficient indicates that the Gender effect is not significant. The outlier diagnostics based on the S estimates find 19 outliers that are assigned lower weights by the S method than by the OLS method.

## Output 80.4.3 S Estimates and S Diagnostics Summary

| Scale                   | 0   | 6.1715   |                |                       |         |            |            |

| Diagnostics Summary |            |        |
|---------------------|------------|--------|
| Observation Type    | Proportion | Cutoff |
| Outlier             | 0.0190     | 3.0000 |

To further compare the OLS and S outputs, the following statements plot the BMI predictions in variable Age for both methods in the same graph, which is shown in [Output 80.4.4](#):

```

data out2_s;
 set out_s;
 if gender="F" then label="F, S ";
 if gender="M" then label="M, S ";
run;

data out2_ols;
 merge bmi out_ols;
 if gender='F' then label='F, OLS';
 if gender='M' then label='M, OLS';
 keep pred bmi gender age label;
run;

data out2;
 set out2_ols out2_s;
run;

proc sgplot data=out2;
 series x=age y=pred/group=label;
run;

```

Output 80.4.4 OLS and S Predictions

You can observe the following differences between the OLS and S predictions:

- The OLS prediction is larger
- The OLS curves have a local maximum near Age = 35

Then, a question remains: is the significance of the Gender effect for the OLS regression due solely to the outlying observations? To tentatively answer this question, the following statements drop the observations with the top 10% of BMI values from the original data set and reapply OLS and S methods on the reduced data set:

```
data three;
 set bmi;
 where bmi<38.315;
run;

proc robustreg data=three method=s seed=100;
 class gender;
 effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
 model bmi = gender age_sp;
 output out=out_s P=pred R=res;
run;
```

```

data out2_s;
 set out_s;
 if gender="F" then label="F, S ";
 if gender="M" then label="M, S ";
run;

proc glmselect data=three outdesign=four;
 class gender;
 effect Age_Sp=spl(age/degree=2 knotmethod=percentiles(3));
 model bmi = gender age_sp /selection=none showpvalues;
 output out=out_ols P=pred R=res;
run;

data out2_ols;
 merge three out_ols;
 if gender='F' then label='F, OLS';
 if gender='M' then label='M, OLS';
 keep pred bmi gender age label;
run;

data out2;
 set out2_ols out2_s;
run;

proc sgplot data=out2;
 series x=age y=pred/group=label;
run;
ods graphics off;

```

### Output 80.4.5 S Estimates

**Output 80.4.7** OLS and S Predictions on the Reduced Data Set

In the reduced data set, 71 female observations and 29 male observations are dropped. [Output 80.4.5](#) and [Output 80.4.6](#) respectively show the refitted S and OLS parameter estimates, and [Output 80.4.7](#) displays the fitted curves on the reduced data set. You can see that Gender is no longer significant for the OLS model, and the OLS turning pattern has also disappeared, but the new S curves do not change much from the previous ones. The OLS BMI by Age curves in [Output 80.4.7](#) are closer to the S curves than to the OLS curves in [Output 80.4.4](#). This suggests that indeed the difference between the OLS and S estimate results are due solely to the influence of the outlying observations.

## Example 80.5: Robust Diagnostics

This example models the selling price of a house as a function of several covariates. One of these covariates is a classification variable that indicates whether a house is located on a corner lot (called a corner house in this example). Because corner houses are relatively rare, the inclusion of this classification effect in the model introduces a low-dimensional structure (that is, the majority of the observations are located in a lower dimensional hyperplane defined by being non-corner houses) into the design matrix. As discussed in “Robust Distance” on page 6853, the presence of this low dimensional structure causes difficulties in the traditional computation of robust distances. This example illustrates how you can use the projected robust distance to address those difficulties and to obtain meaningful leverage diagnostics. It also shows how you can use the RD PLOT= and DD PLOT= options to illustrate the outlier-leverage relationship.

The following house price data set contains 66 home resale records on seven variables from February 15 to April 30, 1993 (Data and Story Library 2005). The records are randomly selected from the database maintained by the Albuquerque Board of Realtors.

```
data house;
 input price sqft age feats ne cor tax @@;
 label price = "Selling price"
 sqft = "Square feet of living space"
 age = "Age of home in year"
 feats = "Number out of 11 features (dishwasher, refrigerator,
 microwave, disposer, washer, intercom, skylight(s),
 compactor, dryer, handicap fit, cable TV access)"
 ne = "Located in northeast sector of city (1) or not (0)"
 cor = "Corner location (1) or not (0)"
 tax = "Annual taxes";
 sum = sqft+age+feats+ne+cor+tax;
 id = _N_;
 datalines;
2050 2650 13 7 1 0 1639
2150 2664 6 5 1 0 1193
2150 2921 3 6 1 0 1635
1999 2580 4 4 1 0 1732

... more lines ...

870 1273 4 4 0 0 638
869 1165 7 4 0 0 694
766 1200 7 4 0 1 634
739 970 4 4 0 1 541
;
```

To illustrate the dependence detection ability of the generalized MCD algorithm, an extra variable `sum` is created such that all the observations satisfy  $\text{sum} = \text{sqft} + \text{age} + \text{feats} + \text{ne} + \text{cor} + \text{tax}$ . Adding `sum` does not change the rank of the original design matrix, so that `sum` is expected to be ignored in the model and also in the diagnostics. The next statements apply the MM method and the generalized MCD algorithm to the house price data.

```
ods graphics on;
proc robustreg data=house method=MM plots=all;
 model price = sqft age feats ne cor tax sum /
 leverage(opc mcdinfo) diagnostics;
run;
```

As shown in [Output 80.5.1](#) and [Output 80.5.2](#), PROC ROBUSTREG finds the design dependence equation and forces the parameter estimate of variable sum to be zero.

**Output 80.5.1** MM Estimates

| Scale                   | 0  | 157.5593 |                |                       |          |            |            |

**Output 80.5.2** Design Dependence Equations

NOTE: The following variables have been ignored in the MCD computation because of linear dependence.

$$\text{sum} = \text{sqft} + \text{age} + \text{feats} + \text{ne} + \text{cor} + \text{tax}$$

Moreover, PROC ROBUSTREG also identifies a robust dependence equation on cor in [Output 80.5.3](#), which holds for 77.27% of the observations but not for the entire data set.

**Output 80.5.3** Robust Dependence Equations

NOTE: The following robust dependence equations simultaneously hold for 77.27% of the observations in the data set. The breakdown setting for the MCD algorithm is 22.73%.

$$\text{cor} = 0$$

Another way to represent the low-dimensional structure is to specify the coefficients of the MCD-dropped components on the data (see [Output 80.5.4](#)), which form a basis of the complementary space to the relevant low-dimensional hyperplane.

**Output 80.5.4** Coefficients for MCD-Dropped Components

| Coefficients for MCD-Dropped Components |              |              |
|-----------------------------------------|--------------|--------------|
| Parameter                               | Design Drop0 | Robust Drop1 |
| sqft                                    | 0            | 0            |
| age                                     | 0            | 0            |
| feats                                   | 0            | 0            |
| ne                                      | 0            | 0            |
| cor                                     | 0            | 1.0000       |
| tax                                     | 0            | 0            |
| sum                                     | 1.0000       | 0            |

By the definitions of projected robust distance and leverage point, an observation is called an off-plane leverage point if at least one of the robust or design dependence equations does not apply to the observation. In this example, the observations with  $cor = 1$  are all off-plane leverage points. [Output 80.5.5](#) lists the leverage points and outliers along with the relevant distance measurements and standardized residuals.

**Output 80.5.5** Diagnostics

From [Output 80.5.6](#) and [Output 80.5.7](#), you can see that there is no apparent corner-related difference for the houses in terms of standardized robust residual and projected MD versus projected RD, although all the corner houses are defined as off-plane leverage points.

Output 80.5.6 Projected RDPLLOT

Output 80.5.7 Projected DDPLLOT

Output 80.5.8 shows more details of the robust diagnostics. The number of dimensions indicates that six regressors are used in the MCD analysis. Since sum is excluded in model fitting, it is ignored in the MCD analysis. The number of robust dropped components equals 1 due to cor. The number of off-plane points implies the 15 corner-house observations. The reweighted value of H is the number of observations that are finally used to estimate the MCD covariance.

You might speculate that the projected MD and projected RD are equal to the regular MD and RD on the same data set without the variable `cor`. In fact, this is not true. (See [Output 80.5.9](#) and [Output 80.5.10](#) for the RD PLOT and DD PLOT on the data set without `cor`.) When included in the MODEL, `cor` is dropped in the distance calculation, but it is still used for the initial orthonormalization step and the  $h$ -subset searching. In this example, inclusion of `cor` causes all the other covariates to be centered separately for corner houses and non-corner houses. However, without `cor`, the centering process does not distinguish corner houses from non-corner houses, so that the MCD algorithm can still be influenced by `cor` through the correlation between `cor` and other covariates. The following statements drop the variable `cor` and produce the RD PLOT and DD PLOT for the reduced model, which are shown in [Output 80.5.9](#) and [Output 80.5.10](#):

```
proc robustreg data=house method=MM plots=all;
 model price = sqft age feats ne tax/leverage(mcdinfo) diagnostics;
run;
ods graphics off;
```

**Output 80.5.9** RD PLOT for the Reduced Model

**Output 80.5.10** DDPLLOT for the Reduced Model

Compared with [Output 80.5.8](#), [Output 80.5.11](#) shows the changes of the MCD information by removing *cor* from the model. You can see that the corner houses are no longer identified as off-plane points and the reweighted value of *H* is increased from 47 to 52. The breakdown value is intact because it depends only on the specified value of *H* and the total number of observations.

**Output 80.5.11** MCD Information for the Reduced Model

| MCD Profile                         |        |

### Overview: RSREG Procedure

The RSREG procedure uses the method of least squares to fit quadratic response surface regression models. Response surface models are a kind of general linear model in which attention focuses on characteristics of the fit response function and in particular, where optimum estimated response values occur.

In addition to fitting a quadratic function, you can use the RSREG procedure to do the following:

- test for lack of fit
- test for the significance of individual factors
- analyze the canonical structure of the estimated response surface
- compute the ridge of optimum response
- predict new values of the response

The RSREG procedure uses ODS Graphics to display the response surfaces, residuals, fit diagnostics, and ridges of optimum response. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

---

## Comparison to Other SAS Software

Other SAS/STAT procedures can be used to fit the response surface, but the RSREG procedure is more specialized. PROC RSREG uses a much more compact model syntax than other procedures; for example, the following statements model a three-factor response surface in the REG, GLM, and RSREG procedures:

```
proc reg;
 model y=x1 x1*x1
 x2 x1*x2 x2*x2
 x3 x1*x3 x2*x3 x3*x3;
run;

proc glm;
 model y=x1|x2|x3@2;
run;

proc rsreg;
 model y=x1 x2 x3;
run;
```

Additionally, PROC RSREG includes specialized methodology for analyzing the fitted response surface, such as canonical analysis and optimum response ridges.

Note that the ADX Interface in SAS/QC software provides an *interactive* environment for constructing and analyzing many different kinds of experiments, including response surface experiments. The ADX Interface is the preferred interactive SAS System tool for analyzing experiments, since it includes facilities for checking underlying assumptions and graphically optimizing the response surface; see *Getting Started with the SAS ADX Interface for Design of Experiments* for more information. The RSREG procedure is appropriate for analyzing experiments in a batch environment.

---

## Terminology

Variables are referred to according to the following conventions:

|                        |                                                                                                                                                                                                                                                                                               |
|------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| factor variables       | independent variables used to construct the quadratic response surface. To estimate the necessary parameters, each variable must have at least three distinct values in the data. Independent variables must be numeric.                                                                      |
| response variables     | the dependent variables to which the quadratic response surfaces are fit. Dependent variables must be numeric.                                                                                                                                                                                |
| covariates             | additional independent variables for use in the regression but not in the formation of the quadratic response surface. Covariates must be numeric.                                                                                                                                            |
| <b>WEIGHT</b> variable | a variable for weighting the observations in the regression. The <b>WEIGHT</b> variable must be numeric.                                                                                                                                                                                      |
| <b>ID</b> variables    | variables not previously described that are transferred to an output data set containing statistics for each observation in the input data set. This data set is created by using the <b>OUT=</b> option in the PROC RSREG statement. <b>ID</b> variables can be either character or numeric. |
| <b>BY</b> variables    | variables for grouping observations. Separate analyses are obtained for each <b>BY</b> group. <b>BY</b> variables can be either character or numeric.                                                                                                                                         |

---

## Getting Started: RSREG Procedure

### A Response Surface with a Simple Optimum

This example uses the three-factor quadratic model discussed in John (1971). Settings of the temperature, gas–liquid ratio, and packing height are controlled factors in the production of a certain chemical; Schneider and Stockett (1963) performed an experiment in order to determine the values of these three factors that minimize the unpleasant odor of the chemical. The following statements input the SAS data set `smell`; the variable `Odor` is the response, while the variables `T`, `R`, and `H` are the independent factors.

```

title 'Response Surface with a Simple Optimum';
data smell;
 input Odor T R H @@;
 label
 T = "Temperature"
 R = "Gas-Liquid Ratio"
 H = "Packing Height";
 datalines;
66 40 .3 4 39 120 .3 4 43 40 .7 4 49 120 .7 4
58 40 .5 2 17 120 .5 2 -5 40 .5 6 -40 120 .5 6
65 80 .3 2 7 80 .7 2 43 80 .3 6 -22 80 .7 6
-31 80 .5 4 -35 80 .5 4 -26 80 .5 4
;

```

The following statements invoke PROC RSREG on the data set `smell`. Figure 81.1 through Figure 81.3 display the results of the analysis, including a lack-of-fit test requested with the `LACKFIT` option.

```
proc rsreg data=smell;
 model Odor = T R H / lackfit;
run;
```

Figure 81.1 displays the coding coefficients for the transformation of the independent variables to lie between  $-1$  and  $1$ , simple statistics for the response variable, hypothesis tests for linear, quadratic, and crossproduct terms, and the lack-of-fit test. The hypothesis tests can be used to gain a rough idea of importance of the effects; here the crossproduct terms are not significant. However, the lack of fit for the model is significant, so more complicated modeling or further experimentation with additional variables should be performed before firm conclusions are made concerning the underlying process.

**Figure 81.1** Summary Statistics and Analysis of Variance

| Total Error                                       | 5              | 2526.416667           | 505.283333  |         |        |

Parameter estimates and the factor ANOVA are shown in Figure 81.2. Looking at the parameter estimates, you can see that the crossproduct terms are not significantly different from zero, as noted previously. The Estimate column contains estimates based on the raw data, and the Parameter Estimate from Coded Data column contains estimates based on the coded data. The factor ANOVA table displays tests for all four parameters corresponding to each factor—the parameters corresponding to the linear effect, the quadratic effect, and the effects of the crossproducts with each of the other two factors. The only factor with a significant overall effect is R, indicating that the level of noise left unexplained by the model is still too high to estimate the effects of T and H accurately. This might be due to the lack of fit.

**Figure 81.2** Parameter Estimates and Hypothesis Tests

| Parameter | DF | Estimate     | Standard Error | t Value | Pr >  t | Parameter Estimate from Coded Data |
|-----------|----|--------------|----------------|---------|---------|------------------------------------|
| Intercept | 1  | 568.958333   | 134.609816     | 4.23    | 0.0083  | -30.666667                         |
| T         | 1  | -4.102083    | 1.489024       | -2.75   | 0.0401  | -12.125000                         |
| R         | 1  | -1345.833333 | 335.220685     | -4.01   | 0.0102  | -17.000000                         |
| H         | 1  | -22.166667   | 29.780489      | -0.74   | 0.4902  | -21.375000                         |
| T*T       | 1  | 0.020052     | 0.007311       | 2.74    | 0.0407  | 32.083333                          |
| R*T       | 1  | 1.031250     | 1.404907       | 0.73    | 0.4959  | 8.250000                           |
| R*R       | 1  | 1195.833333  | 292.454665     | 4.09    | 0.0095  | 47.833333                          |
| H*T       | 1  | 0.018750     | 0.140491       | 0.13    | 0.8990  | 1.500000                           |
| H*R       | 1  | -4.375000    | 28.098135      | -0.16   | 0.8824  | -1.750000                          |
| H*H       | 1  | 1.520833     | 2.924547       | 0.52    | 0.6252  | 6.083333                           |

| Factor | DF | Sum of Squares | Mean Square | F Value | Pr > F | Label            |
|--------|----|----------------|-------------|---------|--------|------------------|
| T      | 4  | 5258.016026    | 1314.504006 | 2.60    | 0.1613 | Temperature      |
| R      | 4  | 11045          | 2761.150641 | 5.46    | 0.0454 | Gas-Liquid Ratio |
| H      | 4  | 3813.016026    | 953.254006  | 1.89    | 0.2510 | Packing Height   |

Figure 81.3 displays the canonical analysis and eigenvectors. The canonical analysis indicates that the directions of principal orientation for the predicted response surface are along the axes associated with the three factors, confirming the small interaction effect in the regression ANOVA (Figure 81.1). The largest eigenvalue (48.8588) corresponds to the eigenvector (0.238091, 0.971116, -0.015690), the largest component of which (0.971116) is associated with R; similarly, the second-largest eigenvalue (31.1035) is associated with T. The third eigenvalue (6.0377), associated with H, is quite a bit smaller than the other two, indicating that the response surface is relatively insensitive to changes in this factor. The coded form of the canonical analysis indicates that the estimated response surface is at a minimum when T and R are both near the middle of their respective ranges (that is, the coded critical values for T and R are both near 0) and H is relatively high; in uncoded terms, the model predicts that the unpleasant odor is minimized when  $T = 84.876502$ ,  $R = 0.539915$ , and  $H = 7.541050$ .

Figure 81.3 Canonical Analysis and Eigenvectors

| Factor                                          | Critical Value |           | Label            |
|-------------------------------------------------|----------------|-----------|------------------|
|                                                 | Coded          | Uncoded   |                  |
| T                                               | 0.121913       | 84.876502 | Temperature      |
| R                                               | 0.199575       | 0.539915  | Gas-Liquid Ratio |
| H                                               | 1.770525       | 7.541050  | Packing Height   |
| Predicted value at stationary point: -52.024631 |                |           |                  |
| Eigenvalues                                     | Eigenvectors   |           |                  |
|                                                 | T              | R         | H                |
| 48.858807                                       | 0.238091       | 0.971116  | -0.015690        |
| 31.103461                                       | 0.970696       | -0.237384 | 0.037399         |
| 6.037732                                        | -0.032594      | 0.024135  | 0.999177         |
| Stationary point is a minimum.                  |                |           |                  |

To plot the response surface with respect to two of the factor variables, fix H, the least significant factor variable, at its estimated optimum value. The following statements use ODS Graphics to display the surface:

```
ods graphics on;
proc rsreg data=smell
 plots(unpack)=surface(3d at (H=7.541050));
 model Odor = T R H;
 ods select 'T * R = Pred';
run;
ods graphics off;
```

Note that the ODS SELECT statement is specified to select the plot of interest.

Figure 81.4 The Response Surface at the Optimum H

Alternatively, the following statements produce an output data set containing the surface information, which you can then use for plotting surfaces or searching for optima. The first DATA step fixes H, the least significant factor variable, at its estimated optimum value (7.541), and generates a grid of points for T and R. To ensure that the grid data do not affect parameter estimates, the response variable (Odor) is set to missing. (See the section “Missing Values” on page 6924.) The second DATA step concatenates these grid points to the original data. Then PROC RSREG computes predictions for the combined data. The last DATA step subsets the predicted values over just the grid points, which excludes the predictions at the original data.

```

data grid;
 do;
 Odor = . ;
 H = 7.541;
 do T = 20 to 140 by 5;
 do R = .1 to .9 by .05;
 output;
 end;
 end;
 end;
run;
data grid;

```

```

 set smell grid;
run;

proc rsreg data=grid out=predict noprint;
 model Odor = T R H / predict;
run;

data grid;
 set predict;
 if H = 7.541;
run;

```

---

## Syntax: RSREG Procedure

The following statements are available in the RSREG procedure.

```

PROC RSREG < options > ;
 MODEL responses = independents < / options > ;
 RIDGE < options > ;
 WEIGHT variable ;
 ID variables ;
 BY variables ;

```

The PROC RSREG and MODEL statements are required.

The BY, ID, MODEL, RIDGE, and WEIGHT statements are described after the PROC RSREG statement, and they can appear in any order.

---

## PROC RSREG Statement

```

PROC RSREG < options > ;

```

The PROC RSREG statement invokes the RSREG procedure. [Table 81.1](#) summarizes the options available in the PROC RSREG statement.

**Table 81.1** PROC RSREG Statement Options

| Option  | Description                                      |
|---------|--------------------------------------------------|
| DATA=   | Names the input SAS data set                     |
| NOPRINT | Suppresses the normal display of results         |
| OUT=    | Creates the output SAS data set                  |
| PLOTS   | Controls the plots produced through ODS Graphics |

The following list describes these options.

**DATA=SAS-data-set**

specifies the input SAS data set that contains the data to be analyzed. By default, PROC RSREG uses the most recently created SAS data set.

**NOPRINT**

suppresses the normal display of results when only the output data set is required.

For more information, see the description of the NOPRINT option in the [MODEL](#) and [RIDGE](#) statements.

Note that this option temporarily disables the Output Delivery System (ODS); see Chapter 20, “[Using the Output Delivery System](#),” for more information.

**OUT=SAS-data-set**

creates an output SAS data set that contains statistics for each observation in the input data set. In particular, this data set contains the [BY](#) variables, the [ID](#) variables, the [WEIGHT](#) variable, the variables in the [MODEL](#) statement, and the [output options](#) requested in the [MODEL](#) statement. You must specify [output statistic options](#) in the [MODEL](#) statement; otherwise, the output data set is created but contains no observations. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. For more details, see the section “[OUT=SAS-data-set](#)” on page 6928.

**PLOTS** < (*global-plot-option*) >=*plot-request*< (*options*)>**PLOTS** < (*global-plot-option*) >=*(plot-request*< (*options*)>< . . . *plot-request*< (*options*)> >

controls the plots produced through ODS Graphics. When you specify only one *plot-request*, you can omit the parentheses from around the *plot-request*. For example:

```
plots = all
plots = (diagnostics ridge surface(unpack))
plots(unpack) = surface(overlaypairs)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc rsreg plots=all;
 model y=x;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, no graphs are created; you must specify the PLOTS= option to make graphs. See [Figure 81.4](#), [Output 81.1.5](#), [Output 81.1.6](#), [Output 81.2.3](#), and [Output 81.2.4](#) for examples of the ODS graphical displays.

The following *global-plot-option* is available.

**UNPACKPANELS | UNPACK**

suppresses paneling. By default, multiple plots can appear in some output *panels*. Specify the UNPACK option to display each plot separately.

The following *plot-requests* are available.

**ALL**

produces all appropriate plots. You can specify other options with ALL; for example, to display all plots and unpack the SURFACE contours you can specify `plots=(all surface(unpack))`.

**DIAGNOSTICS <(LABEL | UNPACK)>**

displays a panel of summary fit diagnostic plots. The plots produced and their usage are discussed in Table 81.2.

**Table 81.2** Diagnostic Plots

| Diagnostic Plot                                                           | Usage                                                                                                                                                                                                                                  |
|---------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Cook's <i>D</i> statistic versus observation number                       | Evaluate influence of an observation on the entire parameter estimate vector                                                                                                                                                           |
| Dependent variable values versus predicted values                         | Evaluate adequacy of fit and detect influential observations                                                                                                                                                                           |
| Externally studentized residuals (RStudent) versus leverage               | Detect outliers and influential (high-leverage) observations                                                                                                                                                                           |
| Externally studentized residuals versus predicted values                  | Evaluate adequacy of fit and detect outliers                                                                                                                                                                                           |
| Histogram of residuals                                                    | Confirm normality of error terms                                                                                                                                                                                                       |
| Normal quantile plot of residuals                                         | Confirm normality and homogeneity of error terms, and detect outliers                                                                                                                                                                  |
| Residuals versus predicted values<br><i>Residual-fit</i> (RF) spread plot | Evaluate adequacy of fit and detect outliers<br>side-by-side quantile plots of the centered fit and the residuals show "how much variation in the data is explained by the fit and how much remains in the residuals" (Cleveland 1993) |

Observations satisfying  $RStudent > 2$  or  $RStudent < -2$  are called *outliers*, and observations with leverage  $> 2p/n$  are called *influential*, where  $n$  is the number of observations used in fitting the model and  $p$  is the number of parameters used in the model (Rawlings, Pantula, and Dickey 1998). Specifying the LABEL option labels the influential and outlying observations—the label is the first ID variable if the ID statement is specified; otherwise, it is the observation number. Note in the Cook's *D* plot that only observations with *D* exceeding  $4/n$  are labeled; these are also called influential observations. The UNPACK option displays each diagnostic plot separately. See Output 81.2.3 for an example of the diagnostics panel.

**FIT** <(GRIDSIZE=*number*)>

plots the predicted values against a single predictor when you have only one factor or only one covariate in the model. The GRIDSIZE= option specifies the number of points at which the fitted values are computed; by default, GRIDSIZE=200.

**NONE**

suppresses all plots.

**RESIDUALS** <(UNPACK | SMOOTH)>

displays plots of residuals against each factor and covariate. The UNPACK option displays each residual plot separately. The SMOOTH option overlays a loess smooth on each residual plot; see Chapter 53, “The LOESS Procedure,” for more information. See [Output 81.1.5](#) for an example of this plot.

**RIDGE** <(UNPACK)>

displays the maximum and/or minimum ridge plots. This option is available only when a **MAXIMUM** or **MINIMUM** option is specified in the RIDGE statement. The UNPACK option displays the estimated response and factor level ridge plots separately. See [Output 81.1.5](#) for an example of this plot.

**SURFACE** <(surface-options)>

displays the response surface for each response variable and each pair of factors with all other factors and covariates fixed at their means. By default a panel of contour plots is produced; see [Output 81.1.6](#) for an example of this plot. The following *surface-options* can be specified:

**3D**

displays three-dimensional surface plots instead of contour plots. See [Figure 81.4](#) for an example of this plot.

**AT** <keyword><(variable=value-list | keyword <...variable=value-list | keyword>)>

specifies fixed values for factors and covariates. You can specify one or more numbers in the *value-list* or one of the following *keywords*:

|          |                                                                  |
|----------|------------------------------------------------------------------|
| MIN      | sets the variable to its minimum value.                          |
| MEAN     | sets the variable to its mean value.                             |
| MIDRANGE | sets the variable to the middle value: $\frac{\max + \min}{2}$ . |
| MAX      | sets the variable to its maximum value.                          |

Specifying a keyword immediately after AT sets the default value of all variables; for example, **AT MIN** sets all variables not displayed on an axis to their minimum values. By default, continuous variables are set to their means (**AT MEAN**) when they are not used on an axis. For example, if your model contains variables X1, X2, and X3, then specifying **AT (X1=7 9)** produces a contour plot of X2 versus X3 fixing X1 = 7 and then another contour plot with X1 = 9, along with contour plots of X1 versus X2 fixing X3 at its mean, and X1 versus X3 fixing X2 at its mean.

**EXTEND**=*value*

extends the surface *value*-times the range of each factor in each direction, which enables you to see more of the fitted surface. For example, if factor A has range [0, 10], then specifying **EXTEND=0.1** will compute and display the surface for A in [-1, 11]. You can specify *value* ≥ 0; by default, *value* = 0.1.

**FILL=PRED | SE | NONE**

produces a filled contour plot for either the predicted values or the standard errors. FILL=SE is the default. If the 3D option is also specified, then the contour plot is projected onto the surface.

**GRIDSIZE=*n***

creates an  $n \times n$  grid of points at which the estimated values for the surface and standard errors are computed, for  $n \geq 1$ . By default,  $n = 50$ .

**LINE=<PRED | SE | NONE>**

produces a contour line plot for either the predicted values or the standard errors. LINE=PRED is the default. If the 3D option is also specified, then specifying LINE displays a grid on the surface, and the other LINE= specifications are ignored.

**NODESIGN**

suppresses the display of the design points on the contour surface plots and the overlaid contour-line plots.

**OVERLAYPAIRS**

produces overlaid contour line plots for all pairs of response variables in addition to the contour surface plots. See Figure 81.6 for an example of this plot.

**ROTATE=*angle***

rotates the 3-D surface plots *angle* degrees,  $-180 < angle < 180$ . By default, *angle* = 57.

**TILT=*angle***

tilts the 3-D surface plots *angle* degrees,  $-180 < angle < 180$ . By default, *angle* = 20.

**UNPACKPANELS | UNPACK**

suppresses paneling, and displays each surface plot separately.

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC RSREG to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the RSREG procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## ID Statement

**ID** *variables* ;

The ID statement names variables that are to be transferred to the data set created by the **OUT=** option in the PROC RSREG statement.

---

## MODEL Statement

**MODEL** *responses = independents* </ *options* > ;

In the MODEL statement, you specify the response (dependent) variables followed by an equal sign and then the independent variables, some of which can be covariates.

Table 81.3 summarizes the *options* available in the MODEL statement. The *statistic options* specify which statistics are output to the **OUT=** data set. If none of the *statistic options* are selected, the data set is created but contains no observations. The *statistic option* keywords become values of the special variable **\_TYPE\_** in the output data set.

**Table 81.3** MODEL Statement Options

| Option                           | Description                                                                                            |
|----------------------------------|--------------------------------------------------------------------------------------------------------|
| BYOUT                            | Uses only the first BY group to estimate the model                                                     |
| COVAR=                           | Declares variables to be simple linear regressors                                                      |
| LACKFIT                          | Performs a lack-of-fit test                                                                            |
| NOCODE                           | Performs the canonical and ridge analyses using original values                                        |
| PRESS                            | Displays the predicted residual sum of squares (PRESS) statistic                                       |
| <b>Suppress Displayed Output</b> |                                                                                                        |
| NOANOVA                          | Suppresses the analysis of variance and parameter estimates                                            |
| NOOPTIMAL                        | Suppresses the canonical analysis                                                                      |
| NOPRINT                          | Suppresses both the analysis of variance and the canonical analysis                                    |
| <b>Output Statistics</b>         |                                                                                                        |
| ACTUAL                           | Includes observed response values                                                                      |
| PREDICT                          | Includes values predicted by the model                                                                 |
| RESIDUAL                         | Includes the residuals                                                                                 |
| L95                              | Includes the lower bound of a 95% confidence interval for an individual predicted value                |
| U95                              | Includes the upper bound of a 95% confidence interval for an individual predicted value                |
| L95M                             | Includes the lower bound of a 95% confidence interval for the expected value of the dependent variable |
| U95M                             | Includes the upper bound of a 95% confidence interval for the expected value of the dependent variable |
| D                                | Includes Cook's <i>D</i> influence statistic                                                           |

The following list describes these options in alphabetical order.

**ACTUAL**

specifies that the observed response values from the input data set be written to the output data set.

**BYOUT**

uses only the first BY group to estimate the model. Subsequent BY groups have scoring statistics computed in the output data set only. The BYOUT option is used only when a BY statement is specified.

**COVAR=*n***

declares that the first *n* variables on the right side of the model are simple linear regressors (covariates) and not factors in the quadratic response surface. By default, PROC RSREG forms quadratic and crossproduct effects for all regressor variables in the MODEL statement.

See the section “[Handling Covariates](#)” on page 6926 for more details and [Example 81.2](#) for an example that uses covariates.

**D**

specifies that Cook’s *D* influence statistic be written to the output data set.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

**LACKFIT**

performs a lack-of-fit test.

See Draper and Smith (1981) for a discussion of lack-of-fit tests.

**L95**

specifies that the lower bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

**L95M**

specifies that the lower bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

**NOANOVA****NOAOV**

suppresses the display of the analysis of variance and parameter estimates from the model fit.

**NOCODE**

performs the canonical and ridge analyses with the parameter estimates derived from fitting the response to the original values of the factor variables, rather than their coded values (see the section “[Coding the Factor Variables](#)” on page 6923 for more details). Use this option if the data are already stored in a coded form.

**NOOPTIMAL****NOOPT**

suppresses the display of the canonical analysis for the quadratic response surface.

**NOPRINT**

suppresses the display of both the analysis of variance and the canonical analysis.

**PREDICT**

specifies that the values predicted by the model be written to the output data set.

**PRESS**

computes and displays the predicted residual sum of squares (PRESS) statistic for each dependent variable in the model. The PRESS statistic is added to the summary information at the beginning of the analysis of variance, so if the **NOANOVA** or **NOPRINT** option is specified, then the PRESS option has no effect.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

**RESIDUAL**

specifies that the residuals, calculated as **ACTUAL – PREDICTED**, be written to the output data set.

**U95**

specifies that the upper bound of a 95% confidence interval for an individual predicted value be written to the output data set. The variance used in calculating this bound is a function of both the mean square error and the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

**U95M**

specifies that the upper bound of a 95% confidence interval for the expected value of the dependent variable be written to the output data set. The variance used in calculating this bound is a function of the variance of the parameter estimates.

See Chapter 4, “[Introduction to Regression Procedures](#),” for details and formulas.

**RIDGE Statement**

**RIDGE** < options > ;

A RIDGE statement computes the ridge of optimum response. The ridge starts at a given point  $x_0$ , and the point on the ridge at radius  $r$  from  $x_0$  is the collection of factor settings that optimizes the predicted response at this radius. You can think of the ridge as climbing or falling as fast as possible on the surface of predicted response. Thus, the ridge analysis can be used as a tool to help interpret an existing response surface or to indicate the direction in which further experimentation should be performed.

The default starting point,  $x_0$ , has each coordinate equal to the point midway between the highest and lowest values of the factor in the design. The default radii at which the ridge is computed are 0, 0.1, . . . , 0.9, 1. If the ridge analysis is based on the response surface fit to coded values for the factor variables (see the section “[Coding the Factor Variables](#)” on page 6923 for details), then this results in a ridge that starts at the point with a coded zero value for each coordinate and extends toward, but not beyond, the edge of the range of

experimentation. Alternatively, both the center point of the ridge and the radii at which it is to be computed can be specified.

You can specify the following options in the RIDGE statement:

**CENTER**=*uncoded-factor-values*

gives the coordinates of the point  $x_0$  from which to begin the ridge. The coordinates should be given in the original (uncoded) factor variable values and should be separated by commas. There must be as many coordinates specified as there are factors in the model, and the order of the coordinates must be the same as that used in the **MODEL** statement. This starting point should be well inside the range of experimentation. The default sets each coordinate equal to the value midway between the highest and lowest values for the associated factor.

**MAXIMUM**

**MAX**

computes the ridge of maximum response. Both the **MIN** and **MAX** options can be specified; at least one must be specified.

**MINIMUM**

**MIN**

computes the ridge of minimum response. Both the **MIN** and **MAX** options can be specified; at least one must be specified.

**NOPRINT**

suppresses the display of the ridge analysis when only an output data set is required.

**OUTR**=*SAS-data-set*

creates an output SAS data set containing the computed optimum ridge.

For details, see the section “**OUTR**=*SAS-data-set*” on page 6929.

**RADIUS**=*coded-radii*

gives the distances from the ridge starting point at which to compute the optima. The values in the list represent distances between coded points. The list can take any of the following forms or can be composed of mixtures of them:

$m_1, m_2, \dots, m_n$  specifies several values.

$m$  TO  $n$  specifies a sequence where  $m$  equals the starting value,  $n$  equals the ending value, and the increment equals 1.

$m$  TO  $n$  BY  $i$  specifies a sequence where  $m$  equals the starting value,  $n$  equals the ending value, and  $i$  equals the increment.

Mixtures of the preceding forms should be separated by commas. The default list runs from 0 to 1 by increments of 0.1. The following are examples of valid lists.

```
radius=0 to 5 by .5;
radius=0, .2, .25, .3, .5 to 1.0 by .1;
```

---

## WEIGHT Statement

**WEIGHT** variable ;

When a WEIGHT statement is specified, a weighted residual sum of squares

$$\sum_i w_i (y_i - \hat{y}_i)^2$$

is minimized, where  $w_i$  is the value of the variable specified in the WEIGHT statement,  $y_i$  is the observed value of the response variable, and  $\hat{y}_i$  is the predicted value of the response variable.

The observation is used in the analysis only if the value of the WEIGHT statement variable is greater than zero. The WEIGHT statement has no effect on degrees of freedom or number of observations. If the weights for the observations are proportional to the reciprocals of the error variances, then the weighted least squares estimates are best linear unbiased estimators (BLUE).

---

## Details: RSREG Procedure

---

### Introduction to Response Surface Experiments

Many industrial experiments are conducted to discover which values of given factor variables optimize a response. If each factor is measured at three or more values, a quadratic response surface can be estimated by least squares regression. The predicted optimal value can be found from the estimated surface if the surface is shaped like a simple hill or valley. If the estimated surface is more complicated, or if the predicted optimum is far from the region of experimentation, then the shape of the surface can be analyzed to indicate the directions in which new experiments should be performed.

Suppose that a response variable  $y$  is measured at combinations of values of two factor variables,  $x_1$  and  $x_2$ . The quadratic response surface model for this variable is written as

$$y = \beta_0 + \beta_1 x_1 + \beta_2 x_2 + \beta_3 x_1^2 + \beta_4 x_2^2 + \beta_5 x_1 x_2 + \epsilon$$

The steps in the analysis for such data are as follows:

1. [model fitting and analysis of variance](#), including [lack-of-fit testing](#), to estimate parameters
2. [canonical analysis](#) to investigate the shape of the predicted response surface
3. [ridge analysis](#) to search for the region of optimum response

### Model Fitting and Analysis of Variance

The first task in analyzing the response surface is to estimate the parameters of the model by least squares regression and to obtain information about the fit in the form of an analysis of variance. The estimated surface is typically curved: a *hill* with the peak occurring at the unique estimated point of maximum response, a *valley*, or a *saddle surface* with no unique minimum or maximum. Use the results of this phase of the analysis to answer the following questions:

- What is the contribution of each type of effect—linear, quadratic, and crossproduct—to the statistical fit? The ANOVA table with sources labeled “Regression” addresses this question.
- What part of the residual error is due to lack of fit? Does the quadratic response model adequately represent the true response surface? If you specify the **LACKFIT** option in the MODEL statement, then the ANOVA table with sources labeled “Residual” addresses this question. See the section “**Lack-of-Fit Test**” on page 6922 for details.
- What is the contribution of each factor variable to the statistical fit? Can the response be predicted accurately if the variable is removed? The ANOVA table with sources labeled “Factor” addresses this question.
- What are the predicted responses for a grid of factor values? (See the section “**Plotting the Surface**” on page 6924 and the section “**Searching for Multiple Response Conditions**” on page 6924.)

### Lack-of-Fit Test

The lack-of-fit test compares the variation around the model with *pure* variation within replicated observations. This measures the adequacy of the quadratic response surface model. In particular, if there are  $n_i$  replicated observations  $Y_{i1}, \dots, Y_{in_i}$  of the response all at the same values  $\mathbf{x}_i$  of the factors, then you can predict the true response at  $\mathbf{x}_i$  either by using the predicted value  $\hat{Y}_i$  based on the model or by using the mean  $\bar{Y}_i$  of the replicated values. The lack-of-fit test decomposes the residual error into a component due to the variation of the replications around their mean value (the *pure* error) and a component due to the variation of the mean values around the model prediction (the *bias* error):

$$\sum_i \sum_{j=1}^{n_i} (Y_{ij} - \hat{Y}_i)^2 = \sum_i \sum_{j=1}^{n_i} (Y_{ij} - \bar{Y}_i)^2 + \sum_i n_i (\bar{Y}_i - \hat{Y}_i)^2$$

If the model is adequate, then both components estimate the nominal level of error; however, if the bias component of error is much larger than the pure error, then this constitutes evidence that there is significant lack of fit.

If some observations in your design are replicated, you can test for lack of fit by specifying the **LACKFIT** option in the MODEL statement. Note that, since all other tests use total error rather than pure error, you might want to hand-calculate the tests with respect to pure error if the lack of fit is significant. On the other hand, significant lack of fit indicates that the quadratic model is inadequate, so if this is a problem you can also try to refine the model, possibly by using PROC GLM for general polynomial modeling; see Chapter 42, “**The GLM Procedure**,” for more information. **Example 81.1** illustrates the use of the **LACKFIT** option.

### Canonical Analysis

The second task in analyzing the response surface is to examine the overall shape of the curve and determine whether the estimated stationary point is a maximum, a minimum, or a saddle point. The canonical analysis can be used to answer the following questions:

- Is the surface shaped like a hill, a valley, or a saddle, or is it flat?
- If there is a unique optimum combination of factor values, where is it?

- To which factor or factors are the predicted responses most sensitive?

The eigenvalues and eigenvectors in the matrix of second-order parameters characterize the shape of the response surface. The eigenvectors point in the directions of principal orientation for the surface, and the signs and magnitudes of the associated eigenvalues give the shape of the surface in these directions. Positive eigenvalues indicate directions of upward curvature, and negative eigenvalues indicate directions of downward curvature. The larger an eigenvalue is in absolute value, the more pronounced is the curvature of the response surface in the associated direction. Often, all the coefficients of an eigenvector except for one are relatively small, indicating that the vector points roughly along the axis associated with the factor corresponding to the single large coefficient. In this case, the canonical analysis can be used to determine the relative sensitivity of the predicted response surface to variations in that factor. (See the section “Getting Started: RSREG Procedure” on page 6907 for an example.)

## Ridge Analysis

If the estimated surface is found to have a simple optimum well within the range of experimentation, the analysis performed by the preceding two steps might be sufficient. In more complicated situations, further search for the region of optimum response is required. The method of ridge analysis computes the estimated ridge of optimum response for increasing radii from the center of the original design. The ridge analysis answers the following question:

- If there is not a unique optimum of the response surface within the range of experimentation, in which direction should further searching be done in order to locate the optimum?

You can use the `RIDGE` statement to compute the ridge of maximum or minimum response.

---

## Coding the Factor Variables

For the results of the canonical and ridge analyses to be interpretable, the values of different factor variables should be comparable. This is because the canonical and ridge analyses of the response surface are not invariant with respect to differences in scale and location of the factor variables. The analysis of variance is not affected by these changes. Although the actual predicted surface does not change, its parameterization does. The usual solution to this problem is to code each factor variable so that its minimum in the experiment is  $-1$  and its maximum is  $1$  and to carry through the analysis with the coded values instead of the original ones. This practice has the added benefit of making  $1$  a reasonable boundary radius for the ridge analysis since  $1$  represents approximately the edge of the experimental region. By default, PROC RSREG computes the linear transformation to perform this coding as the data are initially read in, and the canonical and ridge analyses are performed on the model fit to the coded data. The actual form of the coding operation for each value of a variable is

$$\text{coded value} = (\text{original value} - M)/S$$

where  $M$  is the average of the highest and lowest values for the variable in the design and  $S$  is half their difference.

---

## Missing Values

If an observation has missing data for any of the variables used by the procedure, then that observation is not used in the estimation process. If one or more response variables are missing, but no factor or covariate variables are missing, then predicted values and confidence limits are computed for the output data set, but the residual and Cook's  $D$  statistic are missing.

---

## Plotting the Surface

Specifying the `PLOTS=SURFACE` option in the PROC RSREG statement displays contour plots for all pairs of factors in the model (see Example 81.1), while specifying the `PLOTS=SURFACE(3D)` option displays a three-dimensional surface as shown in Figure 81.4.

You can also generate predicted values for a grid of points with the `PREDICT` option (see the section “Getting Started: RSREG Procedure” on page 6907 for an example) and then use these values to create a contour plot or a three-dimensional plot of the response surface over a two-dimensional grid. Any two factor variables can be chosen to form the grid for the plot. Several plots can be generated by using different pairs of factor variables.

---

## Searching for Multiple Response Conditions

Suppose you have the following data with two factors and three responses, and you want to find the factor setting that produces responses in a certain region:

```
data a;
 input x1 x2 y1 y2 y3;
 datalines;
-1 -1 1.8 1.940 3.6398
-1 1 2.6 1.843 4.9123
 1 -1 5.4 1.063 6.0128
 1 1 0.7 1.639 2.3629
 0 0 8.5 0.134 9.0910
 0 0 3.0 0.545 3.7349
 0 0 9.8 0.453 10.4412
 0 0 4.1 1.117 5.0042
 0 0 4.8 1.690 6.6245
 0 0 5.9 1.165 6.9420
 0 0 7.3 1.013 8.7442
 0 0 9.3 1.179 10.2762
 1.4142 0 3.9 0.945 5.0245
-1.4142 0 1.7 0.333 2.4041
 0 1.4142 3.0 1.869 5.2695
 0 -1.4142 5.7 0.099 5.4346
;
```

You want to find the values of  $x_1$  and  $x_2$  that maximize  $y_1$  subject to  $y_2 < 2$  and  $y_3 < y_2 + y_1$ . The exact answer is not easy to obtain analytically, but you can obtain a practically feasible solution by checking conditions

across a grid of values in the range of interest. First, append a grid of factor values to the observed data, with missing values for the responses:

```
data b;
 set a end=eof;
 output;
 if eof then do;
 y1=.;
 y2=.;
 y3=.;
 do x1=-2 to 2 by .1;
 do x2=-2 to 2 by .1;
 output;
 end;
 end;
 end;
run;
```

Next, use PROC RSREG to fit a response surface model to the data and to compute predicted values for both the observed data and the grid, putting the predicted values in a data set c:

```
proc rsreg data=b out=c;
 model y1 y2 y3=x1 x2 / predict;
run;
```

Finally, find the subset of predicted values that satisfy the constraints, sort by the unconstrained variable, and display the top five predictions:

```
data d;
 set c;
 if y2<2;
 if y3<y2+y1;

proc sort data=d;
 by descending y1;
run;

data d; set d;
 if (_n_ <= 5);
proc print;
run;
```

The results are displayed in [Figure 81.5](#). They indicate that optimal values of the factors are around 0.3 for  $x_1$  and around  $-0.5$  for  $x_2$ .

**Figure 81.5** Top Five Predictions

| Obs | x1  | x2   | _TYPE_  | y1      | y2      | y3      |
|-----|-----|------|---------|---------|---------|---------|
| 1   | 0.3 | -0.5 | PREDICT | 6.92570 | 0.75784 | 7.60471 |
| 2   | 0.3 | -0.6 | PREDICT | 6.91424 | 0.74174 | 7.54194 |
| 3   | 0.3 | -0.4 | PREDICT | 6.91003 | 0.77870 | 7.64341 |
| 4   | 0.4 | -0.6 | PREDICT | 6.90769 | 0.73357 | 7.51836 |
| 5   | 0.4 | -0.5 | PREDICT | 6.90540 | 0.75135 | 7.56883 |

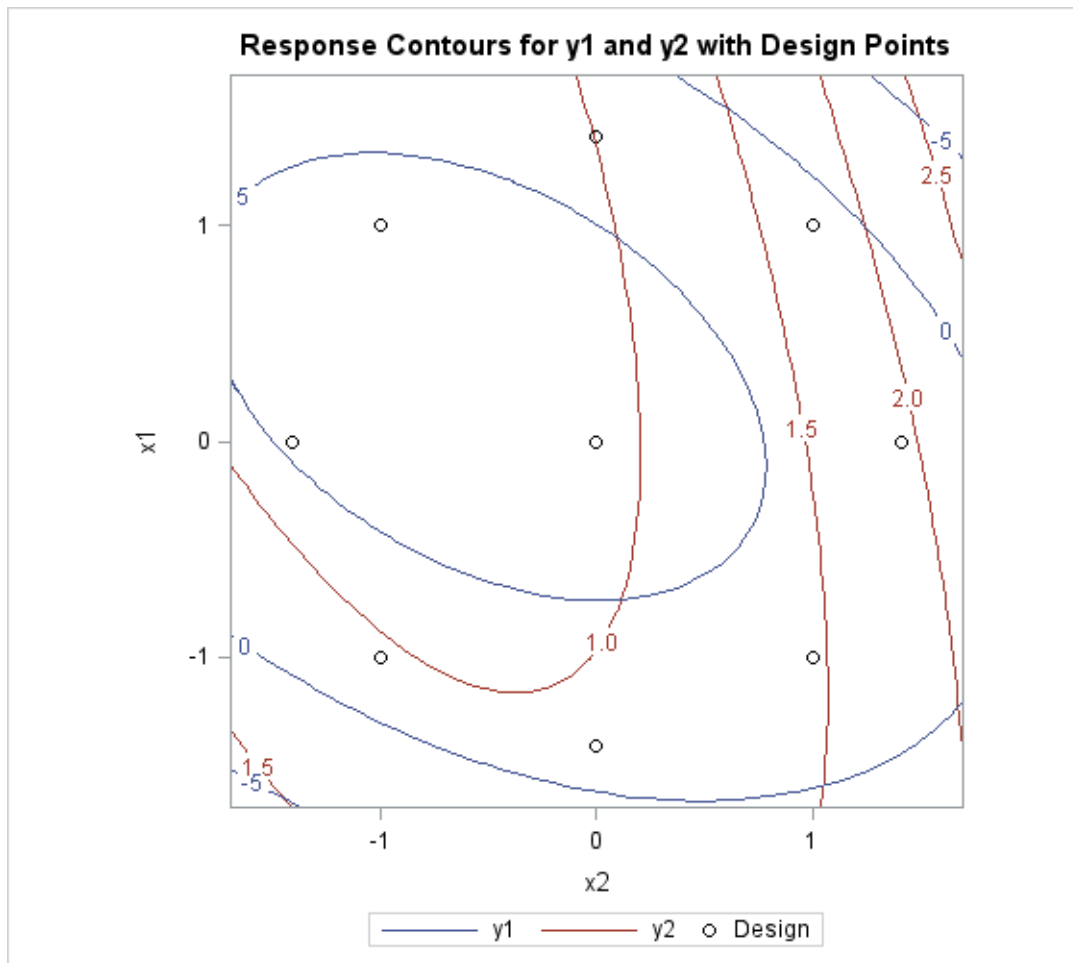

If you are also interested in simultaneously optimizing  $y_1$  and  $y_2$ , you can specify the following statements to make a visual comparison of the two response surfaces by overlaying their contour plots:

```
ods graphics on;
proc rsreg data=a plots=surface(overlaypairs);
 model y1 y2=x1 x2;
run;
ods graphics off;
```

Figure 81.6 shows that you have to make some compromises in any attempt to maximize both  $y_1$  and  $y_2$ ; however, you might be able to maximize  $y_1$  while minimizing  $y_2$ .

**Figure 81.6** Overlaid Line Contours of Predicted Responses

## Handling Covariates

Covariate regressors are added to a response surface model because they are believed to account for a sizable yet relatively uninteresting portion of the variation in the data. What the experimenter is really interested in is the response corrected for the effect of the covariates. A common example is the block effect in a block design. In the canonical and ridge analyses of a response surface, which estimate responses at hypothetical

levels of the factor variables, the actual value of the predicted response is computed by using the average values of the covariates. The estimated response values do optimize the estimated surface of the response corrected for covariates, but true prediction of the response requires actual values for the covariates. You can use the `COVAR=` option in the `MODEL` statement to include covariates in the response surface model. Example 81.2 illustrates the use of this option.

---

## Computational Method

### Canonical Analysis

For each response variable, the model can be written in the form

$$y_i = \mathbf{x}_i' \mathbf{A} \mathbf{x}_i + \mathbf{b}' \mathbf{x}_i + \mathbf{c}' \mathbf{z}_i + \epsilon_i$$

where

$y_i$  is the  $i$ th observation of the response variable.

$\mathbf{x}_i = (x_{i1}, x_{i2}, \dots, x_{ik})'$  are the  $k$  factor variables for the  $i$ th observation.

$\mathbf{z}_i = (z_{i1}, z_{i2}, \dots, z_{iL})'$  are the  $L$  covariates, including the intercept term.

$\mathbf{A}$  is the  $k \times k$  symmetrized matrix of quadratic parameters, with diagonal elements equal to the coefficients of the pure quadratic terms in the model and off-diagonal elements equal to half the coefficient of the corresponding crossproduct.

$\mathbf{b}$  is the  $k \times 1$  vector of linear parameters.

$\mathbf{c}$  is the  $L \times 1$  vector of covariate parameters, one of which is the intercept.

$\epsilon_i$  is the error associated with the  $i$ th observation. Tests performed by PROC RSREG assume that errors are independently and normally distributed with mean zero and variance  $\sigma^2$ .

The parameters in  $\mathbf{A}$ ,  $\mathbf{b}$ , and  $\mathbf{c}$  are estimated by least squares. To optimize  $y$  with respect to  $\mathbf{x}$ , take partial derivatives, set them to zero, and solve:

$$\frac{\partial y}{\partial \mathbf{x}} = 2\mathbf{x}'\mathbf{A} + \mathbf{b}' = \mathbf{0} \implies \mathbf{x} = -\frac{1}{2}\mathbf{A}^{-1}\mathbf{b}$$

You can determine if the solution is a maximum or minimum by looking at the eigenvalues of  $\mathbf{A}$ :

| <b>If the eigenvalues...</b> | <b>then the solution is...</b> |
|------------------------------|--------------------------------|
| are all negative             | a maximum                      |
| are all positive             | a minimum                      |
| have mixed signs             | a saddle point                 |
| contain zeros                | in a flat area                 |

## Ridge Analysis

If the largest eigenvalue is positive, its eigenvector gives the direction of steepest ascent from the stationary point; if the largest eigenvalue is negative, its eigenvector gives the direction of steepest descent. The eigenvectors corresponding to small or zero eigenvalues point in directions of relative flatness.

The point on the optimum response ridge at a given radius  $R$  from the ridge origin is found by optimizing

$$(\mathbf{x}_0 + \mathbf{d})' \mathbf{A}(\mathbf{x}_0 + \mathbf{d}) + \mathbf{b}'(\mathbf{x}_0 + \mathbf{d})$$

over  $\mathbf{d}$  satisfying  $\mathbf{d}'\mathbf{d} = R^2$ , where  $\mathbf{x}_0$  is the  $k \times 1$  vector containing the ridge origin and  $\mathbf{A}$  and  $\mathbf{b}$  are as previously discussed. By the method of Lagrange multipliers, the optimal  $\mathbf{d}$  has the form

$$\mathbf{d} = -(\mathbf{A} - \mu\mathbf{I})^{-1}(\mathbf{A}\mathbf{x}_0 + 0.5\mathbf{b})$$

where  $\mathbf{I}$  is the  $k \times k$  identity matrix and  $\mu$  is chosen so that  $\mathbf{d}'\mathbf{d} = R^2$ . There can be several values of  $\mu$  that satisfy this constraint; the correct one depends on which sort of response ridge is of interest. If you are searching for the ridge of maximum response, then the appropriate  $\mu$  is the unique one that satisfies the constraint and is greater than all the eigenvalues of  $\mathbf{A}$ . Similarly, the appropriate  $\mu$  for the ridge of minimum response satisfies the constraint and is less than all the eigenvalues of  $\mathbf{A}$ . (See Myers and Montgomery (1995) for details.)

---

## Output Data Sets

### OUT=SAS-data-set

An output data set containing statistics requested with options in the MODEL statement for each observation in the input data set is created whenever the OUT= option is specified in the PROC RSREG statement. The data set contains the following variables:

- the BY variables
- the ID variables
- the WEIGHT variable
- the independent variables in the MODEL statement
- the variable \_TYPE\_, which identifies the observation type in the output data set. \_TYPE\_ is a character variable with a length of eight, and it takes on the values 'ACTUAL', 'PREDICT', 'RESIDUAL', 'U95M', 'L95M', 'U95', 'L95', and 'D', corresponding to the options specified.
- the response variables containing special output values identified by the \_TYPE\_ variable

All confidence limits use the two-tailed Student's  $t$  value.

## OUTR=SAS-data-set

An output data set containing the optimum response ridge is created when the **OUTR=** option is specified in the **RIDGE** statement. The data set contains the following variables:

- the current values of the **BY** variables
- a character variable **\_DEPVAR\_** containing the name of the dependent variable
- a character variable **\_TYPE\_** identifying the type of ridge being computed, **MINIMUM** or **MAXIMUM**. If both **MAXIMUM** and **MINIMUM** are specified, the data set contains observations for the minimum ridge followed by observations for the maximum ridge.
- a numeric variable **\_RADIUS\_** giving the distance from the ridge starting point
- the values of the model factors at the estimated optimum point at distance **\_RADIUS\_** from the ridge starting point
- a numeric variable **\_PRED\_**, which is the estimated expected value of the dependent variable at the optimum
- a numeric variable **\_STDERR\_**, which is the standard error of the estimated expected value

---

## Displayed Output

All estimates and hypothesis tests assume that the model is correctly specified and the errors are distributed according to classical statistical assumptions.

The output displayed by PROC RSREG includes the following.

### Estimation and Analysis of Variance

- The actual form of the coding operation for each value of a variable is

$$\text{coded value} = \frac{1}{S}(\text{original value} - M)$$

where  $M$  is the average of the highest and lowest values for the variable in the design and  $S$  is half their difference. The **Subtracted off** column contains the  $M$  values for this formula for each factor variable, and  $S$  is found in the **Divided by** column.

- The summary table for the response variable contains the following information.
  - “Response Mean” is the mean of the response variable in the sample. When a **WEIGHT** statement is specified, the mean  $\bar{y}$  is calculated by

$$\bar{y} = \frac{\sum_i w_i y_i}{\sum_i w_i}$$

- “Root MSE” estimates the standard deviation of the response variable and is calculated as the square root of the “Total Error” mean square.

- The “R-Square” value is  $R^2$ , or the coefficient of determination.  $R^2$  measures the proportion of the variation in the response that is attributed to the model rather than to random error.
- The “Coefficient of Variation” is 100 times the ratio of the “Root MSE” to the “Response Mean.”
- A table analyzing the significance of the terms of the regression is displayed. Terms are brought into the regression in four steps: (1) the “Intercept” and any covariates in the model, (2) “Linear” terms like  $X_1$  and  $X_2$ , (3) pure “Quadratic” terms like  $X_1*X_1$  or  $X_2*X_2$ , and (4) “Crossproduct” terms like  $X_1*X_2$ . The table displays the following information:
  - the degrees of freedom in the DF column, which should be the same as the number of corresponding parameters unless one or more of the parameters are not estimable
  - Type I Sum of Squares, also called the sequential sums of squares, which measures the reduction in the error sum of squares as sets of terms (Linear, Quadratic, and so forth) are added to the model
  - R-Square, which measures the portion of total  $R^2$  contributed as each set of terms (Linear, Quadratic, and so forth) is added to the model
  - F Value, which tests the null hypothesis that all parameters in the term are zero by using the Total Error mean square as the denominator. This is a test of a Type I hypothesis, containing the usual  $F$  test numerator, conditional on the effects of subsequent variables not being in the model.
  - $\text{Pr} > F$ , which is the significance value or probability of obtaining at least as great an  $F$  ratio given that the null hypothesis is true.
- The Sum of Squares column partitions the “Total Error” into “Lack of Fit” and “Pure Error.” When “Lack of Fit” is significant, there is variation around the model other than random error (such as cubic effects of the factor variables).
  - The “Total Error” Mean Square estimates  $\sigma^2$ , the variance.
  - F Value tests the null hypothesis that the variation is adequately described by random error.
- A table containing the parameter estimates from the model is displayed.
  - The Estimate column contains the parameter estimates based on the *uncoded* values of the factor variables. If an effect is a linear combination of previous effects, the parameter for the effect is not estimable. When this happens, the degrees of freedom are zero, the parameter estimate is set to zero, and estimates and tests on other parameters are conditional on this parameter being zero.
  - The Standard Error column contains the estimated standard deviations of the parameter estimates based on *uncoded* data.
  - The t Value column contains  $t$  values of a test of the null hypothesis that the true parameter is zero when the *uncoded* values of the factor variables are used.
  - The  $\text{Pr} > |T|$  column gives the significance value or probability of a greater absolute  $t$  ratio given that the true parameter is zero.
  - The Parameter Estimate from Coded Data column contains the parameter estimates based on the *coded* values of the factor variables. These are the estimates used in the subsequent canonical and ridge analyses.

- The sum of squares are partitioned by the factors in the model, and an analysis table is displayed. The test on a factor is a joint test on all the parameters involving that factor. For example, the test for the factor X1 tests the null hypothesis that the true parameters for X1, X1\*X1, and X1\*X2 are all zero.

## Canonical Analysis

- The Critical Value columns contain the values of the factor variables that correspond to the stationary point of the fitted response surface. The critical values can be at a minimum, maximum, or saddle point.
- The eigenvalues and eigenvectors are from the matrix of quadratic parameter estimates based on the coded data. They characterize the shape of the response surface.

## Ridge Analysis

- The Coded Radius column contains the distance from the coded version of the associated point to the coded version of the origin of the ridge. The origin is given by the point at radius zero.
- The Estimated Response column contains the estimated value of the response variable at the associated point. The standard error of this estimate is also given. This quantity is useful for assessing the relative credibility of the prediction at a given radius. Typically, this standard error increases rapidly as the ridge moves up to and beyond the design perimeter, reflecting the inherent difficulty of making predictions beyond the range of experimentation.
- The Uncoded Factor Values columns contain the values of the uncoded factor variables that give the optimum response at this radius from the ridge origin.

---

## ODS Table Names

PROC RSREG assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 81.4. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 81.4** ODS Tables Produced by PROC RSREG

| ODS Table Name     | Description                                       | Statement |
|--------------------|---------------------------------------------------|-----------|
| Coding             | Coding coefficients for the independent variables | default   |
| ErrorANOVA         | Error analysis of variance                        | default   |
| FactorANOVA        | Factor analysis of variance                       | default   |
| FitStatistics      | Overall statistics for fit                        | default   |
| ModelANOVA         | Model analysis of variance                        | default   |
| ParameterEstimates | Estimated linear parameters                       | default   |
| Ridge              | Ridge analysis for optimum response               | RIDGE     |
| Spectral           | Spectral analysis                                 | default   |
| StationaryPoint    | Stationary point of response surface              | default   |

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

PROC RSREG assigns a name to each graph it creates using ODS. The names are listed in Table 81.5. You can use these names to reference the graphs when using ODS. You must also specify the PLOTS= option and any other options indicated in Table 81.5.

**Table 81.5** Graphs Produced by PROC RSREG

| ODS Graph Name      | Plot Description                     | PLOTS= Option                |
|---------------------|--------------------------------------|------------------------------|
| FitPlot             | Fit plot for 1 predictor             | FIT                          |
| DiagnosticsPanel    | Panel of fit diagnostics             | DIAGNOSTICS                  |
| CooksDPlot          | Cook’s <i>D</i> plot                 | DIAGNOSTICS(UNPACK)          |
| ObservedByPredicted | Observed by predicted                | DIAGNOSTICS(UNPACK)          |

## Examples: RSREG Procedure

---

### Example 81.1: A Saddle Surface Response Using Ridge Analysis

Myers (1976) analyzes an experiment reported by Frankel (1961) aimed at maximizing the yield of mercaptobenzothiazole (MBT) by varying processing time and temperature. Myers (1976) uses a two-factor model in which the estimated surface does not have a unique optimum. A ridge analysis is used to determine the region in which the optimum lies. The objective is to find the settings of time and temperature in the processing of a chemical that maximize the yield. The following statements produce [Output 81.1.1](#) through [Output 81.1.6](#):

```
data d;
 input Time Temp MBT;
 label Time = "Reaction Time (Hours)"
 Temp = "Temperature (Degrees Centigrade)"
 MBT = "Percent Yield Mercaptobenzothiazole";
 datalines;
 4.0 250 83.8
 20.0 250 81.7
 12.0 250 82.4
 12.0 250 82.9
 12.0 220 84.7
 12.0 280 57.9
 12.0 250 81.2
 6.3 229 81.3
 6.3 271 83.1
 17.7 229 85.3
 17.7 271 72.7
 4.0 250 82.0
 ;

ods graphics on;
proc rsreg data=d plots=(ridge surface);
 model MBT=Time Temp / lackfit;
 ridge max;
run;
ods graphics off;
```

[Output 81.1.1](#) displays the coding coefficients for the transformation of the independent variables to lie between  $-1$  and  $1$  and some simple statistics for the response variable.

**Output 81.1.1** Coding and Response Variable Information

| The RSREG Procedure                               |                |            |
|---------------------------------------------------|----------------|------------|
| Coding Coefficients for the Independent Variables |                |            |
| Factor                                            | Subtracted off | Divided by |
| Time                                              | 12.000000      | 8.000000   |
| Temp                                              | 250.000000     | 30.000000  |

| Response Surface for Variable MBT: Percent Yield Mercaptobenzothiazole |           |
|------------------------------------------------------------------------|-----------|
| Response Mean                                                          | 79.916667 |
| Root MSE                                                               | 4.615964  |
| R-Square                                                               | 0.8003    |
| Coefficient of Variation                                               | 5.7760    |

**Output 81.1.2** shows that the lack of fit for the model is highly significant. Since the quadratic model does not fit the data very well, firm statements about the underlying process should not be based only on the current analysis. Note from the analysis of variance for the model that the test for the time factor is not significant. If further experimentation is undertaken, it might be best to fix Time at a moderate to high value and to concentrate on the effect of temperature. In the actual experiment discussed here, extra runs were made that confirmed the results of the following analysis.

**Output 81.1.2** Analyses of Variance

| Regression   | DF | Type I Sum<br>of Squares | R-Square | F Value | Pr > F |
|--------------|----|--------------------------|----------|---------|--------|
| Linear       | 2  | 313.585803               | 0.4899   | 7.36    | 0.0243 |
| Quadratic    | 2  | 146.768144               | 0.2293   | 3.44    | 0.1009 |
| Crossproduct | 1  | 51.840000                | 0.0810   | 2.43    | 0.1698 |
| Total Model  | 5  | 512.193947               | 0.8003   | 4.81    | 0.0410 |

| Residual    | DF | Sum of<br>Squares | Mean Square | F Value | Pr > F |
|-------------|----|-------------------|-------------|---------|--------|

| Total Error | 6  | 127.842720        | 21.307120   |         |        |

**Output 81.1.2** *continued*

| Parameter | DF | Estimate    | Standard Error | t Value | Pr >  t | Parameter Estimate from Coded Data |
|-----------|----|-------------|----------------|---------|---------|------------------------------------|
| Intercept | 1  | -545.867976 | 277.145373     | -1.97   | 0.0964  | 82.173110                          |
| Time      | 1  | 6.872863    | 5.004928       | 1.37    | 0.2188  | -1.014287                          |
| Temp      | 1  | 4.989743    | 2.165839       | 2.30    | 0.0608  | -8.676768                          |
| Time*Time | 1  | 0.021631    | 0.056784       | 0.38    | 0.7164  | 1.384394                           |
| Temp*Time | 1  | -0.030075   | 0.019281       | -1.56   | 0.1698  | -7.218045                          |
| Temp*Temp | 1  | -0.009836   | 0.004304       | -2.29   | 0.0623  | -8.852519                          |

| Factor | DF | Sum of Squares | Mean Square | F Value | Pr > F |
|--------|----|----------------|-------------|---------|--------|
| Time   | 3  | 61.290957      | 20.430319   | 0.96    | 0.4704 |
| Temp   | 3  | 461.250925     | 153.750308  | 7.22    | 0.0205 |

| Factor | Label                            |
|--------|----------------------------------|
| Time   | Reaction Time (Hours)            |
| Temp   | Temperature (Degrees Centigrade) |

The canonical analysis (Output 81.1.3) indicates that the predicted response surface is shaped like a saddle. The eigenvalue of 2.5 shows that the valley orientation of the saddle is less curved than the hill orientation, with an eigenvalue of -9.99. The coefficients of the associated eigenvectors show that the valley is more aligned with Time and the hill with Temp. Because the canonical analysis resulted in a saddle point, the estimated surface does not have a unique optimum.

**Output 81.1.3** Canonical Analysis

| Factor | Critical Value |            | Label                            |
|--------|----------------|------------|----------------------------------|
|        | Coded          | Uncoded    |                                  |
| Time   | -0.441758      | 8.465935   | Reaction Time (Hours)            |
| Temp   | -0.309976      | 240.700718 | Temperature (Degrees Centigrade) |

Predicted value at stationary point: 83.741940

| Eigenvalues | Eigenvectors |           |
|-------------|--------------|-----------|
|             | Time         | Temp      |
| 2.528816    | 0.953223     | -0.302267 |
| -9.996940   | 0.302267     | 0.953223  |

Stationary point is a saddle point.

However, the ridge analysis in Output 81.1.4 and the ridge plot in Output 81.1.5 indicate that maximum yields result from relatively high reaction times and low temperatures. A contour plot of the predicted response surface, shown in Output 81.1.6, confirms this conclusion.

**Output 81.1.4** Ridge Analysis

| Estimated Ridge of Maximum Response for Variable<br>MBT: Percent Yield Mercaptobenzothiazole |                       |                   |                       |            |

**Output 81.1.5** Ridge Plot of Predicted Response Surface

**Output 81.1.6** Contour Plot of Predicted Response Surface

## Example 81.2: Response Surface Analysis with Covariates

One way of viewing covariates is as extra sources of variation in the dependent variable that can mask the variation due to primary factors. This example demonstrates the use of the `COVAR=` option in PROC RSREG to fit a response surface model to the dependent variables corrected for the covariates.

You have a chemical process with a yield that you hypothesize to be dependent on three factors: reaction time, reaction temperature, and reaction pressure. You perform an experiment to measure this dependence. You are willing to include up to 20 runs in your experiment, but you can perform no more than 8 runs on the same day, so the design for the experiment is composed of three blocks. Additionally, you know that the grade of raw material for the reaction has a significant impact on the yield. You have no control over this, but you keep track of it. The following statements create a SAS data set containing the results of the experiment:

```
data Experiment;
 input Day Grade Time Temp Pressure Yield;
 datalines;
1 67 -1 -1 -1 32.98
1 68 -1 1 1 47.04
1 70 1 -1 1 67.11
```

```

1 66 1 1 -1 26.94
1 74 0 0 0 103.22
1 68 0 0 0 42.94
2 75 -1 -1 1 122.93
2 69 -1 1 -1 62.97
2 70 1 -1 -1 72.96
2 71 1 1 1 94.93
2 72 0 0 0 93.11
2 74 0 0 0 112.97
3 69 1.633 0 0 78.88
3 67 -1.633 0 0 52.53
3 68 0 1.633 0 68.96
3 71 0 -1.633 0 92.56
3 70 0 0 1.633 88.99
3 72 0 0 -1.633 102.50
3 70 0 0 0 82.84
3 72 0 0 0 103.12
;

```

Your first analysis neglects to take the covariates into account. The following statements use PROC RSREG to fit a response surface to the observed yield, but note that Day and Grade are omitted:

```

proc rsreg data=Experiment;
 model Yield = Time Temp Pressure;
run;

```

The ANOVA results shown in [Output 81.2.1](#) indicate that *no* process variable effects are significantly larger than the background noise.

**Output 81.2.1** Analysis of Variance Ignoring Covariates

| The RSREG Procedure |    |                          |                   |             |        |
|---------------------|----|--------------------------|-------------------|-------------|--------|
| Regression          | DF | Type I Sum<br>of Squares | R-Square          | F Value     | Pr > F |
| Linear              | 3  | 1880.842426              | 0.1353            | 0.67        | 0.5915 |
| Quadratic           | 3  | 2370.438681              | 0.1706            | 0.84        | 0.5023 |
| Crossproduct        | 3  | 241.873250               | 0.0174            | 0.09        | 0.9663 |
| Total Model         | 9  | 4493.154356              | 0.3233            | 0.53        | 0.8226 |
|                     |    |                          |                   |             |        |
|                     |    |                          | Sum of<br>Squares | Mean Square |        |
| Residual            | DF |                          |                   |             |        |
| Total Error         | 10 | 9405.129724              |                   | 940.512972  |        |

However, when the yields are adjusted for covariate effects of day and grade of raw material, very strong process variable effects are revealed. The following statements produce the ANOVA results in [Output 81.2.2](#). Note that in order to include the effects of the classification factor Day as covariates, you need to create dummy variables indicating each day separately.

```

data Experiment;
 set Experiment;
 d1 = (Day = 1);
 d2 = (Day = 2);
 d3 = (Day = 3);

ods graphics on;
proc rsreg data=Experiment plots=all;
 model Yield = d1-d3 Grade Time Temp Pressure / covar=4;
run;
ods graphics off;

```

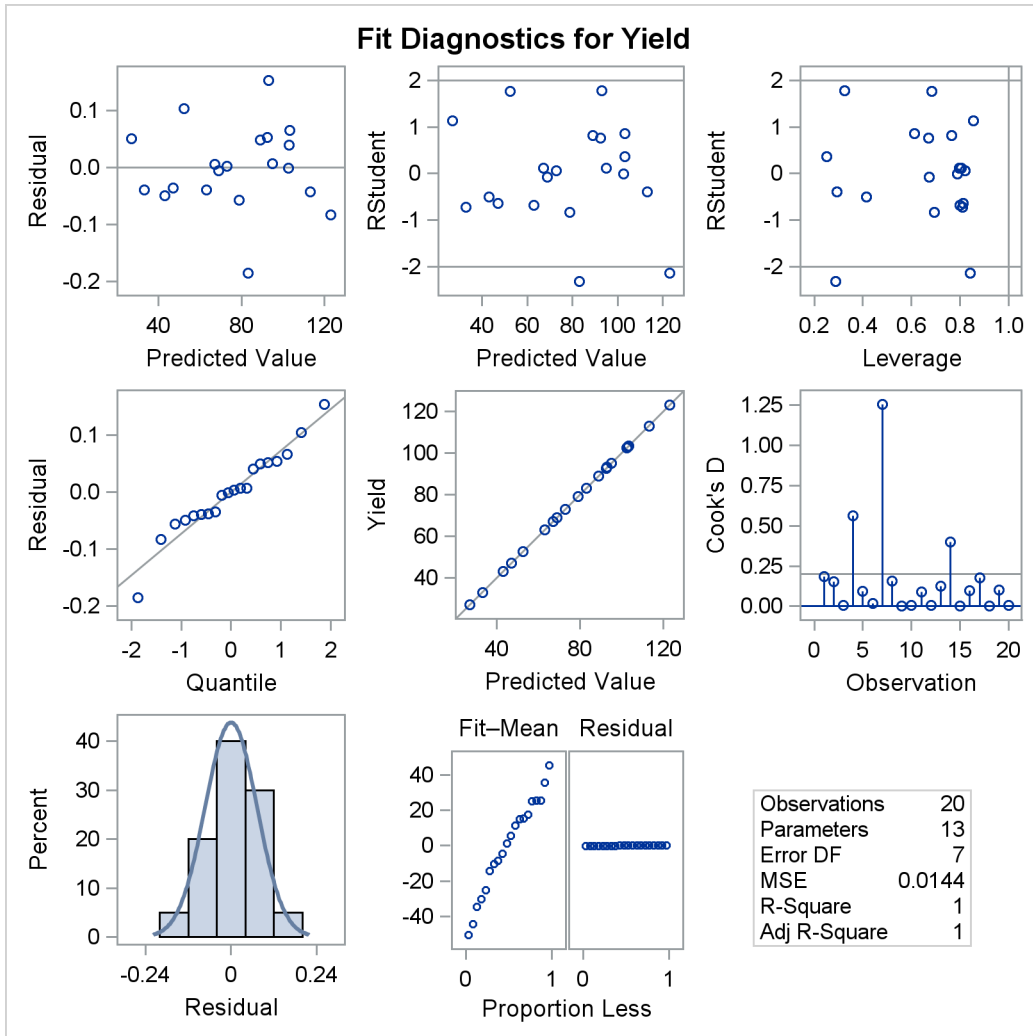

The results show very strong effects due to both the covariates and the process variables.

### Output 81.2.2 Analysis of Variance Including Covariates

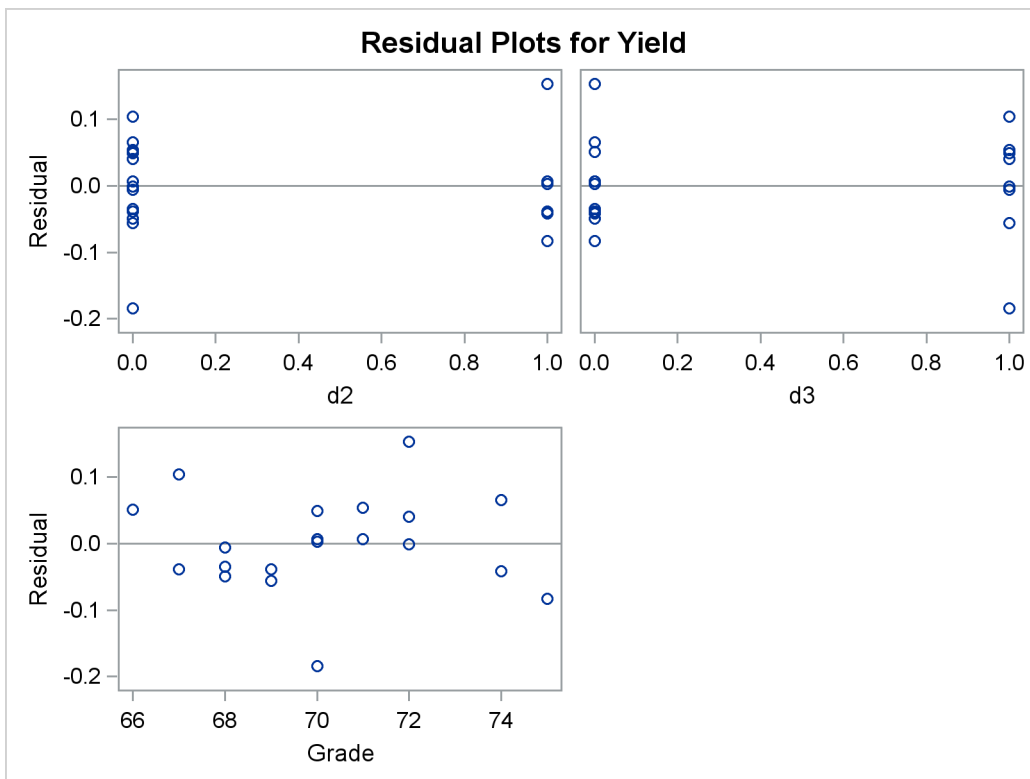

| The RSREG Procedure |    |                          |             |         |        |
|---------------------|----|--------------------------|-------------|---------|--------|
| Regression          | DF | Type I Sum<br>of Squares | R-Square    | F Value | Pr > F |
| Covariates          | 3  | 13695                    | 0.9854      | 316957  | <.0001 |
| Linear              | 3  | 156.524497               | 0.0113      | 3622.53 | <.0001 |
| Quadratic           | 3  | 22.989775                | 0.0017      | 532.06  | <.0001 |
| Crossproduct        | 3  | 23.403614                | 0.0017      | 541.64  | <.0001 |
| Total Model         | 12 | 13898                    | 1.0000      | 80413.2 | <.0001 |
| Residual            | DF | Sum of<br>Squares        | Mean Square |         |        |
| Total Error         | 7  | 0.100820                 | 0.014403    |         |        |

The number of observations in the data set might be too small for the diagnostic plots in [Output 81.2.3](#) to dependably identify problems; however, some outliers are indicated. The residual plots in [Output 81.2.4](#) do not display any obvious structure.

**Output 81.2.3** Fit Diagnostics

Output 81.2.4 Residual Plots

### Overview: SCORE Procedure

The SCORE procedure multiplies values from two SAS data sets, one containing coefficients (for example, factor-scoring coefficients or regression coefficients) and the other containing raw data to be scored using the coefficients from the first data set. The result of this multiplication is a SAS data set containing linear combinations of the coefficients and the raw data values.

Many statistical procedures output coefficients that PROC SCORE can apply to raw data to produce scores. The new score variable is formed as a linear combination of raw data and scoring coefficients. For each observation in the raw data set, PROC SCORE multiplies the value of a variable in the raw data set by the matching scoring coefficient from the data set of scoring coefficients. This multiplication process is repeated for each variable in the VAR statement. The resulting products are then summed to produce the value of the new score variable. This entire process is repeated for each observation in the raw data set. In other words, PROC SCORE cross multiplies part of one data set with another.

---

## Raw Data Set

The raw data set can contain the original data used to calculate the scoring coefficients, or it can contain an entirely different data set. The raw data set must contain all the variables needed to produce scores. In addition, the scoring coefficients and the variables in the raw data set that are used in scoring must have the same names. See the section “Getting Started: SCORE Procedure” on page 6947 for more information.

---

## Scoring Coefficients Data Set

The data set containing scoring coefficients must contain two special variables: the `_TYPE_` variable and the `_NAME_` or `_MODEL_` variable.

- The `_TYPE_` variable identifies the observations that contain scoring coefficients.
- The `_NAME_` or `_MODEL_` variable provides a SAS name for the new score variable.

PROC SCORE first looks for a `_NAME_` variable in the SCORE= input data set. If there is such a variable, the variable's value is what SCORE uses to name the new score variable. If the SCORE= data set does not have a `_NAME_` variable, then PROC SCORE looks for a `_MODEL_` variable.

For example, PROC FACTOR produces an output data set that contains factor-scoring coefficients. In this output data set, the scoring coefficients are identified by `_TYPE_='SCORE'`. For `_TYPE_='SCORE'`, the `_NAME_` variable has values of 'Factor1', 'Factor2', and so forth. PROC SCORE gives the new score variables the names Factor1, Factor2, and so forth.

As another example, the REG procedure produces an output data set that contains parameter estimates. In this output data set, the parameter estimates are identified by `_TYPE_='PARMS'`. The `_MODEL_` variable contains the label used in the MODEL statement in PROC REG, or it uses `MODEL $n$`  if no label is specified. This label is the name PROC SCORE gives to the new score variable.

---

## Standardization of Raw Data

PROC SCORE automatically standardizes or centers the DATA= variables for you, based on information from the original variables and analysis from the SCORE= data set.

If the SCORE= scoring coefficients data set contains observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`, then PROC SCORE standardizes the raw data before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP without the COV option.

If the SCORE= scoring coefficients data set contains observations with `_TYPE_='MEAN'` but `_TYPE_='STD'` is absent, then PROC SCORE centers the raw data (the means are subtracted) before scoring. For example, this type of SCORE= data set can come from PROC PRINCOMP with the COV option.

If the SCORE= scoring coefficients data set does not contain observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`, or if you use the NOSTD option, then PROC SCORE does not center or standardize the raw data.

If the SCORE= scoring coefficients are obtained from observations with `_TYPE_='USCORE'`, then PROC SCORE “standardizes” the raw data by using the uncorrected standard deviations identified by `_TYPE_='USTD'`, and the means are not subtracted from the raw data. For example, this type of SCORE= data set can come from PROC PRINCOMP with the NOINT option. For more information about `_TYPE_='USCORE'` scoring coefficients in TYPE=UCORR or TYPE=UCOV output data sets, see Appendix A, “Special SAS Data Sets.”

You can use PROC SCORE to score the data that were also used to generate the scoring coefficients, although more typically, scoring results are directly obtained from the OUT= data set in a procedure that computes scoring coefficients. When scoring new data, it is important to realize that PROC SCORE assumes that the new data have approximately the same scales as the original data. For example, if you specify the COV option with PROC PRINCOMP for the original analysis, the scoring coefficients in the PROC PRINCOMP OUTSTAT= data set are not appropriate for standardized data. With the COV option, PROC PRINCOMP will not output `_TYPE_='STD'` observations to the OUTSTAT= data set, and PROC SCORE will only subtract the means of the original (not new) variables from the new variables before multiplying. Without the COV option in PROC PRINCOMP, both the original variable means and standard deviations will be in the OUTSTAT= data set, and PROC SCORE will subtract the original variable means from the new variables and divide them by the original variable standard deviations before multiplying.

In general, procedures that output scoring coefficients in their OUTSTAT= data sets provide the necessary information for PROC SCORE to determine the appropriate standardization. However, if you use PROC SCORE with a scoring coefficients data set that you constructed without `_TYPE_='MEAN'` and `_TYPE_='STD'` observations, you might have to do the relevant centering or standardization of the new data first. If you do this, you must use the means and standard deviations of the original variables—that is, the variables that were used to generate the coefficients—not the means and standard deviations of the variables to be scored.

See the section “Getting Started: SCORE Procedure” on page 6947 for further illustration.

---

## Getting Started: SCORE Procedure

The SCORE procedure multiplies the values from two SAS data sets and creates a new data set to contain the results of the multiplication. The variables in the new data set are linear combinations of the variables in the two input data sets. Typically, one of these data sets contains raw data that you want to score, and the other data set contains scoring coefficients.

The following example demonstrates how to use the SCORE procedure to multiply values from two SAS data sets, one containing factor-scoring coefficients and the other containing raw data to be scored using the scoring coefficients.

Suppose you are interested in the performance of three different types of schools: private schools, state-run urban schools, and state-run rural schools. You want to compare the schools’ performances as measured by student grades on standard tests in English, mathematics, and biology. You administer these tests and record the scores for each of the three types of schools.

The following DATA step creates the SAS data set Schools. The data are provided by Chaseling (1996).

```

data Schools;
 input Type $ English Math Biology @@;
 datalines;
p 52 55 45 p 42 49 40 p 63 64 54
p 47 50 51 p 64 69 47 p 63 67 54
p 59 63 42 p 56 61 41 p 41 44 72
p 39 42 45 p 56 63 44 p 63 73 42

 ... more lines ...

r 50 47 49 r 55 48 46 r 38 36 51
;

```

The data set `Schools` contains the character variable `Type`, which represents the type of school. Valid values are `p` (private schools), `r` (state-run rural schools), and `u` (state-run urban schools).

The three numeric variables in the data set are `English`, `Math`, and `Biology`, which represent the student scores for English, mathematics, and biology, respectively. The double trailing at sign (`@@`) in the `INPUT` statement specifies that observations are input from each line until all values are read.

The following statements invoke the `FACTOR` procedure to compute the data set of factor scoring coefficients. The statements perform a principal components factor analysis that uses all three numeric variables in the SAS data set `Schools`. The `OUTSTAT=` option requests that `PROC FACTOR` output the factor scores to the data set `Scores`. The `NOPRINT` option suppresses display of the output.

```

proc factor data=Schools score outstat=Scores noprint;
 var english math biology;
run;

proc score data=schools score=Scores out=New;
 var english math biology;
 id type;
run;

```

The SCORE procedure is then invoked using Schools as the raw data set to be scored and Scores as the scoring data set. The OUT= option creates the SAS data set New to contain the linear combinations.

The VAR statement specifies that the variables English, Math, and Biology are used in computing scores. The ID statement copies the variable Type from the Schools data set to the output data set New.

The following statements print the SAS output data set Scores, the first two observations from the original data set Schools, and the first two observations of the resulting data set New.

```

title 'OUTSTAT= Data Set from PROC FACTOR';
proc print data=Scores;
run;

title 'First Two Observations of the DATA= Data Set from PROC SCORE';
proc print data=Schools(obs=2);
run;

title 'First Two Observations of the OUT= Data Set from PROC SCORE';
proc print data=New(obs=2);
run;

```

Figure 82.1 displays the output data set Scores produced by the FACTOR procedure. The last observation (number 11) contains the scoring coefficients (`_TYPE_='SCORE'`). Only one factor has been retained.

**Figure 82.1** Listing of the Data Set Created by PROC FACTOR

| OUTSTAT= Data Set from PROC FACTOR |          |         |         |         |         |
|------------------------------------|----------|---------|---------|---------|---------|
| Obs                                | _TYPE_   | _NAME_  | English | Math    | Biology |
| 1                                  | MEAN     |         | 55.525  | 52.325  | 50.350  |

Figure 82.3 lists the first two observations of the output data set New created by PROC SCORE.

**Figure 82.3** Listing of the New Data Set

| First Two Observations of the OUT= Data Set from PROC SCORE |      |          |
|-------------------------------------------------------------|------|----------|
| Obs                                                         | Type | Factor1  |
| 1                                                           | p    | -0.17604 |
| 2                                                           | p    | -0.80294 |

The score variable Factor1 in the New data set is named according to the value of the `_NAME_` variable in the Scores data set. The values of the variable Factor1 are computed as follows: the DATA= data set variables are standardized using the same means and standard deviations that PROC FACTOR used when extracting the factors because the Scores data set contains observations with `_TYPE_='MEAN'` and `_TYPE_='STD'`.

Note that in order to correctly use standardized scoring coefficients created by other procedures such as PROC FACTOR in this example, the data to be scored must be standardized in the same way that the data were standardized when the scoring coefficients were computed. Otherwise, the resulting scores might be incorrect. PROC SCORE does this automatically if the SCORE= data set is the original OUTSTAT= data set output from the procedure creating the scoring coefficients.

These standardized variables are then multiplied by their respective standardized scoring coefficients from the data set Scores. These products are summed over all three variables, and the sum is the value of the new variable Factor1. The first two values of the scored variable Factor1 are obtained as follows:

$$\left( \frac{(52 - 55.525)}{12.949} \times 0.390 \right) + \left( \frac{(55 - 52.325)}{12.356} \times 0.378 \right) + \left( \frac{(45 - 50.350)}{12.239} \times 0.347 \right) = -0.17604$$

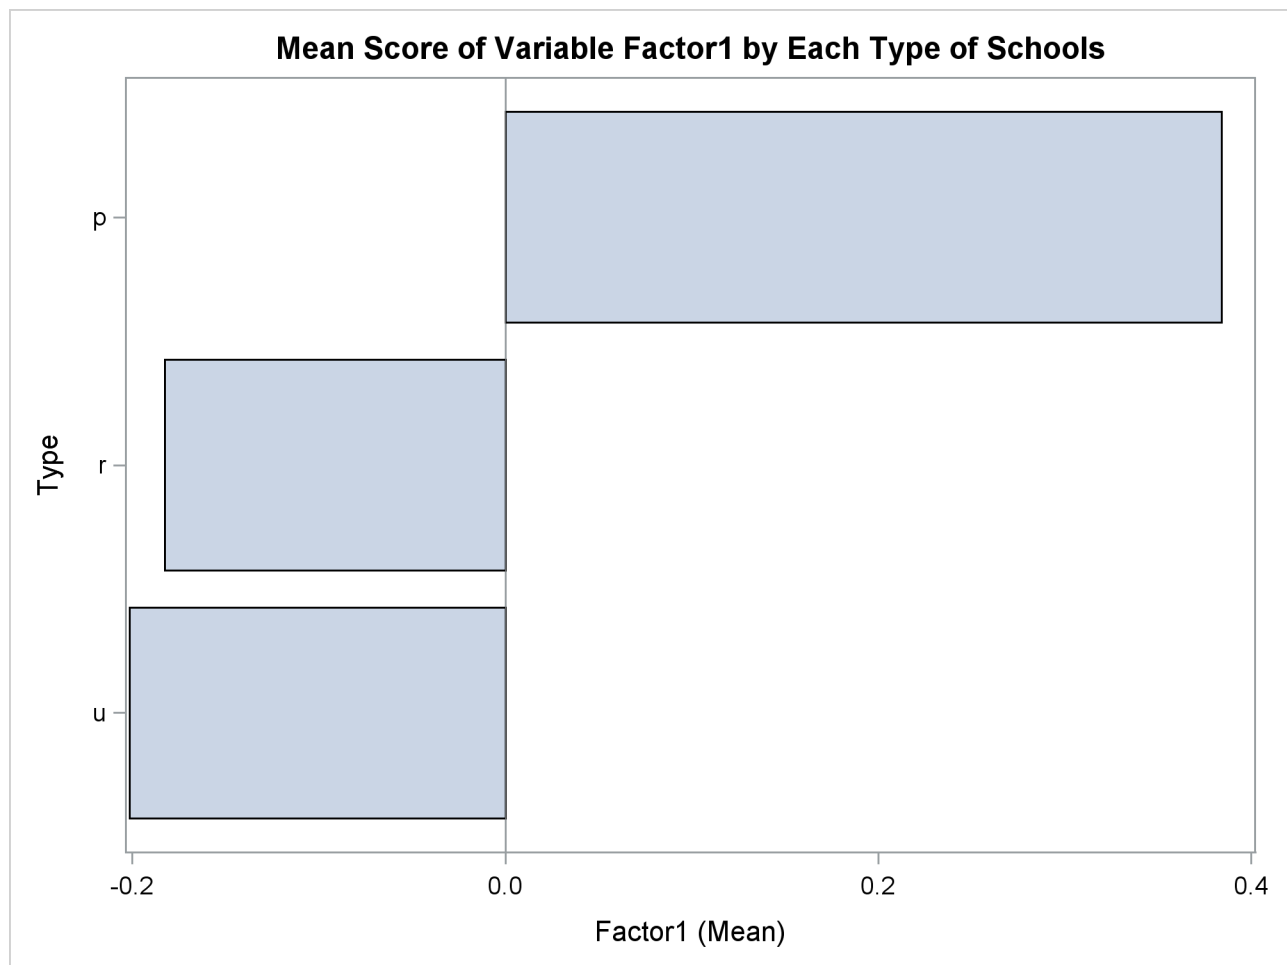

$$\left( \frac{(42 - 55.525)}{12.949} \times 0.390 \right) + \left( \frac{(49 - 52.325)}{12.356} \times 0.378 \right) + \left( \frac{(40 - 50.350)}{12.239} \times 0.347 \right) = -0.80294$$

The following statements request that the SGPLOT procedure produce a horizontal bar chart of the variable `Type`. The length of each bar represents the mean of the variable `Factor1`.

```
title 'Mean Score of Variable Factor1 by Each Type of Schools';
proc sgplot data=New;
 hbar type / stat = mean response=Factor1;
run;
```

Figure 82.4 displays the mean score of the variable `Factor1` for each of the three school types. For private schools (`Type=p`), the average value of the variable `Factor1` is 0.384, while for state-run schools the average values are much lower. The state-run urban schools (`Type=u`) have the lowest mean value of  $-0.202$ , and the state-run rural schools (`Type=r`) have a mean value of  $-0.183$ .

**Figure 82.4** Bar Chart of School Type

## Syntax: SCORE Procedure

The following statements are available in the SCORE procedure:

```
PROC SCORE DATA=SAS-data-set < options > ;
 BY variables ;
 ID variables ;
 VAR variables ;
```

The only required statement is the PROC SCORE statement. The BY, ID, and VAR statements are described following the PROC SCORE statement.

## PROC SCORE Statement

```
PROC SCORE DATA=SAS-data-set < options > ;
```

The PROC SCORE statement invokes the SCORE procedure. Table 82.1 summarizes the options available in the PROC SCORE statement.

**Table 82.1** PROC SCORE Statement Options

| Option          | Description                                                   |
|-----------------|---------------------------------------------------------------|
| <b>DATA=</b>    | Names the input SAS data set containing the raw data to score |
| <b>NOSTD</b>    | Suppresses centering and scaling of the raw data              |
| <b>OUT=</b>     | Specifies the name of the SAS data set                        |
| <b>PREDICT</b>  | Treats coefficients of $-1$ as $0$                            |
| <b>RESIDUAL</b> | Reverses the sign of each score                               |
| <b>SCORE=</b>   | Names the data set containing the scoring coefficients        |
| <b>TYPE=</b>    | Specifies the observations that contain scoring coefficients  |

You can specify the following options in the PROC SCORE statement.

### **DATA=SAS-data-set**

names the input SAS data set containing the raw data to score. This option is required.

### **NOSTD**

suppresses centering and scaling of the raw data. Ordinarily, if PROC SCORE finds `_TYPE_='MEAN'`, `_TYPE_='USCORE'`, `_TYPE_='USTD'`, or `_TYPE_='STD'` observations in the SCORE= data set, the procedure uses these to standardize the raw data before scoring.

### **OUT=SAS-data-set**

specifies the name of the SAS data set created by PROC SCORE. If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*. If the OUT= option is omitted, PROC SCORE still creates an output data set and automatically names it according to the DATA $n$  convention, as if you omitted a data set name in a DATA statement.

**PREDICT**

specifies that PROC SCORE should treat coefficients of  $-1$  in the SCORE= data set as 0. In regression applications, the dependent variable is coded with a coefficient of  $-1$ . Applied directly to regression results, PROC SCORE produces negative residuals (see the description of the RESIDUAL option, which follows); the PREDICT option produces predicted values instead.

**RESIDUAL**

reverses the sign of each score. Applied directly to regression results, PROC SCORE produces negative residuals (PREDICT–ACTUAL); the RESIDUAL option produces positive residuals (ACTUAL–PREDICT) instead.

**SCORE=SAS-data-set**

names the data set containing the scoring coefficients. If you omit the SCORE= option, the most recently created SAS data set is used. This data set must have two special variables: `_TYPE_` and either `_NAME_` or `_MODEL_`.

**TYPE=name or 'string'**

specifies the observations in the SCORE= data set that contain scoring coefficients. The TYPE= procedure option is unrelated to the data set option that has the same name. PROC SCORE examines the values of the special variable `_TYPE_` in the SCORE= data set. When the value of `_TYPE_` matches `TYPE=name`, the observation in the SCORE= data set is used to score the raw data in the DATA= data set.

If you omit the TYPE= option, scoring coefficients are read from observations with either `_TYPE_='SCORE'` or `_TYPE_='USCORE'`. Because the default for PROC SCORE is `TYPE=SCORE`, you need not specify the TYPE= option for factor scoring or for computing scores from OUTSTAT= data sets from the CANCELL, CANDISC, PRINCOMP, or VARCLUS procedure. When you use regression coefficients from PROC REG, specify `TYPE=PARMS`.

The maximum length of the argument specified in the TYPE= option depends on the length defined by the VALIDVARIABLE= SAS system option. For additional information, see *SAS System Options: Reference*.

Note that the TYPE= option setting is not case sensitive. For example, the two option settings `TYPE='MyScore'` and `TYPE='myscore'` are equivalent.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC SCORE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.

- Specify the `NOTSORTED` or `DESCENDING` option in the `BY` statement for the `SCORE` procedure. The `NOTSORTED` option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the `BY` variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the `BY` variables by using the `DATASETS` procedure (in Base SAS software).

For more information about `BY`-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the `DATASETS` procedure, see the discussion in the *Base SAS Procedures Guide*.

You can specify a `BY` statement to apply separate groups of scoring coefficients to the entire `DATA=` data set.

If the `DATA=` data set does not contain any of the `BY` variables, the entire `DATA=` data set is scored by each `BY` group of scoring coefficients in the `SCORE=` data set.

If the `DATA=` data set contains some but not all of the `BY` variables, or if some `BY` variables do not have the same type or length in the `DATA=` data set as in the `SCORE=` data set, then `PROC SCORE` prints an error message and stops.

If all the `BY` variables appear in the `DATA=` data set with the same type and length as in the `SCORE=` data set, then each `BY` group in the `DATA=` data set is scored using scoring coefficients from the corresponding `BY` group in the `SCORE=` data set. The `BY` groups in the `DATA=` data set must be in the same order as in the `SCORE=` data set. All `BY` groups in the `DATA=` data set must also appear in the `SCORE=` data set. If you do not specify the `NOTSORTED` option, some `BY` groups can appear in the `SCORE=` data set but not in the `DATA=` data set; such `BY` groups are not used in computing scores.

---

## ID Statement

**ID** *variables* ;

The `ID` statement identifies variables from the `DATA=` data set to be included in the `OUT=` data set. If there is no `ID` statement, all variables from the `DATA=` data set are included in the `OUT=` data set. The `ID` variables can be character or numeric.

---

## VAR Statement

**VAR** *variables* ;

The `VAR` statement specifies the variables to be used in computing scores. These variables must be in both the `DATA=` and `SCORE=` input data sets and must be numeric. If you do not specify a `VAR` statement, the procedure uses all numeric variables in the `SCORE=` data set. You should almost always specify a `VAR` statement with `PROC SCORE` because you would rarely use all the numeric variables in your data set to compute scores.

---

## Details: SCORE Procedure

---

### Missing Values

If one of the scoring variables in the DATA= data set has a missing value for an observation, all the scores have missing values for that observation. The exception to this criterion is that if the PREDICT option is specified, the variable with a coefficient of  $-1$  can tolerate a missing value and still produce a prediction score. Also, a variable with a coefficient of  $0$  can tolerate a missing value.

If a scoring coefficient in the SCORE= data set has a missing value for an observation, the coefficient is not used in creating the new score variable for the observation. In other words, missing values of scoring coefficients are treated as zeros. This treatment affects only the observation in which the missing value occurs.

---

### Regression Parameter Estimates from PROC REG

If the SCORE= data set is an OUTEST= data set produced by PROC REG and if you specify TYPE=PARMS, the interpretation of the new score variables depends on the PROC SCORE options chosen and the variables listed in the VAR statement. If the VAR statement contains only the independent variables used in a model in PROC REG, the new score variables give the predicted values. If the VAR statement contains the dependent variables and the independent variables used in a model in PROC REG, the interpretation of the new score variables depends on the PROC SCORE options chosen. If you omit both the PREDICT and the RESIDUAL options, the new score variables give negative residuals (PREDICT–ACTUAL). If you specify the RESIDUAL option, the new score variables give positive residuals (ACTUAL–PREDICT). If you specify the PREDICT option, the new score variables give predicted values.

Unless you specify the NOINT option for PROC REG, the OUTEST= data set contains the variable Intercept. The SCORE procedure uses the intercept value in computing the scores.

---

### Output Data Set

PROC SCORE produces an output data set but displays no output. The output OUT= data set contains the following variables:

- the ID variables, if any
- all variables from the DATA= data set, if no ID variables are specified
- the BY variables, if any
- the new score variables, named from the `_NAME_` or `_MODEL_` values in the SCORE= data set

---

## Computational Resources

Let

- $v$  = number of variables used in computing scores
- $s$  = number of new score variables
- $b$  = maximum number of new score variables in a BY group
- $n$  = original input value

### Memory

The array storage required is approximately  $8(4v + (3 + v)b + s)$  bytes. When you do not use BY processing, the array storage required is approximately  $8(4v + (4 + v)s)$  bytes.

### Time

The time required to construct the scoring matrix is roughly proportional to  $vs$ , and the time needed to compute the scores is roughly proportional to  $nvs$ .

---

## Examples: SCORE Procedure

The following three examples use a subset of the Fitness data set. The complete data set is given in Chapter 79, “The REG Procedure.”

---

### Example 82.1: Factor Scoring Coefficients

This example shows how to use PROC SCORE with factor scoring coefficients. First, the FACTOR procedure produces an output data set containing scoring coefficients in observations identified by `_TYPE_='SCORE'`. These data, together with the original data set Fitness, are supplied to PROC SCORE, resulting in a data set containing scores Factor1 and Factor2. The following statements produce Output 82.1.1 through Output 82.1.3:

```

/* This data set contains only the first 12 observations */
/* from the full data set used in the chapter on PROC REG. */
data Fitness;
 input Age Weight Oxygen RunTime RestPulse RunPulse @@;
 datalines;
44 89.47 44.609 11.37 62 178 40 75.07 45.313 10.07 62 185
44 85.84 54.297 8.65 45 156 42 68.15 59.571 8.17 40 166

44 73.03 50.541 10.13 45 168 45 87.66 37.388 14.03 56 186
;

```

```

proc factor data=Fitness outstat=FactOut
 method=prin rotate=varimax score;
 var Age Weight RunTime RunPulse RestPulse;
 title 'Factor Scoring Example';
run;

proc print data=FactOut;
 title2 'Data Set from PROC FACTOR';
run;

proc score data=Fitness score=FactOut out=FScore;
 var Age Weight RunTime RunPulse RestPulse;
run;

proc print data=FScore;
 title2 'Data Set from PROC SCORE';
run;

```

Output 82.1.1 shows the PROC FACTOR output. The scoring coefficients for the two factors are shown at the end of the PROC FACTOR output.

**Output 82.1.1** Creating an OUTSTAT= Data Set with PROC FACTOR

Since the PROC SCORE statement does not contain the NOSTD option, the data in the Fitness data set are standardized before scoring. For each variable specified in the VAR statement, the mean and standard deviation are obtained from the FactOut data set. For each observation in the Fitness data set, the variables are then standardized. For example, for observation 1 in the Fitness data set, the variable Age is standardized to  $0.5569 = [(44 - 42.4167)/2.8431]$ .

After the data in the Fitness data set are standardized, the standardized values of the variables in the VAR statement are multiplied by the matching coefficients in the FactOut data set, and the resulting products are summed. This sum is output as a value of the new score variable.

Output 82.1.3 displays the FScore data set produced by PROC SCORE. This data set contains the variables Age, Weight, Oxygen, RunTime, RestPulse, and RunPulse from the Fitness data set. It also contains Factor1 and Factor2, the two new score variables.

**Example 82.2: Regression Parameter Estimates**

In this example, PROC REG computes regression parameter estimates for the Fitness data. (See [Example 82.1](#) to for more information about how to create the Fitness data set.) The parameter estimates are output to a data set and used as scoring coefficients. For the first part of this example, PROC SCORE is used to score the Fitness data, which are the same data used in the regression.

In the second part of this example, PROC SCORE is used to score a new data set, Fitness2. For PROC SCORE, the TYPE= specification is PARMS, and the names of the score variables are found in the variable `_MODEL_`, which gets its values from the model label. The following code produces [Output 82.2.1](#) through [Output 82.2.3](#):

```
proc reg data=Fitness outest=RegOut;
 OxyHat: model Oxygen=Age Weight RunTime RunPulse RestPulse;
 title 'Regression Scoring Example';
run;

proc print data=RegOut;
 title2 'OUTEST= Data Set from PROC REG';
run;

proc score data=Fitness score=RegOut out=RScoreP type=parms;
 var Age Weight RunTime RunPulse RestPulse;
run;
```

```

proc print data=RScoreP;
 title2 'Predicted Scores for Regression';
run;

proc score data=Fitness score=RegOut out=RScoreR type=parms;
 var Oxygen Age Weight RunTime RunPulse RestPulse;
run;

proc print data=RScoreR;
 title2 'Negative Residual Scores for Regression';
run;

```

Output 82.2.1 shows the PROC REG output. The column labeled “Parameter Estimates” lists the parameter estimates. These estimates are output to the RegOut data set.

**Output 82.2.1** Creating an OUTEST= Data Set with PROC REG

Output 82.2.3 lists the data sets created by PROC SCORE. Since the SCORE= data set does not contain observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, the data in the Fitness data set are not standardized before scoring. The SCORE= data set contains the variable Intercept, so this intercept value is used in computing the score. To produce the RScoreP data set, the VAR statement in PROC SCORE includes only the independent variables from the model in PROC REG. As a result, the OxyHat variable contains predicted values. To produce the RScoreR data set, the VAR statement in PROC SCORE includes both the dependent variables and the independent variables from the model in PROC REG. As a result, the OxyHat variable contains negative residuals (PREDICT-ACTUAL) as shown in Output 82.2.4. If the RESIDUAL option is specified, the variable OxyHat contains positive residuals (ACTUAL-PREDICT). If the PREDICT option is specified, the OxyHat variable contains predicted values.

**Output 82.2.3** Predicted Scores from the OUT= Data Set Created by PROC SCORE

PROC SCORE scores the Fitness2 data set by using the parameter estimates in the RegOut data set. These parameter estimates result from fitting a regression equation to the Fitness data set. The NOSTD option is specified, so the raw data are not standardized before scoring. (However, the NOSTD option is not necessary here. The SCORE= data set does not contain observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, so standardization is not performed.) The VAR statement contains the dependent variables and the independent variables used in PROC REG. In addition, the PREDICT option is specified. This combination gives predicted values for the new score variable. The name of the new score variable is OxyHat, from the value of the `_MODEL_` variable in the SCORE= data set. [Output 82.2.6](#) shows the data set produced by PROC SCORE.

**Output 82.2.6** Predicted Scores from the OUT= Data Set Created by PROC SCORE and Reproduced Using PROC PRINT

### Example 82.3: Custom Scoring Coefficients

This example uses a specially created custom scoring data set and produces [Output 82.3.1](#) and [Output 82.3.2](#). The first scoring coefficient creates a variable that is Age–Weight; the second scoring coefficient evaluates the variable RunPulse–RstPulse; and the third scoring coefficient totals all six variables. Since the scoring coefficients data set (data set A) does not contain any observations with `_TYPE_='MEAN'` or `_TYPE_='STD'`, the data in the Fitness data set (see [Example 82.1](#)) are not standardized before scoring.

The following statements produce [Output 82.3.1](#) and [Output 82.3.2](#):

```
data A;
 input _type_ $ _name_ $
 Age Weight RunTime RunPulse RestPulse;
 datalines;
SCORE AGE_WGT 1 -1 0 0 0
SCORE RUN_RST 0 0 0 1 -1
SCORE TOTAL 1 1 1 1 1
;
proc print data=A;
 title 'Constructed Scoring Example';
 title2 'Scoring Coefficients';
run;

proc score data=Fitness score=A out=B;
 var Age Weight RunTime RunPulse RestPulse;
run;

proc print data=B;
 title2 'Scored Data';
run;
```

**Output 82.3.1** Custom Scoring Data Set and Scored Fitness Data: PROC PRINT

## Overview: SEQDESIGN Procedure

The purpose of the SEQDESIGN procedure is to design interim analyses for clinical trials. Clinical trials are experiments on human subjects to demonstrate the efficacy and safety of new drugs or treatments. A simple example is a trial to test the effectiveness of a new drug in humans by comparing the outcomes in a group of patients who receive the new drug with the outcomes in a comparable group of patients who receive a placebo.

A clinical trial is conducted according to a plan called a *protocol*. A protocol details the objectives of the trial, the data collection process, and the analysis. The protocol specifies the null hypothesis and an alternative hypothesis, a test statistic, the probability  $\alpha$  of a Type I error, the probability  $\beta$  of a Type II error, the sample size needed to attain a specified power of  $1 - \beta$  at an alternative reference, and critical values that are associated with the test statistic.

In a fixed-sample trial, data about all individuals are first collected and then examined at the end of the study. Most major trials have committees that periodically monitor safety and efficacy data during the trial and recommend that a trial be stopped for safety concerns such as an unacceptable toxicity level. In certain situations, the committee might recommend that a trial be stopped for efficacy. In contrast to a fixed-sample trial, a group sequential trial provides for interim analyses before the completion of the trial while maintaining the specified overall Type I and Type II error probabilities.

A group sequential trial is most useful in situations where it is important to monitor the trial to prevent unnecessary exposure of patients to an unsafe new drug, or alternatively to a placebo treatment if the new drug shows significant improvement. In most cases, if a group sequential trial stops early for safety concerns,

fewer patients are exposed to the new treatment than in the fixed-sample trial. If a trial stops early for efficacy reasons, the new treatment is available sooner than it would be in a fixed-sample trial. Early stopping can also save time and resources.

A group sequential design provides detailed specifications for a group sequential trial. In addition to the usual specification for a fixed-sample design, it provides the total number of stages (the number of interim stages plus a final stage) and a stopping criterion to reject, to accept, or to either reject or accept the null hypothesis at each interim stage. It also provides critical values and the sample size at each stage for the trial.

At each interim stage, the data collected at the current stage in addition to the data collected at previous stages are analyzed, and statistics such as a maximum likelihood test statistic and its associated standard error are computed. The test statistic is then compared with critical values that are generated from the sequential design, and the trial is stopped or continued. If a trial continues to the final stage, the null hypothesis is either rejected or accepted. The critical values for each stage are chosen in such a way that the overall  $\alpha$  and  $\beta$  are maintained at the specified levels.

Figure 83.1 shows a two-sided symmetric group sequential trial that stops early to reject the null hypothesis that the parameter  $\text{Trt}$  is zero.

**Figure 83.1** Sequential Plot for Two-Sided Test

The trial has four stages, which are indicated by the vertical lines labeled 1, 2, 3, and 4. With early stopping to reject the null hypothesis, the lower rejection boundary is constructed by connecting the lower critical values for the stages. Similarly, the upper rejection boundary is constructed by connecting the upper critical values for the stages. The horizontal axis indicates the sample size for the group sequential trial, and the vertical axis indicates the values of the test statistic on the standardized  $Z$  scale.

At each interim stage, if the test statistic falls into a rejection region (the darker shaded areas in [Figure 83.1](#)), the trial stops and the null hypothesis is rejected. Otherwise, the trial continues to the next stage. At the final stage (stage 4), the null hypothesis is rejected if  $Z$  falls into a rejection region. Otherwise, the null hypothesis is not rejected. In [Figure 83.1](#), the test statistic does not fall into the rejection regions for stages 1 and 2, and so the trial continues to stage 3. At stage 3, the test statistic falls into the rejection region, and the null hypothesis is rejected.

A group sequential trial usually involves six steps:

1. You specify the statistical details of the design, including the null and alternative hypotheses, a test statistic for the hypothesis test, the Type I and II error probabilities, a stopping criterion, the total number of stages, and the relative information level at each stage.
2. You compute the boundary values for the trial based on the specifications in Step 1. You also compute the sample size required at each stage for the specified hypothesis test.
3. At each stage, you collect additional data with the required sample sizes. The data available at each stage include the data collected at previous stages in addition to the data collected at the current stage.
4. At each stage, you analyze the available data with a procedure such as the REG procedure, and you compute the test statistic.
5. At each stage, you compare the test statistic with the corresponding boundary values. You stop the trial to reject or accept the hypothesis, or you continue the trial to the next stage. If you continue the trial to the final stage, you either accept or reject the hypothesis.
6. After the trial stops, you compute parameter estimates, confidence limits for the parameter, and a  $p$ -value for the hypothesis test.

You use the SEQDESIGN procedure at Step 2 to compute the initial boundary values and required sample sizes for the trial. You use the companion SEQTEST procedure at Step 5 to compare the test statistic with its boundary values. At stage 1, the boundary values are derived by using the boundary information tables created by the SEQDESIGN procedure. These boundary information tables are structured for input to the SEQTEST procedure. At each subsequent stage, the boundary values are derived by using the test information tables created by the SEQTEST procedure at the previous stage. These test information tables are also structured for input to the SEQTEST procedure. You also use the SEQTEST procedure at Step 6 to compute parameter estimates, confidence limits, and  $p$ -values after the trial stops.

The flowchart in [Figure 83.2](#) summarizes the steps in a typical group sequential trial and the relevant SAS procedures.

Figure 83.2 Group Sequential Trial

## Features of the SEQDESIGN Procedure

The SEQDESIGN procedure assumes that the standardized  $Z$  test statistics for the null hypothesis  $H_0 : \theta = 0$  at the stages have the joint canonical distribution with the information levels at the stages for the parameter  $\theta$ . This implies that these test statistics are normally distributed. If the test statistic is not normally distributed, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution. See the section “Statistical Assumptions for Group Sequential Designs” on page 7015 for a detailed description of the joint canonical distribution.

You can use the SEQDESIGN procedure to compute required sample sizes for commonly used hypothesis tests. Note that for a fixed-sample design, you should use the POWER and GLMPOWER procedures to compute sample sizes.

The applicable tests include tests for binomial proportions and the log-rank test for two survival distributions. See the section “Applicable One-Sample Tests and Sample Size Computation” on page 7050, the section “Applicable Two-Sample Tests and Sample Size Computation” on page 7052, and the section “Applicable Regression Parameter Tests and Sample Size Computation” on page 7061 for examples of applicable tests in group sequential trials.

At each stage, the data are analyzed with a statistical procedure such as the REG procedure, and a test statistic and its associated information level are computed. The information level is the amount of information available about the unknown parameter. For a maximum likelihood statistic, the information level is the inverse of its variance.

At each stage, you use the SEQTEST procedure to derive the boundary values that correspond to the information level associated with the test statistic. You then use the SEQTEST procedure to compare the test statistic with these boundary values. When a trial is stopped at an interim stage or at the final stage, the SEQTEST procedure also derives parameter estimates, confidence limits for the parameter, and a  $p$ -value for hypothesis testing.

---

## Output from the SEQDESIGN Procedure

In addition to computing the boundary values for a group sequential design, the SEQDESIGN procedure computes the following quantities:

- maximum sample size (as a percentage of the corresponding fixed-sample size) if the trial does not stop at an interim stage
- average sample numbers (as percentages of the corresponding fixed-sample sizes for nonsurvival data or fixed-sample numbers of events for survival data) under various hypothetical references, including the null and alternative references
- stopping probabilities at each stage under various hypothetical references to indicate how likely it is that the trial will stop at that stage
- sample sizes required at each stage for the specified hypothesis test
- numbers of events required at each stage for the specified hypothesis test with survival data

You can create more than one design with multiple DESIGN statements in the SEQDESIGN procedure and then choose the design with the most desirable features. The next two subsections introduce some basic aspects of group sequential designs that are useful for getting started with the SEQDESIGN procedure.

---

## Boundaries for Group Sequential Designs

A one-sided test is a test of a hypothesis with either a lower alternative ( $H_1 : \theta < 0$ ) or an upper alternative ( $H_1 : \theta > 0$ ), and a two-sided test is a test with a two-sided alternative ( $H_1 : \theta \neq 0$ ). The number of critical values for a test depends on whether the alternative is one-sided or two-sided, and it also depends on whether the trial is conducted with a fixed-sample design or a group sequential design.

For a fixed-sample trial, a one-sided test has one critical value and a two-sided test has two critical values. These critical values are computed with the specified Type I error probability  $\alpha$ . In contrast, at each interim stage of a group sequential trial, a one-sided test has up to two critical values and a two-sided group sequential test has up to four critical values. Thus, there are two or four possible boundaries for a group sequential design, and each boundary is a set of critical values, one from each stage.

Figure 83.3 illustrates the boundaries for a one-sided test with an upper alternative that allows for early stopping to either reject or accept the null hypothesis.

**Figure 83.3** Boundary Plot for One-Sided Design

With an upper alternative, as in this example, the design has the following two boundaries: an upper  $\alpha$  (rejection) boundary for the rejection region that consists of upper rejection critical values and an upper  $\beta$  (acceptance) boundary for the acceptance region that consists of upper acceptance critical values. The stages are indicated by vertical lines with accompanying stage numbers. In Figure 83.3, the horizontal axis indicates the cumulative sample size for the group sequential trial. The vertical axis indicates the critical values at each stage on the standardized Z scale. Other scales can be used for the vertical axis, including the MLE scale, score statistic scale, and  $p$ -value scale.

At each interim stage, if the test statistic is in the rejection region (darker shaded area in Figure 83.3), the trial stops and the null hypothesis is rejected. If the test statistic is in the acceptance region (lightly shaded area in Figure 83.3), the trial stops and the hypothesis is accepted. Otherwise, the trial continues to the next stage. If the trial proceeds to the final stage (stage 4), the upper  $\alpha$  and upper  $\beta$  critical values are identical, and the trial stops to either reject or accept the null hypothesis.

If you do not want to stop a trial when a test statistic falls in the acceptance region at an interim stage, you can derive a design with a nonbinding acceptance boundary to allow the trial to continue while maintaining the Type I error level. You need to increase the sample size for a design with this nonbinding feature. See the section “Acceptance ( $\beta$ ) Boundary” on page 7035 for a description of the nonbinding acceptance boundary.

---

## Group Sequential Methods

For a group sequential design, there are two possible boundaries for a one-sided test and four possible boundaries for a two-sided test. Each boundary consists of one boundary value (critical value) for each stage. The SEQDESIGN procedure provides various methods for computing the boundary values.

The boundary value for a fixed-sample test cannot be applied to each stage of sequential design because, as shown by Armitage, McPherson, and Rowe (1969), repeated significance tests at a fixed level on accumulating data increase the probability of a Type I error. For example, with a fixed-sample two-sided test, the critical values  $\pm 1.96$  for a standardized  $Z$  statistic produce a Type I error probability level  $\alpha = 0.05$ . But for a two-sided group sequential test with two equally spaced stages, if the same critical values  $\pm 1.96$  are used to reject the null hypothesis at these two stages, the Type I error probability level is  $\alpha = 0.083$ , larger than the fixed-sample  $\alpha$ .

Numerous methods are available for deriving the critical values for each boundary in a sequential design. Pocock (1977) applies repeated significance tests to group sequential trials with equal-size groups and derives a constant critical value on the standardized normal  $Z$  scale across all stages that maintains the specified Type I error probability level. O'Brien and Fleming (1979) propose a sequential procedure that has boundary values (in absolute value) decrease over the stages on the standardized normal  $Z$  scale.

The SEQDESIGN procedure provides the following three types of methods:

- fixed boundary shape methods, which derive boundaries with specified boundary shapes
- Whitehead methods, which adjust boundaries derived for continuous monitoring so that they apply to discrete monitoring
- error spending methods

Each type of methods uses a distinct approach to derive the boundary values for a group sequential trial. Whitehead methods require much less computation with resulting Type I error probability and power that are close but differ slightly from the specified values due to the approximations used in deriving the tests (Jennison and Turnbull 2000, p. 106). Fixed boundary shape methods derive boundary values by estimating a fixed number of parameters and require more computation. Error spending methods derive boundary values at each stage sequentially and require much more computation than other types of methods for group sequential trials with a large number of stages.

Within each type of methods, you can choose methods that creating boundary values range from conservative stopping boundary values at early stages to liberal stopping boundary values at very early stages.

You can use the SEQDESIGN procedure to specify methods from the same type for each design. A different method can be specified for each boundary separately, but all methods in a design must be of the same type.

### Fixed Boundary Shape Methods

The fixed boundary shape methods include the unified family methods and the Haybittle-Peto method. The unified family methods (Kittelson and Emerson 1999) derive boundaries from specified boundary shapes. These methods include Pocock's method (Pocock 1977) and the O'Brien-Fleming method (O'Brien and Fleming 1979) as special cases.

The Haybittle-Peto method (Haybittle 1971; Peto et al. 1976) uses a value of 3 for the critical values in interim stages, so the critical value at the final stage is close to the critical value for the fixed-sample design. In the SEQDESIGN procedure, the Haybittle-Peto method has been generalized to allow for different boundary values at interim stages.

## Whitehead Methods

Whitehead and Stratton (1983) and Whitehead (1997, 2001) develop triangular and straight-line boundaries by adapting tests constructed for continuous monitoring to discrete monitoring of group sequential tests. With continuous monitoring, the values for each boundary fall in a straight line when plotted on the score statistic scale. The discrete boundary is derived by subtracting the expected overshoot from the continuous boundary to obtain the desired Type I and Type II error probabilities. For a design with early stopping to either reject or accept the null hypothesis, the boundaries form a triangle when plotted on the score statistic scale. See the section “Score Statistic” on page 7005 for a detailed description of the score statistic.

## Error Spending Methods

For every sequential design, the  $\alpha$  and  $\beta$  errors at each stage can be computed from the boundary values. On the other hand, you can derive the boundary values from specified  $\alpha$  and  $\beta$  errors for each stage. The error spending function approach (Lan and DeMets 1983) uses an error spending function to specify the errors at each stage for each boundary and then derives the boundary values.

---

## Getting Started: SEQDESIGN Procedure

This section illustrates a clinical study design that uses a two-sided O’Brien-Fleming design (O’Brien and Fleming 1979) to stop the trial early for ethical concerns about possible harm or for unexpectedly strong efficacy of the new drug.

Suppose that a pharmaceutical company is conducting a clinical trial to test the efficacy of a new cholesterol-lowering drug. The primary focus is low-density lipoprotein (LDL), the so-called bad cholesterol, which is a risk factor for coronary heart disease. LDL is measured in *mg / dL*, milligrams per deciliter of blood.

The trial consists of two groups of equally allocated patients with elevated LDL levels: an experimental group given the new drug and a placebo control group. Suppose the changes in LDL level after the treatment for individuals in the experimental and control groups are normally distributed with means  $\mu_e$  and  $\mu_c$ , respectively, and have a common variance  $\sigma^2$ . Then the null hypothesis of no effect for the new drug is  $H_0 : \theta = 0$ , where  $\theta = \mu_e - \mu_c$ .

For a fixed-sample design with a total sample size  $N$ , the MLE for  $\theta$  is computed as  $\hat{\theta} = \hat{\mu}_e - \hat{\mu}_c$ , where  $\hat{\mu}_e$  and  $\hat{\mu}_c$  are the sample means of the decreases in LDL level in the experimental and control groups, respectively.

Following the derivation in the section “Test for the Difference between Two Normal Means” on page 7053, the statistic  $\hat{\theta}$  has a normal distribution

$$\hat{\theta} \sim N\left(\theta, \frac{4\sigma^2}{N}\right)$$

Thus, under the null hypothesis  $H_0 : \theta = 0$ , the standardized statistic

$$Z = \frac{\hat{\theta}}{\sqrt{\frac{4\sigma^2}{N}}} \sim N(0, 1)$$

The  $Z$  statistic can be used to test the null hypothesis  $H_0$ . If the variance  $\sigma^2$  is unknown, the sample variance can be used to compute the test statistic if it is assumed that the sample variance is computed from a large sample such that the  $Z$  statistic has an approximately standard normal distribution.

With a Type I error probability  $\alpha = 0.05$ , the critical values for the  $Z$  statistic are given by  $\Phi^{-1}(\alpha/2) = -1.96$  and  $\Phi^{-1}(1 - \alpha/2) = 1.96$ , where  $\Phi$  is the cumulative standard normal distribution function. At the end of study, if  $Z \geq 1.96$ , the null hypothesis is rejected for harmful drug effect, and if  $Z \leq -1.96$ , the null hypothesis is rejected for efficacy of the new drug. Otherwise, the null hypothesis is not rejected and the drug effect is not significant.

Also suppose that for the trial, the alternative reference  $\theta = -10$  is the clinically meaningful difference that the trial should detect with a high probability (power). Further suppose that a good estimate of the standard deviation for the changes in LDL level is  $\hat{\sigma} = 20$ . The following statements invoke the SEQDESIGN procedure and request a four-stage O'Brien-Fleming design for standardized normal test statistics:

```
ods graphics on;
proc seqdesign altref=-10
 plots=boundary(hscale=samplesize)
 ;
 TwoSidedOBrienFleming: design nstages=4
 method=obf
 ;
 samplesize model=twosamplemean(stddev=20);
ods output Boundary=Bnd_LDL;
run;
ods graphics off;
```

The ALTREF= option specifies the alternative reference, and the actual maximum information is derived in the SEQDESIGN procedure. With ODS Graphics enabled, the PLOTS=BOUNDARY option displays a boundary plot with the rejection and acceptance regions.

In the DESIGN statement, the label **TwoSidedOBrienFleming** identifies the design in the output tables. By default (or equivalently if you specify ALT=TWOSIDED and STOP=REJECT in the DESIGN statement), the design has a two-sided alternative hypothesis in which early stopping in the interim stages occurs to reject the null hypothesis. That is, at each interim stage, the trial either is stopped to reject the null hypothesis or continues to the next stage.

The NSTAGES=4 option in the DESIGN statement specifies the total number of stages in the group sequential trial, including three interim stages and a final stage. In the SEQDESIGN procedure, the null hypothesis for the design is  $H_0 : \theta = 0$ . By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10 in the DESIGN statement), the design has a Type I error probability  $\alpha = 0.05$ , and a Type II error probability  $\beta = 0.10$ ; the latter corresponds to a power of  $1 - \beta = 0.90$  at the alternative reference  $H_1 : \theta = -10$ .

For a two-sided design with early stopping to reject the null hypothesis, there are two boundaries for the design: an upper  $\alpha$  boundary that consists of upper rejection critical values and a lower  $\alpha$  boundary that consists of lower rejection critical values. Each boundary is a set of critical values, one from each stage.

With the METHOD=OBF option in the DESIGN statement, the O'Brien-Fleming method is used for the two boundaries for the design; see [Figure 83.7](#).

A property of the boundaries constructed with the O'Brien-Fleming design is that the null hypothesis is more difficult to reject in the early stages than in the later stages. That is, the trial is rejected in the early stages only with overwhelming evidence, because in these stages there might not be a sufficient number of responses for a reliable estimate of the treatment effect.

The SAMPLESIZE statement with the MODEL=TWOSAMPLEMEAN option uses the derived maximum information to compute required sample sizes for a two-sample test for mean difference. The ODS OUTPUT statement with the BOUNDARY=BND\_LDL option creates an output data set named BND\_LDL which contains the resulting boundary information.

In a clinical trial, the amount of information about an unknown parameter available from the data can be measured by the Fisher information. For a maximum likelihood statistic, the information level is the inverse of its variance. See the section “[Maximum Likelihood Estimator](#)” on page 7004 for a detailed description of Fisher information. At each stage of the trial, data are collected and analyzed with a statistical procedure, and a test statistic and its corresponding information level are computed.

In this example, you can use the REG procedure to compute the maximum likelihood estimate  $\hat{\theta}$  for the drug effect and the corresponding standard error for  $\hat{\theta}$ . At stage 1, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries derived from the boundary information stored in the BOUND\_LDL data set. At each subsequent stage, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries derived from the boundary information stored in the test information table created by the SEQTEST procedure at the previous stage. The test information tables are structured for input to the SEQTEST procedure.

At each interim stage, the trial will either be stopped to reject the null hypothesis or continue to the next stage. At the final stage, the null hypothesis is either rejected or accepted.

By default (or equivalently if you specify INFO=EQUAL in the DESIGN statement), the SEQDESIGN procedure derives boundary values with equally spaced information levels for all stages—that is, the same information increment between successive stages. The “Design Information,” “Method Information,” and “Boundary Information” tables are displayed by default, as shown in [Figure 83.4](#), [Figure 83.5](#), and [Figure 83.6](#), respectively.

The “Design Information” table in [Figure 83.4](#) displays design specifications and four derived statistics: the actual maximum information, the maximum information, the average sample number under the null hypothesis (Null Ref ASN), and the average sample number under the alternative hypothesis (Alt Ref ASN). Except for the actual maximum information, each statistic is expressed as a percentage of the identical statistic for the corresponding fixed-sample information. The average sample number is the expected sample size (for nonsurvival data) or expected number of events (for survival data). Note that for a symmetric two-sided design, the ALTREF=-10 option implies a lower alternative reference of -10 and an upper alternative reference of 10.

**Figure 83.4** O'Brien-Fleming Design Information

| The SEQDESIGN Procedure                   |                 |
|-------------------------------------------|-----------------|
| Design: TwoSidedOBrienFleming             |                 |
| Design Information                        |                 |
| Statistic Distribution                    | Normal          |
| Boundary Scale                            | Standardized Z  |
| Alternative Hypothesis                    | Two-Sided       |
| Early Stop                                | Reject Null     |
| Method                                    | O'Brien-Fleming |
| Boundary Key                              | Both            |
| Alternative Reference                     | -10             |
| Number of Stages                          | 4               |
| Alpha                                     | 0.05            |
| Beta                                      | 0.1             |
| Power                                     | 0.9             |
| Max Information (Percent of Fixed Sample) | 102.2163        |
| Max Information                           | 0.107403        |
| Null Ref ASN (Percent of Fixed Sample)    | 101.5728        |
| Alt Ref ASN (Percent of Fixed Sample)     | 76.7397         |

The maximum information is the information level at the final stage of the group sequential trial. The Max Information (Percent Fixed-Sample) is the maximum information for the sequential design expressed as a percentage of the information for the corresponding fixed-sample design. In Figure 83.4, the Max Information (Percent Fixed-Sample) is 102.22%, which means that the information needed for the group sequential trial is 2.22% more than that of the corresponding fixed-sample design if the trial does not stop at any interim stage.

The Null Ref ASN (Percent Fixed-Sample) is the average sample number (expected sample size) required under the null hypothesis for the group sequential design expressed as a percentage of the sample size for the corresponding fixed-sample design. In Figure 83.4, the Null Ref ASN is 101.57%, which means that the expected sample size for the group sequential trial is 1.57% greater than the corresponding fixed-sample size.

Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the average sample number (expected sample size) required under the alternative hypothesis for the group sequential design expressed as a percentage of the sample size for the corresponding fixed-sample design. In Figure 83.4, the Alt Ref ASN is 76.74%, which means that the expected sample size for the group sequential trial is 76.74% of the corresponding fixed-sample size. That is, if the alternative hypothesis is true, then on average, only 76.74% of the fixed-sample size is needed for the group sequential trial.

In this example, the O'Brien-Fleming design requires only a slight increase in sample size if the trial proceeds to the final stage. On the other hand, if the alternative hypothesis is correct, this design provides a substantial saving in sample size on average.

The “Method Information” table in [Figure 83.5](#) displays the computed Type I and Type II error probabilities  $\alpha$  and  $\beta$ , and the derived drift parameter for the design. For a two-sided test with early stopping to reject the null hypothesis, both lower and upper  $\alpha$  boundaries are created. With the specified ALTREF= option, the alternative references are also included.

With the zero null reference, the drift parameter is the standardized alternative reference at the final stage  $\theta_1 \sqrt{I_X}$ , where  $\theta_1$  is the alternative reference and  $I_X$  is the maximum information. See the section “[Specified and Derived Parameters](#)” on page 7039 for a detailed description of the drift parameter. The drift parameters for the design are derived in the SEQDESIGN procedure even if the alternative reference is not specified or derived in the procedure.

| Method Information |                       |          |
|--------------------|-----------------------|----------|
| Boundary           | Alternative Reference | Drift    |
| Upper Alpha        | 10                    | 3.277238 |
| Lower Alpha        | -10                   | -3.27724 |

The O'Brien-Fleming method belongs to the unified family of designs, which is parameterized by two parameters,  $\rho$  and  $\tau$ , as implemented in the SEQDESIGN procedure. See [Table 83.3](#) for parameter values of commonly used methods in the unified family. The “Method Information” table in [Figure 83.5](#) displays the values of  $\rho = 0.5$  and  $\tau = 0$ , which are the parameters for the O'Brien-Fleming method. The table also displays the derived parameter  $C_\alpha = 2.0243$ , which is used in the construction of symmetric lower and upper  $\alpha$  boundaries; see the section “[Unified Family Methods](#)” on page 7025.

The “Boundary Information” table in [Figure 83.6](#) displays the information level, including the proportion, actual level, and corresponding sample size (N) at each stage. The table also displays the lower and upper alternative references, and the lower and upper boundary values at each stage.

Figure 83.6 Boundary Information

| 3                                           | 0.7500                      | 0.080552 | 128.8835 | -2.83817              | 2.83817 |
| 4                                           | 1.0000                      | 0.107403 | 171.8447 | -3.27724              | 3.27724 |

| Boundary Information (Standardized Z Scale) |                           |             |  |
|---------------------------------------------|---------------------------|-------------|--|
| Null Reference = 0                          |                           |             |  |
| _Stage_                                     | -----Boundary Values----- |             |  |
|                                             | ---Lower---               | ---Upper--- |  |
|                                             | Alpha                     | Alpha       |  |
| 1                                           | -4.04859                  | 4.04859     |  |
| 2                                           | -2.86278                  | 2.86278     |  |
| 3                                           | -2.33745                  | 2.33745     |  |
| 4                                           | -2.02429                  | 2.02429     |  |

The information proportion is the proportion of maximum information available at each stage and N is the corresponding sample size. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the procedure displays boundary values with the standardized Z scale in the boundary information table and the boundary plot. The alternative reference on the standardized Z scale at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information available at stage  $k$ ,  $k = 1, 2, 3, 4$ . These standardized alternative references for the design are derived in the SEQDESIGN procedure even if the alternative reference is not specified or derived in the procedure.

In this example, a standardized Z statistic is computed by standardizing the parameter estimate of the effect in LDL level. A lower Z test statistic indicates a beneficial effect. Consequently, at each interim stage, if the standardized Z test statistic is less than or equal to the corresponding lower  $\alpha$  boundary value, the hypothesis  $H_0 : \theta = 0$  is rejected for efficacy. If the test statistic is greater than or equal to the corresponding upper  $\alpha$  boundary value, the hypothesis  $H_0$  is rejected for harmful effect. Otherwise, the process continues to the next stage. At the final stage (stage 4), the hypothesis  $H_0$  is rejected for efficacy if the Z statistic is less than or equal to the corresponding lower  $\alpha$  boundary value  $-2.0243$ , and the hypothesis  $H_0$  is rejected for harmful effect if the Z statistic is greater than or equal to the corresponding upper  $\alpha$  boundary value  $2.0243$ . Otherwise, the hypothesis of no significant difference is accepted.

Note that in a typical trial, the actual information levels do not match the information levels specified in the design. The SEQTEST procedure modifies the boundary values stored in the BOUND\_LDL data set to adjust for these new information levels.

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Figure 83.7. This plot displays the boundary values in the “Boundary Information” table in Figure 83.6. The stages are indicated by vertical lines with accompanying stage numbers. The horizontal axis indicates the sample sizes for the stages. Note that comparing with a fixed-sample design, only a small increase in sample size is needed for the O’Brien-Fleming design, as shown in Figure 83.7.

If a test statistic at an interim stage is in the rejection region (shaded area), the trial stops and the null hypothesis is rejected. If the statistic is not in any rejection region, the trial continues to the next stage.

**Figure 83.7** Boundary Plot

The boundary plot also displays critical values for the corresponding fixed-sample design. The symbol “o” identifies the fixed-sample critical values of  $-1.96$  and  $1.96$ , and the accompanying vertical line indicates the required sample size for the fixed-sample design at the horizontal axis. Note that the boundary values  $\pm 2.0243$  at the final stage are close to the fixed-sample critical values  $\pm 1.96$ .

When you specify the `SAMPLESIZE` statement, the maximum information (either explicitly specified or derived in the `SEQDESIGN` procedure) is used to compute the required sample sizes for the study. The `MODEL=TWOSAMPLEMEAN(STDDEV=20)` option specifies the test for the difference between two normal means. See the section “[Test for the Difference between Two Normal Means](#)” on page 7053 for a detailed derivation of these required sample sizes.

The “Sample Size Summary” table in Figure 83.8 displays the parameters for the sample size computation and the resulting maximum and expected sample sizes.

**Figure 83.8** Sample Size Summary

| Sample Size Summary             |                  |
|---------------------------------|------------------|
| Test                            | Two-Sample Means |
| Mean Difference                 | -10              |
| Standard Deviation              | 20               |
| Max Sample Size                 | 171.8447         |
| Expected Sample Size (Null Ref) | 170.7627         |
| Expected Sample Size (Alt Ref)  | 129.0137         |

The “Sample Sizes (N)” table in Figure 83.9 displays the required sample sizes at each stage for the trial, in both fractional and integer numbers. The derived fractional sample sizes are displayed under the heading “Fractional N.” These sample sizes are rounded up to integers under the heading “Ceiling N.” By default (or equivalently if you specify WEIGHT=1 in the MODEL=TWOSAMPLEMEAN option), the sample sizes for the two groups are equal for the two-sample test.

**Figure 83.9** Derived Sample Sizes

| Sample Sizes (N)                      |        |          |          |             |
|---------------------------------------|--------|----------|----------|-------------|
| Two-Sample Z Test for Mean Difference |        |          |          |             |
| -----Fractional N-----                |        |          |          |             |
| _Stage_                               | N      | N(Grp 1) | N(Grp 2) | Information |
| 1                                     | 42.96  | 21.48    | 21.48    | 0.0269      |
| 2                                     | 85.92  | 42.96    | 42.96    | 0.0537      |
| 3                                     | 128.88 | 64.44    | 64.44    | 0.0806      |
| 4                                     | 171.84 | 85.92    | 85.92    | 0.1074      |
| Sample Sizes (N)                      |        |          |          |             |
| Two-Sample Z Test for Mean Difference |        |          |          |             |
| -----Ceiling N-----                   |        |          |          |             |
| _Stage_                               | N      | N(Grp 1) | N(Grp 2) | Information |
| 1                                     | 44     | 22       | 22       | 0.0275      |
| 2                                     | 86     | 43       | 43       | 0.0538      |
| 3                                     | 130    | 65       | 65       | 0.0812      |
| 4                                     | 172    | 86       | 86       | 0.1075      |

In practice, integer sample sizes are used in the trial, and the resulting information levels increase slightly. Thus, 22, 43, 65, and 86 individuals are needed in each of the two groups for the four stages, respectively.

## Syntax: SEQDESIGN Procedure

The following statements are available in the SEQDESIGN procedure:

```
PROC SEQDESIGN < options > ;
 < label: > DESIGN options ;
 SAMPLESIZE < MODEL= option > ;
```

The PROC SEQDESIGN statement and the DESIGN statement are required for the SEQDESIGN procedure. Each DESIGN statement requests a new group sequential design, and multiple DESIGN statements can be used to create more than one design for comparison of features. The label, which must be a valid SAS name, is used to identify the design in the output tables and graphics. The SAMPLESIZE statement computes the required sample sizes for the design specified in each DESIGN statement. With a selected design, the SAMPLESIZE statement computes the required sample sizes for the trial.

## PROC SEQDESIGN Statement

```
PROC SEQDESIGN < options > ;
```

The PROC SEQDESIGN statement invokes the SEQDESIGN procedure. [Table 83.1](#) summarizes the options available in the PROC SEQDESIGN statement.

**Table 83.1** Summary of PROC SEQDESIGN Options

| Option                   | Description                                          |
|--------------------------|------------------------------------------------------|
| <b>Design Parameters</b> |                                                      |
| ALTREF=                  | Specifies the alternative reference                  |
| BOUNDARYSCALE=           | Specifies the statistic scale for the boundary       |
| MAXINFO=                 | Specifies the maximum information level              |
| <b>Table Output</b>      |                                                      |
| ERRSPEND                 | Displays the cumulative error spending at each stage |
| PSS                      | Displays powers and expected sample sizes            |
| STOPPROB                 | Displays expected cumulative stopping probabilities  |
| <b>Graphics Output</b>   |                                                      |
| PLOTS=ASN                | Displays the expected sample numbers plot            |
| PLOTS=BOUNDARY           | Displays the detailed boundary plot                  |
| PLOTS=COMBINEDBOUNDARY   | Displays the combined boundary plot                  |
| PLOTS=ERRSPEND           | Displays the error spending plot                     |
| PLOTS=POWER              | Displays the powers plot                             |

By default, the SEQDESIGN procedure displays tables of design information, method information, and boundary information for each specified design. If ODS Graphics is enabled, it also displays a detailed boundary plot.

In addition, you can use output options to display output tables such as expected cumulative stopping probability at each stage under various hypothetical references. If ODS Graphics is enabled, you can also use output options to display plots such as powers and expected sample sizes under various hypothetical references.

The following options can be used in the PROC SEQDESIGN statement to derive boundary values for all sequential designs in the procedure. They are listed in alphabetical order.

**ALTREF= $\theta_1$  < (< LOWER= $\theta_{1l}$  > < UPPER= $\theta_{1u}$  > ) >**

specifies the alternative reference—that is, the hypothetical reference under the alternative hypothesis at which the power is computed. The LOWER= and UPPER= options are applicable only for a two-sided design with different lower and upper alternative references.

For a one-sided design,  $\theta_{1l} = -|\theta_1|$  is the lower alternative reference and  $\theta_{1u} = |\theta_1|$  is the upper alternative reference. For a two-sided design, the specified  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. If the LOWER= option is not specified,  $\theta_{1l} = -|\theta_1|$ , and if the UPPER= option is not specified,  $\theta_{1u} = |\theta_1|$ .

The specification of the ALTREF= option depends on the hypothesis used in the clinical trial. For example, suppose the null hypothesis  $H_0 : \theta = 0$  with an alternative hypothesis  $H_1 : \theta = \theta_1$  is used to compare two binomial populations,  $p_a = p_b$ . Then  $\theta_1$  is the proportion difference under  $H_1$  if  $\theta = p_a - p_b$ , and  $\theta_1$  is the log odds ratio under  $H_1$  if  $\theta = \log\left(\frac{p_a(1-p_b)}{p_b(1-p_a)}\right)$ .

If the ALTREF= option is not specified, the alternative reference  $\theta_1$  can also be specified or derived in the SAMPLESIZE statement. If  $\theta_1$  is specified or derived in the SAMPLESIZE statement,  $\theta_{1l} = -|\theta_1|$  and  $\theta_{1u} = |\theta_1|$  are the lower and upper alternative references, respectively.

Note that if the SAMPLESIZE statement is specified with a two-sided design, the sample sizes derived by using the lower and upper alternatives might be different. If  $\theta_1$  is specified or derived in the SAMPLESIZE statement, it is used to compute the sample sizes. Otherwise, the  $\theta_1$  specified in the ALTREF= option is used.

**BOUNDARYSCALE=MLE | SCORE | STDZ | PVALUE**

**BSCALE=MLE | SCORE | STDZ | PVALUE**

specifies the scale for the statistic that is displayed in the boundary table and boundary plots. The keywords MLE, SCORE, STDZ, and PVALUE correspond to the boundary with the maximum likelihood estimate scale, the score statistic scale, the standardized normal Z scale, and the  $p$ -value scale, respectively. The default is BOUNDARYSCALE=STDZ.

With the BOUNDARYSCALE=MLE or BOUNDARYSCALE=SCORE option, the maximum information must be either explicitly specified with the MAXINFO= option or derived in the SEQDESIGN procedure to provide the necessary information level at each stage to compute the boundary values. See the section “Boundary Scales” on page 7017 for a detailed description of the statistic scale for the boundary values.

Note that for a two-sided design, the  $p$ -value scale displays the one-sided fixed-sample  $p$ -value under the null hypothesis with a lower alternative hypothesis.

**MAXINFO=number**

specifies the maximum information level for the design. If the MAXINFO=option is specified and the alternative reference is either specified explicitly with the ALTREF= option or derived from the SAMPLESIZE statement, then the Type I and Type II error probability levels cannot be met simultaneously. In this case, the ALPHA= option in the DESIGN statement is applicable only with the BOUNDARYKEY=ALPHA option (which is the default) in the DESIGN statement, and the Type II error probability  $\beta$  is derived. The BETA= option in the DESIGN statement is applicable only with the BOUNDARYKEY=BETA option in the DESIGN statement, and the Type I error probability  $\alpha$  is derived.

**Table Output Options**

The following options can be used in the PROC SEQDESIGN statement to display addition table output. They are listed in alphabetical order.

**ERRSPEND**

displays the error spending at each stage for each boundary in the design.

**PSS <( CREF=  $c_1 < c_2 \dots >$  )>**

displays powers and expected sample sizes under various hypothetical references, where the numbers  $c_i \geq 0$ .

For a one-sided design, the power and expected sample sizes under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, the power and expected sample sizes under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. The default is CREF= 0 0.5 1.0 1.5.

Note that for a symmetric two-sided design, only the power and expected sample sizes under hypotheses  $\theta = c_i \theta_{1u}$  are derived. See the section “Type I and Type II Errors” on page 7022 for a detailed description of the power computation. See the section “Powers and Expected Sample Sizes” on page 7069 for a detailed description of the expected sample size computation.

**STOPPROB <( CREF=  $c_1 < c_2 \dots >$  )>**

displays expected cumulative stopping probabilities under various hypothetical references, where the numbers  $c_i \geq 0$ .

For a one-sided design, expected cumulative stopping probabilities at each stage under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, expected cumulative stopping probabilities at each stage under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only expected cumulative stopping probabilities under hypotheses  $\theta = c_i \theta_{1u}$  are derived. The default is CREF= 0 0.5 1.0 1.5.

## Graphics Output Options

This section describes the options for using ODS Graphics with the SEQDESIGN procedure to create plots.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc seqdesign altref=-10 plots=boundary(hscale=samplesize);
 TwoSidedOBrienFleming: design nstages=4 method=obf;
 samplesize model=twosamplemean(stddev=20);
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The following options can be used in the PROC SEQDESIGN statement to display graphs with ODS Graphics. They are listed in alphabetical order.

**PLOTS** < ( **ONLY** ) > < = *plot-request* >

**PLOTS** < ( **ONLY** ) > < = ( *plot-request* < ... *plot-request* > ) >

specifies options that control the details of the plots. The default is PLOTS=BOUNDARY. The global plot option ONLY suppresses the default plots and displays only plots specifically requested.

The plot request options are as follows.

### ALL

produces all appropriate plots.

**ASN** < ( **CREF=**  $c_1 < c_2 \dots >$  ) >

displays a plot of the average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references, where the numbers  $c_i \geq 0$ . These average sample numbers are displayed as percentages of the average sample numbers for the corresponding fixed-sample design.

For a one-sided design, expected sample numbers under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, expected sample numbers under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only the average sample numbers under hypotheses  $\theta = c_i \theta_{1u}$  are derived. The default is CREF= 0 to 1.5 by 0.01.

**BOUNDARY** < ( **HSCALE=INFO** | **SAMPLESIZE** ) >

displays a plot of the resulting sequential boundaries with the acceptance and rejection regions for each design. Either the information level (HSCALE=INFO) or the sample size (HSCALE=SAMPLESIZE) is displayed on the horizontal axis. If the maximum information is not available for the design, the information in percentage of its corresponding fixed-sample design are used in the plot. The stage number for each stage is displayed inside the plot. The default is HSCALE=INFO.

If the HSCALE=SAMPLESIZE option is specified, the SAMPLESIZE statement must also be specified. The options MODEL=INPUTNEVENTS, MODEL=TWOSAMPLESURVIVAL, and MODEL=PHREG in the SAMPLESIZE statement indicate survival data. For a sample that

does not contain survival data, the sample size at each stage is displayed on the horizontal axis. For survival data, the number of events is displayed on the horizontal axis at each stage. The critical values for the corresponding fixed-sample design are also displayed in the plot.

**COMBINEDBOUNDARY** < ( **HSCALE=INFO** | **SAMPLESIZE** | **STAGE** ) >

displays a plot of the resulting sequential boundaries for all designs simultaneously. You can display the information level (**HSCALE=INFO**), the sample size (**HSCALE=SAMPLESIZE**), or the stage number (**HSCALE=STAGE**) on the horizontal axis. The default is **HSCALE=INFO**. With **HSCALE=INFO**, if the maximum information is not available for the design, then the information in percentage of its corresponding fixed-sample design is used in the plot.

If the **HSCALE=SAMPLESIZE** option is specified, the **SAMPLESIZE** statement must also be specified. The options **MODEL=INPUTNEVENTS**, **MODEL=TWOSAMPLESURVIVAL**, and **MODEL=PHREG** in the **SAMPLESIZE** statement indicate survival data. For a sample that does not contain survival data, the sample size at each stage is displayed on the horizontal axis. For survival data, the number of events is displayed on the horizontal axis at each stage.

**ERRSPEND** < ( **HSCALE=INFO** | **STAGE** ) >

displays a plot of the error spending for all sequential boundaries in the designs simultaneously. You can display the information level (**HSCALE=INFO**) or the stage number (**HSCALE=STAGE**) on the horizontal axis. With **HSCALE=INFO**, the information fractions are used in the plot. The default is **HSCALE=STAGE**.

**NONE**

suppresses all plots.

**POWER** < ( **CREF=**  $c_1 < c_2 \dots$  ) >

displays a plot of the power curves under various hypothetical references, where the numbers  $c_i \geq 0$ .

For a one-sided design, powers under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the **CREF=** option.

For a two-sided design, powers under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only powers under hypotheses  $\theta = c_i \theta_{1u}$  are derived. The default is **CREF=** 0 to 1.5 by 0.01.

---

## DESIGN Statement

< label: > **DESIGN** < options > ;

The **DESIGN** statement requests a new group sequential design. You can use multiple **DESIGN** statements, and each **DESIGN** statement corresponds to a separate group sequential design.

Table 83.2 summarizes the options available in the DESIGN statement.

**Table 83.2** Design Statement Options

| Option                   | Description                                                                                                        |
|--------------------------|--------------------------------------------------------------------------------------------------------------------|
| <b>Design Parameters</b> |                                                                                                                    |
| ALPHA=                   | Specifies the Type I error probability level $\alpha$                                                              |
| ALT=                     | Specifies the type of alternative hypothesis                                                                       |
| BETA=                    | Specifies the Type II error probability level $\beta$                                                              |
| BETAOVERLAP=             | Checks for overlapping of the lower and upper $\beta$ boundaries in a two-sided design with error spending methods |
| BOUNDARYKEY=             | Specifies the type of error probability to maintain                                                                |
| INFO=                    | Specifies the information levels                                                                                   |
| NSTAGES=                 | Specifies the number of stages                                                                                     |
| STOP=                    | Specifies the condition for early stopping                                                                         |
| <b>Boundary Methods</b>  |                                                                                                                    |
| METHOD=                  | Specifies methods for boundary values                                                                              |

The required NSTAGES= option specifies the number of stages. The METHOD= option is required if the number of stages specified in the NSTAGES= option is greater than one. The following options can be used in the DESIGN statement. They are listed in alphabetical order.

**ALPHA= $\alpha$  < (< LOWER= $\alpha_l$  > < UPPER= $\alpha_u$  > ) >**

specifies the Type I error probability  $\alpha$ . The default is  $\alpha = 0.05$ . The LOWER= and UPPER= options are applicable only for the two-sided design. The LOWER= option specifies the lower Type I error probability  $\alpha_l$ , and the upper Type I error probability is computed as  $\alpha_u = \alpha - \alpha_l$ . The UPPER= option specifies the upper Type I error probability  $\alpha_u$ , and the lower Type I error probability is computed as  $\alpha_l = \alpha - \alpha_u$ . If both LOWER= and UPPER= options are not specified,  $\alpha_l = \alpha_u = \alpha/2$ .

If both the MAXINFO= and ALTREF= options are specified, then the Type I and Type II error probability levels cannot be met simultaneously. In this case, the ALPHA= option is applicable only with the BOUNDARYKEY=ALPHA option (which is the default), and the Type II error probability  $\beta$  is derived.

**ALT=LOWER | UPPER | TWOSIDED**

specifies the type of alternative hypothesis in the design. For a test of  $H_0 : \theta = 0$ , the keywords LOWER, UPPER, and TWOSIDED correspond to the alternatives of  $\theta < 0$ ,  $\theta > 0$ , and  $\theta \neq 0$ , respectively. The default is ALT=TWOSIDED.

**BETA= $\beta$  < (< LOWER= $\beta_l$  > < UPPER= $\beta_u$  > ) >**

specifies the Type II error probability level  $\beta$ . The default is  $\beta = 0.10$ . The LOWER= and UPPER= options are applicable only for the two-sided design. The LOWER= option specifies the lower Type II error probability level  $\beta_l$ , and the UPPER= option specifies the upper Type II error probability level  $\beta_u$ . If the LOWER= or UPPER= option is not specified,  $\beta$  is used.

If both the MAXINFO= and ALTREF= options are specified, then the Type I and Type II error probability levels cannot be met simultaneously. In this case, the BETA= option is applicable only with the BOUNDARYKEY=BETA option, and the Type I error probability  $\alpha$  is derived.

**BETAOVERLAP=ADJUST | NOADJUST****OVERLAP=ADJUST | NOADJUST**

specifies whether to check for overlapping of the lower and upper  $\beta$  boundaries for the two corresponding one-sided tests. This option applies to two-sided designs with STOP=ACCEPT or STOP=BOTH that are constructed with error spending methods, and this type of overlapping might result from a small  $\beta$  spending at an interim stage. When you specify BETAOVERLAP=ADJUST, the procedure checks for this type of overlapping. If such overlapping is found, the  $\beta$  boundaries for the two-sided design at that stage are set to missing, and the  $\beta$  spending values at subsequent stages are adjusted, as described in the section “[Boundary Adjustments for Overlapping Lower and Upper  \$\beta\$  Boundaries](#)” on page 7039”.

You can specify BETAOVERLAP=NOADJUST to request that no adjustment be made. The default is BETAOVERLAP=ADJUST.

**BOUNDARYKEY=ALPHA | BETA | BOTH | NONE**

specifies types of errors to be maintained in the resulting boundary. The default is BOUNDARYKEY=ALPHA if both ALTREF= and MAXINFO= options are specified. Otherwise, the default is BOUNDARYKEY=NONE for Whitehead methods with the STOP=BOTH option, and it is BOUNDARYKEY=BOTH for others.

See the section “[Applicable Boundary Keys](#)” on page 7041 for a detailed description of applicable boundary keys.

**INFO=EQUAL****INFO=CUM( numbers )**

specifies relative information levels for all stages in the design. The INFO=EQUAL option specifies equally spaced information levels, and the INFO=CUM option specifies cumulative relative information levels. The default is INFO=EQUAL.

If the number of information levels specified in the INFO=CUM option is less than the number of stages specified in the NSTAGES= option, the last available information increment is used as the information increment for each subsequent stage.

**METHOD=WHITEHEAD < ( TAU= $\tau$  < ( < LOWER= $\tau_l$  > < UPPER= $\tau_u$  > ) > ) >****METHOD=method****METHOD(boundary) = method**

specifies the methods for the boundaries in the design, where  $0 \leq \tau < 0.5$ .

For a one-sided design, an  $\alpha$  boundary is created with the STOP=REJECT or STOP=BOTH option, and a  $\beta$  boundary is created with the STOP=ACCEPT or STOP=BOTH option. For a two-sided design, lower and upper  $\alpha$  boundaries are created with the STOP=REJECT or STOP=BOTH option, and lower and upper  $\beta$  boundaries are created with the STOP=ACCEPT or STOP=BOTH option.

There are three types of methods available in the SEQDESIGN procedure. The unified family methods and Haybittle-Peto methods derive boundary values with fixed boundary shape; the Whitehead methods derive boundary values by adjusting the boundary values generated from continuous monitoring; and the error spending methods derive the boundary values from the specified errors used at each stage. You can specify different methods for the same design, but all methods must be from the same group.

For a design with early stopping to reject or accept the null hypothesis, the METHOD=WHITEHEAD option uses Whitehead’s triangular design and double-triangular design for a one-sided design and

two-sided design, respectively (Whitehead and Stratton 1983; Whitehead 1997, 2001). For a design with early stopping only to reject the null hypothesis or only to accept the null hypothesis, you can specify the slope of the boundary line in the score statistic scale with the TAU=  $\tau$  option. The default is TAU=0.25. See the section “[Whitehead Methods](#)” on page 7030 for a detailed description of the Whitehead methods.

The following options specify available error spending methods for the boundary. Each of these methods can be specified with the METHOD= option for all boundaries, or with the METHOD(*boundary*) = option for an individual boundary. See the section “[Error Spending Methods](#)” on page 7034 for a detailed description of these error spending methods.

**ERRFUNCGAMMA < ( GAMMA=  $\gamma$  ) >**

specifies a gamma cumulative error spending function for the boundary (Hwang, Shih, and DeCani 1990). The GAMMA= option specifies the gamma parameter  $\gamma$  in the function, where  $\gamma \leq 3$ . The boundaries created with  $\gamma = 1$  are similar to the boundaries from the Pocock method, and the boundaries created with  $\gamma = -4$  or  $\gamma = -5$  are similar to the boundaries from the O’Brien-Fleming method. The default is GAMMA=-2, which is the average of  $\gamma = 1$  and  $\gamma = -5$ .

**ERRFUNCOBF**

specifies the O’Brien-Fleming-type cumulative error spending function for the boundary (Lan and DeMets 1983).

**ERRFUNCPOC**

specifies the Pocock-type cumulative error spending function for the boundary (Lan and DeMets 1983).

**ERRFUNCPW < ( RHO= $\rho$  ) >**

specifies a power cumulative error spending function for the boundary (Jennison and Turnbull 2000, p. 148). The RHO= option specifies the power parameter  $\rho$  in the function, where  $\rho \geq 0.25$ . The boundaries created with  $\rho = 1$  are similar to the boundaries from the Pocock method, and the boundaries created with  $\rho = 3$  are similar to the boundaries from the O’Brien-Fleming method. The default is RHO=2, which is the average of  $\rho = 1$  and  $\rho = 3$ .

**ERRSPEND ( *numbers* )**

specifies the relative cumulative error spending at each stage.

With a fixed boundary shape, you can use the following available Haybittle-Peto methods and unified family methods to derive the boundary. You can specify each of these methods in the METHOD= option for all boundaries, or in the METHOD(*boundary*) = option for an individual boundary. See the section “[Haybittle-Peto Method](#)” on page 7029 for a detailed description of the Haybittle-Peto methods, and see the section “[Unified Family Methods](#)” on page 7025 for a detailed description of unified family methods.

**HP | HAYBITTLE | PETO < ( Z= *numbers* | PVALUE= *numbers* ) >**

specifies the Haybittle-Peto method (Haybittle 1971; Peto et al. 1976). The values specified are used to create the boundary values. The boundary value at the final stage can be derived in the procedure to maintain the Type I and Type II error probability levels. The default is Z=3.

**OBF | OBRIENFLEMING**

specifies the O'Brien-Fleming method (O'Brien and Fleming 1979). The O'Brien-Fleming method is equivalent to a power family method with  $RHO=0.5$ .

**POC | POCOCK**

specifies the Pocock method (Pocock 1977). The Pocock method is equivalent to a power family method with  $RHO=0$ .

**POW | POWER < ( RHO= $\rho$  ) >**

specifies a power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994). The  $RHO=$  option specifies the power parameter  $\rho$  in the power family method, where  $\rho \geq -0.25$ . The power family method with  $\rho = 0$  corresponds to the Pocock method, and the power family method with  $\rho = 0.5$  corresponds to the O'Brien-Fleming method. The default is  $RHO=0.25$ , a value halfway between the Pocock and O'Brien-Fleming methods. A power family method is equivalent to a unified family method with  $RHO=\rho$  and  $TAU=0$ .

**TRI | TRIANGULAR < ( TAU= $\tau$  ) >**

specifies a unified family triangular method (Kittelson and Emerson 1999), where  $0 \leq \tau \leq 1$ . The default is  $TAU=1.0$ . The triangular method is identical to the unified family method with  $RHO=0.5$  and  $TAU=\tau$ . Note that this unified family triangular method is different from Whitehead's triangular method.

**UNI | UNIFIED < ( < TAU= $\tau$  > < RHO= $\rho$  > ) >**

specifies a unified family method (Kittelson and Emerson 1999). The  $TAU=$  and  $RHO=$  options specify the  $\tau$  and  $\rho$  parameters in a unified family method, respectively, where  $\rho \geq 0$  and  $0 \leq \tau \leq 2\rho$ . The defaults are  $TAU=0$  and  $RHO=0.25$ . See the section "Unified Family Methods" on page 7025 for a detailed description of the unified family methods.

The O'Brien-Fleming, Pocock, power family, and triangular methods are all special cases of the unified family methods. Table 83.3 summarizes the corresponding parameters in the unified family for these methods.

**Table 83.3** Parameters in the Unified Family for Various Methods

| Method          | Option             | Unified Family |        |
|-----------------|--------------------|----------------|--------|
|                 |                    | Rho            | Tau    |
| Pocock          | POC                | 0              | 0      |
| O'Brien-Fleming | OBF                | 0.5            | 0      |
| Power family    | POW (RHO= $\rho$ ) | $\rho$         | 0      |
| Triangular      | TRI (TAU= $\tau$ ) | 0.5            | $\tau$ |

Note that the power parameter  $\rho = 1/2 - \Delta = \rho^* - 1/2$ , where  $\Delta$  is the power parameter used in Jennison and Turnbull (2000) and Wang and Tsiatis (1987) and  $\rho^*$  is the power parameter used in Kittelson and Emerson (1999).

If a method with specified parameters is used for all boundaries in the design, you can use the `METHOD=` option to specify the method. Otherwise, you can use the following `METHOD(boundary)=` options to specify different methods from the same group for the boundaries.

**METHOD(ALPHA)=method**

**METHOD(REJECT)=method**

specifies the method for the  $\alpha$  boundary of a one-sided design or the lower and upper  $\alpha$  boundaries for a two-sided design.

**METHOD(LOWERALPHA)=method**

**METHOD(LOWERREJECT)=method**

specifies the method for the lower  $\alpha$  boundary of a two-sided design.

**METHOD(UPPERALPHA)=method**

**METHOD(UPPERREJECT)=method**

specifies the method for the upper  $\alpha$  boundary of a two-sided design.

**METHOD(BETA)=method**

**METHOD(ACCEPT)=method**

specifies the method for the  $\beta$  boundary of a one-sided design or the lower and upper  $\beta$  boundaries for a two-sided design.

**METHOD(LOWERBETA)=method**

**METHOD(LOWERACCEPT)=method**

specifies the method for the lower  $\beta$  boundary of a two-sided design.

**METHOD(UPPERBETA)=method**

**METHOD(UPPERACCEPT)=method**

specifies the method for the upper  $\beta$  boundary of a two-sided design.

**NSTAGES=number**

specifies the number of stages for the design. This option is required in the `DESIGN` statement, and the maximum allowed number of stages is 25.

**STOP=ACCEPT**

**STOP=REJECT**

**STOP=BOTH < ( BETABOUNDARY=BINDING | NONBINDING ) >**

specifies the early stopping criterion for the design. The keywords `ACCEPT`, `REJECT`, and `BOTH` correspond to early stopping only to accept, only to reject, and either to accept or reject the null hypothesis  $H_0$ , respectively. The default is `STOP=REJECT`. With `STOP=BOTH`, the `BETABOUNDARY=BINDING` suboption computes the Type I error probability with the acceptance boundary, and the `BETABOUNDARY=NONBINDING` suboption computes the Type I error probability without the acceptance boundary. The default is `BETABOUNDARY=BINDING`. The `BETABOUNDARY=NONBINDING` option is not applicable with `METHOD=WHITEHEAD`.

## SAMPLESIZE Statement

**SAMPLESIZE** < **MODEL=** *option* > ;

If each observation in the data set provides one unit of information in a hypothesis testing such as a one-sample test for the mean, the SAMPLESIZE statement computes the required sample sizes for the sequential design specified in each DESIGN statement. However, for a survival analysis, an individual in the survival time data might provide only partial information because of censoring. For this hypothesis, the SAMPLESIZE statement computes the required numbers of events. With additional accrual information in a survival analysis, the sample sizes can also be computed.

Only one SAMPLESIZE statement can be specified. For each specified group sequential design, the SAMPLESIZE statement computes the required sample sizes or numbers of events. The SAMPLESIZE statement is not required if the SEQDESIGN procedure is used only to compare features among different designs. Table 83.4 summarizes the options available in the SAMPLESIZE statement.

**Table 83.4** SAMPLESIZE Statement Options

| Option                     | Description                                                        |
|----------------------------|--------------------------------------------------------------------|
| <b>Fixed-Sample Models</b> |                                                                    |
| INPUTNOBS                  | Specifies the sample size for fixed-sample design                  |
| INPUTNEVENTS               | Specifies the number of events for fixed-sample design             |
| <b>One-Sample Models</b>   |                                                                    |
| ONESAMPLEMEAN              | Specifies the one-sample Z test for mean                           |
| ONESAMPLEFREQ              | Specifies the one-sample test for binomial proportion              |
| <b>Two-Sample Models</b>   |                                                                    |
| TWOSAMPLEMEAN              | Specifies the two-sample Z test for mean difference                |
| TWOSAMPLEFREQ              | Specifies the two-sample test for binomial proportions             |
| TWOSAMPLESURVIVAL          | Specifies the log-rank test for two survival distributions         |
| <b>Regression Models</b>   |                                                                    |
| REG                        | Specifies the test for a regression parameter                      |
| LOGISTIC                   | Specifies the test for a logistic regression parameter             |
| PHREG                      | Specifies the test for a proportional hazards regression parameter |

The MODEL= option specifies the input sample size or number of events from a fixed-sample study, or it specifies a statistical model to compute the required sample size. The MODEL=INPUTNOBS option specifies the input sample size from a fixed-sample study of nonsurvival data, and the MODEL=INPUTNEVENTS option specifies the number of events from a fixed-sample study of survival data. The remaining MODEL= options specify the statistical models used to compute the required sample size. The default is MODEL=TWOSAMPLEMEAN, the two-sample Z test for the mean difference.

With the MODEL=INPUTNOBS or MODEL=INPUTNEVENTS option, the required sample size or number of events for the group sequential trial is computed by multiplying the input sample size or number of events by the ratio between the design information level and its corresponding fixed-sample information level. This ratio can be obtained by dividing the Max Information (Percent Fixed-Sample) in the “Design Information” table by 100. See the section “Design Information” on page 7068 for a description of the “Design Information” table.

## Fixed-Sample Models

The following two options compute the required sample size or number of events for a group sequential trial by using the sample size or number of events for the fixed-sample design.

### MODEL=INPUTNOBS ( options )

specifies the sample size information for a fixed-sample design. The available options are as follows:

- N=  $n$
- SAMPLE= ONE | TWO
- WEIGHT=  $w_a < w_b >$
- MATCHNOBS= YES | NO

The required N= $n$  option specifies the sample size  $n$  for the fixed-sample design. The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. The default is SAMPLE=ONE.

With a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups. If  $w_b$  is not specified,  $w_b = 1$  is used. The default is WEIGHT=1, equal allocation for the two groups. The derived fractional sample sizes are rounded up to integers, and the MATCHNOBS=YES option requests these integer sample sizes to match the sample size allocation.

See the section “[Input Sample Size for Fixed-Sample Design](#)” on page 7044 for a detailed description of the input sample size for the fixed-sample design in sample size computation.

### MODEL=INPUTNEVENTS ( D= $d$ < options > )

specifies the sample size information for a fixed-sample survival test. The required D= $d$  option specifies the fixed-sample number of events  $d$ . To derive the sample size, you need to specify additional options from the following list:

- ACCNOBS=  $n_a$
- ACCRATE=  $r_a$
- ACCRUAL= UNIFORM | EXP(PARM= $\gamma_0$ )
- ACCTIME=  $T_a$
- FOLTIME=  $T_f$
- HAZARD=  $h_a < h_b >$
- LOSS= NONE | EXP( HAZARD= $\tau$  | MEDLOSSTIME= $t_\tau$  )
- MEDSURVTIME=  $t_a < t_b >$
- SAMPLE= ONE | TWO
- TOTALTIME=  $T$
- WEIGHT=  $w_a < w_b >$

The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. The default is SAMPLE=ONE. With a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups. If  $w_b$  is not specified,  $w_b=1$  is used. The default is WEIGHT=1.

For a one-sample test, the HAZARD=  $h_a$  option specifies the hazard rate  $h_a$  explicitly, and the MEDSURVTIME= $t_a$  option specifies the hazard rate implicitly through the median survival time  $t_a$ . Similarly, for a two-sample test, the HAZARD=  $h_a h_b$  option specifies the hazard rates  $h_a$  and  $h_b$  for groups A and B explicitly, and the MEDSURVTIME= $t_a t_b$  option specifies hazard rates for groups A and B implicitly through the median survival times  $t_a$  and  $t_b$ . Also, for a two-sample test,  $h_b = h_a$  if  $h_b$  is not specified and  $t_b = t_a$  if  $t_b$  is not specified.

The ACCRUAL= option specifies the method for individual accrual. The default ACCRUAL=UNIFORM option specifies that the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$ , and the ACCRUAL=EXP(PARM= $\gamma_0$ ) option specifies that the individual accrual is truncated exponential with a scaled power parameter  $\gamma_0$ , where  $\gamma_0 \geq -10$  and  $\gamma_0 \neq 0$ . With a scaled parameter  $\gamma_0$ , the power parameter for the truncated exponential with the accrual time  $T_a$  is given by  $\gamma = \gamma_0/T_a$ .

The ACCTIME= and FOLTIME= options specify the accrual time  $T_a$  and follow-up time  $T_f$ , respectively. The TOTALTIME= option specifies the total study time,  $T = T_a + T_f$ .

The ACCRATE= option specifies the constant accrual rate  $r_a$ . If you specify the ACCRATE= option, then you must also specify one of the ACCTIME=, FOLTIME=, and TOTALTIME= options for the sample size computation. Otherwise, you must specify two of the ACCTIME=, FOLTIME=, and TOTALTIME= options to compute the accrual rate and sample size.

The ACCNOBS= option specifies the total number of individuals in the study. If you specify the ACCNOBS= option, then you must also specify one of the ACCTIME=, FOLTIME=, and TOTALTIME= options for the sample size computation. Otherwise, you must specify two of the ACCTIME=, FOLTIME=, and TOTALTIME= options to compute the accrual rate and sample size.

The LOSS= option specifies the individual loss to follow up in the sample size computation. The default LOSS=NONE option specifies no loss to follow up, and the LOSS=EXP option specifies exponential loss function. The HAZARD= $\tau$  suboption specifies the exponential loss hazard rate  $\tau$ , and the MEDLOSSTIME= $t_\tau$  suboption specifies the exponential loss hazard rate through the median loss times  $t_\tau$ .

See the section “[Input Number of Events for Fixed-Sample Design](#)” on page 7044 for a detailed description of the input number of events for the fixed-sample design in sample size computation.

## One-Sample Models

The following two options compute the required sample size for a one-sample group sequential test:

**MODEL=ONESAMPLEMEAN** < ( options ) >

specifies the one-sample  $Z$  test for mean. The available options are as follows:

- MEAN=  $\mu_1$
- STDDEV=  $\sigma$

The MEAN= option specifies the alternative reference  $\mu_1$  and is required if the alternative reference is not specified or derived in the procedure. If the MEAN=option is not specified, the specified or derived alternative reference is used.

The STDDEV= option specifies the standard deviation  $\sigma$ . The default is STDDEV=1. See the section “[Test for a Normal Mean](#)” on page 7050 for a detailed description of the one-sample  $Z$  test for mean.

Note that the one-sample  $Z$  test for mean also includes the paired difference in two-treatment comparison (Jennison and Turnbull 2000, pp. 51–52), where  $\mu_1$  is the mean of differences within pairs under the alternative hypothesis and  $\sigma$  is the standard deviation for the mean of differences within pairs.

**MODEL=ONESAMPLEFREQ** < ( options ) >

specifies the one-sample test for binomial proportion with the null hypothesis  $H_0 : \theta = 0$  and the alternative hypothesis  $H_1 : \theta = \theta_1$ , where  $\theta = p - p_0$  and  $\theta_1 = p_1 - p_0$ . The available options are as follows:

- NULLPROP=  $p_0$
- PROP=  $p_1$
- REF= NULLPROP | PROP

The NULLPROP= and PROP= options specify the proportions under the null and alternative hypotheses, respectively. The default for the null reference is NULLPROP=0.5. The PROP= option is required if the alternative reference is not specified or derived in the procedure. If the PROP= option is not specified, the specified or derived alternative reference  $\theta_1$  is used to compute the alternative reference  $p_1 = p_0 + \theta_1$ .

The REF= option specifies the hypothesis under which the proportion is used in the sample size computation. The REF=NULLPROP option uses the null hypothesis, and the REF=PROP option uses the alternative hypothesis to compute the sample size. The default is REF=PROP. See the section “[Test for a Binomial Proportion](#)” on page 7051 for a detailed description of the one-sample tests for proportion.

## Two-Sample Models

The following three options compute the required sample size or number of events for a two-sample group sequential trial.

**MODEL=TWOSAMPLEMEAN** < ( options ) >

specifies the two-sample  $Z$  test for mean difference. The available options are as follows:

- MEANDIFF=  $\theta_1$
- STDDEV=  $\sigma_a$  <  $\sigma_b$  >
- WEIGHT=  $w_a$  <  $w_b$  >
- MATCHNOBS= YES | NO

The MEANDIFF= option specifies the alternative reference  $\theta_1$  and is required if the alternative reference is not specified or derived in the procedure. If the MEANDIFF= option is not specified, the specified or derived alternative reference is used.

The STDDEV= option specifies the standard deviations  $\sigma_a$  and  $\sigma_b$ . If  $\sigma_b$  is not specified,  $\sigma_b = \sigma_a$ . The default is STDDEV=1.

The WEIGHT= option specifies the sample size allocation weights for the two groups. If  $w_b$  is not specified,  $w_b = 1$  is used. The default is WEIGHT=1, equal sample size for the two groups. The derived fractional sample sizes are rounded up to integers, and the MATCHNOBS=YES option requests these integer sample sizes to match the sample size allocation. The default is MATCHNOBS=NO.

See the section “[Test for the Difference between Two Normal Means](#)” on page 7053 for a detailed description of the two-sample  $Z$  test for mean difference.

**MODEL=TWOSAMPLEFREQ** < ( options ) >

specifies the two-sample test for binomial proportions. The available options are as follows:

- NULLPROP=  $p_{0a} < p_{0b} >$
- PROP=  $p_{1a}$
- TEST= PROP | LOGOR | LOGRR
- REF= NULLPROP | PROP | AVGNULLPROP | AVGPROP
- WEIGHT=  $w_a < w_b >$
- MATCHNOBS= YES | NO

The NULLPROP= option specifies proportions  $p_a = p_{0a}$  and  $p_b = p_{0b}$  in groups A and B, respectively, under the null hypothesis. If  $p_{0b}$  is not specified,  $p_{0b} = p_{0a}$ . The default is NULLPROP=0.5.

The PROP= option specifies proportion  $p_a = p_{1a}$  in group A under the alternative hypothesis. The proportion  $p_{1b}$  in group B under the alternative hypothesis is given by  $p_{1b} = p_{0b}$ . The PROP= option is required if the alternative reference is not specified or derived in the procedure. If the PROP= option is not specified, the specified or derived alternative reference is used to compute  $p_{1a}$ , the proportion in group A under the alternative hypothesis.

The TEST= option specifies the null hypothesis  $H_0 : \theta = 0$  in the test. The TEST=PROP option uses the difference in proportions  $\theta = (p_a - p_b) - (p_{0a} - p_{0b})$ , the TEST=LOGOR option uses the log odds-ratio test  $\theta = \delta - \delta_0$ , where

$$\delta = \log \left( \frac{p_a(1 - p_b)}{p_b(1 - p_a)} \right) \quad \delta_0 = \log \left( \frac{p_{0a}(1 - p_{0b})}{p_{0b}(1 - p_{0a})} \right)$$

and the TEST=LOGRR option uses the log relative risk test with  $\theta = \delta - \delta_0$ , where

$$\delta = \log \left( \frac{p_a}{p_b} \right) \quad \delta_0 = \log \left( \frac{p_{0a}}{p_{0b}} \right)$$

The default is TEST=LOGOR.

The REF= option specifies the hypothesis under which the proportions are used in the sample size computation. The REF=NULLPROP option uses the null proportions  $p_{0a}$  and  $p_{0b}$ , the REF=PROP option uses the alternative proportions  $p_{1a}$  and  $p_{1b}$ , the REF=AVGNULLPROP option uses the average null proportion, and the REF=AVGPROP option uses the average alternative proportion. The default is REF=PROP.

The WEIGHT= option specifies the sample size allocation weights for the two groups. If  $w_b$  is not specified,  $w_b = 1$  is used. The default is WEIGHT=1, equal sample size for the two groups. The derived fractional sample sizes are also rounded up to integers, and the MATCHNOBS=YES option requests that these integer sample sizes match the sample size allocation.

See the section “Test for the Difference between Two Binomial Proportions” on page 7054, the section “Test for Two Binomial Proportions with a Log Odds Ratio Statistic” on page 7056, and the section “Test for Two Binomial Proportions with a Log Relative Risk Statistic” on page 7057 for a detailed description of the two-sample tests for proportions.

**MODEL=TWOSAMPLESURVIVAL** < ( options ) >

**MODEL=TWOSAMPLESURV** < ( options ) >

specifies the log-rank test for two survival distributions with the null hypothesis  $H_0 : \theta = \delta - \delta_0 = 0$ , where the parameter  $\delta = -\log(h_a/h_b)$ ,  $\delta_0$  is the value of  $\delta$  under the null hypothesis and the values  $h_a$  and  $h_b$  are the constant hazard rates for groups A and B, respectively.

The available options for the number of events are as follows:

- NULLHAZARD=  $h_{0a} < h_{0b} >$
- NULLMEDSURVTIME=  $t_{0a} < t_{0b} >$
- HAZARD=  $h_{1a}$
- HAZARDRATIO=  $\lambda_1$
- MEDSURVTIME=  $t_{1a}$

The NULLHAZARD= option specifies hazard rates  $h_a = h_{0a}$  and  $h_b = h_{0b}$  for groups A and B, respectively, under the null hypothesis. If  $h_{0b}$  is not specified,  $h_{0b} = h_{0a}$ . The NULLMEDSURVTIME= option specifies the median survival times  $t_a = t_{0a}$  and  $t_b = t_{0b}$  under the null hypothesis. If  $t_{0b}$  is not specified,  $t_{0b} = t_{0a}$ . If both NULLHAZARD= and NULLMEDSURVTIME= option are not specified, NULLHAZARD=0.06931, which corresponds to NULLMEDSURVTIME=10, is used.

The hazard rate for group B under the alternative hypothesis,  $h_{1b}$ , is identical to the hazard rate under the null hypothesis,  $h_{0b}$ . The HAZARD=, MEDSURVTIME=, and HAZARDRATIO= options specify the group A hazard rate  $h_{1a}$ , the group A median survival time  $t_{1a}$ , and the hazard ratio  $\lambda_1 = h_{1a}/h_{1b}$ , respectively, under the alternative hypothesis. The HAZARD=, MEDSURVTIME=, or HAZARDRATIO= option is required if the alternative reference is not specified or derived in the procedure. If these three options are not specified, the specified or derived alternative reference  $\theta_1$  is used to compute  $h_{1a}$  from the equation:

$$\theta_1 = -\log\left(\frac{h_{1a}}{h_{1b}}\right) - \left(-\log\left(\frac{h_{0a}}{h_{0b}}\right)\right) = -\log\left(\frac{h_{1a}}{h_{0a}}\right)$$

To derive the sample size, you need to specify additional *options* from the following list:

- ACCNOBS=  $n_a$
- ACCRATE=  $r_a$
- ACCRUAL= UNIFORM | EXP(PARM= $\gamma_0$ )
- ACCTIME=  $T_a$
- FOLTIME=  $T_f$
- LOSS= NONE | EXP( HAZARD= $\tau$  | MEDLOSSTIME= $t_\tau$  )
- REF= NULLHAZARD | HAZARD
- TOTALTIME=  $T$
- WEIGHT=  $w_a < w_b >$

The REF= option specifies the hypothesis under which the hazard is used in the sample size computation. The REF=NULLHAZARD option uses the null hypothesis, and the REF=HAZARD option uses the alternative hypothesis. The default is REF=HAZARD.

The WEIGHT= option specifies the sample size allocation weights for the two groups. If  $w_b$  is not specified,  $w_b = 1$  is used. The default is WEIGHT=1, equal sample size for the two groups.

The ACCRUAL= option specifies the method for individual accrual. The default ACCRUAL=UNIFORM option specifies that the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$ , and the ACCRUAL=EXP(PARM= $\gamma_0$ ) option specifies that the individual accrual is truncated exponential with a scaled power parameter  $\gamma_0$ , where  $\gamma_0 \geq -10$  and  $\gamma_0 \neq 0$ . With a scaled parameter  $\gamma_0$ , the power parameter for the truncated exponential with the accrual time  $T_a$  is given by  $\gamma = \gamma_0/T_a$ .

The ACCTIME= and FOLTIME= options specify the accrual time  $T_a$  and follow-up time  $T_f$ , respectively. The TOTALTIME= option specifies the total study time,  $T = T_a + T_f$ .

The ACCRATE= option specifies the constant accrual rate  $r_a$ . If you specify the ACCRATE= option, then you must also specify one of the ACCTIME=, FOLTIME=, and TOTALTIME= options for the sample size computation. Otherwise, you must specify two of the ACCTIME=, FOLTIME=, and TOTALTIME= options to compute the accrual rate and sample size.

The ACCNOBS= option specifies the total number of individuals in the study. If you specify the ACCNOBS= option, then you must also specify one of the ACCTIME=, FOLTIME=, and TOTALTIME= options for the sample size computation. Otherwise, you must specify two of the ACCTIME=, FOLTIME=, and TOTALTIME= options to compute the accrual rate and sample size.

The LOSS= option specifies the individual loss to follow up in the sample size computation. The default LOSS=NONE option specifies no loss to follow up, and the LOSS=EXP option specifies exponential loss function. The HAZARD= $\tau$  suboption specifies the exponential loss hazard rate  $\tau$ , and the MEDLOSSTIME= $t_\tau$  suboption specifies the exponential loss hazard rate through the median loss times  $t_\tau$ .

See the section “[Test for Two Survival Distributions with a Log-Rank Test](#)” on page 7059 for a detailed description of the two-sample log-rank test for survival data.

## Regression Models

The following three options compute the required sample size or number of events for group sequential tests on a regression parameter.

**MODEL=REG** < ( options ) >

specifies the Z test for a normal regression parameter. The available options are as follows:

- BETA=  $\beta_1$
- VARIANCE=  $\sigma_y^2$
- XVARIANCE=  $\sigma_x^2$
- XRSQUARE=  $r_x^2$

The BETA= option specifies the alternative reference  $\beta_1$  and is required if the alternative reference is not specified or derived in the procedure. If the BETA= option is not specified,  $\beta_1 = \theta_1$ , the specified or derived alternative reference.

The VARIANCE= and XVARIANCE= options specify the variances for the response variable Y and covariate X, respectively. The defaults are VARIANCE=1 and XVARIANCE=1. For a model with

more than one covariate, the XRSQUARE= option can be used to derive the variance of X after adjusting for other covariates. The default is XRSQUARE=0.

See the section “[Test for a Parameter in the Regression Model](#)” on page 7061 for a detailed description of the Z test for the regression parameter.

**MODEL=LOGISTIC** < ( options ) >

specifies the Z test for a logistic regression parameter. The available options are as follows:

- BETA=  $\beta_1$
- PROP=  $p$
- XVARIANCE=  $\sigma_x^2$
- XRSQUARE=  $r_x^2$

The BETA= option specifies the alternative reference  $\beta_1$  and is required if the alternative reference is not specified or derived in the procedure. If the BETA= option is not specified,  $\beta_1 = \theta_1$ , the specified or derived alternative reference.

The PROP= option specifies the proportion of the binary response variable Y. The default is PROP=0.5. The XVARIANCE= option specifies the variance of the covariate X. The default is XVARIANCE=1. For a model with more than one covariate, the XRSQUARE= option can be used to derive the variance of X after adjusting for other covariates. The default is XRSQUARE=0.

See the section “[Test for a Parameter in the Logistic Regression Model](#)” on page 7062 for a detailed description of the Z test for the logistic regression parameter.

**MODEL=PHREG** < ( options ) >

specifies the Z test for a proportional hazards regression parameter. The available options for the number of events are as follows:

- BETA=  $\beta_1$
- XVARIANCE=  $\sigma_x^2$
- XRSQUARE=  $r_x^2$

The BETA= option specifies the alternative reference  $\beta_1$  and is required if the alternative reference is not specified or derived in the procedure. If the BETA= option is not specified,  $\beta_1 = \theta_1$ , the specified or derived alternative reference.

The XVARIANCE= option specifies the variance of the covariate X. The default is XVARIANCE=1. For a model with more than one covariate, the XRSQUARE= option can be used to derive the variance of X after adjusting for other covariates. The default is XRSQUARE=0.

To derive the sample size, you need to specify additional *options* from the following list:

- ACCNOBS=  $n_a$
- ACCRATE=  $r_a$
- ACCRUAL= UNIFORM | EXP(PARM= $\gamma_0$ )
- ACCTIME=  $T_a$
- FOLTIME=  $T_f$

- HAZARD=  $h_a$
- LOSS= NONE | EXP( HAZARD= $\tau$  | MEDLOSSTIME= $t_\tau$  )
- MEDSURVTIME=  $t_a$
- TOTALTIME=  $T$

The hazard rate is required for the sample size computation. The HAZARD=  $h_a$  option specifies the hazard rate  $h_a$  explicitly, and the MEDSURVTIME= $t_a$  option specifies the hazard rate implicitly through the median survival time  $t_a$ .

The ACCRUAL= option specifies the method for individual accrual. The default ACCRUAL=UNIFORM option specifies that the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$ , and the ACCRUAL=EXP(PARM= $\gamma_0$ ) option specifies that the individual accrual is truncated exponential with a scaled power parameter  $\gamma_0$ , where  $\gamma_0 \geq -10$  and  $\gamma_0 \neq 0$ . With a scaled parameter  $\gamma_0$ , the power parameter for the truncated exponential with the accrual time  $T_a$  is given by  $\gamma = \gamma_0/T_a$ .

The ACCTIME= and FOLTIME= options specify the accrual time  $T_a$  and follow-up time  $T_f$ , respectively. The TOTALTIME= option specifies the total study time,  $T = T_a + T_f$ .

The ACCRATE= option specifies the constant accrual rate  $r_a$ . If you specify the ACCRATE= option, then you must also specify one of the ACCTIME=, FOLTIME=, and TOTALTIME= options for the sample size computation. Otherwise, you must specify two of the ACCTIME=, FOLTIME=, and TOTALTIME= options to compute the accrual rate and sample size.

The ACCNOBS= option specifies the total number of individuals in the study. If you specify the ACCNOBS= option, then you must also specify one of the ACCTIME=, FOLTIME=, and TOTALTIME= options for the sample size computation. Otherwise, you must specify two of the ACCTIME=, FOLTIME=, and TOTALTIME= options to compute the accrual rate and sample size.

The LOSS= option specifies the individual loss to follow up in the sample size computation. The default LOSS=NONE option specifies no loss to follow up, and the LOSS=EXP option specifies exponential loss function. The HAZARD= $\tau$  suboption specifies the exponential loss hazard rate  $\tau$ , and the MEDLOSSTIME= $t_\tau$  suboption specifies the exponential loss hazard rate through the median loss times  $t_\tau$ .

See the section “Test for a Parameter in the Proportional Hazards Regression Model” on page 7063 for a detailed description of the  $Z$  test for the proportional hazards regression parameter.

## Details: SEQDESIGN Procedure

### Fixed-Sample Clinical Trials

A clinical trial is a research study in consenting human beings to answer specific health questions. One type of trial is a treatment trial, which tests the effectiveness of an experimental treatment. An example is a planned experiment designed to assess the efficacy of a treatment in humans by comparing the outcomes in a group of patients who receive the test treatment with the outcomes in a comparable group of patients who

receive a placebo control treatment, where patients in both groups are enrolled, treated, and followed over the same time period.

A clinical trial is conducted according to a plan called a protocol. The protocol provides detailed description of the study. For a fixed-sample trial, the study protocol contains detailed information such as the null hypothesis, the one-sided or two-sided test, and the Type I and II error probability levels. It also includes the test statistic and its associated critical values in the hypothesis testing.

Generally, the efficacy of a new treatment is demonstrated by testing a hypothesis  $H_0 : \theta = 0$  in a clinical trial, where  $\theta$  is the parameter of interest. For example, to test whether a population mean  $\mu$  is greater than a specified value  $\mu_0$ ,  $\theta = \mu - \mu_0$  can be used with an alternative  $\theta > 0$ .

A one-sided test is a test of the hypothesis with either an upper (greater) or a lower (lesser) alternative, and a two-sided test is a test of the hypothesis with a two-sided alternative. The drug industry often prefers to use a one-sided test to demonstrate clinical superiority based on the argument that a study should not be run if the test drug would be worse (Chow, Shao, and Wang 2003, p. 28). But in practice, two-sided tests are commonly performed in drug development (Senn 1997, p. 161). For a fixed Type I error probability  $\alpha$ , the sample sizes required by one-sided and two-sided tests are different. See Senn (1997, pp. 161–167) for a detailed description of issues involving one-sided and two-sided tests.

For independent and identically distributed observations  $y_1, y_2, \dots, y_n$  of a random variable, the likelihood function for  $\theta$  is

$$L(\theta) = \prod_{j=1}^n L_j(\theta)$$

where  $\theta$  is the population parameter and  $L_j(\theta)$  is the probability or probability density of  $y_j$ . Using the likelihood function, two statistics can be derived that are useful for inference: the maximum likelihood estimator and the score statistic.

### Maximum Likelihood Estimator

The maximum likelihood estimate (MLE) of  $\theta$  is the value  $\hat{\theta}$  that maximizes the likelihood function for  $\theta$ . Under mild regularity conditions,  $\hat{\theta}$  is an asymptotically unbiased estimate of  $\theta$  with variance  $1/E_\theta(I(\theta))$ , where  $I(\theta)$  is the Fisher information

$$I(\theta) = -\frac{\partial^2 \log(L(\theta))}{\partial \theta^2}$$

and  $E_\theta(I(\theta))$  is the expected Fisher information (Diggle et al. 2002, p. 340)

$$E_\theta(I(\theta)) = -E_\theta \left( \frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \right)$$

The score function for  $\theta$  is defined as

$$S(\theta) = \frac{\partial \log(L(\theta))}{\partial \theta}$$

and usually, the MLE can be derived by solving the likelihood equation  $S(\theta) = 0$ . Asymptotically, the MLE is normally distributed (Lindgren 1976, p. 272):

$$\hat{\theta} \sim N \left( \theta, \frac{1}{E_\theta(I(\theta))} \right)$$

If the Fisher information  $I(\theta)$  does not depend on  $\theta$ , then  $I(\theta)$  is known. Otherwise, either the expected information evaluated at the MLE  $\hat{\theta}$  ( $E_{\theta=\hat{\theta}}(I(\theta))$ ) or the observed information  $I(\hat{\theta})$  can be used for the Fisher information (Cox and Hinkley 1974, p. 302; Efron and Hinkley 1978, p. 458), where the observed Fisher information

$$I(\hat{\theta}) = - \left( \frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \Big|_{\theta = \hat{\theta}} \right)$$

If the Fisher information  $I(\theta)$  does depend on  $\theta$ , the observed Fisher information is recommended for the variance of the maximum likelihood estimator (Efron and Hinkley 1978, p. 457).

Thus, asymptotically, for large  $n$ ,

$$\hat{\theta} \sim N \left( \theta, \frac{1}{I} \right)$$

where  $I$  is the information, either the expected Fisher information  $E_{\theta=0}(I(\theta))$  or the observed Fisher information  $I(\hat{\theta})$ .

So to test  $H_0 : \theta = 0$  versus  $H_1 : \theta \neq 0$ , you can use the standardized  $Z$  test statistic

$$Z = \frac{\hat{\theta}}{\sqrt{\text{Var}(\hat{\theta})}} = \hat{\theta} \sqrt{I} \sim N(0, 1)$$

and the two-sided  $p$ -value is given by

$$\text{Prob}(|Z| > |z_0|) = 1 - 2\Phi(|z_0|)$$

where  $\Phi$  is the cumulative standard normal distribution function and  $z_0$  is the observed  $Z$  statistic.

If the BOUNDARYSCALE=SCORE is specified in the SEQDESIGN procedure, the boundary values for the test statistic are displayed in the score statistic scale. With the standardized  $Z$  statistic, the score statistic  $S = Z\sqrt{I} = \hat{\theta}I$  and

$$S \sim N(0, I)$$

## Score Statistic

The score statistic is based on the score function for  $\theta$ ,

$$S(\theta) = \frac{\partial \log(L(\theta))}{\partial \theta}$$

Under the null hypothesis  $H_0 : \theta = 0$ , the score statistic  $S(0)$  is the first derivative of the log likelihood evaluated at the null reference 0:

$$S(0) = \frac{\partial \log(L(\theta))}{\partial \theta} \Big|_{\theta = 0}$$

Under regularity conditions,  $S(0)$  is asymptotically normally distributed with mean zero and variance  $E_{\theta=0}(I(\theta))$ , the expected Fisher information evaluated at the null hypothesis  $\theta = 0$  (Kalbfleisch and Prentice 1980, p. 45), where  $I(\theta)$  is the Fisher information

$$I(\theta) = -E \left( \frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \right)$$

That is, for large  $n$ ,

$$S(0) \sim N(0, E_{\theta=0}(I(\theta)))$$

Asymptotically, the variance of the score statistic  $S(0)$ ,  $E_{\theta=0}(I(\theta))$ , can also be replaced by the expected Fisher information evaluated at the MLE  $\theta = \hat{\theta}$  ( $E_{\theta=\hat{\theta}}(I(\theta))$ ), the observed Fisher information evaluated at the null hypothesis  $\theta = 0$  ( $I(0)$ ), or the observed Fisher information evaluated at the MLE  $\theta = \hat{\theta}$  ( $I(\hat{\theta})$ ) (Kalbfleisch and Prentice 1980, p. 46), where

$$I(0) = - \left( \frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \Big|_{\theta=0} \right)$$

$$I(\hat{\theta}) = - \left( \frac{\partial^2 \log(L(\theta))}{\partial \theta^2} \Big|_{\theta=\hat{\theta}} \right)$$

Thus, asymptotically, for large  $n$ ,

$$S(0) \sim N(0, I)$$

where  $I$  is the information, either an expected Fisher information ( $E_{\theta=0}(I(\theta))$  or  $E_{\theta=\hat{\theta}}(I(\theta))$ ) or a observed Fisher information ( $I(0)$  or  $I(\hat{\theta})$ ).

So to test  $H_0 : \theta = 0$  versus  $H_1 : \theta \neq 0$ , you can use the standardized  $Z$  test statistic

$$Z = \frac{S(0)}{\sqrt{I}}$$

If the BOUNDARYSCALE=MLE is specified in the SEQDESIGN procedure, the boundary values for the test statistic are displayed in the MLE scale. With the standardized  $Z$  statistic, the MLE statistic  $\hat{\theta} = Z/\sqrt{I} = U(0)/I$  and

$$\hat{\theta} \sim N\left(0, \frac{1}{I}\right)$$

## One-Sample Test for Mean

The following one-sample test for mean is used to demonstrate fixed-sample clinical trials in the section “One-Sided Fixed-Sample Tests in Clinical Trials” on page 7007 and the section “Two-Sided Fixed-Sample Tests in Clinical Trials” on page 7010.

Suppose  $y_1, y_2, \dots, y_n$  are  $n$  observations of a response variable  $Y$  from a normal distribution

$$y_i \sim N(\theta, \sigma^2)$$

where  $\theta$  is the unknown mean and  $\sigma^2$  is the known variance.

Then the log likelihood function for  $\theta$  is

$$\log(L(\theta)) = \sum_{j=1}^n -\frac{1}{2} \frac{(y_j - \theta)^2}{\sigma^2} + c$$

where  $c$  is a constant. The first derivative is

$$\frac{\partial \log(L(\theta))}{\partial \theta} = \frac{1}{\sigma^2} \sum_{j=1}^n (y_j - \theta) = \frac{n}{\sigma^2} (\bar{y} - \theta)$$

where  $\bar{y}$  is the sample mean.

Setting the first derivative to zero, the MLE of  $\theta$  is  $\hat{\theta} = \bar{y}$ , the sample mean. The variance for  $\hat{\theta}$  can be derived from the Fisher information

$$I(\theta) = -\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} = \frac{n}{\sigma^2}$$

Since the Fisher information  $I_0 = I(\theta)$  does not depend on  $\theta$  in this case,  $1/I_0$  is used as the variance for  $\hat{\theta}$ . Thus the sample mean  $\bar{y}$  has a normal distribution with mean  $\theta$  and variance  $\sigma^2/n$ :

$$\hat{\theta} = \bar{y} \sim N\left(\theta, \frac{1}{I_0}\right) = N\left(\theta, \frac{\sigma^2}{n}\right)$$

Under the null hypothesis  $H_0 : \theta = 0$ , the score statistic

$$S(0) = \frac{\partial \log(L(\theta))}{\partial \theta} \Big|_{\theta=0} = \frac{n}{\sigma^2} \bar{y}$$

has a mean zero and variance

$$I(\theta) = -\frac{\partial^2 \log(L(\theta))}{\partial \theta^2} = \frac{n}{\sigma^2}$$

With the MLE  $\hat{\theta}$ , the corresponding standardized statistic is computed as  $Z = \hat{\theta} \sqrt{I_0} = \bar{y}/(\sigma/\sqrt{n})$ , which has a normal distribution with variance 1:

$$Z \sim N\left(\theta \sqrt{I_0}, 1\right) = N\left(\frac{\theta}{\sigma/\sqrt{n}}, 1\right)$$

Also, the corresponding score statistic is computed as  $S = \hat{\theta} I_0 = n\bar{y}/\sigma^2$  and

$$S \sim N\left(\theta I_0, I_0\right) = N\left(\frac{n\theta}{\sigma^2}, \frac{n}{\sigma^2}\right)$$

which is identical to  $S(0)$  computed under the null hypothesis  $H_0 : \theta = 0$ .

Note that if the variable  $Y$  does not have a normal distribution, then it is assumed that the sample size  $n$  is large such that the sample mean has an approximately normal distribution.

## One-Sided Fixed-Sample Tests in Clinical Trials

A one-sided test has either an upper (greater) or a lower (lesser) alternative. This section describes one-sided tests with upper alternatives only. Corresponding results for one-sided tests with lower alternatives can be derived similarly.

For a one-sided test of  $H_0 : \delta \leq \delta_0$  with an upper alternative  $H_1 : \delta > \delta_0$ , an equivalent null hypothesis is  $H_0 : \theta \leq 0$  with an upper alternative  $H_1 : \theta > 0$ , where  $\theta = \delta - \delta_0$ . A fixed-sample test rejects  $H_0$  if the

standardized test statistic  $Z_0 = \hat{\theta} \sqrt{I_0} \geq C_\alpha$ , where  $\hat{\theta}$  is the sample estimate of  $\theta$  and  $C_\alpha = \Phi^{-1}(1 - \alpha)$  is the critical value.

The  $p$ -value of the test is given by  $1 - \Phi(Z_0)$ , and the hypothesis  $H_0$  is rejected if the  $p$ -value is less than  $\alpha$ . An upper  $(1 - \alpha)$  confidence interval has the lower limit

$$\theta_l = \hat{\theta} - \frac{\Phi^{-1}(1 - \alpha)}{\sqrt{I_0}} = \frac{Z_0 - \Phi^{-1}(1 - \alpha)}{\sqrt{I_0}}$$

The hypothesis  $H_0$  is rejected if the confidence interval for the parameter  $\theta$  does not contain zero—that is, if the lower limit  $\theta_l$  is greater than 0.

With an alternative reference  $\theta = \theta_1$ ,  $\theta_1 > 0$ , a Type II error probability is defined as

$$\beta = P_{\theta=\theta_1}(Z_0 < C_\alpha)$$

which is equivalent to

$$\beta = P_{\theta=\theta_1}(Z_0 - \theta_1 \sqrt{I_0} < C_\alpha - \theta_1 \sqrt{I_0}) = \Phi(C_\alpha - \theta_1 \sqrt{I_0})$$

Thus,  $\Phi^{-1}(\beta) = C_\alpha - \theta_1 \sqrt{I_0}$ . Then, with  $C_\alpha = \Phi^{-1}(1 - \alpha)$ ,

$$\theta_1 \sqrt{I_0} = \Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta)$$

The drift parameter  $\theta_1 \sqrt{I_0}$  can be computed for specified  $\alpha$  and  $\beta$  and the maximum information is given by

$$I_0 = \left( \frac{\Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta)}{\theta_1} \right)^2$$

If the maximum information is available, then the required sample size can be derived. For example, in a one-sample test for the mean with a specific standard deviation  $\sigma$ , the sample size  $n$  required for the test is

$$n = \sigma^2 I_0 = \sigma^2 \left( \frac{\Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta)}{\theta_1} \right)^2$$

On the other hand, if the alternative reference  $\theta_1$ , standard deviation  $\sigma$ , and sample size  $n$  are all specified, then  $\alpha$  can be derived for a given  $\beta$  and, similarly,  $\beta$  can be derived for a given  $\alpha$ .

With an alternative reference  $\theta = \theta_1$ ,  $\theta_1 > 0$ , the power  $1 - \beta$  is the probability of correctly rejecting the null hypothesis  $H_0$  at  $\theta_1$ :

$$1 - \beta = 1 - P_{\theta=\theta_1}(Z_0 < C_\alpha) = \Phi(\theta_1 \sqrt{I_0} - C_\alpha)$$

## Superiority Trials

A superiority trial that tests the response to a new drug is clinically superior to a comparative placebo control or active control therapy. If a positive value indicates a beneficial effect, a test for superiority has

$$H_0 : \theta \leq 0 \quad H_1 : \theta > 0$$

where  $H_0$  is the hypothesis of nonsuperiority and  $H_1$  is the alternative hypothesis of superiority.

The superiority test rejects the hypothesis  $H_0$  and declares superiority if the standardized statistic  $Z_0 = \hat{\theta}\sqrt{T_0} \geq C_\alpha$ , where the critical value  $C_\alpha = \Phi^{-1}(1 - \alpha)$ .

For example, if  $\theta$  is the response difference between the treatment and placebo control groups, then a superiority trial can be

$$H_0 : \theta \leq 0 \quad H_1 : \theta = 6$$

with a Type I error probability level  $\alpha = 0.025$  and a power  $1 - \beta = 0.90$  at  $\theta_1 = 6$ .

## Noninferiority Trials

A noninferiority trial does not compare the response to a new treatment with the response to a placebo. Instead, it demonstrates the effectiveness of a new treatment compared with that of a nonexisting placebo by showing that the response of a new treatment is not clinically inferior to the response of a standard therapy with an established effect. That is, this type of trial attempts to demonstrate that the new treatment effect is not worse than the standard therapy effect by an acceptable margin. These trials are often performed when there is an existing effective therapy for a serious disease, and therefore a placebo control group cannot be ethically included.

It can be difficult to specify an appropriate noninferiority margin. One practice is to choose with reference to the effect of the active control in historical placebo-controlled trials (Snapinn 2000, p. 20). With this practice, there is some basis to imply that the new treatment is better than the placebo for a positive noninferiority trial.

If a positive value indicates a beneficial effect, a test for noninferiority has a null hypothesis  $\delta \leq -\delta_0$  and an alternative hypothesis  $\delta = \delta_1 > -\delta_0$ , where  $\delta_0 > 0$  is the specified noninferiority margin.

An equivalent test has

$$H_0 : \theta \leq 0 \quad H_1 : \theta = \theta_1 > 0$$

where the parameter  $\theta = \delta + \delta_0$ ,  $H_0$  is the null hypothesis of inferiority, and  $H_1$  is the alternative hypothesis of noninferiority,

The noninferiority test rejects the hypothesis  $H_0$  and declares noninferiority if the standardized statistic  $Z_0 = \hat{\theta}\sqrt{T_0} = (\hat{\delta} + \delta_0)\sqrt{T_0} \geq C_\alpha$ , where the critical value  $C_\alpha = \Phi^{-1}(1 - \alpha)$ .

For example, if  $\delta$  is the response difference between the treatment and active control groups and  $\delta_0 = 2$  is the noninferiority margin, then a noninferiority trial with a power  $1 - \beta = 0.90$  at  $\delta_1 = 1$  might be

$$H_0 : \theta \leq 0 \quad H_1 : \theta = 3$$

where  $\theta = \delta + \delta_0 = \delta + 2$ .

## Two-Sided Fixed-Sample Tests in Clinical Trials

A two-sided test is a test of a hypothesis with a two-sided alternative. Two-sided tests include simple symmetric tests and more complicated asymmetric tests that might have distinct lower and upper alternative references.

### Symmetric Two-Sided Tests for Equality

For a symmetric two-sided test with the null hypothesis  $\delta = \delta_0$  against the alternative  $\delta \neq \delta_0$ , an equivalent null hypothesis is  $H_0 : \theta = 0$  with a two-sided alternative  $H_1 : \theta \neq 0$ , where  $\theta = \delta - \delta_0$ . A fixed-sample test rejects  $H_0$  if  $|\hat{\theta}\sqrt{I_0}| \geq C_{\alpha/2}$ , where  $\hat{\theta}$  is a sample estimate of  $\theta$  and  $C_{\alpha/2} = \Phi^{-1}(1 - \alpha/2)$  is the critical value.

A common two-sided test is the test for the response difference between a treatment group and a control group. The null and alternative hypotheses are  $H_0 : \theta = 0$  and  $H_1 : \theta \neq 0$ , respectively, where  $\theta$  is the response difference between the two groups. If a greater value indicates a beneficial effect, then there are three possible results:

- The test rejects the hypothesis  $H_0$  of equality and indicates that the treatment is significantly better if the standardized statistic  $Z_0 = \hat{\theta}\sqrt{I_0} \geq C_{\alpha/2}$ .
- The test rejects the hypothesis  $H_0$  and indicates the treatment is significantly worse if the standardized statistic  $Z_0 = \hat{\theta}\sqrt{I_0} \leq -C_{\alpha/2}$ .
- The test indicates no significant difference between the two responses if  $-C_{\alpha/2} < \hat{\theta}\sqrt{I_0} < C_{\alpha/2}$ .

The  $p$ -value of the test is  $2(1 - \Phi(Z_0))$  if  $Z_0 > 0$  and  $2\Phi(Z_0)$  if  $Z_0 \leq 0$ . The hypothesis  $H_0$  is rejected if the  $p$ -value of the test is less than  $\alpha$ —that is, if  $1 - \Phi(Z_0) < \alpha/2$  or  $\Phi(Z_0) < \alpha/2$ . A symmetric  $(1 - \alpha)$  confidence interval for  $\theta$  has lower and upper limits

$$\left( \hat{\theta} - \frac{C_{\alpha/2}}{\sqrt{I_0}}, \hat{\theta} + \frac{C_{\alpha/2}}{\sqrt{I_0}} \right)$$

which is

$$\left( \frac{1}{\sqrt{I_0}} (Z_0 - C_{\alpha/2}), \frac{1}{\sqrt{I_0}} (Z_0 + C_{\alpha/2}) \right)$$

The hypothesis  $H_0$  is rejected if the confidence interval for the parameter  $\theta$  does not contain zero. That is, the lower limit is greater than zero or the upper limit is less than zero.

With an alternative reference  $\theta = \theta_1 > 0$ , a Type II error probability is defined as

$$\beta = P_{\theta=\theta_1}(-C_{\alpha/2} < Z_0 < C_{\alpha/2})$$

which is

$$\beta = P_{\theta=\theta_1} \left( (-C_{\alpha/2} - \theta_1\sqrt{I_0}) < (Z_0 - \theta_1\sqrt{I_0}) < (C_{\alpha/2} - \theta_1\sqrt{I_0}) \right)$$

Thus

$$\beta = \Phi\left(C_{\alpha/2} - \theta_1 \sqrt{I_0}\right) - \Phi\left(-C_{\alpha/2} - \theta_1 \sqrt{I_0}\right)$$

The resulting power  $1 - \beta$  is the probability of correctly rejecting the null hypothesis, which includes the probability for the lower alternative and the probability for the upper alternative. The SEQDESIGN procedure uses only the probability of correctly rejecting the null hypothesis for the correct alternative in the power computation.

Thus, under the upper alternative hypothesis, the power in the SEQDESIGN procedure is computed as the probability of rejecting the null hypothesis for the upper alternative,  $1 - \Phi\left(C_{\alpha/2} - \theta_1 \sqrt{I_0}\right) = \Phi\left(\theta_1 \sqrt{I_0} - C_{\alpha/2}\right)$ , and a very small probability of rejecting the null hypothesis for the lower alternative,  $\Phi\left(-C_{\alpha/2} - \theta_1 \sqrt{I_0}\right)$ , is ignored. This power computation is more rational than the power based on the probability of correctly rejecting the null hypothesis (Whitehead 1997, p. 75).

That is,

$$\beta = P_{\theta=\theta_1}\left((Z_0 - \theta_1 \sqrt{I_0}) < (C_{\alpha/2} - \theta_1 \sqrt{I_0})\right) = \Phi\left(C_{\alpha/2} - \theta_1 \sqrt{I_0}\right)$$

Then with  $\Phi^{-1}(\beta) = C_{\alpha/2} - \theta_1 \sqrt{I_0}$ ,

$$\theta_1 \sqrt{I_0} = C_{\alpha/2} - \Phi^{-1}(\beta) = \Phi^{-1}(1 - \alpha/2) + \Phi^{-1}(1 - \beta)$$

The drift parameter  $\theta_1 \sqrt{I_0}$  can be derived for specified  $\alpha$  and  $\beta$ , and the maximum information is given by

$$I_0 = \left(\frac{\Phi^{-1}(1 - \alpha/2) + \Phi^{-1}(1 - \beta)}{\theta_1}\right)^2$$

If the maximum information is available, then the required sample size can be derived. For example, in a one-sample test for mean, if the standard deviation  $\sigma$  is known, the sample size  $n$  required for the test is

$$n = \sigma^2 I_0 = \sigma^2 \left(\frac{\Phi^{-1}(1 - \alpha/2) + \Phi^{-1}(1 - \beta)}{\theta_1}\right)^2$$

On the other hand, if the alternative reference  $\theta_1$ , standard deviation  $\sigma$ , and sample size  $n$  are all known, then  $\alpha$  can be derived with a given  $\beta$  and, similarly,  $\beta$  can be derived with a given  $\alpha$ .

### Generalized Two-Sided Tests for Equality

For a generalized two-sided test with the null hypothesis  $\delta = \delta_0$  against the alternative  $\delta \neq \delta_0$ , an equivalent null hypothesis is  $H_0 : \theta \leq 0$  with a two-sided alternative  $H_1 : \theta \neq 0$ , where  $\theta = \delta - \delta_0$ . A fixed-sample test rejects  $H_0$  if the standardized statistic  $Z_0 = \hat{\theta} \sqrt{I_0} < -C_{\alpha_l}$  or  $Z_0 = \hat{\theta} \sqrt{I_0} > C_{\alpha_u}$ , where the critical values  $C_{\alpha_l} = \Phi^{-1}(1 - \alpha_l)$  and  $C_{\alpha_u} = \Phi^{-1}(1 - \alpha_u)$ .

With the lower alternative reference  $\theta_{1l} < 0$ , a lower Type II error probability is defined as

$$\beta_l = P_{\theta=\theta_{1l}}\left(-C_{\alpha_l} \leq Z_{0l} \sqrt{I_0}\right) = P_{\theta=\theta_{1l}}\left(-C_{\alpha_l} - \theta_{1l} \sqrt{I_0} \leq Z_{0l} \sqrt{I_0} - \theta_{1l} \sqrt{I_0}\right)$$

This implies

$$\beta_l = 1 - \Phi(-C_{\alpha_l} - \theta_{1l} \sqrt{I_0})$$

and the power is the probability of correctly rejecting the null hypothesis for the lower alternative,

$$1 - \beta_l = \Phi(-C_{\alpha_l} - \theta_{1l} \sqrt{I_0})$$

The lower drift parameter is derived as

$$\theta_{1l} \sqrt{I_0} = -(\Phi^{-1}(1 - \alpha_l) + \Phi^{-1}(1 - \beta_l))$$

Then, with specified  $\alpha_l$  and  $\beta_l$ , if the maximum information is known, the lower alternative reference  $\theta_{1l}$  can be derived. If the maximum information is unknown, then with the specified lower alternative reference  $\theta_{1l}$ , the maximum information required is

$$I_{0l} = \left( \frac{\Phi^{-1}(1 - \alpha_l) + \Phi^{-1}(1 - \beta_l)}{-\theta_{1l}} \right)^2$$

Similarly, the upper drift parameter is derived as

$$\theta_{1u} \sqrt{I_0} = \Phi^{-1}(1 - \alpha_u) + \Phi^{-1}(1 - \beta_u)$$

For a given  $\alpha_u$ ,  $\beta_u$ , and the upper alternative reference  $\theta_{1u}$ , the maximum information required is

$$I_{0u} = \left( \frac{\Phi^{-1}(1 - \alpha_u) + \Phi^{-1}(1 - \beta_u)}{\theta_{1u}} \right)^2$$

Thus, the maximum information required for the design is given by

$$I_0 = \max(I_{0l}, I_{0u})$$

Note that with the maximum information level  $I_0$ , if  $I_{0l} < I_0$ , then the derived power from the lower alternative is larger than the specified  $1 - \beta_l$ . Similarly, if  $I_{0u} < I_0$ , then the derived power from the upper alternative is larger than the specified  $1 - \beta_u$ .

If maximum information is available, the required sample size can be derived. For example, in a one-sample test for mean, if the standard deviation  $\sigma$  is known, the sample size  $n$  required for the test is  $n = \sigma^2 I_0$ .

On the other hand, if the alternative references, Type I error probabilities  $\alpha_l$  and  $\alpha_u$ , standard deviation  $\sigma$ , and sample size  $n$  are all specified, then the Type II error probabilities  $\beta_l$  and  $\beta_u$  and the corresponding powers can be derived.

---

## Group Sequential Methods

A group sequential design provides interim analyses before the formal completion of a trial. The monitoring process provides possible early stopping for either positive or negative results and thus reduces the time to complete the trial. With a specified number of stages, the design creates critical values such that at each

interim analysis, a hypothesis can be rejected, accepted, or continued to the next time point. At the final stage, a hypothesis is either rejected or accepted. Usually, the critical values are derived such that the specified overall Type I and Type II error probability levels are maintained in the design.

For example, to test a null hypothesis  $H_0$  with an upper alternative in a fixed-sample design, a critical value  $c_\alpha$  is created. The null hypothesis  $H_0$  is rejected if the test statistic is greater than or equal to the critical value  $c_\alpha$ . Otherwise,  $H_0$  is accepted. But, for a group sequential design with early stopping to reject or accept the null hypothesis  $H_0$ , there are two critical values created at each interim analysis: an  $\alpha$  critical value  $c_{\alpha k}$  to reject the null hypothesis and a  $\beta$  critical value  $c_{\beta k}$  to accept the null hypothesis. The null hypothesis  $H_0$  is rejected if the test statistic is greater than or equal to the  $\alpha$  critical value  $c_{\alpha k}$ , and  $H_0$  is accepted if the test statistic is less than the  $\beta$  critical value  $c_{\beta k}$ . If the test statistic is between these two critical values, the process continues to the next stage. At the final stage, the two critical values are equal, and the hypothesis is either rejected or accepted.

Armitage, McPherson, and Rowe (1969) showed that repeated significance tests at a fixed level on accumulating data increase the probability of obtaining a significant result under the null hypothesis. For example, with a significance level 0.05 in a two-sided fixed-sample test, the critical value is 1.96. If this value is used in a five-stage group sequential trial with early stopping to reject the null hypothesis, then the probability of rejecting the null hypothesis at or before the fifth stage is 0.14169, much larger than the nominal value 0.05 (Armitage, McPherson, and Rowe 1969, p. 239).

Pocock (1977) applied these repeated significance tests to group sequential trials with equally spaced information levels and derives a constant critical value on the standardized normal  $Z$  scale across all stages that maintains the Type I error probability level. For example, with a significance level 0.05 in a two-sided test, the derived critical value at each stage is 2.413 on the standardized normal  $Z$  scale, larger than the fixed-sample critical value 1.96. The corresponding nominal  $p$ -value is 0.0158, which is smaller than the fixed-sample  $p$ -value 0.025 (Pocock 1977, p. 193).

O'Brien and Fleming (1979) proposed a sequential procedure that has boundary values decrease over the stages on the standardized normal  $Z$  scale to make the early stop less likely. The procedure has conservative stopping boundary values at very early stages, and boundary values at the final stage are close to the fixed-sample design. For example, with a significance level 0.05 in a two-sided test, the derived critical values at these five stages on the standardized normal  $Z$  scale are 4.562, 3.226, 2.634, 2.281, and 2.040.

The following references: Wang and Tsiatis (1987); Emerson and Fleming (1989); Pampallona and Tsiatis (1994) generalized the Pocock and O'Brien-Fleming methods to the power family, where a power parameter is used to allow a continuous set of designs between the Pocock and O'Brien-Fleming methods.

Kittelson and Emerson (1999) extended the methods in the power family even further to the unified family, which also includes the exact triangular method. The shape and location of each of the four boundaries can be independently specified in the unified family methods.

Whitehead and Stratton (1983) and Whitehead (1997, 2001) developed triangular methods by adapting tests for continuous monitoring to discrete monitoring. With early stopping to reject or accept the null hypothesis in a one-sided test, the derived continuation region has a triangular shape for the score-scaled boundaries. Only elementary calculations are needed to derive the boundary values for Whitehead's triangular methods.

For a sequential design, you can derive the  $\alpha$  and  $\beta$  error probabilities at each stage from the boundaries. On the other hand, you can derive the boundaries from specified  $\alpha$  and  $\beta$  error probabilities at each stage. The error spending function approach (Lan and DeMets 1983) uses the error spending function to specify the error probabilities at each stage and then uses these probabilities to derive the boundaries. You can specify  $\alpha$  and  $\beta$  explicitly or implicitly with an error spending function for the cumulative probabilities.

See Jennison and Turnbull (2000, pp. 5–11) for a more detailed history of group sequential methods.

The following three types of methods are available in the SEQDESIGN procedure to derive boundaries in a sequential design:

- fixed boundary shape methods, which derive boundaries with specified boundary shapes. These include the unified family method and Haybittle-Peto method.
- Whitehead methods, which adjust the boundaries from continuous monitoring for discrete monitoring
- error spending methods

You can use the SEQDESIGN procedure to specify methods from the same group for each design. A different method can be specified for each boundary separately, but all methods in a design must be from the same group.

### Fixed Boundary Shape Methods

The fixed boundary shape methods include the unified family method (Kittelson and Emerson 1999) and the Haybittle-Peto method (Haybittle 1971; Peto et al. 1976). The unified family methods derive the boundary values with the specified boundary shape. The unified family methods include the Pocock method (Pocock 1977), the O'Brien-Fleming method (O'Brien and Fleming 1979), the power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994), and the triangular method (Kittelson and Emerson 1999). See the section “[Unified Family Methods](#)” on page 7025 for a detailed description of the methods that use the unified family approach.

The Haybittle-Peto method uses a value of 3 for the critical values in interim stages, so that the critical value at the final stage is close to the original design without interim monitoring. In the SEQDESIGN procedure, the Haybittle-Peto method has been generalized to allow for different boundary values at different stages. See the section “[Haybittle-Peto Method](#)” on page 7029 for a detailed description of the Haybittle-Peto method.

### Whitehead Methods

The Whitehead methods (Whitehead and Stratton 1983; Whitehead 1997, 2001) derive the boundary values by adapting the continuous monitoring tests to the discrete monitoring of group sequential tests. The Type I error probability and power corresponding to the resulting boundaries are extremely close but differ slightly from the specified values because of the approximations used in deriving the tests (Jennison and Turnbull 2000, p. 106). The SEQDESIGN procedure provides the BOUNDARYKEY= option to adjust the boundary value at the final stage for the exact Type I or Type II error probability level. See the section “[Whitehead Methods](#)” on page 7030 for a detailed description of Whitehead's methods.

### Error Spending Methods

An error spending method (Lan and DeMets 1983) uses the error spending function to specify the error spending at each stage and then uses these error probabilities to derive the boundary values. You can specify these errors explicitly or with an error spending function for these cumulative errors. See the section “[Error Spending Methods](#)” on page 7034 for a detailed description of the error spending methods.

Error spending methods derive boundary values at each stage sequentially and require much more computation than other types of methods for group sequential trials with a large number of stages, especially for a two-sided asymmetric design with early stopping to accept  $H_0$ , or to reject or accept  $H_0$ .

The sample size requirement for some applicable tests can also be computed in the procedure. After the actual data from a clinical trial are collected, you can then use the boundary information created in the SEQDESIGN procedure to perform a group sequential test in the SEQTEST procedure.

---

## Statistical Assumptions for Group Sequential Designs

The SEQDESIGN procedure assumes that with a total number of stages  $K$ , the sequence of the standardized test statistics  $\{Z_1, Z_2, \dots, Z_K\}$  has the canonical joint distribution with information levels  $\{I_1, I_2, \dots, I_K\}$  for the parameter  $\theta$  (Jennison and Turnbull 2000, p. 49):

- $(Z_1, Z_2, \dots, Z_K)$  is multivariate normal
- $Z_k \sim N(\theta\sqrt{I_k}, 1)$ ,  $k = 1, 2, \dots, K$
- $\text{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{(I_{k_1}/I_{k_2})}$ ,  $1 \leq k_1 \leq k_2 \leq K$

In terms of the maximum likelihood estimator,  $\hat{\theta}_k = Z_k/\sqrt{I_k}$ ,  $k = 1, 2, \dots, K$ , the canonical joint distribution can be expressed as follows:

- $(\hat{\theta}_1, \hat{\theta}_2, \dots, \hat{\theta}_K)$  is multivariate normal
- $\hat{\theta}_k \sim N(\theta, 1/I_k)$ ,  $k = 1, 2, \dots, K$
- $\text{Cov}(\hat{\theta}_{k_1}, \hat{\theta}_{k_2}) = 1/I_{k_2}$ ,  $1 \leq k_1 \leq k_2 \leq K$

Furthermore, in terms of the score statistics  $S_k = Z_k\sqrt{I_k}$ ,  $k = 1, 2, \dots, K$ , the canonical joint distribution can be expressed as follows:

- $(S_1, S_2, \dots, S_K)$  is multivariate normal
- $S_k \sim N(\theta I_k, I_k)$ ,  $k = 1, 2, \dots, K$
- $\text{Cov}(S_{k_1}, S_{k_2}) = \text{Var}(S_{k_1}) = I_{k_1}$ ,  $1 \leq k_1 \leq k_2 \leq K$

That is, the increments  $S_1, S_2 - S_1, \dots$ , and  $S_K - S_{(K-1)}$  are independently distributed.

If the test statistic is computed from the data that are not from a normal distribution, such as a binomial distribution, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution.

If the increments  $S_1, S_2 - S_1, \dots$ , and  $S_K - S_{(K-1)}$  are not independently distributed, then it is inappropriate to use group sequential methods in the SEQDESIGN procedure. One such example is the Gehan statistic, which is a weighted log-rank statistic for censored data. See Jennison and Turnbull (2000, pp.

232–233, 276–277) and Proschan, Lan, and Wittes (2006, pp. 150–151) for a description of statistics with nonindependent increments.

If a trial stops at an early interim stage with only a small number of responses observed, it can lead to a distrust of the statistical findings, which rely on the assumption that the sample is large (Whitehead 1997, p. 167). A group sequential design can be specified such that at the first interim analysis, there are a sufficient number of responses to ensure that the analysis to be conducted is both reliable and persuasive (Whitehead 1997, p. 167).

Alternatively, a method such as the O'Brien-Fleming method can be used to derive conservative stopping boundary values at very early stages to make the early stop less likely. That is, the trial is stopped in early stages only with overwhelming evidence.

A simple example of the group sequential tests is the test for a normal mean,  $\mu = \mu_0$ . Suppose  $y_1, y_2, \dots, y_n$  are  $n$  observations of a response variable  $Y$  in a data set from a normal distribution with an unknown mean  $\mu$  and a known variance  $\sigma^2$ . Then the maximum likelihood estimate of  $\mu$  is the sample mean

$$\bar{y} = \frac{1}{n} \sum_{j=1}^n y_j$$

The sample mean has a normal distribution with mean  $\mu$  and variance  $\sigma^2/n$ :

$$\bar{y} \sim N\left(\mu, \frac{\sigma^2}{n}\right)$$

An equivalent hypothesis for  $\mu = \mu_0$  is  $H_0 : \theta = 0$ , where  $\theta = \mu - \mu_0$ . The MLE statistic for  $\theta$ ,

$$\hat{\theta} = \bar{y} - \mu_0 \sim N(\theta, I_0^{-1})$$

where the information  $I_0 = n/\sigma^2$ .

For a group sequential test with  $K$  stages, there are  $N_1, N_2, \dots, N_K$  observations available at these stages. At stage  $k$ , the sample mean is computed as

$$\bar{y}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

where  $y_{kj}$  is the value of the  $j$ th observation available at the  $k$ th stage and  $N_k$  is the cumulative sample size at stage  $k$ , which includes the  $N_{k-1}$  observations collected at previous stages and the  $N_k - N_{k-1}$  observations collected at the current stage.

The maximum likelihood estimate

$$\hat{\theta}_k = \bar{y}_k - \mu_0 \sim N(\theta, I_k^{-1})$$

where the information

$$I_k = \frac{1}{\text{Var}(\bar{y}_k)} = \frac{N_k}{\sigma^2}$$

is the inverse of the variance.

Thus, the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} = (\bar{y}_k - \mu_0) \sqrt{I_k} \sim N(\theta \sqrt{I_k}, 1)$$

The covariance of  $Z_{k_1}$  and  $Z_{k_2}$ ,  $1 \leq k_1 \leq k_2 \leq K$  can be expressed as

$$\text{Cov}(Z_{k_1}, Z_{k_2}) = \frac{1}{\sqrt{(I_{k_1} I_{k_2})}} \text{Cov}(S_{k_1}, S_{k_2})$$

where  $S_{k_1} = Z_{k_1} \sqrt{I_{k_1}}$  and  $S_{k_2} = Z_{k_2} \sqrt{I_{k_2}}$ .

Since  $S_{k_2} - S_{k_1}$  is independent of  $S_{k_1}$ ,  $\text{Cov}(S_{k_1}, S_{k_2}) = \text{Var}(S_{k_1}) = I_{k_1}$  and

$$\text{Cov}(Z_{k_1}, Z_{k_2}) = \frac{1}{\sqrt{(I_{k_1} I_{k_2})}} I_{k_1} = \sqrt{I_{k_1}/I_{k_2}}$$

Thus the statistics  $\{Z_1, Z_2, \dots, Z_K\}$  has the canonical joint distribution with information levels  $\{I_1, I_2, \dots, I_K\}$  for the parameter  $\mu$ . See the section “[Applicable One-Sample Tests and Sample Size Computation](#)” on page 7050, the section “[Applicable Two-Sample Tests and Sample Size Computation](#)” on page 7052, and the section “[Applicable Regression Parameter Tests and Sample Size Computation](#)” on page 7061 for more examples of applicable tests in group sequential trials.

## Boundary Scales

The boundaries computed by the SEQDESIGN procedure are applied to test statistics computed during the analysis, and so generally, the scale you select for the boundaries is determined by the scale of the statistics that you will be using.

The following scales are available in the SEQDESIGN procedure:

- MLE, maximum likelihood estimate
- standardized Z
- score statistic  $S$
- $p$ -value

These scales are all equivalent for a given set of boundary values—that is, there exists a unique transformation between any two of these scales. If you know the boundary values in terms of statistics from one scale, you can uniquely derive the boundary values of statistics for other scales. You can specify the scale with the BOUNDARYSCALE= option; the default is BOUNDARYSCALE=STDZ, the standardized Z scale.

You can also select the boundary scale to better examine the features of an individual group sequential design or to compare features among multiple designs. For example, with the standardized Z scale, the boundary values for the Pocock design are identical across all stages, and the O’Brien-Fleming design has boundary values (in absolute value) that decrease over the stages.

The remaining section demonstrates the transformations from one scale to the other scales. If the maximum likelihood estimate  $\hat{\theta}$  is computed by the analysis, then

$$\hat{\theta} \sim N\left(\theta, \frac{1}{I}\right)$$

where  $I$  is the Fisher information if it does not depend on  $\theta$ . Otherwise,  $I$  is either the expected Fisher information evaluated at  $\hat{\theta}$  or the observed Fisher information. See the section “[Maximum Likelihood Estimator](#)” on page 7004 for a detailed description of these statistics.

With the MLE statistic  $\hat{\theta}$ , the corresponding standardized  $Z$  statistic is computed as

$$Z = \hat{\theta} \sqrt{I} \sim N\left(\theta \sqrt{I}, 1\right)$$

and the corresponding score statistic is computed as

$$S = \hat{\theta} I \sim N(\theta I, I)$$

Similarly, if a score statistic  $S$  is computed by the analysis, then with

$$S \sim N(\theta I, I)$$

where  $I$  is the information, either an expected Fisher information ( $E_{\theta=0}(I(\theta))$  or  $E_{\theta=\hat{\theta}}(I(\theta))$ ) or an observed Fisher information ( $I(0)$  or  $I(\hat{\theta})$ ).

The corresponding standardized  $Z$  statistic is computed as

$$Z = \frac{S}{\sqrt{I}} \sim N\left(\theta \sqrt{I}, 1\right)$$

and the corresponding MLE-scaled statistic is computed as

$$\hat{\theta} = \frac{S}{I} \sim N\left(\theta, \frac{1}{I}\right)$$

With a standardized normal  $Z$  statistic, the corresponding fixed-sample nominal  $p$ -value depends on the type of alternative hypothesis. With an upper alternative, the nominal  $p$ -value is defined as the one-sided  $p$ -value under the null hypothesis  $H_0 : \theta = 0$  with an upper alternative:

$$p_k = 1 - \Phi(Z)$$

With a lower alternative or a two-sided alternative, the nominal  $p$ -value is defined as the one-sided  $p$ -value under the null hypothesis  $H_0 : \theta = 0$  with a lower alternative:

$$p_k = \Phi(Z)$$

which is an increasing function of the standardized  $Z$  statistic (Emerson, Kittelson, and Gillen 2005, p. 12).

The BOUNDARYSCALE= MLE, STDZ, SCORE, and PVALUE options display the boundary values in the MLE, standardize  $Z$ , score, and  $p$ -value scales, respectively. For example, suppose  $y_{k1}, y_{k2}, \dots, y_{kn_k}$

are  $n_k$  observations of a response variable  $Y$  in a data set from a normal distribution with an unknown mean  $\mu$  and a known variance  $\sigma^2$ . Then

$$y_{kj} \sim N(\mu, \sigma^2)$$

for  $k = 1, 2, \dots, K$ , where  $K$  is the number of groups and  $n_k$  is the number of observations at group  $k$ .

If  $N_k$  is the cumulative number of observations for the first  $k$  groups, then the sample mean from these  $N_k$  observations

$$\bar{y}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

has a normal distribution with mean  $\theta$  and variance  $\sigma^2/N_k$ :

$$\bar{y}_k \sim N\left(\theta, \frac{\sigma^2}{N_k}\right)$$

To test the null hypothesis  $\mu = \mu_0$ ,  $H_0 : \theta = 0$ , where  $\theta = \mu - \mu_0$  can be used. The MLE of  $\theta$  is  $\hat{\theta}_k = \bar{y}_k - \mu_0$  and

$$\hat{\theta}_k \sim N\left(\theta, \frac{1}{I_k}\right)$$

where the information is the inverse of the variance of  $\bar{y}_k$ ,

$$I_k = \frac{N_k}{\sigma^2}$$

The corresponding standardized  $Z$  statistic is

$$Z_k = \hat{\theta}_k I_k^{\frac{1}{2}} \sim N\left(\theta I_k^{\frac{1}{2}}, 1\right)$$

The score statistic in the SEQDESIGN procedure is then given by

$$S_k = \hat{\theta}_k I_k = Z_k I_k^{\frac{1}{2}} \sim N(\theta I_k, I_k)$$

For a null hypothesis  $H_0 : \theta = 0$  with an upper alternative, the nominal  $p$ -value of the standardized  $Z$  statistic is  $p_k = 1 - \Phi(Z_k)$ . For a null hypothesis  $H_0 : \theta = 0$  with a lower alternative or a two-sided alternative, the nominal  $p$ -value of the standardized  $Z$  statistic is  $p_k = \Phi(Z_k)$ .

## Boundary Variables

The boundaries created in group sequential trials depend on the type of the alternative hypothesis and the early stopping criterion. Table 83.5 shows the boundaries created with various design specifications.

**Table 83.5** Boundary Variables

| Alternative Hypothesis | Specifications<br>Early Stopping | Boundary Variables |      |       |       |
|------------------------|----------------------------------|--------------------|------|-------|-------|
|                        |                                  | Lower              |      | Upper |       |
|                        |                                  | Alpha              | Beta | Beta  | Alpha |
| Lower                  | Accept $H_0$                     |                    | X    |       |       |
|                        | Reject $H_0$                     | X                  |      |       |       |
|                        | Accept/Reject $H_0$              | X                  | X    |       |       |
| Upper                  | Accept $H_0$                     |                    |      | X     |       |
|                        | Reject $H_0$                     |                    |      |       | X     |
|                        | Accept/Reject $H_0$              |                    |      | X     | X     |
| Two-sided              | Accept $H_0$                     |                    | X    | X     |       |
|                        | Reject $H_0$                     | X                  |      |       | X     |
|                        | Accept/Reject $H_0$              | X                  | X    | X     | X     |

Up to four boundaries can be generated in a group sequential design:

- the upper  $\alpha$  boundary, to reject the null hypothesis for the upper alternative
- the upper  $\beta$  boundary, to accept the null hypothesis with an upper alternative
- the lower  $\beta$  boundary, to accept the null hypothesis with a lower alternative
- the lower  $\alpha$  boundary, to reject the null hypothesis for the lower alternative

For a two-sided design, the null hypothesis is accepted only if both the hypothesis is accepted with an upper alternative and the hypothesis is accepted with a lower alternative.

For a one-sided design with a lower alternative, only the lower boundaries are created. Similarly, for a one-sided design with an upper alternative, only the upper boundaries are created. For example, Figure 83.10 shows the boundary plot for a one-sided test with an upper alternative.

Figure 83.10 Boundary Plot for One-Sided Test

Figure 83.10 corresponds to a one-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

For a two-sided design, both the lower and upper boundaries are created. For a design with early stopping to reject the null hypothesis,  $\alpha$  boundaries are created. Similarly, for a design with early stopping to accept the null hypothesis,  $\beta$  boundaries are created. For a design with early stopping to accept or reject the null hypothesis, both the  $\alpha$  and  $\beta$  boundaries are created.

For example, Figure 83.11 shows the boundary plot for a two-sided test.

**Figure 83.11** Boundary Plot for Two-Sided Test

Figure 83.11 corresponds to a two-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

## Type I and Type II Errors

The Type I error is the error of rejecting the null hypothesis when the null hypothesis is correct, and the Type II error is the error of not rejecting the null hypothesis when the null hypothesis is incorrect. The level of significance  $\alpha$  is the probability of making a Type I error. The Type II error depends on the hypothetical reference of the alternative hypothesis, and the Type II error probability  $\beta$  is defined as the probability of not rejecting the null hypothesis when a specific alternative reference is true. The power  $1 - \beta$  is then defined as the probability of rejecting the null hypothesis at the alternative reference.

In a sequential design, if the maximum information and alternative reference are not both specified, the critical values are created such that both the specified Type I and the specified Type II error probability

levels are maintained in the design. Otherwise, the critical values are created such that either the specified Type I error probability or the specified Type II error probability is maintained.

### One-Sided Tests

For a  $K$ -stage group sequential design with an upper alternative hypothesis  $H_1 : \theta = \theta_1$  and early stopping to reject or accept the null hypothesis  $H_0 : \theta = 0$ , the boundaries contain the upper  $\alpha$  critical values  $a_k$  and upper  $\beta$  critical values  $b_k$ ,  $k = 1, 2, \dots, K$ . At each interim stage,  $b_k < a_k$ , the null hypothesis  $H_0$  is rejected if the observed statistic  $z_k \geq a_k$ ,  $H_0$  is accepted if  $z_k < b_k$ , or the process is continued to the next stage if  $b_k \leq z_k < a_k$ . At the final stage  $b_K = a_K$ , the hypothesis is either rejected or accepted.

The overall Type I error probability  $\alpha$  is given by

$$\alpha = \sum_{k=1}^K \alpha_k$$

where  $\alpha_k$  is the  $\alpha$  spending at stage  $k$ . That is, at stage 1,

$$\alpha_1 = P_{\theta=0}(z_1 \geq a_1)$$

At a subsequent stage  $k$ ,

$$\alpha_k = P_{\theta=0}(b_j \leq z_j < a_j, j = 1, 2, \dots, k-1, z_k \geq a_k)$$

Similarly, the Type II error probability

$$\beta = \sum_{k=1}^K \beta_k$$

where  $\beta_k$  is the  $\beta$  spending at stage  $k$ . That is, at stage 1,

$$\beta_1 = P_{\theta=\theta_1}(z_1 < b_1)$$

At a subsequent stage  $k$ ,

$$\beta_k = P_{\theta=\theta_1}(b_j \leq z_j < a_j, j = 1, 2, \dots, k-1, z_k < b_k)$$

With an upper alternative hypothesis  $H_1 : \theta = \theta_1 > 0$ , the power  $1 - \beta$  is the probability of rejecting the null hypothesis for the upper alternative.

$$1 - \beta = 1 - \sum_{k=1}^K \beta_k = \sum_{k=1}^K P_{\theta=\theta_1}(b_j \leq z_j < a_j, j = 1, 2, \dots, k-1, z_k \geq a_k)$$

For a design with early stopping to reject  $H_0$  only, the interim upper  $\beta$  critical values are set to  $-\infty$ ,  $b_k = -\infty$ ,  $k = 1, 2, \dots, K-1$ , and  $\beta = \beta_K$ . For a design with early stopping to accept  $H_0$  only, the interim upper  $\alpha$  critical values are set to  $\infty$ ,  $a_k = \infty$ ,  $k = 1, 2, \dots, K-1$ , and  $\alpha = \alpha_K$ .

Similarly, the Type I and Type II error probabilities for a  $K$ -stage design with a lower alternative hypothesis  $H_0 : \theta = -\theta_1$  can also be derived.

## Two-Sided Tests

For a  $K$ -stage group sequential design with two-sided alternative hypotheses  $H_{1u} : \theta = \theta_{1u}$  and  $H_{1l} : \theta = \theta_{1l}$ , and early stopping to reject or accept the null hypothesis  $H_0 : \theta = 0$ , the boundaries contain the upper  $\alpha$  critical values  $a_k$ , upper  $\beta$  critical values  $b_k$ , lower  $\beta$  critical values  ${}_b b_k$ , and lower  $\alpha$  critical values  ${}_a a_k$ ,  $k = 1, 2, \dots, K$ . At each interim stage,  ${}_a a_k < {}_b b_k \leq b_k < a_k$ , the null hypothesis  $H_0$  is rejected if the observed statistic  $z_k \geq a_k$  or  $z_k \leq {}_a a_k$ ,  $H_0$  is accepted if  ${}_b b_k < z_k < b_k$ , or the process is continued to the next stage if  $b_k \leq z_k < a_k$  or  ${}_a a_k < z_k \leq {}_b b_k$ . At the final stage  $b_K = a_K$  and  ${}_b b_K = {}_a a_K$ , the hypothesis is either rejected or accepted.

The overall upper Type I error probability  $\alpha_u$  is given by

$$\alpha_u = \sum_{k=1}^K \alpha_{uk}$$

where  $\alpha_{uk}$  is the  $\alpha$  spending at stage  $k$  for the upper alternative. That is, at stage 1,

$$\alpha_{u1} = P_{\theta=0}(z_1 \geq a_1)$$

At a subsequent stage  $k$ ,

$$\alpha_{uk} = P_{\theta=0}({}_a a_j < z_j \leq {}_b b_j \text{ or } b_j \leq z_j < a_j, j = 1, 2, \dots, k-1, z_k \geq a_k)$$

Similarly, the overall lower Type I error probability  $\alpha_l$  can also be derived, and the overall Type I error probability  $\alpha = \alpha_l + \alpha_u$ .

The overall upper Type II error probability  $\beta_u$  is given by

$$\beta_u = \sum_{k=1}^K \beta_{uk}$$

where  $\beta_{uk}$  is the upper  $\beta$  spending at stage  $k$ . That is, at stage 1,

$$\beta_{u1} = P_{\theta=\theta_{1u}}(z_1 < {}_a a_1 \text{ or } {}_b b_1 < z_1 < b_1)$$

At a subsequent stage  $k$ ,

$$\beta_{uk} = P_{\theta=\theta_{1u}}({}_a a_j < z_j \leq {}_b b_j \text{ or } b_j \leq z_j < a_j, j = 1, 2, \dots, k-1, z_k < {}_a a_k \text{ or } {}_b b_k < z_k < b_k)$$

With an upper alternative hypothesis  $H_1 : \theta = \theta_{1u} > 0$ , the power  $1 - \beta_u$  is the probability of rejecting the null hypothesis for the upper alternative:

$$1 - \beta_u = 1 - \sum_{k=1}^K \beta_{uk}$$

which is

$$P_{\theta=\theta_{1u}}({}_a a_j < z_j \leq {}_b b_j \text{ or } b_j \leq z_j < a_j, j = 1, 2, \dots, k-1, z_k \geq a_k)$$

The overall lower Type II error probability  $\beta_l$  and power  $1 - \beta_l$  can be similarly derived.

For a design with early stopping only to reject  $H_0$ , both the interim lower and upper  $\beta$  critical values are set to missing,  $k = 1, 2, \dots, K - 1$ , and  $\beta_{lK} = \beta_l$ ,  $\beta_{uK} = \beta_u$ . For a design with early stopping only to accept  $H_0$ , the interim upper  $\alpha$  critical values are set to  $\infty$ ,  $\alpha_{uk} = \infty$ , and the interim lower  $\alpha$  critical values are set to  $-\infty$ ,  $\alpha_{lk} = -\infty$ ,  $k = 1, 2, \dots, K - 1$ , and  $\alpha_{uK} = \alpha_u$ ,  $\alpha_{lK} = \alpha_l$ .

## Unified Family Methods

Unified family methods (Kittelsohn and Emerson 1999) derive boundary values with a specified boundary shape. For example, Pocock's method (Pocock 1977) derives equal boundary values for all stages in the standardized  $Z$  scale. In addition to Pocock's method, the unified family methods include the O'Brien-Fleming, power family, and unified family triangular methods.

The boundary values at each stage depend on the information fractions

$$\Pi_k = \frac{I_k}{I_X}$$

where  $I_k$  is the information available at stage  $k$  and  $I_X$  is the maximum information, the information available at the end of the trial if the trial does not stop early.

### Boundary Values in Standardized $Z$ Scale

With the unified family method, the boundary values for the upper  $\alpha$  boundary  $Z_{\alpha u}$ , upper  $\beta$  boundary  $Z_{\beta u}$ , lower  $\beta$  boundary  $Z_{\beta l}$ , and lower  $\alpha$  boundary  $Z_{\alpha l}$ , using the standardized normal scale, are given by the following:

- $Z_{\alpha u}(\Pi_k) = f_{\alpha u}(\Pi_k) C_{\alpha u}$
- $Z_{\beta u}(\Pi_k) = \theta_{1u} I_k^{\frac{1}{2}} - f_{\beta u}(\Pi_k) C_{\beta u}$
- $Z_{\beta l}(\Pi_k) = \theta_{1l} I_k^{\frac{1}{2}} + f_{\beta l}(\Pi_k) C_{\beta l}$
- $Z_{\alpha l}(\Pi_k) = -f_{\alpha l}(\Pi_k) C_{\alpha l}$

where  $\theta_{1l} (< 0)$  and  $\theta_{1u} (> 0)$  are the lower and upper alternative references,  $f_{\alpha l}(\Pi_k)$ ,  $f_{\beta l}(\Pi_k)$ ,  $f_{\beta u}(\Pi_k)$ , and  $f_{\alpha u}(\Pi_k)$  are the specified shape functions, and  $C_{\alpha l}$ ,  $C_{\beta l}$ ,  $C_{\beta u}$ , and  $C_{\alpha u}$  are the critical values derived to achieve the specified  $\alpha$  and  $\beta$  levels.

If a derived lower  $\beta$  boundary value  $Z_{\beta l}(\Pi_k)$  is greater than its corresponding upper  $\beta$  boundary value  $Z_{\beta u}(\Pi_k)$ , then both values are set to missing.

Note that the drift parameters  $d_l = \theta_{1l} \sqrt{I_X}$  and  $d_u = \theta_{1u} \sqrt{I_X}$  are derived in the SEQDESIGN procedure. The boundary values in standardized  $Z$  scale can be derived without specifying the maximum information and alternative reference.

## Shape Parameters

The shape function in the SEQDESIGN procedure is given by

$$f(\Pi_k) = f(\Pi_k; \tau, \rho) = \tau \Pi_k^{\frac{1}{2}} + \Pi_k^{-\rho} = \Pi_k^{\frac{1}{2}} (\tau + \Pi_k^{-(\rho+\frac{1}{2})})$$

where the parameters  $\rho \geq 0$  and  $0 \leq \tau \leq 2\rho$  can be specified for each boundary separately.

The parameters  $\tau$  and  $\rho$  determine the shape of the boundaries. Special cases of the unified family methods also include power family methods and triangular methods. Table 83.6 summarizes the corresponding parameter values in the unified family for these methods.

**Table 83.6** Parameters in the Unified Family for Various Methods

| Method          | Option             | Unified Family |        |
|-----------------|--------------------|----------------|--------|
|                 |                    | Rho            | Tau    |
| Pocock          | POC                | 0              | 0      |
| O'Brien-Fleming | OFB                | 0.5            | 0      |
| Power family    | POW (RHO= $\rho$ ) | $\rho$         | 0      |
| Triangular      | TRI (TAU= $\tau$ ) | 0.5            | $\tau$ |

Note that the power parameter  $\rho = 1/2 - \Delta = \rho^* - 1/2$ , where  $\Delta$  is the power parameter used in Jennison and Turnbull (2000) and Wang and Tsiatis (1987) and  $\rho^*$  is the power parameter used in Kittelson and Emerson (1999).

Also note that instead of the three parameters used in the unified family methods by Kittelson and Emerson (1999), only two parameters are used in the SEQDESIGN procedure. The other parameter is fixed at zero.

## Boundary Values in MLE Scale

If the maximum information is available, the boundary values derived from a unified family method can also be displayed in the MLE scale:

- $\theta_{\alpha u}(\Pi_k) = I_k^{-\frac{1}{2}} f_{\alpha u}(\Pi_k) C_{\alpha u}$
- $\theta_{\beta u}(\Pi_k) = \theta_{1u} - I_k^{-\frac{1}{2}} f_{\beta u}(\Pi_k) C_{\beta u}$
- $\theta_{\beta l}(\Pi_k) = \theta_{1l} + I_k^{-\frac{1}{2}} f_{\beta l}(\Pi_k) C_{\beta l}$
- $\theta_{\alpha l}(\Pi_k) = -I_k^{-\frac{1}{2}} f_{\alpha l}(\Pi_k) C_{\alpha l}$

These MLE scale boundary values are computed by multiplying  $I_k^{-\frac{1}{2}}$  by the standardized  $Z$  scale boundary values at stage  $k$ .

### Boundary Values in Score Scale

If the maximum information is available, the boundary values derived from a unified family method can also be displayed in the score scale:

- $S_{\alpha u}(\Pi_k) = I_k^{\frac{1}{2}} f_{\alpha u}(\Pi_k) C_{\alpha u}$
- $S_{\beta u}(\Pi_k) = \theta_{1u} I_k - I_k^{\frac{1}{2}} f_{\beta u}(\Pi_k) C_{\beta u}$
- $S_{\beta l}(\Pi_k) = \theta_{1l} I_k + I_k^{\frac{1}{2}} f_{\beta l}(\Pi_k) C_{\beta l}$
- $S_{\alpha l}(\Pi_k) = -I_k^{\frac{1}{2}} f_{\alpha l}(\Pi_k) C_{\alpha l}$

These MLE scale boundary values are computed by multiplying  $I_k^{\frac{1}{2}}$  by the standardized  $Z$  scale boundary values at stage  $k$ .

### Boundary Values in $p$ -Value Scale

For a design with a lower alternative or a two-sided alternative, the  $p$ -value scale boundary values are the cumulative normal distribution function values of the standardized  $Z$  boundary values:

- $P_{\alpha u}(\Pi_k) = \Phi(Z_{\alpha u}(\Pi_k))$
- $P_{\beta u}(\Pi_k) = \Phi(Z_{\beta u}(\Pi_k))$
- $P_{\beta l}(\Pi_k) = \Phi(Z_{\beta l}(\Pi_k))$
- $P_{\alpha l}(\Pi_k) = \Phi(Z_{\alpha l}(\Pi_k))$

These nominal  $p$ -values are the one-sided fixed-sample  $p$ -values under the null hypothesis with a lower alternative.

For a one-sided design with an upper alternative, the  $p$ -value scale boundary values are the one-sided fixed-sample  $p$ -values under the null hypothesis with an upper alternative:

- $P_{\alpha u}(\Pi_k) = 1 - \Phi(Z_{\alpha u}(\Pi_k))$
- $P_{\beta u}(\Pi_k) = 1 - \Phi(Z_{\beta u}(\Pi_k))$

### Pocock's Method

The shape function for Pocock's method (Pocock 1977) is given by

$$f(\Pi_k) = 1$$

The resulting boundary values for a two-sided design with an early stopping to reject the null hypothesis  $H_0 : \theta = 0$  are as follows:

- $Z_{\alpha u}(\Pi_k) = C_{\alpha u}$
- $Z_{\alpha l}(\Pi_k) = -C_{\alpha l}$

That is, the rejection boundary values are constant over all stages of different information levels in the standardized  $Z$  scale.

Note that compared with other designs, Pocock's design tends to stop the trials early with a larger  $p$ -value. For a new treatment, Pocock's design to stop a trial early with a large  $p$ -value might not be persuasive enough to make a new treatment widely accepted (Pocock and White 1999). A Pocock design is illustrated in Example 83.3.

### O'Brien-Fleming Method

The shape function for the O'Brien-Fleming method (O'Brien and Fleming 1979) is given by

$$f(\Pi_k) = \Pi_k^{-\frac{1}{2}}$$

The resulting boundary values for a two-sided design with early stopping to reject the null hypothesis  $H_0 : \theta = 0$  are as follows:

- $Z_{\alpha u}(\Pi_k) = \Pi_k^{-\frac{1}{2}} C_{\alpha u}$
- $Z_{\alpha l}(\Pi_k) = -\Pi_k^{-\frac{1}{2}} C_{\alpha l}$

That is, the rejection boundaries are inversely proportional to the square root of the information levels in the standardized  $Z$  scale.

In the score scale, these boundaries can be displayed as follows:

- $S_{\alpha u}(\Pi_k) = C_{\alpha u} I_X^{\frac{1}{2}}$
- $S_{\alpha l}(\Pi_k) = -C_{\alpha l} I_X^{\frac{1}{2}}$

which are constants over all stages in the score scale. An O'Brien-Fleming design is illustrated in Example 83.2.

### Power Family Method

The shape function for a power family method (Wang and Tsatis 1987; Emerson and Fleming 1989; Pampallona and Tsatis 1994) is given by

$$f(\Pi_k) = \Pi_k^{-\rho}$$

The resulting boundary values for a two-sided design with early stopping to reject the null hypothesis  $H_0 : \theta = 0$  are as follows:

- $Z_{\alpha u}(\Pi_k) = \Pi_k^{-\rho} C_{\alpha u}$
- $Z_{\alpha l}(\Pi_k) = -\Pi_k^{-\rho} C_{\alpha l}$

The rejection boundaries depend on the power parameter  $\rho$ . The power family includes the Pocock and O'Brien-Fleming methods, and the power parameter is used to allow continuous movement between these two methods.

### Triangular Method

The shape function for a triangular method (Kittelson and Emerson 1999) in the unified family is given by

$$f(\Pi_k) = \Pi_k^{-\frac{1}{2}} + \tau \Pi_k^{\frac{1}{2}}$$

The resulting boundary values for a two-sided design with early stopping to reject the null hypothesis  $H_0 : \theta = 0$  are as follows:

- $Z_{\alpha u}(\Pi_k) = (\Pi_k^{-\frac{1}{2}} + \tau \Pi_k^{\frac{1}{2}}) C_{\alpha u} = C_{\alpha u} \Pi_k^{-\frac{1}{2}} (1 + \tau \Pi_k)$
- $Z_{\alpha l}(\Pi_k) = -(\Pi_k^{-\frac{1}{2}} + \tau \Pi_k^{\frac{1}{2}}) C_{\alpha l} = -C_{\alpha l} \Pi_k^{-\frac{1}{2}} (1 + \tau \Pi_k)$

In the score scale, these boundaries are as follows:

- $S_{\alpha u}(\Pi_k) = C_{\alpha u} I_X^{\frac{1}{2}} (1 + \tau \Pi_k) = C_{\alpha u} I_X^{\frac{1}{2}} + C_{\alpha u} \tau I_X^{-\frac{1}{2}} I_k$
- $S_{\alpha l}(\Pi_k) = -C_{\alpha l} I_X^{\frac{1}{2}} (1 + \tau \Pi_k) = -C_{\alpha l} I_X^{\frac{1}{2}} - C_{\alpha l} \tau I_X^{-\frac{1}{2}} I_k$

Thus, in the score scale, the boundary function is a linear function of the information  $I_k$ . With these straight-line boundaries, a triangular method for a one-sided trial with early stopping to reject or accept the null hypothesis produces a triangular continuation region. Similarly, for a two-sided design, the continuation region is a union of two separate triangular regions. A triangular method is illustrated in [Example 83.6](#).

---

### Haybittle-Peto Method

The Haybittle-Peto method (Haybittle 1971; Peto et al. 1976) uses a value of 3 for the critical values in interim stages, so that the critical value at the final stage is close to the original design without interim monitoring.

In the SEQDESIGN procedure, the Haybittle-Peto method has been generalized to allow for different boundary values at different stages. That is, with the standardized normal scale, the boundary values are given by the following:

- $Z_{\alpha u}(\Pi_k) = z_{\alpha u k}$
- $Z_{\beta u}(\Pi_k) = \theta_{1u} I_k^{\frac{1}{2}} - z_{\beta u k}$

- $Z_{\beta l}(\Pi_k) = \theta_{1l} I_k^{\frac{1}{2}} + z_{\beta lk}$
- $Z_{\alpha l}(\Pi_k) = -z_{\alpha lk}$

where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references and the boundary values  $z_{\alpha uk}$ ,  $z_{\beta uk}$ ,  $z_{\beta lk}$ , and  $z_{\alpha lk}$  are specified either explicitly with the HP( *Z= numbers*) option or implicitly with the HP( *PVALUE= numbers*) option. The HP( *PVALUE= numbers*) option specifies the nominal  $p$ -values  $p_k$  for the corresponding boundary values  $z_k$ :

$$z_k = \Phi^{-1}(1 - p_k)$$

The Haybittle-Peto method is illustrated in [Example 83.5](#).

## Whitehead Methods

The Whitehead methods (Whitehead and Stratton 1983; Whitehead 1997, 2001) derive boundary values by adjusting the boundary values generated from continuous monitoring. With continuous monitoring, the boundary values are on a straight line in the score scale for each boundary. For a group sequential design, the boundary values at an interim stage  $k$  depend on the information fractions

$$\Pi_k = \frac{I_k}{I_X}$$

where  $I_k$  is the information available at stage  $k$  and  $I_X$  is the maximum information, the information available at the end of the trial if the trial does not stop early.

## One-Sided Symmetric Designs

A one-sided symmetric design is a one-sided design with identical Type I and Type II error probabilities. For a one-sided symmetric design with an upper alternative,  $\alpha_u = \beta_u$ , the boundary values in the score scale from continuous monitoring are as follows:

- $S_{\alpha u}(\Pi_k) = C_u \theta_u^{-1} + \tau_u \theta_u I_k$
- $S_{\beta u}(\Pi_k) = \theta_u I_k - (C_u \theta_u^{-1} - \tau_u \theta_u I_k)$

where  $\theta_u$  is the upper alternative reference,  $\tau_u$  is a specified constant for the slope,  $0 \leq \tau_u < \frac{1}{2}$ , and  $C_u$  is a constant, fixed for STOP=BOTH and derived for STOP=ACCEPT and STOP=REJECT.

The upper  $\beta$  boundary value can also be expressed as

- $S_{\beta u}(\Pi_k) = -C_u \theta_u^{-1} + (1 - \tau_u) \theta_u I_k$

Thus, these straight-line boundaries form a triangle in the score statistic scale.

To adjust for the nature of discrete monitoring, the group sequential boundary values are given by the following:

- $S_{\alpha u}(\Pi_k) = C_u \theta_u^{-1} + \tau_u \theta_u I_k - g_k$
- $S_{\beta u}(\Pi_k) = -C_u \theta_u^{-1} + (1 - \tau_u) \theta_u I_k + g_k$

where  $g_1 = 0.583\sqrt{I_1}$  and  $g_k = 0.583\sqrt{I_k - I_{(k-1)}}$ ,  $k > 1$  are the adjustments.

Note that with the adjustment  $g_k$ , the resulting boundaries form a Christmas tree shape within the original triangle and are referred to as the Christmas tree boundaries (Whitehead 1997, p. 73).

### One-Sided Asymmetric Designs

For a one-sided asymmetric design with an upper alternative,  $\alpha_u \neq \beta_u$ , the boundary values computed using the score scale, are given by the following:

- $S_{\alpha u}(\Pi_k) = C_u \tilde{\theta}_u^{-1} + \tau_u \tilde{\theta}_u I_k - g_k$
- $S_{\beta u}(\Pi_k) = -C_u \tilde{\theta}_u^{-1} + (1 - \tau_u) \tilde{\theta}_u I_k + g_k$

where  $\tilde{\theta}_u$  is the modified alternative reference

$$\tilde{\theta}_u = \frac{2\Phi^{-1}(1 - \alpha_u)}{\Phi^{-1}(1 - \alpha_u) + \Phi^{-1}(1 - \beta_u)} \theta_u$$

The modified alternative reference  $\tilde{\theta}_u = \theta_u$  if  $\alpha_u = \beta_u$ .

For a design with early stopping to reject or accept the null hypothesis,  $S_{\alpha u}(1) = S_{\beta u}(1)$ , the boundary values at the final stage are equal. The modified drift parameter  $\tilde{d}_u$  is given by

$$\tilde{d}_u = \tilde{\theta}_u \sqrt{I_X} = \frac{1}{1 - 2\tau_u} \left( \sqrt{h_K^2 + 2C_u(1 - 2\tau_u)} - h_K \right)$$

where  $h_K = g_K I_X^{-\frac{1}{2}} = 0.583\sqrt{1 - \Pi_{(K-1)}}$ .

A one-sided Whitehead design with early stopping to reject or accept the null hypothesis is illustrated in Example 83.7.

### Two-Sided Designs

The boundary values for a two-sided design are generated by combining boundary values from two one-sided designs. With the STOP=BOTH option, this produces a double triangular design (Whitehead 1997, p. 98).

The boundary values for a two-sided design, using the score scale, are then given by the following:

- $S_{\alpha u}(\Pi_k) = C_u \tilde{\theta}_u^{-1} + \tau_u \tilde{\theta}_u I_k - g_k$
- $S_{\beta u}(\Pi_k) = -C_u \tilde{\theta}_u^{-1} + (1 - \tau_u) \tilde{\theta}_u I_k + g_k$
- $S_{\beta l}(\Pi_k) = -C_l \tilde{\theta}_l^{-1} + (1 - \tau_l) \tilde{\theta}_l I_k - g_k$
- $S_{\alpha l}(\Pi_k) = C_l \tilde{\theta}_l^{-1} + \tau_l \tilde{\theta}_l I_k + g_k$

where the modified alternative references are

$$\tilde{\theta}_u = \frac{2\Phi^{-1}(1 - \alpha_u)}{\Phi^{-1}(1 - \alpha_u) + \Phi^{-1}(1 - \beta_u)} \theta_u$$

$$\tilde{\theta}_l = \frac{2\Phi^{-1}(1 - \alpha_l)}{\Phi^{-1}(1 - \alpha_l) + \Phi^{-1}(1 - \beta_l)} \theta_l$$

The modified alternative reference  $\tilde{\theta}_u = \theta_u$  if  $\alpha_u = \beta_u$  and  $\tilde{\theta}_l = \theta_l$  if  $\alpha_l = \beta_l$ .

For a design with early stopping to reject or accept the null hypothesis, the two upper boundary values at the final stage are identical and the two lower boundary values at the final stage are identical. That is,  $S_{\alpha l}(1) = S_{\beta l}(1)$  and  $S_{\alpha u}(1) = S_{\beta u}(1)$ . These modified drift parameters are then given by

$$\tilde{d}_l = \tilde{\theta}_l \sqrt{I_X} = \frac{1}{1 - 2\tau_l} \left( \sqrt{h_K^2 + 2C_l(1 - 2\tau_l)} - h_K \right)$$

$$\tilde{d}_u = \tilde{\theta}_u \sqrt{I_X} = \frac{1}{1 - 2\tau_u} \left( \sqrt{h_K^2 + 2C_u(1 - 2\tau_u)} - h_K \right)$$

where  $h_K = g_K I_X^{-\frac{1}{2}} = 0.583 \sqrt{1 - \Pi_{(K-1)}}$ .

For a design with early stopping to reject the null hypothesis, or a design with early stopping to accept the null hypothesis, you can specify the slope parameters  $\tau_u$  and  $\tau_l$  in the TAU= option, and then the intercept parameters  $C_u$  and  $C_l$ , and the resulting boundary values are derived. If both the maximum information and alternative references are specified, the procedure derives  $C_u$  and  $C_l$  by maintaining either the overall  $\alpha$  levels (BOUNDARYKEY=ALPHA) or the overall  $\beta$  levels (BOUNDARYKEY=BETA). If the maximum information and alternative reference are not both specified, the procedure derives the boundary values  $C_u$  and  $C_l$  by maintaining both the overall  $\alpha$  and overall  $\beta$  levels.

For a design with early stopping to reject or accept the null hypothesis (STOP=BOTH), Whitehead's triangular test uses  $\tau_u = \tau_l = 0.25$  and compute  $C_u = -2 \log(2\alpha_u)$  and  $C_l = -2 \log(2\alpha_l)$  for the boundary values. If the maximum information and alternative reference are both specified, the BOUNDARYKEY=ALPHA option uses the specified  $\alpha$  values to compute the  $\beta$  values and boundary values. The final-stage boundary values are modified to maintain the overall  $\alpha$  levels if they exist. Similarly, the BOUNDARYKEY=BETA option uses the specified  $\beta$  values to compute the  $\alpha$  values and boundary values. The final-stage boundary values are modified to maintain the overall  $\beta$  levels if they exist.

If the maximum information and alternative reference are not both specified, the specified  $\alpha$  and  $\beta$  values are used to derive boundary values. The BOUNDARYKEY=NONE option uses these boundary values without adjustment. The BOUNDARYKEY=ALPHA option modifies the final-stage boundary values to maintain the overall  $\alpha$  levels if they exist. Similarly, the BOUNDARYKEY=BETA option modifies the final-stage boundary values to maintain the overall  $\beta$  levels if they exist.

## Applicable Boundary Keys

Table 83.7 lists applicable boundary keys for a design that uses Whitehead methods.

**Table 83.7** Applicable Boundary Keys for Whitehead Methods

| Early Stopping      | Specified Parameters |      | Boundary Keys |      |      |      |
|---------------------|----------------------|------|---------------|------|------|------|
|                     | (Alt Ref – Max Info) | Tau  | Alpha         | Beta | None | Both |
| Reject $H_0$        | X                    | X    | X             | X    |      |      |
| Accept $H_0$        | X                    | X    | X             | X    |      |      |
| Reject/Accept $H_0$ | X                    | 0.25 | X             | X    |      |      |
| Reject $H_0$        |                      | X    |               |      |      | X    |
| Accept $H_0$        |                      | X    |               |      |      | X    |
| Reject/Accept $H_0$ |                      | 0.25 | X             | X    | X    |      |

Note that the symbol “X” under “(Alt Ref – Max Info)” indicates that both alternative reference and maximum information are specified.

For a design with early stopping to reject the null hypothesis, or a design with early stopping to accept the null hypothesis, you can specify the slope parameter  $\tau_u$  in the TAU= option, and then the intercept parameter  $C_u$  and the resulting boundary values are derived. If both the maximum information and alternative reference are specified, the procedure derives  $C_u$  by maintaining either the overall  $\alpha$  levels (BOUNDARYKEY=ALPHA) or the overall  $\beta$  levels (BOUNDARYKEY=BETA). If the maximum information and alternative reference are not both specified, the procedure derives the boundary values and  $C_u$  by maintaining both the overall  $\alpha$  and overall  $\beta$  levels.

For a design with early stopping to reject or accept the null hypothesis (STOP=BOTH), Whitehead’s triangular test uses  $\tau_u = 0.25$  and solves  $C_u = 2 \log\left(\frac{1}{2\alpha_u}\right)$  for the boundary values. If the maximum information and alternative reference are both specified, the BOUNDARYKEY=ALPHA option uses the specified  $\alpha$  value to compute the  $\beta$  value and boundary values. The final-stage boundary value is modified to maintain the overall  $\alpha$  level if it exists. Similarly, the BOUNDARYKEY=BETA option uses the specified  $\beta$  value to compute the  $\alpha$  value and boundary values. The final-stage boundary value is modified to maintain the overall  $\beta$  level if it exists.

If the maximum information and alternative reference are not both specified, the specified  $\alpha$  and  $\beta$  values are used to derive boundary values. The BOUNDARYKEY=NONE option uses these boundary values without adjustment. The BOUNDARYKEY=ALPHA option modifies the final-stage boundary value to maintain the overall  $\alpha$  level if it exists. Similarly, the BOUNDARYKEY=BETA option modifies the final-stage boundary value to maintain the overall  $\beta$  level if it exists.

## Error Spending Methods

For each sequential design, the  $\alpha$  and  $\beta$  errors spent at each stage can be computed from the boundary values. For example, for a  $K$ -stage design with an upper alternative hypothesis  $H_1 : \theta = \theta_1$  and early stopping to reject the null hypothesis  $H_0 : \theta = 0$ , the boundary values in a standardized  $Z$  scale are the upper  $\alpha$  critical values  $a_k, k = 1, 2, \dots, K$ . At each interim stage, the null hypothesis  $H_0$  is rejected if the observed standardized  $Z$  statistic  $z_k \geq a_k$ . Otherwise, the process continues to the next stage. At the final stage, the hypothesis is rejected if  $z_K \geq a_K$ . Otherwise, the null hypothesis is accepted.

The boundary values  $a_k$  are derived such that the overall Type I error probability

$$\alpha = \sum_{k=1}^K \alpha_k$$

where  $\alpha_k$  is the  $\alpha$  spending at stage  $k$ . That is, at stage 1,

$$\alpha_1 = P_{\theta=0}(z_1 \geq a_1)$$

At a subsequent stage  $k$ ,

$$\alpha_k = P_{\theta=0}(z_j < a_j, j = 1, 2, \dots, k-1, z_k \geq a_k)$$

Since each design can be uniquely identified by the  $\alpha$  and  $\beta$  errors spent at each stage, a design can then be derived by specifying the  $\alpha$  and  $\beta$  errors to be used at each stage. The error spending method (Lan and DeMets 1983) distributes the error to be used at each stage and then derives the boundary values. Numerous forms of the error spending function are available. Kim and DeMets (1987) examine the functions  $f(t) = t$ ,  $f(t) = t^{\frac{3}{2}}$ , and  $f(t) = t^2$ , where  $t$  is the information fraction. Jennison and Turnbull (2000, p. 148) generalize these functions to the power functions  $f(t; \rho) = t^\rho, \rho > 0$ .

The ERRFUNCPOC option uses the cumulative error spending function (Lan and DeMets 1983)

$$E(t) = \begin{cases} 1 & \text{if } t \geq 1 \\ \log(1 + (e-1)t) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

With a specified error of  $\alpha$  or  $\beta$ , the cumulative error spending at stage  $k$  is  $\alpha E(\Pi_k)$  or  $\beta E(\Pi_k)$ , where  $\Pi_k = I_k/I_X$  is the information fraction at stage  $k$ . The method produces boundaries similar to those produced with Pocock's method.

The ERRFUNCOBF option uses the cumulative error spending function (Lan and DeMets 1983)

$$E(t; a) = \begin{cases} 1 & \text{if } t \geq 1 \\ \frac{1}{a} 2(1 - \Phi(\frac{z(1-a/2)}{\sqrt{t}})) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where  $a$  is either  $\alpha$  for the  $\alpha$  spending function or  $\beta$  for the  $\beta$  spending function. That is, with a specified error of  $\alpha$  or  $\beta$ , the cumulative error spending at stage  $k$  is  $\alpha E(\Pi_k; \alpha)$  or  $\beta E(\Pi_k; \beta)$ . The method produces boundaries similar to those produced with the O'Brien-Fleming method.

The ERRFUNCGAMMA option uses the gamma cumulative error spending function (Hwang, Shih, and DeCani 1990)

$$E(t; \gamma) = \begin{cases} 1 & \text{if } t \geq 1 \\ \frac{1-e^{-\gamma t}}{1-e^{-\gamma}} & \text{if } 0 < t < 1, \gamma \neq 0 \\ t & \text{if } 0 < t < 1, \gamma = 0 \\ 0 & \text{otherwise} \end{cases}$$

where  $\gamma$  is the parameter  $\gamma$  specified in the GAMMA= option. That is, with a specified error of  $\alpha$  or  $\beta$ , the cumulative error spending at stage  $k$  is  $\alpha E(\Pi_k; \gamma)$  or  $\beta E(\Pi_k; \gamma)$ .

The ERRFUNCPOW option uses the cumulative error spending function (Jennison and Turnbull 2000, p. 148)

$$E(t; \rho) = \begin{cases} 1 & \text{if } t \geq 1 \\ t^\rho & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where  $\rho$  is the power parameter specified in the RHO= option. That is, with a specified error of  $\alpha$  or  $\beta$ , the cumulative error spending at stage  $k$  is  $\alpha E(\Pi_k; \rho)$  or  $\beta E(\Pi_k; \rho)$ .

Error spending methods derive boundary values at each stage sequentially and require much more computation than other types of methods for group sequential trials with a large number of stages, especially for a two-sided asymmetric design with early stopping to accept  $H_0$ , or to reject or accept  $H_0$ .

Note that for a two-sided design with the STOP=BOTH or STOP=ACCEPT option, at each interim stage, the SEQDESIGN procedure first produces the lower and upper  $\beta$  boundary values based on the one-sided  $\beta$  spending. If the lower  $\beta$  boundary value is greater than or equal to its corresponding upper  $\beta$  boundary value, there is no early stopping to accept the null hypothesis at this stage, and the corresponding  $\beta$  spending is distributed proportionally to the remaining stages.

For the error spending functions not available in the SEQDESIGN procedure, you can first compute the corresponding error spending at each stage explicitly, then use the SEQDESIGN procedure with the ERRSPEND= option to specify these errors directly.

For example, if the information levels are equally spaced in a five-stage design, the option ERRFUNCPOW (RHO=2) produces relative cumulative errors of  $(1/5)^2$ ,  $(2/5)^2$ ,  $(3/5)^2$ ,  $(4/5)^2$ , and 1. This is equivalent to using the option ERRSPEND (1 4 9 16 25).

A one-sided error spending design is illustrated in [Example 83.8](#) and a two-sided asymmetric error spending design is illustrated in [Example 83.11](#).

---

## Acceptance ( $\beta$ ) Boundary

In a group sequential trial, the rejection boundary is derived under the null hypothesis  $H_0$  and is used to stop the trial early to reject  $H_0$ . Similarly, the acceptance boundary is derived under the alternative hypothesis and is used to stop the trial early to accept  $H_0$ . But, for a trial with early stopping either to reject or to accept the null hypothesis, dependency exists between these two boundaries. This section describes the effects of the acceptance boundary on the derivation of the rejection boundary in a group sequential trial.

The following statements create a one-sided four-stage group sequential design with early stopping either to reject or to accept  $H_0$ :

```
ods graphics on;
proc seqdesign altref=10;
 ErrSpendPower_2: design nstages=4
 method=errfuncpow(rho=2)
 alt=upper stop=both
 alpha=0.025 beta=0.10;
run;
ods graphics off;
```

The ALTREF=10 option specifies the alternative reference 10. The METHOD=ERRFUNCPOW(RHO=2) option uses a  $\rho = 2$  power family error spending method to generate the rejection boundary. The ALPHA=0.025 and BETA=0.10 options specify the Type I error level 0.025 and Type II error level 0.10, respectively.

The power parameter  $\rho = 2$  used in the design lies between  $\rho = 1$  and  $\rho = 3$ , where the boundaries created with the  $\rho = 1$  power family error spending method are similar to the boundaries created from the Pocock method, and the boundaries created with  $\rho = 3$  are similar to the boundaries created from the O'Brien-Fleming method.

The “Boundary Information” table in Figure 83.12 shows the rejection and acceptance boundary values at the stages. With an error spending function method, the boundary values are derived sequentially. In particular, the rejection boundary value at a stage is derived conditionally on both rejection and acceptance boundary values at the previous stage. See the section “Error Spending Methods” on page 7034 for a detailed description of the error spending methods.

With ODS Graphics enabled, the “Boundary Plot” is displayed by default, as shown in Figure 83.13. The continuation region is affected by the acceptance boundary, and the rejection boundary is thus adjusted for this acceptance boundary to maintain the Type I error level.

Figure 83.13 Boundary Plot

For a design with early stopping either to accept or to reject  $H_0$ , the shapes of boundaries affect the critical value at the final stage. For the acceptance boundary, a liberal method at early stages, such as a  $\rho = 1$  power family error spending method, lowers the critical value at the final stage. For the rejection boundary, a conservative method at early stages, such as a  $\rho = 3$  power family error spending method, also lowers the critical value at the final stage. In addition, a larger Type II error level also lowers the critical value at the final stage. The resulting critical value at the final stage might even be less than the critical value for the corresponding fixed-sample design.

To illustrate how this can occur, the following statements use a  $\rho = 1$  power family error spending method for the acceptance boundary and a  $\rho = 3$  power family error spending method for the rejection boundary to create a group sequential design:

```
proc seqdesign altref=10;
 ErrSpendPower_3_1: design nstages=4
 method(alpha)=errfuncpow(rho=3)
 method(beta)= errfuncpow(rho=1)
 alt=upper stop=both
 alpha=0.025 beta=0.10;
run;
```

The resulting “Boundary Information” table in Figure 83.14 shows that the boundary value at the final stage 1.9267 is less than 1.96, the critical value of the corresponding fixed-sample design.

**Figure 83.14** Boundary Information

| 2                                           | 0.5000                  | 0.05945  | 2.43824                | 0.63117                   | 2.76024 |
| 3                                           | 0.7500                  | 0.089175 | 2.98622                | 1.31554                   | 2.35119 |
| 4                                           | 1.0000                  | 0.1189   | 3.44819                | 1.92672                   | 1.92672 |

That is,  $H_0$  can be rejected even if the test statistic at the final stage is less than the critical value for the corresponding fixed-sample design, which is not desirable. Therefore, for a design with an acceptance boundary, the design should be used with care.

Another reason why the rejection boundary should not be affected by the acceptance boundary is that a Data and Safety Monitoring Board (DSMB) might not strictly adhere to this acceptance boundary, and thus the Type I error level might not be maintained. Therefore, it might not be desirable for the rejection boundary to be affected by the acceptance boundary (Lan and DeMets 2009, p. 103).

To use a design whose rejection boundary is not affected by the acceptance boundary and that can still stop the trial early to accept  $H_0$ , you can use one of the following strategies:

- You can use the conditional power approach for a design that stops early only to reject  $H_0$ . For this design, the conditional power at an interim stage  $k$  can be defined as the total probability of rejecting  $H_0$  at any future stages under a specified hypothetical reference, given the observed statistic at stage  $k$ . A small conditional power indicates a small probability of success (rejecting  $H_0$ ) given the current data, and the trial can be stopped early to accept  $H_0$  (Lan, Simon, and Halperin 1982; Lan and DeMets 2009, p. 101). For a detailed description of conditional power, see the section “Stochastic Curtailment” in Chapter 84, “The SEQTEST Procedure.”
- You can use a design with a nonbinding acceptance boundary (Zhu, Ni, and Yao 2011, pp. 132–133). For this design, the rejection boundary is created by ignoring the acceptance boundary. Thus, the Type I error level is maintained even when a trial is allowed to continue for a test statistic that falls in the acceptance region, and the rejection boundary values (with the standardized Z statistic scale) are identical to the boundary values that are derived in the corresponding design that stops early only to reject  $H_0$ .

## Boundary Adjustments for Overlapping Lower and Upper $\beta$ Boundaries

For the fixed boundary shape methods and Whitehead methods, the boundary values for all stages are derived simultaneously for each boundary. For a two-sided design with STOP=ACCEPT or STOP=BOTH, simultaneous derivation might result in overlapping of the lower and upper  $\beta$  boundaries. That is, at an interim stage  $k$ , the lower  $\beta$  boundary value might be greater than its corresponding upper  $\beta$  boundary value. In this case, these two  $\beta$  boundary values are set to missing and the design does not stop at stage  $k$  to accept the null hypothesis (Jennison and Turnbull 2000, p. 113).

For the error spending methods, the boundary values are derived sequentially for the stages. For a two-sided design with STOP=ACCEPT or STOP=BOTH, a small  $\beta$  spending at an interim stage might result in overlapping of the lower and upper  $\beta$  boundaries for the two corresponding one-sided tests. Specifically, this form of overlapping occurs at an interim stage  $k$  if the upper  $\beta$  boundary value derived from the one-sided test for the upper alternative is less than the lower  $\beta$  boundary value derived from the one-sided test for the lower alternative (Kittelson and Emerson 1999, pp. 881–882; Rudser and Emerson 2007, p. 6). You can use the BETAOVERLAP= option to specify how this type of overlapping is to be handled.

If BETAOVERLAP=ADJUST (which is the default) is specified, the procedure derives the boundary values for the two-sided design and then checks for overlapping of the two one-sided  $\beta$  boundaries at interim stages. If overlapping occurs at a particular stage, the  $\beta$  boundary values for the two-sided design are set to missing (so the trial does not stop to accept the null hypothesis at this stage), and the  $\beta$  spending values at subsequent stages are adjusted proportionally as follows.

If the  $\beta$  boundary values are set to missing at stage  $k$  in a  $K$ -stage trial, the adjusted  $\beta$  spending value at stage  $k$ ,  $e'_k$ , is updated for these missing  $\beta$  boundary values, and then the  $\beta$  spending values at subsequent stages are adjusted proportionally by

$$e'_j = e'_k + \frac{e_j - e_k}{e_K - e_k} (e_K - e'_k)$$

for  $j = k + 1, \dots, K$ , where  $e_j$  and  $e'_j$  are the cumulative  $\beta$  spending values at stage  $j$  before and after the adjustment, respectively.

After all these adjusted  $\beta$  spending values are computed, the boundary values are then further modified for these adjusted  $\beta$  spending values.

If you specify BETAOVERLAP=NOADJUST, no adjustment is made when overlapping of one-sided  $\beta$  boundaries occurs. The BETAOVERLAP= option is illustrated in [Example 83.10](#).

---

## Specified and Derived Parameters

In the SEQDESIGN procedure, the type of alternative hypothesis (ALT= option) and the condition for early stopping (STOP= option) must be specified for each sequential design. The drift parameters are derived for each design specified. Other parameters, such as Type I error probability  $\alpha$ , Type II error probability  $\beta$ , the alternative reference  $\theta_1$ , and maximum information are either specified or derived in the SEQDESIGN procedure.

Table 83.8 summarizes the available combinations for the specified and derived parameters in the SEQDESIGN procedure.

**Table 83.8** Specified and Derived Parameters in the SEQDESIGN Procedure

| Specified Parameters |          |       |      | Derived Parameters |          |       |      |       |
|----------------------|----------|-------|------|--------------------|----------|-------|------|-------|
| Alt Ref              | Max Info | Alpha | Beta | Alt Ref            | Max Info | Alpha | Beta | Drift |
| Z                    | X        | X     |      |                    |          |       | X    | X     |
| Z                    | X        |       | X    |                    |          | X     |      | X     |
| Z                    | X        |       |      |                    |          | X     | X    | X     |
| Z                    |          | X     | X    |                    | X        |       |      | X     |
|                      | X        | X     | X    | X                  |          |       |      | X     |
|                      |          | X     | X    |                    |          |       |      | X     |

The symbol “X” indicates that the parameter is either specified or derived in the design and the symbol “Z” indicates that the alternative reference is either specified explicitly with the ALTREF= option or derived from the SAMPLESIZE statement. The drift parameter is always derived in the SEQDESIGN procedure.

For example, if the ALTREF= option is specified without the MAXINFO= option being specified, then the maximum information is derived in the SEQDESIGN procedure with the specified  $\alpha$  and  $\beta$ , as illustrated in Example 83.5.

The drift parameter is the standardized reference difference at the final stage. For a design, the drift parameter is

$$d_l = \theta_{1l} \sqrt{I_X}$$

if it has a lower alternative, and

$$d_u = \theta_{1u} \sqrt{I_X}$$

if it has an upper alternative, where  $I_X$  is the maximum information and  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively.

If the alternative reference and the maximum information are not both specified, then the specified  $\alpha$  and  $\beta$  are used to derive the drift parameter. Then if either the alternative reference or the maximum information is specified, the other is derived from the drift parameter.

If both the alternative reference and the maximum information are specified, then either the  $\alpha$  error or the  $\beta$  error is derived in the procedure. However, for a Haybittle-Peto method with the BOUNDARYKEY=NONE option, both  $\alpha$  and  $\beta$  errors are derived from the completely specified boundary values.

For a nonsymmetric two-sided design with different lower and upper specifications (such as different lower and upper  $\alpha$  errors,  $\beta$  errors, or alternative references in absolute values), the derived lower and upper boundaries are not symmetric. If the alternative references  $\theta_{1l}$  and  $\theta_{1u}$  are not both specified, then the SEQDESIGN procedure assumes symmetric alternative references,  $\theta_1 = \theta_{1u} = -\theta_{1l}$ , for the computation of the boundary values.

## Applicable Boundary Keys

In the SEQDESIGN procedure, the BOUNDARYKEY= option in the DESIGN statement specifies the types of errors to be maintained for the design. Table 83.9 lists applicable boundary keys for designs that use unified family and Haybittle-Peto methods, designs that use error spending methods, and designs that use the Haybittle-Peto method only.

**Table 83.9** Applicable Boundary Keys for Designs without Whitehead Methods

| Method                 | Specified Parameters<br>(Alt Ref – Max Info) | Boundary Keys |      |      |      |
|------------------------|----------------------------------------------|---------------|------|------|------|
|                        |                                              | Alpha         | Beta | None | Both |
| Unified                | X                                            | X             | X    |      |      |
| Unified/Haybittle-Peto | X                                            | X             | X    |      |      |
| Error spending         | X                                            | X             | X    |      |      |
| Haybittle-Peto         | X                                            | X             | X    | X    |      |
| Unified/Haybittle-Peto |                                              |               |      |      | X    |
| Error spending         |                                              |               |      |      | X    |
| Haybittle-Peto         |                                              |               |      |      | X    |

Note that the symbol “X” under “(Alt Ref – Max Info)” indicates that both the alternative reference and maximum information are specified, and the method “Unified/Haybittle-Peto” indicates that both the unified method and the Haybittle-Peto method are used in the same design.

If the ALTREF= and MAXINFO= options are both specified, then Type I and Type II error probability levels cannot be met simultaneously if both error probabilities are specified. The BOUNDARYKEY=ALPHA option maintains the Type I error probability level  $\alpha$  and derives Type II error probability  $\beta$ . The BOUNDARYKEY=BETA option maintains the Type II error probability level  $\beta$  and derives Type I error probability  $\alpha$ .

If the Haybittle-Peto method is used for all boundaries, the BOUNDARYKEY=NONE option uses the specified  $\alpha$  boundary value (STOP=REJECT or STOP=BOTH) and the specified  $\beta$  boundary value (STOP=ACCEPT) at the final stage for the design.

If the ALTREF= and MAXINFO= options are not both specified, the BOUNDARYKEY=BOTH option derives boundary values that maintain both Type I and Type II error probability levels.

Table 83.10 lists applicable boundary keys for a design that uses Whitehead methods.

**Table 83.10** Applicable Boundary Keys for Whitehead Methods

| Early Stopping      | Specified Parameters |      | Boundary Keys |      |      |      |
|---------------------|----------------------|------|---------------|------|------|------|
|                     | (Alt Ref – Max Info) | Tau  | Alpha         | Beta | None | Both |
| Reject $H_0$        | X                    | X    | X             | X    |      |      |
| Accept $H_0$        | X                    | X    | X             | X    |      |      |
| Reject/Accept $H_0$ | X                    | 0.25 | X             | X    |      |      |
| Reject $H_0$        |                      | X    |               |      |      | X    |
| Accept $H_0$        |                      | X    |               |      |      | X    |
| Reject/Accept $H_0$ |                      | 0.25 | X             | X    | X    |      |

Note that the symbol “X” under “(Alt Ref – Max Info)” indicates that both alternative reference and maximum information are specified.

If the ALTREF= and MAXINFO= options are both specified, then Type I and Type II error probability levels cannot be achieved simultaneously if both are specified. the BOUNDARYKEY=ALPHA option maintains the Type I error probability level  $\alpha$  and derives Type II error probability  $\beta$ . The BOUNDARYKEY=BETA option maintains the Type II error probability level  $\beta$  and derives the Type I error probability  $\alpha$ .

If the ALTREF= and MAXINFO= options are not both specified, then for a design with the STOP=REJECT or STOP=ACCEPT option, the BOUNDARYKEY=BOTH option derives boundary values that maintain both Type I and Type II error probability levels. If the STOP=BOTH option is specified, Whitehead’s triangular method produces boundaries with approximate Type I and Type II error probabilities. The BOUNDARYKEY=NONE option specifies no adjustment to these boundaries. The BOUNDARYKEY=ALPHA and BOUNDARYKEY=BETA options maintain the Type I error probability level  $\alpha$  and Type II error probability level  $\beta$ , respectively, by adjusting boundary values at the final stage.

## Sample Size Computation

The SEQDESIGN procedure assumes that the data are from a multivariate normal distribution and the sequence of the standardized test statistics  $\{Z_1, Z_2, \dots, Z_K\}$  has the following canonical joint distribution:

- $(Z_1, Z_2, \dots, Z_K)$  is multivariate normal
- $Z_k \sim N(\theta\sqrt{I_k}, 1)$
- $\text{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{I_{k_1}/I_{k_2}}$ ,  $1 \leq k_1 \leq k_2 \leq K$

where  $K$  is the total number of stages and  $I_k$  is the information available at stage  $k$ .

If the test statistic is computed from the data that are not from a normal distribution, such as a binomial distribution, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution.

In a typical clinical trial, the sample size required depends on the Type I error probability level  $\alpha$ , alternative reference  $\theta_1$ , power  $1 - \beta$ , and variance of the response variable. Given a one-sided null hypothesis  $H_0 : \theta = 0$  with an upper alternative hypothesis  $H_1 : \theta = \theta_1$ , the information required for a fixed-sample test is given by

$$I_0 = \frac{(\Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta))^2}{\theta_1^2}$$

The parameter  $\theta$  and the subsequent alternative reference  $\theta_1$  depend on the test specified in the clinical trial. For example, suppose you are comparing two binomial populations  $p_a = p_b$ ; then  $\theta = p_a - p_b$  is the difference between two proportions if the proportion difference statistic is used, and  $\theta = \log\left(\frac{p_a(1-p_b)}{p_b(1-p_a)}\right)$ , the log odds ratio for the two proportions if the log odds ratio statistic is used.

If the maximum likelihood estimate  $\hat{\theta}$  from the likelihood function can be derived, then the asymptotic variance for  $\hat{\theta}$  is  $\text{Var}(\hat{\theta}) = 1/I$ , where  $I$  is Fisher information for  $\theta$ . The resulting statistic  $\hat{\theta}$  corresponds to the MLE statistic scale as specified in the BOUNDARYSCALE=MLE option in the PROC SEQDESIGN statement,  $\hat{\theta}\sqrt{I}$  corresponds to the standardized Z scale (BOUNDARYSCALE=STDZ), and  $\hat{\theta} I$  corresponds to the score statistic scale (BOUNDARYSCALE=SCORE).

Alternatively, if the score statistic  $S$  is derived in a statistical procedure, it can be used as the test statistic and its asymptotic variance is given by Fisher information,  $I$ . In this case,  $S/\sqrt{I}$  corresponds to the standardized Z scale and  $S/I$  corresponds to the MLE statistic scale.

For a group sequential trial, the maximum information  $I_X$  is derived in the SEQDESIGN procedure with the specified  $\alpha$ ,  $\beta$ , and  $\theta_1$ . With the maximum information

$$I_X = \frac{1}{\text{Var}(\hat{\theta})}$$

the sample size required for a specified test statistic in the trial can be evaluated or estimated from the known or estimated variance of the response variable. Note that different designs might produce different maximum information levels for the same hypothesis, and this in turn might require a different number of observations for the trial.

If each observation in the data set provides one unit of information in a hypothesis testing, such as a one-sample test for the mean, the required sample size for the sequential design can be derived from the maximum information. However, for a survival analysis, an individual in the survival time data might provide only partial information because of censoring. In this case, the required number of events can be derived from the maximum information. With addition accrual information, the sample size can also be computed.

The SEQDESIGN procedure provides sample size computation for some one-sample and two-sample tests in the SAMPLESIZE statement. It also provides sample size computation for tests of a parameter in regression models such as normal regression, logistic regression, and proportional hazards regression. In addition, the procedure can also compute the required sample size or number of events from the corresponding number in the fixed-sample design.

Table 83.11 lists the options available in the SAMPLESIZE statement.

**Table 83.11** SAMPLESIZE Statement Options

| Option                     | Description                                                    |
|----------------------------|----------------------------------------------------------------|
| <b>Fixed-Sample Models</b> |                                                                |
| INPUTNOBS                  | Specifies sample size for fixed-sample design                  |
| INPUTNEVENTS               | Specifies number of events for fixed-sample design             |
| <b>One-Sample Models</b>   |                                                                |
| ONESAMPLEMEAN              | Specifies one-sample Z test for mean                           |
| ONESAMPLEFREQ              | Specifies one-sample test for binomial proportion              |
| <b>Two-Sample Models</b>   |                                                                |
| TWOSAMPLEMEAN              | Specifies two-sample Z test for mean difference                |
| TWOSAMPLEFREQ              | Specifies two-sample test for binomial proportions             |
| TWOSAMPLESURVIVAL          | Specifies log-rank test for two survival distributions         |
| <b>Regression Models</b>   |                                                                |
| REG                        | Specifies test for a regression parameter                      |
| LOGISTIC                   | Specifies test for a logistic regression parameter             |
| PHREG                      | Specifies test for a proportional hazards regression parameter |

The MODEL=INPUTNOBS and MODEL=INPUTNEVENTS options are described next, and the remaining options are described in the next three sections.

### Input Sample Size for Fixed-Sample Design

The MODEL=INPUTNOBS option derives the sample size required for a group sequential trial from the sample size  $n_0$  for the corresponding fixed-sample design. With the N=  $n_0$  option specifying the sample size  $n_0$  for a fixed-sample design, the sample size required for a group sequential trial is then computed as

$$N_X = \frac{I_X}{I_0} n_0$$

where  $I_X$  is the maximum information for the group sequential design and  $I_0$  is the information for the corresponding fixed-sample design. The information ratio between  $I_X$  and  $I_0$  is derived in the SEQDESIGN procedure.

The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. For a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups.

### Input Number of Events for Fixed-Sample Design

The MODEL=INPUTNEVENTS option derives the number of events required for a group sequential trial from the number of events  $d_0$  for the corresponding fixed-sample design. With the D=  $d_0$  option specifying the number of events  $d_0$  for a fixed-sample survival analysis, the number of events required for a group sequential trial is then computed as

$$d_X = \frac{I_X}{I_0} d_0$$

where  $I_X$  is the maximum information for the group sequential design and  $I_0$  is the information for the corresponding fixed-sample design. The information ratio between  $I_X$  and  $I_0$  is derived in the SEQDESIGN procedure.

The SAMPLE=ONE option specifies a one-sample test, and the SAMPLE=TWO option specifies a two-sample test. For a two-sample test, the WEIGHT= option specifies the sample size allocation weights for the two groups.

The ACCRUAL= option specifies the method for individual accrual. The default ACCRUAL=UNIFORM option specifies that the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$ , and the ACCRUAL=EXP(PARM= $\gamma_0$ ) option specifies that the individual accrual is truncated exponential with a scaled power parameter  $\gamma_0$ , where  $\gamma_0 \geq -10$  and  $\gamma_0 \neq 0$ . With a scaled parameter  $\gamma_0$ , the power parameter for the truncated exponential with the accrual time  $T_a$  is given by  $\gamma = \gamma_0/T_a$ .

The LOSS= option specifies the individual loss to follow up in the sample size computation. The default LOSS=NONE option specifies no loss to follow up, and the EXP(POWER= $\tau$ ) option specifies exponential loss function with a power parameter  $\tau$ .

With the computed number of events  $d_X$  for a group sequential survival design, the required total sample size and sample size at each stage can be derived from specifications of hazard rates, accrual information, and losses to follow-up information. For each study group, the hazard rate  $h$  is constant (which corresponds to an exponential survival distribution) in the sample size computation.

The next four subsections describe required sample sizes for uniform accrual (with and without losses to follow up) and for truncated exponential accrual (with and without losses to follow up).

### Uniform Accrual without Losses to Follow Up

For a study group with a constant hazard rate  $h$ , if the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$ , Kim and Tsatis (1990, pp. 83–84) show that the expected number of events by time  $t$  is given by

$$D_h(t) = \begin{cases} r_a \left( t - \frac{1-e^{-ht}}{h} \right) & \text{if } t \leq T_a \\ r_a \left( T_a - \frac{e^{-ht}}{h} (e^{hT_a} - 1) \right) & \text{if } t > T_a \end{cases}$$

For a one-sample design (such as a proportional hazards regression), the expected number of events by time  $t$  is  $E(t) = D_h(t)$ , where  $h$  is the hazard rate for the group. For a two-sample design (such as a log-rank test for two survival distributions), the expected number of events by time  $t$  is

$$E(t) = \frac{R}{R+1} D_{h_a}(t) + \frac{1}{R+1} D_{h_b}(t)$$

where  $h_a$  and  $h_b$  are hazard rates in groups A and B, respectively, and  $R$  is the ratio of the sample size allocation weights  $w_a/w_b$ .

If the accrual rate  $r_a$  is specified with one of the three time parameters—the accrual time, follow-up time, and total study time—then PROC SEQDESIGN derives the other two time parameters by solving the equation for the expected number of events. Similarly, if the accrual rate  $r_a$  is not specified but two of the three time parameters are specified, then PROC SEQDESIGN derives the accrual rate.

If the accrual rate  $r_a$  is specified without the accrual time  $T_a$ , follow-up time  $T_f$ , and total study time  $T = T_a + T_f$ , the minimum and maximum accrual times can be computed from the following equation, as described in Kim and Tsiatis (1990, p. 85):

$$\frac{d_X}{r_a} \leq T_a \leq E^{-1}(d_X)$$

With the accrual rate  $r_a$  and the accrual time  $T_a$ , the total sample size is

$$N_X = r_a T_a$$

At each stage  $k$ , the number of events is given by

$$d_k = \frac{I_k}{I_X} d_X$$

The corresponding time  $T_k$  can be derived from the equation for the expected number of events,  $E(t) = d_k$ , and the resulting sample size is computed as

$$N_k = \begin{cases} r_a T_k & \text{if } T_k \leq T_a \\ r_a T_a & \text{if } T_k > T_a \end{cases}$$

### Uniform Accrual with Losses to Follow Up

With the LOSS=EXP(HAZARD= $\tau$ ) option, the individual loss to follow up has an exponential loss distribution function

$$H(t) = 1 - e^{-\tau t}$$

where  $\tau \geq 0$  is the loss hazard rate. The loss hazard rate can also be specified implicitly with the MEDTIME= $t_\tau$  suboption through the median loss time  $t_\tau$ .

For a study group with a constant hazard rate  $h$ , if the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$  and the individual loss to follow up has an exponential loss distribution function  $H(t)$ , Lachin and Foulkes (1986, p. 511) derive the expected number of events by time  $t$  (where  $t > T_a$ ) as

$$D_h(t, T_a) = r_a T_a \frac{h}{h + \tau} \left( 1 - \frac{1}{(h + \tau) T_a} e^{-(h + \tau)t} (e^{(h + \tau)T_a} - 1) \right)$$

For  $t \leq T_a$ , the SEQDESIGN procedure estimates the expected number of events by time  $t$  as

$$D_h(t, T_a) = r_a t \frac{h}{h + \tau} \left( 1 - \frac{1}{(h + \tau)t} (1 - e^{-(h + \tau)t}) \right)$$

For a one-sample design (such as a proportional hazards regression), the expected number of events by time  $t$  is  $E(t, T_a) = D_h(t, T_a)$ , where  $h$  is the hazard rate for the group. For a two-sample design (such as a log-rank test for two survival distributions), the expected number of events by time  $t$  is

$$E(t, T_a) = \frac{R}{R + 1} D_{h_a}(t, T_a) + \frac{1}{R + 1} D_{h_b}(t, T_a)$$

where  $h_a$  and  $h_b$  are hazard rates in groups A and B, respectively, and  $R$  is the ratio of the sample size allocation weights  $w_a/w_b$ .

If the accrual rate  $r_a$  is specified with one of the three time parameters—the accrual time, follow-up time, and total study time—then PROC SEQDESIGN derives the other two time parameters by solving the equation for the expected number of events. Similarly, if the accrual rate  $r_a$  is not specified, but two of the three time parameters are specified, then PROC SEQDESIGN derives the accrual rate.

If the accrual rate  $r_a$  is specified without the accrual time  $T_a$ , follow-up time  $T_f$ , and total study time  $T = T_a + T_f$ , the SEQDESIGN procedure computes the minimum accrual time  $T_a$  by solving the equation

$$E(\infty, T_a) = d_X$$

A closed-form solution is then given by

$$\frac{d_X}{r_a} \left( \frac{R}{R+1} \frac{h_a}{h_a + \tau} + \frac{1}{R+1} \frac{h_b}{h_b + \tau} \right)^{-1}$$

Similarly, the SEQDESIGN procedure derives the maximum accrual time  $T_a$  by solving the equation

$$E(T_a, T_a) = d_X$$

The maximum accrual time  $T_a$  is then obtained by an iterative process.

With the accrual rate  $r_a$  and the accrual time  $T_a$ , the total sample size is

$$N_X = r_a T_a$$

At each stage  $k$ , the number of events is given by

$$d_k = \frac{I_k}{I_X} d_X$$

The corresponding time  $T_k$  can be derived from the equation for the expected number of events,  $E(t) = d_k$ , and the resulting sample size is computed as

$$N_k = \begin{cases} r_a T_k & \text{if } T_k \leq T_a \\ r_a T_a & \text{if } T_k > T_a \end{cases}$$

### Truncated Exponential Accrual without Losses to Follow Up

For a study group with a constant hazard rate  $h$ , if the individual accrual is truncated exponential with parameter  $\gamma$  over the accrual period from 0 to  $T_a$  with distribution

$$F(t) = \frac{1 - e^{-\gamma t}}{1 - e^{-\gamma T_a}} \quad \text{for } 0 \leq t \leq T_a$$

Lachin and Foulkes (1986, p. 510) derive the expected number of events by time  $t$  (where  $t > T_a$ ) as

$$D_h(t, N) = N \left( 1 + \frac{\gamma}{h - \gamma} \frac{e^{-ht} - e^{-h(t-T_a)} e^{-\gamma T_a}}{1 - e^{-\gamma T_a}} \right)$$

where  $N$  is the total sample size.

For  $t \leq T_a$ , the SEQDESIGN procedure estimates the expected number of events by time  $t$  as

$$D_h(t, N) = N F(t) \left( 1 + \frac{\gamma}{h - \gamma} \frac{e^{-ht} - e^{-\gamma t}}{1 - e^{-\gamma t}} \right)$$

For the truncated exponential accrual function with a parameter  $\gamma$  over the accrual period from 0 to  $T_a$ , you specify the scaled parameter  $\gamma_0 = \gamma T_a$  in the ACCRUAL=EXP(PARM= $\gamma_0$ ) option, where  $\gamma_0 \geq -10$  and  $\gamma_0 \neq 0$ .

For a one-sample design (such as a proportional hazards regression), the expected number of events by time  $t$  is  $E(t, N) = D_h(t, N)$ , where  $h$  is the hazard rate for the group. For a two-sample design (such as a log-rank test for two survival distributions), the expected number of events by time  $t$  is

$$E(t, N) = \frac{R}{R + 1} D_{h_a}(t, N) + \frac{1}{R + 1} D_{h_b}(t, N)$$

where  $h_a$  and  $h_b$  are hazard rates in groups A and B, respectively, and  $R$  is the ratio of the sample size allocation weights  $w_a/w_b$ .

If the total sample size  $N$  is specified, then at least one of the three time parameters—the accrual time, follow-up time, and total study time—must be specified, and then PROC SEQDESIGN derives the other two time parameters by solving the equation for the expected number of events. Similarly, if the total sample size  $N$  is not specified, then at least two of the three time parameters must be specified, and PROC SEQDESIGN derives the sample size.

If the accrual sample size  $N$  is not specified, the SEQDESIGN procedure computes the minimum accrual sample size by solving the equation

$$E(\infty, N) = d_X$$

That is,  $N = d_X$ .

Similarly, if the total sample size  $N$  is not specified but the accrual time  $T_a$  is specified, the SEQDESIGN procedure derives the maximum accrual sample size  $N$  by solving the equation

$$E(T_a, N) = d_X$$

At each stage  $k$ , the number of events is given by

$$d_k = \frac{I_k}{I_X} d_X$$

The corresponding time  $T_k$  can be derived from the equation for the expected number of events,  $E(t) = d_k$ , and the resulting sample size is computed as

$$N_k = \begin{cases} N F(T_k) & \text{if } T_k \leq T_a \\ N & \text{if } T_k > T_a \end{cases}$$

### Truncated Exponential Accrual with Losses to Follow Up

With the LOSS=EXP(HAZARD= $\tau$ ) option, the individual loss to follow up has an exponential loss distribution function

$$H(t) = 1 - e^{-\tau t}$$

where  $\tau \geq 0$  is the loss hazard rate. The loss hazard rate can also be specified implicitly with the MEDTIME= $t_\tau$  suboption through the median loss time  $t_\tau$ .

For a study group with a constant hazard rate  $h$ , if the individual accrual is truncated exponential with parameter  $\gamma$  over the accrual period from 0 to  $T_a$  with distribution

$$F(t) = \frac{1 - e^{-\gamma t}}{1 - e^{-\gamma T_a}} \quad \text{for } 0 \leq t \leq T_a$$

and the individual loss to follow up has an exponential loss distribution function  $H(t)$ , Lachin and Foulkes (1986, p. 513) derive the expected number of events by time  $t$  (where  $t > T_a$ ) as

$$D_h(t, N) = N \frac{h}{h + \tau} \left( 1 + \frac{\gamma}{h + \tau - \gamma} \frac{e^{-(h+\tau)t} - e^{-(h+\tau)(t-T_a)} e^{-\gamma T_a}}{1 - e^{-\gamma T_a}} \right)$$

For  $t \leq T_a$ , the SEQDESIGN procedure estimates the expected number of events by time  $t$  as

$$D_h(t, N) = N F(t) \frac{h}{h + \tau} \left( 1 + \frac{\gamma}{h + \tau - \gamma} \frac{e^{-(h+\tau)t} - e^{-\gamma t}}{1 - e^{-\gamma t}} \right)$$

For the truncated exponential accrual function with a parameter  $\gamma$  over the accrual period from 0 to  $T_a$ , you specify the scaled parameter  $\gamma_0 = \gamma T_a$  in the ACCRUAL=EXP(PARM= $\gamma_0$ ) option, where  $\gamma_0 \geq -10$  and  $\gamma_0 \neq 0$ .

For a one-sample design (such as a proportional hazards regression), the expected number of events by time  $t$  is  $E(t, N) = D_h(t, N)$ , where  $h$  is the hazard rate for the group. For a two-sample design (such as a log-rank test for two survival distributions), the expected number of events by time  $t$  is

$$E(t, N) = \frac{R}{R + 1} D_{h_a}(t, N) + \frac{1}{R + 1} D_{h_b}(t, N)$$

where  $h_a$  and  $h_b$  are hazard rates in groups A and B, respectively, and  $R$  is the ratio of the sample size allocation weights  $w_a/w_b$ .

If the total sample size  $N$  is specified, then at least one of the three time parameters—the accrual time, follow-up time, and total study time—must be specified, and then PROC SEQDESIGN derives the other two time parameters by solving the equation for the expected number of events. Similarly, if the total sample size  $N$  is not specified, then at least two of the three time parameters must be specified, and PROC SEQDESIGN derives the sample size.

If the accrual sample size is not specified, the SEQDESIGN procedure computes the minimum sample size  $N$  by solving the equation

$$E(\infty, N) = d_X$$

A closed-form solution is then given by

$$d_X \left( \frac{R}{R+1} \frac{h_a}{h_a + \tau} + \frac{1}{R+1} \frac{h_b}{h_b + \tau} \right)^{-1}$$

Similarly, if the accrual sample size  $N$  is not specified but the accrual time  $T_a$  is specified, the SEQDESIGN procedure derives the maximum accrual sample size  $N$  by solving the equation

$$E(T_a, N) = d_X$$

At each stage  $k$ , the number of events is given by

$$d_k = \frac{I_k}{I_X} d_X$$

The corresponding time  $T_k$  can be derived from the equation for the expected number of events,  $E(t) = d_k$ , and the resulting sample size is computed as

$$N_k = \begin{cases} N F(T_k) & \text{if } T_k \leq T_a \\ N & \text{if } T_k > T_a \end{cases}$$

The following three sections describe examples of test statistics with their resulting information levels, which can then be used to derive the required sample size. The maximum likelihood estimators are used for all tests except to compare two survival distributions with a log-rank test, where a score statistic is used.

## Applicable One-Sample Tests and Sample Size Computation

The SEQDESIGN procedure provides sample size computation for two one-sample tests: normal mean and binomial proportion. The required sample size depends on the variance of the response variable—that is, the sample proportion for a binomial proportion test.

In a typical clinical trial, a hypothesis is designed to reject, not accept, the null hypothesis to show the evidence for the alternative hypothesis. Thus, in most cases, the proportion under the alternative hypothesis is used to derive the required sample size. For a test of the binomial proportion, the REF=NULLPROP and REF=PROP options use proportions under the null and alternative hypotheses, respectively.

### Test for a Normal Mean

The MODEL=ONESAMPLEMEAN option in the SAMPLESIZE statement derives the sample size required to test a normal mean by using the sample mean statistic for the null hypothesis  $\mu = \mu_0$ . At stage  $k$ , the sample mean is computed as

$$\bar{y}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

where  $y_{kj}$  is the value of the  $j$ th observation available in the  $k$ th stage and  $N_k$  is the cumulative sample size at stage  $k$ .

An equivalent hypothesis is  $H_0 : \theta = 0$ , where  $\theta = \mu - \mu_0$ .

The MLE statistic for  $\theta$ ,

$$\hat{\theta}_k = \bar{y}_k - \mu_0 \sim N(\theta, I_k^{-1})$$

where the information

$$I_k = \frac{1}{\text{Var}(\hat{\theta})} = \frac{1}{\text{Var}(\bar{y}_k)} = \frac{N_k}{\sigma^2}$$

is the inverse of the variance.

That is, the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} = (\bar{y}_k - \mu_0) \sqrt{I_k} \sim N(\theta \sqrt{I_k}, 1)$$

Thus, to test the hypothesis  $H_0 : \theta = 0$  against a two-sided alternative  $H_1 : \theta = \theta_1$ ,  $H_0$  is rejected at stage  $k$  if the statistic  $Z_k$  is less than or equal to the lower  $\alpha$  boundary value or if  $Z_k$  is greater than or equal to the upper  $\alpha$  boundary value at stage  $k$ .

If the variance  $\sigma^2$  is unknown, the sample variance can be used if it is assumed that the sample variance is computed from a large sample such that the test statistic has an approximately normal distribution.

The maximum information is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the MEAN= $\theta_1$  option in the SAMPLESIZE statement is used to specify the alternative reference and thus to derive the maximum information.

In the SEQDESIGN procedure, the computed total sample size

$$N_K = \sigma^2 I_X$$

where  $I_X$  is the maximum information and  $\sigma$  is the specified standard deviation. With an available maximum information, you can specify the MODEL=ONESAMPLEMEAN( STDDEV=  $\sigma$ ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC MEANS can be used to derive a one-sample  $Z$  test for a normal mean.

### Test for a Binomial Proportion

The MODEL=ONESAMPLEFREQ option in the SAMPLESIZE statement derives the sample size required to test a binomial proportion by using the null hypothesis  $p = p_0$ , where  $p$  is the proportion of a binomial population. At stage  $k$ , the MLE for  $p$  is computed as

$$\hat{p}_k = \frac{1}{N_k} \sum_{j=1}^{N_k} y_{kj}$$

where  $y_{kj}$  is the value of the  $j$ th observation available in the  $k$ th stage and  $N_k$  is the cumulative sample size at stage  $k$ .

An equivalent hypothesis is  $H_0 : \theta = 0$ , where  $\theta = p - p_0$ . If  $p_0$  is not close to 0 or 1, then for a large sample,  $\hat{\theta}_k = \hat{p}_k - p_0$  has an approximately normal distribution

$$\hat{\theta}_k \sim N(\theta, I_k^{-1})$$

where the information  $I_k = (p(1-p)/N_k)^{-1}$  is the inverse of the variance  $\text{Var}(\hat{\theta})$ .

Then the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} \sim N(\theta \sqrt{I_k}, 1)$$

In practice, the estimated sample proportion  $\hat{p}$  at stage  $k$  can be used to derive the information  $I_k$  and test statistic  $Z_k$ . Thus, to test the hypothesis  $H_0$  against an upper alternative  $H_1 : \theta = \theta_1 > 0$ ,  $H_0$  is rejected at stage  $k$  if the statistic  $Z_k$  is greater than or equal to the upper  $\alpha$  boundary at stage  $k$ .

The maximum information  $I_X$  is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to specify the alternative reference and to derive the maximum information for the sample size calculation.

It is assumed that the sample size is sufficiently large such that the test statistic has an approximately normal distribution. With the hypotheses  $H_0 : p = p_0$  and  $H_1 : p = p_1$ , the SEQDESIGN procedure derives the total sample size

$$N_X = p^* (1 - p^*) I_X$$

where  $p^* = p_0$  if REF=NULLPROP is specified. Otherwise,  $p^* = p_1$ .

If the PROP= option in the SAMPLESIZE statement is not specified, then the alternative reference  $\theta_1$  derived in the SEQDESIGN procedure is used to compute  $p_1 = p_0 + \theta_1$ .

The ALTREF= option in the PROC statement can be used to specify  $\theta_1$ . Otherwise, the PROP= option in the SAMPLESIZE statement must be specified.

For example, with  $H_0 : p = 0.5$ ,  $H_1 : p = 0.6$ , and REF=PROP (which is the default),

$$N_K = p^*(1 - p^*) I_X = (0.6 \times 0.4) I_X = 0.24 I_X$$

You can specify the MODEL=ONESAMPLEFREQ option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC GENMOD with the default DIST=NORMAL option in the MODEL statement can be used to derive the Z test for a binomial proportion.

---

## Applicable Two-Sample Tests and Sample Size Computation

The SEQDESIGN procedure provides sample size computation for two-sample tests: the test for the difference between two normal means, tests for binomial proportions, and the log-rank test for two survival distributions. These tests for binomial proportions include the test for the difference between two binomial proportions, the log odds ratio test for binomial proportions, and the log relative risk test for binomial proportions,

For a test of difference between two sample means, the required sample size depends on the assumed sample variances. Similarly, for a test of two-sample proportions, the required sample size depends on the assumed sample proportions. For a log-rank test of two survival distributions, the required sample size depends on the assumed sample hazard rates, accrual rate, and accrual time.

If the REF=NULLPROP or REF=NULLHAZARD option is specified, the proportions or hazard rates under the null hypothesis are used to derive the required sample size or number of events. Otherwise, the REF=PROP option (which is the default in the MODEL=TWOSAMPLEFREQ option) or the REF=HAZARD option (which is the default in the MODEL=TWOSAMPLESURVIVAL option) uses proportions or hazard rates under the alternative hypothesis to derive the required sample size or number of events.

### Test for the Difference between Two Normal Means

The MODEL=TWOSAMPLEMEAN option in the SAMPLESIZE statement derives the sample size required to test the difference between the means of two normal populations  $\mu_a$  and  $\mu_b$  by using the null hypothesis  $H_0 : \theta = 0$ , where  $\theta = \mu_a - \mu_b$ .

At stage  $k$ , the MLE for  $\theta$  is computed as

$$\hat{\theta}_k = \bar{y}_{ak} - \bar{y}_{bk} = \frac{1}{N_{ak}} \sum_{j=1}^{N_{ak}} y_{akj} - \frac{1}{N_{bk}} \sum_{j=1}^{N_{bk}} y_{bjk}$$

where  $y_{akj}$  and  $y_{bjk}$  are the values of the  $j$ th observation available in the  $k$ th stage groups A and B, respectively, and  $N_{ak}$  and  $N_{bk}$  are the cumulative sample sizes at stage  $k$  for these two groups.

The statistic  $\hat{\theta}_k$  has a normal distribution

$$\hat{\theta}_k \sim N(\theta, I_k^{-1})$$

where the information  $I_k$  is the inverse of the variance  $\text{Var}(\hat{\theta}_k) = \sigma_a^2/N_{ak} + \sigma_b^2/N_{bk}$ .

Then the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} \sim N(\theta \sqrt{I_k}, 1)$$

Thus, to test the hypothesis  $H_0 : \theta = 0$  against an upper alternative  $H_1 : \theta = \theta_1, \theta_1 > 0$ ,  $H_0$  is rejected at stage  $k$  if the statistic  $Z_k \geq a_k$ , the upper  $\alpha$  boundary for the standardized  $Z$  statistic at stage  $k$ .

If the variances  $\sigma_a^2$  and  $\sigma_b^2$  are unknown, the sample variances can be used to derive the information  $I_k$  if it is assumed that each sample variance is computed from a large sample such that the test statistic has an approximately normal distribution.

The maximum information is needed to derive the required sample size. If the maximum information is not specified or derived in the procedure, the alternative reference  $\theta_1^*$  specified in the MEANDIFF option is used to derive the maximum information.

Note that in order to derive the sample sizes  $N_{ak}$  and  $N_{bk}$  uniquely from the information,  $N_{ak} = R N_{bk}$  is assumed for  $k = 1, 2, \dots, K$ , where  $R = w_a/w_b$  is the constant allocation ratio computed from the WEIGHT= $w_a w_b$  option in the SAMPLESIZE statement.

In PROC SEQDESIGN, the computed total sample sizes for the two groups are

$$N_{aK} = (\sigma_a^2 + R\sigma_b^2) I_X = R \left( \frac{\sigma_a^2}{R} + \sigma_b^2 \right) I_X$$

$$N_{bK} = \left( \frac{\sigma_a^2}{R} + \sigma_b^2 \right) I_X$$

where  $I_X$  is the maximum information derived in the SEQDESIGN procedure,  $R$  is the constant allocation ratio, and  $\sigma_a$  and  $\sigma_b$  are the specified standard deviations.

For  $R = 1$ , the two sample sizes are equal, then

$$N_{aK} = N_{bK} = \frac{N_K}{2} = (\sigma_a^2 + \sigma_b^2) I_X$$

If the variances from the two groups are equal,  $\sigma_a^2 = \sigma_b^2 = \sigma^2$ , then the total sample sizes for the two groups are

$$N_{aK} = (1 + R) \sigma^2 I_X$$

$$N_{bK} = \left( 1 + \frac{1}{R} \right) \sigma^2 I_X$$

and the total sample size is

$$N_X = N_{aK} + N_{bK} = \frac{(R + 1)^2}{R} \sigma^2 I_X$$

Furthermore, for  $R = 1$ , the two sample sizes are equal, then

$$N_{aK} = N_{bK} = \frac{N_X}{2} = 2 \sigma^2 I_X$$

With an available maximum information, you can specify the MODEL=TWOSAMPLEMEAN(WEIGHT= $R$  STDDEV= $\sigma_a$   $\sigma_b$ ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC GLM can be used to derive the two-sample  $Z$  test for the mean difference.

### Test for the Difference between Two Binomial Proportions

The MODEL=TWOSAMPLEFREQ(TEST=PROP) option in the SAMPLESIZE statement derives the sample size required to test the difference between two binomial populations with  $H_0 : \theta = 0$ , where  $\theta = p_a - p_b$ . At stage  $k$ , the MLE for  $\theta$  is

$$\hat{\theta}_k = \hat{p}_{ak} - \hat{p}_{bk} = \frac{1}{N_{ak}} \sum_{j=1}^{N_{ak}} y_{akj} - \frac{1}{N_{bk}} \sum_{j=1}^{N_{bk}} y_{bjk}$$

where  $y_{akj}$  and  $y_{bjk}$  are the values of the  $j$ th observation available in the  $k$ th stage for groups A and B, respectively, and  $N_{ak}$  and  $N_{bk}$  are the cumulative sample sizes at stage  $k$  for these two groups.

For sufficiently large sample sizes  $N_{ak}$  and  $N_{bk}$ , the statistic  $\hat{\theta}_k$  has an approximate normal distribution

$$\hat{\theta}_k \sim N(\theta, I_k^{-1})$$

where the information is the inverse of the variance

$$\text{Var}(\hat{\theta}_k) = \frac{p_a(1-p_a)}{N_{ak}} + \frac{p_b(1-p_b)}{N_{bk}}$$

Thus, the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} \sim N(\theta \sqrt{I_k}, 1)$$

In practice,  $p_a = \hat{p}_a$  and  $p_b = \hat{p}_b$ , the estimated sample proportions for groups A and B, respectively, at stage  $k$ , can be used to derive the information  $I_k$  and the test statistic  $Z_k$ . Thus, to test the hypothesis  $H_0$  against an upper alternative  $H_1 : \theta > 0$ ,  $H_0$  is rejected at stage  $k$  if the statistic  $Z_k \geq a_k$ , the upper  $\alpha$  boundary for the standardized  $Z$  statistic at stage  $k$ .

The maximum information  $I_X$  is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to provide proportions under the alternative hypothesis for the alternative reference and then to derive the maximum information.

The proportions in the two groups are needed to derive the sample size. Also, in order to derive the sample sizes  $N_{ak}$  and  $N_{bk}$  uniquely from the information,  $N_{ak} = R N_{bk}$  is assumed for  $k = 1, 2, \dots, K$ , where  $R = w_a/w_b$  is the constant allocation ratio computed from the WEIGHT= $w_a w_b$  option in the SAMPLESIZE statement. Then

$$I_X = \left( \frac{p_a(1-p_a)}{N_{aK}} + \frac{p_b(1-p_b)}{N_{bK}} \right)^{-1} = \frac{N_{aK}}{p_a(1-p_a) + R p_b(1-p_b)}$$

In PROC SEQDESIGN, the total sample sizes in the two groups are computed as

$$N_{aK} = (p_a^*(1-p_a^*) + R p_b^*(1-p_b^*)) I_X$$

$$N_{bK} = \frac{1}{R} N_{aK}$$

where  $R = w_a/w_b$  is the constant allocation ratio, and  $p_a^*$  and  $p_b^*$  are proportions specified with the REF= option:

- REF=NULLPROP uses proportions under  $H_0$ :  $p_a^* = p_{0a}$ ,  $p_b^* = p_{0b}$
- REF=AVGNULPROP uses the average proportion under  $H_0$ :  $p_a^* = p_b^* = (R p_{0a} + p_{0b})/(R + 1)$
- REF=PROP uses proportions under  $H_1$ :  $p_a^* = p_{1a}$ ,  $p_b^* = p_{1b}$
- REF=AVGPROP uses the average proportion under  $H_1$ :  $p_a^* = p_b^* = (R p_{1a} + p_{1b})/(R + 1)$

The total sample size is given by

$$N_X = N_{aK} + N_{bK} = (R + 1) \left( \frac{1}{R} p_a^* (1 - p_a^*) + p_b^* (1 - p_b^*) \right) I_X$$

For  $R = 1$ , the two sample sizes are equal,

$$N_{aK} = N_{bK} = \frac{N_X}{2} = (p_a^* (1 - p_a^*) + p_b^* (1 - p_b^*)) I_X$$

You can specify the MODEL=TWOSAMPLEFREQ( TEST=PROP WEIGHT=R ) option in the SAMPLE-SIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC GENMOD with the default DIST=NORMAL option in the MODEL statement can be used to derive the two-sample  $Z$  test for proportion difference.

### Test for Two Binomial Proportions with a Log Odds Ratio Statistic

The MODEL=TWOSAMPLEFREQ(TEST=LOGOR) option in the SAMPLESIZE statement derives the sample size required to test two binomial proportions by using a log odds ratio statistic. The odds ratio is the ratio of the odds in one group to the odds in the other group, and the log odds ratio is the logarithm of the odds ratio

$$\theta = \log \left( \frac{p_a / (1 - p_a)}{p_b / (1 - p_b)} \right) = \log \left( \frac{p_a (1 - p_b)}{p_b (1 - p_a)} \right)$$

The hypothesis of no difference between two proportions,  $p_a = p_b$ , can be tested through the null hypothesis  $H_0 : \theta = 0$ , where  $\theta$  is the log odds ratio. For example, with  $H_0 : p_a = p_b = 0.6$  and  $H_1 : p_a = 0.8, p_b = 0.6$ , it corresponds to the equivalent hypothesis  $H_0 : \theta = 0$  and  $H_1 : \theta = \log \left( \frac{0.8(1-0.6)}{0.6(1-0.8)} \right) = \log(8/3) = 0.98083$ .

The maximum likelihood estimate of  $\theta$  is given by

$$\hat{\theta} = \log \left( \frac{\hat{p}_a (1 - \hat{p}_b)}{\hat{p}_b (1 - \hat{p}_a)} \right)$$

with an asymptotic variance

$$\text{Var}(\hat{\theta}) = I^{-1} = \frac{1}{N_a p_a (1 - p_a)} + \frac{1}{N_b p_b (1 - p_b)}$$

where  $I$  is the information (Diggle et al. 2002, pp. 341–342). That is, the standardized statistic

$$Z_k = \hat{\theta}_k \sqrt{I_k} \sim N \left( \theta \sqrt{I_k}, 1 \right)$$

In practice,  $p_a = \hat{p}_a$  and  $p_b = \hat{p}_b$ , the estimated sample proportions for groups A and B, respectively, at stage  $k$ , can be used to derive the information  $I_k$  and the test statistic  $Z_k = \hat{\theta}_k \sqrt{I_k}$  if the two sample sizes  $N_a$  and  $N_b$  are sufficiently large such that the test statistic has an approximately normal distribution.

The maximum information  $I_X$  is needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to provide proportions under the alternative hypothesis for the alternative reference and then to derive the maximum information.

In order to derive the sample sizes  $N_{ak}$  and  $N_{bk}$  uniquely from the information,  $N_{ak} = R N_{bk}$  is assumed for  $k = 1, 2, \dots, K$ , where  $R = w_a/w_b$  is the constant allocation ratio computed from the WEIGHT= $w_a/w_b$  option in the SAMPLESIZE statement. Then with

$$I_X = N_{bK} \left( \frac{1}{R p_a(1 - p_a)} + \frac{1}{p_b(1 - p_b)} \right)^{-1}$$

the sample size can be computed.

In PROC SEQDESIGN, the total sample sizes in the two groups are computed as

$$N_{bK} = I_X \left( \frac{1}{R p_a^*(1 - p_a^*)} + \frac{1}{p_b^*(1 - p_b^*)} \right)$$

$$N_{aK} = R N_{bK}$$

where  $R = w_a/w_b$  is the constant allocation ratio, and  $p_a^*$  and  $p_b^*$  are proportions specified with the REF= option:

- REF=NULLPROP uses proportions under  $H_0$ :  $p_a^* = p_{0a}$ ,  $p_b^* = p_{0b}$
- REF=AVGNULLPROP uses the average proportion under  $H_0$ :  $p_a^* = p_b^* = (R p_{0a} + p_{0b}) / (R + 1)$
- REF=PROP uses proportions under  $H_1$ :  $p_a^* = p_{1a}$ ,  $p_b^* = p_{1b}$
- REF=AVGPROP uses the average proportion under  $H_1$ :  $p_a^* = p_b^* = (R p_{1a} + p_{1b}) / (R + 1)$

You can specify the MODEL=TWOSAMPLEFREQ( TEST=LOGOR WEIGHT= $R$ ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC LOGISTIC can be used to derive the log odds ratio statistic.

### Test for Two Binomial Proportions with a Log Relative Risk Statistic

The MODEL=TWOSAMPLEFREQ(TEST=LOGRR) option in the SAMPLESIZE statement derives the sample size required to test two binomial proportions by using a log relative risk statistic. The relative risk is the ratio of the proportion in one group to the proportion in the other group. The log relative risk statistic is the logarithm of the relative risk

$$\theta = \log \left( \frac{p_a}{p_b} \right)$$

The hypothesis of no difference between two proportions,  $p_a = p_b$ , can be tested through the null hypothesis  $H_0 : \theta = 0$ . For example, with  $H_0 : p_a = p_b = 0.6$  and  $H_1 : p_a = 0.8$ ,  $p_b = 0.6$ , it corresponds to the equivalent hypothesis  $H_0 : \theta = 0$  and  $H_1 : \theta = \log \left( \frac{0.8}{0.6} \right) = \log(4/3) = 0.28768$ .

The maximum likelihood estimate of  $\theta$  is given by

$$\hat{\theta} = \log\left(\frac{\hat{p}_a}{\hat{p}_b}\right)$$

with an asymptotic variance

$$I^{-1} = \frac{1 - p_a}{N_a p_a} + \frac{1 - p_b}{N_b p_b}$$

where  $I$  is the information (Chow and Liu 1998, p. 329).

In practice,  $p_a = \hat{p}_a$  and  $p_b = \hat{p}_b$ , the estimated sample proportions for groups A and B, respectively, at stage  $k$ , are used to derive the information  $I_k$  and the test statistic  $Z_k = \hat{\theta}_k \sqrt{I_k}$ .

The maximum information  $I_X$  and proportions  $p_a$  and  $p_b$  are needed to derive the required sample size. If the maximum information is not specified or derived with the ALTREF= option in the procedure, the PROP= option in the SAMPLESIZE statement is used to provide proportions under the alternative hypothesis for the alternative reference and then to derive the maximum information.

Note that in order to derive the sample sizes  $N_{ak}$  and  $N_{bk}$  uniquely from the information,  $N_{ak} = R N_{bk}$  is assumed for  $k = 1, 2, \dots, K$ , where  $R = w_a/w_b$  is the constant allocation ratio computed from the WEIGHT= $w_a w_b$  option in the SAMPLESIZE statement. Then the sample size can be computed from

$$I_X = N_{bK} \left( \frac{1 - p_a}{R p_a} + \frac{1 - p_b}{p_b} \right)^{-1}$$

In PROC SEQDESIGN, the computed sample sizes in the two groups are

$$N_{bK} = I_X \left( \frac{1 - p_a^*}{R p_a^*} + \frac{1 - p_b^*}{p_b^*} \right)$$

$$N_{aK} = R N_{bK}$$

where  $R = w_a/w_b$  is the constant allocation ratio, and  $p_a^*$  and  $p_b^*$  are proportions specified with the REF= option:

- REF=NULLPROP uses proportions under  $H_0$ :  $p_a^* = p_{0a}$ ,  $p_b^* = p_{0b}$
- REF=AVGNULPROP uses the average proportion under  $H_0$ :  $p_a^* = p_b^* = (R p_{0a} + p_{0b})/(R + 1)$
- REF=PROP uses proportions under  $H_1$ :  $p_a^* = p_{1a}$ ,  $p_b^* = p_{1b}$
- REF=AVGPROP uses the average proportion under  $H_1$ :  $p_a^* = p_b^* = (R p_{1a} + p_{1b})/(R + 1)$

You can specify the MODEL=TWOSAMPLEFREQ( TEST=LOGRR WEIGHT= $R$ ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A procedure such as PROC LOGISTIC can be used to derive the log relative risk statistic.

### Test for Two Survival Distributions with a Log-Rank Test

The MODEL=TWOSAMPLESURV option in the SAMPLESIZE statement derives the number of events required for a log-rank test of two survival distributions. The analysis of survival data involves the survival times for both censored and uncensored data. A noncensored survival time is the time from treatment to an event such as remission or relapse for an individual. A censored survival time is the time from treatment to the time of analysis for an individual surviving at that time, and the status is unknown beyond that time.

Let  $T$  be the random variable of the survival time. Then the survival function

$$S(t) = \Pr(T > t)$$

is the probability that an individual from the population has a survival time that exceeds  $t$ . And the hazard function is given by

$$h(t) = \frac{f(t)}{S(t)}$$

where  $f(t)$  is the density function of  $T$ .

The hazard functions can be used to test the equality of two survival distributions  $S_a(t) = S_b(t)$  with the null hypothesis  $H_0 : h_a(t) = h_b(t), t > 0$ , where  $S_a(t)$  and  $S_b(t)$  are survival functions for groups A and B, respectively, and  $h_a(t)$  and  $h_b(t)$  are the corresponding hazard functions.

If the two hazards are proportional,  $h_a(t) = \lambda h_b(t)$ , where  $\lambda$  is a constant, then an equivalent null hypothesis is

$$H_0 : \lambda = \frac{h_a(t)}{h_b(t)} = 1$$

Alternatively, another equivalent null hypothesis is given by

$$H_0 : \theta = -\log(\lambda) = 0$$

Suppose that the hazard rate  $h$  is a constant. Then with a specified median survival time  $T_m$ , the hazard rate can be derived from the equation

$$e^{-hT_m} = \frac{1}{2}$$

Denote the distinct event times at stage  $k$  as  $\tau_{kj}, j = 1, 2, \dots, t_k$ , where  $t_k$  is the total number of distinct event times. Then the score statistic is the log-rank statistic (Jennison and Turnbull 2000, pp. 259–261; Whitehead 1997, pp. 36–39)

$$S_k = \sum_{j=1}^{t_k} (d_{akj} - e_{akj})$$

where  $d_{akj}$  is the number of events from group A and  $e_{akj}$  is the number of expected events from A. The number of expected events from A is computed as

$$e_{akj} = d_{kj} \frac{r_{akj}}{r_{kj}}$$

where  $d_{kj}$  is the number of events from both groups,  $r_{akj}$  is the number of individuals from the treatment group who survived up to time  $\tau_{kj}$ , and  $r_{bkj}$  is the number of individuals from both groups who survived up to time  $\tau_{kj}$ .

If the number of events  $d_{kj}$  is small relative to  $r_{kj}$ , the number of individuals survived up to time  $\tau_{kj}$ , then with a sufficiently large sample size,  $S_k$  has an approximately normal distribution

$$S_k \sim N(\theta I_k, I_k)$$

where the variance of  $S_k$  is the estimated information

$$I_k = \sum_{j=1}^{t_k} \frac{r_{akj} r_{bkj} d_{kj}}{r_{kj}^2}$$

In order to derive the number of events from the information  $I_k$ ,  $N_{ak} = R N_{bk}$  is assumed for  $k = 1, 2, \dots, K$ , where  $R = w_a/w_b$  is the constant allocation ratio computed from the WEIGHT= $w_a w_b$  option in the SAMPLESIZE statement.

The maximum information  $I_X$  is needed to derive the required sample size. If the maximum information is specified or derived with the ALTREF= option in the procedure, the HAZARD=, MEDSURVTIME=, and HAZARDRATIO= options are not applicable. Otherwise, the HAZARD=, MEDSURVTIME=, or HAZARDRATIO= option is used to compute the alternative reference and then to derive the maximum information for the sample size calculation.

With  $N_{aK} = R N_{bK}$ , if the number of events is few relative to the number of individuals who survived, then  $r_{aKj} \approx R r_{bKj}$ , and

$$I_X \approx \sum_{j=1}^{t_K} \frac{R}{(R+1)^2} d_{Kj} = \frac{R}{(R+1)^2} D_X$$

where  $D_X$  is the total number of events.

Thus, the required total number of events

$$D_X = \frac{(R+1)^2}{R} I_X$$

For a study group, if the hazard rate is constant, corresponding to an exponential survival distribution, and the individual accrual is uniform in the accrual time  $T_a$  with a constant accrual rate  $r_a$ , then the required total sample size and sample size at each stage can be derived. See the section “[Input Number of Events for Fixed-Sample Design](#)” on page 7044 for a detailed description of the sample size computation that uses hazard rates, accrual rate, and accrual time.

You can specify the MODEL=TWOSAMPLESURVIVAL option in the SAMPLESIZE statement to compute the required total number of events and individual number of events at each stage. With the specifications of hazard rates, accrual rate, and accrual time, the required total sample size and individual sample size at each stage can also be derived. If the REF=NULLHAZARD option is specified, the hazard rates under the null hypothesis,  $h_{0a}$  and  $h_{0b}$ , are used in the sample size computation. Otherwise, the hazard rates under the alternative hypothesis,  $h_{1a}$  and  $h_{1b}$ , are used. A procedure such as PROC LIFETEST can be used to derive the log-rank statistic.

## Applicable Regression Parameter Tests and Sample Size Computation

The SEQDESIGN procedure provides sample size computation for tests of a regression parameter in three regression models: normal regression, logistic regression, and proportional hazards regression.

To test a parameter  $\beta_1$  in a regression model, the variance of the parameter estimate  $\hat{\beta}_1$  is needed for the sample size computation. In a simple regression model with one covariate X1, the variance of  $\hat{\beta}_1$  is inversely related to the variance of X1,  $\sigma_x^2$ . That is,

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{N \sigma_x^2}$$

for the normal regression and logistic regression models, where  $N$  is the sample size, and

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{D \sigma_x^2}$$

for the proportional hazards regression model, where  $D$  is the number of events.

For a regression model with more than one covariate, the variance of  $\hat{\beta}_1$  for the normal regression and logistic regression models is inversely related to the variance of X1 after adjusting for other covariates. That is,

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{N (1 - r_x^2) \sigma_x^2}$$

where  $\hat{\beta}_1$  is the estimate of the parameter  $\beta_1$  in the model and  $r_x^2$  is the R square from the regression of X1 on other covariates—that is, the proportion of the variance  $\sigma_x^2$  explained by these covariates.

Similarly, for a proportional hazards regression model,

$$\text{Var}(\hat{\beta}_1) \propto \frac{1}{D (1 - r_x^2) \sigma_x^2}$$

Thus, with the derived maximum information, the required sample size or number of events can also be computed for the testing of a parameter in a regression model with covariates.

### Test for a Parameter in the Regression Model

The MODEL=REG option in the SAMPLESIZE statement derives the sample size required for a  $Z$  test of a normal regression. For a normal linear regression model, the response variable is normally distributed with the mean equal to a linear function of the explanatory variables and the constant variance  $\sigma^2$ .

The normal linear model is

$$y \sim N(\mathbf{X}\boldsymbol{\beta}, \sigma_y^2 \mathbf{I}_{(N)})$$

where  $\mathbf{Y}_{(N \times 1)}$  is the vector of the  $N$  observed responses,  $\mathbf{X}_{(N \times p)}$  is the design matrix for these  $N$  observations,  $\boldsymbol{\beta}_{(p \times 1)}$  is the parameter vector, and  $\mathbf{I}_{(N)}$  is the  $(N \times N)$  identity matrix.

The least squares estimate is

$$\hat{\boldsymbol{\beta}} = (\mathbf{X}'\mathbf{X})^{-1} \mathbf{X}'\mathbf{Y}$$

and is normally distributed with mean  $\beta$  and variance

$$\text{Var}(\hat{\beta}) = \sigma_y^2 (\mathbf{X}'\mathbf{X})^{-1}$$

For a model with only one covariate X1,

$$\hat{\beta}_1 \sim N(\beta_1, \text{Var}(\hat{\beta}_1))$$

where the variance

$$\text{Var}(\hat{\beta}_1) = I_{\beta_1}^{-1} = \sigma_y^2 \frac{1}{N \sigma_x^2}$$

Thus, with the derived maximum information  $I_X = I_{\beta_1}$ , the required sample size is given by

$$N = I_X \frac{\sigma_y^2}{\sigma_x^2}$$

For a normal linear model with more than one covariate, the variance of a single parameter  $\beta_1$  is

$$\text{Var}(\hat{\beta}_1) = \sigma_y^2 (\mathbf{X}'\mathbf{X})_{(11)}^{-1} = \sigma_y^2 \frac{1}{N \sigma_x^2 (1 - r_x^2)}$$

where  $(\mathbf{X}'\mathbf{X})_{(11)}^{-1}$  is the diagonal element of the  $(\mathbf{X}'\mathbf{X})^{-1}$  matrix corresponding to the parameter  $\beta_1$ ,  $\sigma_x^2$  is the variance of the variable X1, and  $r_x^2$  is the proportion of variance of X1 explained by other covariates. The value  $\sigma_x^2 (1 - r_x^2)$  represents the variance of X1 after adjusting for all other covariates.

Thus, with the derived maximum information  $I_X$ , the required sample size is

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2) \sigma_x^2}$$

In the SEQDESIGN procedure, you can specify the MODEL=REG( VARIANCE= $\sigma_y^2$  XVARIANCE= $\sigma_x^2$  XRSQUARE= $r_x^2$ ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage. A SAS procedure such as PROC REG can be used to compute the parameter estimate and its standard error at each stage.

### Test for a Parameter in the Logistic Regression Model

The MODEL=LOGISTIC option in the SAMPLESIZE statement derives the sample size required for a Z test of a logistic regression parameter. The linear logistic model has the form

$$\text{logit}(p) = \log\left(\frac{p}{1-p}\right) = \mathbf{x}\beta$$

where  $p$  is the response probability to be modeled and  $\beta$  is a vector of parameters.

Following the derivation in the section “Test for a Parameter in the Regression Model” on page 7061, the required sample size for testing a parameter in  $\beta$  is given by

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2) \sigma_x^2}$$

With the variance of the logit response,  $\sigma_y^2 = 1/(p(1-p))$ ,

$$N = I_X \frac{1}{p(1-p)} \frac{1}{(1-r_x^2)\sigma_x^2}$$

where  $\sigma_x^2$  is the variance of X and  $r_x^2$  is the proportion of variance explained by other covariates.

In the SEQDESIGN procedure, you can specify the MODEL=LOGISTIC( PROP= $p$  XVARIANCE= $\sigma_x^2$  XRSQUARE= $r_x^2$ ) option in the SAMPLESIZE statement to compute the required total sample size and individual sample size at each stage.

A SAS procedure such as PROC LOGISTIC can be used to compute the parameter estimate and its standard error at each stage.

### Test for a Parameter in the Proportional Hazards Regression Model

The MODEL=PHREG option in the SAMPLESIZE statement derives the number of events required for a Z test of a proportional hazards regression parameter. For analyses of survival data, Cox's semiparametric model is often used to examine the effect of explanatory variables on hazard rates. The survival time of each observation in the population is assumed to follow its own hazard function,  $h_i(t)$ , expressed as

$$h_i(t) = h(t; \mathbf{X}_i) = h_0(t) \exp(\mathbf{X}_i' \boldsymbol{\beta})$$

where  $h_0(t)$  is an arbitrary and unspecified baseline hazard function,  $\mathbf{x}_i$  is the vector of explanatory variables for the  $i$ th individual, and  $\boldsymbol{\beta}$  is the vector of regression parameters associated with the explanatory variables.

Hsieh and Lavori (2000, p. 553) show that the required number of events for testing a parameter in  $\boldsymbol{\beta}$ ,  $\beta_1$ , associated with the variable X1 is given by

$$D_X = I_X \frac{1}{(1-r_x^2)\sigma_x^2}$$

where  $\sigma_x^2$  is the variance of X1 and  $r_x^2$  is the proportion of variance of X1 explained by other covariates.

In the SEQDESIGN procedure, you can specify the MODEL=PHREG( XVARIANCE= $\sigma_x^2$  XRSQUARE= $r_x^2$ ) option in the SAMPLESIZE statement to compute the required number of events and individual number of events at each stage.

A SAS procedure such as PROC PHREG can be used to compute the parameter estimate and its standard error at each stage.

Note that for a two-sample test, X1 is an indicator variable and is the only covariate in the model. Thus, if the two sample sizes are equal, then the variance  $\sigma_x^2 = 1/4$  and the required number of events for testing the parameter  $\beta_1$  is given by

$$D_X = I_X \frac{1}{\sigma_x^2} = 4 I_X$$

See the section "Input Number of Events for Fixed-Sample Design" on page 7044 for a detailed description of the sample size computation that uses hazard rates, accrual rate, and accrual time.

## Aspects of Group Sequential Designs

This section summarizes various aspects of group sequential designs that are encountered in applications of the SEQDESIGN procedure. Features are illustrated through two-sided designs with  $\alpha = 0.05$  and  $\beta = 0.10$ . The null hypothesis  $H_0 : \theta = 0$  and an alternative reference  $\theta_1 = \pm 0.25$  are used for the designs with early stopping only to reject the null hypothesis.

### Canonical Joint Distribution

The SEQDESIGN procedure assumes that with a total number of stages  $K$ , the sequence of the standardized test statistics  $\{Z_1, Z_2, \dots, Z_K\}$  has the canonical joint distribution with information levels  $\{I_1, I_2, \dots, I_K\}$  for the parameter  $\theta$  (Jennison and Turnbull 2000, p. 49):

- $(Z_1, Z_2, \dots, Z_K)$  is multivariate normal
- $Z_k \sim N(\theta\sqrt{I_k}, 1)$ ,  $k = 1, 2, \dots, K$
- $\text{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{(I_{k_1}/I_{k_2})}$ ,  $1 \leq k_1 \leq k_2 \leq K$

### Normality Assumption

The SEQDESIGN procedure derives the boundary values by assuming that the sequence of the standardized test statistics  $\{Z_1, Z_2, \dots, Z_K\}$  has the canonical joint distribution with information levels  $\{I_1, I_2, \dots, I_K\}$  for the parameter  $\theta$ . If the test statistic  $Z_k$  does not have a normal distribution, it is assumed that the test statistic is computed from a large sample, so that the resulting statistic has an approximately normal distribution.

### Number of Stages

For group sequential trials with fixed significance level  $\alpha$ , power  $1 - \beta$ , and alternative reference, if the number of stages is increased, the required maximum information is also increased, but the average sample number under the alternative hypothesis is likely to decrease.

For example, for two-sided designs with early stopping only to reject the null hypothesis  $H_0 : \theta = 0$ ,  $\alpha = 0.05$ , and  $\beta = 0.10$  at the alternative reference  $\theta_1 = \pm 0.25$ , the O'Brien-Fleming method increases the maximum information from 168.12 for a fixed-sample design to 169.32 for a two-stage design, 172.57 for a five-stage design, and then 174.42 for a ten-stage design. In the mean time, the average sample number (as a percentage of fixed-sample) under the alternative hypothesis decreases from 100 for a fixed-sample design to 85.11 for a two-stage design, 75.03 for a five-stage design, and then 71.80 for a ten-stage design. The reduction in average sample number decreases as the number of stages increases. Thus there seems to be little to gain from choosing a design with more than five stages (Pocock 1982, p. 155).

### Alternative Reference

The alternative reference  $\theta_1$  is the hypothetical reference under the alternative hypothesis at which the power is computed. It is a treatment value that the investigators would hope to detect with high probability (Jennison and Turnbull 2000, p. 21).

For a group sequential design with specified parameters such as  $\alpha$  and  $\beta$  errors, the drift parameter  $\theta_1\sqrt{I_X}$  is always derived in the SEQDESIGN procedure. Thus, with a smaller alternative reference  $\theta_1$ , a larger maximum information level  $I_X$  is needed. That is, in order to detect a smaller difference with the same high power, a larger sample size is required.

### Maximum Information

In a clinical trial, the amount of information about an unknown parameter available from the data can be measured by the Fisher information, the variance of the score statistic. The maximum information is the information level needed at the final stage of the group sequential trial if the trial does not stop at an interim stage. For a group sequential design, the maximum information can be derived with the specified alternative reference.

The maximum information is proportional to the sample size or number of events required for the design. Thus, it can also be used to compare different designs. Generally, a design with a larger probability to stop the trial early tends to have a larger maximum information. For example, for two-sided four-stage designs with early stopping only to reject  $H_0$ ,  $\alpha = 0.05$ , and  $\beta = 0.10$  at the alternative reference  $\theta_1 = \pm 0.25$ , the Pocock method has a maximum information of 198.91 and the O'Brien-Fleming method has a maximum information of 171.84, indicating a much larger information level required for the Pocock method.

### Drift Parameter

The drift parameter  $\theta_1\sqrt{I_X}$  is derived for each design in the SEQDESIGN procedure, where  $\theta_1$  is the alternative reference. It is proportional to the square root of maximum information required for the design and can be used to compare maximum information for different designs with the same alternative reference. For example, for two-sided four-stage designs with early stopping only to reject  $H_0$ ,  $\alpha = 0.05$ , and  $\beta = 0.10$ , the Pocock method has a drift parameter 3.526 and the O'Brien-Fleming method has a drift parameter 3.277, indicating that a larger maximum information level is required for the Pocock method than for the O'Brien-Fleming method.

### Average Sample Number

The average sample number is the expected sample size (for nonsurvival data) or expected number of events (for survival data) of the design under a specific hypothetical reference. The percent average sample numbers with respect to the corresponding fixed-sample design are displayed in the SEQDESIGN procedure.

The design that requires a larger maximum information level tends to have a smaller average sample number under the alternative hypothesis. For example, for two-sided four-stage designs with early stopping only to reject  $H_0$ ,  $\alpha = 0.05$ , and  $\beta = 0.10$  at the alternative reference  $\theta_1 = \pm 0.25$ , the Pocock design has a maximum information of 198.91 and an average sample number (in percentage of fixed-sample design) of 69.75 under the alternative hypothesis, and the O'Brien-Fleming design has a maximum information of 171.84 and an average sample number of 76.74.

### Sample Size

The maximum information for the sequential design expressed as a percentage of its corresponding fixed-sample information is derived in the SEQDESIGN procedure. The sample size or number of events needed for a group sequential trial is computed by multiplying the sample size or number of events for the corresponding fixed-sample design by the derived percentage.

If the sample size or number of events for the fixed-sample design is available, you can use the MODEL=INPUTNOBS or MODEL=INPUTNEVENTS option in the SAMPLESIZE statement to derive the sample size or number of events needed at each stage. Otherwise, with the specified or derived maximum information, you can use the MODEL= option in the SAMPLESIZE statement to specify a hypothesis test and then to derive the sample size or number of events needed at each stage. See the section “Sample Size Computation” on page 7042 for the sample size computation for commonly used tests.

---

## Summary of Methods in Group Sequential Designs

There are three different types of methods available in the SEQDESIGN procedure: fixed boundary shape methods for specified boundary shape, Whitehead methods for boundaries from continuous monitoring, and error spending methods for specified error spending at each stage.

The fixed boundary shape methods include unified family methods and Haybittle-Peto methods. The unified family methods include Pocock, O’Brien-Fleming, power family, and triangular methods.

### Pocock Method

Pocock derives the constant boundary on the standardized  $Z$  scale to demonstrate the sequential design while maintaining the overall  $\alpha$  and  $\beta$  levels (Pocock 1977). The resulting boundary tends to stop the trials early with a larger  $p$ -value. This boundary is commonly called a Pocock boundary, but Pocock himself does not advocate these boundary values for stopping a trial early to reject the null hypothesis, because large  $p$ -values might not be persuasive enough (Pocock and White 1999). Also, the nominal  $p$ -value at the final stage is much smaller than the overall  $p$ -value of the design. That is, the trial might stop at the final stage with a small nominal  $p$ -value, but the test is not rejected, which might not be easy to justify.

### O’Brien-Fleming Method

O’Brien-Fleming boundary values are inversely proportional to the square root of information levels on the standardized  $Z$  scale (O’Brien and Fleming 1979). The O’Brien-Fleming boundary is conservative in the early stages and tends to stop the trials early only with a small  $p$ -value. But the nominal value at the final stage is close to the overall  $p$ -value of the design.

### Power Family Method

The power family method (Wang and Tsiatis 1987; Emerson and Fleming 1989; Pampallona and Tsiatis 1994) generalizes the Pocock and O’Brien-Fleming methods with a power parameter to allow continuous movement between the Pocock and O’Brien-Fleming methods. The power parameter is  $\rho = 0$  for the Pocock method and  $\rho = 0.5$  for the O’Brien-Fleming method.

### Triangular Method

The unified family triangular method (Kittelson and Emerson 1999) contains straight-line boundaries on the score scale. For a one-sided trial with early stopping either to reject and to accept the null hypothesis, the method produces a triangular continuation region. The boundary shape is specified with the slope parameter  $\tau$ .

## Unified Family Method

The unified family method (Kittelson and Emerson 1999) extends power family methods to incorporate the triangular method, which contains straight-line boundaries on the score scale.

## Haybittle-Peto Method

The Haybittle-Peto method (Haybittle 1971; Peto et al. 1976) uses a  $Z$  value of 3 for the critical values in interim stages and derives the critical value at the final stage. With this method, the final-stage critical value is close to the original design without interim monitoring. The SEQDESIGN procedure extends this method further to allow for different  $Z$  or nominal  $p$ -values for the boundaries.

## Whitehead Method

Whitehead methods (Whitehead and Stratton 1983; Whitehead 1997, 2001) derive the boundary values by adapting the continuous monitoring tests to the discrete monitoring of group sequential tests. With early stopping to reject or accept the null hypothesis in a one-sided test, the derived continuation region has a triangular shape on the score-scaled boundaries. Only elementary calculations are needed to derive the boundary values in Whitehead's triangular methods. The resulting Type I error probability and power are extremely close but differ slightly from the specified values due to the approximations used in deriving the tests (Jennison and Turnbull 2000, p. 106). The SEQDESIGN procedure provides the BOUNDARYKEY= option to adjust the boundary value at the final stage for the exact Type I or Type II error probability levels.

## Error Spending Method

The error spending method uses the specified  $\alpha$  and  $\beta$  errors to be used at each stage of the design to derive the boundary values.

## Error Spending Function Method

The error spending function method uses the error spending function to compute the  $\alpha$  and  $\beta$  errors to be used at each stage of the design and then to derive the boundary values for these errors. The following four error spending functions are available in the SEQDESIGN procedure:

- The Pocock-type error spending function (Lan and DeMets 1983) produces boundaries similar to those produced with Pocock's method.
- The O'Brien-Fleming-type error spending function (Lan and DeMets 1983) produces boundaries similar to those produced with the O'Brien-Fleming method.
- The gamma error spending function (Hwang, Shih, and DeCani 1990) specifies a gamma cumulative error spending function indexed by the gamma parameter  $\gamma$ . The boundaries created with  $\gamma = 1$  are similar to the boundaries from the Pocock method, and the boundaries created with  $\gamma = -4$  or  $\gamma = -5$  are similar to the boundaries from the O'Brien-Fleming method.
- The power error spending function (Jennison and Turnbull 2000, p. 148) specifies a power cumulative error spending function indexed by the power parameter  $\rho$ . The boundaries created with  $\rho = 1$  are similar to the boundaries from the Pocock method, and the boundaries created with  $\rho = 3$  are similar to the boundaries from the O'Brien-Fleming method.

---

## Table Output

For each design, the SEQDESIGN procedure displays the “Design Information,” “Method Information,” and “Boundary Information” tables by default.

### Boundary Information

The “Boundary Information” table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is either specified or derived
- alternative references with the specified statistic scale. If a  $p$ -value scale is specified, the standardized  $Z$  scale is used.
- boundary values with the specified statistic scale to reject or accept the null hypothesis

Note that implicitly, the boundary information table also contains variables for the boundary scale, stopping criterion, and type of alternative hypothesis. That is, if an ODS statement is used to save the table, the data set also contains the variables `_Scale_` for the boundary scale, `_Stop_` for the stopping criterion, and `_ALT_` for the type of alternative hypothesis.

### Design Information

The “Design Information” table displays the design specifications and derived statistics. The derived Max Information (Percent Fixed-Sample) is the maximum information for the sequential design in percentage of the corresponding fixed-sample information.

The Null Ref ASN (Percent Fixed-Sample) is the average sample number (expected sample size for nonsurvival data or expected number of events for survival data) required under the null hypothesis for the group sequential design in percentage of the corresponding fixed-sample design. Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the average sample number required under the alternative reference for the group sequential design in percentage of the corresponding fixed-sample design.

If both the maximum information (MAXINFO= option) and the alternative reference  $\theta_1$  (ALTREF= option) are specified, then either the ALPHA= option is used to derive the Type II error probability  $\beta$  (BOUNDARYKEY=ALPHA) or the BETA= option is used to derive the Type I error probability  $\alpha$  (BOUNDARYKEY=BETA).

### Error Spending Information

The “Error Spending Information” table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is either specified or derived
- cumulative error spending for each boundary

## Method Information

The “Method Information” table displays detailed method information for the design. For each boundary, it displays the following:

- the group sequential method used
- the  $\alpha$  or  $\beta$  errors
- the specified parameter  $\rho$ , if an error spending function is used
- the specified parameters  $\rho$  and  $\tau$  with the derived critical value  $C$ , if a unified family method is used
- the alternative reference  $\theta_1$ , if either the ALTREF= or the MAXINFO= option is specified
- the derived drift parameter,  $\theta_1 \sqrt{I_X}$ , where  $I_X$  is the maximum information and  $\theta_1$  is the alternative reference

Note that the alternative references are displayed with the MLE scale in the “Method Information” table. In contrast, the alternative references in the “Boundary Information” table are displayed with the specified statistic scale (if the  $p$ -value scale is not specified) or the standardized  $Z$  scale (if the  $p$ -value scale is specified).

## Powers and Expected Sample Sizes

The “Powers and Expected Sample Sizes” table displays the following information under each of the specified hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i$  are values specified in the CREF= option.

- coefficient  $c_i$  for the hypothetical references. The value  $c_i = 0$  corresponds to the null hypothesis and  $c_i = 1$  corresponds to the alternative hypothesis
- power
- expected sample size, as percentage of fixed-sample size

For a one-sided design, the power and expected sample sizes under the hypothetical references  $\theta = c_i \theta_1$  are displayed.

For a two-sided symmetric design, the power and expected sample sizes under each of the hypothetical references  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1u}$  is the upper alternative reference.

For a two-sided asymmetric design, the power and expected sample sizes under each of the hypothetical references  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively.

For a two-sided design, the power is the probability of correctly rejecting the null hypothesis for the correct alternative. Thus, under the null hypothesis, the displayed power corresponds to a one-sided Type I error probability level—that is, the lower  $\alpha$  level or the upper  $\alpha$  level.

The expected sample size as a percentage of the corresponding fixed-sample design is

$$100 \times \frac{\sum_{k=1}^K p_k I_k}{I_0}$$

where  $p_k$  is the stopping probability at stage  $k$ ,  $\sum_{k=1}^K p_k I_k$  is the expected information level, and  $I_0$  is the information level for the fixed-sample design.

### Sample Size Summary

When you use the SAMPLESIZE statement with the SEQDESIGN procedure, the “Sample Size Summary” table displays parameters for the sample size computation. It also displays the expected sample sizes or numbers of events for the model under both the null and alternative hypotheses.

The expected sample size is the average sample size

$$\frac{\sum_{k=1}^K p_k I_k}{I_0} N_0$$

where  $p_k$  is the stopping probability at stage  $k$ ,  $\sum_{k=1}^K p_k I_k$  is the expected information level,  $I_0$  is the information level for the fixed-sample design, and  $N_0$  is the sample size for the fixed-sample design.

The expected number of events is the average number of events

$$\frac{\sum_{k=1}^K p_k I_k}{I_0} D_0$$

where  $D_0$  is the fixed-sample number of events for the model.

### Sample Size Information

The “Sample Sizes (N)” table displays the required sample sizes and information levels at each stage, in both fractional and integer numbers. The derived fractional sample sizes are under the heading “Fractional N.” These sample sizes are rounded up to integers under the heading “Ceiling N.” The matched integer sample sizes are also displayed for two-sample tests.

The “Required Number of Events (D)” table displays the required number of events required and information level at each stage.

The “Number of Events (D) and Sample Sizes (N)” table displays the number of events and sample size required at each stage with the study time. The derived times under the heading “Fractional Time” are not integers. These times are rounded up to integers under the heading “Ceiling Time.”

### Stopping Probabilities

The “Expected Cumulative Stopping Probabilities” table displays the following information under each of the specified hypothetical references  $\theta = c_i \theta_1$ , where  $c_i$  are values specified in the CREF= option, and  $\theta_1$  is the alternative reference:

- coefficient  $c_i$  for the hypothetical references. The value  $c_i = 0$  corresponds to the null hypothesis, and  $c_i = 1$  corresponds to the alternative hypothesis

- expected stopping stage
- source of the stopping probability: reject  $H_0$  (with STOP=REJECT or STOP=BOTH), accept  $H_0$  (with STOP=ACCEPT or STOP=BOTH), or either reject or accept  $H_0$  (with STOP=BOTH)
- expected cumulative stopping probabilities at each stage

For a one-sided design, the expected cumulative stopping probabilities under the hypothetical references  $\theta = c_i\theta_{1l}$  are displayed.

For a two-sided design, the expected cumulative stopping probabilities under each of the hypothetical references  $\theta = c_i\theta_{1l}$  and  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively.

Note that for a symmetric two-sided design, only the expected cumulative stopping probabilities under the hypothetical references  $\theta = c_i\theta_{1u}$  are derived.

The expected stopping stage is given by  $k_0 + d$ , where the integer  $k_0$  and the fraction  $d$  ( $0 \leq d < 1$ ) are derived from the expected information level equation

$$\sum_{k=1}^K p_k I_k = I_{k_0} + d (I_{(k_0+1)} - I_{k_0})$$

where  $p_k$  is the stopping probability at stage  $k$ .

For equally spaced information levels, the expected stopping stage is reduced to the weighted average

$$\sum_{k=1}^K p_k k$$

## ODS Table Names

PROC SEQDESIGN assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in Table 83.12. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 83.12** ODS Tables Produced by PROC SEQDESIGN

| ODS Table Name    | Description                    | Statement  | Option   |
|-------------------|--------------------------------|------------|----------|
| Boundary          | Boundary values                |            |          |
| Design            | Design information             |            |          |
| ErrSpend          | Error spending                 |            | ERRSPEND |
| Method            | Method information             |            |          |
| PowerSampleSize   | Power and expected sample size |            | PSS      |
| SampleSize        | Derived sample sizes           | SAMPLESIZE |          |
| SampleSizeSummary | Sample size summary            | SAMPLESIZE |          |
| StopProb          | Stopping probabilities         |            | STOPPROB |

## Graphics Output

This section describes the use of ODS for creating graphics with the SEQDESIGN procedure. To request these graphs, ODS Graphics must be enabled and you must specify the associated graphics options in the PROC SEQDESIGN statement. Except for the PLOTS=BOUNDARY option, where a detailed boundary plot is generated for each design separately, each option produces a plot for all designs together. For more information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

### Sequential ASN Plot

The PLOTS=ASN option displays the average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references. The average sample numbers are connected for each design, and these connected curves for all designs are displayed in the “Sequential ASN Plot” graph.

For a one-sided design, average sample numbers under the hypothetical references  $\theta = c_i\theta_1$  are displayed, where  $c_i$  are the values specified in the CREF= option and  $\theta_1$  is the alternative reference. The horizontal axis displays the  $c_i$  values of these hypothetical references.

For a two-sided design, average sample numbers under each of the hypothetical references  $\theta = c_i\theta_{1l}$  and  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. The horizontal axis displays  $-c_i$  values for lower hypothetical references  $\theta = c_i\theta_{1l}$  and  $c_i$  values for upper hypothetical references  $\theta = c_i\theta_{1u}$ .

Note that for a symmetric two-sided design, only average sample numbers under the hypothetical references  $\theta = c_i\theta_{1u}$  are derived.

### Sequential Boundary Plot

The PLOTS=BOUNDARY option displays boundary values and the acceptance and rejection regions at each stage for each design separately in the “Detailed Boundary Information” graph. The BOUNDARYSCALE= option is used to specify the scale of the boundaries on the vertical axis. The keywords MLE, SCORE, STDZ, and PVALUE in the BOUNDARYSCALE= option correspond to the boundary with the MLE scale, score statistic scale, standardized normal Z scale, and  $p$ -value scale, respectively.

The stage numbers are displayed on the horizontal axis. In addition, the HSCALE= option in the PLOTS=BOUNDARY option can be used to specify the scale on the horizontal axis. The keywords INFO and SAMPLESIZE in the HSCALE= option correspond to the information levels and sample sizes, respectively.

### Combined Sequential Boundary Plot

The PLOTS=COMBINEDBOUNDARY option displays boundary values. The boundary values are connected for each boundary in each design, and these connected curves for all designs are displayed in the “Sequential Boundary Information” graph. The BOUNDARYSCALE= option is used to specify the scale of the boundaries on the vertical axis. The keywords MLE, SCORE, STDZ, and PVALUE in the BOUNDARYSCALE= option correspond to the boundary with the MLE scale, score statistic scale, standardized normal Z scale, and  $p$ -value scale, respectively.

The HSCALE= option in the PLOTS=COMBINEDBOUNDARY option can be used to specify the scale on the horizontal axis. The keywords INFO, SAMPLESIZE, and STAGE in the HSCALE= option correspond to the information levels, sample sizes, and stage numbers, respectively.

## Sequential Error Spending Plot

The PLOTS=ERRSPEND option displays the cumulative error spending at each stage on each boundary in the “Sequential Error Spending Plot” graph. A legend table uses the design labels to identify the curves for the corresponding design in the plot. Another legend table uses symbols to identify boundaries in the plot.

## Sequential Power Plot

The PLOTS=POWER option displays the powers under various hypothetical references. The powers are connected for each design, and these connected curves for all designs are displayed in the “Sequential Power Plot” graph.

For a one-sided design, powers under hypothetical references  $\theta = c_i\theta_1$  are displayed, where  $c_i$  are the values specified in the CREF= option and  $\theta_1$  is the alternative reference. The horizontal axis displays the  $c_i$  values of these hypothetical references.

For a two-sided design, powers under hypothetical references  $\theta = c_i\theta_{1l}$  and  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. The horizontal axis displays  $-c_i$  values for lower hypothetical references  $\theta = c_i\theta_{1l}$  and  $c_i$  values for upper hypothetical references  $\theta = c_i\theta_{1u}$ .

Note that for a symmetric two-sided design, only powers under hypothetical references  $\theta = c_i\theta_{1u}$  are derived.

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

PROC SEQDESIGN assigns a name to each graph it creates. You can use these names to reference the graphs when using ODS. To request these graphs, ODS Graphics must be enabled and you must specify the options indicated in [Table 83.13](#).

**Table 83.13** Graphs Produced by PROC SEQDESIGN

| ODS Graph Name       | Plot Description         | Option                 |
|----------------------|--------------------------|------------------------|
| ASNPlot              | Average sample numbers   | PLOTS=ASN              |
| BoundaryPlot         | Detailed boundary values | PLOTS=BOUNDARY         |
| CombinedBoundaryPlot | Boundary values          | PLOTS=COMBINEDBOUNDARY |
| ErrSpendPlot         | Error spending           | PLOTS=ERRSPEND         |
| PowerPlot            | Power curves             | PLOTS=POWER            |

---

## Examples: SEQDESIGN Procedure

The following examples demonstrate the usage of group sequential methods. [Example 83.1](#) uses the NSTAGES=1 option to derive boundaries of critical values for a fixed-sample design. The remaining examples use different methods to create boundaries for various group sequential designs.

---

### Example 83.1: Creating Fixed-Sample Designs

This example demonstrates a one-sided fixed-sample design and a two-sided fixed-sample design. The following statements request a fixed-sample design with an upper alternative:

```
ods graphics on;
proc seqdesign pss
 ;
 OneSidedFixedSample: design nstages=1
 alt=upper
 alpha=0.025 beta=0.10
 ;
 samplesize model=onesamplemean(mean=0.25);
run;
ods graphics off;
```

In the DESIGN statement, the label `OneSidedFixedSample` identifies the design in the output tables. The NSTAGES=1 option specifies that the design has only one stage; this corresponds to a fixed-sample design. In the SEQDESIGN procedure, the null hypothesis for the design is  $H_0 : \theta = 0$  and the ALT=UPPER option specifies an upper alternative hypothesis  $H_1 : \theta = \theta_1 > 0$ . The MEAN=0.25 option in the SAMPLESIZE statement specifies the upper alternative reference  $\theta_1 = 0.25$ .

The options ALPHA=0.025 and BETA=0.10 specify the Type I error probability level  $\alpha = 0.025$  and the Type II error probability level  $\beta = 0.10$ . That is, the design has a power  $1 - \beta = 0.90$  at  $\theta_1 = 0.25$ .

The “Design Information” table in [Output 83.1.1](#) displays design specifications and the derived statistics such as power. As expected, the derived statistics such as maximum information and average sample number (in percentage of its corresponding fixed-sample information) are 100 for the fixed-sample design (NSTAGES=1). Also, for a fixed-sample design, the STOP= and METHOD= options in the DESIGN statement are not applicable.

**Output 83.1.1** One-Sided Fixed-Sample Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|
| Design: OneSidedFixedSample               |                |
| Design Information                        |                |
| Statistic Distribution                    | Normal         |
| Boundary Scale                            | Standardized Z |
| Alternative Hypothesis                    | Upper          |
| Alternative Reference                     | 0.25           |
| Number of Stages                          | 1              |
| Alpha                                     | 0.025          |
| Beta                                      | 0.1            |
| Power                                     | 0.9            |
| Max Information (Percent of Fixed Sample) | 100            |
| Max Information                           | 168.1188       |
| Null Ref ASN (Percent of Fixed Sample)    | 100            |
| Alt Ref ASN (Percent of Fixed Sample)     | 100            |

The “Method Information” table in [Output 83.1.2](#) displays the  $\alpha$  and  $\beta$  error levels. It also displays the derived drift parameter, which is the standardized reference improvement,  $\theta_1 \sqrt{I_0}$ , where  $\theta_1$  is the alternative reference and  $I_0$  is the maximum information for the design. If either  $\theta_1$  or  $I_0$  is specified, the other statistic is derived in the SEQDESIGN procedure. For a fixed-sample design,

$$\theta_1 \sqrt{I_0} = \Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta) = \Phi^{-1}(0.975) + \Phi^{-1}(0.90) = 3.2415$$

**Output 83.1.2** Method Information

| Method Information |         |         |                       |          |
|--------------------|---------|---------|-----------------------|----------|
| Boundary           | Alpha   | Beta    | Alternative Reference | Drift    |
| Upper Alpha        | 0.02500 | 0.10000 | 0.25                  | 3.241516 |

The “Boundary Information” table in [Output 83.1.3](#) displays information level, alternative reference, and boundary value at each stage. The information proportion indicates the proportion of maximum information available at the stage. With only one stage for a fixed-sample design, the proportion is 1. With the SAMPLESIZE statement, the required sample size  $N$  is also displayed under the heading “Information Level.”

**Output 83.1.3** Boundary Information

| Boundary Information (Standardized Z Scale) |                             |          |          |                        |                          |         |
|---------------------------------------------|-----------------------------|----------|----------|------------------------|--------------------------|---------|
| Null Reference = 0                          |                             |          |          |                        |                          |         |
| _Stage_                                     | -----Information Level----- |          |          | -Alternative-          | -Boundary Values-        |         |
|                                             | Proportion                  | Actual   | N        | --Reference--<br>Upper | -----Upper-----<br>Alpha |         |
| 1                                           | 1.0000                      | 168.1188 | 168.1188 | 3.24152                |                          | 1.95996 |

By default (or equivalently if you specify BOUNDARYSCALE=STDZ), output alternative references and boundaries are displayed with the standardized normal Z scale. The alternative reference on the standardized Z scale at stage 1 is given by  $\theta_1 \sqrt{I_1}$ , where  $I_1$  is the information level at stage 1. With a boundary value 1.96, the hypothesis of  $\theta = 0$  is rejected if the standardized normal statistic  $Z \geq 1.96$ .

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.1.4](#). The boundary values in the “Boundary Information” table in [Figure 83.1.3](#) are displayed in the plot.

**Output 83.1.4** Boundary Plot

The “Sample Size Summary” table in [Output 83.1.5](#) displays parameters for the sample size computation of the test for a normal mean.

**Output 83.1.5** Sample Size Summary

| Sample Size Summary             |                 |
|---------------------------------|-----------------|
| Test                            | One-Sample Mean |
| Mean                            | 0.25            |
| Standard Deviation              | 1               |
| Max Sample Size                 | 168.1188        |
| Expected Sample Size (Null Ref) | 168.1188        |
| Expected Sample Size (Alt Ref)  | 168.1188        |

The “Sample Sizes (N)” table in [Output 83.1.6](#) displays the derived sample sizes, in both fractional and integer numbers. With the resulting integer sample sizes, the corresponding information level is slightly larger than the level from the design. This can increase the power slightly if the integer sample size is used in the trial.

**Output 83.1.6** Derived Sample Sizes

| Sample Sizes (N)           |                        |             |                     |             |
|----------------------------|------------------------|-------------|---------------------|-------------|
| One-Sample Z Test for Mean |                        |             |                     |             |
| _Stage_                    | -----Fractional N----- |             | -----Ceiling N----- |             |
|                            | N                      | Information | N                   | Information |
| 1                          | 168.12                 | 168.1       | 169                 | 169.0       |

The following statements request a two-sided fixed-sample design with a specified alternative reference:

```
ods graphics on;
proc seqdesign altref=1.2
 pss
 ;
 TwoSidedFixedSample: design nstages=1
 alt=twosided
 alpha=0.05 beta=0.10
 ;
 samplesize model=twosamplemean(stddev=2 weight=2);
run;
ods graphics off;
```

In the SEQDESIGN procedure, the null hypothesis for the design is  $H_0 : \theta = 0$ . The ALT=TWOSIDED option specifies a two-sided alternative hypothesis  $H_1 : \theta = \theta_1 \neq 0$ . The ALTREF=1.2 option in the PROC SEQDESIGN statement specifies the alternative reference  $\theta_1 = \pm 1.2$ .

The ALPHA=0.05 option (which is the default) specifies the two-sided Type I error probability level  $\alpha = 0.05$ . That is, the lower and upper Type I error probabilities  $\alpha_l = \alpha_u = 0.025$ . The BETA=0.10 option (which is the default) specifies the Type II error probability level  $\beta = 0.10$ , and the design has a power  $1 - \beta = 0.90$  at the alternative reference  $\theta_1 = \pm 1.2$ .

The “Design Information” table in [Output 83.1.7](#) displays design specifications and the derived power. With a specified alternative reference, the maximum information is derived.

**Output 83.1.7** Two-Sided Fixed-Sample Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|
| Design: TwoSidedFixedSample               |                |
| Design Information                        |                |
| Statistic Distribution                    | Normal         |
| Boundary Scale                            | Standardized Z |
| Alternative Hypothesis                    | Two-Sided      |
| Alternative Reference                     | 1.2            |
| Number of Stages                          | 1              |
| Alpha                                     | 0.05           |
| Beta                                      | 0.1            |
| Power                                     | 0.9            |
| Max Information (Percent of Fixed Sample) | 100            |
| Max Information                           | 7.296822       |
| Null Ref ASN (Percent of Fixed Sample)    | 100            |
| Alt Ref ASN (Percent of Fixed Sample)     | 100            |

The “Method Information” table in [Output 83.1.8](#) displays the  $\alpha$  and  $\beta$  errors, alternative references, and drift parameter. For a fixed-sample design, the derived drift parameter

$$\theta_1 \sqrt{I_0} = \Phi^{-1}\left(1 - \frac{\alpha}{2}\right) + \Phi^{-1}(1 - \beta) = \Phi^{-1}(0.975) + \Phi^{-1}(0.90) = 3.2415$$

**Output 83.1.8** Method Information

| Method Information |         |         |                       |          |
|--------------------|---------|---------|-----------------------|----------|
| Boundary           | Alpha   | Beta    | Alternative Reference | Drift    |
| Upper Alpha        | 0.02500 | 0.10000 | 1.2                   | 3.241516 |
| Lower Alpha        | 0.02500 | 0.10000 | -1.2                  | -3.24152 |

With a specified alternative reference  $\theta_1 = 1.2$ , the maximum information

$$I_0 = \left( \frac{3.2415}{1.2} \right)^2 = 7.2968$$

The default “Boundary Information” table in [Output 83.1.9](#) displays information level, alternative reference, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized normal Z scale. Thus, the standardized alternative references  $\pm\theta_1\sqrt{I_0}$  are displayed.

**Output 83.1.9** Boundary Information

| Boundary Information (Standardized Z Scale) |                             |          |          |                       |         |
|---------------------------------------------|-----------------------------|----------|----------|-----------------------|---------|
| Null Reference = 0                          |                             |          |          |                       |         |
| _Stage_                                     | -----Information Level----- |          |          | -----Alternative----- |         |
|                                             | Proportion                  | Actual   | N        | Lower                 | Upper   |
| 1                                           | 1.0000                      | 7.296822 | 131.3428 | -3.24152              | 3.24152 |
| Boundary Information (Standardized Z Scale) |                             |          |          |                       |         |
| Null Reference = 0                          |                             |          |          |                       |         |
| _Stage_                                     | -----Boundary Values----    |          |          |                       |         |
|                                             | Alpha                       | Alpha    |          |                       |         |
| 1                                           | -1.95996                    | 1.95996  |          |                       |         |

With boundary values of  $-1.96$  and  $1.96$ , the hypothesis of  $\theta = 0$  is rejected if the standardized normal statistic  $Z \geq 1.96$  or  $Z \leq -1.96$ .

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.1.10](#). The boundary values in the “Boundary Information” table in [Figure 83.1.9](#) are displayed in the plot.

**Output 83.1.10** Boundary Plot

The “Sample Size Summary” table in [Output 83.1.11](#) displays parameters for the sample size computation of the test for a normal mean.

**Output 83.1.11** Sample Size Summary

| Sample Size Summary             |                  |
|---------------------------------|------------------|
| Test                            | Two-Sample Means |
| Mean Difference                 | 1.2              |
| Standard Deviation              | 2                |
| Max Sample Size                 | 131.3428         |
| Expected Sample Size (Null Ref) | 131.3428         |
| Expected Sample Size (Alt Ref)  | 131.3428         |
| Weight (Group A)                | 2                |
| Weight (Group B)                | 1                |

The “Sample Sizes (N)” table in [Output 83.1.12](#) displays the derived sample sizes, in both fractional and integer numbers. With the WEIGHT=2 option, the allocation ratio is 2 for the first group and 1 for the second group. With the resulting integer sample sizes, the corresponding information level is slightly larger

than the level from the design. This can increase the power slightly if the integer sample size is used in the trial.

**Output 83.1.12** Derived Sample Sizes

| Sample Sizes (N)                      |        |          |          |             |
|---------------------------------------|--------|----------|----------|-------------|
| Two-Sample Z Test for Mean Difference |        |          |          |             |
| -----Fractional N-----                |        |          |          |             |
| _Stage_                               | N      | N(Grp 1) | N(Grp 2) | Information |
| 1                                     | 131.34 | 87.56    | 43.78    | 7.2968      |
| Sample Sizes (N)                      |        |          |          |             |

**Example 83.2: Creating a One-Sided O'Brien-Fleming Design**

This example demonstrates a group sequential design for a clinical study. A clinic is conducting a study on the effect of vitamin C supplements in treating flu symptoms. The study groups consist of patients in the clinic with their first sign of flu symptoms within the last 24 hours. These individuals are randomly assigned to either the control group, which receives the placebo pills, or the treatment group, which receives large doses of vitamin C supplements. At the end of a five-day period, the flu symptoms of each individual are recorded.

Suppose that from past experience, 60% of individuals experiencing flu symptoms have the symptoms disappeared within five days. The clinic wants to detect a 75% symptoms disappearance with a high probability in the trial. A test that compares the proportions directly is to specify a null hypothesis  $H_0 : \theta = p_a - p_b = 0$  with a Type I error probability level  $\alpha = 0.025$ , where  $p_a$  and  $p_b$  are the proportions of symptoms' disappearance in the treatment group and control group, respectively. A one-sided alternative  $H_1 : \theta > 0$  is also specified with a power of  $1 - \beta = 0.90$  at  $H_1 : \theta = 0.15$ .

For a one-sided fixed-sample design, the critical value for the standardized Z test statistic is given by  $C_\alpha = \Phi^{-1}(1 - \alpha) = 1.96$ . That is, at the end of study, if the test statistic  $z \geq C_\alpha$ , then the null hypothesis is rejected and the efficacy of vitamin C supplements is declared. Otherwise, the null hypothesis is not rejected and the effect of vitamin C supplements is not significant.

To achieve a  $1 - \beta = 0.90$  power at  $H_1 : \theta = 0.15$  for a fixed-sample design, the information required is given by

$$I_0 = \frac{(\Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta))^2}{0.15^2} = \frac{(1.96 + 1.28155)^2}{0.0225} = 466.99$$

With an equal sample size on the treatment and control groups,  $N_a = N_b$ , the sample size required for each group under  $H_1$  is computed from the information  $I_0$ :

$$N_a = N_b = (p_{1a}(1 - p_{1a}) + p_{1b}(1 - p_{1b})) I_0$$

where  $p_{1a} = 0.75$  and  $p_{1b} = 0.60$  are proportions in the treatment and control groups under  $H_1$ . That is,

$$N_a = N_b = (0.75 \times 0.25 + 0.6 \times 0.4) \times 466.99 = 199.64$$

Thus, 200 individuals are required for each group in the fixed-sample study. See the section “[Test for the Difference between Two Binomial Proportions](#)” on page 7054 for a detailed derivation of these required sample sizes.

Instead of a fixed-sample design for the trial, a group sequential design is used to stop the trial early for ethical concerns of possible harm or an unexpected strong efficacy outcome of the new drug. It can also save time and resources in the process. The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design that uses an O’Brien-Fleming method for normally distributed statistics. The design uses a one-sided alternative hypothesis  $H_1$  with early stopping to reject or accept  $H_0$ .

```
ods graphics on;
proc seqdesign altref=0.15
 ;
 OneSidedOBrienFleming: design nstages=4
 method=obf
 alt=upper stop=both
 alpha=0.025 beta=0.10
 ;
 sample size model=twosamplefreq(nullprop=0.6 test=prop);
ods output Boundary=Bnd_Prop;
run;
ods graphics off;
```

In a sequential design, a hypothesis can be rejected, accepted, or continued to the next time point at each interim stage. The STOP=BOTH option specifies early stopping to reject or accept the null hypothesis. The “Design Information,” “Method Information,” and “Boundary Information” tables are displayed by default.

The “Design Information” table in [Output 83.2.1](#) displays design specifications and derived statistics such as power and maximum information. With a specified alternative reference, ALTREF=0.15, the maximum information  $I_X$  is derived.

**Output 83.2.1** Design Information

| The SEQDESIGN Procedure                   |                    |
|-------------------------------------------|--------------------|

| Number of Stages                          | 4                  |
| Alpha                                     | 0.025              |
| Beta                                      | 0.1                |
| Power                                     | 0.9                |
| Max Information (Percent of Fixed Sample) | 107.6741           |
| Max Information                           | 502.8343           |
| Null Ref ASN (Percent of Fixed Sample)    | 61.12891           |
| Alt Ref ASN (Percent of Fixed Sample)     | 75.89782           |

The Max Information (Percent Fixed-Sample) is the ratio in percentage between the maximum information for the group sequential design and the information required for a corresponding fixed-sample design:

$$100 \times \frac{I_X}{I_0} = 100 \times \frac{502.83}{466.99} = 107.67$$

That is, if the group sequential trial does not stop at any interim stages, the information needed is 7.67% more than is needed for the corresponding fixed-sample design. For a two-sample test for binomial proportions, the information is proportional to the sample size. Thus, 7.67% more observations are needed for the group sequential trial.

The Null Ref ASN (Percent Fixed-Sample) is the ratio in percentage between the expected sample size required under the null hypothesis for the group sequential design and the sample size required for the corresponding fixed-sample design. With a ratio of 61.1%, the expected sample size for the group sequential trial under the null hypothesis is 61.1% of the sample size in the corresponding fixed-sample design.

Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the ratio in percentage between the expected sample size required under the alternative hypothesis for the group sequential design and the sample size required for the corresponding fixed-sample design. With a ratio of 75.9%, the expected sample size for the group sequential trial under the alternative hypothesis is 75.9% of the sample size in the corresponding fixed-sample design.

For a one-sided design with an upper alternative and early stopping to reject or accept the null hypothesis, upper  $\alpha$  and  $\beta$  boundaries are created. The “Method Information” table in [Output 83.2.2](#) displays the Type I error probability  $\alpha$ , the Type II error probability  $\beta$ , and the derived drift parameter. The drift parameter is the standardized reference improvement between the alternative and null hypotheses at the final stage. It is also the standardized alternative reference at the final stage if the null reference is zero.

**Output 83.2.2** Method Information

| Method Information |                 |                       |         |                          |     |        |
|--------------------|-----------------|-----------------------|---------|--------------------------|-----|--------|
| Boundary           | Method          | Alpha                 | Beta    | -----Unified Family----- |     |        |
|                    |                 |                       |         | Rho                      | Tau | C      |
| Upper Alpha        | O'Brien-Fleming | 0.02500               | .       | 0.5                      | 0   | 1.9784 |
| Upper Beta         | O'Brien-Fleming | .                     | 0.10000 | 0.5                      | 0   | 1.3852 |
| Method Information |                 |                       |         |                          |     |        |
|                    | Boundary        | Alternative Reference |         | Drift                    |     |        |
|                    | Upper Alpha     | 0.15                  |         | 3.363595                 |     |        |
|                    | Upper Beta      | 0.15                  |         | 3.363595                 |     |        |

With the METHOD=OBF option, the O'Brien-Fleming method is used for each boundary. The O'Brien-Fleming method is one of the unified family methods, and the “Method Information” table displays the corresponding parameter  $\rho$  in the unified family method. The table also displays the critical values  $C_\alpha = 1.9784$  for the  $\alpha$  boundary and  $C_\beta = 1.3852$  for the  $\beta$  boundary. These critical values are used to create the boundary values.

The “Boundary Information” table in [Output 83.2.3](#) displays information level, alternative reference, and boundary values at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative references and boundary values are displayed with the standardized Z statistic scale. The resulting standardized alternative reference at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, 3, 4$ .

**Output 83.2.3** Boundary Information

| Boundary Information (Standardized Z Scale) |                             |          |          |                        |                         |         |
|---------------------------------------------|-----------------------------|----------|----------|------------------------|-------------------------|---------|
| Null Reference = 0                          |                             |          |          |                        |                         |         |
| _Stage_                                     | -----Information Level----- |          |          | -Alternative-          | ----Boundary Values---- |         |
|                                             | Proportion                  | Actual   | N        | --Reference--<br>Upper | -----Upper-----<br>Beta | Alpha   |
| 1                                           | 0.2500                      | 125.7086 | 107.4808 | 1.68180                | -1.08860                | 3.95679 |
| 2                                           | 0.5000                      | 251.4171 | 214.9617 | 2.37842                | 0.41946                 | 2.79788 |
| 3                                           | 0.7500                      | 377.1257 | 322.4425 | 2.91296                | 1.31347                 | 2.28446 |
| 4                                           | 1.0000                      | 502.8343 | 429.9233 | 3.36360                | 1.97840                 | 1.97840 |

By default (or equivalently if you specify INFO=EQUAL), equally spaced information levels are used. An information proportion is the proportion of maximum information available at each stage. With the derived maximum information, the actual information level at each stage is also displayed. With the SAMPLESIZE statement, the required sample size  $N$  is also displayed under the heading “Information Level.”

At each interim stage, if the standardized  $Z$  test statistic is larger than or equal to the corresponding upper  $\alpha$  boundary, then the hypothesis  $H_0 : \theta = 0$  is rejected. If the test statistic is less than the corresponding upper  $\beta$  boundary, then the trial is stopped and the hypothesis  $H_0$  is accepted. Otherwise, the process continues to the next stage. At the final stage, stage 4, the trial stops and the hypothesis  $H_0$  is rejected if the standardized  $Z$  statistic  $Z_4 \geq 1.9784$ . Otherwise, the trial is accepted.

The ODS OUTPUT statement with the BOUNDARY=BND\_PROP option creates an output data set that contains the resulting boundary information. After the actual data from the clinical trial are collected and analyzed at each stage with a procedure such as PROC GENMOD, the SEQTEST procedure is used to test the resulting statistics at stage 1 with the boundary information stored in the BOUND\_PROP data set.

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.2.4](#).

Output 83.2.4 Boundary Plot

The horizontal axis indicates the information levels for the design. The stages are indicated by vertical lines with accompanying stage numbers. If at any stage a test statistic is in a rejection region, the trial stops and the hypothesis is rejected. If a test statistic is in an acceptance region, then the trial also stops and the hypothesis is accepted. If the statistic is not in a rejection region or an acceptance region, the trial continues to the next stage. The boundary plot also displays the information level and the critical value for the corresponding fixed-sample design.

The SEQDESIGN procedure derives the drift parameter  $\theta_1 \sqrt{I_X}$ , where  $\theta_1$  is the alternative reference and  $I_X$  is the maximum information. If either  $\theta_1$  or  $I_X$  is specified, the other can be derived. With the SAMPLESIZE statement, the maximum information is used to compute the required sample size for the study.

The “Sample Size Summary” table in [Output 83.2.5](#) displays parameters for the sample size computation. With the MODEL=TWOSAMPLEFREQ( NULLPROP=0.6 TEST=PROP) option in the SAMPLESIZE statement, the total sample size in each group for testing the difference between two proportions is computed. By default (or equivalently if you specify REF=PROP in the MODEL=TWOSAMPLEFREQ option), the required sample sizes are computed under the alternative hypothesis. That is,

$$N_a = N_b = (p_{1a}(1 - p_{1a}) + p_{1b}(1 - p_{1b})) I_X$$

where  $p_{1b} = 0.60$  and  $p_{1a} = p_{1b} + \theta_1 = 0.75$  are the proportions in the control and treatment groups, respectively, under the alternative hypothesis  $H_1$ . See the section “[Test for the Difference between Two Binomial Proportions](#)” on page 7054 for a detailed description of these parameters.

**Output 83.2.5** Sample Size Summary

| Sample Size Summary             |                        |
|---------------------------------|------------------------|
| Test                            | Two-Sample Proportions |
| Null Proportion                 | 0.6                    |
| Proportion (Group A)            | 0.75                   |
| Test Statistic                  | Z for Proportion       |
| Reference Proportions           | Alt Ref                |
| Max Sample Size                 | 429.9233               |
| Expected Sample Size (Null Ref) | 244.0768               |
| Expected Sample Size (Alt Ref)  | 303.0464               |

The “Sample Sizes (N)” table in [Output 83.2.6](#) displays the required sample sizes at each stage, in both fractional and integer numbers. The derived fractional sample sizes are under the heading “Fractional N.” These sample sizes are rounded up to integers under the heading “Ceiling N.” In practice, integer sample sizes are used, and the resulting information levels increase slightly. Thus, 54, 108, 162, and 215 individuals are needed in each group for the four stages, respectively.

**Output 83.2.6** Derived Sample Sizes

| Sample Sizes (N)                            |        |          |          |             |
|---------------------------------------------|--------|----------|----------|-------------|
| Two-Sample Z Test for Proportion Difference |        |          |          |             |
| -----Fractional N-----                      |        |          |          |             |
| _Stage_                                     | N      | N(Grp 1) | N(Grp 2) | Information |
| 1                                           | 107.48 | 53.74    | 53.74    | 125.7       |
| 2                                           | 214.96 | 107.48   | 107.48   | 251.4       |
| 3                                           | 322.44 | 161.22   | 161.22   | 377.1       |
| 4                                           | 429.92 | 214.96   | 214.96   | 502.8       |

| Sample Sizes (N)                            |     |          |          |             |
|---------------------------------------------|-----|----------|----------|-------------|
| Two-Sample Z Test for Proportion Difference |     |          |          |             |
| -----Ceiling N-----                         |     |          |          |             |
| _Stage_                                     | N   | N(Grp 1) | N(Grp 2) | Information |
| 1                                           | 108 | 54       | 54       | 126.3       |
| 2                                           | 216 | 108      | 108      | 252.6       |
| 3                                           | 324 | 162      | 162      | 378.9       |
| 4                                           | 430 | 215      | 215      | 502.9       |

**Example 83.3: Creating Two-Sided Pocock and O'Brien-Fleming Designs**

This example requests two 4-stage group sequential designs for normally distributed statistics with equally spaced information levels at all stages. One design uses Pocock's method and the other uses the O'Brien-Fleming method. The following statements invoke the SEQDESIGN procedure and request these two designs:

```
proc seqdesign altref=0.4
 pss
 stopprob
 errspend
 ;
 TwoSidedPocock: design nstages=4 method=poc;
 TwoSidedOBrienFleming: design nstages=4 method=obf;
 sample size model=twosamplemean(stddev=0.8 weight=2);
run;
```

By default (or equivalently if you specify ALT=TWOSIDED and STOP=REJECT in the DESIGN statement), each design has a null hypothesis  $H_0$  with a two-sided alternative with early stopping to reject  $H_0$ .

The “Design Information” table in [Output 83.3.1](#) displays design specifications and derived statistics for the Pocock’s design. With the specified ALTREF= option, the maximum information  $I_X = 77.6984$  is also derived.

**Output 83.3.1** Pocock Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|
| Design: TwoSidedPocock                    |                |
| Design Information                        |                |
| Statistic Distribution                    | Normal         |
| Boundary Scale                            | Standardized Z |
| Alternative Hypothesis                    | Two-Sided      |
| Early Stop                                | Reject Null    |
| Method                                    | Pocock         |
| Boundary Key                              | Both           |
| Alternative Reference                     | 0.4            |
| Number of Stages                          | 4              |
| Alpha                                     | 0.05           |
| Beta                                      | 0.1            |
| Power                                     | 0.9            |
| Max Information (Percent of Fixed Sample) | 118.3143       |
| Max Information                           | 77.69844       |
| Null Ref ASN (Percent of Fixed Sample)    | 115.6074       |
| Alt Ref ASN (Percent of Fixed Sample)     | 69.74805       |

With the corresponding fixed-sample information

$$I_0 = \frac{(\Phi^{-1}(1 - \alpha/2) + \Phi^{-1}(1 - \beta))^2}{0.4^2} = \frac{(1.96 + 1.28155)^2}{0.16} = 65.6728$$

the fixed-sample information ratio is  $77.6984/65.6728 = 1.1831$ .

For a two-sided design with early stopping to reject the null hypothesis, lower and upper  $\alpha$  boundaries are created. The “Method Information” table in [Output 83.3.2](#) displays the  $\alpha$  and  $\beta$  errors, alternative references, and derived drift parameters, which are the standardized alternative references at the final stage.

**Output 83.3.2** Method Information

| Method Information |        |         |         |                          |     |         |
|--------------------|--------|---------|---------|--------------------------|-----|---------|
| Boundary           | Method | Alpha   | Beta    | -----Unified Family----- |     |         |
|                    |        |         |         | Rho                      | Tau | C       |
| Upper Alpha        | Pocock | 0.02500 | 0.10000 | 0                        | 0   | 2.36129 |
| Lower Alpha        | Pocock | 0.02500 | 0.10000 | 0                        | 0   | 2.36129 |

| Method Information |                       |          |
|--------------------|-----------------------|----------|
| Boundary           | Alternative Reference | Drift    |
| Upper Alpha        | 0.4                   | 3.525869 |
| Lower Alpha        | -0.4                  | -3.52587 |

With the METHOD=POC option, the Pocock method is used for each boundary. The Pocock method is one of the unified family methods, and the table also displays its corresponding parameters  $\rho = 0$  as a unified family method and the derived parameters  $C = 2.3613$  for the boundary values.

With the PSS option, the “Power and Expected Sample Sizes” table in [Output 83.3.3](#) displays powers and expected sample sizes under various hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i$  are values specified in the CREF= option. By default,  $c_i = 0, 0.5, 1.0, 1.5$ .

**Output 83.3.3** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes   |         |                                          |
|------------------------------------|---------|------------------------------------------|
| Reference = CRef * (Alt Reference) |         |                                          |

| 0.0000                             | 0.02500 | 115.6074                                 |
| 0.5000                             | 0.34252 | 104.0615                                 |
| 1.0000                             | 0.90000 | 69.7480                                  |
| 1.5000                             | 0.99869 | 43.6600                                  |

Note that at  $c_i = 0$ , the null reference  $\theta = 0$ , and the power 0.025 corresponds to the one-sided Type I error probability 0.025. At  $c_i = 1$ ,  $\theta = \theta_1$ , the power 0.9 is the power of the design. The expected sample sizes are displayed in a percentage scale to its corresponding fixed-sample size design. With the specified SAMPLESIZE statement, the expected sample sizes for the specified model in the SAMPLESIZE statement are also displayed.

With the STOPPROB option, the “Expected Cumulative Stopping Probabilities” table in Output 83.3.4 displays the expected cumulative stopping stage and cumulative stopping probability to reject the null hypothesis  $H_0$  at each stage under various hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i$  are values specified in the CREF= option. By default,  $c_i = 0, 0.5, 1.0, 1.5$ .

**Output 83.3.4** Stopping Probabilities

| Expected Cumulative Stopping Probabilities |                         |             |                                  |         |         |         |  |
|--------------------------------------------|-------------------------|-------------|----------------------------------|---------|---------|---------|--|
| Reference = CRef * (Alt Reference)         |                         |             |                                  |         |         |         |  |
| CRef                                       | Expected Stopping Stage | Source      | -----Stopping Probabilities----- |         |         |         |  |
|                                            |                         |             | Stage_1                          | Stage_2 | Stage_3 | Stage_4 |  |
| 0.0000                                     | 3.908                   | Reject Null | 0.01821                          | 0.03155 | 0.04176 | 0.05000 |  |
| 0.5000                                     | 3.518                   | Reject Null | 0.07005                          | 0.15939 | 0.25242 | 0.34327 |  |
| 1.0000                                     | 2.358                   | Reject Null | 0.27482                          | 0.58074 | 0.78638 | 0.90002 |  |
| 1.5000                                     | 1.476                   | Reject Null | 0.61145                          | 0.92348 | 0.98900 | 0.99869 |  |

Note that at  $c_i = 0$ , the cumulative stopping probability to reject  $H_0$  at the final stage is the overall Type I error probability 0.05. At  $c_i = 1$ , the alternative hypothesis  $H_1 : \theta = \theta_1$ , the cumulative stopping probability to reject  $H_0$  includes both the probability in the lower rejection region and the probability in the upper rejection region. This stopping probability to reject  $H_0$  at the final stage, 0.90002, is slightly greater than the power  $1 - \beta = 0.90$ , which corresponds to the cumulative stopping probability in the upper rejection region only. See the section “Type I and Type II Errors” on page 7022 for a detailed description of the Type II error probability  $\beta$ .

The “Boundary Information” table in Output 83.3.5 displays the information level, alternative references, and boundary values at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized Z scale is used to display the alternative references and boundary values. The resulting standardized alternative reference at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, 3, 4$ .

**Output 83.3.5** Boundary Information

| Boundary Information (Standardized Z Scale) |                             |          |          |                       |         |
|---------------------------------------------|-----------------------------|----------|----------|-----------------------|---------|

| _Stage_                                     | -----Information Level----- |          |          | -----Alternative----- |         |
|                                             | Proportion                  | Actual   | N        | Lower                 | Upper   |
| 1                                           | 0.2500                      | 19.42461 | 55.94288 | -1.76293              | 1.76293 |
| 2                                           | 0.5000                      | 38.84922 | 111.8858 | -2.49317              | 2.49317 |
| 3                                           | 0.7500                      | 58.27383 | 167.8286 | -3.05349              | 3.05349 |
| 4                                           | 1.0000                      | 77.69844 | 223.7715 | -3.52587              | 3.52587 |

| Boundary Information (Standardized Z Scale) |                           |         |         |
|---------------------------------------------|---------------------------|---------|---------|
| Null Reference = 0                          |                           |         |         |
| _Stage_                                     | -----Boundary Values----- |         | Alpha   |
|                                             | Lower                     | Upper   |         |
| 1                                           | -2.36129                  | 2.36129 | 2.36129 |
| 2                                           | -2.36129                  | 2.36129 | 2.36129 |
| 3                                           | -2.36129                  | 2.36129 | 2.36129 |
| 4                                           | -2.36129                  | 2.36129 | 2.36129 |

By default (or equivalently if you specify INFO=EQUAL in the DESIGN statement), equally spaced information levels are used. With the SAMPLESIZE statement, the required sample size  $N$  is also displayed under the heading “Information Level.” With the Pocock method, the standardized  $Z$  boundary values are identical at all stages for each  $\alpha$  boundary.

At each interim stage, the hypothesis of  $H_0 : \theta = 0$  is rejected if the standardized normal test statistic  $z \leq -2.36129$ , the lower  $\alpha$  boundary, or  $z \geq 2.36129$ , the upper  $\alpha$  boundary. Otherwise, the trial continues to the next stage. At the final stage, stage 4, the trial stops and the hypothesis is rejected if the test statistic  $|z_4| \geq 2.36129$ . Otherwise, the hypothesis is accepted.

The “Error Spending Information” in [Output 83.3.6](#) displays cumulative error spending at each stage for each boundary. It shows that more  $\alpha$  errors are used in early stages than in later stages.

**Output 83.3.6** Error Spending Information

| Error Spending Information |                                   |                                     |         |         |         |  |
|----------------------------|-----------------------------------|-------------------------------------|---------|---------|---------|--|
| _Stage_                    | -Information Level-<br>Proportion | -----Cumulative Error Spending----- |         |         |         |  |
|                            |                                   | Alpha                               | Beta    | Beta    | Alpha   |  |
| 1                          | 0.2500                            | 0.00911                             | 0.00002 | 0.00002 | 0.00911 |  |
| 2                          | 0.5000                            | 0.01577                             | 0.00002 | 0.00002 | 0.01577 |  |
| 3                          | 0.7500                            | 0.02088                             | 0.00002 | 0.00002 | 0.02088 |  |
| 4                          | 1.0000                            | 0.02500                             | 0.10000 | 0.10000 | 0.02500 |  |

The “Sample Size Summary” table in [Output 83.3.7](#) displays the specified parameters for the sample size computation of the two-sample test for mean difference.

**Output 83.3.7** Sample Size Summary

| Sample Size Summary             |                  |
|---------------------------------|------------------|
| Test                            | Two-Sample Means |
| Mean Difference                 | 0.4              |
| Standard Deviation              | 0.8              |
| Max Sample Size                 | 223.7715         |
| Expected Sample Size (Null Ref) | 218.652          |
| Expected Sample Size (Alt Ref)  | 131.9167         |
| Weight (Group A)                | 2                |
| Weight (Group B)                | 1                |

The “Sample Sizes (N)” table in [Output 83.3.8](#) displays the derived sample sizes at each stage, in both fractional and integer numbers. With the WEIGHT=2 option, the allocation ratio is 2 for the first group and 1 for the second group. See the section “[Test for the Difference between Two Normal Means](#)” on page 7053 for the derivation of these sample sizes. With the fixed-sample information ratio 1.1831, the derived sample sizes in fractional numbers are derived by multiplying 1.1831 by the corresponding sample sizes in the fixed-sample design.

**Output 83.3.8** Sample Sizes

| Sample Sizes (N)                      |        |          |          |             |
|---------------------------------------|--------|----------|----------|-------------|

| Sample Sizes (N)                      |     |          |          |             |
|---------------------------------------|-----|----------|----------|-------------|
| Two-Sample Z Test for Mean Difference |     |          |          |             |
| -----Ceiling N-----                   |     |          |          |             |
| _Stage_                               | N   | N(Grp 1) | N(Grp 2) | Information |
| 1                                     | 57  | 38       | 19       | 19.7917     |
| 2                                     | 113 | 75       | 38       | 39.4082     |
| 3                                     | 168 | 112      | 56       | 58.3333     |
| 4                                     | 225 | 150      | 75       | 78.1250     |

These fractional sample sizes are rounded up to integers under the heading “Ceiling N.” When the resulting integer sample sizes are used, the corresponding information levels are slightly larger than the levels from the design. This can increase the power slightly if a trial uses these integer sample sizes.

Note that compared with other designs, a Pocock design can stop the trial early with a larger  $p$ -value. However, this might not be persuasive enough to make a new treatment widely accepted (Pocock and White 1999).

The “Design Information” table in [Output 83.3.9](#) displays design specifications and the derived statistics for the O’Brien-Fleming design. With the specified ALTREF= option, the maximum information  $I_X = 67.1268$  is derived.

**Output 83.3.9** O’Brien-Fleming Design Information

| The SEQDESIGN Procedure                   |                 |
|-------------------------------------------|-----------------|
| Design: TwoSidedOBrienFleming             |                 |
| Design Information                        |                 |
| Statistic Distribution                    | Normal          |
| Boundary Scale                            | Standardized Z  |
| Alternative Hypothesis                    | Two-Sided       |
| Early Stop                                | Reject Null     |
| Method                                    | O'Brien-Fleming |
| Boundary Key                              | Both            |
| Alternative Reference                     | 0.4             |
| Number of Stages                          | 4               |
| Alpha                                     | 0.05            |
| Beta                                      | 0.1             |
| Power                                     | 0.9             |
| Max Information (Percent of Fixed Sample) | 102.2163        |
| Max Information                           | 67.12682        |
| Null Ref ASN (Percent of Fixed Sample)    | 101.5728        |
| Alt Ref ASN (Percent of Fixed Sample)     | 76.7397         |

With the corresponding fixed-sample information

$$I_0 = \frac{(\Phi^{-1}(1 - \alpha/2) + \Phi^{-1}(1 - \beta))^2}{0.4^2} = \frac{(1.96 + 1.28155)^2}{0.16} = 65.6728$$

the fixed-sample information ratio is  $67.1268/65.6728 = 1.022$ . That is, the maximum information for the O’Brien-Fleming design is only 2.2% more than for the corresponding fixed-sample design.

The “Method Information” table in [Output 83.3.10](#) displays the Type I  $\alpha$  level and Type II  $\beta$  level. It also displays the derived drift parameter  $\theta_1 \sqrt{I_X}$ , which is the standardized alternative reference at the final stage.

**Output 83.3.10** Method Information

| Method Information |                 |         |         |                          |     |         |

|--------------------|-----------------------|----------|
| Boundary           | Alternative Reference | Drift    |
| Upper Alpha        | 0.4                   | 3.277238 |
| Lower Alpha        | -0.4                  | -3.27724 |

With the METHOD=OBF option, the O'Brien-Fleming method is used for each boundary. The O'Brien-Fleming method is one of the unified family methods, and the table also displays its corresponding parameters  $\rho = 0.5$  as a unified family method and the derived parameter  $C = 2.0243$  for the boundary values.

With the PSS option, the "Power and Expected Sample Sizes" table in [Output 83.3.11](#) displays powers and expected sample sizes under various hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i$  are values specified in the CREF= option.

**Output 83.3.11** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes   |         |                                          |
|------------------------------------|---------|------------------------------------------|
| Reference = CRef * (Alt Reference) |         |                                          |
| CRef                               | Power   | -Sample Size-<br>Percent<br>Fixed-Sample |
| 0.0000                             | 0.02500 | 101.5728                                 |
| 0.5000                             | 0.36495 | 96.3684                                  |
| 1.0000                             | 0.90000 | 76.7397                                  |
| 1.5000                             | 0.99821 | 57.2590                                  |

Compared with the corresponding Pocock design, the O'Brien-Fleming design has a smaller maximum sample size, and smaller expected sample sizes under hypothetical references  $\theta = 0$  and  $\theta = 0.5 \theta_1$ , but larger expected sample sizes under hypothetical references  $\theta = \theta_1$  and  $\theta = 1.5 \theta_1$ .

With the STOPPROB option, the "Expected Cumulative Stopping Probabilities" table in [Output 83.3.12](#) displays the expected stopping stage and cumulative stopping probability to reject the null hypothesis at each stage under various hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i$  are values specified in the CREF= option.

**Output 83.3.12** Stopping Probabilities

| Expected Cumulative Stopping Probabilities |                         |             |                                  |         |         |         |  |
|--------------------------------------------|-------------------------|-------------|----------------------------------|---------|---------|---------|--|
| Reference = CRef * (Alt Reference)         |                         |             |                                  |         |         |         |  |
| CRef                                       | Expected Stopping Stage | Source      | -----Stopping Probabilities----- |         |         |         |  |
|                                            |                         |             | Stage_1                          | Stage_2 | Stage_3 | Stage_4 |  |
| 0.0000                                     | 3.975                   | Reject Null | 0.00005                          | 0.00422 | 0.02091 | 0.05000 |  |
| 0.5000                                     | 3.771                   | Reject Null | 0.00062                          | 0.04430 | 0.18392 | 0.36515 |  |
| 1.0000                                     | 3.003                   | Reject Null | 0.00798                          | 0.29296 | 0.69603 | 0.90000 |  |
| 1.5000                                     | 2.241                   | Reject Null | 0.05584                          | 0.73031 | 0.97315 | 0.99821 |  |

Compared with the corresponding Pocock design, the O'Brien-Fleming design has smaller stopping probabilities in early stages under each hypothetical reference.

The "Boundary Information" table in [Output 83.3.13](#) displays the boundary values for the design that uses the O'Brien-Fleming method. Compared with the Pocock method, the standardized statistics  $\alpha$  boundary values derived from the O'Brien-Fleming method in absolute values are larger in early stages and smaller in later stages. This makes the O'Brien-Fleming design less likely to reject the null hypothesis in early stages than the Pocock design. With the derived parameter  $C = 2.0243$  for the  $\alpha$  boundary, the  $\alpha$  boundaries at stage  $j$  are computed as  $C\sqrt{4/j}$ ,  $j = 1, \dots, 4$ .

**Output 83.3.13** Boundary Information

| Boundary Information (Standardized Z Scale) |                             |          |          |                       |         |
|---------------------------------------------|-----------------------------|----------|----------|-----------------------|---------|
| Null Reference = 0                          |                             |          |          |                       |         |
| _Stage_                                     | -----Information Level----- |          |          | -----Alternative----- |         |
|                                             | Proportion                  | Actual   | N        | Lower                 | Upper   |
| 1                                           | 0.2500                      | 16.7817  | 48.33131 | -1.63862              | 1.63862 |

| 3                                           | 0.7500                      | 50.34511 | 144.9939 | -2.83817              | 2.83817 |
| 4                                           | 1.0000                      | 67.12682 | 193.3252 | -3.27724              | 3.27724 |

| Boundary Information (Standardized Z Scale) |                           |             |  |
|---------------------------------------------|---------------------------|-------------|--|
| Null Reference = 0                          |                           |             |  |
| _Stage_                                     | -----Boundary Values----- |             |  |
|                                             | ---Lower---               | ---Upper--- |  |
|                                             | Alpha                     | Alpha       |  |
| 1                                           | -4.04859                  | 4.04859     |  |
| 2                                           | -2.86278                  | 2.86278     |  |
| 3                                           | -2.33745                  | 2.33745     |  |
| 4                                           | -2.02429                  | 2.02429     |  |

The “Error Spending Information” in [Output 83.3.14](#) displays cumulative error spending at each stage for each boundary. With smaller  $\alpha$  spending in early stages for the O'Brien-Fleming method, it also indicates that the O'Brien-Fleming design is less likely to reject the null hypothesis in early stages than the Pocock design.

**Output 83.3.14** Error Spending Information

| Error Spending Information |                                   |                                     |         |                 |         |         |
|----------------------------|-----------------------------------|-------------------------------------|---------|-----------------|---------|---------|
| _Stage_                    | -Information Level-<br>Proportion | -----Cumulative Error Spending----- |         |                 |         |         |
|                            |                                   | -----Lower-----                     |         | -----Upper----- |         |         |

| 1                          | 0.2500                            | 0.00003                             | 0.00000 | 0.00000         | 0.00000 | 0.00003 |
| 2                          | 0.5000                            | 0.00211                             | 0.00000 | 0.00000         | 0.00000 | 0.00211 |
| 3                          | 0.7500                            | 0.01046                             | 0.00000 | 0.00000         | 0.00000 | 0.01046 |
| 4                          | 1.0000                            | 0.02500                             | 0.10000 | 0.10000         | 0.10000 | 0.02500 |

The “Sample Size Summary” table in [Output 83.3.15](#) displays the specified parameters for the sample size computation of the two-sample test for mean difference.

**Output 83.3.15** Sample Size Summary

| Sample Size Summary             |                  |
|---------------------------------|------------------|
| Test                            | Two-Sample Means |
| Mean Difference                 | 0.4              |
| Standard Deviation              | 0.8              |
| Max Sample Size                 | 193.3252         |
| Expected Sample Size (Null Ref) | 192.1081         |
| Expected Sample Size (Alt Ref)  | 145.1404         |
| Weight (Group A)                | 2                |
| Weight (Group B)                | 1                |

The “Sample Sizes (N)” table in [Output 83.3.16](#) displays the derived sample sizes at each stage, in both fractional and integer numbers. With the fixed-sample information ratio 1.0222, the required sample sizes in fractional numbers are derived by multiplying 1.0222 by the corresponding sample sizes in the fixed-sample design.

**Output 83.3.16** Derived Sample Sizes

| Sample Sizes (N)                      |        |          |          |             |
|---------------------------------------|--------|----------|----------|-------------|
| Two-Sample Z Test for Mean Difference |        |          |          |             |
| -----Fractional N-----                |        |          |          |             |

**Example 83.4: Generating Graphics Display for Sequential Designs**

This example creates the same group sequential design as in [Example 83.3](#) and creates graphics by using ODS Graphics. The following statements request all available graphs in the SEQDESIGN procedure:

```
ods graphics on;
proc seqdesign altref=0.4
 plots=all
 ;
 TwoSidedPocock: design nstages=4 method=poc;
 TwoSidedOBrienFleming: design nstages=4 method=obf;
run;
ods graphics off;
```

With the PLOTS=ALL option, a detailed boundary plot with the rejection region and acceptance region is displayed for the Pocock design, as shown in [Output 83.4.1](#). By default (or equivalently if you specify STOP=REJECT), the rejection boundaries are also generated at interim stages.

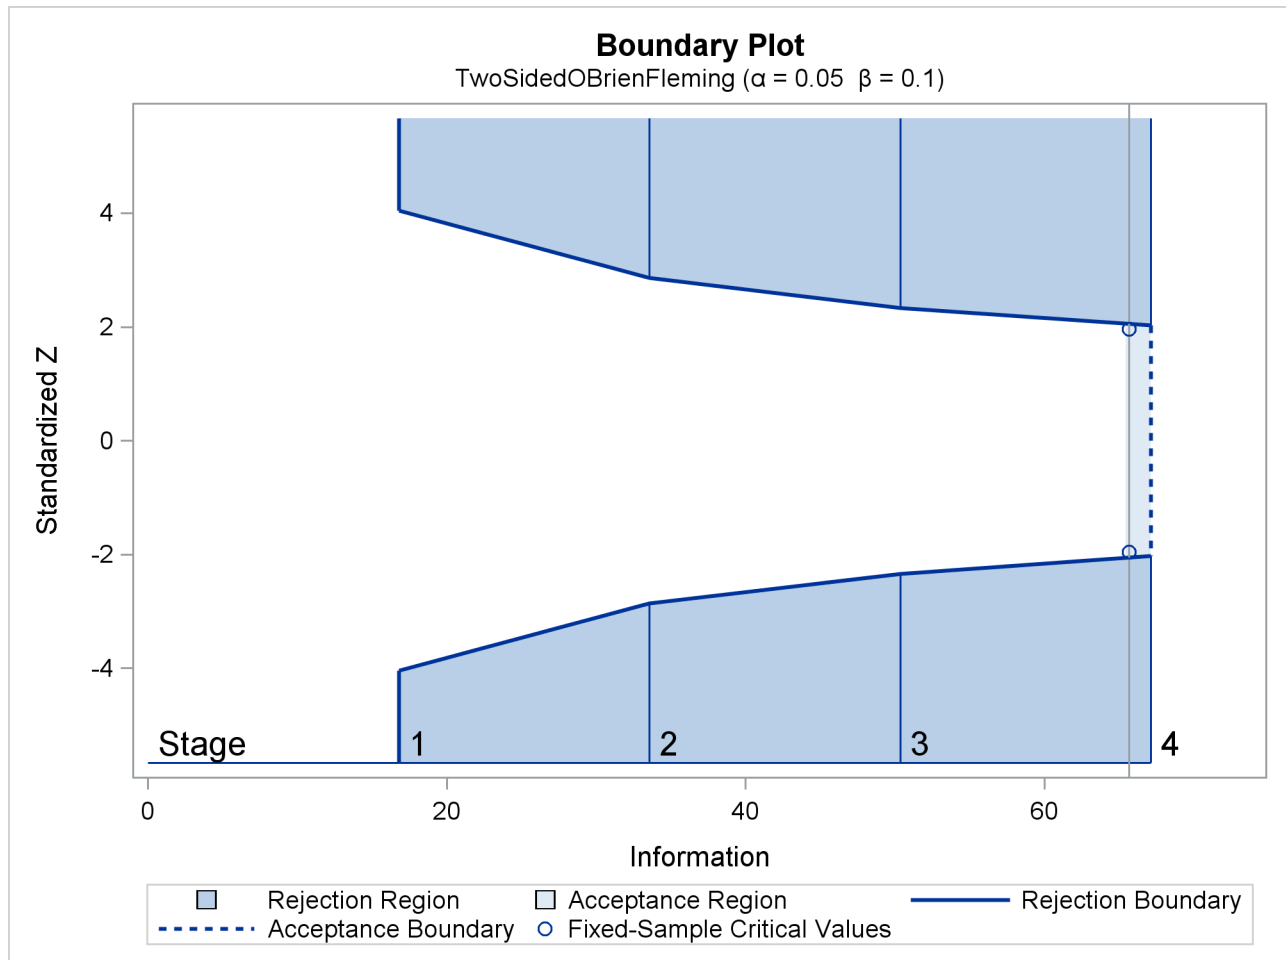

Output 83.4.1 Pocock Boundary Plot

The plot shows identical boundary values in each boundary in the standardized Z scale for the Pocock design. The information level and the critical value for the corresponding fixed-sample design are also displayed.

With the PLOTS=ALL option, a detailed boundary plot with the rejection region and acceptance region is also displayed for the O'Brien-Fleming design, as shown in Output 83.4.2. The plot shows that the rejection boundary values are decreasing as the trial advances in the standardized Z scale.

Output 83.4.2 O'Brien-Fleming Boundary Plot

With the PLOTS=ALL option, the procedure displays a plot of average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references for all designs simultaneously, as shown in Output 83.4.3. By default, the option CREF= 0, 0.01, 0.02, ..., 1.50 and expected sample sizes under the hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i$  are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

Output 83.4.3 ASN Plot

The plot shows that the Pocock design has a larger expected sample size than the O'Brien-Fleming design under the null hypothesis ( $c_i = 0$ ) and has a smaller expected sample size under the alternative hypothesis ( $c_i = 1$ ).

With the PLOTS=ALL option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in Output 83.4.4. By default, the option CREF=0, 0.01, 0.02, ..., 1.50 and powers under hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i$  are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

Output 83.4.4 Power Plot

Under the null hypothesis,  $c_i = 0$ , the power is 0.025, the upper Type I error probability. Under the alternative hypothesis,  $c_i = 1$ , the power is 0.9, one minus the Type II error probability. The plot shows only minor difference between the two designs.

With the PLOTS=ALL option, the procedure displays a plot of sequential boundaries for all designs simultaneously, as shown in [Output 83.4.5](#). By default (or equivalently if you specify HSCALE=INFO in the COMBINEDBOUNDARY option), the information levels are used on the horizontal axis.

**Output 83.4.5** Combined Boundary Plot

The plot shows that the  $\alpha$  boundary values (in absolute value) created from the O'Brien-Fleming method are greater in early stages and smaller in later stages than the boundary values from the Pocock method. The plot also shows that the information level in the Pocock design is larger than the corresponding level in the O'Brien-Fleming design at each stage.

With the PLOTS=ALL option, the procedure displays a plot of cumulative error spends for all boundaries in the designs simultaneously, as shown in [Output 83.4.6](#). With a symmetric two-sided design, cumulative error spending is displayed only for the upper  $\alpha$  boundary. The plot shows that for the upper  $\alpha$  boundary, the O'Brien-Fleming method spends fewer errors in early stages and more errors in later stages than the corresponding Pocock method.

Output 83.4.6 Error Spending Plot

### Example 83.5: Creating Designs Using Haybittle-Peto Methods

This example requests two 3-stage group sequential designs for normally distributed statistics. Each design uses a Haybittle-Peto method with a two-sided alternative and early stopping to reject the hypothesis. One design uses the specified interim boundary  $Z$  values and derives the final-stage boundary value for the specified  $\alpha$  and  $\beta$  errors. The other design uses the specified boundary  $Z$  values and derives the overall  $\alpha$  and  $\beta$  errors.

The following statements specify the interim boundary  $Z$  values and derive the final-stage boundary value for the specified  $\alpha = 0.05$  and  $\beta = 0.10$ :

```
ods graphics on;
proc seqdesign altref=0.25
 errspend
 stopprob
 plots=errspend
;
```

```

OneSidedPeto: design nstages=3
 method=peto(z=3)
 alt=upper stop=reject
 alpha=0.05 beta=0.10;

run;
ods graphics off;

```

The “Design Information” table in [Output 83.5.1](#) displays design specifications and maximum information in percentage of its corresponding fixed-sample design.

**Output 83.5.1** Haybittle-Peto Design Information

| The SEQDESIGN Procedure                   |                |

The “Boundary Information” table in [Output 83.5.4](#) displays information level, alternative references, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized  $Z$  scale is used to display the alternative references and boundary values. The resulting standardized alternative reference at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, 3$ .

**Output 83.5.4** Boundary Information

| Boundary Information (Standardized Z Scale) |                         |          |                        |                          |
|---------------------------------------------|-------------------------|----------|------------------------|--------------------------|
| Null Reference = 0                          |                         |          |                        |                          |
| _Stage_                                     | ---Information Level--- |          | -Alternative-          | -Boundary Values-        |
|                                             | Proportion              | Actual   | --Reference--<br>Upper | -----Upper-----<br>Alpha |
| 1                                           | 0.3333                  | 45.7864  | 1.69164                | 3.00000                  |
| 2                                           | 0.6667                  | 91.57281 | 2.39234                | 3.00000                  |
| 3                                           | 1.0000                  | 137.3592 | 2.93001                | 1.65042                  |

At each interim stage, if the standardized statistic  $z \geq 3$ , the trial is stopped and the null hypothesis is rejected. If the statistic  $z < 3$ , the trial continues to the next stage. At the final stage, the null hypothesis is rejected if the statistic  $z_3 > 1.65$ . Otherwise, the hypothesis is accepted. Note that the boundary values at the final stage, 1.65, are close to the critical values 1.645 in the corresponding fixed-sample design.

The “Error Spending Information” in [Output 83.5.5](#) displays cumulative error spending at each stage for each boundary. The stage 1  $\alpha$  spending 0.00135 corresponds to the one-sided  $p$ -value for a standardized  $Z$  statistic,  $Z > 3$ .

**Output 83.5.5** Error Spending Information

| Error Spending Information |                                   |                                                |         |  |
|----------------------------|-----------------------------------|------------------------------------------------|---------|--|
| _Stage_                    | -Information Level-<br>Proportion | -Cumulative Error Spending-<br>-----Upper----- |         |  |
|                            |                                   | Beta                                           | Alpha   |  |
| 1                          | 0.3333                            | 0.00000                                        | 0.00135 |  |
| 2                          | 0.6667                            | 0.00000                                        | 0.00246 |  |
| 3                          | 1.0000                            | 0.10000                                        | 0.05000 |  |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Output 83.5.6. With the STOP=REJECT option, the interim rejection boundaries are displayed.

**Output 83.5.6** Boundary Plot

With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in [Output 83.5.7](#). The error spending values in the “Error Spending Information” in [Output 83.5.4](#) are displayed in the plot. As expected, the error spending at each of the first two stages is small, with the standardized  $Z$  boundary value 3.

**Output 83.5.7** Error Spending Plot

The following statements specify the boundary  $Z$  values and derive the  $\alpha$  and  $\beta$  errors from these completely specified boundary values:

```
ods graphics on;
proc seqdesign altref=0.25
 maxinfo=200
 errspend
 stopprob
 plots=errspend
 ;
 OneSidedPeto: design nstages=3
 method=peto(z=3 2.5 2)
 alt=upper stop=reject
 boundarykey=none
 ;
run;
ods graphics off;
```

The “Design Information” table in [Output 83.5.8](#) displays design specifications and derived  $\alpha$  and  $\beta$  error levels.

**Output 83.5.8** Design Information

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.5.13](#). With the STOP=REJECT option, the interim rejection boundaries are displayed.

**Output 83.5.13** Boundary Plot

With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in [Output 83.5.14](#). The error spending values in the “Error Spending Information” table in [Output 83.5.10](#) are displayed in the plot.

Output 83.5.14 Error Spending Plot

### Example 83.6: Creating Designs with Various Stopping Criteria

This example requests three 5-stage group sequential designs for normally distributed statistics. Each design uses a triangular method with the specified one-sided upper alternative reference  $\theta_1 = 0.2$ . The resulting boundary values are displayed with the score scale. Note that these unified family triangular designs are different from Whitehead's triangular designs.

The following statements request three designs with different stopping criterion:

```
ods graphics on;
proc seqdesign altref=0.2

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.6.5](#). With the STOP=BOTH option, both the acceptance and rejection boundaries at interim stages are displayed. With the score scale, the acceptance and rejection boundaries are straight lines and form a triangular-shape continuation region.

**Output 83.6.5** Boundary Plot with Score Statistics

The second design has early stopping only to reject the null hypothesis  $H_0$ .

The “Design Information” table in [Output 83.6.6](#) displays design specifications and derived statistics. With the specified alternative reference, the maximum information is derived.

**Output 83.6.6** Triangular Design Information

| The SEQDESIGN Procedure                   |             |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.6.15](#). For a triangular design, these rejection boundaries form a straight line with the score scale.

**Output 83.6.15** Boundary Plot with Score Scale

With the PLOTS=COMBINEDBOUNDARY option, a plot of the resulting sequential boundaries for all designs is displayed, as shown in [Output 83.6.16](#). The plot shows that the design with early stopping to reject and to accept  $H_0$  has larger maximum information than the other two designs.

**Output 83.6.16** Combined Boundary Plot with Score Scale

With the `PLOTS=ERRSPEND(HSCALE=INFO)` option, the error spending plot is displayed with the information level on the horizontal axis, as shown in [Output 83.6.17](#). The design with early stopping to reject or accept the null hypothesis  $H_0$  has larger  $\alpha$  spending and larger  $\beta$  spending in early stages than the other two designs.

**Output 83.6.17** Error Spending Plot

### Example 83.7: Creating Whitehead's Triangular Designs

This example requests three 4-stage Whitehead's triangular designs for normally distributed statistics. Each design has a one-sided alternative hypothesis with early stopping to reject or accept the null hypothesis  $H_0$ . Note that Whitehead's triangular designs are different from unified family triangular designs.

Suppose that a clinic is conducting a study of the effect of a new cancer treatment. The study consists of exposing mice to a carcinogen and randomly assigning them to either the control group or the treatment group. The event of interest is death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Following the derivations in the section "Test for Two Survival Distributions with a Log-Rank Test" on page 7059, the hypothesis  $H_0 : \theta = -\log(\lambda) = 0$  with an alternative hypothesis  $H_1 : \theta = \theta_1 > 0$  is used, where  $\lambda$  is the hazard ratio between the treatment group and the control group.

Also suppose that from past experience, the median survival time for the control group is  $t_0 = 20$  weeks, and the study wants to detect a  $t_1 = 40$  weeks' median survival time with a 80% power in the trial. Assuming exponential survival functions for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where  $j = 0, 1$ .

Thus, with  $h_0 = 0.03466$  and  $h_1 = 0.01733$ , the hazard ratio  $\lambda_1 = h_1/h_0 = 1/2$ , and the alternative reference is

$$\theta_1 = -\log(\lambda_1) = -\log\left(\frac{1}{2}\right) = 0.693147$$

The following statements invoke the SEQDESIGN procedure and specify three Whitehead's triangular designs:

```
ods graphics on;
proc seqdesign altref=0.693147
 bscale=score
 plots=combinedboundary
 ;
 BoundaryKeyNone: design nstages=4
 method=whitehead
 boundarykey=none
 alt=upper stop=both
 alpha=0.05 beta=0.20
 ;
 BoundaryKeyAlpha: design nstages=4
 method=whitehead
 boundarykey=alpha
 alt=upper stop=both
 alpha=0.05 beta=0.20
 ;
```

```

BoundaryKeyBeta: design nstages=4
 method=whitehead
 boundarykey=beta
 alt=upper stop=both
 alpha=0.05 beta=0.20
 ;

run;
ods graphics off;

```

Whitehead methods with early stopping to reject or accept the null hypothesis create boundaries that approximately satisfy the Type I and Type II error probability specification. The BOUNDARYKEY=NONE option specifies no adjustment to the boundary value at the final stage to maintain either a Type I or a Type II error probability level.

The “Design Information” table in [Output 83.7.1](#) displays design specifications and maximum information. Note that with the BOUNDARYKEY=NONE option, the derived errors  $\alpha = 0.05071$  and  $\beta = 0.19771$  are not the same as the specified errors  $\alpha = 0.05$  and  $\beta = 0.20$ .

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.7.8](#).

**Output 83.7.8** Boundary Plot

The third design specifies the BOUNDARYKEY=BETA option to derive the boundary values to maintain the Type II error probability level  $\beta$ .

The “Design Information” table in Output 83.7.9 displays design specifications and the derived maximum information. Note that with the BOUNDARYKEY=BETA option, the specified Type II error probability  $\beta = 0.20$  is maintained.

**Output 83.7.9** Whitehead Design Information

| 4                                  | 1.0000                 | 16.70639 | 11.57998               | 7.78899                   | 7.78899 |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.7.12](#).

**Output 83.7.12** Boundary Plot

With the PLOTS=COMBINEDBOUNDARY option, a combined plot of group sequential boundaries for all designs is displayed, as shown in [Output 83.7.13](#). It shows that three designs are similar, with a slightly smaller boundary value at the final stage for the design with the BOUNDARYKEY=NONE option.

**Output 83.7.13** Combined Boundary Plot

The following statements invoke the SEQDESIGN procedure and specify the SAMPLESIZE statement to derive required sample sizes for a log-rank test comparing two survival distributions for the treatment effect (Jennison and Turnbull 2000, pp. 77–79; Whitehead 1997, pp. 36–39):

```
proc seqdesign altref=0.693147
 bscale=score
 ;
 BoundaryKeyAlpha: design nstages=4
 method=whitehead
 boundarykey=alpha
 alt=upper stop=both
 alpha=0.05 beta=0.20
 ;
 samplesize model=twosamplesurvival
 (nullhazard=0.03466 accrate=10);
run;
```

The design is identical to the previous design with the BOUNDARYKEY=ALPHA option except with the addition of the sample size computation.

The “Sample Size Summary” table in [Output 83.7.14](#) displays parameters for the sample size computation. Since the ACCTIME= option is not specified for the accrual time, the minimum and maximum accrual times are derived for the specified accrual rate.

**Output 83.7.14** Sample Size Summary

| The SEQDESIGN Procedure  |                     |          |
|--------------------------|---------------------|----------|
| Design: BoundaryKeyAlpha |                     |          |
| Sample Size Summary      |                     |          |
| Test                     | Two-Sample Survival |          |
| Null Hazard Rate         |                     | 0.03466  |
| Hazard Rate (Group A)    |                     | 0.01733  |
| Hazard Rate (Group B)    |                     | 0.03466  |
| Hazard Ratio             |                     | 0.5      |
| log(Hazard Ratio)        |                     | -0.69315 |
| Reference Hazards        |                     | Alt Ref  |
| Accrual                  |                     | Uniform  |
| Accrual Rate             |                     | 10       |
| Min Accrual Time         |                     | 6.682556 |
| Min Sample Size          |                     | 66.82556 |
| Max Accrual Time         |                     | 25.40111 |
| Max Sample Size          |                     | 254.0111 |
| Max Number of Events     |                     | 66.82556 |

If the ACCTIME=20 option is specified in the SAMPLESIZE statement, the “Sample Size Summary” table in [Output 83.7.15](#) also displays the follow-up time and maximum sample size with the specified accrual time.

**Output 83.7.15** Sample Size Summary

The “Number of Events (D) and Sample Sizes (N)” table in [Output 83.7.16](#) displays the required time at each stage, in both fractional and integer numbers. The derived times under the heading “Fractional Time” are not integers. These times are rounded up to integers under the heading “Ceiling Time.” The table also displays the numbers of events and sample sizes at each stage.

**Output 83.7.16** Number of Events and Sample Sizes

### Example 83.8: Creating a One-Sided Error Spending Design

This example requests a five-stage, one-sided group sequential design for normally distributed statistics. The design uses an O’Brien-Fleming-type error spending function for the  $\alpha$  boundary and a Pocock-type error spending function for the  $\beta$  boundary. The following statements request a one-sided design by using different  $\alpha$  and  $\beta$  spending functions:

```
ods graphics on;
proc seqdesign altref=0.2 errspend
 pss(cref=0 0.5 1)
 stopprob(cref=0 0.5 1)
 plots=(asn power errspend)
 ;
 OneSidedErrorSpending: design nstages=5
 method(alpha)=errfuncobf
 method(beta)=errfuncpoc
 alt=upper stop=both
 alpha=0.025
 ;
run;
ods graphics off;
```

The “Design Information” table in [Output 83.8.1](#) displays design specifications and the derived statistics. With the specified alternative reference, the maximum information is derived.

**Output 83.8.1** Error Spending Method Design Information

| The SEQDESIGN Procedure                   |                    |

With the PSS option, the “Power and Expected Sample Sizes” table in [Output 83.8.4](#) displays powers and expected sample sizes under various hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i = 0, 0.5, 1, 1.5$  are the default values in the CREF= option.

**Output 83.8.4** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes<br>Reference = CRef * (Alt Reference) |         |                                          |
|------------------------------------------------------------------------|---------|------------------------------------------|
| CRef                                                                   | Power   | -Sample Size-<br>Percent<br>Fixed-Sample |
| 0.0000                                                                 | 0.02500 | 50.3541                                  |
| 0.5000                                                                 | 0.38724 | 78.7219                                  |
| 1.0000                                                                 | 0.90000 | 78.7722                                  |

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in [Output 83.8.5](#). By default, expected sample sizes under the hypotheses  $\theta = c_i \theta_1$ ,  $c_i = 0, 0.01, 0.02, \dots, 1.50$ , are displayed, where  $\theta_1$  is the alternative reference.

**Output 83.8.5** ASN Plot

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in [Output 83.8.6](#). By default, the option CREF= 0, 0.01, 0.02, . . . , 1.50 and powers under hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i$  are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

Under the null hypothesis,  $c_i = 0$ , the power is 0.025, the upper Type I error probability. Under the alternative hypothesis,  $c_i = 1$ , the power is 0.9, one minus the Type II error probability. The plot shows only minor difference between the two designs.

**Output 83.8.6** Power Plot

The “Boundary Information” table in [Output 83.8.7](#) displays information level, alternative reference, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized Z scale. That is, the resulting standardized alternative reference at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the specified alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, \dots, 5$ .

**Output 83.8.7** Boundary Information

| Boundary Information (Standardized Z Scale) |                         |          |                        |                           |         |
|---------------------------------------------|-------------------------|----------|------------------------|---------------------------|---------|
| Null Reference = 0                          |                         |          |                        |                           |         |
| _Stage_                                     | ---Information Level--- |          | -Alternative-          | -----Boundary Values----- |         |

| 4                          | 0.8000                            | 0.08648                     | 0.01221                  |  |
| 5                          | 1.0000                            | 0.10000                     | 0.02500                  |  |

With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in [Output 83.8.10](#). This plot displays the cumulative error spending at each stage in the “Error Spending Information” table in [Output 83.8.9](#). The O’Brien-Fleming-type  $\alpha$  spending function is conservative in early stages because it uses much less at early stages than in the later stages. In contrast, the Pocock-type  $\beta$  spending function uses more at early stages than in the later stages.

Output 83.8.10 Error Spending Plot

### Example 83.9: Creating Designs with Various Number of Stages

This example requests three group sequential designs for normally distributed statistics. Each design uses the power family error spending function with the default power parameter  $\rho = 2$ . The specified error spending method is between the approximated Pocock method ( $\rho = 1$ ) and the approximated O'Brien-Fleming method ( $\rho = 3$ ) (Jennison and Turnbull 2000, p. 148). The three designs are identical except for the specified number of stages. The following statements request these three group sequential designs:

```
ods graphics on;
proc seqdesign plots=(asn
 power
 combinedboundary
 errspend(hscale=info)
)
;
TwoStageDesign: design nstages=2
 method=errfuncpow
 alt=upper stop=reject
;
FiveStageDesign: design nstages=5
 method=errfuncpow
 alt=upper stop=reject
;
TenStageDesign: design nstages=10
 method=errfuncpow
 alt=upper stop=reject
;
run;
ods graphics off;
```

The “Design Information” table in [Output 83.9.1](#) displays design information for the two-stage design.

**Output 83.9.1** Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|
| Design: TwoStageDesign                    |                |
| Design Information                        |                |
| Statistic Distribution                    | Normal         |
| Boundary Scale                            | Standardized Z |
| Alternative Hypothesis                    | Upper          |
| Early Stop                                | Reject Null    |
| Method                                    | Error Spending |
| Boundary Key                              | Both           |
| Number of Stages                          | 2              |
| Alpha                                     | 0.05           |
| Beta                                      | 0.1            |
| Power                                     | 0.9            |
| Max Information (Percent of Fixed Sample) | 102.4167       |
| Null Ref ASN (Percent of Fixed Sample)    | 101.7766       |
| Alt Ref ASN (Percent of Fixed Sample)     | 79.81021       |

The “Boundary Information” table in [Output 83.9.2](#) displays the information level, alternative reference, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized normal Z scale. The resulting standardized alternative reference at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2$ .

**Output 83.9.2** Boundary Information in Z Scale

| Boundary Information (Standardized Z Scale) |                                           |                                                  |                                                        |
|---------------------------------------------|-------------------------------------------|--------------------------------------------------|--------------------------------------------------------|
| Null Reference = 0                          |                                           |                                                  |                                                        |
| <u>_Stage_</u>                              | <u>-Information Level-<br/>Proportion</u> | <u>-Alternative-<br/>--Reference--<br/>Upper</u> | <u>-Boundary Values-<br/>-----Upper-----<br/>Alpha</u> |
| 1                                           | 0.5000                                    | 2.09414                                          | 2.24140                                                |
| 2                                           | 1.0000                                    | 2.96156                                          | 1.69970                                                |

The “Design Information” table in [Output 83.9.3](#) displays design information for the five-stage design. Compared with the two-stage design in [Output 83.9.1](#), the maximum information increases from 102.42 to 105.62, and the average sample number under the alternative reference (Alt Ref ASN) decreases from 79.81 to 69.64.

**Output 83.9.3** Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|

| 8                                           | 0.8000                                    | 2.71076                                          | 2.04503                                                |
| 9                                           | 0.9000                                    | 2.87519                                          | 1.94355                                                |
| 10                                          | 1.0000                                    | 3.03072                                          | 1.84765                                                |

With the PLOTS=ASN option, the procedure displays a plot of average sample numbers under various hypothetical references for all designs simultaneously, as shown in [Output 83.9.7](#). By default, the option CREF= 0, 0.01, 0.02, . . . , 1.50 and expected sample sizes under the hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i$  are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

Output 83.9.7 ASN Plot

The plot shows that as the number of stages increases, the average sample number as a percentage of the fixed-sample design increases under the null hypothesis ( $c_i = 0$ ) but decreases under the alternative hypothesis ( $c_i = 1$ ).

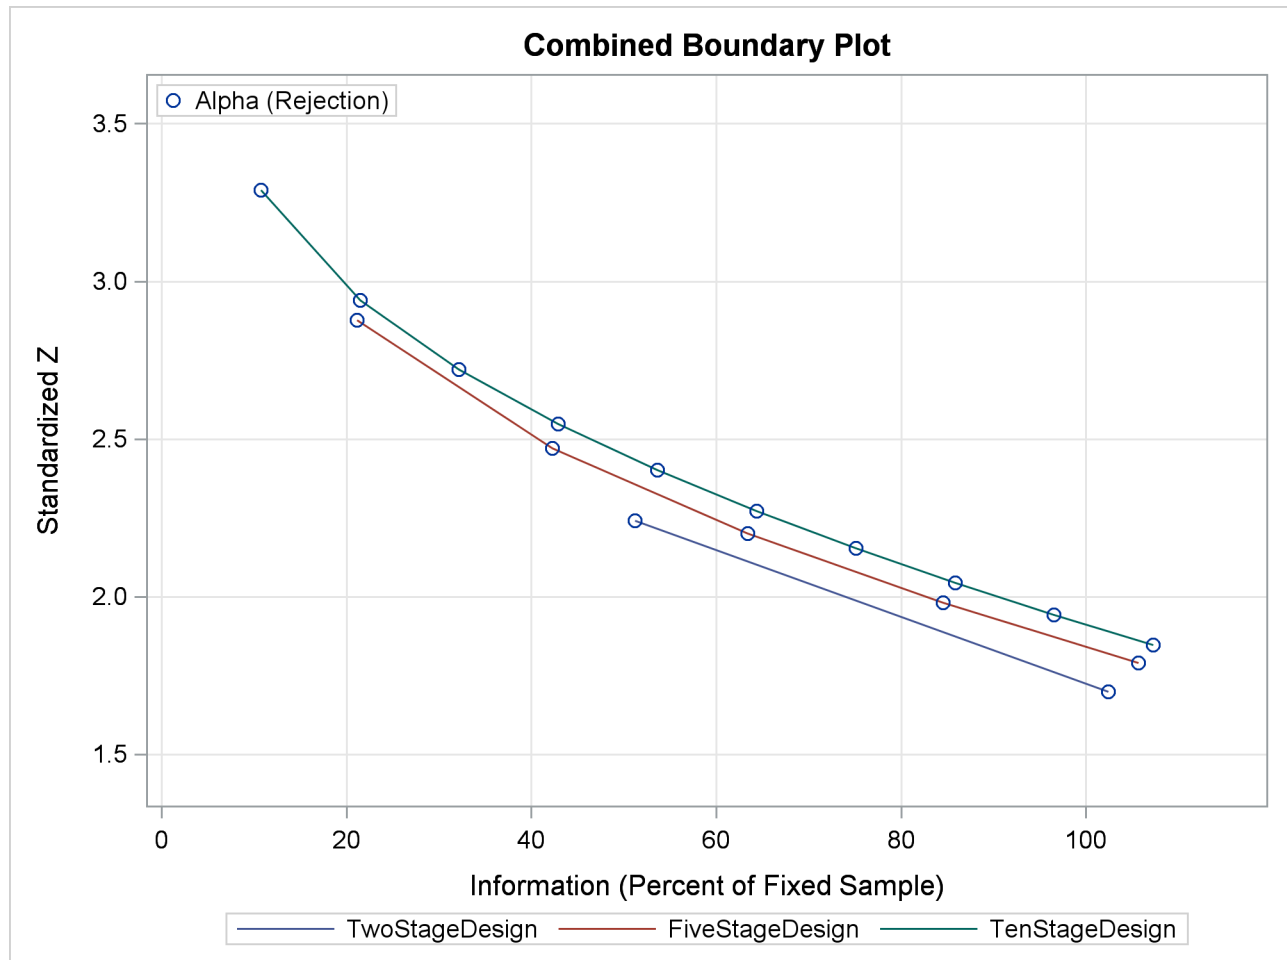

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in [Output 83.9.8](#). By default, the option CREF= 0, 0.01, 0.02, ..., 1.50 and powers under hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i$  are values specified in the CREF= option. These CREF= values are displayed on the horizontal axis.

Output 83.9.8 Power Plot

Under the null hypothesis,  $c_i = 0$ , the power is 0.05, the upper Type I error probability. Under the alternative hypothesis,  $c_i = 1$ , the power is 0.9, one minus the Type II error probability. The plot shows only minor difference among the three designs.

With the `PLOTS=COMBINEDBOUNDARY` option, the procedure displays a plot of sequential boundaries for all designs simultaneously, as shown in [Output 83.9.9](#). By default (or equivalently if you specify `COMBINEDBOUNDARY(HSCALE=INFO)`), the information levels are used on the horizontal axis. Since the maximum information is not available for the design, the percent information ratios with respect to the corresponding fixed-sample design are displayed in the plot.

**Output 83.9.9** Combined Boundary Plot

The plot shows that as the number of stages increases, the maximum information increases and the  $\alpha$  boundary values also increase.

With the PLOTS=ERRSPEND(HSCALE=INFO) option, the procedure displays a plot of cumulative error spends for all boundaries in the designs simultaneously, as shown in [Output 83.9.10](#).

**Output 83.9.10** Error Spending Plot

The plot shows similar error spending for these three designs since all three designs are generated from the same power family error spending function.

### Example 83.10: Creating Two-Sided Error Spending Designs with and without Overlapping Lower and Upper $\beta$ Boundaries

This example requests two three-stage group sequential designs for normally distributed statistics. Each design uses a power family error spending function with a specified two-sided alternative hypothesis  $H_1 : \theta_1 = \pm 0.2$  and early stopping only to accept the null hypothesis  $H_0$ .

The first design uses the BETAOVERLAP=NOADJUST option to derive acceptance boundary values without adjusting for the possible overlapping of the lower and upper  $\beta$  boundaries computed from the two corresponding one-sided tests. The second design uses the BETAOVERLAP=ADJUST option to test the overlapping of the  $\beta$  boundaries at each interim stage based on the two corresponding one-sided tests and then to set the  $\beta$  boundary values at the stage to missing if overlapping occurs at that stage.

The following statements request a two-sided design with the BETAOVERLAP=NOADJUST option:

```
ods graphics on;
proc seqdesign altref=0.2 errspend;
 design nstages=3
 method=errfuncpow
 alt=twosided stop=accept
 betaoverlap=noadjust
 beta=0.09
 ;
run;
ods graphics off;
```

The “Design Information” table in Output 83.10.1 displays design specifications and the derived statistics for the first design. With the specified alternative reference  $\theta_1 = 0.2$ , the maximum information is derived.

**Output 83.10.1** Design Information

The “Boundary Information” table in [Output 83.10.2](#) displays the information level, alternative reference, and boundary values. With a specified alternative reference  $\theta_1$ , the maximum information is derived from the procedure, and the actual information level at each stage is displayed in the table. By default (or equivalently if you specify `BOUNDARYSCALE=STDZ`), the alternative reference and boundary values are displayed with the standardized Z scale. The alternative reference at stage  $k$  is given by  $\theta_1\sqrt{I_k}$ , where  $\theta_1$  is the specified alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, 3$ .

**Output 83.10.2** Boundary Information

| Boundary Information (Standardized Z Scale) |                       |          |                       |                     |                         |             |

| 2                          | 0.6667              |  | 0.00000                             | 0.04000 | 0.04000         | 0.00000 |
| 3                          | 1.0000              |  | 0.02500                             | 0.09000 | 0.09000         | 0.02500 |

With the `STOP=ACCEPT` option, the design does not stop at interim stages to reject  $H_0$ , and the  $\alpha$  spending at each interim stage is zero. For the power family error spending function with the default parameter  $\rho = 2$ , the beta spending at stage 1 is  $(1/3)^\rho \beta = (1/3)^2 0.09 = 0.01$ , and the cumulative beta spending at stage 2 is  $(2/3)^\rho \beta = (2/3)^2 0.09 = 0.04$ .

With ODS Graphics enabled, a detailed boundary plot with the acceptance and rejection regions is displayed, as shown in [Output 83.10.4](#).

Output 83.10.4 Boundary Plot

The following statements request a two-sided design with the BETAOVERLAP=ADJUST option, which is the default:

```
ods graphics on;
proc seqdesign altref=0.2 errspend;
 design nstages=3
 method=errfuncpow
 alt=twosided
 stop=accept
 betaoverlap=adjust
 beta=0.09
 ;
run;
ods graphics off;
```

With the BETAOVERLAP=ADJUST option, the procedure first derives the usual  $\beta$  boundary values for the two-sided design and then checks for overlapping of the  $\beta$  boundaries for the two corresponding one-sided tests at each stage. If this type of overlapping occurs at a particular stage, the  $\beta$  boundary values for that stage are set to missing, the  $\beta$  spending values at that stage are reset to zero, and the  $\beta$  spending values at subsequent stages are adjusted proportionally.

The boundary values without adjusting for the possible overlapping of the two one-sided  $\beta$  boundaries are identical to the boundary values derived in the first design (with the BETAOVERLAP=NOADJUST option, as shown in Output 83.10.2). At stage 1, the upper  $\beta$  boundary value for the corresponding one-sided test is

$$\theta_1 \sqrt{I_1} - \Phi^{-1}(1 - \beta_1) = 0.2 \sqrt{94.31094} - \Phi^{-1}(0.99) = 1.94228 - 2.32635 = -0.38407$$

where  $\theta_1 = 0.2$  is the upper alternative reference,  $I_1 = 94.31094$  is the information level at stage 1, and  $\beta_1 = 0.01$  is the  $\beta$  spending at stage 1 (as shown in Output 83.10.3).

Similarly, the lower  $\beta$  boundary value for the corresponding one-sided test is computed as 0.38407. Since the upper  $\beta$  boundary value is less than the lower  $\beta$  boundary at stage 1, overlapping occurs, and so the  $\beta$  boundary values for the two-sided design are set to missing at stage 1.

With the  $\beta$  boundary values set to missing at stage 1 and the  $\beta$  spending  $\beta'_1 = 0$  the  $\beta$  spending values at subsequent interim stages are adjusted proportionally. In this example, the adjusted  $\beta$  spending at stage 2 is computed as

$$\beta'_2 = \beta'_1 + \frac{\beta_2 - \beta_1}{\beta_3 - \beta_1} (\beta_3 - \beta'_1) = 0 + \frac{0.04 - 0.01}{0.09 - 0.01} 0.09 = 0.03375$$

where  $\beta_k$  is the cumulative  $\beta$  spending at stage  $k$  before the adjustment,  $k = 1, 2, 3$ .

The “Design Information” table in Output 83.10.5 displays design specifications and derived statistics for the design.

With ODS Graphics enabled, a detailed boundary plot with the acceptance and rejection regions is displayed, as shown in [Output 83.10.8](#).

Output 83.10.8 Boundary Plot

### Example 83.11: Creating a Two-Sided Asymmetric Error Spending Design with Early Stopping to Reject $H_0$

This example requests a three-stage two-sided asymmetric group sequential design for normally distributed statistics.

The O'Brien-Fleming boundary can be approximated using a power family error spending function with parameter  $\rho = 3$ , and the Pocock boundary can be approximated using a power family error spending function with parameter  $\rho = 1$  (Jennison and Turnbull 2000, p. 148). The following statements use the power family error spending function to create a two-sided asymmetric design with early stopping to reject the null hypothesis  $H_0$ :

```
ods graphics on;
proc seqdesign altref=1.0
 pss(cref=0 0.5 1)
 stopprob(cref=0 0.5 1)
 errspend
 plots=(asn power errspend)
;

TwoSidedErrorSpending: design nstages=3
 method(upperalpha)=errfuncpow(rho=3)
 method(loweralpha)=errfuncpow(rho=1)
 info=cum(2 3 4)
 alt=twosided
 stop=reject
 alpha=0.075(upper=0.025)
;

run;
ods graphics off;
```

The design uses power family error spending functions with  $\rho = 1$  for the lower  $\alpha$  boundary and  $\rho = 3$  for the upper  $\alpha$  boundary. Thus, the design is conservative in the early stages and tends to stop the trials early only with a small  $p$ -value for the upper  $\alpha$  boundary. The upper  $\alpha$  level 0.025 is specified explicitly, and the lower  $\alpha$  level is computed as  $0.075 - 0.025 = 0.05$ .

The “Design Information” table in [Output 83.11.1](#) displays design specifications and the derived maximum information. Note that in order to attain the same information level for the asymmetric lower and upper boundaries, the derived power at the lower alternative 0.92963 is larger than the default 0.90.

**Output 83.11.1** Design Information

The “Method Information” table in [Output 83.11.2](#) displays the specified  $\alpha$  and  $\beta$  error levels and the derived drift parameter. With the same information level used for the asymmetric lower and upper boundaries, only one of the  $\beta$  levels is maintained, and the other is derived to have the level less than or equal to the default level.

**Output 83.11.2** Method Information

| Method Information |                |                          |          |                                    |

With the STOPPROB(CREF=0 0.5 1) option, the “Expected Cumulative Stopping Probabilities” table in **Output 83.11.3** displays the expected stopping stage and cumulative stopping probability to reject the null hypothesis  $H_0$  at each stage under hypothetical references  $\theta = 0$  (null hypothesis  $H_0$ ),  $\theta = 0.5\theta_1$ , and  $\theta = \theta_1$  (alternative hypothesis  $H_1$ ), where  $\theta_1$  is the alternative reference.

| 1.0000                                     | Upper Alt | 0.33927                        | 0.69357 | 0.90001 |

“Rej Null (Lower Alt)” and “Rej Null (Upper Alt)” under the heading “Source” indicate the probabilities of rejecting the null hypothesis for the lower alternative and for the upper alternative, respectively. “Reject Null” indicates the probability of rejecting the null hypothesis for either the lower or upper alternative.

Note that with the STOP=REJECT option, the cumulative stopping probability of accepting the null hypothesis  $H_0$  at each interim stage is zero and is not displayed.

With the PSS(CREF=0.5 1.0) option, the “Power and Expected Sample Sizes” table in [Output 83.11.4](#) displays powers and expected sample sizes under hypothetical references  $\theta = 0$  (null hypothesis  $H_0$ ),  $\theta = 0.5\theta_1$ , and  $\theta = \theta_1$  (alternative hypothesis  $H_1$ ), where  $\theta_1$  is the alternative reference. The expected sample sizes are displayed in a percentage scale relative to the corresponding fixed-sample size design.

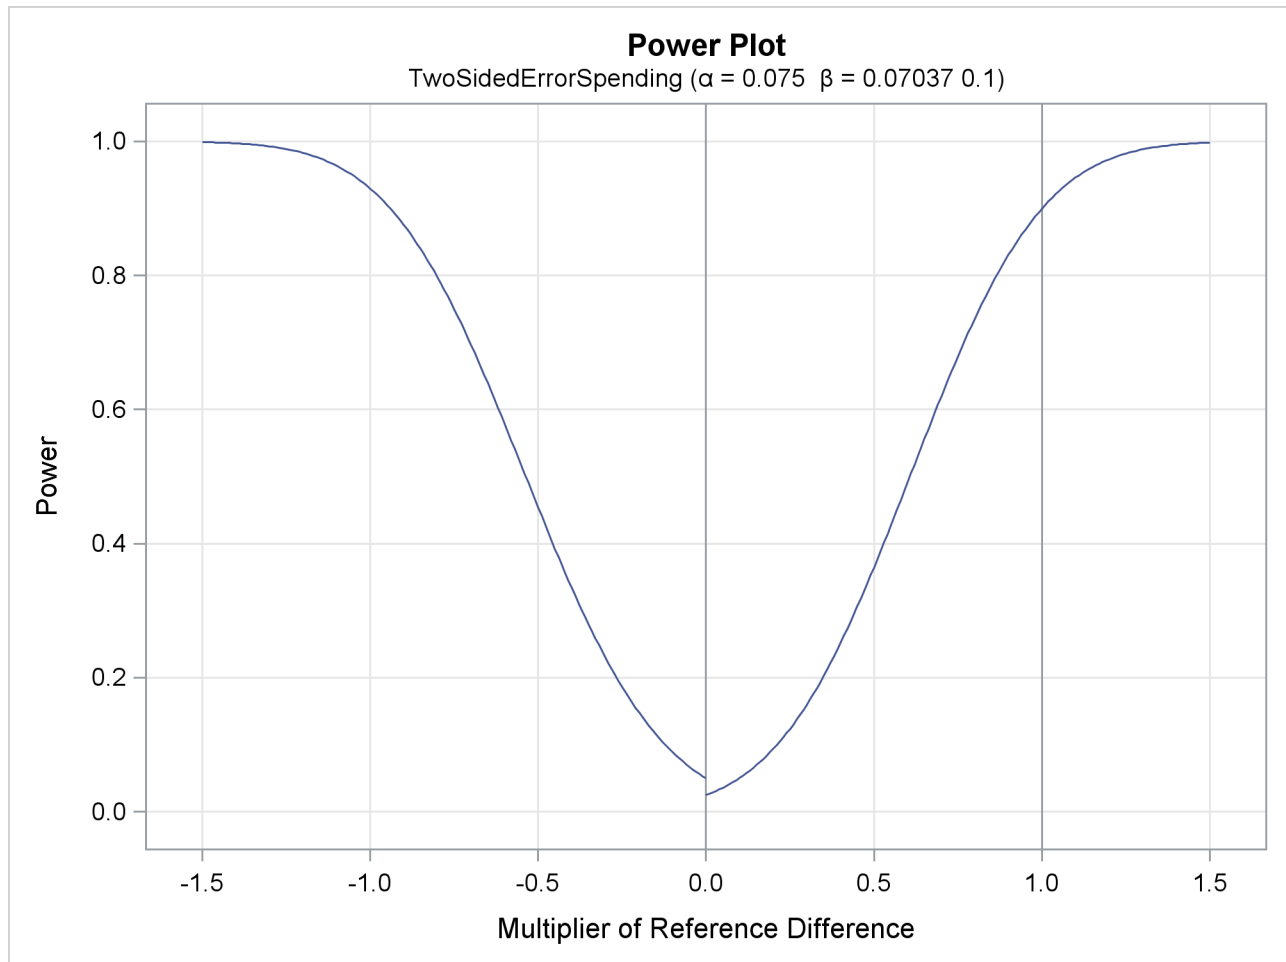

**Output 83.11.4** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes   |           |         |                                          |

| Reference = CRef * (Alt Reference) |           |         |                                          |
| CRef                               | Ref       | Power   | -Sample Size-<br>Percent<br>Fixed-Sample |
| 0.0000                             | Lower Alt | 0.05000 | 100.4877                                 |
| 0.5000                             | Lower Alt | 0.45370 | 88.5090                                  |
| 1.0000                             | Lower Alt | 0.92963 | 64.8288                                  |
| 0.0000                             | Upper Alt | 0.02500 | 100.4877                                 |
| 0.5000                             | Upper Alt | 0.36458 | 96.2309                                  |
| 1.0000                             | Upper Alt | 0.90000 | 75.9878                                  |

Note that at  $c_i = 0$ , the null reference  $\theta = 0$ , the power with the lower alternative is the lower  $\alpha$  error 0.05, and the power with the upper alternative is the upper  $\alpha$  error 0.025. At  $c_i = 1$ , the alternative reference  $\theta = \theta_1$ , the power with the upper alternative is the specified power 0.90, and the power with the lower alternative 0.92963 is greater than the specified power 0.90 because the same information level is used for these two asymmetric boundaries.

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references, as shown in [Output 83.11.5](#). By default, powers under the lower hypotheses  $\theta = c_i\theta_{1l}$  and under the upper hypotheses  $\theta = c_i\theta_{1u}$  are displayed for a two-sided asymmetric design, where  $c_i = 0, 0.01, 0.02, \dots, 1.50$  and  $\theta_{1l} = -1$  and  $\theta_{1u} = 1$  are the lower and upper alternative references, respectively.

Output 83.11.5 Power Plot

The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to  $c_i$  for the upper alternative hypothesis, and a negative multiplier corresponds to  $-c_i$  for the lower alternative hypothesis. For lower reference hypotheses, the power is the lower  $\alpha$  error 0.05 under the null hypothesis ( $c_i = 0$ ) and is 0.92963 under the alternative hypothesis ( $c_i = 1$ ). For upper reference hypotheses, the power is the upper  $\alpha$  error 0.025 under the null hypothesis ( $c_i = 0$ ) and is 0.90 under the alternative hypothesis ( $c_i = 1$ ).

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in [Output 83.11.6](#). By default, expected sample sizes under the lower hypotheses  $\theta = c_i \theta_{1l}$  and under the upper hypotheses  $\theta = c_i \theta_{1u}$ ,  $c_i = 0, 0.01, 0.02, \dots, 1.50$ , are displayed for a two-sided asymmetric design, where  $\theta_{1l} = -1$  and  $\theta_{1u} = 1$  are the lower and upper alternative references, respectively.

**Output 83.11.6** ASN Plot

The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to  $c_i$  for the upper alternative hypothesis and a negative multiplier corresponds to  $-c_i$  for the lower alternative hypothesis.

The “Boundary Information” table in [Output 83.11.7](#) displays the information levels, alternative references, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized  $Z$  scale is used to display the alternative references and boundary values. The resulting standardized alternative references at stage  $k$  are given by  $\pm\theta_1\sqrt{I_k}$ , where  $\theta_1$  is the specified alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, 3$ .

**Output 83.11.7** Boundary Information

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.11.8](#).

**Output 83.11.8** Boundary Plot

The “Error Spending Information” table in [Output 83.11.9](#) displays the cumulative error spending at each stage for each boundary.

**Output 83.11.9** Error Spending Information

| _Stage_ | -Information Level-<br>Proportion | -----Cumulative Error Spending----- |         |                 |         |
|---------|-----------------------------------|-------------------------------------|---------|-----------------|---------|
|         |                                   | -----Lower-----                     |         | -----Upper----- |         |
|         |                                   | Alpha                               | Beta    | Beta            | Alpha   |
| 1       | 0.5000                            | 0.02500                             | 0.00000 | 0.00001         | 0.00313 |
| 2       | 0.7500                            | 0.03750                             | 0.00000 | 0.00001         | 0.01055 |
| 3       | 1.0000                            | 0.05000                             | 0.07037 | 0.10000         | 0.02500 |

With the STOP=REJECT option, there is no early stopping to accept  $H_0$ , and the corresponding  $\beta$  spending at an interim stage is computed from the rejection region. For example, the upper  $\beta$  spending at stage 1 (0.00001) is the probability of rejecting  $H_0$  for the lower alternative under the upper alternative reference.

With the PLOTS=ERRSPEND option, the procedure displays a plot of the cumulative error spending on each boundary at each stage, as shown in Output 83.11.10.

**Output 83.11.10** Error Spending Plot

### Example 83.12: Creating a Two-Sided Asymmetric Error Spending Design with Early Stopping to Reject or Accept $H_0$

This example requests a four-stage two-sided asymmetric group sequential design for normally distributed statistics. The O'Brien-Fleming boundary can be approximated by a gamma family error spending function with parameter  $\gamma = -4$  or  $-5$ , and the Pocock boundary can be approximated with parameter  $\gamma = 1$  (Hwang, Shih, and DeCani 1990, p. 1440). The following statements use the gamma error spending function with early stopping to reject or accept the null hypothesis  $H_0$ :

```
ods graphics on;
proc seqdesign altref=2
 pss(cref=0 0.5 1)
 stopprob(cref=0 1)
 errspend
 plots=(asn power errspend)
 ;
TwoSidedAsymmetric: design nstages=4
 method=errfuncgamma(gamma=1)
 method(beta)=errfuncgamma(gamma=-2)
 method(upperalpha)=errfuncgamma(gamma=-5)
 alt=twosided
 stop=both
 beta=0.1
 ;
run;
ods graphics off;
```

The design uses gamma family error spending functions with  $\gamma = -5$  for the upper  $\alpha$  boundary,  $\gamma = 1$  for the lower  $\alpha$  boundary, and  $\gamma = -2$  for the lower and upper  $\beta$  boundaries.

The “Design Information” table in [Output 83.12.1](#) displays design specifications and the derived maximum information. Note that in order to attain the same information level for the asymmetric lower and upper boundaries, the derived power at the upper alternative 0.93655 is larger than the specified  $1 - \beta = 0.90$ .

**Output 83.12.1** Design Information

| 1.0000                                     | Upper Alt | 0.05945                          | 0.33802 | 0.72323 | 0.93655 |
| 1.0000                                     | Upper Alt | 0.05947                          | 0.33804 | 0.72325 | 0.93657 |
| 1.0000                                     | Upper Alt | 0.00000                          | 0.01182 | 0.03131 | 0.06343 |
| 1.0000                                     | Upper Alt | 0.05947                          | 0.34986 | 0.75456 | 1.00000 |

“Rej Null (Lower Alt)” and “Rej Null (Upper Alt)” under the heading “Source” indicate the probabilities of rejecting the null hypothesis for the lower alternative and for the upper alternative, respectively. “Reject Null” indicates the probability of rejecting the null hypothesis for either the lower or upper alternative, “Accept Null” indicates the probability of accepting the null hypothesis, and “Total” indicates the total probability of stopping the trial.

With the PSS(CREF=0 0.5 1.0) option, the “Power and Expected Sample Sizes” table in [Output 83.12.4](#) displays powers and expected sample sizes under hypothetical references  $\theta = 0$  (null hypothesis  $H_0$ ),  $\theta = 0.5\theta_1$ , and  $\theta = \theta_1$  (alternative hypothesis  $H_1$ ), where  $\theta_1$  is the alternative reference. The expected sample sizes are displayed in a scale that indicates a percentage of its corresponding fixed-sample size design.

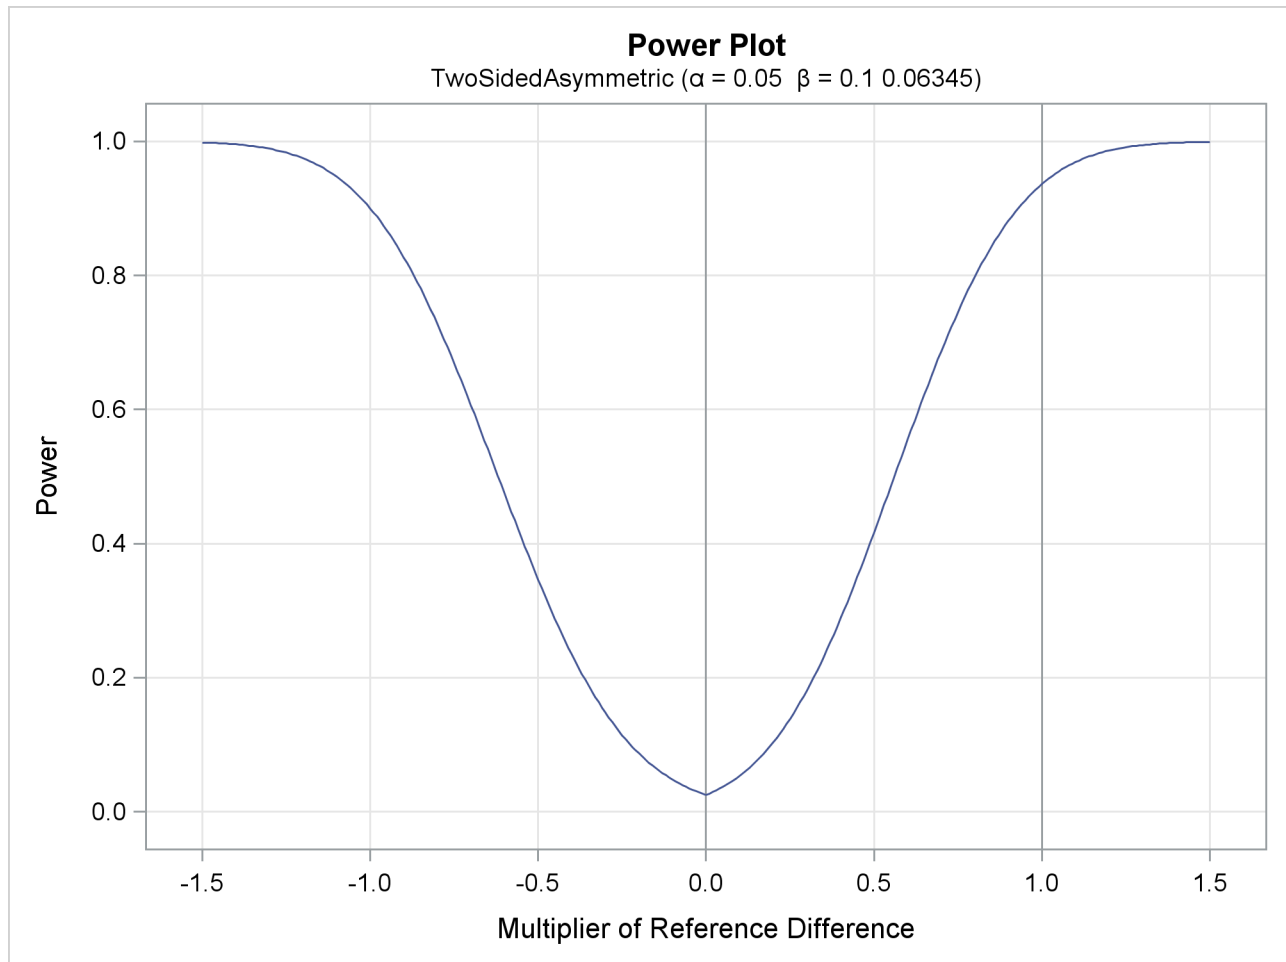

**Output 83.12.4** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes   |           |         |                                          |
|------------------------------------|-----------|---------|------------------------------------------|
| Reference = CRef * (Alt Reference) |           |         |                                          |
| CRef                               | Ref       | Power   | -Sample Size-<br>Percent<br>Fixed-Sample |
| 0.0000                             | Lower Alt | 0.02500 | 74.1665                                  |
| 0.5000                             | Lower Alt | 0.34601 | 75.8425                                  |
| 1.0000                             | Lower Alt | 0.90000 | 59.1027                                  |
| 0.0000                             | Upper Alt | 0.02500 | 74.1665                                  |
| 0.5000                             | Upper Alt | 0.41647 | 85.3976                                  |
| 1.0000                             | Upper Alt | 0.93655 | 73.7880                                  |

Note that at  $c_i = 0$ , the null reference  $\theta = 0$ , the power with the lower alternative is the lower  $\alpha$  error 0.025, and the power with the upper alternative is the upper  $\alpha$  error 0.025. At  $c_i = 1$ , the alternative reference  $\theta = \theta_1$ , the power with the lower alternative is the specified power 0.90, and the power with the upper alternative 0.93655 is greater than the specified power 0.90 because the same information level is used for these two asymmetric boundaries.

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references, as shown in [Output 83.12.5](#). By default, powers under the lower hypotheses  $\theta = c_i \theta_{1l}$  and under the upper hypotheses  $\theta = c_i \theta_{1u}$ , are displayed for a two-sided asymmetric design, where  $c_i = 0, 0.01, 0.02, \dots, 1.50$  and  $\theta_{1l} = -1$  and  $\theta_{1u} = 1$  are the lower and upper alternative references, respectively.

Output 83.12.5 Power Plot

The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to  $c_i$  for the upper alternative hypothesis, and a negative multiplier corresponds to  $-c_i$  for the lower alternative hypothesis. For lower reference hypotheses, the power is the lower  $\alpha$  error 0.025 under the null hypothesis ( $c_i = 0$ ) and is 0.90 under the alternative hypothesis ( $c_i = 1$ ). For upper reference hypotheses, the power is the upper  $\alpha$  error 0.025 under the null hypothesis ( $c_i = 0$ ) and is 0.93655 under the alternative hypothesis ( $c_i = 1$ ).

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in Output 83.12.6. By default, expected sample sizes under the lower hypotheses  $\theta = c_i \theta_{1l}$  and under the upper hypotheses  $\theta = c_i \theta_{1u}$  are displayed for a two-sided asymmetric design, where  $c_i = 0, 0.01, 0.02, \dots, 1.50$  and  $\theta_{1l} = -1$  and  $\theta_{1u} = 1$  are the lower and upper alternative references, respectively.

**Output 83.12.6** ASN Plot

The horizontal axis displays the multiplier of the reference difference. A positive multiplier corresponds to  $c_i$  for the upper alternative hypothesis, and a negative multiplier corresponds to  $-c_i$  for the lower alternative hypothesis.

By default (or equivalently if you specify BETAOVERLAP=ADJUST), the SEQDESIGN procedure first derives boundary values without adjusting for the possible overlapping of the two one-sided  $\beta$  boundaries based on two corresponding one-sided tests. Then the procedure checks for overlapping of the  $\beta$  boundaries at the interim stages. Since the two  $\beta$  boundaries overlap at stage 1, the  $\beta$  boundary values for stage 1 are set to missing, the  $\beta$  spending values at stage 1 are set to zero, and the  $\beta$  spending values at subsequent stages are adjusted proportionally.

The “Boundary Information” table in [Output 83.12.7](#) displays the information levels, alternative references, and boundary values. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the standardized Z scale is used to display the alternative references and boundary values. The resulting standardized alternative references at stage  $k$  is given by  $\pm\theta_1\sqrt{I_k}$ , where  $\theta_1$  is the specified alternative reference and  $I_k$  is the information level at stage  $k$ ,  $k = 1, 2, 3, 4$ .

**Output 83.12.7** Boundary Information

| Boundary Information (Standardized Z Scale) |                         |          |                       |         |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.12.8](#).

**Output 83.12.8** Boundary Plot

The “Error Spending Information” in **Output 83.12.9** displays the cumulative error spending at each stage for each boundary.

**Output 83.12.9** Error Spending Information

| _Stage_ | -Information Level-<br>Proportion | -----Cumulative Error Spending----- |         |                 |         |
|---------|-----------------------------------|-------------------------------------|---------|-----------------|---------|
|         |                                   | -----Lower-----                     |         | -----Upper----- |         |
|         |                                   | Alpha                               | Beta    | Beta            | Alpha   |
| 1       | 0.2500                            | 0.00875                             | 0.00000 | 0.00002         | 0.00042 |
| 2       | 0.5000                            | 0.01556                             | 0.01863 | 0.01184         | 0.00190 |
| 3       | 0.7500                            | 0.02087                             | 0.04935 | 0.03132         | 0.00704 |
| 4       | 1.0000                            | 0.02500                             | 0.10000 | 0.06345         | 0.02500 |

With the  $\beta$  boundary values missing at stage 1, there is no early stopping to accept  $H_0$  at stage 1, and the corresponding  $\beta$  spending at stage 1 is computed from the rejection region. For example, the upper  $\beta$  spending at stage 1 (0.00002) is the probability of rejecting  $H_0$  for the lower alternative under the upper alternative reference.

With the PLOTS=ERRSPEND option, the procedure displays a plot of the cumulative error spending on each boundary at each stage, as shown in Output 83.12.10.

**Output 83.12.10** Error Spending Plot

### Example 83.13: Creating a Design with a Nonbinding Beta Boundary

This example requests a two-sided design similar to Example 83.2, but with a nonbinding beta boundary. With a nonbinding acceptance boundary, the trial does not need to stop to accept the null hypothesis when a test statistic falls in the acceptance region at interim stages. The design maintains the specified Type I error level, but at the cost of increased sample size.

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design with early stopping to reject or accept  $H_0$ :

```
ods graphics on;
proc seqdesign altref=0.15 errspend
 ;
 NonbindingDesign: design nstages=4
 method=obf
 alt=upper
 stop=both(betaboundary=nonbinding)
 alpha=0.025 beta=0.10
 ;
 samplesize model=twosamplefreq(nullprop=0.6 test=prop);
run;
ods graphics off;
```

The STOP=BOTH option specifies early stopping to reject or accept the null hypothesis, and the BETABOUNDARY=NONBINDING suboption requests the nonbinding beta boundary.

The “Design Information,” “Method Information,” and “Boundary Information” tables are displayed by default. The “Design Information” table in [Output 83.13.1](#) displays design specifications and derived statistics such as power and maximum information. With a specified alternative reference, ALTREF=0.15, the maximum information  $I_X$  is derived.

**Output 83.13.1** Design Information

| The SEQDESIGN Procedure                   |                                   |

| Boundary Key                              | Both                              |
| Alternative Reference                     | 0.15                              |
| Number of Stages                          | 4                                 |
| Alpha (Binding Beta Boundary)             | 0.02228                           |
| Alpha (Nonbinding Beta Boundary)          | 0.025                             |
| Beta                                      | 0.1                               |
| Power                                     | 0.9                               |
| Max Information (Percent of Fixed Sample) | 110.7138                          |
| Max Information                           | 517.0296                          |
| Null Ref ASN (Percent of Fixed Sample)    | 62.29796                          |
| Alt Ref ASN (Percent of Fixed Sample)     | 78.5392                           |

With the BETABOUNDARY=NONBINDING option, there are two ways to compute the Type I error level: with or without the beta boundary. Alpha (Binding Beta Boundary) displays the Type I error level with the beta boundary, and Alpha (Nonbinding Beta Boundary) displays the Type I error level without the beta boundary.

The maximum information is the information level at the final stage of the group sequential trial. The Max Information (Percent Fixed-Sample) row displays the maximum information for the sequential design

expressed as a percentage of the information for the corresponding fixed-sample design (which has a Type I error level 0.025). In [Output 83.13.1](#), Max Information (Percent Fixed-Sample) is 110.71%, which means that the information needed for the group sequential trial is 10.71% more than the information needed for the corresponding fixed-sample design if the trial does not stop at any interim stage.

Compared to the corresponding design with a binding beta boundary, which has a Max Information (Percent Fixed-Sample) of 107.67% as displayed in [Output 83.2.1](#), the nonbinding design requires a larger sample size if the trial proceeds to the final stage.

The “Method Information” table in [Output 83.13.2](#) displays the values of  $\rho = 0.5$  and  $\tau = 0$ , which are the parameters for the O’Brien-Fleming method. The table also displays the drift parameter 3.4107, which is greater than the drift parameter 3.3636 in the corresponding binding boundary design, as displayed in [Output 83.2.2](#).

**Output 83.13.2** Method Information

| Method Information |                 |         |         |                          |     |         |

| Boundary           | Alternative Reference | Drift       |      |
|                    |                       | Upper Alpha | 0.15 |
| Upper Beta         | 0.15                  | 3.410743    |      |

The “Boundary Information” table in [Output 83.13.3](#) displays information level, alternative reference, and boundary values at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative reference and boundary values are displayed with the standardized Z statistic scale. The resulting standardized alternative reference at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information level at stage  $k$ , for  $k= 1, 2, 3, 4$ .

**Output 83.13.3** Boundary Information

| Boundary Information (Standardized Z Scale)  |                             |          |          |                        |                         |         |

By default (or equivalently if you specify INFO=EQUAL), equally spaced information levels are used. With the derived maximum information, the actual information level at each stage is also displayed. With the SAMPLESIZE statement, the required sample size  $N$  is also displayed under the heading “Information Level.”

Note that with the standardized  $Z$  statistic scale, the rejection boundary values are identical to the boundary values that are derived in the corresponding design with early stopping to reject  $H_0$ .

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 83.13.4](#).

**Output 83.13.4** Boundary Plot

The horizontal axis indicates the information levels for the design. The stages are indicated by vertical lines with accompanying stage numbers. The boundary plot also displays the information level and the critical value for the corresponding fixed-sample design.

The “Error Spending Information (Nonbinding Beta Boundary)” table in [Output 83.13.5](#) displays cumulative error spending at each stage for each boundary. With a nonbinding beta boundary, the  $\alpha$  spending at each stage is computed by using the  $\alpha$  boundary only.

**Output 83.13.5** Error Spending Information

| Error Spending Information (Nonbinding Beta Boundary) |                                   |                             |         |  |
|-------------------------------------------------------|-----------------------------------|-----------------------------|---------|--|
| _Stage_                                               | -Information Level-<br>Proportion | -Cumulative Error Spending- |         |  |

| 1                                                     | 0.2500                            | 0.00278                     | 0.00003 |  |
| 2                                                     | 0.5000                            | 0.02603                     | 0.00211 |  |
| 3                                                     | 0.7500                            | 0.06343                     | 0.01046 |  |
| 4                                                     | 1.0000                            | 0.10000                     | 0.02500 |  |

The SEQDESIGN procedure derives the drift parameter  $\theta_1 \sqrt{I_X}$ , where  $\theta_1$  is the alternative reference and  $I_X$  is the maximum information. With the SAMPLESIZE statement, the maximum information is used to compute the required sample size for the study.

The “Sample Size Summary” table in [Output 83.13.6](#) displays parameters for the sample size computation. With the MODEL=TWOSAMPLEFREQ(NULLPROP=0.6 TEST=PROP) option in the SAMPLESIZE statement, the total sample size and expected sample sizes under the null and alternative hypotheses for testing the difference between two proportions are displayed.

**Output 83.13.6** Sample Size Summary

| Sample Size Summary             |                        |          |
|---------------------------------|------------------------|----------|
| Test                            | Two-Sample Proportions |          |
| Null Proportion                 |                        | 0.6      |
| Proportion (Group A)            |                        | 0.75     |
| Test Statistic                  | Z for Proportion       |          |
| Reference Proportions           | Alt                    | Ref      |
| Max Sample Size                 |                        | 442.0603 |
| Expected Sample Size (Null Ref) |                        | 248.7446 |
| Expected Sample Size (Alt Ref)  |                        | 313.5929 |

The “Sample Sizes (N)” table in [Output 83.13.7](#) displays the required sample sizes at each stage, in both fractional and integer numbers. The derived fractional sample sizes are under the heading “Fractional N.” These sample sizes are rounded up to integers under the heading “Ceiling N.” As expected, the sample sizes in the table are larger than the corresponding sample sizes in the corresponding design with binding beta boundary.

**Output 83.13.7** Derived Sample Sizes

| Sample Sizes (N)                            |        |          |          |             |

**Example 83.14: Computing Sample Size for Survival Data**

This example illustrates sample size computation for survival data when the accrual is not uniform and when the data contain individual loss to follow up.

Suppose that a clinic is conducting a study of the effect of a new cancer treatment. The study consists of exposing mice to a carcinogen and randomly assigning them to either the control group or the treatment group. The event of interest is death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Following the derivations in the section “Test for Two Survival Distributions with a Log-Rank Test” on page 7059, this example uses the hypothesis  $H_0 : \theta = -\log(\lambda) = 0$  with an alternative hypothesis  $H_1 : \theta = \theta_1 > 0$ , where  $\lambda$  is the hazard ratio between the treatment group and the control group.

Suppose that from past experience, the median survival time for the control group is  $t_0 = 20$  weeks, and the study wants to detect a  $t_1 = 40$  weeks’ median survival time with a 80% power in the trial. If exponential survival functions are assumed for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where  $j = 0, 1$ .

Thus, with  $h_0 = 0.03466$  and  $h_1 = 0.01733$ , the hazard ratio  $\lambda_1 = h_1/h_0 = 1/2$ , and the alternative reference is

$$\theta_1 = -\log(\lambda_1) = -\log\left(\frac{1}{2}\right) = 0.693147$$

The following statements invoke the SEQDESIGN procedure:

```
proc seqdesign altref=0.693147
 ;
 OBrienFleming: design nstages=4
 method=obf
 ;
 samplesize model=twosamplesurvival
 (nullhazard=0.03466
 accrual=exp(parm=-0.1)
 loss=exp(hazard=0.05)
 acctime=20);
run;
```

The ALTREF= option specifies the alternative reference  $\theta_1 = -\log(\frac{1}{2}) = 0.693147$ . The DESIGN statement requests a group sequential design, and the METHOD=OBF option specifies the O'Brien-Fleming design. By default, the design has a two-sided alternative hypothesis in which early stopping in the interim stages occurs to reject the null hypothesis. The SAMPLESIZE statement derives required sample sizes for the test, and the MODEL=TWOSAMPLESURVIVAL option specifies a log-rank test to compare two survival distributions for the treatment effect.

The “Design Information” table in [Output 83.14.1](#) displays design specifications and four derived statistics: the actual maximum information, the maximum information, the average sample number under the null hypothesis (Null Ref ASN), and the average sample number under the alternative hypothesis (Alt Ref ASN).

**Output 83.14.1** O'Brien-Fleming Design Information

| The SEQDESIGN Procedure                   |                 |
|-------------------------------------------|-----------------|
| Design: OBrienFleming                     |                 |

| 1                                           | -4.04859                  | 4.04859     |  |
| 2                                           | -2.86278                  | 2.86278     |  |
| 3                                           | -2.33745                  | 2.33745     |  |
| 4                                           | -2.02429                  | 2.02429     |  |

In the SAMPLESIZE statement, the MODEL=TWOSAMPLESURVIVAL option specifies a log-rank test to compare two survival distributions for the treatment effect. The NULLHAZARD=0.03466 option specifies null hazard rates for the two groups under the null hypothesis. The ACCTIME= option specifies the accrual time  $T_a$ , and the ACCRUAL=EXP(POWER=-0.1) option specifies that the individual accrual is truncated exponential with a scaled power parameter  $\gamma_0 = -0.1$ . That is, the truncated exponential accrual has a power parameter  $\gamma = \gamma_0 / T_a = -0.1 / 20 = -0.005$  in the accrual time  $T_a$ . The LOSS=EXP(HAZARD=0.05) option specifies an exponential loss function with a hazard rate  $\tau = 0.05$ . Since the ACCNOBS= option is not included with the specified accrual time, the minimum and maximum sample sizes are derived from the specified accrual time. See the section “[Test for Two Survival Distributions with a Log-Rank Test](#)” on page 7059 for a detailed derivation of these required sample sizes.

The “Sample Size Summary” table in [Output 83.14.3](#) displays parameters for the sample size computation. Since the ACCNOBS= option is not included with the specified accrual time, the minimum and maximum sample sizes are derived.

**Output 83.14.3** Sample Size Summary

| Sample Size Summary          |                                   |
|------------------------------|-----------------------------------|
| Test                         | Two-Sample Survival               |
| Null Hazard Rate             | 0.03466                           |

| Hazard Rate (Group B)        | 0.03466                           |
| Hazard Ratio                 | 0.5                               |
| log(Hazard Ratio)            | -0.69315                          |
| Reference Hazards            | Alt Ref                           |
| Accrual                      | Truncated Exponential with Losses |
| Scaled Exponential Parameter | -0.1                              |
| Loss Hazard Rate             | 0.05                              |
| Accrual Time                 | 20                                |
| Min Accrual Sample Size      | 269                               |
| Max Accrual Sample Size      | 553                               |
| Max Number of Events         | 89.41808                          |

The “Numbers of Events (D)” table in [Output 83.14.4](#) displays the required number of events and corresponding information level at each stage.

**Output 83.14.4** Derived Sample Sizes

| Numbers of Events (D)<br>Two-Sample Log-Rank Test |       |             |
|---------------------------------------------------|-------|-------------|
| _Stage_                                           | D     | Information |
| 1                                                 | 22.35 | 5.5886      |
| 2                                                 | 44.71 | 11.1773     |
| 3                                                 | 67.06 | 16.7659     |
| 4                                                 | 89.42 | 22.3545     |

With the minimum and maximum sample sizes of 269 and 553, respectively, the ACCNOBS=360 option specifies an accrual sample size of 360 for the trial.

```
proc seqdesign altref=0.693147
 ;
 OBrienFleming: design nstages=4
 method=obf
 ;
 samplesize model=twosamplesurvival
 (nullhazard=0.03466
 accrual=exp(parm=-0.1)
 loss=exp(hazard=0.05)
 accnobs=360 acctime=20);
run;
```

With the specified accrual sample size and accrual time, the “Sample Size Summary” table in [Output 83.14.5](#) also displays the follow-up time and maximum sample size with the specified accrual time.

**Output 83.14.5** Sample Size Summary

The “Number of Events (D) and Sample Sizes (N)” table in [Output 83.14.6](#) displays the required time at each stage, in both fractional and integer numbers. The derived times under the heading “Fractional Time” are not integers. These times are rounded up to integers under the heading “Ceiling Time.” The table also displays the numbers of events and sample sizes at each stage.

## Output 83.14.6 Number of Events and Sample Sizes

## Overview: SEQTEST Procedure

The purpose of the SEQTEST procedure is to perform interim analyses for clinical trials. Clinical trials are experiments on human beings to demonstrate the efficacy and safety of new drugs or treatments. A simple example is a trial to test the effectiveness of a new drug in humans by comparing the outcomes in a group of patients who receive the new drug with the outcomes in a comparable group of patients who receive a placebo.

A clinical trial is conducted according to a plan called a *protocol*. A protocol details the objectives of the trial, the data collection process, and the analyses of the data. The protocol contains information such as a null hypothesis and an alternative hypothesis, a test statistic, the probability  $\alpha$  of a Type I error (incorrectly rejecting the null hypothesis), the probability  $\beta$  of a Type II error (incorrectly accepting the null hypothesis), the sample size needed to attain a specified power (probability of correctly rejecting the null hypothesis) of  $1 - \beta$  at an alternative reference, and critical values that are associated with the test statistic for hypothesis testing.

In a fixed-sample trial, data about all individuals are first collected and then examined at the end of the study. Most major trials have data safety monitoring boards or data monitoring committees that periodically monitor safety and efficacy data during the trial and recommend that a trial be stopped for safety concerns such as an unacceptable toxicity level. In certain rare situations, the board or committee might even recommend that a trial be stopped for efficacy. In contrast to a fixed-sample trial, a group sequential trial provides for interim analyses before the formal completion of the trial while maintaining the specified overall Type I and Type II error probability levels.

A group sequential trial is most useful in situations where it is important to monitor the trial to prevent unnecessary exposure of patients to an unsafe new drug, or alternatively to a placebo treatment if the new drug shows significant improvement. If a group sequential trial stops early, then it usually requires fewer participants than a corresponding fixed-sample trial.

Thus, in most cases, if a group sequential trial stops early for safety of the new treatment, fewer patients will be exposed to the new treatment than in the fixed-sample trial. Also, if a trial stops early for efficacy of the new treatment, the new treatment will be available sooner than it would be in a fixed-sample trial. Furthermore, if a trial stops early, this can also save time and resources.

A group sequential design provides detailed specifications for a group sequential trial. In addition to the usual specification for a fixed-sample design, it provides the total number of stages (the number of interim stages plus a final stage) and a stopping criterion to reject, to accept, or to either reject or accept the null hypothesis at each interim stage. It also provides critical values and the sample size at each stage for the trial.

At each interim stage, the data collected at the current stage in addition to the data collected at previous stages are analyzed, and statistics such as a maximum likelihood test statistic and its associated standard error are computed. The test statistic is then compared with its corresponding critical values at the stage, and the trial is stopped or continued. If a trial continues to the final stage, the null hypothesis is either rejected or accepted. The critical values for each stage are chosen in such a way to maintain the overall  $\alpha$  level, the overall  $\beta$  level, or both the overall  $\alpha$  and  $\beta$  levels.

Figure 84.1 shows a two-sided symmetric group sequential trial that stops early to reject the null hypothesis that the parameter  $\text{Trt}$  is zero.

**Figure 84.1** Sequential Plot for Two-Sided Test

The trial has four stages, which are indicated by vertical lines with accompanying stage numbers. With early stopping to reject the null hypothesis, the lower rejection boundary is constructed by connecting the lower critical values (boundary values) for the stages. Similarly, the upper rejection boundary is constructed by connecting the upper critical values for the stages. The horizontal axis indicates the sample size for the group sequential trial, and the vertical axis indicates the boundary values and test statistics on the standardized  $Z$  scale.

At each interim stage, if the standardized  $Z$  test statistic falls into a rejection region (the darker shaded areas in Figure 84.1), the trial stops and the null hypothesis is rejected. Otherwise, the trial continues to the next stage. At the final stage (stage 4), the trial is rejected if  $Z$  falls into a rejection region. Otherwise, the trial is accepted. In Figure 84.1, the test statistic does not fall into the rejection regions for stages 1 and 2, and so the trial continues to stage 3. At stage 3, the test statistic falls into the rejection region, and the null hypothesis is rejected.

A group sequential trial usually involves six steps:

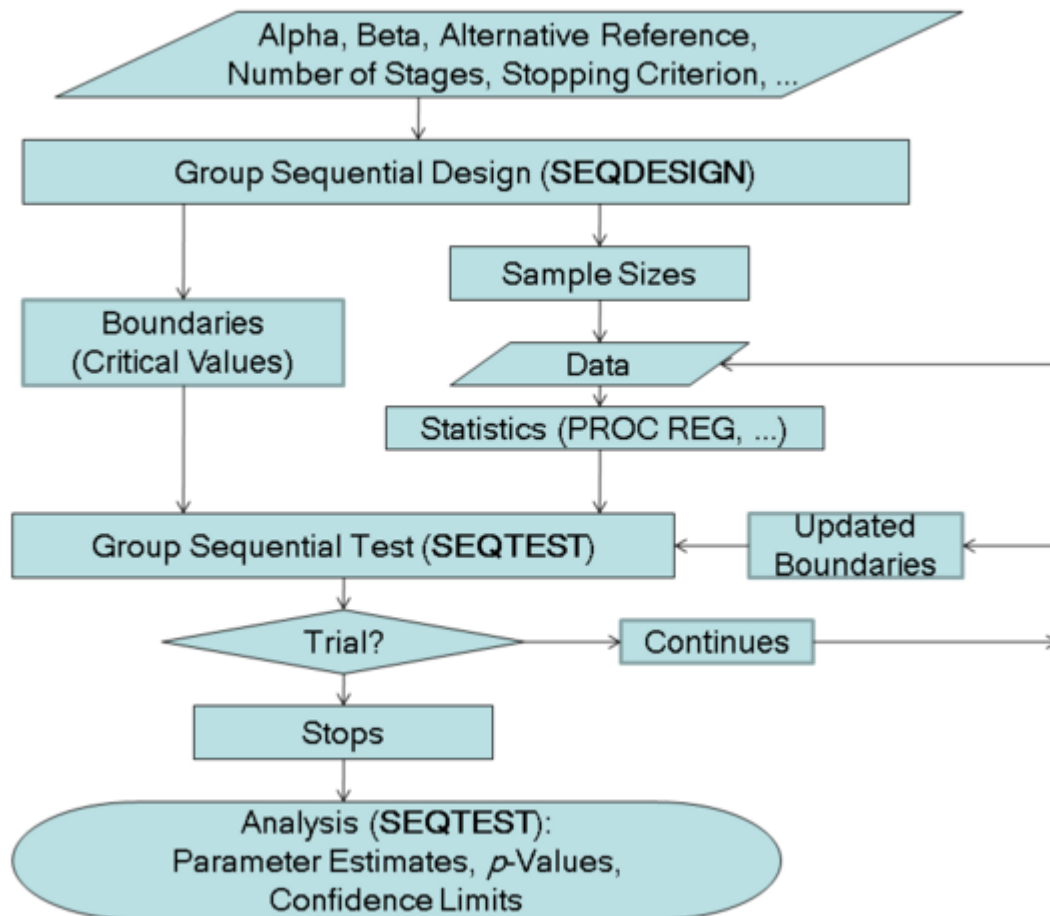

1. You specify the statistical details of the design, including the null and alternative hypotheses, a test statistic for the hypothesis test, the Type I and II error probabilities, a stopping criterion, the total number of stages, and the relative information level at each stage.
2. You compute the boundary values for the trial based on the specifications in Step 1. You also compute the sample size required at each stage for the specified hypothesis test.
3. At each stage, you collect additional data with the required sample sizes. The data available at each stage include the data collected at previous stages in addition to the data collected at the current stage.
4. At each stage, you analyze the available data with a procedure such as the REG procedure, and you compute the test statistic.
5. At each stage, you compare the test statistic with the corresponding boundary values. You stop the trial to reject or accept the hypothesis, or you continue the trial to the next stage. If you continue the trial to the final stage, you either accept or reject the hypothesis.
6. After the trial stops, you compute parameter estimates, confidence limits for the parameter, and a  $p$ -value for the hypothesis test.

You use the companion SEQDESIGN procedure at Step 2 to compute the boundary values and required sample sizes for the trial. You use the SEQTEST procedure at Step 5 to compare the test statistic with its boundary values. At stage 1, the boundary values are derived by using the boundary information tables created by the SEQDESIGN procedure. These boundary information tables are structured for input to the SEQTEST procedure. At each subsequent stage, the boundary values are derived by using the test information tables created by the SEQTEST procedure at the previous stage. These test information tables are also structured for input to the SEQTEST procedure. You also use the SEQTEST procedure at Step 6 to compute parameter estimates, confidence limits, and  $p$ -values after the trial stops.

Note that for some clinical trials, the information levels are derived from statistics based on individuals specified in the design plan and might not reach the target maximum information level. For example, if an estimate of the variance is used to compute the required sample size for a group sequential trial, the computed variance at each stage might not be the same as the estimated variance. Thus, instead of specifying the number of individuals in the protocol, the information level can be specified. You can then adjust the sample sizes with the updated variance estimates at interim stages to achieve the target maximum information level for the trial (Jennison and Turnbull 2000, p. 295).

The flowchart in [Figure 84.2](#) summarizes the steps in a typical group sequential trial and the relevant SAS procedures.

Figure 84.2 Group Sequential Trial

## Features of the SEQTEST Procedure

At each stage, the data are analyzed with a statistical procedure such as the REG procedure, and a test statistic and its associated information level are computed. The information level is the amount of information available about the unknown parameter. For a maximum likelihood statistic, the information level is the inverse of its variance.

At each stage, you use the SEQTEST procedure to compare the test statistic with its boundary values. At stage 1, the boundary values are derived by using the boundary information tables created by the SEQDESIGN procedure. At each subsequent stage, the boundary values are derived by using the test information tables created by the SEQTEST procedure at the previous stage.

If the observed information level does not match the corresponding information level in the BOUNDARY= data set, the SEQTEST procedure modifies the boundary values to adjust for new information levels at the current and subsequent stages. See the section “[Boundary Adjustments for Information Levels](#)” on page 7223 for a detailed description of these boundary adjustments.

Either you can specify the test statistic and its information level in the DATA= input data set, or you can specify the test statistic and its associated standard error in the PARMS= input data set. With the PARMS=

input data set, the information level for the test statistic is computed from its standard error. See the section “[Input Data Sets](#)” on page 7217 for a detailed description of these input data sets.

At the end of a trial, the parameter estimate is computed. The median unbiased estimate, confidence limits, and  $p$ -value depend on the specified sample space ordering. A sample space ordering specifies the ordering for test statistics that result in the stopping of a trial. That is, for all the statistics in the rejection region and in acceptance region, the SEQTEST procedure provides three different sample space orderings: the stagewise ordering uses counterclockwise ordering around the continuation region, the LR ordering uses the distance between the observed  $Z$  statistic  $z$  and its hypothetical value, and the MLE ordering uses the observed maximum likelihood estimate. See the section “[Available Sample Space Orderings in a Sequential Test](#)” on page 7230 for a detailed description of these orderings.

---

## Output from the SEQTEST Procedure

In addition to the adjusted boundary values and test results for the group sequential trial, the SEQTEST procedure also computes the following quantities:

- average sample numbers (as percentages of the corresponding fixed-sample sizes for nonsurvival data or fixed-sample numbers of events for survival data) under various hypothetical references, including the null and alternative references
- stopping probabilities at each stage under various hypothetical references to indicate how likely it is that the trial will stop at that stage
- conditional power given the most recently observed statistic under specified hypothetical references
- predictive power given the most recently observed statistic
- repeated confidence intervals for the parameter from the observed statistic at each stage
- parameter estimate,  $p$ -value for hypothesis testing, and median and confidence limits for the parameter at the conclusion of a sequential trial

---

## Getting Started: SEQTEST Procedure

The following example illustrates a clinical study that uses a two-sided O’Brien-Fleming design (O’Brien and Fleming 1979) to stop the trial early for ethical concerns about possible harm or for unexpectedly strong efficacy of the new drug.

Suppose that a pharmaceutical company is conducting a clinical trial to test the efficacy of a new cholesterol-lowering drug. The primary focus is low-density lipoprotein (LDL), the so-called bad cholesterol, which is a risk factor for coronary heart disease. LDL is measured in  $mg / dL$ , milligrams per deciliter of blood.

The trial consists of two groups of equally allocated patients with elevated LDL level: an experimental group given the new drug and a placebo control group. Suppose the changes in LDL level after the treatment for patients in the experimental and control groups are normally distributed with means  $\mu_e$  and  $\mu_c$ , respectively,

and have a common variance  $\sigma^2$ . Then the null hypothesis of no effect for the new drug is  $H_0 : \theta = \mu_e - \mu_c = 0$ . Also suppose that the alternative reference  $\theta = -10$  is the clinically meaningful difference that the trial should detect with a high probability (power), and that a good estimate of the standard deviation for the changes in LDL level is  $\hat{\sigma} = 20$ .

The following statements invoke the SEQDESIGN procedure and request a four-stage O'Brien-Fleming design for standardized normal test statistics:

```
ods graphics on;
proc seqdesign altref=-10.0;
 TwoSidedOBrienFleming: design nstages=4
 method=obf
 ;
 samplesize model=twosamplemean(stddev=20);
 ods output Boundary=Bnd_LDL;
run;
ods graphics off;
```

The ALTREF= option specifies the alternative reference, and the actual maximum information is derived in the SEQDESIGN procedure.

In the DESIGN statement, the label **TwoSidedOBrienFleming** identifies the design in the output tables. By default (or equivalently if you specify ALT=TWOSIDED and STOP=REJECT), the design has a two-sided alternative hypothesis with early stopping in the interim stages only to reject the null hypothesis. That is, at each interim stage, the trial will either be stopped to reject the null hypothesis or continue to the next stage.

The NSTAGES=4 option in the DESIGN statement specifies the total number of stages in the group sequential trial, including three interim stages and a final stage. In the SEQDESIGN procedure, the null hypothesis for the design is  $H_0 : \theta = 0$ . By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10), the design has a Type I error probability  $\alpha = 0.05$ , and a Type II error probability  $\beta = 0.10$ , which corresponds to a power of  $1 - \beta = 0.90$  at the alternative reference  $H_1 : \theta = -10$ .

For a two-sided design with early stopping to reject the null hypothesis, there are two boundaries for the design: an upper  $\alpha$  (rejection) boundary that consists of upper rejection critical values and a lower  $\alpha$  boundary that consists of lower rejection critical values. Each boundary is a set of critical values, one from each stage. With the METHOD=OBF option in the DESIGN statement, the O'Brien-Fleming method is used for the two boundaries for the design; see [Figure 84.5](#).

The SAMPLESIZE statement with the MODEL=TWOSAMPLEMEAN option uses the derived maximum information to compute required sample sizes for a two-sample test for mean difference.

The ODS OUTPUT statement with the BOUNDARY=BND\_LDL option creates an output data set named BND\_LDL which contains the resulting boundary information. At each stage of the trial, data are collected and analyzed with a statistical procedure, and a test statistic and its corresponding information level are computed.

In this example, you can use the REG procedure to compute the maximum likelihood estimate  $\hat{\theta}$  for the drug effect and the corresponding standard error for  $\hat{\theta}$ . At stage 1, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries that are derived from the boundary information stored in the BOUND\_LDL data set. At each subsequent stage, you can use the SEQTEST procedure to compare the test statistic with adjusted boundaries that are derived from the boundary information stored in the test information table that was created by the SEQTEST procedure at the previous stage. The test information tables are structured for input to the SEQTEST procedure.

At each interim stage, the trial will either be stopped to reject the null hypothesis or continue to the next stage. At the final stage, the null hypothesis is either rejected or accepted.

By default (or equivalently if you specify `INFO=EQUAL`), the SEQDESIGN procedure derives boundary values with equally spaced information levels for all stages—that is, the same information increment between successive stages.

The “Design Information” table in Figure 84.3 displays design specifications and three derived statistics: the maximum information, the average sample number under the null hypothesis (Null Ref ASN), and the average sample number under the alternative hypothesis (Alt Ref ASN). Each statistic is expressed as a percentage of the identical statistic for the corresponding fixed-sample information. The average sample number is the expected sample size (for nonsurvival data) or expected number of events (for survival data). When you specify an alternative reference (in this case, `ALTREF=-10`), the actual maximum information 0.1074 is also computed. Note that for a symmetric two-sided design, the `ALTREF=-10` option implies a lower alternative reference of  $-10$  and an upper alternative reference of  $10$ .

**Figure 84.3** O'Brien-Fleming Design Information

| 3                                           | 0.7500                      | 0.080552 | 128.8835 | -2.83817              | 2.83817 |
| 4                                           | 1.0000                      | 0.107403 | 171.8447 | -3.27724              | 3.27724 |

| Boundary Information (Standardized Z Scale) |                          |            |  |
|---------------------------------------------|--------------------------|------------|--|
| Null Reference = 0                          |                          |            |  |
| _Stage_                                     | -----Boundary Values---- |            |  |
|                                             | ---Lower--               | ---Upper-- |  |
|                                             | Alpha                    | Alpha      |  |
| 1                                           | -4.04859                 | 4.04859    |  |
| 2                                           | -2.86278                 | 2.86278    |  |
| 3                                           | -2.33745                 | 2.33745    |  |
| 4                                           | -2.02429                 | 2.02429    |  |

The information proportion is the proportion of maximum information available at each stage. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), the alternative references and boundary values are displayed with the standardized  $Z$  statistic scale. The alternative reference in the standardized  $Z$  scale at stage  $k$  is given by  $\theta_1 \sqrt{I_k}$ , where  $\theta_1$  is the alternative reference and  $I_k$  is the information available at stage  $k$ ,  $k = 1, 2, 3, 4$ .

In this example, a standardized  $Z$  statistic is computed by standardizing the parameter estimate of the effect in LDL level. A lower  $Z$  test statistic indicates a beneficial effect. Consequently, at each interim stage, if the standardized  $Z$  test statistic is less than or equal to the corresponding lower  $\alpha$  boundary value, the hypothesis  $H_0 : \theta = 0$  is rejected for efficacy. If the test statistic is greater than or equal to the corresponding upper  $\alpha$  boundary value, the hypothesis  $H_0$  is rejected for harmful effect. Otherwise, the process continues to the next stage. At the final stage (stage 4), the hypothesis  $H_0$  is rejected for efficacy if the  $Z$  statistic is less than or equal to the corresponding lower  $\alpha$  boundary value  $-2.0243$ , and the hypothesis  $H_0$  is rejected for harmful effect if the  $Z$  statistic is greater than or equal to the corresponding upper  $\alpha$  boundary value  $2.0243$ . Otherwise, the hypothesis of no significant difference is accepted.

Note that in a typical trial, the actual information levels do not match the information levels specified in the design. Consequently, the SEQTEST procedure modifies the boundary values stored in the BND\_LDL data set to adjust for these new information levels.

If ODS Graphics is enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in Figure 84.5.

**Figure 84.5** O'Brien-Fleming Boundary Plot

This boundary plot displays the boundary values in the “Boundary Information” table in Figure 84.4. The stages are indicated by vertical lines with accompanying stage numbers. The horizontal axis indicates the information levels for the stages. If a test statistic at an interim stage is in the rejection region (shaded area), the trial stops and the null hypothesis is rejected. If the statistic is not in any rejection region, the trial continues to the next stage. The plot also displays critical values for the corresponding fixed-sample design. The symbol “o” identifies the fixed-sample critical values of  $-1.96$  and  $1.96$ .

When you specify the SAMPLESIZE statement, the maximum information (either explicitly specified or derived in the SEQDESIGN procedure) is used to compute the required sample sizes for the study. The MODEL=TWOSAMPLEMEAN(STDDEV=20) option specifies the test for the difference between two normal means. See the section “Test for the Difference between Two Normal Means” in the chapter “The SEQDESIGN Procedure” for a detailed description of how these required sample sizes are calculated.

The “Sample Size Summary” table in Figure 84.6 displays the parameters for the sample size computation and the resulting maximum and expected sample sizes.

**Figure 84.6** Required Sample Size Summary

| Sample Size Summary             |                  |
|---------------------------------|------------------|
| Test                            | Two-Sample Means |
| Mean Difference                 | -10              |
| Standard Deviation              | 20               |
| Max Sample Size                 | 171.8447         |
| Expected Sample Size (Null Ref) | 170.7627         |
| Expected Sample Size (Alt Ref)  | 129.0137         |

With the derived maximum information 0.1074 and the specified MODEL=TWOSAMPLEMEAN (STDDEV=20) option in the SAMPLESIZE statement, the total sample size in each group is

$$N_a = N_b = 2\sigma^2 I_X = 2 \times 20^2 \times 0.1074 = 85.92$$

The “Sample Sizes (N)” table in Figure 84.7 displays the required sample sizes at each stage for the trial, in both fractional and integer numbers. The derived fractional sample sizes are displayed under the heading “Fractional N.” These sample sizes are rounded up to integers under the heading “Ceiling N.” By default (or equivalently if you specify WEIGHT=1 in the MODEL=TWOSAMPLEMEAN option), the sample sizes for the two groups are equal for the two-sample test.

**Figure 84.7** Required Sample Sizes

| Sample Sizes (N)                      |        |          |          |             |
|---------------------------------------|--------|----------|----------|-------------|
| Two-Sample Z Test for Mean Difference |        |          |          |             |
| -----Fractional N-----                |        |          |          |             |
| _Stage_                               | N      | N(Grp 1) | N(Grp 2) | Information |
| 1                                     | 42.96  | 21.48    | 21.48    | 0.0269      |
| 2                                     | 85.92  | 42.96    | 42.96    | 0.0537      |
| 3                                     | 128.88 | 64.44    | 64.44    | 0.0806      |
| 4                                     | 171.84 | 85.92    | 85.92    | 0.1074      |

| Sample Sizes (N)                      |     |          |          |             |
|---------------------------------------|-----|----------|----------|-------------|
| Two-Sample Z Test for Mean Difference |     |          |          |             |
| -----Ceiling N-----                   |     |          |          |             |
| _Stage_                               | N   | N(Grp 1) | N(Grp 2) | Information |
| 1                                     | 44  | 22       | 22       | 0.0275      |
| 2                                     | 86  | 43       | 43       | 0.0538      |
| 3                                     | 130 | 65       | 65       | 0.0812      |
| 4                                     | 172 | 86       | 86       | 0.1075      |

In practice, integer sample sizes are used in the trial, and the resulting information levels increase slightly. Thus, each of the two groups needs 22, 43, 65, and 86 patients for the four stages, respectively.

Suppose that 22 patients are available in each group at stage 1 and that their measurements for LDL are saved in the data set LDL\_1. Figure 84.8 lists the first 10 observations in the data set LDL\_1.

**Figure 84.8** Clinical Trial Data

| First 10 Obs in the Trial Data |     |        |
|--------------------------------|-----|--------|
| Obs                            | Trt | Ldl    |
| 1                              | 0   | 33.33  |
| 2                              | 1   | -14.89 |
| 3                              | 0   | 15.30  |
| 4                              | 1   | 4.71   |
| 5                              | 0   | 26.89  |
| 6                              | 1   | -48.74 |
| 7                              | 0   | -39.35 |
| 8                              | 1   | -8.13  |
| 9                              | 0   | -8.22  |
| 10                             | 1   | 12.35  |

The variable Trt is an indicator variable with value 1 for patients in the treatment group and value 0 for patients in the placebo control group. The variable Ldl is the LDL level of these patients.

The following statements use the REG procedure to estimate the mean treatment difference and its associated standard error at stage 1:

```
proc reg data=LDL_1;
 model Ldl=Trt;
 ods output ParameterEstimates=Parms_LDL1;
run;
```

The following statements create the data set for the mean treatment difference and its associated standard error as a PARMS= data set, which will subsequently serve as an input data set for PROC SEQTEST. Note that all of the variables are required for a PARMS= data set, as described in the section “PARMS= Data Set” on page 7219.

```
data Parms_LDL1;
 set Parms_LDL1;
 if Variable='Trt';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_LDL1;
 title 'Statistics Computed at Stage 1';
run;
```

Figure 84.9 displays the statistics computed at stage 1.

**Figure 84.9** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Trt      | -2.52591 | 5.68572 | MLE     | 1       |

Since the sample sizes derived are based on the estimated variance at the designing phase, the information level that corresponds to the test statistic at stage 1 is estimated by

$$I_1 = \frac{1}{s_1^2} = \frac{1}{5.686^2} = 0.0309$$

where  $s_1$  is the standard error of the treatment estimate.

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_LDL
 Parms(Testvar=Trt)=Parms_LDL1
 infoadj=prop
 ;
 ods output Test=Test_LDL1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_LDL1 option specifies the input data set PARMS\_LDL1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRT option identifies the test variable TRT in the data set.

By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the maximum information and the Type I error level are maintained. Furthermore, with the INFOADJ=PROP option (which is the default), the information levels at future interim stages (2 and 3) are adjusted proportionally from the levels provided in the BOUNDARY= data set.

The ODS OUTPUT statement with the TEST=TEST\_LDL1 option creates an output data set named TEST\_LDL1 which contains the updated boundary information for the test at stage 1, and the boundary information that is needed for the group sequential test at the next stage. See the section “[Boundary Adjustments for Information Levels](#)” on page 7223 for details.

The “Design Information” table in [Figure 84.10](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are adjusted for the updated information levels to maintain the Type I  $\alpha$  level, and the maximum information remains the same as in the BOUNDARY= data set. But the derived Type II error probability  $\beta$  and power  $1 - \beta$  are slightly different with new information levels. With the updated power  $1 - \beta$ , the corresponding fixed-sample design is also updated.

**Figure 84.10** Design Information

| The SEQTEST Procedure                     |                 |
|-------------------------------------------|-----------------|
| Design Information                        |                 |
| BOUNDARY Data Set                         | WORK.BND_LDL    |
| Data Set                                  | WORK.PARMS_LDL1 |
| Statistic Distribution                    | Normal          |
| Boundary Scale                            | Standardized Z  |
| Alternative Hypothesis                    | Two-Sided       |
| Early Stop                                | Reject Null     |
| Number of Stages                          | 4               |
| Alpha                                     | 0.05            |
| Beta                                      | 0.10074         |
| Power                                     | 0.89926         |
| Max Information (Percent of Fixed Sample) | 102.4815        |
| Max Information                           | 0.10740291      |
| Null Ref ASN (Percent of Fixed Sample)    | 101.7765        |
| Alt Ref ASN (Percent of Fixed Sample)     | 75.4928         |

The “Test Information” table in Figure 84.11 displays the boundary values for the test statistic. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), these statistics are displayed with the standardized Z scale. With the INFOADJ=PROP option (which is the default), information levels at future interim stages are derived proportionally from the corresponding levels provided in the BOUNDARY= data set.

**Figure 84.11** Sequential Tests

| Test Information (Standardized Z Scale) |                       |          |                       |                 |                         |             |
|-----------------------------------------|-----------------------|----------|-----------------------|-----------------|-------------------------|-------------|

| _Stage_                                 | --Information Level-- |          | -----Alternative----- |                 | ----Boundary Values---- |             |
|                                         | Proportion            | Actual   | -----Reference-----   | -----Upper----- | ---Lower---             | ---Upper--- |
|                                         |                       |          | Lower                 | Upper           | Alpha                   | Alpha       |
| 1                                       | 0.2880                | 0.030934 | -1.75879              | 1.75879         | -3.39532                | 3.39532     |
| 2                                       | 0.5253                | 0.056423 | -2.37536              | 2.37536         | -2.77374                | 2.77374     |
| 3                                       | 0.7627                | 0.081913 | -2.86205              | 2.86205         | -2.32412                | 2.32412     |
| 4                                       | 1.0000                | 0.107403 | -3.27724              | 3.27724         | -2.03147                | 2.03147     |

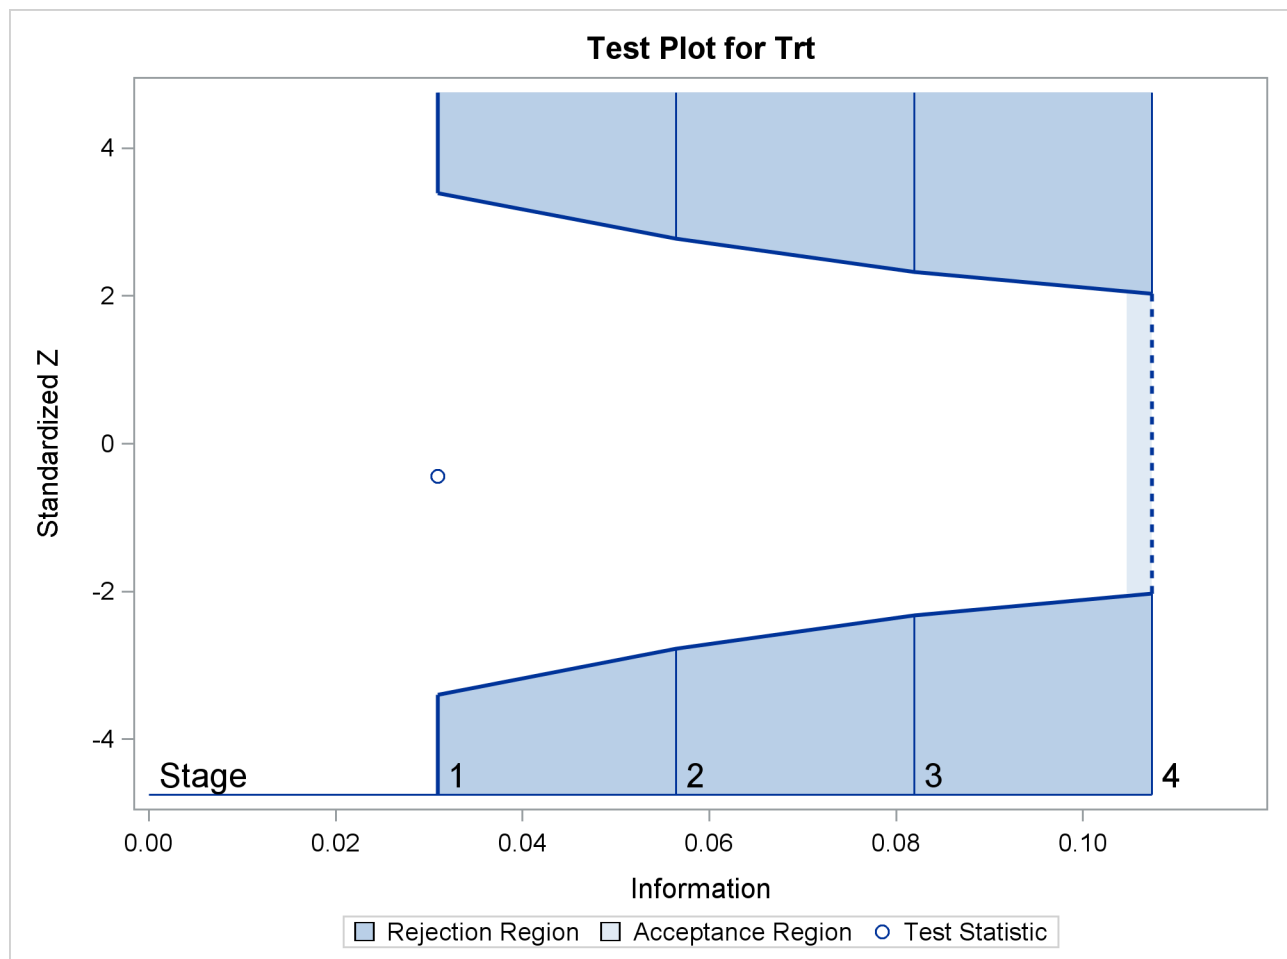

| Test Information (Standardized Z Scale) |                |               |
|-----------------------------------------|----------------|---------------|
| Null Reference = 0                      |                |               |
| _Stage_                                 | -----Test----- |               |
|                                         | Estimate       | -----Trt----- |
|                                         |                | Action        |
| 1                                       | -0.44426       | Continue      |
| 2                                       | .              |               |
| 3                                       | .              |               |
| 4                                       | .              |               |

At stage 1, the standardized  $Z$  statistic  $-0.44426$  is between the lower and upper  $\alpha$  boundary values, and so the trial continues to the next stage. With the observed information level at stage 1,  $I_1 = 0.0309$  (which is not substantially different from the target information level at stage 1), the trial continues to the next stage without adjustment of the sample size according to the study plan.

If an observed information level is different from its target level at an interim stage, the sample sizes at future stages can be adjusted to achieve the target maximum information level according to the study plan. That is, a study plan might modify the final sample size to achieve the target maximum information level if the observed information level is different from its target level by a specified amount at the interim stage. For example, if the variance estimate is used to compute the required sample size of a two-sample  $Z$  test for mean difference, the study plan might use the current variance estimate to update the required sample size for the trial (Jennison and Turnbull 2000, p. 295). See the section “Applicable Two-Sample Tests and Sample Size Computation” in “The SEQDESIGN Procedure” for a description of how to compute the sample size from the variance estimate.

If ODS Graphics is enabled, a detailed test plot with the rejection and acceptance regions is displayed, as shown in Figure 84.12. This plot displays the boundary values in the “Test Information” table in Figure 84.11. The stages are indicated by vertical lines with accompanying stage numbers. The horizontal axis indicates the information levels for the stages. As expected, the test statistic is in the continuation region between the lower and upper  $\alpha$  boundaries.

**Figure 84.12** Sequential Test Plot

The following statements use the REG procedure with the data available at the first two stages to estimate the mean treatment difference and its associated standard error at stage 2:

```
proc reg data=LDL_2;
 model Ldl=Trt;
 ods output ParameterEstimates=Parms_LDL2;
run;
```

The following statements create and display (in Figure 84.13) the data set for the mean treatment difference and its associated standard error:

```
data Parms_LDL2;
 set Parms_LDL2;
 if Variable='Trt';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_LDL2;
 title 'Statistics Computed at Stage 2';
run;
```

**Figure 84.13** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Trt      | -8.37628 | 4.24405 | MLE     | 2       |

Using the standard error for the treatment estimate available at stage 2, the information level that corresponds to the test statistic at stage 2 is estimated by

$$I_2 = \frac{1}{s_2^2} = \frac{1}{4.244^2} = 0.0555$$

where  $s_2$  is the standard error of the treatment estimate at stage 2.

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_LDL1
 Parms (Testvar=Trt) =Parms_LDL2
 infoadj=prop
 ;
 ods output Test=Test_LDL2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_LDL2 option creates an output data set named TEST\_LDL2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Test Information” table in Figure 84.14 displays the boundary values for the test statistic with the default standardized Z scale

**Figure 84.14** Sequential Tests

| The SEQTEST Procedure                   |                       |          |                       |                     |                         |             |
|-----------------------------------------|-----------------------|----------|-----------------------|---------------------|-------------------------|-------------|

| Test Information (Standardized Z Scale) |                |               |          |
|-----------------------------------------|----------------|---------------|----------|
| Null Reference = 0                      |                |               |          |
| _Stage_                                 | -----Test----- |               | Action   |
|                                         | Estimate       | -----Trt----- |          |
| 1                                       | -0.44426       |               | Continue |
| 2                                       | -1.97365       |               | Continue |
| 3                                       | .              |               |          |
| 4                                       | .              |               |          |

At stage 2, the standardized test statistic,  $z = -8.37628/4.24405 = -1.97365$ , is between its corresponding lower and upper  $\alpha$  boundary values. Therefore, the trial continues to the next stage.

The following statements use the REG procedure with the data available at the first three stages to estimate the mean treatment difference and its associated standard error at stage 3:

```
proc reg data=LDL_3;
 model Ldl=Trt;
 ods output ParameterEstimates=Parms_LDL3;
run;
```

The following statements create and display (in Figure 84.15) the data set for the mean treatment difference and its associated standard error:

```
data Parms_LDL3;
 set Parms_LDL3;
 if Variable='Trt';
 Scale='MLE';
 Stage= 3;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_LDL3;
 title 'Statistics Computed at Stage 3';
run;
```

**Figure 84.15** Statistics Computed at Stage 3

| Statistics Computed at Stage 3 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Trt      | -9.21369 | 3.42149 | MLE     | 3       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 3:

```
ods graphics on;
proc seqtest Boundary=Test_LDL2
 Parms(Testvar=Trt)=Parms_LDL3
 infoadj=prop
 ;
 ods output Test=Test_LDL3;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 3, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 3, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_LDL3 option creates an output data set named TEST\_LDL3 which contains the updated boundary information for the test at stage 3. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Test Information” table in Figure 84.16 displays the boundary values for the test statistic with the default standardized Z scale.

| 2                                       | 0.5169                | 0.055519 | -2.35624              | 2.35624             | -2.78456                | 2.78456    |
| 3                                       | 0.7953                | 0.085422 | -2.92271              | 2.92271             | -2.25480                | 2.25480    |
| 4                                       | 1.0000                | 0.107403 | -3.27724              | 3.27724             | -2.04573                | 2.04573    |

| Test Information (Standardized Z Scale) |                |             |
|-----------------------------------------|----------------|-------------|
| Null Reference = 0                      |                |             |
| _Stage_                                 | -----Test----- |             |
|                                         | Estimate       | Action      |
| 1                                       | -0.44426       | Continue    |
| 2                                       | -1.97365       | Continue    |
| 3                                       | -2.69289       | Reject Null |
| 4                                       | .              |             |

The sequential test stops at stage 3 to reject the null hypothesis for the lower alternative because the test statistic  $-2.69289$  is less than the corresponding upper  $\alpha$  boundary  $-2.25480$ . That is, the test demonstrates significant beneficial effect for the new drug.

The “Test Plot” displays boundary values for the design and the test statistic at the first three stages, as shown in Figure 84.17. It shows that the test statistic is in the “Rejection Region” below the lower  $\alpha$  boundary at stage 3.

Figure 84.17 Sequential Test Plot

When a trial stops, the “Parameter Estimates” table in Figure 84.18 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and  $p$ -value under the null hypothesis  $H_0 : \theta = 0$ . As expected, the  $p$ -value 0.0108 is significant at the two-sided  $\alpha$  level,  $\alpha = 0.05$ , and the confidence interval does not contain the value zero. The  $p$ -value, unbiased median estimate, and confidence limits depend on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic. See the section “Analysis after a Sequential Test” on page 7229 for a detailed description of these statistics.

## Syntax: SEQTEST Procedure

The following statement is available in the SEQTEST procedure:

```
PROC SEQTEST < options > ;
```

## PROC SEQTEST Statement

The PROC SEQTEST statement invokes the SEQTEST procedure. Table 84.1 summarizes the options available in the PROC SEQTEST statement.

**Table 84.1** Summary of PROC SEQTEST Options

| Option                 | Description                                                                                                                         |
|------------------------|-------------------------------------------------------------------------------------------------------------------------------------|
| <b>Input Data Sets</b> |                                                                                                                                     |
| BOUNDARY=              | Specifies the data set for boundary information                                                                                     |
| DATA=                  | Specifies the data set for parameter estimates and information levels                                                               |
| PARMS=                 | Specifies the data set for parameter estimates and standard errors                                                                  |
| <b>Boundaries</b>      |                                                                                                                                     |
| BETABOUNDARY=          | Specifies whether the $\beta$ boundary is used in the computation of the Type I error level $\alpha$                                |
| BETAOVERLAP=           | Checks for overlapping of the lower and upper $\beta$ boundaries at the current and subsequent interim stages in a two-sided design |
| BOUNDARYKEY=           | Specifies the boundary key to maintain Type I and II error probability levels                                                       |
| BOUNDARYSCALE=         | Specifies the boundary scale                                                                                                        |
| ERRSPENDADJ=           | Specifies error spending methods for boundary adjustments                                                                           |
| ERRSPENDMIN=           | Specifies minimum error spending values for the boundaries                                                                          |
| INFOADJ=               | Specifies whether information levels at future interim stages should be adjusted                                                    |

Table 84.1 continued

| Option                                          | Description                                                                                          |
|-------------------------------------------------|------------------------------------------------------------------------------------------------------|
| NSTAGES=                                        | Specifies the number of stages                                                                       |
| <b>Test Statistics</b>                          |                                                                                                      |
| DATA( TESTVAR= )                                | Specifies the test variable in the DATA= data set                                                    |
| PARMS( TESTVAR= )                               | Specifies the test variable in the PARMS= data set                                                   |
| <b><i>p</i>-Values and Confidence Intervals</b> |                                                                                                      |
| CIALPHA=                                        | Specifies the significance levels for the confidence interval                                        |
| CITYPE=                                         | Specifies the types of confidence interval                                                           |
| ORDER=                                          | Specifies the ordering of the sample space used to derive the <i>p</i> -values and confidence limits |
| <b>Table Output</b>                             |                                                                                                      |
| CONDPOWER                                       | Displays conditional powers                                                                          |
| ERRSPEND                                        | Displays the cumulative error spending at each stage                                                 |
| PREDPOWER                                       | Displays the predictive powers                                                                       |
| PSS                                             | Displays the powers and expected sample sizes                                                        |
| RCI                                             | Displays the repeated confidence intervals                                                           |
| STOPPROB                                        | Displays the expected cumulative stopping probabilities                                              |
| <b>Graphics Output</b>                          |                                                                                                      |
| PLOTS=ASN                                       | Displays the expected sample numbers plot                                                            |
| PLOTS=CONDPOWER                                 | Displays the conditional powers plot                                                                 |
| PLOTS=ERRSPEND                                  | Displays the error spending plot                                                                     |
| PLOTS=POWER                                     | Displays the powers plot                                                                             |
| PLOTS=RCI                                       | Displays the repeated confidence intervals plot                                                      |
| PLOTS=TEST                                      | Displays the boundary plot with test statistics                                                      |

The BOUNDARY= option provides the information for the design and is required in the PROC SEQTEST statement. By default, the SEQTEST procedure displays tables of design information and test information. If ODS Graphics is enabled, the procedure also displays a sequential test plot.

The following options can be used in the PROC SEQTEST statement. They are listed in alphabetical order.

#### **BETABOUNDARY=BINDING | NONBINDING**

specifies whether the  $\beta$  boundary is used in the computation of the Type I error level  $\alpha$ . The BETABOUNDARY=BINDING option computes the Type I error probability with the  $\beta$  (acceptance) boundary, and the BETABOUNDARY=NONBINDING suboption computes the Type I error probability without the  $\beta$  boundary (Zhu, Ni, and Yao 2011, pp. 132–133). For a detailed description of nonbinding acceptance boundary, see the section “Acceptance ( $\beta$ ) Boundary” in Chapter 83, “The SEQDESIGN Procedure.” The default is BETABOUNDARY=BINDING.

#### **BETAOVERLAP=ADJUST | NOADJUST**

##### **OVERLAP=ADJUST | NOADJUST**

specifies whether to check for overlapping of the lower and upper  $\beta$  boundaries for the two corresponding one-sided tests at the current and subsequent interim stages. This option applies to two-sided designs with early stopping to accept  $H_0$ , or to either accept or reject  $H_0$ . This type of over-

lapping might result from a small  $\beta$  spending at an interim stage. When you specify BETAOVERLAP=ADJUST, the procedure checks for this type of overlapping at the current and subsequent interim stages. If such overlapping is found, the  $\beta$  boundaries for the two-sided design at that stage are set to missing, and the  $\beta$  spending values at subsequent stages are adjusted, as described in the section “Boundary Adjustments for Overlapping Lower and Upper  $\beta$  Boundaries” on page 7225.

You can specify BETAOVERLAP=NOADJUST to request that no adjustment be made. The default is BETAOVERLAP=ADJUST.

#### **BOUNDARY=SAS-data-set**

names the required SAS data set that contains the design boundary information. At stage 1, the data set is usually created from the “Boundary Information” table created by the SEQDESIGN procedure. At each subsequent stage, the data set is usually created from the “Test Information” table created by the SEQTEST procedure at the previous stage. The data set includes the variables `_Scale_` for the boundary scale, `_Stop_` for the stopping criterion, and `_ALT_` for the type of alternative hypothesis. It also includes `_Stage_` for the stage number, `Info_Prop` for the information proportion, and a set of the boundary variables from `Bound_LA`, `Bound_LB`, `Bound_UB`, and `Bound_UA` for boundary values at each stage.

The data set might also include `_Info_` for the actual information level, `NObs` for the number of observation, and `Events` for the number of events required at each stage.

#### **BOUNDARYKEY=ALPHA | BETA | BOTH**

specifies the boundary key to be maintained in the boundary adjustments. The BOUNDARYKEY=ALPHA option maintains the Type I  $\alpha$  level and derives the Type II error probability, and the BOUNDARYKEY=BETA option maintains the Type II  $\beta$  level and derives the Type I error probability. The BOUNDARYKEY=BOTH option maintains both  $\alpha$  and  $\beta$  levels simultaneously by deriving a new maximum information. The default is BOUNDARYKEY=ALPHA.

#### **BOUNDARYSCALE=MLE | SCORE | STDZ | PVALUE**

##### **BSCALE=MLE | SCORE | STDZ | PVALUE**

specifies the boundary scale to be displayed in the output boundary table and plot. The BOUNDARYSCALE=MLE, BOUNDARYSCALE=SCORE, BOUNDARYSCALE=STDZ, and BOUNDARYSCALE=PVALUE options correspond to the boundary with the maximum likelihood estimator scale, score statistic scale, standardized normal Z scale, and  $p$ -value scale, respectively. The default is BOUNDARYSCALE=STDZ.

With the BOUNDARYSCALE=MLE or BOUNDARYSCALE=SCORE option, either the MAXINFO= option must be specified or the `_Info_` variable must be in the BOUNDARY= data set to provide the necessary information level at each stage to derive the boundary values. Usually, these values are obtained from analysis output in SAS procedures.

Note that for a two-sided design, the  $p$ -value scale displays the one-sided fixed-sample  $p$ -value under the null hypothesis with a lower alternative hypothesis.

#### **CIALPHA= $\alpha$ (< < LOWER= $\alpha_l$ > < UPPER= $\alpha_u$ > )>**

specifies the significance levels for the confidence interval, where  $0 < \alpha < 1$ ,  $0 < \alpha_l < 0.5$ , and  $0 < \alpha_u < 0.5$ . The default is CIALPHA=0.05.

For a lower confidence interval (CITYPE=LOWER), the CIALPHA= $\alpha$  option produces a  $(1 - \alpha)$  lower confidence interval. For an upper confidence interval (CITYPE=UPPER), the CIALPHA= $\alpha$

option produces a  $(1 - \alpha)$  upper confidence interval. The LOWER= and UPPER= suboptions are applicable only for a two-sided confidence interval (CITYPE=TWOSIDED). The LOWER= suboption specifies the lower significance level  $\alpha_l$  and the upper significance level  $\alpha_u = 1 - \alpha_l$ . The UPPER= suboption specifies the upper significance level  $\alpha_u$  and the lower significance level  $\alpha_l = 1 - \alpha_u$ . If both LOWER= and UPPER= suboptions are not specified,  $\alpha_l = \alpha_u = \alpha/2$ . The significance levels  $\alpha_l$  and  $\alpha_u$  are then used for the  $(1 - \alpha_l)$  lower confidence limit and  $(1 - \alpha_u)$  upper confidence limit, respectively.

**CITYPE=LOWER | UPPER | TWOSIDED**

specifies the type of confidence interval. The CITYPE=LOWER, CITYPE=UPPER, and CITYPE=TWOSIDED options correspond to the lower confidence interval, upper confidence interval, and two-sided confidence interval, respectively. The default is CITYPE=LOWER for the design with an upper alternative, CITYPE=UPPER for the design with a lower alternative, and CITYPE=TWOSIDED for the design with a two-sided alternative.

**DATA < (TESTVAR=variable) >=SAS-data-set**

names the SAS data set that contains the test statistic and its associated information level for the stage. The data set includes the stage variable `_Stage_` and a variable to identify or derive the information level: `_Info_` for the information level, `NObs` for the number of observation, or `Events` for the number of events. If the information level that corresponds to the test statistic is not available, the information level derived in the BOUNDARY= data set is used.

If the TESTVAR= option is specified, the data set also includes the test variable specified in the TESTVAR= option and the scale variable `_Scale_` for the test statistic. Usually, these test variable values are obtained from analysis output in SAS procedures.

**ERRSPENDADJ=method**

**ERRSPENDADJ(boundary)=method**

**BOUNDARYADJ=method**

**BOUNDARYADJ(boundary)=method**

specifies methods to compute the error spending values at the current and future interim stages for the boundaries. This option is applicable only if the observed information level at the current stage does not match the value provided in the BOUNDARY= data set. These error spending values are then used to derive the updated boundary values. The default is ERRSPENDADJ=ERRLINE. Note that the information levels at future interim stages are determined by the INFOADJ= option.

The following options specify available error spending methods for boundary adjustment:

**NONE**

specifies that the cumulative error spending at each interim stage not be changed, even if the corresponding information level has been changed.

**ERRLINE**

specifies the linear interpolation method for the adjustment.

**ERRFUNCGAMMA < ( GAMMA=  $\gamma$  ) >**

specifies the gamma function method for the adjustment. The GAMMA= suboption specifies the  $\gamma$  parameter in the function, where  $\gamma \leq 3$ . The default is GAMMA=-2.

**ERRFUNCOBF**

specifies the approximate O'Brien-Fleming cumulative error spending function for the adjustment.

**ERRFUNCPOC**

specifies the approximate Pocock cumulative error spending function for the adjustment.

**ERRFUNCPOW < ( RHO=  $\rho$  ) >**

specifies the power function method for the adjustment. The RHO= suboption specifies the power parameter  $\rho$  in the function, where  $\rho \geq 0.25$ . The default is RHO=2.

See the section “[Boundary Adjustments for Information Levels](#)” on page 7223 for a detailed description of the available error spending methods for boundary adjustment in the SEQTEST procedure.

If an error spending method for boundary adjustments is used for all boundaries in a group sequential test, you can use the ERRSPENDADJ=*method* option to specify the method. Otherwise, you can use the following ERRSPENDADJ(*boundary*)=*method* options to specify different methods for the boundaries.

**ERRSPENDADJ(ALPHA)=*method***

**ERRSPENDADJ(REJECT)=*method***

**BOUNDARYADJ(ALPHA)=*method***

**BOUNDARYADJ(REJECT)=*method***

specifies the adjustment method for the  $\alpha$  (rejection) boundary of a one-sided design or the lower and upper  $\alpha$  boundaries of a two-sided design.

**ERRSPENDADJ(LOWERALPHA)=*method***

**ERRSPENDADJ(LOWERREJECT)=*method***

**BOUNDARYADJ(LOWERALPHA)=*method***

**BOUNDARYADJ(LOWERREJECT)=*method***

specifies the adjustment method for the lower  $\alpha$  boundary of a two-sided design.

**ERRSPENDADJ(UPPERALPHA)=*method***

**ERRSPENDADJ(UPPERREJECT)=*method***

**BOUNDARYADJ(UPPERALPHA)=*method***

**BOUNDARYADJ(UPPERREJECT)=*method***

specifies the adjustment method for the upper  $\alpha$  boundary of a two-sided design.

**ERRSPENDADJ(BETA)=*method***

**ERRSPENDADJ(ACCEPT)=*method***

**BOUNDARYADJ(BETA)=*method***

**BOUNDARYADJ(ACCEPT)=*method***

specifies the adjustment method for the  $\beta$  (acceptance) boundary of a one-sided design or the lower and upper  $\beta$  boundaries of a two-sided design.

**ERRSPENDADJ(LOWERBETA)=method**

**ERRSPENDADJ(LOWERACCEPT)=method**

**BOUNDARYADJ(LOWERBETA)=method**

**BOUNDARYADJ(LOWERACCEPT)=method**

specifies the adjustment method for the lower  $\beta$  boundary of a two-sided design.

**ERRSPENDADJ(UPPERBETA)=method**

**ERRSPENDADJ(UPPERACCEPT)=method**

**BOUNDARYADJ(UPPERBETA)=method**

**BOUNDARYADJ(UPPERACCEPT)=method**

specifies the adjustment method for the upper  $\beta$  boundary of a two-sided design.

**ERRSPENDMIN=numbers**

**ERRSPENDMIN(boundary)=numbers**

specifies the minimum error spending values at the current observed and future interim stages for the boundaries specified in the BOUNDARYKEY= option. The default is ERRSPENDMIN=0.

If a set of numbers is used for each boundary in the design, you can use the ERRSPENDMIN=numbers option. Otherwise, you can use the following ERRSPENDMIN(boundary)=numbers options to specify different sets of minimum error spending values for the boundaries. For a boundary, the error spending value at stage 1 is identical to its nominal  $p$ -value.

**ERRSPENDMIN(ALPHA)=numbers**

**ERRSPENDMIN(REJECT)=numbers**

specifies the minimum error spending values for the  $\alpha$  boundary of a one-sided design or the lower and upper  $\alpha$  boundaries of a two-sided design.

**ERRSPENDMIN(LOWERALPHA)=numbers**

**ERRSPENDMIN(LOWERREJECT)=numbers**

specifies the minimum error spending values for the lower  $\alpha$  boundary of a two-sided design.

**ERRSPENDMIN(UPPERALPHA)=numbers**

**ERRSPENDMIN(UPPERREJECT)=numbers**

specifies the minimum error spending values for the upper  $\alpha$  boundary of a two-sided design.

**ERRSPENDMIN(BETA)=numbers**

**ERRSPENDMIN(ACCEPT)=numbers**

specifies the minimum error spending values for the  $\beta$  boundary of a one-sided design or the lower and upper  $\beta$  boundaries of a two-sided design.

**ERRSPENDMIN(LOWERBETA)=numbers**

**ERRSPENDMIN(LOWERACCEPT)=numbers**

specifies the minimum error spending values for the lower  $\beta$  boundary of a two-sided design.

**ERRSPENDMIN(UPPERBETA)=numbers**

**ERRSPENDMIN(UPPERACCEPT)=numbers**

specifies the minimum error spending values for the upper  $\beta$  boundary of a two-sided design.

**INFOADJ=NONE | PROP**

specifies whether information levels at future interim stages are to be adjusted. If you specify INFOADJ=NONE, no adjustment is made, and the information levels are preserved at the levels provided in the BOUNDARY= data set. If you specify INFOADJ=PROP (which is the default), the information levels are adjusted proportionally from the levels provided in the BOUNDARY= data set. The section “[Information Level Adjustments at Future Stages](#)” on page 7223 describes how the adjustments are computed.

Note that if you specify BOUNDARYKEY=BOTH, the INFOADJ=NONE option is not applicable, and the INFOADJ=PROP option is used to adjust the information levels at future stages proportionally from the levels provided in the BOUNDARY= data set to maintain both  $\alpha$  and  $\beta$  levels.

**NSTAGES=*number***

specifies the number of stages for the clinical trial. The default is the number derived from the BOUNDARY= data set.

The specified NSTAGES= number might or might not be the same as the number derived in the BOUNDARY= data set. You can use the NSTAGES= option to set the next stage as the final stage to compute the conditional power, as described in the section “[Conditional Power Approach](#)” on page 7226.

**ORDER=LR | MLE | STAGEWISE**

specifies the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the observed standardized  $Z$  statistic. The ordering is used to derive the  $p$ -values for the observed  $(k, z)$  statistic and to create unbiased median estimate and confidence limits from the statistic. The ORDER=LR option specifies the LR ordering that compares the distances between observed standardized  $Z$  statistics and their corresponding hypothetical values, the ORDER=MLE option specifies the MLE ordering that compares values in the MLE scale, and the ORDER=STAGEWISE specifies the stagewise ordering that uses counterclockwise ordering around the continuation region. The default is ORDER=STAGEWISE. See the section “[Available Sample Space Orderings in a Sequential Test](#)” on page 7230 for a detailed description of these sample space orderings.

**PARMS <(TESTVAR=*variable*)> =SAS-*data-set***

names the SAS data set that contains the parameter estimate and its associated standard error for the stage. The data set includes the stage variable `_Stage_`, the test statistic Estimate, the standard error of the estimate StdErr, and the test statistic scale variable `_Scale_`. The standard error is used to derive the information level. If the standard error is not available, the information level derived in the BOUNDARY= data set is used.

The data set also includes the variable Parameter, Effect, Variable, or Parm that contains the test variable specified in the TESTVAR= option. Usually, these test variable values are obtained from analysis output in SAS procedures.

**Table Output Options**

You can specify the following *options* in the PROC SEQTEST statement to display additional table output. They are listed in alphabetical order.

**CONDPOWER** < ( options ) >

displays conditional powers given the most recently observed statistic under specified hypothetical references.

You can specify the following *options*:

**CREF=**  $c_1 < c_2 \dots >$ 

specifies the hypothetical references, where  $c_i \geq 0$ . For a one-sided test, the powers are derived under the hypothetical references  $\theta = \hat{\theta}$  and  $\theta = c_i \theta_1$ , where  $\hat{\theta}$  is the observed statistic,  $\theta_1$  is the alternative reference, and  $c_i$  are the values specified in the CREF= option. For a two-sided test, the powers are derived under hypothetical references  $\theta = \hat{\theta}$ ,  $\theta = c_i \theta_{1l}$ , and  $\theta = c_i \theta_{1u}$ , where  $\theta_{1l}$  is the lower alternative reference and  $\theta_{1u}$  is the upper alternative reference. The default is CREF= 0 0.5 1.0 1.5.

**TYPE=ALLSTAGES | FINALSTAGE**

specifies the probability to be computed for the conditional power. Two types of conditional power can be computed: TYPE=ALLSTAGES computes the conditional power as the total probability of rejecting the null hypothesis at all future stages given the observed statistic, and TYPE=FINALSTAGE computes the conditional power as the probability that the test statistic at the final stage would exceed the rejection critical value given the observed statistic. The default is TYPE=ALLSTAGES.

If interim stages exist between the current stage and the final stage, the conditional power that is computed when TYPE=FINALSTAGE is not the conditional probability to reject the null hypothesis  $H_0$ . In this case, you can set the next stage as the final stage, and the resulting conditional power is the conditional probability to reject  $H_0$ .

**ERRSPEND**

displays the error spending at each stage for each sequential boundary.

**PREDPOWER**

displays predictive powers given the most recently observed statistic. The predictive power is the posterior probability that the test statistic at the final stage would exceed the rejection critical value given the observed statistic and a prior distribution of the hypothetical reference. A noninformative prior is used in the procedure.

**PSS** < ( CREF=  $c_1 < c_2 \dots >$  ) >

displays powers and expected sample sizes under various hypothetical references, where  $c_i \geq 0$ .

For a one-sided design with the null reference  $\theta_0 = 0$ , the power and expected sample sizes under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, the power and expected sample sizes under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. The default is CREF= 0 0.5 1.0 1.5.

Note that for a symmetric two-sided design, only the power and expected sample sizes under hypotheses  $\theta = c_i \theta_{1u}$  are derived.

**RCI**

displays repeated confidence intervals for the parameter from the observed statistic at each stage. Repeated confidence intervals include both rejection and acceptance confidence intervals.

With the STOP=REJECT or STOP=BOTH option, rejection confidence limits can be derived, and the null hypothesis  $H_0 : \theta = 0$  is rejected if the lower rejection confidence limit is greater than 0 or the upper rejection confidence limit is less than 0.

With the STOP=ACCEPT or STOP=BOTH option, acceptance confidence limits can be derived, and the null hypothesis is accepted with alternative hypotheses  $H_{1l} : \theta = \theta_{1l}$  and  $H_{1u} : \theta = \theta_{1u}$  if the upper acceptance confidence limit is less than  $\theta_{1u}$  and the lower acceptance confidence limit is greater than  $\theta_{1l}$ .

**STOPPROB <( CREF=  $c_1 < c_2 \dots >$  ) >**

displays expected cumulative stopping probabilities under various hypothetical references, where  $c_i \geq 0$ .

For a one-sided design, expected cumulative stopping probabilities at each stage under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, expected cumulative stopping probabilities at each stage under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only expected cumulative stopping probabilities under hypotheses  $\theta = c_i \theta_{1u}$  are derived. The default is CREF= 0 0.5 1.0 1.5.

**Graphics Output Options**

The following options can be used in the PROC SEQTEST statement to display plots with ODS Graphics. They are listed in alphabetical order.

**PLOTS <( ONLY )> <= *plot-request* >****PLOTS <( ONLY )> <= ( *plot-request* < ... *plot-request* ) >**

specifies options that control the details of the plots. The default is PLOTS=TEST. The global plot option ONLY suppresses the default plots and displays only plots specifically requested.

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc seqtest Boundary=Bnd_LDL
 Parms(Testvar=Trt)=Parms_LDL1
 Plots=(test errspend);
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The plot request options include the following.

**ALL**

produces all appropriate plots.

**ASN** < ( **CREF=**  $c_1 < c_2 \dots >$  ) >

displays a plot of the average sample numbers (expected sample sizes for nonsurvival data or expected number of events for survival data) under various hypothetical references, where  $c_i \geq 0$ .

For a one-sided design, expected sample numbers under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, expected sample numbers under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only the average sample numbers under hypotheses  $\theta = c_i \theta_{1u}$  are derived. The default is CREF= 0 to 1.5 by 0.01.

**CONDPOWER** < ( *options* ) >

displays a plot of conditional powers given the most recently observed statistic under specified hypothetical references.

You can specify the following *options*:

**CREF=**  $c_1 < c_2 \dots >$

specifies the hypothetical references, where  $c_i \geq 0$ . For a one-sided test, the powers are derived under hypothetical references  $\theta = \hat{\theta}$  and  $\theta = c_i \theta_1$ , where  $\hat{\theta}$  is the observed statistic,  $\theta_1$  is the alternative reference, and  $c_i$  are the values specified in the CREF= option. For a two-sided test, the powers are derived under hypothetical references  $\theta = \hat{\theta}$ ,  $\theta = c_i \theta_{1l}$ , and  $\theta = c_i \theta_{1u}$ , where  $\theta_{1l}$  is the lower alternative reference and  $\theta_{1u}$  is the upper alternative reference. The default is CREF= 0 to 1.5 by 0.01.

**TYPE=ALLSTAGES | FINALSTAGE**

specifies the probability to be computed for the conditional power. Two types of conditional power can be computed: TYPE=ALLSTAGES computes the conditional power as the total probability of rejecting the null hypothesis at all future stages given the observed statistic, and TYPE=FINALSTAGE computes the conditional power as the probability that the test statistic at the final stage would exceed the rejection critical value given the observed statistic. The default is TYPE=ALLSTAGES.

**ERRSPEND** < ( **HSCALE=INFO | STAGE** ) >

displays a plot of the error spending for all sequential boundaries in the designs simultaneously. You can display the information level (HSCALE=INFO) or the stage number (HSCALE=STAGE) on the horizontal axis. With HSCALE=INFO, the information fractions are used in the plot. The default is HSCALE=STAGE.

**NONE**

suppresses all plots.

**POWER <( CREF=  $c_1 < c_2 \dots >$  ) >**

displays a plot of the power curves under various hypothetical references, where  $c_i \geq 0$ .

For a one-sided design, powers under hypotheses  $\theta = c_i \theta_1$  are displayed, where  $\theta_1$  is the alternative reference and  $c_i$  are the values specified in the CREF= option.

For a two-sided design, powers under hypotheses  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. Note that for a symmetric two-sided design, only powers under hypotheses  $\theta = c_i \theta_{1u}$  are derived. The default is CREF= 0 to 1.5 by 0.01.

**RCI**

displays a plot of repeated confidence intervals. Repeated confidence intervals include both rejection and acceptance confidence intervals.

With the STOP=REJECT or STOP=BOTH option, rejection confidence limits can be derived and the null hypothesis  $H_0 : \theta = 0$  is rejected if the lower rejection confidence limit is greater than 0 or the upper rejection confidence limit is less than 0.

With the STOP=ACCEPT or STOP=BOTH option, acceptance confidence limits can be derived and the null hypothesis is accepted with alternative hypotheses  $H_{1l} : \theta = \theta_{1l}$  and  $H_{1u} : \theta = \theta_{1u}$  if the upper acceptance confidence limit is less than  $\theta_{1u}$  and the lower acceptance confidence limit is greater than  $\theta_{1l}$ .

**TEST <( HSCALE=INFO | SAMPLESIZE ) >**

displays a plot of the sequential boundaries and test variables. Either the information level (HSCALE=INFO) or the sample size (HSCALE=SAMPLESIZE) is displayed on the horizontal axis. The HSCALE=SAMPLESIZE option is applicable only if the sample size information is available in both the input BOUNDARY= data set and input DATA= data set. The stage number for each stage is displayed inside the plot. The default is HSCALE=INFO.

## Details: SEQTEST Procedure

### Input Data Sets

The BOUNDARY= data set option is required, and if neither the DATA= nor the PARMS= data set option is specified, the procedure derives statistics such as Type I and Type II error probabilities from the BOUNDARY= data set. The resulting boundaries are displayed with the scale specified in the BOUNDARYSCALE= option.

### BOUNDARY= Data Set

The BOUNDARY= data set provides the boundary information for the sequential test. At stage 1, the data set is usually created with an ODS OUTPUT statement from the “Boundary Information” table created by the SEQDESIGN procedure. At each subsequent stage, the data set is usually created with an ODS OUTPUT statement from the “Test Information” table that was created by the SEQTEST procedure at the

previous stage. See the section “Getting Started: SEQTEST Procedure” on page 7192 for an illustration of the BOUNDARY= data set option.

The BOUNDARY= data set contains the following variables:

- `_Scale_`, the boundary scale, with the value MLE for the maximum likelihood estimate, STDZ for the standardized Z, SCORE for the score statistic, or PVALUE for the nominal  $p$ -value. Note that for a two-sided design, the nominal  $p$ -value is the one-sided fixed-sample  $p$ -value under the null hypothesis with a lower alternative hypothesis.
- `_Stop_`, the stopping criterion, with the value REJECT for rejecting the null hypothesis  $H_0$ , ACCEPT for accepting  $H_0$ , or BOTH for both rejecting and accepting  $H_0$
- `_ALT_`, the type of alternative hypothesis, with the value UPPER for an upper alternative, LOWER for a lower alternative, or TWOSIDED for a two-sided alternative
- `_Stage_`, the stage number
- the boundary variables, a subset of Bound\_LA for lower  $\alpha$  boundary, Bound\_LB for lower  $\beta$  boundary, Bound\_UB for upper  $\beta$  boundary, and Bound\_UA for upper  $\alpha$  boundary
- AltRef\_L, the lower alternative reference, if ALT=LOWER or ALT=TWOSIDED
- AltRef\_U, the upper alternative reference, if ALT=UPPER or ALT=TWOSIDED
- `_InfoProp_`, the information proportion at each stage

Optionally, the BOUNDARY= data set also contains the following variables:

- `_Info_`, the information level at each stage
- NObs, the required number of observations for nonsurvival data at each stage
- Events, the required number of events for survival data at each stage
- Parameter, the variable specified in the DATA(TESTVAR=) or PARMS(TESTVAR=) option
- Estimate, the parameter estimate

If the BOUNDARY= data set contains the variable Parameter for the test variable that is specified in the TESTVAR= option, and the variable Estimate for the test statistics, then these test statistics are also displayed in the output test information table and output test plot.

## DATA= Data Set

The DATA= data set provides the test variable information for the current stage of the trial. Such data sets are usually created with an ODS OUTPUT statement by using a procedure such as PROC MEANS. See “Example 84.4: Testing a Binomial Proportion” on page 7284 for an illustration of the DATA= data set option.

The DATA= data set includes the following variables:

- `_Stage_`, the stage number
- `_Scale_`, the scale for the test statistic, with the value MLE for the maximum likelihood estimate, STDZ for the standardized Z, SCORE for the score statistic, or PVALUE for the nominal  $p$ -value
- `_Info_`, the information level
- NObs, the number of observations for nonsurvival data at each stage
- Events, the number of events for survival data at each stage
- test variable, specified in the TESTVAR= option, contains the test variable value in the scale specified in the `_Scale_` variable

With the specified DATA= data set, PROC SEQTEST derives boundary values from the information levels in the `_Info_` variable. If the data set does not include the `_Info_` variable, then the information levels are derived from the NObs or Events variable in the DATA= data set if that variable is also in the input BOUNDARY= data set. That is, the information level at stage  $k$  is computed as  $I_k^* = I_k \times (n_k^*/n_k)$ , where  $I_k$  and  $n_k$  are the information level and sample size, respectively, at stage  $k$  in the BOUNDARY= data set and  $n_k^*$  is the sample size at stage  $k$  in the DATA= data set. Otherwise, the information levels from the BOUNDARY= data set are used.

If the TESTVAR= option is specified, the DATA= data set must also include the test variable for the test statistic and `_Scale_` variable for the corresponding scale. Note that for a two-sided design, the nominal  $p$ -value is the one-sided fixed-sample  $p$ -value under the null hypothesis with a lower alternative hypothesis.

### PARMS= Data Set

The PARMS= data set provides a parameter estimate and associated standard error for the current stage of the trial. Such data sets are usually created with an ODS OUTPUT statement by using procedures such as the GENMOD, GLM, LOGISTIC, and REG procedures. See the section “Getting Started: SEQTEST Procedure” on page 7192 for an illustration of the PARMS= data set option.

The PARMS= data set includes the following variables:

- `_Stage_`, the stage number
- `_Scale_`, the scale for the test statistic, with the value MLE for the maximum likelihood estimate, STDZ for the standardized Z, SCORE for the score statistic, or PVALUE for the nominal  $p$ -value
- Parameter, Effect, Variable, or Parm, which contains the variable specified in the TESTVAR= option
- Estimate, the parameter estimate
- StdErr, standard error of the parameter estimate
- NObs, the number of observations for nonsurvival data at each stage
- Events, the number of events for survival data at each stage

With the specified PARMs= data set, the information level is derived from the StdErr variable. For a score statistic, the information level  $I_k$  is the variance of the statistic,  $\hat{s}_k^2$ , where  $\hat{s}_k$  is the standard error in the StdErr variable. Otherwise, the information level is the inverse of the variance of the statistic,  $\hat{s}_k^{-2}$ . If the data set does not include the StdErr variable, the information levels derived from the BOUNDARY= data set are used.

If the data set does not include the StdErr variable, then the information levels are derived from the NObs or Events variable in the PARMs= data set if that variable is also in the input BOUNDARY= data set. That is, the information level at stage  $k$  is computed as  $I_k^* = I_k \times (n_k^*/n_k)$ , where  $I_k$  and  $n_k$  are the information level and sample size, respectively, at stage  $k$  in the BOUNDARY= data set and  $n_k^*$  is the sample size at stage  $k$  in the PARMs= data set. Otherwise, the information levels from the BOUNDARY= data set are used.

If the TESTVAR= option is specified, the PARMs= data set also includes the variable Parameter, Effect, Variable, or Parm for the test variable, Estimate for the test statistic, and \_Scale\_ variable for the corresponding scale. Note that for a two-sided design, the nominal  $p$ -value is the one-sided fixed-sample  $p$ -value under the null hypothesis with a lower alternative hypothesis.

## Boundary Variables

The boundaries created in group sequential trials depend on the type of the alternative hypothesis and the early stopping criterion. Table 84.2 shows the boundaries created with various design specifications.

**Table 84.2** Boundary Variables

| Alternative Hypothesis | Specifications<br>Early Stopping | Boundary Variables |      |       |       |
|------------------------|----------------------------------|--------------------|------|-------|-------|
|                        |                                  | Lower              |      | Upper |       |
|                        |                                  | Alpha              | Beta | Beta  | Alpha |
| Lower                  | Accept $H_0$                     |                    | X    |       |       |
|                        | Reject $H_0$                     | X                  |      |       |       |
|                        | Accept/Reject $H_0$              | X                  | X    |       |       |
| Upper                  | Accept $H_0$                     |                    |      | X     |       |
|                        | Reject $H_0$                     |                    |      |       | X     |
|                        | Accept/Reject $H_0$              |                    |      | X     | X     |
| Two-sided              | Accept $H_0$                     |                    | X    | X     |       |
|                        | Reject $H_0$                     | X                  |      |       | X     |
|                        | Accept/Reject $H_0$              | X                  | X    | X     | X     |

Up to four different boundaries can be generated in a group sequential design:

- the upper  $\alpha$  boundary, used to reject the null hypothesis in favor of an upper alternative hypothesis
- the upper  $\beta$  boundary, used to accept the null hypothesis with an upper alternative hypothesis
- the lower  $\beta$  boundary, used to accept the null hypothesis with a lower alternative hypothesis

- the lower  $\alpha$  boundary, used to reject the null hypothesis in favor of a lower alternative hypothesis

For a two-sided design, the null hypothesis is accepted only if both the null hypothesis is accepted with an upper alternative hypothesis and the null hypothesis is accepted with a lower alternative hypothesis.

For a one-sided design with a lower alternative, only the lower boundaries are created. Similarly, for a one-sided design with an upper alternative, only the upper boundaries are created. For example, Figure 84.19 shows the boundary plot for a one-sided test with an upper alternative.

**Figure 84.19** Boundary Plot for One-Sided Test

Figure 84.19 corresponds to a one-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

For a two-sided design, both the lower and upper boundaries are created. For a design with early stopping to reject the null hypothesis,  $\alpha$  boundaries are created. Similarly, for a design with early stopping to accept the null hypothesis,  $\beta$  boundaries are created. For a design with early stopping to accept or reject the null hypothesis, both the  $\alpha$  and  $\beta$  boundaries are created.

For example, Figure 84.20 shows the boundary plot for a two-sided test.

**Figure 84.20** Boundary Plot for Two-Sided Test

Figure 84.20 corresponds to a two-sided sequential design with early stopping to reject or accept the null hypothesis. For a sequential test with early stopping only to reject the null hypothesis, there are no acceptance boundary values at interim stages. The acceptance boundary value and its associated acceptance region are displayed only at the final stage. Similarly, for a sequential test with early stopping only to accept the null hypothesis, there are no rejection boundary values at interim stages. The rejection boundary value and its associated rejection region are displayed only at the final stage.

## Information Level Adjustments at Future Stages

In a group sequential clinical trial, the information level for the observed test statistic at the current stage generally does not match the corresponding information level in the BOUNDARY= data set. By default (or equivalently if you specify INFOADJ=PROP), the SEQTEST procedure accommodates the observed information level by adjusting the information levels at future interim stages. The adjustment of information levels depends on the boundary key to be maintained in the boundary adjustments, which in turn is determined by the BOUNDARYKEY= option.

If you specify BOUNDARYKEY=ALPHA (which is the default) or BOUNDARYKEY=BETA, the maximum information level (the information level at the final stage) provided in the BOUNDARY= data set is maintained. In this case, if an observed information level at the current stage is different from the level provided in the BOUNDARY= data set, you can use the INFOADJ= option to determine whether the information levels at subsequent interim stages are to be adjusted. Specifying INFOADJ=NONE preserves the levels provided in the BOUNDARY= data set without adjustment. Specifying INFOADJ=PROP proportionally adjusts the levels provided in the BOUNDARY= data set as follows.

Denote the information level at stage  $k$  for the  $K$ -stage design that is stored in the BOUNDARY= data set by  $I_k$ ,  $k = 1, 2, \dots, K$ . Also denote the information level that corresponds to the test statistic at an interim stage  $k_0$  by  $I'_{k_0}$ ,  $1 \leq k_0 \leq (K - 1)$ . Then for the updated design, the information level at stage  $k$ ,  $k = k_0 + 1, \dots, (K - 1)$ , is computed as

$$I'_k = I'_{k_0} + (I_K - I'_{k_0}) \frac{I_k - I_{k_0}}{I_K - I_{k_0}}$$

Note that if  $I'_{k_0} \geq I_K$ , the information level at stage  $k_0$  reaches the maximum information level in the design, the trial stops at stage  $k_0$ , and no future information levels are derived.

If you specify BOUNDARYKEY=BOTH, the maximum information level for the trial is not necessarily the same as the maximum information level saved in the BOUNDARY= data set. In this case, the INFOADJ=NONE option is not applicable, and the INFOADJ=PROP option is used to proportionally adjust the information levels at future interim stages with the updated maximum information  $I'_K$ . That is, with an updated  $I'_K$ , the information level at a future interim stage  $k$  is computed as

$$I'_k = I'_{k_0} + (I'_K - I'_{k_0}) \frac{I_k - I_{k_0}}{I'_K - I_{k_0}}$$

## Boundary Adjustments for Information Levels

In a group sequential clinical trial, if the information level for the observed test statistic does not match the corresponding information level in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) can be used to modify information levels at future stages to accommodate this observed information level. With the adjusted information levels, the ERRSPENDADJ= option provides various methods to compute error spending values at the current and future interim stages. These error spending values are then used to derive boundary values in the SEQTEST procedure. See the section “Error Spending Methods” in the chapter “The SEQDESIGN Procedure” for a detailed description of how to use these error spending values to derive boundary values.

The ERRSPENDADJ=NONE option keeps the error spending the same at each stage. The ERRSPENDADJ=ERRLINE option uses a linear interpolation on the cumulative error spending in the

design stored in the BOUNDARY= data set to derive the error spending for each unmatched information level (Kittelson and Emerson 1999, p. 882). That is, the cumulative error spending for an information level  $I$  is computed as

$$e(I) = \begin{cases} e_1 \left( \frac{I}{I_1} \right) & \text{if } I < I_1 \\ e_j + (\alpha_{j+1} - \alpha_j) \left( \frac{I - I_j}{I_{j+1} - I_j} \right) & \text{if } I_j \leq I < I_{j+1} \\ e_K & \text{if } I \geq I_K \end{cases}$$

where  $e_1, e_2, \dots, e_K$  are the cumulative errors at the  $K$  stages of the design that is stored in the BOUNDARY= data set.

The ERRSPENDADJ=ERRFUNCPOC option uses Pocock-type cumulative error spending function (Lan and DeMets 1983):

$$E(t) = \begin{cases} 1 & \text{if } t \geq 1 \\ \log(1 + (e - 1)t) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

With an error level of  $\alpha$  or  $\beta$ , the cumulative error spending for an information level  $I$  is  $e(I) = \alpha E(I/I_K)$  or  $e(I) = \beta E(I/I_K)$ .

The ERRSPENDADJ=ERRFUNCOBF option uses O'Brien-Fleming-type cumulative error spending function (Lan and DeMets 1983):

$$E(t; a) = \begin{cases} 1 & \text{if } t \geq 1 \\ \frac{1}{a} 2 (1 - \Phi(\frac{z(1-a/2)}{\sqrt{t}})) & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where  $a$  is either  $\alpha$  for the  $\alpha$  spending function or  $\beta$  for the  $\beta$  spending function, and  $\Phi$  is the cumulative distribution function of the standardized  $Z$  statistic. That is, with an error level of  $\alpha$  or  $\beta$ , the cumulative error spending for an information level  $I$  is  $e(I) = \alpha E(I/I_K; \alpha)$  or  $e(I) = \beta E(I/I_K; \beta)$ .

The ERRSPENDADJ=ERRFUNCGAMMA option uses gamma cumulative error spending function (Hwang, Shih, and DeCani 1990):

$$E(t; \gamma) = \begin{cases} 1 & \text{if } t \geq 1 \\ \frac{1 - e^{-\gamma t}}{1 - e^{-\gamma}} & \text{if } 0 < t < 1, \gamma \neq 0 \\ t & \text{if } 0 < t < 1, \gamma = 0 \\ 0 & \text{otherwise} \end{cases}$$

where  $\gamma$  is the parameter  $\gamma$  specified in the GAMMA= option. That is, with an error level of  $\alpha$  or  $\beta$ , the cumulative error spending for an information level  $I$  is  $e(I) = \alpha E(I/I_K; \gamma)$  or  $e(I) = \beta E(I/I_K; \gamma)$ .

The ERRSPENDADJ=ERRFUNCPOW option uses power cumulative error spending function (Jennison and Turnbull 2000, p. 148):

$$E(t; \rho) = \begin{cases} 1 & \text{if } t \geq 1 \\ t^\rho & \text{if } 0 < t < 1 \\ 0 & \text{otherwise} \end{cases}$$

where  $\rho$  is the power parameter specified in the RHO= suboption. With an error level of  $\alpha$  or  $\beta$ , the cumulative error spending for an information level  $I$  is  $e(I) = \alpha E(I/I_K; \rho)$  or  $e(I) = \beta E(I/I_K; \rho)$ .

If the BOUNDARYKEY=BOTH option is specified, the maximum information required for the trial might not be the same as the maximum information level stored in the BOUNDARY= data set. In this case, the information levels at future stages are adjusted proportionally, and the same error spending values that were computed based on the maximum information level stored in the BOUNDARY= data set are used to derive boundary values for the trial.

If an error spending function is used to create boundaries for the design in the SEQDESIGN procedure, then in order to better maintain the design features throughout the group sequential trial, the same error spending function to create boundaries for the design in the SEQDESIGN procedure should be used to modify boundaries in the SEQTEST procedure at each subsequent stage.

---

## Boundary Adjustments for Minimum Error Spending

In a group sequential clinical trial, boundary values created from a design such as an O'Brien-Fleming design might be too conservative in early stages. Thus the trial is unlikely to stop in early stages. Lan and DeMets (1983, p. 662) suggest truncating boundary values to a number such as 3.5 for the trial to have a reasonable probability of stopping at early stages. Instead of truncating boundary values by a specified number, the ERRSPENDMIN= option provides individual minimum error spending at each interim stage to stop the trial early.

For a  $K$ -stage trial, denote the derived cumulative error spending at stage  $k$  after adjusting for information levels by  $e_k, k = 1, 2, \dots, K$ . Also denote the specified minimum error spending at interim stage  $k$  by  $\epsilon_k, k = 1, 2, \dots, K - 1$ . Then the cumulative error spending at stage 1 is  $e'_1 = \max(e_1, \epsilon_1)$ . If  $e_1 < e'_1$ , the error spending values at subsequent interim stages are adjusted proportionally by

$$e'_j = e'_1 + \frac{e_j - e_1}{e_K - e_1} (e_K - e'_1)$$

for  $j = 2, \dots, K - 1$ .

The process is repeated at each subsequent interim stage. That is, at stage  $k, k = 2, \dots, K - 1$ , denote the updated cumulative  $\beta$  spending at stage  $j$  by  $e_j, j = k, k + 1, \dots, K$ . Then the cumulative error spending at stage  $k$  is  $e'_k = \max(e_k, e'_{k-1} + \epsilon_k)$ . If  $e_k < e'_k$ , the error spending values at subsequent interim stages are adjusted proportionally by

$$e'_j = e'_k + \frac{e_j - e_k}{e_K - e_k} (e_K - e'_k)$$

for  $j = k + 1, \dots, K - 1$ .

Note that the ERRSPENDMIN= option is applicable only to the boundaries specified in the BOUNDARYKEY= option. That is, the ERRSPENDMIN= option is applicable to the  $\alpha$  boundaries with BOUNDARYKEY=ALPHA or BOUNDARYKEY=BOTH, and it is applicable to the  $\beta$  boundaries with BOUNDARYKEY=BETA or BOUNDARYKEY=BOTH.

---

## Boundary Adjustments for Overlapping Lower and Upper $\beta$ Boundaries

In the SEQTEST procedure, the  $\alpha$  and  $\beta$  spending values at the stages are used to derive the boundary values for the trial. For a two-sided design with early stopping to accept  $H_0$ , or to either reject or accept

$H_0$ , a zero  $\beta$  spending at an interim stage sets the  $\beta$  boundary values to missing. A small  $\beta$  spending at the current or subsequent interim stage might result in overlapping of the lower and upper  $\beta$  boundaries for the two corresponding one-sided tests. Specifically, this form of overlapping occurs at an interim stage  $k$  if the upper  $\beta$  boundary value that is derived from the one-sided test for the upper alternative is less than the lower  $\beta$  boundary value that is derived from the one-sided test for the lower alternative (Kittelson and Emerson 1999, pp. 881–882; Rudser and Emerson 2007, p. 6). You can use the BETAOVERLAP= option to specify how this type of overlapping is to be handled.

If BETAOVERLAP=ADJUST (which is the default) is specified, the procedure derives the boundary values for the two-sided design and then checks for overlapping of the two one-sided  $\beta$  boundaries at the current and subsequent interim stages. If overlapping occurs at a particular stage, the  $\beta$  boundary values for the two-sided design are set to missing (so the trial does not stop to accept the null hypothesis at this stage), and the  $\beta$  spending values at subsequent stages are adjusted proportionally as follows.

If the  $\beta$  boundary values are set to missing at stage  $k$  in a  $K$ -stage trial, the adjusted  $\beta$  spending value at stage  $k$ ,  $e'_k$ , is updated for these missing  $\beta$  boundary values, and then the  $\beta$  spending values at subsequent stages are adjusted proportionally by

$$e'_j = e'_k + \frac{e_j - e_k}{e_K - e_k} (e_K - e'_k)$$

for  $j = k + 1, \dots, K$ , where  $e_j$  and  $e'_j$  are cumulative  $\beta$  spending values at stage  $j$  before and after the adjustment, respectively.

After all these adjusted  $\beta$  spending values are computed, the boundary values are then further modified for these adjusted  $\beta$  spending values.

If you specify BETAOVERLAP=NOADJUST, no adjustment is made when overlapping of one-sided  $\beta$  boundaries occurs.

## Stochastic Curtailment

Lan, Simon, and Halperin (1982) introduce stochastic curtailment to stop a trial if, given current data, it is likely to predict the outcome of the trial with high probability. That is, a trial can be stopped to reject the null hypothesis  $H_0$  if, given current data in the analyses, the conditional probability of rejecting  $H_0$  under  $H_0$  at the end of the trial is greater than  $\gamma$ , where the constant  $\gamma$  should be between 0.5 and 1 and values of 0.8 or 0.9 are recommended (Jennison and Turnbull 2000, p. 206). Similarly, a trial can be stopped to accept the null hypothesis  $H_0$  if, given current data in the analyses, the conditional probability of rejecting  $H_0$  under the alternative hypothesis  $H_1$  at the end of the trial is less than  $\gamma$ .

The following two approaches for stochastic curtailment are available in the SEQTEST procedures: conditional power approach and predictive power approach. For each approach, the derived group sequential test is used as the reference test for rejection.

## Conditional Power Approach

In the SEQTEST procedure, you can compute two types of conditional power as described in the following sections:

**TYPE=ALLSTAGES**

The default TYPE=ALLSTAGES suboption in the CONDPOWER and PLOT=CONDPOWER options computes the conditional power at an interim stage  $k$  as the total probability of rejecting the null hypothesis at all future stages given the observed statistic (Zhu, Ni, and Yao 2011, pp. 131–132).

For a one-sided test with an upper alternative, the conditional power at an interim stage  $k$  is given by

$$\begin{aligned} p_{ku}(\theta) &= P_{\theta}(z_{k+1} > a_{k+1} | z_k, \theta) \\ &+ P_{\theta}(b_{k+1} \leq z_{k+1} < a_{k+1}, z_{k+2} > a_{k+2} | z_k, \theta) \\ &+ \dots \\ &+ P_{\theta}(b_j \leq z_j < a_j, j = k + 1, \dots, K - 1, z_K > a_K | z_k, \theta) \end{aligned}$$

where  $z_k$  is the observed statistic and  $\theta$  is the hypothetical reference. The conditional power for a one-sided test with a lower alternative is similarly derived.

For a two-sided test, the conditional power for the upper alternative is given by

$$\begin{aligned} p_{ku}(\theta) &= P_{\theta}(z_{k+1} > a_{k+1} | z_k, \theta) \\ &+ P_{\theta}(\_a_{k+1} < z_{k+1} \leq \_b_{k+1} \text{ or } b_{k+1} \leq z_{k+1} < a_{k+1}, z_{k+2} > a_{k+2} | z_k, \theta) \\ &+ \dots \\ &+ \theta(\_a_j < z_j \leq \_b_j \text{ or } b_j \leq z_j < a_j, j = k + 1, \dots, K - 1, z_K > a_K | z_k, \theta) \end{aligned}$$

The conditional power for the lower alternative is similarly derived.

**TYPE=FINALSTAGE**

The TYPE=FINALSTAGE suboption in the CONDPOWER and PLOT=CONDPOWER options computes the conditional power at an interim stage  $k$  as the probability that the test statistic at the final stage (stage  $K$ ) would exceed the rejection critical value given the observed statistic (Jennison and Turnbull 2000, p. 207).

The conditional distribution of  $Z_K$  given the observed statistic  $z_k$  at the  $k$ th stage and the hypothetical reference  $\theta$  is

$$Z_K | (z_k, \theta) \sim N \left( z_k \Pi_k^{\frac{1}{2}} + \theta I_X^{\frac{1}{2}} (1 - \Pi_k), 1 - \Pi_k \right)$$

where  $\Pi_k = I_k / I_X$  is the fraction of information at the  $k$ th stage.

The power for the upper alternative,  $\text{prob}(Z_K > a_K | z_k, \theta)$ , is then given by

$$p_{ku}(\theta) = \Phi \left( (1 - \Pi_k)^{-\frac{1}{2}} (z_k \Pi_k^{\frac{1}{2}} - a_K) + \theta I_X^{\frac{1}{2}} (1 - \Pi_k)^{\frac{1}{2}} \right)$$

where  $\Phi$  is the cumulative distribution function of the standardized  $Z$  statistic and  $a_K$  is the upper critical value at the final stage.

Similarly, the power for the lower alternative,  $\text{prob}(Z_K < a_{-K} | z_k, \theta)$ , is

$$p_{kl}(\theta) = 1 - \Phi \left( (1 - \Pi_k)^{-\frac{1}{2}} (z_k \Pi_k^{\frac{1}{2}} - a_{-K}) + \theta I_X^{\frac{1}{2}} (1 - \Pi_k)^{\frac{1}{2}} \right)$$

where  $a_{-K}$  is the lower critical value at the final stage.

If  $\theta = \hat{\theta}_k = z_k I_k^{-\frac{1}{2}}$ , the maximum likelihood estimate at stage  $k$ , the powers for the upper and lower alternatives can be simplified:

$$p_{ku}(\theta) = \Phi \left( (1 - \Pi_k)^{-\frac{1}{2}} (z_k \Pi_k^{-\frac{1}{2}} - a_K) \right)$$

$$p_{kl}(\theta) = 1 - \Phi \left( (1 - \Pi_k)^{-\frac{1}{2}} (z_k \Pi_k^{-\frac{1}{2}} - a_{-K}) \right)$$

If there exist interim stages between the  $k$ th stage and the final stage,  $k < K - 1$ , the conditional power computed with TYPE=FINALSTAGE is not the conditional probability to reject the null hypothesis  $H_0$ . In this case, you can set the next stage as the final stage, and the conditional power is the conditional probability of rejecting  $H_0$ .

A special case of the conditional power is the futility index (Ware, Muller, and Braunwald 1985). It is 1 minus the conditional power under  $H_1 : \theta = \theta_1$ :

$$1 - p_{ku}(\theta_1) \text{ or } 1 - p_{kl}(\theta_1)$$

That is, it is the probability of accepting the null hypothesis under the alternative hypothesis given current data. A high futility index indicates a small probability of success (rejecting  $H_0$ ) given the current data.

### Predictive Power Approach

The conditional power depends on the specified reference  $\theta$ , which might be supported by the current data (Jennison and Turnbull 2000, p. 210). An alternative is to use the predictive power (Herson 1979), which is a weighted average of the conditional power over values of  $\theta$ . Without prior knowledge about  $\theta$ , then with  $\hat{\theta} = z_k / \sqrt{I_k}$ , the maximum likelihood estimate at stage  $k$ , the posterior distribution for  $\theta$  (Jennison and Turnbull 2000, p. 211) is

$$\theta | Z_K \sim N \left( \frac{z_k}{\sqrt{I_k}}, \frac{1}{I_k} \right)$$

Thus, the predictive power at stage  $k$  for the upper and lower alternatives can be derived as

$$p_{ku} = 1 - \Phi \left( (1 - \Pi_k)^{-\frac{1}{2}} (a_K \Pi_k^{\frac{1}{2}} - z_k) \right)$$

$$p_{kl} = \Phi \left( (1 - \Pi_k)^{-\frac{1}{2}} (a_{-K} \Pi_k^{\frac{1}{2}} - z_k) \right)$$

where  $a_K$  and  $a_{-K}$  are the upper and lower critical values at the final stage.

---

### Repeated Confidence Intervals

In a group sequential test, repeated confidence intervals for a parameter  $\theta$  are defined as a sequence of intervals  $(\hat{\theta}_{kl}, \hat{\theta}_{ku})$ ,  $k = 1, 2, \dots, K$ , for which a simultaneous coverage probability is maintained (Jennison and Turnbull 2000, p. 189). That is, a  $(1 - \alpha)$  sequence of repeated confidence intervals has

$$\text{Prob}(\hat{\theta}_{kl} \leq \theta \leq \hat{\theta}_{ku}) = 1 - \alpha$$

These confidence limits  $\hat{\theta}_{kl}$  and  $\hat{\theta}_{ku}$  can be created from observed statistic and boundary values at each stage.

## Two-Sided Repeated Confidence Intervals

Two sequences of repeated confidence intervals can be derived for a two-sided test. One is a  $(1 - \alpha_l - \alpha_u)$  rejection repeated confidence intervals  $(\hat{\theta}_{kl}(\alpha), \hat{\theta}_{ku}(\alpha))$ ,  $k = 1, 2, \dots, K$ , and the other is a  $(1 - \beta_l - \beta_u)$  acceptance repeated confidence intervals  $(\hat{\theta}_{kl}(\beta), \hat{\theta}_{ku}(\beta))$ ,  $k = 1, 2, \dots, K$ , where  $\alpha_l$  and  $\alpha_u$  are the lower and upper Type I error probabilities for the test and  $\beta_l$  and  $\beta_u$  are the lower and upper Type II error probabilities for the test (Jennison and Turnbull 2000, p. 196).

The rejection lower and upper repeated confidence limits at stage  $k$  are

$$\hat{\theta}_{kl}(\alpha) = \hat{\theta}_k - \frac{a_k}{\sqrt{I_k}} \quad \hat{\theta}_{ku}(\alpha) = \hat{\theta}_k - \frac{a_k}{\sqrt{I_k}}$$

The hypothesis is rejected for upper alternative if the lower limit  $\hat{\theta}_{kl}(\alpha) > \theta_{0u}$  and is rejected for lower alternative if the upper limit  $\hat{\theta}_{ku}(\alpha) < \theta_{0l}$ . That is, the hypothesis is rejected if both  $\theta_{0l}$  and  $\theta_{0u}$  are not in a rejection repeated confidence interval  $(\hat{\theta}_{kl}(\alpha), \hat{\theta}_{ku}(\alpha))$ .

The acceptance lower and upper repeated confidence limits at stage  $k$  are

$$\hat{\theta}_{kl}(\beta) = \hat{\theta}_k + \left( \theta_{1l} - \frac{b_k}{\sqrt{I_k}} \right) \quad \hat{\theta}_{ku}(\beta) = \hat{\theta}_k + \left( \theta_{1u} - \frac{b_k}{\sqrt{I_k}} \right)$$

The hypothesis is accepted if the lower limit  $\hat{\theta}_{kl}(\beta) > \theta_{1l}$  and the upper limit  $\hat{\theta}_{ku}(\beta) < \theta_{1u}$ . That is, a repeated confidence interval is contained in the interval  $(\theta_{1l}, \theta_{1u})$ .

## One-Sided Repeated Confidence Intervals

Like the two-sided repeated confidence intervals, two sequences of repeated confidence intervals can be derived for a one-sided test. Suppose the one-sided test has an upper alternative  $\theta_{1u}$ . Then one sequence of repeated confidence intervals is a  $(1 - \alpha_u)$  rejection repeated confidence intervals  $(\hat{\theta}_{kl}(\alpha), \infty)$ ,  $k = 1, 2, \dots, K$ , and the other is a  $(1 - \beta_u)$  acceptance repeated confidence intervals  $(-\infty, \hat{\theta}_{ku}(\beta))$ ,  $k = 1, 2, \dots, K$ , where  $\alpha_u$  and  $\beta_u$  are the upper Type I and Type II error probabilities for the test. Thus, a sequence of repeated confidence intervals with confidence level greater than or equal to  $(1 - \alpha_u - \beta_u)$  is given by  $(\hat{\theta}_{kl}(\alpha), \hat{\theta}_{ku}(\beta))$ .

The rejection lower repeated confidence limit and the acceptance upper repeated confidence limit at stage  $k$  are

$$\hat{\theta}_{kl}(\alpha) = \hat{\theta}_k - \left( \frac{a_k}{\sqrt{I_k}} - \theta_{0u} \right) \quad \hat{\theta}_{ku}(\beta) = \hat{\theta}_k + \left( \theta_{1u} - \frac{b_k}{\sqrt{I_k}} \right)$$

The hypothesis is rejected if the lower limit  $\hat{\theta}_{kl}(\alpha) > \theta_{0u}$ . and it is accepted if the upper limit  $\hat{\theta}_{ku}(\beta) < \theta_{1u}$ .

---

## Analysis after a Sequential Test

At the end of a trial, the hypothesis is either rejected or accepted. But the  $p$ -value, median, and confidence limits depend on the ordering the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic.

Following the notations used in Jennison and Turnbull (2000, pp. 179–180),  $(k', z') \succ (k, z)$  if  $(k', z')$  has a higher order or more extreme than  $(k, z)$ . Then for a given ordering, the  $p$ -value, median, and confidence limits associated with the observed statistics  $(k, z)$  can be derived.

***p*-value**

With the observed pair of statistics  $(k_0, z_0)$  when the trial is stopped, a one-sided upper *p*-value is computed as

$$\text{Prob}\{ (k, z) \succeq (k_0, z_0) \}$$

A one-sided lower *p*-value is computed as

$$\text{Prob}\{ (k, z) \preceq (k_0, z_0) \}$$

A two-sided *p*-value is twice the smaller of the lower and upper *p*-values.

**Median Unbiased Estimate**

With the observed pair  $(k_0, z_0)$ , a median unbiased estimate  $\theta_m$  is computed from

$$\text{Prob}\{ (k, z) \succeq (k_0, z_0) \mid \theta_m \} = 0.50$$

**Confidence Limits**

With the observed pair  $(k_0, z_0)$ , a lower  $(1 - \alpha_l)$  confidence limit for  $\theta$ ,  $\theta_l$ , is computed from

$$\text{Prob}\{ (k, z) \succeq (k_0, z_0) \mid \theta_l \} = \alpha_l$$

Similarly, an upper  $(1 - \alpha_u)$  confidence limit for  $\theta$ ,  $\theta_u$ , is computed from

$$\text{Prob}\{ (k, z) \preceq (k_0, z_0) \mid \theta_u \} = \alpha_u$$

**Available Sample Space Orderings in a Sequential Test**

At the end of a trial, the hypothesis is either rejected or accepted. Denote the stage number and the statistic at the end of a trial by a pair of statistics  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic. Then an ordering on the sample space  $(k, z)$  is needed to derive the *p*-value, median, and confidence limits associated with the observed statistics  $(k^*, z^*)$ .

The SEQTEST procedure provides the stagewise, LR, and MLE orderings. See Jennison and Turnbull (2000, pp. 179–187) for a detailed description and comparison of these orderings.

**Stagewise Ordering**

If the continuation regions of a design are intervals, the stagewise ordering (Fairbanks and Madsen 1982; Tsiatis, Rosner, and Mehta 1984; Jennison and Turnbull 2000, pp. 179–180) uses counter-clockwise ordering around the continuation region to compute the *p*-value, unbiased median estimate, and confidence limits. This ordering depends on the stopping region, stopping stage, and standardized statistic at the stopping stage. But it does not depend on information levels beyond the observed stage. For a one-sided design with an upper alternative,  $(k', z') \succ (k, z)$  if one of the following criteria holds:

- $k' = k$  and  $z' > z$
- $k' < k$  and  $z' \geq a_{k'}$ , the upper  $\alpha$  boundary at stage  $k'$
- $k' > k$  and  $z < b_k$ , the upper  $\beta$  boundary at stage  $k$

Similar criteria can be derived for a one-sided design with a lower alternative.

For a two-sided design with early stopping to reject the null hypothesis,  $(k', z') \succ (k, z)$  if one of the following criteria holds:

- $k' = k$  and  $z' > z$
- $k' < k$  and  $z' \geq a_{k'}$ , the upper  $\alpha$  boundary at stage  $k'$
- $k' > k$  and  $z \leq -a_k$ , the lower  $\alpha$  boundary at stage  $k$

Note that the stagewise ordering is not applicable for two-sided designs with early stopping to accept  $H_0$  or to either accept or reject  $H_0$ , which might have two disjoint continuous intervals at each interim stage.

For a two-sided design with early stopping either to reject or to accept the null hypothesis,  $(k', z') \succ (k, z)$  if one of the following criteria holds:

- $z' \geq a_{k'}$  and  $z < b_k$
- $z' > -b_{k'}$  and  $z \leq -a_k$

That is, each value in the continuation region is less extreme than each value in the upper rejection region and more extreme than each value in the lower rejection region. Then, combining with the ordering defined for a two-sided design with early stopping to reject the null hypothesis, the  $p$ -value, median, and confidence limits can be derived for the observed statistics in the lower or upper rejection region.

Thus, if the stagewise ordering is specified in the SEQTEST procedure for a two-sided design with early stopping to either reject or accept the null hypothesis, the stagewise ordering is used to derive these statistics only if the observed statistics is in the lower or upper rejection region. Otherwise, the LR ordering is used.

## LR Ordering

The LR ordering (Chang 1989) depends on the observed standardized  $Z$  statistic  $z$ , information levels, and a specified hypothetical reference. For the LR ordering under a given hypothesis  $H : \theta = \theta_g$ ,  $(k', z') \succ (k, z)$  if

$$(z' - \theta_g \sqrt{I_{k'}}) > (z - \theta_g \sqrt{I_k})$$

Under the null hypothesis  $H_0 : \theta = 0$ , it reduces to

$$z' > z$$

and can be used to derive statistics under  $H_0$ , such as  $p$ -values.

The LR ordering is applicable to all designs if all information levels are available. But depending on the boundary shape, some observed statistics  $(k, z)$  in the rejection region might be less extreme than the statistics in the acceptance region. That is, the  $p$ -value for observed statistics in the rejection region might be greater than the significance level.

## MLE Ordering

The MLE ordering (Emerson and Fleming 1990) depends only on the observed maximum likelihood estimate.  $(k', z') \succ (k, z)$  if

$$\frac{z'}{\sqrt{I_{k'}}} > \frac{z}{\sqrt{I_k}}$$

The MLE ordering is applicable to all designs if all information levels are available.

---

## Applicable Tests and Sample Size Computation

The SEQDESIGN procedure assumes that the data are from a multivariate normal distribution and the sequence of the standardized test statistics  $\{Z_1, Z_2, \dots, Z_K\}$  have the following canonical joint distribution:

- $Z_k \sim N(\theta\sqrt{I_k}, 1)$
- $\text{Cov}(Z_{k_1}, Z_{k_2}) = \sqrt{I_{k_1}/I_{k_2}}$ ,  $1 \leq k_1 \leq k_2 \leq K$

where  $K$  is the total number of stages and  $I_k$  is the information available at stage  $k$ .

If the data are not from a normal distribution such as binomial distribution, then it is assumed that the test statistic is computed from a large sample such that the statistic has an approximately normal distribution.

In a clinical trial, the sample size required depends on the Type I error probability  $\alpha$ , reference improvement  $\theta_1$ , power  $1 - \beta$ , and variance of the response variable. Given a null hypothesis  $H_0 : \theta = 0$  with an upper alternative hypothesis  $H_1 : \theta = \theta_1$ , the information required for a fixed-sample test is given by

$$I_0 = \frac{(\Phi^{-1}(1 - \alpha) + \Phi^{-1}(1 - \beta))^2}{\theta_1^2}$$

where the parameter  $\theta$  depends on the test specified in the clinical trial. For example, if you are comparing two binomial populations  $H_0 : \theta = 0$ , then  $\theta = p_t - p_c$  is the difference between two proportions if the proportion difference statistic is used, and  $\theta = \log\left(\frac{p_t(1-p_c)}{p_c(1-p_t)}\right)$ , the log odds ratio for the two proportions if the log odds ratio statistic is used.

If the maximum likelihood estimate  $\hat{\theta}$  from the likelihood function can be derived, then the asymptotic variance for  $\hat{\theta}$  is  $\text{Var}(\hat{\theta}) = 1/I$ , where  $I$  is Fisher's information for  $\theta$ .

The resulting statistic  $\hat{\theta}$  corresponds to the MLE scale as specified in the BOUNDARYSCALE=MLE option in the PROC SEQDESIGN statement,  $\hat{\theta}\sqrt{I}$  corresponds to the standardized Z scale (BOUNDARYSCALE=STDZ), and  $\hat{\theta}I$  corresponds to the score scale (BOUNDARYSCALE=SCORE).

Alternatively, if the score statistic is derived, it can also be used as the test statistic and its asymptotic variance is given by Fisher's information.

For a group sequential trial, the maximum information  $I_X$  is derived in the SEQDESIGN procedure by using the specified  $\alpha$ ,  $\beta$ , and  $\theta_1$ . With the maximum information

$$I_X = \frac{1}{\text{Var}(\hat{\theta})}$$

the sample size required for a specified test statistic in the trial can be evaluated or estimated from the known or estimated variance of the response variable. Note that different designs might produce different maximum information levels for the same hypothesis, and this in turn might require a different number of observations for the trial.

With a specified test statistic, the required sample sizes at the stages can be computed. These tests include commonly used tests for normal means, binomial proportions, and survival distributions. See the section “Sample Size Computation” in “The SEQDESIGN Procedure” for a description of these tests.

## Table Output

The SEQTEST procedure displays the “Design Information” and “Test Information” tables by default.

### Conditional Power

The “Conditional Power Information” table displays the following information under a hypothetical reference:

- stopping stage
- MLE, observed maximum likelihood estimate
- conditional power under the hypothetical reference

For a one-sided test, the power are derived under hypothetical references  $\theta = \hat{\theta}$  and  $\theta = c_i \theta_1$ , where  $\hat{\theta}$  is the observed statistic,  $\theta_1$  is the alternative reference, and  $c_i$  are the values specified in the CREF= option. For a two-sided test, the power are derived under the hypothetical references  $\theta = \hat{\theta}$ ,  $\theta = c_i \theta_{1l}$ , and  $\theta = c_i \theta_{1u}$ , where  $\theta_{1l}$  is the lower alternative reference and  $\theta_{1u}$  is the upper alternative reference. The default is CREF= 0 0.5 1.0 1.5.

### Design Information

The “Design Information” table displays the design specifications and derived statistics. The derived Max Information (Percent Fixed-Sample) is the maximum information for the sequential design in percentage of the corresponding fixed-sample information.

The Null Ref ASN (Percent Fixed-Sample) is the average sample size required under the null hypothesis for the group sequential design in percentage of the corresponding fixed-sample design. Similarly, the Alt Ref ASN (Percent Fixed-Sample) is the average sample size required under the alternative reference for the group sequential design in percentage of the corresponding fixed-sample design.

### Error Spending Information

The “Error Spending Information” table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is either specified or derived
- cumulative error spending for each boundary

## Parameter Estimates

The “Parameter Estimates” table displays the following information at the conclusion of a sequential trial:

- stopping stage
- parameter estimate
- median and confidence limits based on the specified ordering
- $p$ -value for the hypothesis  $H_0$  based on the specified ordering

## Powers and Expected Sample Sizes

The “Powers and Expected Sample Sizes” table displays the following information under each of the specified hypothetical references  $\theta = c_i\theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i$  are values specified in the CREF= option.

- coefficient  $c_i$  for the hypothetical references. The value  $c_i = 0$  corresponds to the null hypothesis and  $c_i = 1$  corresponds to the alternative hypothesis
- power
- expected sample size, as percentage of fixed-sample size

For a one-sided design, the power and expected sample sizes under the hypothetical references  $\theta = c_i\theta_1$  are displayed.

For a two-sided symmetric design, the power and expected sample sizes under each of the hypothetical references  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1u}$  is the upper alternative reference.

For a two-sided asymmetric design, the power and expected sample sizes under each of the hypothetical references  $\theta = c_i\theta_{1l}$  and  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively.

For a two-sided design, the power is the probability of correctly rejecting the null hypothesis for the correct alternative. Thus, under the null hypothesis, the displayed power corresponds to a one-sided Type I error probability level—that is, the lower  $\alpha$  level or the upper  $\alpha$  level.

The expected sample size as a percentage of the corresponding fixed-sample design is

$$100 \times \frac{\sum_{k=1}^K p_k I_k}{I_0}$$

where  $p_k$  is the stopping probability at stage  $k$ ,  $\sum_{k=1}^K p_k I_k$  is the expected information level, and  $I_0$  is the information level for the fixed-sample design.

## Predictive Power

The “Predictive Power Information” table displays the following information:

- stopping stage
- MLE, observed maximum likelihood estimate
- predictive power

## Repeated Confidence Intervals

The “Repeated Confidence Intervals” table displays the following information for the observed statistic at each stage:

- information level
- parameter estimate
- rejection confidence limits. The null hypothesis is rejected for the upper alternative if the lower rejection confidence limit is greater than the null parameter value. Similarly, the null hypothesis is rejected for the lower alternative if the upper rejection confidence limit is less than the null parameter value.
- acceptance confidence limits. The upper alternative hypothesis is rejected if the upper acceptance confidence limit is less than the upper alternative value. Similarly, the lower alternative hypothesis is rejected if the lower acceptance confidence limit is greater than the upper alternative value. For a two-sided design, if both upper and lower alternative hypothesis are rejected, the null hypothesis is accepted.

## Stopping Probabilities

The “Expected Cumulative Stopping Probabilities” table displays the following information under each of the specified hypothetical references  $\theta = c_i \theta_1$ , where  $c_i$  are values specified in the CREF= option, and  $\theta_1$  is the alternative reference:

- coefficient  $c_i$  for the hypothetical references. The value  $c_i = 0$  corresponds to the null hypothesis, and  $c_i = 1$  corresponds to the alternative hypothesis
- expected stopping stage
- source of the stopping probability: reject  $H_0$  (with STOP=REJECT or STOP=BOTH), accept  $H_0$  (with STOP=ACCEPT or STOP=BOTH), or either reject or accept  $H_0$  (with STOP=BOTH)
- expected cumulative stopping probabilities at each stage

For a one-sided design, the expected cumulative stopping probabilities under the hypothetical references  $\theta = c_i \theta_{1l}$  are displayed.

For a two-sided design, the expected cumulative stopping probabilities under each of the hypothetical references  $\theta = c_i \theta_{1l}$  and  $\theta = c_i \theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively.

Note that for a symmetric two-sided design, only the expected cumulative stopping probabilities under the hypothetical references  $\theta = c_i \theta_{1u}$  are derived.

The expected stopping stage is given by  $k_0 + d$  and is derived from the expected information level

$$\sum_{k=1}^K p_k I_k = I_{k_0} + d (I_{(k_0+1)} - I_{k_0})$$

where  $p_k$  is the stopping probability at stage  $k$  and  $0 \leq d < 1$ .

For equally spaced information levels, the expected stopping stage is reduced to the weighted average

$$\sum_{k=1}^K p_k k$$

## Test Information

The “Test Information” table displays the following information at each stage:

- proportion of information
- actual information level, if the maximum information is available from the input BOUNDARY= data set
- alternative references with the specified statistic scale. If a  $p$ -value scale is specified, the standardized  $Z$  scale is used.
- boundary values with the specified statistic scale to reject or accept the null hypothesis

Note that implicitly, the test information table also contains variables for the boundary scale, stopping criterion, and type of alternative hypothesis. That is, if an ODS statement is used to save the table, the data set also contains the variables `_Scale_` for the boundary scale, `_Stop_` for the stopping criterion, and `_ALT_` for the type of alternative hypothesis.

If the test variable is specified, the table also displays the following:

- test statistic
- resulting action of test statistic: continue to the next stage, accept the null hypothesis  $H_0$ , or reject  $H_0$

## ODS Table Names

PROC SEQTEST assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in Table 84.3. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 84.3** ODS Tables Produced by PROC SEQTEST

| ODS Table Name     | Description                         | Option                                   |
|--------------------|-------------------------------------|------------------------------------------|
| CondPower          | Conditional power                   | CONDPOWER                                |
| Design             | Design information                  |                                          |
| ErrSpend           | Error spending                      | ERRSPEND                                 |
| ParameterEstimates | Parameter estimates                 | DATA( TESTVAR= ) or<br>PARMS( TESTVAR= ) |
| PowerSampleSize    | Power and expected sample sizes     | PSS                                      |
| PredPower          | Predictive power                    | PREDPOWER                                |
| RepeatedCI         | Repeated confidence intervals       | RCI                                      |
| StopProb           | Stopping probabilities              | STOPPROB                                 |
| Test               | Test statistics and boundary values |                                          |

## Graphics Output

This section describes the use of ODS for creating graphics with the SEQTEST procedure. To request these graphs, ODS Graphics must be enabled and you must specify the associated graphics options in the PROC SEQTEST statement. For more information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

### Sequential ASN Plot

The PLOTS=ASN option displays the average sample numbers (expected sample sizes for nonsurvival data or expected numbers of events for survival data) under various hypothetical references. The average sample numbers are connected for each design, and these connected curves for all designs are displayed in the “Sequential ASN Plot” graph.

For a one-sided design, average sample numbers under the hypothetical references  $\theta = c_i\theta_1$  are displayed, where  $c_i$  are the values specified in the CREF= option and  $\theta_1$  is the alternative reference. The horizontal axis displays the  $c_i$  values of these hypothetical references.

For a two-sided design, average sample numbers under each of the hypothetical references  $\theta = c_i\theta_{1l}$  and  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. The horizontal axis displays  $-c_i$  values for lower hypothetical references  $\theta = c_i\theta_{1l}$  and  $c_i$  values for upper hypothetical references  $\theta = c_i\theta_{1u}$ . Note that for a symmetric two-sided design, only average sample numbers under the hypothetical references  $\theta = c_i\theta_{1u}$  are derived.

If the trial stops after the sequential test, the hypothetical reference corresponding to the test statistic is also indicated in the plot.

### Conditional Power Plot

The PLOTS=CONDPOWER option displays the conditional powers given the observed statistic under various hypothetical references. These powers are connected and are displayed in the “Conditional Power Plot” graph.

For a one-sided test, the power are derived under the hypothetical references  $\theta = \hat{\theta}$  and  $\theta = c_i\theta_1$ , where  $\hat{\theta}$  is the observed statistic,  $\theta_1$  is the alternative reference, and  $c_i$  are the values specified in the CREF= option. The horizontal axis displays these  $c_i$  values for hypothetical references.

For a two-sided test, the power are derived under hypothetical references  $\theta = \hat{\theta}$ ,  $\theta = c_i\theta_{1l}$ , and  $\theta = c_i\theta_{1u}$ , where  $\theta_{1l}$  is the lower alternative reference and  $\theta_{1u}$  is the upper alternative reference. The horizontal axis displays  $-c_i$  values for hypothetical references  $\theta = c_i\theta_{1l}$  and  $c_i$  values for hypothetical references  $\theta = c_i\theta_{1u}$ .

If the trial stops after the sequential test, the hypothetical reference corresponding to the test statistic is also indicated in the plot.

### Sequential Error Spending Plot

The PLOTS=ERRSPEND option displays the cumulative error spending at each stage on each boundary in the “Sequential Error Spending Plot” graph. A legend table uses the design labels to identify the curves for the corresponding design in the plot.

### Sequential Power Plot

The PLOTS=POWER option displays the powers under various hypothetical references. The powers are connected for each design, and these connected curves for all designs are displayed in the “Sequential Power Plot” graph.

For a one-sided design, powers under hypothetical references  $\theta = c_i\theta_1$  are displayed, where  $c_i$  are the values specified in the CREF= option and  $\theta_1$  is the alternative reference. The horizontal axis displays the  $c_i$  values of these hypothetical references.

For a two-sided design, powers under hypothetical references  $\theta = c_i\theta_{1l}$  and  $\theta = c_i\theta_{1u}$  are displayed, where  $\theta_{1l}$  and  $\theta_{1u}$  are the lower and upper alternative references, respectively. The horizontal axis displays  $-c_i$  values for lower hypothetical references  $\theta = c_i\theta_{1l}$  and  $c_i$  values for upper hypothetical references  $\theta = c_i\theta_{1u}$ . Note that for a symmetric two-sided design, only powers under hypothetical references  $\theta = c_i\theta_{1u}$  are derived.

If the trial stops after the sequential test, the hypothetical reference corresponding to the test statistic is also indicated in the plot.

### Repeated Confidence Intervals Plot

The PLOTS=RCI option displays repeated confidence intervals at each stage given the observed statistic at that stage. These repeated confidence intervals are displayed in the “Repeated Confidence Intervals Plot” graph.

## Sequential Test Plot

The PLOTS=TEST option displays boundary values and test statistics in the “Test Plot” graph. The boundary values are connected for each boundary, and both the stage number and the information level at each stage are displayed. The legend table identifies the acceptance and rejection regions in the plot.

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

PROC SEQTEST assigns a name to each graph it creates. You can use these names to reference the graphs when using ODS. To request these graphs, ODS Graphics must be enabled and you must specify the options indicated in Table 84.4.

**Table 84.4** Graphs Produced by PROC SEQTEST

| ODS Graph Name | Plot Description                    | Option          |
|----------------|-------------------------------------|-----------------|
| AsnPlot        | Average sample numbers              | PLOTS=ASN       |
| CondPowerPlot  | Conditional power curves            | PLOTS=CONDPower |
| ErrSpendPlot   | Error spending                      | PLOTS=ERRSPEND  |
| PowerPlot      | Power curves                        | PLOTS=POWER     |
| RepeatedCIPlot | Repeated confidence intervals       | PLOTS=RCI       |
| TestPlot       | Boundary values and test statistics | PLOTS=TEST      |

---

## Examples: SEQTEST Procedure

The following examples perform group sequential tests with various designs and test statistics.

Four statistic scales are available for the input boundary values, the input test statistic, and the displayed test information in the SEQTEST procedure. These are the maximum likelihood estimator scale, score statistic scale, standardized normal Z scale, and  $p$ -value scale. There is a unique one-to-one transformation between any two of the scales, and you can use different scales for the input boundary values and input test statistic. These boundary values and test statistic are displayed with the scale specified in the BOUNDARYSCALE= option in the SEQTEST procedure.

## Example 84.1: Testing the Difference between Two Proportions

This example demonstrates group sequential tests that use an O'Brien-Fleming group sequential design. A clinic is studying the effect of vitamin C supplements in treating flu symptoms. The study consists of patients in the clinic who have exhibited the first sign of flu symptoms within the last 24 hours. These patients are randomly assigned to either the control group (which receives placebo pills) or the treatment group (which receives large doses of vitamin C supplements). At the end of a five-day period, the flu symptoms of each patient are recorded.

Suppose that you know from past experience that flu symptoms disappear in five days for 60% of patients who experience flu symptoms. The clinic would like to detect a 75% symptom disappearance with a high probability. A test that compares the proportions directly specifies the null hypothesis  $H_0 : \theta = p_t - p_c = 0$  with a one-sided alternative  $H_1 : \theta > 0$  and a power of 0.90 at  $H_1 : \theta = 0.15$ , where  $p_t$  and  $p_c$  are the proportions of symptom disappearance in the treatment group and control group, respectively.

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design by using an O'Brien-Fleming method for normally distributed data. The design uses a one-sided alternative hypothesis with early stopping either to accept or reject the null hypothesis  $H_0$ . The BOUNDARYSCALE=MLE option uses the MLE scale to display statistics in the boundary table and boundary plots.

```
ods graphics on;
proc seqdesign altref=0.15
 boundaryscale=mle
 ;
 OBrienFleming: design method=obf
 nstages=4
 alt=upper
 stop=both
 alpha=0.025
 ;
 samplesize model=twosamplefreq(nullprop=0.6 test=prop);
 ods output Boundary=Bnd_Count;
run;
ods graphics off;
```

The ODS OUTPUT statement with the BOUNDARY=BND\_COUNT option creates an output data set named BND\_COUNT which contains the resulting boundary information for the subsequent sequential tests.

The “Design Information” table in [Output 84.1.1](#) displays design specifications. With the specified alternative hypothesis  $H_1 : \theta = 0.15$ , the maximum information is derived to achieve a power of 0.90 at  $H_1$ . The derived fixed-sample information ratio 1.0767 is the maximum information needed for a group sequential design relative to its corresponding fixed-sample design.

**Output 84.1.1** O'Brien-Fleming Design Information

| The SEQDESIGN Procedure                   |                    |
|-------------------------------------------|--------------------|
| Design: OBrienFleming                     |                    |
| Design Information                        |                    |
| Statistic Distribution                    | Normal             |

|                                  |                             |          |          | Upper         | Beta                    | Alpha   |
| 1                                | 0.2500                      | 125.7086 | 107.4808 | 0.15000       | -0.09709                | 0.35291 |
| 2                                | 0.5000                      | 251.4171 | 214.9617 | 0.15000       | 0.02645                 | 0.17645 |
| 3                                | 0.7500                      | 377.1257 | 322.4425 | 0.15000       | 0.06764                 | 0.11764 |
| 4                                | 1.0000                      | 502.8343 | 429.9233 | 0.15000       | 0.08823                 | 0.08823 |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.1.3](#). The horizontal axis indicates the information levels for the design. The stages are indicated by vertical lines with accompanying stage numbers. If the test statistic at a stage is in a rejection region, the trial stops and the hypothesis is rejected. If the test statistic is in an acceptance region, then the trial also stops and the hypothesis is accepted. If the statistic is not in a rejection or an acceptance region, the trial continues to the next stage.

**Output 84.1.3** O'Brien-Fleming Boundary Plot

The boundary plot also displays the information level and critical value for the corresponding fixed-sample design. The solid and dashed lines at the fixed-sample information level correspond to the rejection and acceptance lines, respectively.

With the SAMPLESIZE statement, the maximum information is used to derive the required sample size for the study. The “Sample Size Summary” table in [Output 84.1.4](#) displays parameters for the sample size computation.

**Output 84.1.4** Required Sample Size Summary

| Sample Size Summary             |                        |
|---------------------------------|------------------------|
| Test                            | Two-Sample Proportions |
| Null Proportion                 | 0.6                    |
| Proportion (Group A)            | 0.75                   |
| Test Statistic                  | Z for Proportion       |
| Reference Proportions           | Alt Ref                |
| Max Sample Size                 | 429.9233               |
| Expected Sample Size (Null Ref) | 244.0768               |
| Expected Sample Size (Alt Ref)  | 303.0464               |

With the derived maximum information and the specified MODEL= option in the SAMPLESIZE statement, the total sample size in each group for testing the difference between two proportions under the alternative hypothesis is

$$N_1 = N_2 = (p_{1c} (1 - p_{1c}) + p_{1t} (1 - p_{1t})) I_X$$

where  $p_{1c} = 0.6$  and  $p_{1t} = p_{1c} + \theta_1 = 0.75$ . By default (or equivalently if you specify REF=PROP in the MODEL=TWOSAMPLEFREQ option), the required sample sizes are computed under the alternative hypothesis. See the section “Test for the Difference between Two Binomial Proportions” in the chapter “The SEQDESIGN Procedure” for a description of these parameters.

The “Sample Sizes (N)” table in [Output 84.1.5](#) displays the required sample sizes at each stage, in both fractional and integer numbers. The derived sample sizes under the heading Fractional N which correspond to the design are not integers. These sample sizes are rounded up to integers under the heading Ceiling N. In practice, integer sample sizes are used, and the information levels increase slightly. Thus, 54, 108, 162, and 215 patients are needed in each group for the four stages, respectively.

**Output 84.1.5** Required Sample Sizes

| Sample Sizes (N)                            |        |          |          |             |
|---------------------------------------------|--------|----------|----------|-------------|
| Two-Sample Z Test for Proportion Difference |        |          |          |             |
| -----Fractional N-----                      |        |          |          |             |
| _Stage_                                     | N      | N(Grp 1) | N(Grp 2) | Information |
| 1                                           | 107.48 | 53.74    | 53.74    | 125.7       |
| 2                                           | 214.96 | 107.48   | 107.48   | 251.4       |
| 3                                           | 322.44 | 161.22   | 161.22   | 377.1       |
| 4                                           | 429.92 | 214.96   | 214.96   | 502.8       |

| Sample Sizes (N)                            |     |          |          |             |
|---------------------------------------------|-----|----------|----------|-------------|
| Two-Sample Z Test for Proportion Difference |     |          |          |             |
| -----Ceiling N-----                         |     |          |          |             |
| _Stage_                                     | N   | N(Grp 1) | N(Grp 2) | Information |
| 1                                           | 108 | 54       | 54       | 126.3       |
| 2                                           | 216 | 108      | 108      | 252.6       |
| 3                                           | 324 | 162      | 162      | 378.9       |
| 4                                           | 430 | 215      | 215      | 502.9       |

Suppose the trial follows the study plan, and 54 patients are available in each group at stage 1. The data set count\_1 contains these 108 patients. [Output 84.1.6](#) lists the first 10 observations of the data set.

**Output 84.1.6** Clinical Trial Data

| First 10 Obs in the Trial Data |     |      |
|--------------------------------|-----|------|
| Obs                            | Trt | Resp |
| 1                              | 0   | 0    |
| 2                              | 1   | 1    |
| 3                              | 0   | 1    |
| 4                              | 1   | 0    |
| 5                              | 0   | 0    |
| 6                              | 1   | 0    |
| 7                              | 0   | 0    |
| 8                              | 1   | 1    |
| 9                              | 0   | 1    |
| 10                             | 1   | 0    |

The Trt variable is a grouping variable with value 0 for a patient in the placebo control group and value 1 for a patient in the treatment group who is given vitamin C supplements. The Resp variable is an indicator variable with value 1 for a patient without flu symptoms after five days and value 0 for a patient with flu symptoms after five days.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 1:

```
proc genmod data=count_1;
 model Resp= Trt;
 ods output ParameterEstimates=Parms_Count1;
run;
```

Output 84.1.7 displays the treatment effect at stage 1.

**Output 84.1.7** Stage 1 Treatment Difference

| The GENMOD Procedure                               |    |          |                |                            |                 |            |  |
|----------------------------------------------------|----|----------|----------------|----------------------------|-----------------|------------|--|
| Analysis Of Maximum Likelihood Parameter Estimates |    |          |                |                            |                 |            |  |
| Parameter                                          | DF | Estimate | Standard Error | Wald 95% Confidence Limits | Wald Chi-Square | Pr > ChiSq |  |
| Intercept                                          | 1  | 0.6296   | 0.0627         | 0.5066 0.7526              | 100.68          | <.0001     |  |

| Scale                                              | 1  | 0.4611   | 0.0314         | 0.4035 0.5269              |                 |            |  |

NOTE: The scale parameter was estimated by maximum likelihood.

The test statistic is  $\hat{\theta}_1 = \hat{p}_t - \hat{p}_c = 0.1111$ , and its associated standard error is

$$\sqrt{\text{Var}(\hat{\theta}_1)} = \sqrt{\frac{\hat{p}_c(1 - \hat{p}_c)}{54} + \frac{\hat{p}_t(1 - \hat{p}_t)}{54}} = 0.0887$$

The following statements create and display (in [Output 84.1.8](#)) the data set that contains the parameter estimate at stage 1,  $\hat{\theta}_1 = 0.1111$ , and its associated standard error  $\sqrt{\text{Var}(\hat{\theta}_1)} = 0.0887$  which are used in the SEQTEST procedure:

```
data Parms_Count1;
 set Parms_Count1;
 if Parameter='Trt';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Count1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.1.8** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |           |          |        |         |         |
|--------------------------------|-----------|----------|--------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | Trt       | 0.1111   | 0.0887 | MLE     | 1       |

The initial required sample sizes are derived with the proportions  $p_c = 0.6$  and  $p_t = 0.75$ . If the observed proportions are different from these assumed values, or if the number of available patients is different from the study plan in one of the stages, then the information level that corresponds to the test statistic is estimated from

$$I_k = \frac{1}{\text{Var}(\hat{\theta}_k)}$$

The following statements invoke the SEQTEST procedure and test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Count
 Parms (Testvar=Trt)=Parms_Count1
 infoadj=none
 errspendmin=0.001
 boundaryscale=mle
 errspend
 plots=errspend
 ;
 ods output Test=Test_Count1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_COUNT1 option specifies the input data set PARMS\_COUNT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRT option identifies the test variable TRT in the data set. The INFOADJ=NONE option maintains the information levels at future interim stages (2 and 3) as provided in the

BOUNDARY= data set. The BOUNDARYSCALE=MLE option displays the output boundaries in terms of the MLE scale.

The O'Brien-Fleming design is conservative in early stages and might not be desirable in a clinical trial. The ERRSPENDMIN=0.001 option specifies the minimum error spending at each stage to be 0.001, and it might increase the corresponding nominal  $p$ -value in early stages for the trial. The BOUNDARYSCALE=MLE option uses the MLE scale to display test statistics in the boundary table and boundary plots.

The ODS OUTPUT statement with the TEST=TEST\_COUNT1 option creates an output data set named TEST\_COUNT1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.1.9](#) displays design specifications. The derived statistics, such as the overall  $\alpha$  and  $\beta$  levels, are derived from the specified maximum information and boundary values in the BOUNDARY= data set. Note that with a minor change in the information level at stage 1, the power also changes slightly from the design provided in the BOUNDARY= data set.

**Output 84.1.9** Design Information

| The SEQTEST Procedure                     |                    |
|-------------------------------------------|--------------------|
| Design Information                        |                    |

| Power                                     | 0.89853            |
| Max Information (Percent of Fixed Sample) | 108.2301           |
| Max Information                           | 502.834283         |
| Null Ref ASN (Percent of Fixed Sample)    | 61.09917           |
| Alt Ref ASN (Percent of Fixed Sample)     | 73.9745            |

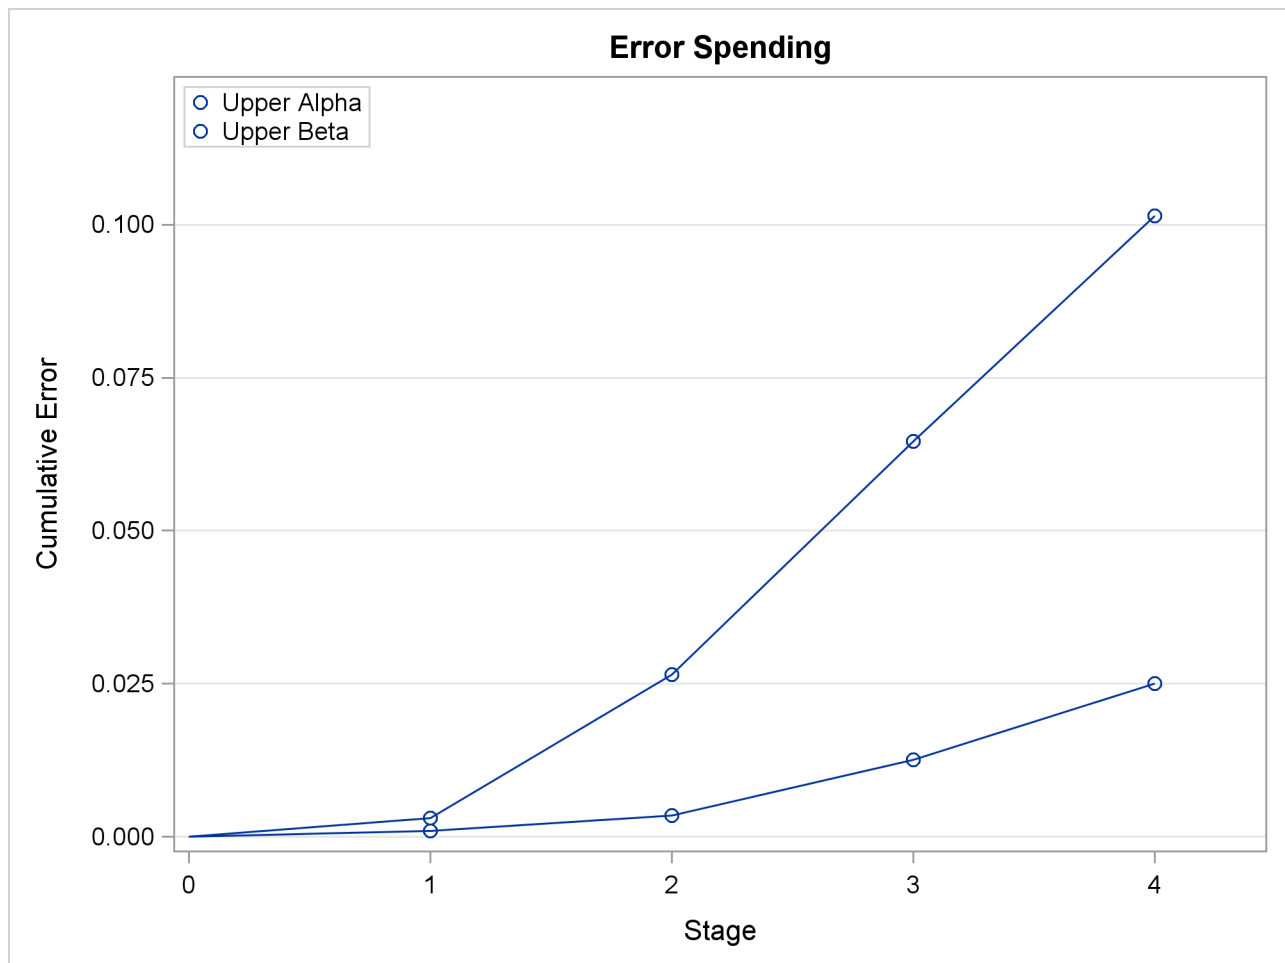

With the ERRSPEND option, the “Error Spending Information” table in [Output 84.1.10](#) displays cumulative error spending at each stage for each boundary. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the Type I error level  $\alpha = 0.025$  is maintained. Furthermore, with the ERRSPENDMIN=0.001 option, the  $\alpha$  spending at each stage is greater than or equal to 0.001.

**Output 84.1.10** Error Spending Information

| Error Spending Information |                         |          |                             |         |
|----------------------------|-------------------------|----------|-----------------------------|---------|
| _Stage_                    | ---Information Level--- |          | -Cumulative Error Spending- |         |
|                            | Proportion              | Actual   | Beta                        | Alpha   |
| 1                          | 0.2525                  | 126.9871 | 0.00308                     | 0.00100 |
| 2                          | 0.5000                  | 251.4171 | 0.02653                     | 0.00343 |
| 3                          | 0.7500                  | 377.1257 | 0.06456                     | 0.01254 |
| 4                          | 1.0000                  | 502.8343 | 0.10147                     | 0.02500 |

With the PLOTS=ERRSPEND option, the procedure displays a plot of error spending for each boundary, as shown in [Output 84.1.11](#). The error spending values in the “Error Spending Information” table in [Output 84.1.10](#) are displayed in the plot.

**Output 84.1.11** Error Spending Plot

The “Test Information” table in [Output 84.1.12](#) displays the boundary values for the design, test statistic, and resulting action at each stage. With the BOUNDARYSCALE=MLE option, the maximum likelihood

estimator scale is used for the test statistic and boundary values. The table shows that the test statistic 0.1111 is between the upper  $\alpha$  and  $\beta$  boundaries, so the trial continues to the next stage.

#### Output 84.1.12 Sequential Test

| Test Information (MLE Scale) |                        |          |                        |                          |         |

| 4                            | 1.0000                 | 502.8343 | 0.15000                | 0.08875                  | 0.08875 |

| Test Information (MLE Scale) |          |                         |
|------------------------------|----------|-------------------------|
| Null Reference = 0           |          |                         |
| _Stage_                      | Estimate | -----Test-----          |
|                              |          | -----Trt-----<br>Action |
| 1                            | 0.11111  | Continue                |
| 2                            | .        |                         |
| 3                            | .        |                         |
| 4                            | .        |                         |

The information level at stage 1 is derived from the standard error,

$$I_1 = \frac{1}{\text{Var}(\hat{\theta}_1)} = \frac{1}{(\text{s.e.}(\hat{\theta}_1))^2} = 126.987$$

By default (or equivalently if you specify PLOTS=TEST), the “Test Plot” graph displays boundary values of the design and the test statistic at stage 1, as shown in [Output 84.1.13](#). It also shows that the observed statistic is in the continuation region.

Output 84.1.13 Sequential Test Plot

The observed information level at stage 1,  $I_1 = 126.987$ , is slightly larger than the target information level at the design. If an observed information level in the study is substantially different from its target level in the design, then the sample sizes should be adjusted in the subsequent stages to achieve the target information levels.

Suppose the trial continues to the next stage, and 108 patients are available in each group at stage 2. The data set COUNT\_2 contains these 216 patients.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 2:

```
proc genmod data=Count_2;
 model Resp= Trt;
 ods output ParameterEstimates=Parms_Count2;
run;
```

The following statements create the parameter estimate at stage 2,  $\hat{\theta}_2 = \hat{p}_2 - \hat{p}_1 = 0.1759$ , and its associated standard error  $\sqrt{\text{Var}(\hat{\theta}_2)} = 0.0623$  into a test data set:

```
data Parms_Count2;
 set Parms_Count2;
 if Parameter='Trt';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Count2;
 title 'Statistics Computed at Stage 2';
run;
```

Output 84.1.14 displays the test statistics at stage 2.

**Output 84.1.14** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |           |          |        |         |         |
|--------------------------------|-----------|----------|--------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | Trt       | 0.1759   | 0.0623 | MLE     | 2       |

The following statements invoke the SEQTEST procedure and test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Count1
 Parms(Testvar=Trt)=Parms_Count2
 infoadj=none
 boundaryscale=mle
 ;
 ods output Test=Test_Count2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_COUNT2 option creates an output data set named TEST\_COUNT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Test Information” table in [Output 84.1.15](#) displays the boundary values, test statistic, and resulting action at each stage. The table shows that the test statistic 0.17593 is larger than the corresponding upper alpha boundary value, so the trial stops to reject the hypothesis.

**Output 84.1.15** Sequential Test

```

The SEQTEST Procedure

Test Information (MLE Scale)
Null Reference = 0

---Information Level---
Stage Proportion Actual -Alternative-
 0.2525 126.9871 --Reference--
 0.5122 257.5571 --Upper
 0.7500 377.1257 Beta
 1.0000 502.8343 Alpha

Test Information (MLE Scale)
Null Reference = 0

-----Test-----
-----Trt-----

 2 0.17593 Reject Null
 3 .
 4 .

```

With ODS Graphics enabled, the “Test Plot” is displayed, as shown in [Output 84.1.16](#). The plot displays boundary values of the design and the test statistics at the first two stages. As expected, the test statistic at stage 2 is in the “Upper Rejection Region” above the upper alpha boundary.

Output 84.1.16 Sequential Test Plot

After a trial is stopped, the “Parameter Estimates” table in [Output 84.1.17](#) displays the stopping stage and the maximum likelihood estimate of the parameter. It also displays the  $p$ -value, median estimate, and confidence limits for the parameter that correspond to the observed statistic by using the specified sample space ordering.

Output 84.1.17 Parameter Estimates

| Parameter Estimates<br>Stagewise Ordering |                |          |                          |                 |              |
|-------------------------------------------|----------------|----------|--------------------------|-----------------|--------------|
| Parameter                                 | Stopping Stage | MLE      | p-Value for<br>H0:Parm=0 | Median Estimate | Lower 95% CL |
| Trt                                       | 2              | 0.175926 | 0.0031                   | 0.174462        | 0.07059      |

The MLE statistic at the stopping stage is the maximum likelihood estimate of the parameter and is biased. The computation of  $p$ -value, unbiased median estimate, and confidence limits depends on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the observed standardized  $Z$  statistic. By default

(or equivalently if you specify ORDER=STAGewise), the stagewise ordering that uses counterclockwise ordering around the continuation region is used to compute the  $p$ -value, unbiased median estimate, and confidence limits. As expected, the  $p$ -value is less than 0.025, and the confidence interval does not contain the null reference zero. With the stagewise ordering, the  $p$ -value is computed as

$$P_{\theta=0}(Z_1 > a_1) + P_{\theta=0}(Z_2 > z_2 \mid b_1 < Z_1 < a_1)$$

where  $z_2$  is the observed standardized  $Z$  statistic at stage 2,  $Z_1$  is the standardized normal variate at stage 1,  $Z_2$  is the standardized normal variate at stage 2, and  $a_1$  and  $b_1$  are the stage 1 upper rejection and acceptance boundary values, respectively.

See the section “Available Sample Space Orderings in a Sequential Test” on page 7230 for a detailed description of the stagewise ordering.

## Example 84.2: Testing an Effect in a Regression Model

This example demonstrates a two-sided group sequential test that uses an error spending design with early stopping to reject the null hypothesis. A study is conducted to examine the effects of Age (years), Weight (kg), RunTime (time in minutes to run 1.5 miles), RunPulse (heart rate while running), and MaxPulse (maximum heart rate recorded while running) on Oxygen (oxygen intake rate, ml per kg body weight per minute). The primary interest is whether oxygen intake rate is associated with weight.

The hypothesis is tested using the following linear model:

$$\text{Oxygen} = \text{Age} + \text{Weight} + \text{RunTime} + \text{RunPulse} + \text{MaxPulse}$$

The null hypothesis is  $H_0 : \beta_w = 0$ , where  $\beta_w$  is the regression parameter for the variable Weight. Suppose that  $\beta_w = 0.10$  is the reference improvement that should be detected at a 0.90 level. Then the maximum information  $I_X$  can be derived in the SEQDESIGN procedure.

Following the derivations in the section “Test for a Parameter in the Regression Model” in the chapter “The SEQDESIGN Procedure,” the required sample size can be derived from

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2) \sigma_x^2}$$

where  $\sigma_y^2$  is the variance of the response variable in the regression model,  $r_x^2$  is the proportion of variance of Weight explained by other covariates, and  $\sigma_x^2$  is the variance of Weight.

Further suppose that from past experience,  $\sigma_y^2 = 5$ ,  $r_x^2 = 0.10$ , and  $\sigma_x^2 = 64$ . Then the required sample size can be derived using the SAMPLESIZE statement in the SEQDESIGN procedure.

The following statements invoke the SEQDESIGN procedure and request a three-stage group sequential design for normally distributed data to test the null hypothesis of a regression parameter  $H_0 : \beta_w = 0$  against the alternative  $H_1 : \beta_w \neq 0$ :

```
ods graphics on;
proc seqdesign altref=0.10;
 OBFErrorFunction: design method=errfuncobf
 nstages=3
 info=cum(2 3 4)
 ;
 sample size model=reg(variance=5 xvariance=64 xrsquare=0.10);
 ods output Boundary=Bnd_Fit;
run;
ods graphics off;
```

By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10), the procedure uses a Type I error probability 0.05 and a Type II error probability 0.10. The ALTREF=0.10 option specifies a power of  $1 - \beta = 0.90$  at the alternative hypothesis  $H_1 : \beta_w = \pm 0.10$ . The INFO=CUM(2 3 4) option specifies that the study perform the first interim analysis with information proportion  $2/4 = 0.5$ —that is, after half of the total observations are collected.

The ODS OUTPUT statement with the BOUNDARY=BND\_FIT option creates an output data set named BND\_FIT which contains the resulting boundary information for the subsequent sequential tests.

The “Design Information” table in [Output 84.2.1](#) displays design specifications and derived statistics. Since the alternative reference is specified, the maximum information is derived.

#### Output 84.2.1 Design Information

| The SEQDESIGN Procedure                   |                |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.2.3](#). The boundary plot also displays the information level and critical value for the corresponding fixed-sample design. This design has characteristics of an O’Brien-Fleming design; the probability for early stopping is low, and the maximum information and critical values at the final stage are similar to those of the corresponding fixed-sample design.

**Output 84.2.3** Boundary Plot

With the MODEL=REG option in the SAMPLESIZE statement, the “Sample Size Summary” table in [Output 84.2.4](#) displays the parameters for the sample size computation.

**Output 84.2.4** Required Sample Size Summary

| Sample Size Summary             |               |
|---------------------------------|---------------|
| Test                            | Reg Parameter |
| Parameter                       | 0.1           |
| Variance                        | 5             |
| X Variance                      | 64            |
| R Square (X)                    | 0.1           |
| Max Sample Size                 | 92.87739      |
| Expected Sample Size (Null Ref) | 92.35845      |
| Expected Sample Size (Alt Ref)  | 70.97617      |

The “Sample Sizes” table in [Output 84.2.5](#) displays the required sample sizes for the group sequential clinical trial.

**Output 84.2.5** Required Sample Sizes

| Sample Sizes (N)                |                        |             |                     |             |
|---------------------------------|------------------------|-------------|---------------------|-------------|
| Z Test for Regression Parameter |                        |             |                     |             |
| _Stage_                         | -----Fractional N----- |             | -----Ceiling N----- |             |
|                                 | N                      | Information | N                   | Information |
| 1                               | 46.44                  | 535.0       | 47                  | 541.4       |
| 2                               | 69.66                  | 802.5       | 70                  | 806.4       |
| 3                               | 92.88                  | 1069.9      | 93                  | 1071.4      |

Thus, 47, 70, and 93 individuals are needed in stages 1, 2, and 3, respectively. Since the sample sizes are derived from estimated values of  $\sigma_y^2$ ,  $r_x^2$ , and  $\sigma_x^2$ , the actual information levels might not achieve the target information levels. Thus, instead of specifying sample sizes in the protocol, you can specify the maximum information levels. Then if an actual information level is much less than the target level, you can increase the sample sizes for the remaining stages to achieve the desired information levels and power.

Suppose that 47 individuals are available at stage 1. [Output 84.2.6](#) lists the first 10 observations of the trial data.

**Output 84.2.6** Clinical Trial Data

| First 10 Obs in the Trial Data |         |     |         |         |           |           |
|--------------------------------|---------|-----|---------|---------|-----------|-----------|
| Obs                            | Oxygen  | Age | Weight  | RunTime | Run Pulse | Max Pulse |
| 1                              | 54.5521 | 44  | 87.7676 | 11.6949 | 178.435   | 181.607   |

| 9                              | 48.0775 | 44  | 85.2290 | 13.1789 | 173.722   | 176.548   |
| 10                             | 68.3357 | 38  | 80.2490 | 8.5066  | 171.824   | 184.011   |

The following statements use the REG procedure to estimate the slope  $\beta_w$  and its associated standard error at stage 1:

```
proc reg data=Fit_1;
 model Oxygen=Age Weight RunTime RunPulse MaxPulse;
 ods output ParameterEstimates=Parms_Fit1;
run;
```

The following statements create and display (in [Output 84.2.7](#)) the input data set that contains slope  $\beta_w$  and its associated standard error for the SEQTEST procedure:

```
data Parms_Fit1;
 set Parms_Fit1;
 if Variable='Weight';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Fit1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.2.7** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Weight   | 0.03772  | 0.04345 | MLE     | 1       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Fit
 Parms(Testvar=Weight)=Parms_Fit1
 infoadj=prop
 errspendadj=errfuncobf
 order=lr
 stopprob
 ;
 ods output Test=Test_Fit1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1 (this data set was generated in the SEQDESIGN procedure). Recall that these boundary values were derived for the information levels specified with the INFO=CUM(2 3 4) option in the SEQDESIGN procedure. The PARMS=PARMS\_FIT1 option specifies the input data set PARMS\_FIT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=WEIGHT option identifies the test variable WEIGHT in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ORDER=LR option uses the LR ordering to derive the  $p$ -value, the unbiased median estimate, and the confidence limits for the regression slope estimate. The ERRSPENDADJ=ERRFUNCBOBF option adjusts the boundaries with the updated error spending values generated from an O'Brien-Fleming-type cumulative error spending function.

The ODS OUTPUT statement with the TEST=TEST\_FIT1 option creates an output data set named TEST\_FIT1 which contains the updated boundary information for the test at stage 1. The adjustment is needed because the observed information level is different from the information level in the BOUNDARY= data set. The data set TEST\_FIT1 also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.2.8](#) displays the design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I  $\alpha$  level. The maximum information remains the same as in the BOUNDARY= data set, but the derived Type II error probability  $\beta$  and power  $1 - \beta$  are different because of the new information level.

**Output 84.2.8** Design Information

| The SEQTEST Procedure                     |                 |

|                                         |          |                  | Action   |
| 1                                       | 0.86798  |                  | Continue |
| 2                                       | .        |                  |          |
| 3                                       | .        |                  |          |

With the INFOADJ=PROP option (which is the default), the information level at stage 2 is derived proportionally from the observed information at stage 1 and the information levels in the BOUNDARY= data set. See the section “[Boundary Adjustments for Information Levels](#)” on page 7223 for details about how the adjusted information levels are computed.

At stage 1, the standardized Z statistic 0.86798 is between the lower  $\alpha$  boundary  $-2.97951$  and the upper  $\alpha$  boundary  $2.97951$ , so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in [Output 84.2.11](#). As expected, the test statistic is in the continuation region between the lower and upper  $\alpha$  boundaries.

Output 84.2.11 Sequential Test Plot

The following statements use the REG procedure to estimate the slope  $\beta_w$  and its associated standard error at stage 2:

```
proc reg data=Fit_2;
 model Oxygen=Age Weight RunTime RunPulse MaxPulse;
 ods output ParameterEstimates=Parms_Fit2;
run;
```

Note that the data set Fit\_2 contains both the data from stage 1 and the data from stage 2.

The following statements create and display (in [Output 84.2.12](#)) the input data set that contains slope  $\beta_w$  and its associated standard error at stage 2 for the SEQTEST procedure:

```
data Parms_Fit2;
 set Parms_Fit2;
 if Variable='Weight';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
```

```
proc print data=Parms_Fit2;
 title 'Statistics Computed at Stage 2';
run;
```

### Output 84.2.12 Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Weight   | 0.02932  | 0.03520 | MLE     | 2       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_Fit1
 Parms(Testvar=Weight)=Parms_Fit2
 infoadj=prop
 errspendadj=errfuncobf
 order=lr
 ;
ods output Test=Test_Fit2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMs= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_FIT2 option creates an output data set named TEST\_FIT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

Since the data set PARMs\_FIT2 does not contain the test information at stage 1, the information level at stage 1 in the TEST\_FIT1 data set is used to generate boundary values for the test at stage 2.

Following the process at stage 1, the slope estimate is also between its corresponding lower and upper  $\alpha$  boundary values, so the trial continues to the next stage.

The following statements use the REG procedure to estimate the slope  $\beta_w$  and its associated standard error at the final stage:

```
proc reg data=Fit_3;
 model Oxygen=Age Weight RunTime RunPulse MaxPulse;
 ods output ParameterEstimates=Parms_Fit3;
run;
```

The following statements create the input data set that contains slope  $\beta_w$  and its associated standard error at stage 3 for the SEQTEST procedure:

```
data Parms_Fit3;
 set Parms_Fit3;
 if Variable='Weight';
 Scale='MLE';
 Stage= 3;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
```

The following statements print (in [Output 84.2.13](#)) the test statistics at stage 3:

```
proc print data=Parms_Fit3;
 title 'Statistics Computed at Stage 3';
run;
```

**Output 84.2.13** Statistics Computed at Stage 3

| Statistics Computed at Stage 3 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Weight   | 0.02189  | 0.03028 | MLE     | 3       |

The following statements invoke the SEQTEST procedure to test the hypothesis:

```
ods graphics on;
proc seqtest Boundary=Test_Fit2
 Parms(testvar=Weight)=Parms_Fit3
 errspendadj=errfuncobf
 order=lr
 pss
 plots=(asn power)
 ;
 ods output Test=Test_Fit3;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 3, which was generated by the SEQTEST procedure at the previous stage. The PARMs= option specifies the input data set that contains the test statistic and its associated standard error at stage 3, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_FIT3 option creates an output data set named TEST\_FIT3 which contains the updated boundary information for the test at stage 3.

The “Design Information” table in [Output 84.2.14](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I  $\alpha$  level.

**Output 84.2.14** Design Information

| The SEQTEST Procedure                     |                 |
|-------------------------------------------|-----------------|
| Design Information                        |                 |
| BOUNDARY Data Set                         | WORK.TEST_FIT2  |
| Data Set                                  | WORK.PARMS_FIT3 |
| Statistic Distribution                    | Normal          |
| Boundary Scale                            | Standardized Z  |
| Alternative Hypothesis                    | Two-Sided       |
| Early Stop                                | Reject Null     |
| Number of Stages                          | 3               |
| Alpha                                     | 0.05            |
| Beta                                      | 0.09514         |
| Power                                     | 0.90486         |
| Max Information (Percent of Fixed Sample) | 102.0102        |
| Max Information                           | 1090.63724      |
| Null Ref ASN (Percent of Fixed Sample)    | 101.4122        |
| Alt Ref ASN (Percent of Fixed Sample)     | 77.22139        |

The maximum information is derived from the standard error associated with the slope estimate at the final stage and is larger than the target level. The derived Type II error probability  $\beta$  and power  $1 - \beta$  are different because of the new information levels.

With the PSS option, the “Power and Expected Sample Sizes” table in [Output 84.2.15](#) displays powers and expected mean sample sizes under various hypothetical references  $\theta = c_i \theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i = 0, 0.5, 1, 1.5$  by default. You can specify the  $c_i$  values with the CREF= option.

**Output 84.2.15** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes   |         |                                          |
|------------------------------------|---------|------------------------------------------|
| Reference = CRef * (Alt Reference) |         |                                          |
| CRef                               | Power   | -Sample Size-<br>Percent<br>Fixed-Sample |
| 0.0000                             | 0.02500 | 101.4122                                 |
| 0.5000                             | 0.37046 | 96.3754                                  |
| 1.0000                             | 0.90486 | 77.2214                                  |
| 1.5000                             | 0.99844 | 58.5301                                  |

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in [Output 84.2.16](#). By default, expected sample sizes under the hypotheses  $\theta = c_i \theta_1$ ,  $c_i = 0, 0.01, 0.02, \dots, 1.50$ , are displayed, where  $\theta_1$  is the alternative reference.

Output 84.2.16 ASN Plot

With the PLOTS=POWER option, the procedure displays a plot of powers under various hypothetical references, as shown in [Output 84.2.17](#). By default, powers under hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i = 0, 0.01, 0.02, \dots, 1.50$  by default. You can specify  $c_i$  values with the CREF= option. The  $c_i$  values are displayed on the horizontal axis.

Output 84.2.17 Power Plot

Under the null hypothesis,  $c_i = 0$ , the power is 0.025, which is the upper Type I error probability. Under the alternative hypothesis,  $c_i = 1$ , the power is 0.90486, which is one minus the Type II error probability.

The “Test Information” table in [Output 84.2.18](#) displays the boundary values for the test statistic with the default standardized Z scale. The information level at the current stage is derived from the standard error for the current stage in the PARMS= data set. At stage 3, the standardized slope estimate 0.72284 is still between the lower and upper  $\alpha$  boundary values. Since it is the final stage, the trial stops to accept the null hypothesis that the variable Weight has no effect on the oxygen intake rate after adjusting for other covariates.

**Output 84.2.18** Sequential Tests

| Test Information (Standardized Z Scale) |                       |          |                       |                     |                         |             |
|-----------------------------------------|-----------------------|----------|-----------------------|---------------------|-------------------------|-------------|
| Null Reference = 0                      |                       |          |                       |                     |                         |             |
| _Stage_                                 | --Information Level-- |          | -----Alternative----- |                     | ----Boundary Values---- |             |
|                                         | Proportion            | Actual   | -----Reference-----   | -----Reference----- | ---Lower---             | ---Upper--- |
|                                         |                       |          | Lower                 | Upper               | Alpha                   | Alpha       |
| 1                                       | 0.4856                | 529.6232 | -2.30135              | 2.30135             | -2.97951                | 2.97951     |
| 2                                       | 0.7401                | 807.1954 | -2.84112              | 2.84112             | -2.34945                | 2.34945     |
| 3                                       | 1.0000                | 1090.637 | -3.30248              | 3.30248             | -2.01885                | 2.01885     |

  

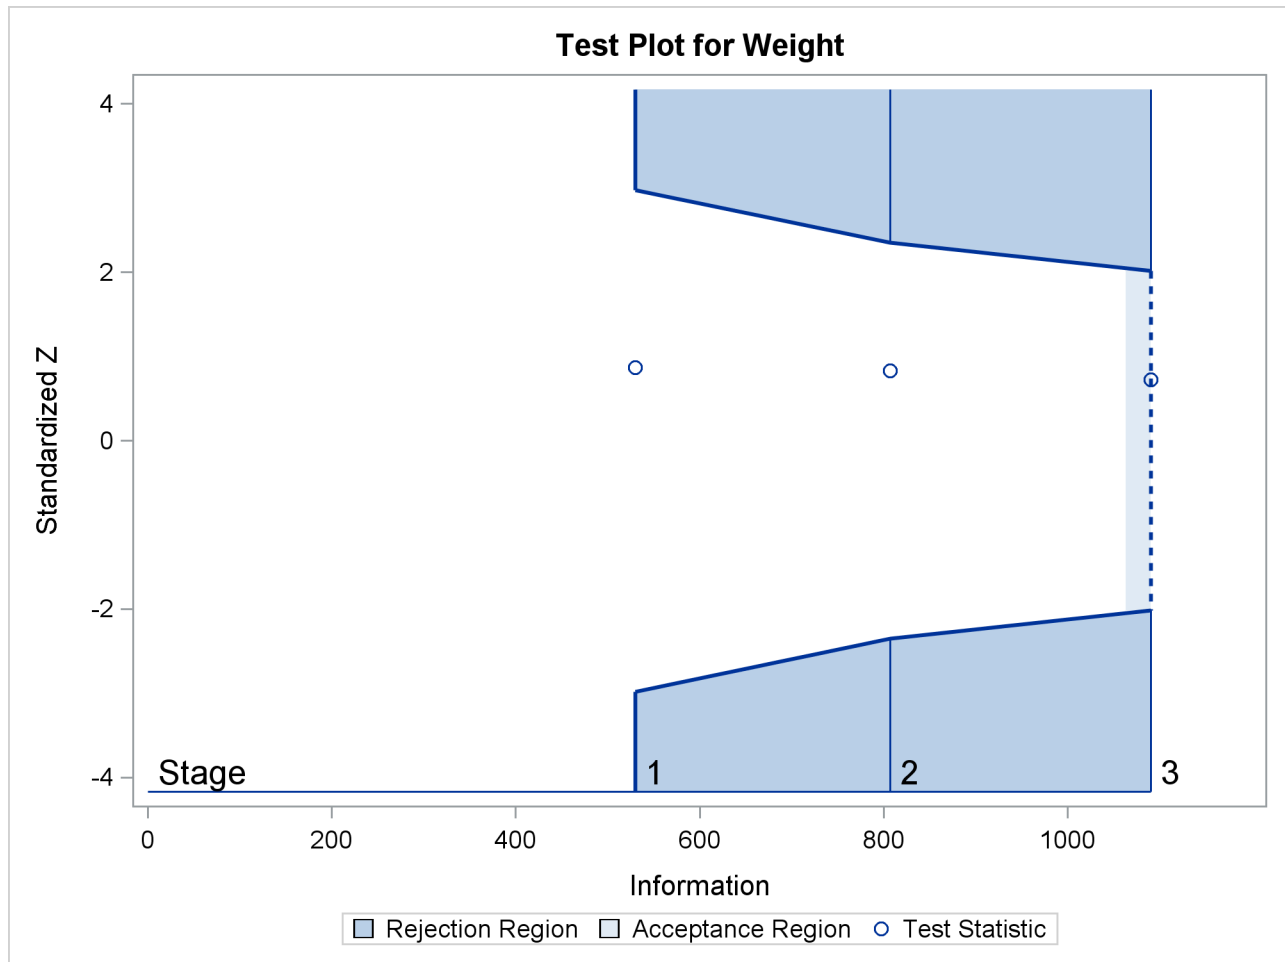

| Test Information (Standardized Z Scale) |                |             |
|-----------------------------------------|----------------|-------------|
| Null Reference = 0                      |                |             |
| _Stage_                                 | -----Test----- |             |
|                                         | Estimate       | Action      |
| 1                                       | 0.86798        | Continue    |
| 2                                       | 0.83305        | Continue    |
| 3                                       | 0.72284        | Accept Null |

Since the data set FIT\_3 contains the test information only at stage 3, the information levels at previous stages in the TEST\_FIT2 data set are used to generate boundary values for the test.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in [Output 84.2.19](#). As expected, the test statistic is in the acceptance region between the lower and upper  $\alpha$  boundaries at the final stage.

**Output 84.2.19** Sequential Test Plot

After a trial is stopped, the “Parameter Estimates” table in [Output 84.2.20](#) displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the  $p$ -value under the null hypothesis  $H_0 : \beta_w = 0$ .

**Output 84.2.20** Parameter Estimates

| Parameter Estimates<br>LR Ordering |                       |          |                                  |                 |
|------------------------------------|-----------------------|----------|----------------------------------|-----------------|
| Parameter                          | Stopping Stage        | MLE      | p-Value for $H_0: \text{Parm}=0$ | Median Estimate |
| Weight                             | 3                     | 0.021888 | 0.4699                           | 0.021884        |
| Parameter Estimates<br>LR Ordering |                       |          |                                  |                 |
| Parameter                          | 95% Confidence Limits |          |                                  |                 |
| Weight                             | -0.03747              | 0.08123  |                                  |                 |

As expected, the  $p$ -value 0.4699 is not significant at the  $\alpha = 0.05$  level, and the confidence interval does contain the value zero. The  $p$ -value, unbiased median estimate, and confidence limits depend on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic. With the specified LR ordering, the  $p$ -values are computed with the ordering  $(k', z') \succ (k, z)$  if  $z' > z$ . See the section “Available Sample Space Orderings in a Sequential Test” on page 7230 for a detailed description of the LR ordering.

---

### Example 84.3: Testing an Effect with Early Stopping to Accept $H_0$

This example demonstrates a two-sided group sequential test that uses an error spending design with early stopping to accept the null hypothesis  $H_0$ . The example is similar to Example 84.2 but with early stopping to accept  $H_0$ .

A study is conducted to examine the effects of Age (years), Weight (kg), RunTime (time in minutes to run 1.5 miles), RunPulse (heart rate while running), and MaxPulse (maximum heart rate recorded while running) on Oxygen (oxygen intake rate, ml per kg body weight per minute). The primary interest is whether oxygen intake rate is associated with weight.

The hypothesis is tested using the following linear model:

$$\text{Oxygen} = \text{Age} + \text{Weight} + \text{RunTime} + \text{RunPulse} + \text{MaxPulse}$$

The null hypothesis is  $H_0 : \beta_w = 0$ , where  $\beta_w$  is the regression parameter for the variable Weight. Suppose that  $\beta_w = 0.10$  is the reference improvement that should be detected at a 0.90 level. Then the maximum information  $I_X$  can be derived in the SEQDESIGN procedure.

Following the derivations in the section “Test for a Parameter in the Regression Model” in the chapter “The SEQDESIGN Procedure,” the required sample size can be derived from

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2) \sigma_x^2}$$

where  $\sigma_y^2$  is the variance of the response variable in the regression model,  $r_x^2$  is the proportion of variance of Weight explained by other covariates, and  $\sigma_x^2$  is the variance of Weight.

Further suppose that from past experience,  $\sigma_y^2 = 5$ ,  $r_x^2 = 0.10$ , and  $\sigma_x^2 = 64$ . Then the required sample size can be derived using the SAMPLESIZE statement in the SEQDESIGN procedure.

The following statements invoke the SEQDESIGN procedure and request a three-stage group sequential design for normally distributed data to test the null hypothesis of a regression parameter  $H_0 : \beta_w = 0$  against the alternative  $H_1 : \beta_w \neq 0$ :

```
ods graphics on;
proc seqdesign altref=0.10;
 OBFErrorFunction: design method=errfuncgamma
 stop=accept
 nstages=3
 info=cum(2 3 4);

 samplesize model=reg(variance=5 xviance=64 xrsquare=0.10);
```

```
ods output Boundary=Bnd_Fit;
run;
ods graphics off;
```

By default (or equivalently if you specify ALPHA=0.05 and BETA=0.10), the procedure uses a Type I error probability 0.05 and a Type II error probability 0.10. The ALTREF=0.10 option specifies a power of  $1 - \beta = 0.90$  at the alternative hypothesis  $H_1 : \beta_w = \pm 0.10$ . The INFO=CUM(2 3 4) option specifies that the study perform the first interim analysis with information proportion  $2/4 = 0.5$ —that is, after half of the total observations are collected.

The ODS OUTPUT statement with the BOUNDARY=BND\_FIT option creates an output data set named BND\_FIT which contains the resulting boundary information for the subsequent sequential tests.

The “Design Information” table in [Output 84.3.1](#) displays design specifications and derived statistics. Since the alternative reference is specified, the maximum information is derived.

**Output 84.3.1** Error Spending Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|
| Design: OBFErrorFunction                  |                |

| 1                                           | -0.44937                  | 0.44937     |  |
| 2                                           | -1.13583                  | 1.13583     |  |
| 3                                           | -1.91428                  | 1.91428     |  |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.3.3](#). The boundary plot also displays the information level and critical value for the corresponding fixed-sample design.

**Output 84.3.3** Boundary Plot

With the MODEL=REG option in the SAMPLESIZE statement, the “Sample Size Summary” table in [Output 84.3.4](#) displays the parameters for the sample size computation.

**Output 84.3.4** Required Sample Size Summary

| Sample Size Summary             |               |
|---------------------------------|---------------|
| Test                            | Reg Parameter |
| Parameter                       | 0.1           |
| Variance                        | 5             |
| X Variance                      | 64            |
| R Square (X)                    | 0.1           |
| Max Sample Size                 | 94.78926      |
| Expected Sample Size (Null Ref) | 68.41207      |
| Expected Sample Size (Alt Ref)  | 92.86057      |

The “Sample Sizes” table in [Output 84.3.5](#) displays the required sample sizes for the group sequential clinical trial.

**Output 84.3.5** Required Sample Sizes

| Sample Sizes (N)                |                        |             |                     |             |
|---------------------------------|------------------------|-------------|---------------------|-------------|
| Z Test for Regression Parameter |                        |             |                     |             |
| _Stage_                         | -----Fractional N----- |             | -----Ceiling N----- |             |
|                                 | N                      | Information | N                   | Information |
| 1                               | 47.39                  | 546.0       | 48                  | 553.0       |
| 2                               | 71.09                  | 819.0       | 72                  | 829.4       |
| 3                               | 94.79                  | 1092.0      | 95                  | 1094.4      |

Thus, 48, 72, and 95 individuals are needed in stages 1, 2, and 3, respectively. Since the sample sizes are derived from estimated values of  $\sigma_y^2$ ,  $r_x^2$ , and  $\sigma_x^2$ , the actual information levels might not achieve the target information levels. Thus, instead of specifying sample sizes in the protocol, you can specify the maximum information levels. Then if an actual information level is much less than the target level, you can increase the sample sizes for the remaining stages to achieve the desired information levels and power.

Suppose that 48 individuals are available at stage 1. [Output 84.3.6](#) lists the first 10 observations of the trial data.

**Output 84.3.6** Clinical Trial Data

| First 10 Obs in the Trial Data |         |     |         |         |           |           |
|--------------------------------|---------|-----|---------|---------|-----------|-----------|
| Obs                            | Oxygen  | Age | Weight  | RunTime | Run Pulse | Max Pulse |
| 1                              | 54.5521 | 44  | 87.7676 | 11.6949 | 178.435   | 181.607   |
| 2                              | 52.2821 | 40  | 75.4853 | 9.8872  | 184.433   | 183.667   |
| 3                              | 62.1871 | 44  | 89.0638 | 8.7950  | 155.540   | 167.108   |
| 4                              | 65.3269 | 42  | 67.7310 | 8.4577  | 162.926   | 173.877   |
| 5                              | 59.9809 | 37  | 93.1902 | 9.3228  | 179.033   | 180.144   |
| 6                              | 52.5588 | 47  | 75.9044 | 12.0385 | 177.753   | 175.033   |
| 7                              | 51.7838 | 40  | 73.5422 | 11.6607 | 175.838   | 178.140   |
| 8                              | 57.0024 | 43  | 81.2861 | 11.2219 | 160.963   | 171.770   |
| 9                              | 48.0775 | 44  | 85.2290 | 13.1789 | 173.722   | 176.548   |
| 10                             | 68.3357 | 38  | 80.2490 | 8.5066  | 171.824   | 184.011   |

The following statements use the REG procedure to estimate the slope  $\beta_w$  and its associated standard error at stage 1:

```
proc reg data=Fit_1;
 model Oxygen=Age Weight RunTime RunPulse MaxPulse;
 ods output ParameterEstimates=Parms_Fit1;
run;
```

The following statements create and display (in [Output 84.3.7](#)) the input data set that contains slope  $\beta_w$  and its associated standard error for the SEQTEST procedure:

```
data Parms_Fit1;
 set Parms_Fit1;
 if Variable='Weight';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Fit1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.3.7** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Weight   | 0.04660  | 0.04308 | MLE     | 1       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Fit
 Parms(testvar=Weight)=Parms_Fit1
 infoadj=none
 errspendadj=errfuncgamma
 stopprob
 order=lr
 ;
 ods output Test=Test_Fit1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_FIT1 option specifies the input data set PARMS\_FIT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=WEIGHT option identifies the test variable WEIGHT in the data set. The INFOADJ=NONE option maintains the information level for stage 2 at the value provided in the BOUNDARY= data set.

The ORDER=LR option uses the LR ordering to derive the  $p$ -value, the unbiased median estimate, and the confidence limits for the regression slope estimate. The ERRSPENDADJ=ERRFUNC GAMMA option adjusts the boundaries with the updated error spending values generated from a gamma cumulative error spending function.

The ODS OUTPUT statement with the TEST=TEST\_FIT1 option creates an output data set named TEST\_FIT1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.3.8](#) displays the design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I  $\alpha$  level. The maximum information remains the same as in the BOUNDARY= data set, but the derived Type II error probability  $\beta$  and power  $1 - \beta$  are different because of the new information level.

**Output 84.3.8** Design Information

| The SEQTEST Procedure                     |                 |
|-------------------------------------------|-----------------|
| Design Information                        |                 |
| BOUNDARY Data Set                         | WORK.BND_FIT    |
| Data Set                                  | WORK.PARMS_FIT1 |
| Statistic Distribution                    | Normal          |
| Boundary Scale                            | Standardized Z  |
| Alternative Hypothesis                    | Two-Sided       |

The “Test Information” table in [Output 84.3.10](#) displays the boundary values for the test statistic. By default (or equivalently if you specify BOUNDARYSCALE=STDZ), these statistics are displayed with the standardized Z scale. The information level at stage 1 is derived from the standard error  $s_1$  in the PARMS= data set,

$$I_1 = \frac{1}{s_1^2} = \frac{1}{0.04308^2} = 538.8$$

**Output 84.3.10** Sequential Tests

| Test Information (Standardized Z Scale) |                         |          |                       |         |

| 1                                       | -0.43033                  | 0.43033             | 1.08174                      | Continue |
| 2                                       | -1.13623                  | 1.13623             | .                            |          |
| 3                                       | -1.91431                  | 1.91431             | .                            |          |

At stage 1, the standardized Z statistic 1.08174 is greater than the upper  $\beta$  boundary 0.43033, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in [Output 84.3.11](#). As expected, the test statistic is in the continuation region.

**Output 84.3.11** Sequential Test Plot

The following statements use the REG procedure to estimate the slope  $\beta_w$  and its associated standard error at stage 2:

```
proc reg data=Fit_2;
 model Oxygen=Age Weight RunTime RunPulse MaxPulse;
 ods output ParameterEstimates=Parms_Fit2;
run;
```

Note that the data set Fit\_2 contains both the data from stage 1 and the data from stage 2,

The following statements create and display (in [Output 84.3.12](#)) the input data set that contains slope  $\beta_w$  and its associated standard error at stage 2 for the SEQTEST procedure:

```
data Parms_Fit2;
 set Parms_Fit2;
 if Variable='Weight';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
```

```
proc print data=Parms_Fit2;
 title 'Statistics Computed at Stage 2';
run;
```

**Output 84.3.12** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |          |          |         |         |         |
|--------------------------------|----------|----------|---------|---------|---------|
| Obs                            | Variable | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | Weight   | 0.02925  | 0.03490 | MLE     | 2       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Fit1
 Parms(testvar=Weight)=Parms_Fit2
errspendadj=errfuncgamma
order=lr
pss
plots=(asn power)
;
ods output Test=Test_Fit2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

Since the data set PARMS\_FIT2 does not contain the test information at stage 1, the information level at stage 1 in the TEST\_FIT1 data set is used to generate boundary values for the test.

The ORDER=LR option uses the LR ordering to derive the  $p$ -value, unbiased median estimate, and confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST\_FIT2 option creates an output data set named TEST\_FIT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.3.13](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I  $\alpha$  level.

**Output 84.3.13** Design Information

| The SEQTEST Procedure                     |                 |
|-------------------------------------------|-----------------|
| Design Information                        |                 |
| BOUNDARY Data Set                         | WORK.TEST_FIT1  |
| Data Set                                  | WORK.PARMS_FIT2 |
| Statistic Distribution                    | Normal          |
| Boundary Scale                            | Standardized Z  |
| Alternative Hypothesis                    | Two-Sided       |
| Early Stop                                | Accept Null     |
| Number of Stages                          | 3               |
| Alpha                                     | 0.05            |
| Beta                                      | 0.10009         |
| Power                                     | 0.89991         |
| Max Information (Percent of Fixed Sample) | 103.9566        |
| Max Information                           | 1091.97232      |
| Null Ref ASN (Percent of Fixed Sample)    | 75.18254        |
| Alt Ref ASN (Percent of Fixed Sample)     | 101.8349        |

The derived Type II error probability  $\beta$  and power  $1 - \beta$  are different because of the new information levels.

With the PSS option, the “Power and Expected Sample Sizes” table in [Output 84.3.14](#) displays powers and expected mean sample sizes under various hypothetical references  $\theta = c_i\theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i = 0, 0.5, 1, 1.5$  are the default values in the CREF= option.

**Output 84.3.14** Power and Expected Sample Size Information

| Powers and Expected Sample Sizes   |         |                                          |
|------------------------------------|---------|------------------------------------------|
| Reference = CRef * (Alt Reference) |         |                                          |
| CRef                               | Power   | -Sample Size-<br>Percent<br>Fixed-Sample |
| 0.0000                             | 0.02500 | 75.1825                                  |
| 0.5000                             | 0.37154 | 88.5975                                  |
| 1.0000                             | 0.89991 | 101.8349                                 |
| 1.5000                             | 0.99758 | 103.8843                                 |

With the PLOTS=ASN option, the procedure displays a plot of expected sample sizes under various hypothetical references, as shown in [Output 84.3.15](#). By default, expected sample sizes under the hypotheses  $\theta = c_i\theta_1$ ,  $c_i = 0, 0.01, 0.02, \dots, 1.50$ , are displayed, where  $\theta_1$  is the alternative reference.

Output 84.3.15 ASN Plot

With the PLOTS=POWER option, the procedure displays a plot of the power curves under various hypothetical references for all designs simultaneously, as shown in [Output 84.3.16](#). By default, powers under hypothetical references  $\theta = c_i \theta_1$  are displayed, where  $c_i = 0, 0.01, 0.02, \dots, 1.50$  by default. You can specify  $c_i$  values with the CREF= option. The  $c_i$  values are displayed on the horizontal axis.

Output 84.3.16 Power Plot

Under the null hypothesis,  $c_i = 0$ , the power is 0.025, which is the upper Type I error probability. Under the alternative hypothesis,  $c_i = 1$ , the power is 0.89991, which is one minus the Type II error probability, as displayed in the “Design Information” table in [Output 84.3.13](#).

The “Test Information” table in [Output 84.3.17](#) displays the boundary values for the test statistic with the default standardized Z scale. At stage 2, the standardized slope estimate 0.83805 is between the lower and upper  $\beta$  boundary values. The trial stops to accept the null hypothesis that the variable Weight has no effect on the oxygen intake rate after adjusting for other covariates.

## Output 84.3.17 Sequential Tests

| Test Information (Standardized Z Scale) |                         |          |                       |         |
|-----------------------------------------|-------------------------|----------|-----------------------|---------|
| Null Reference = 0                      |                         |          |                       |         |

| 2                                       | 0.7517                  | 820.8509 | -2.86505              | 2.86505 |
| 3                                       | 1.0000                  | 1091.972 | -3.30450              | 3.30450 |

  

| Test Information (Standardized Z Scale) |                           |                     |                              |             |
|-----------------------------------------|---------------------------|---------------------|------------------------------|-------------|
| Null Reference = 0                      |                           |                     |                              |             |
| _Stage_                                 | -----Boundary Values----- |                     | -----Test-----               |             |
|                                         | ---Lower---<br>Beta       | ---Upper---<br>Beta | -----Weight-----<br>Estimate | Action      |
| 1                                       | -0.43033                  | 0.43033             | 1.08174                      | Continue    |
| 2                                       | -1.14239                  | 1.14239             | 0.83805                      | Accept Null |
| 3                                       | -1.91408                  | 1.91408             | .                            |             |

Since the data set PARMs\_FIT2 contains the test information only at stage 2, the information level at stage 1 in the TEST\_FIT1 data set is used to generate boundary values for the test.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in [Output 84.3.18](#). As expected, the test statistic is in the acceptance region between the lower and upper  $\alpha$  boundaries at the final stage.

**Output 84.3.18** Sequential Test Plot

After a trial is stopped, the “Parameter Estimates” table in [Output 84.3.19](#) displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the  $p$ -value under the null hypothesis  $H_0 : \beta_w = 0$ . As expected, the  $p$ -value 0.3056 is not significant at the  $\alpha = 0.05$  level, and the confidence interval does contain the value zero. The  $p$ -value, unbiased median estimate, and confidence limits depend on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic. With the specified LR ordering, the  $p$ -values are computed with the ordering  $(k', z') > (k, z)$  if  $z' > z$ . See the section “[Available Sample Space Orderings in a Sequential Test](#)” on page 7230 for a detailed description of the LR ordering.

**Output 84.3.19** Parameter Estimates

| Parameter Estimates<br>LR Ordering |                       |          |                       |                 |
|------------------------------------|-----------------------|----------|-----------------------|-----------------|
| Parameter                          | Stopping Stage        | MLE      | p-Value for H0:Parm=0 | Median Estimate |

| Weight                             | -0.03368 0.10532      |          |                       |                 |

### Example 84.4: Testing a Binomial Proportion

This example tests a binomial proportion by using a four-stage group sequential design. Suppose a supermarket is developing a new store-brand coffee. From past studies, the positive response for the current store-brand coffee from customers is around 60%. The store is interested in whether the new brand has a better positive response than the current brand.

A power family method is used for the group sequential trial with the null hypothesis  $H_0 : p = p_0 = 0.60$  and a one-sided upper alternative with a power of 0.80 at  $H_1 : p = 0.70$ . To accommodate the zero null reference that is assumed in the SEQDESIGN procedure, an equivalent hypothesis  $H_0 : \theta = 0$  with  $H_1 : \theta = 0.10$  is used, where  $\theta = p - p_0$ . The following statements request a power family method with early stopping to reject the null hypothesis:

```
ods graphics on;
proc seqdesign altref=0.10
 boundaryscale=mle
 ;
 PowerFamily: design method=pow
 nstages=4
 alt=upper
 beta=0.20
 ;
 samplesize model=onesamplefreq(nullprop=0.6);
 ods output Boundary=Bnd_Prop;
run;
ods graphics off;
```

The NULLPROP= option in the SAMPLESIZE statement specifies  $p_0 = 0.60$  for the sample size computation. The ODS OUTPUT statement with the BOUNDARY=BND\_PROP option creates an output data set named BND\_PROP which contains the resulting boundary information for the subsequent sequential tests.

With the BOUNDARYSCALE=MLE option, the procedure displays the output boundaries in terms of the maximum likelihood estimates. The “Design Information” table in [Output 84.4.1](#) displays design specifica-

tions and derived statistics. With the specified alternative reference  $\theta_1 = p_1 - p_0 = 0.7 - 0.6 = 0.1$ , the maximum information 670.38 is also derived.

**Output 84.4.1** Design Information

| The SEQDESIGN Procedure                   |              |
|-------------------------------------------|--------------|
| Design: PowerFamily                       |              |
| Design Information                        |              |
| Statistic Distribution                    | Normal       |
| Boundary Scale                            | MLE          |
| Alternative Hypothesis                    | Upper        |
| Early Stop                                | Reject Null  |
| Method                                    | Power Family |
| Boundary Key                              | Both         |
| Alternative Reference                     | 0.1          |
| Number of Stages                          | 4            |
| Alpha                                     | 0.05         |
| Beta                                      | 0.2          |
| Power                                     | 0.8          |
| Max Information (Percent of Fixed Sample) | 108.4306     |
| Max Information                           | 670.3782     |
| Null Ref ASN (Percent of Fixed Sample)    | 106.9276     |
| Alt Ref ASN (Percent of Fixed Sample)     | 78.51072     |

The “Boundary Information” table in [Output 84.4.2](#) displays the information level, alternative reference, and boundary values at each stage. With the STOP=REJECT option, only the rejection boundary values are displayed.

**Output 84.4.2** Boundary Information

| Boundary Information (MLE Scale) |                             |          |          |                        |                          |

|                                  | Proportion                  | Actual   | N        | --Reference--<br>Upper | -----Upper-----<br>Alpha |
| 1                                | 0.2500                      | 167.5945 | 35.19485 | 0.10000                | 0.20018                  |
| 2                                | 0.5000                      | 335.1891 | 70.38971 | 0.10000                | 0.11903                  |
| 3                                | 0.7500                      | 502.7836 | 105.5846 | 0.10000                | 0.08782                  |
| 4                                | 1.0000                      | 670.3782 | 140.7794 | 0.10000                | 0.07077                  |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.4.3](#).

**Output 84.4.3** Boundary Plot

With the MODEL=ONESAMPLEFREQ option in the SAMPLESIZE statement, the “Sample Size Summary” table in **Output 84.4.4** displays the parameters for the sample size computation.

**Output 84.4.4** Required Sample Size Summary

| Sample Size Summary             |                       |
|---------------------------------|-----------------------|
| Test                            | One-Sample Proportion |
| Null Proportion                 | 0.6                   |
| Proportion                      | 0.7                   |
| Test Statistic                  | Z for Proportion      |
| Reference Proportion            | Alt Ref               |
| Max Sample Size                 | 140.7794              |
| Expected Sample Size (Null Ref) | 138.828               |
| Expected Sample Size (Alt Ref)  | 101.9333              |

The “Sample Sizes” table in [Output 84.4.5](#) displays the required sample sizes for the group sequential clinical trial.

**Output 84.4.5** Required Sample Sizes

| Sample Sizes (N)                 |                        |             |                     |             |
|----------------------------------|------------------------|-------------|---------------------|-------------|
| One-Sample Z Test for Proportion |                        |             |                     |             |
| _Stage_                          | -----Fractional N----- |             | -----Ceiling N----- |             |
|                                  | N                      | Information | N                   | Information |
| 1                                | 35.19                  | 167.6       | 36                  | 171.4       |
| 2                                | 70.39                  | 335.2       | 71                  | 338.1       |
| 3                                | 105.58                 | 502.8       | 106                 | 504.8       |
| 4                                | 140.78                 | 670.4       | 141                 | 671.4       |

Thus, 36 customers are needed at stage 1, and 35 new customers are needed at each of the remaining stages. Suppose that 36 customers are available at stage 1. [Output 84.4.6](#) lists the 10 observations in the data set `count_1`.

**Output 84.4.6** Clinical Trial Data

| First 10 Obs in the Trial Data |      |  |
|--------------------------------|------|--|
| Obs                            | Resp |  |
| 1                              | 1    |  |
| 2                              | 1    |  |
| 3                              | 0    |  |
| 4                              | 0    |  |
| 5                              | 1    |  |
| 6                              | 1    |  |
| 7                              | 0    |  |
| 8                              | 1    |  |
| 9                              | 1    |  |
| 10                             | 1    |  |

The `Resp` variable is an indicator variable with a value of 1 for a customer with a positive response and a value of 0 for a customer without a positive response.

The following statements use the `MEANS` procedure to compute the mean response at stage 1:

```
proc means data=Prop_1;
 var Resp;
 ods output Summary=Data_Prop1;
run;
```

The following statements create and display (in [Output 84.4.7](#)) the data set for the centered mean positive response,  $\hat{p} - p_0$ :

```
data Data_Prop1;
 set Data_Prop1;
 Scale='MLE';
 Stage= 1;
 NObs= Resp_N;
 PDiff= Resp_Mean - 0.6;
 keep _Scale_ _Stage_ NObs PDiff;
run;
proc print data=Data_Prop1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.4.7** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |         |         |      |           |
|--------------------------------|---------|---------|------|-----------|
| Obs                            | _Scale_ | _Stage_ | NObs | PDiff     |
| 1                              | MLE     | 1       | 36   | -0.016667 |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Prop
 Data(Testvar=PDiff)=Data_Prop1
 infoadj=prop
 boundarykey=both
 boundaryscale=mle
 ;
 ods output Test=Test_Prop1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The DATA=DATA\_PROP1 option specifies the input data set DATA\_PROP1 that contains the test statistic and its associated sample size at stage 1, and the TESTVAR=PDIFF option identifies the test variable PDIFF in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The BOUNDARYKEY=BOTH option maintains both the  $\alpha$  and  $\beta$  levels. The BOUNDARYSCALE=MLE option displays the output boundaries in terms of the MLE scale.

The ODS OUTPUT statement with the TEST=TEST\_PROP1 option creates an output data set named TEST\_PROP1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.4.8](#) displays design specifications. With the specified BOUNDARYKEY=BOTH option, the information levels and boundary values at future stages are modified to maintain both the  $\alpha$  and  $\beta$  levels.

**Output 84.4.8** Design Information

| The SEQTEST Procedure                     |                 |
|-------------------------------------------|-----------------|
| Design Information                        |                 |

|                              | Proportion                  | Actual   | N        | --Reference--<br>Upper | -----Upper-----<br>Alpha |
| 1                            | 0.2556                      | 171.4286 | 35.98376 | 0.10000                | 0.19638                  |
| 2                            | 0.5037                      | 337.8459 | 70.91565 | 0.10000                | 0.11843                  |
| 3                            | 0.7519                      | 504.2633 | 105.8475 | 0.10000                | 0.08770                  |
| 4                            | 1.0000                      | 670.6807 | 140.7794 | 0.10000                | 0.07080                  |

| Test Information (MLE Scale) |                |          |
|------------------------------|----------------|----------|
| Null Reference = 0           |                |          |
| _Stage_                      | -----Test----- |          |
|                              | Estimate       | PDiff    |
| 1                            | -0.01667       | Continue |
| 2                            | .              |          |
| 3                            | .              |          |
| 4                            | .              |          |

The information level at stage 1 is computed as  $I_1^* = I_1 \times (n_1^*/n_1)$ , where  $I_1$  and  $n_1$  are the information level and sample size at stage 1 in the BOUNDARY= data set, and  $n_1^* = 36$  is the available sample size at stage 1.

With the INFOADJ=PROP option (which is the default), the information levels at interim stages 2 and 3 are derived proportionally from the information levels in the BOUNDARY= data set. At stage 1, the statistic  $\hat{\theta} = \hat{p} - p_0 = 0.58333 - 0.6 = -0.01667$  is less than the upper  $\alpha$  boundary value 0.19638, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.4.10](#). As expected, the test statistic is in the continuation region.

**Output 84.4.10** Sequential Test Plot

The following statements use the MEANS procedure to compute the mean response at stage 2:

```
proc means data=Prop_2;
 var Resp;
 ods output Summary=Data_Prop2;
run;
```

The following statements create and display (in [Output 84.4.11](#)) the data set for the centered mean positive response ( $\hat{p} - p_0$ ) at stage 2:

```
data Data_Prop2;
 set Data_Prop2;
 Scale='MLE';
 Stage= 2;
 NObs= Resp_N;
 PDiff= Resp_Mean - 0.6;
 keep _Scale_ _Stage_ NObs PDiff;
run;

proc print data=Data_Prop2;
 title 'Statistics Computed at Stage 2';
run;
```

**Output 84.4.11** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |         |         |      |           |
|--------------------------------|---------|---------|------|-----------|
| Obs                            | _Scale_ | _Stage_ | NObs | PDiff     |
| 1                              | MLE     | 2       | 71   | -0.064789 |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Prop1
 Data(Testvar=PDiff)=Data_Prop2
 inoadj=prop
 boundarykey=both
 boundaryscale=mle
 condpower(cref=1)
 predpower
 plots=condpower
 ;
 ods output test=Test_Prop2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The DATA= option specifies the input data set that contains the test statistic and its associated sample size at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_PROP2 option creates an output data set named TEST\_PROP2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The CONDPower(CREF=1) option requests the conditional power with the observed statistic under the alternative hypothesis, in addition to the conditional power under the hypothetical reference  $\theta = \hat{\theta}$ , the MLE estimate. The PREDPOWER option requests the noninformative predictive power with the observed statistic.

The “Test Information” table in [Output 84.4.12](#) displays the boundary values for the test statistic with the specified MLE scale. The test statistic  $\hat{\theta} = -0.06479$  is less than the corresponding upper  $\alpha$  boundary 0.11831, so the sequential test does not stop at stage 2 to reject the null hypothesis.

**Output 84.4.12** Sequential Tests

| The SEQTEST Procedure        |                             |          |          |                        |                   |         |
|------------------------------|-----------------------------|----------|----------|------------------------|-------------------|---------|

| 3                            | 0.7522                      | 504.4785 | 105.8882 | 0.10000                |                   | 0.08767 |
| 4                            | 1.0000                      | 670.7092 | 140.7794 | 0.10000                |                   | 0.07081 |

| Test Information (MLE Scale) |                |          |
|------------------------------|----------------|----------|
| Null Reference = 0           |                |          |
| _Stage_                      | -----Test----- |          |
|                              | Estimate       | Action   |
| 1                            | -0.01667       | Continue |
| 2                            | -0.06479       | Continue |
| 3                            | .              |          |
| 4                            | .              |          |

With ODS Graphics enabled, the “Test Plot” displays boundary values of the design and the test statistic, as shown in [Output 84.4.13](#). It also shows that the test statistic is in the “Continuation Region” below the upper  $\alpha$  boundary value at stage 2.

**Output 84.4.13** Sequential Test Plot

The “Conditional Power Information” table in [Output 84.4.14](#) displays conditional powers given the observed statistic under hypothetical references  $\theta = \hat{\theta}$ , the maximum likelihood estimate, and  $\theta = \theta_1$ . The constant  $c$  under CRef for the MLE is derived from  $\hat{\theta} = c\theta_1$ ; that is,  $c = \hat{\theta}/\theta_1 = -0.06479/0.1 = -0.6479$ .

**Output 84.4.14** Conditional Power

| Conditional Power Information      |          |                     |         |                   |
|------------------------------------|----------|---------------------|---------|-------------------|
| Reference = CRef * (Alt Reference) |          |                     |         |                   |
| Stopping Stage                     | MLE      | -----Reference----- |         | Conditional Power |
|                                    |          | Ref                 | CRef    |                   |
| 2                                  | -0.06479 | MLE                 | -0.6479 | 0.00000           |
| 2                                  | -0.06479 | Alternative         | 1.0000  | 0.02369           |

The conditional power is the probability of rejecting the null hypothesis under these hypothetical references given the observed statistic  $\hat{\theta} = -0.06479$ . The table in [Output 84.4.14](#) shows a weak conditional power of 0.02369 under the alternative hypothesis.

With the default TYPE=ALLSTAGES suboption in the CONDPOWER option, the conditional power at the interim stage 2 is the probability that the test statistic would exceed the rejection critical value at all future stages given the observed statistic  $\hat{\theta} = -0.06479$ .

The “Conditional Power Plot” displays conditional powers given the observed statistic under various hypothetical references, as shown in [Output 84.4.15](#). These references include  $\theta = \hat{\theta}$ , the maximum likelihood estimate, and  $\theta = c_i\theta_1$ , where  $\theta_1$  is the alternative reference and  $c_i = 0, 0.01, \dots, 1.50$  are constants that are specified in the CREF= option. [Output 84.4.16](#) shows that the conditional power increases as  $c_i$  increases.

**Output 84.4.15** Conditional Power Plot

The predictive power is the probability to reject the null hypothesis under the posterior distribution with a noninformative prior given the observed statistic  $\hat{\theta} = -0.06479$ . The “Predictive Power Information” table in [Output 84.4.16](#) indicates that the predictive power at  $\hat{\theta} = -0.06479$  is 0.0002.

**Output 84.4.16** Predictive Power

| Predictive Power Information |          |                  |
|------------------------------|----------|------------------|
| Stopping Stage               | MLE      | Predictive Power |
| 2                            | -0.06479 | 0.00020          |

With a predictive power 0.0002 and a conditional power of 0.02369 under  $H_1$ , the supermarket decides to stop the trial and accept the null hypothesis. That is, the positive response for the new store-brand coffee is not better than that for the current store-brand coffee.

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2. The NSTAGES=3 option sets the next stage as the final stage (stage 3), and the BOUNDARYKEY=BOTH option derives the information level at stage 3 that maintain both Type I and Type II error probability levels. The CONDPOWER(CREF=1) option requests the conditional power with the observed statistic under the alternative hypothesis, in addition to the conditional power under the hypothetical reference  $\theta = \hat{\theta}$ , the MLE estimate.

```
proc seqtest Boundary=Test_Prop1
 Data (Testvar=PDiff)=Data_Prop2
 nstages=3
 boundarykey=both
 boundaryscale=mle
 condpower (cref=1)
;
run;
```

The “Test Information” table in [Output 84.4.17](#) displays the boundary values for the test statistic with the specified MLE scale, assuming that the next stage is the final stage.

**Output 84.4.17** Sequential Tests

| The SEQTEST Procedure        |                             |          |          |                        |                          |

| 2                            | -0.06479       | Continue |
| 3                            | .              |          |

The “Conditional Power Information” table in [Output 84.4.18](#) displays conditional powers given the observed statistic, assuming that the next stage is the final stage.

**Output 84.4.18** Conditional Power

| Conditional Power Information      |          |                     |         |                      |
|------------------------------------|----------|---------------------|---------|----------------------|
| Reference = CRef * (Alt Reference) |          |                     |         |                      |
| Stopping<br>Stage                  | MLE      | -----Reference----- |         | Conditional<br>Power |
|                                    |          | Ref                 | CRef    |                      |
| 2                                  | -0.06479 | MLE                 | -0.6479 | 0.00000              |
| 2                                  | -0.06479 | Alternative         | 1.0000  | 0.02278              |

The conditional power is the probability of rejecting the null hypothesis under these hypothetical references given the observed statistic  $\hat{\theta} = -0.06479$ . The table in [Output 84.4.18](#) also shows a weak conditional power of 0.02278 under the alternative hypothesis.

## Example 84.5: Comparing Two Proportions with a Log Odds Ratio Test

This example compares two binomial proportions by using a log odds ratio statistic in a five-stage group sequential test. A clinic is studying the effect of vitamin C supplements in treating flu symptoms. The study consists of patients in the clinic who exhibit the first sign of flu symptoms within the last 24 hours. These patients are randomly assigned to either the control group (which receives placebo pills) or the treatment group (which receives large doses of vitamin C supplements). At the end of a five-day period, the flu symptoms of each patient are recorded.

Suppose that you know from past experience that flu symptoms disappear in five days for 60% of patients who experience flu symptoms. The clinic would like to detect a 70% symptom disappearance with a high probability. A test that compares the proportions directly specifies the null hypothesis  $H_0 : \theta = p_t - p_c = 0$  with a one-sided alternative  $H_1 : \theta > 0$  and a power of 0.90 at  $H_1 : \theta = 0.10$ , where  $p_t$  and  $p_c$  are the proportions of symptom disappearance in the treatment group and control group, respectively. An alternative trial tests an equivalent hypothesis by using the log odds ratio statistics:

$$\theta = \log \left( \frac{\left( \frac{p_t}{1-p_t} \right)}{\left( \frac{p_c}{1-p_c} \right)} \right)$$

Then the null hypothesis is  $H_0 : \theta = \theta_0 = 0$  and the alternative hypothesis is

$$H_1 : \theta = \theta_1 = \log \left( \frac{\left( \frac{0.70}{0.30} \right)}{\left( \frac{0.6}{0.4} \right)} \right) = 0.441833$$

The following statements invoke the SEQDESIGN procedure and request a five-stage group sequential design by using an error spending function method for normally distributed statistics. The design uses a two-sided alternative hypothesis with early stopping to reject the null hypothesis  $H_0$ .

```
ods graphics on;
proc seqdesign altref=0.441833
 boundaryscale=mle
 ;
 OneSidedErrorSpending: design method=errfuncpow
 nstages=5
 alt=upper
 stop=accept
 alpha=0.025;
 sample size model=twosamplefreq(nullprop=0.6 test=logor);
 ods output Boundary=Bnd_CSUP;
run;
ods graphics off;
```

The ODS OUTPUT statement with the BOUNDARY=BND\_CSUP option creates an output data set named BND\_CSUP which contains the resulting boundary information for the subsequent sequential tests.

The “Design Information” table in [Output 84.5.1](#) displays design specifications and derived statistics. With the specified alternative reference, the maximum information 56.30934 is derived.

**Output 84.5.1** Design Information

| The SEQDESIGN Procedure                   |                |
|-------------------------------------------|----------------|
| Design: OneSidedErrorSpending             |                |

| 9                              | Control | 0    |
| 10                             | C_Sup   | 1    |

The `TrtGrp` variable is a grouping variable with the value `Control` for a patient in the placebo control group and the value `C_Sup` for a patient in the treatment group who receives vitamin C supplements. The `Resp` variable is an indicator variable with the value 1 for a patient without flu symptoms after five days and the value 0 for a patient with flu symptoms after five days.

The following statements use the LOGISTIC procedure to compute the log odds ratio statistic and its associated standard error at stage 1:

```
proc logistic data=CSup_1 descending;
 class TrtGrp / param=ref;
 model Resp= TrtGrp;
 ods output ParameterEstimates=Parms_CSUP1;
run;
```

The DESCENDING option is used to reverse the order for the response levels, so the LOGISTIC procedure is modeling the probability that  $\text{Resp} = 1$ .

The following statements create and display (in [Output 84.5.7](#)) the data set for the log odds ratio statistic and its associated standard error:

```
data Parms_CSUP1;
 set Parms_CSUP1;
 if Variable='TrtGrp' and ClassVal0='C_Sup';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_CSUP1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.5.7** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | TrtGrp   | 0.3247   | 0.2856 | MLE     | 1       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_CSUP
 Parms (Testvar=TrtGrp) =Parms_CSUP1
 infoadj=prop
 errspendadj=errfuncpow
 boundarykey=both
 boundaryscale=mle
 ;
 ods output test=Test_CSUP1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARM=PARMS\_CSUP1 option specifies the input data set PARMS\_CSUP1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRTGRP option identifies the test variable TRTGRP in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ERRSPENDADJ=ERRFUNCPOW option adjusts the boundaries with the updated error spending values generated from the power error spending function. The BOUNDARYKEY=BOTH option maintains both the  $\alpha$  and  $\beta$  levels. The BOUNDARYSCALE=MLE option displays the output boundaries in terms of the MLE scale.

The ODS OUTPUT statement with the TEST=TEST\_CSUP1 option creates an output data set named TEST\_CSUP1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.5.8](#) displays design specifications. With the specified BOUNDARYKEY=BOTH option, the information levels and boundary values at future stages are modified to maintain both the  $\alpha$  and  $\beta$  levels.

**Output 84.5.8** Design Information

| The SEQTEST Procedure                     |                  |
|-------------------------------------------|------------------|
| Design Information                        |                  |
| BOUNDARY Data Set                         | WORK.BND_CSUP    |
| Data Set                                  | WORK.PARMS_CSUP1 |
| Statistic Distribution                    | Normal           |
| Boundary Scale                            | MLE              |
| Alternative Hypothesis                    | Upper            |
| Early Stop                                | Accept Null      |
| Number of Stages                          | 5                |
| Alpha                                     | 0.025            |
| Beta                                      | 0.1              |
| Power                                     | 0.9              |
| Max Information (Percent of Fixed Sample) | 104.6673         |
| Max Information                           | 56.3361718       |
| Null Ref ASN (Percent of Fixed Sample)    | 57.02894         |
| Alt Ref ASN (Percent of Fixed Sample)     | 102.1369         |

The “Test Information” table in [Output 84.5.9](#) displays the boundary values for the test statistic with the specified MLE scale. With the INFOADJ=PROP option (which is the default), the information levels at future interim stages are derived proportionally from the observed information at stage 1 and the information levels in the BOUNDARY= data set.

Since the information level at stage 1 is derived from the PARMS= data set and other information levels are not specified, equal increments are used at remaining stages. At stage 1, the MLE statistic 0.32474 is greater than the corresponding upper  $\beta$  boundary value  $-0.29906$ , so the sequential test continues to the next stage.

**Output 84.5.9** Sequential Tests

| Test Information (MLE Scale) |                         |          |                        |

|                              | -----Upper-----<br>Beta | -----TrtGrp-----<br>Estimate | Action   |
| 1                            | -0.29906                | 0.32474                      | Continue |
| 2                            | -0.01067                | .                            |          |
| 3                            | 0.11942                 | .                            |          |
| 4                            | 0.19829                 | .                            |          |
| 5                            | 0.25325                 | .                            |          |

With ODS Graphics enabled, a boundary plot with the boundary values and test statistics is displayed, as shown in [Output 84.5.10](#). As expected, the test statistic is in the continuation region.

Output 84.5.10 Sequential Test Plot

The following statements use the LOGISTIC procedure to compute the log odds ratio statistic and its associated standard error at stage 2:

```
proc logistic data=CSup_2 descending;
 class TrtGrp / param=ref;
 model Resp= TrtGrp;
 ods output ParameterEstimates=Parms_CSup2;
run;
```

The following statements create and display (in Output 84.5.11) the data set for the mean positive response and its associated standard error at stage 2:

```
data Parms_CSup2;
 set Parms_CSup2;
 if Variable='TrtGrp' and ClassVal0='C_Sup';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;
proc print data=Parms_CSup2;
 title 'Statistics Computed at Stage 2';
run;
```

**Output 84.5.11** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | TrtGrp   | 0.2356   | 0.2073 | MLE     | 2       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_CSup1
 Parms (testvar=TrtGrp)=Parms_CSup2
 infoadj=prop
 errspendadj=errfuncpow
 boundarykey=both
 boundaryscale=mle
 ;
ods output Test=Test_CSup2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=CSUP\_LDL2 option creates an output data set named CSUP\_LDL2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Test Information” table in [Output 84.5.12](#) displays the boundary values for the test statistic with the specified MLE scale. The test statistic 0.2356 is greater than the corresponding upper  $\beta$  boundary value  $-0.01068$ , so the sequential test continues to the next stage.

## Output 84.5.12 Sequential Tests

| The SEQTEST Procedure        |                         |          |                        |  |

|                              | Beta              | Estimate | Action           |  |
| 1                            | -0.29906          | 0.32474  | Continue         |  |
| 2                            | -0.01068          | 0.23560  | Continue         |  |
| 3                            | 0.11942           | .        | .                |  |
| 4                            | 0.19829           | .        | .                |  |
| 5                            | 0.25325           | .        | .                |  |

Similar results are found at stages 3 and stage 4, so the trial continues to the final stage. The following statements use the LOGISTIC procedure to compute the log odds ratio statistic and its associated standard error at stage 5:

```
proc logistic data=CSup_5 descending;
 class TrtGrp / param=ref;
 model Resp= TrtGrp;
 ods output ParameterEstimates=Parms_CSup5;
run;
```

The following statements create and display (in Output 84.5.13) the data set for the log odds ratio statistic and its associated standard error at stage 5:

```
data Parms_CSup5;
 set Parms_CSup5;
 if Variable='TrtGrp' and ClassVal0='C_Sup';
 Scale='MLE';
 Stage= 5;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_CSup5;
 title 'Statistics Computed at Stage 5';
run;
```

**Output 84.5.13** Statistics Computed at Stage 5

| Statistics Computed at Stage 5 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | TrtGrp   | 0.2043   | 0.1334 | MLE     | 5       |

The following statements invoke the SEQTEST procedure to test for the hypothesis at stage 5:

```
ods graphics on;
proc seqtest Boundary=Test_CSup4
 Parms (testvar=TrtGrp)=Parms_CSup5
 errspendadj=errfuncpow
 boundaryscale=mle
 cialpha=.025
 rci
 plots=rci
 ;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 5, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 5, and the TESTVAR= option identifies the test variable in the data set. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary value at stage 5 is derived to maintain the  $\alpha$  level.

The “Test Information” table in [Output 84.5.14](#) displays the boundary values for the test statistic with the specified MLE scale. The test statistic 0.2043 is less than the corresponding upper  $\beta$  boundary 0.25375, so the sequential test stops to accept the null hypothesis. That is, there is no reduction in duration of symptoms for the group receiving vitamin C supplements.

**Output 84.5.14** Sequential Tests

| The SEQTEST Procedure        |                        |          |                        |

| 2                            | -0.01068                | 0.23560        | Continue                   |
| 3                            | 0.12134                 | 0.14482        | Continue                   |
| 4                            | 0.19899                 | 0.20855        | Continue                   |
| 5                            | 0.25375                 | 0.20430        | Accept Null                |

The “Test Plot” displays boundary values of the design and the test statistics, as shown in [Output 84.5.15](#). It also shows that the test statistic is in the “Acceptance Region” at the final stage.

**Output 84.5.15** Sequential Test Plot

After a trial is stopped, the “Parameter Estimates” table in [Output 84.5.16](#) displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the  $p$ -value under the null hypothesis  $H_0 : \theta = 0$ . As expected, the  $p$ -value 0.0456 is not significant at  $\alpha = 0.025$  level and the lower 97.5% confidence limit is less than the value  $\theta_0 = 0$ . The  $p$ -value, unbiased median estimate, and confidence limits depend on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic.

**Output 84.5.16** Parameter Estimates

| Parameter Estimates<br>Stagewise Ordering |                |          |                                  |                 |                |
|-------------------------------------------|----------------|----------|----------------------------------|-----------------|----------------|
| Parameter                                 | Stopping Stage | MLE      | p-Value for $H_0: \text{Parm}=0$ | Median Estimate | Lower 97.5% CL |
| TrtGrp                                    | 5              | 0.204303 | 0.0456                           | 0.234494        | -0.03712       |

Since the test is accepted at stage 5, the  $p$ -value computed by using the default stagewise ordering can be expressed as

$$\alpha_u = P_{\theta=0}(z_5 < Z_5 \mid b_k < Z_k, k < 5)$$

where  $z_5 = 1.53105$  is the test statistic at stage 5,  $Z_k$  is a standardized normal variate at stage  $k$ , and  $b_k$  is the upper  $\beta$  boundary value in the standardized  $Z$  scale at stage  $k$ ,  $k = 1, 2, \dots, 5$ .

With the RCI option, the “Repeated Confidence Intervals” table in [Output 84.5.17](#) displays repeated confidence intervals for the parameter. For a one-sided test with an upper alternative hypothesis, since the upper acceptance repeated confidence limit 0.3924 at the final stage is less than the alternative reference 0.441833, the null hypothesis is accepted.

**Output 84.5.17** Repeated Confidence Intervals

| Repeated Confidence Intervals |                      |                       |                                          |
|-------------------------------|----------------------|-----------------------|------------------------------------------|
| <u>_Stage_</u>                | Information<br>Level | Parameter<br>Estimate | -Acceptance Boundary-<br>Upper 89.94% CI |
| 1                             | 12.2601              | 0.32474               | 1.0656                                   |
| 2                             | 23.2792              | 0.23560               | 0.6881                                   |
| 3                             | 34.4879              | 0.14482               | 0.4653                                   |
| 4                             | 45.4468              | 0.20855               | 0.4514                                   |
| 5                             | 56.1607              | 0.20430               | 0.3924                                   |

With the PLOTS=RCI option, the “Repeated Confidence Intervals Plot” displays repeated confidence intervals for the parameter, as shown in [Output 84.5.18](#). It shows that the upper acceptance repeated confidence limit at the final stage is less than the alternative reference 0.441833. This implies that the study accepts the null hypothesis at the final stage.

**Output 84.5.18** Repeated Confidence Intervals Plot

### Example 84.6: Comparing Two Survival Distributions with a Log-Rank Test

This example requests a log-rank test that compares two survival distributions for the treatment effect (Jenkinson and Turnbull 2000, pp. 77–79; Whitehead 1997, pp. 36–39).

A clinic is studying the effect of a new cancer treatment. The study consists of mice exposed to a carcinogen and randomized to either the control group or the treatment group. The event of interest is the death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Following the derivations in the section “Test for Two Survival Distributions with a Log-Rank Test” in the chapter “The SEQDESIGN Procedure,” the hypothesis  $H_0 : \theta = -\log(\lambda) = 0$  with an alternative hypothesis  $H_1 : \theta = \theta_1 > 0$  can be used, where  $\lambda$  is the hazard ratio between the treatment group and control group.

Suppose that from past experience, the median survival time for the control group is  $t_0 = 20$  weeks, and the study would like to detect a  $t_1 = 40$  weeks median survival time with a 80% power in the trial. Assuming exponential survival functions for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where  $j = 0, 1$ .

Thus, with  $h_0 = 0.03466$  and  $h_1 = 0.01733$ , the hazard ratio  $\lambda_1 = h_1/h_0 = 1/2$  and the alternative hypothesis is

$$\theta_1 = -\log(\lambda_1) = -\log\left(\frac{1}{2}\right) = 0.69315$$

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design for normally distributed data. The design uses a one-sided alternative hypothesis with early stopping to reject and to accept the null hypothesis  $H_0$ . Whitehead's triangular method is used to derive the boundaries.

```
ods graphics on;
proc seqdesign altref=0.69315
 boundaryscale=score
 ;
 OneSidedWhitehead: design method=whitehead
 nstages=4
 boundarykey=alpha
 alt=upper stop=both
 beta=0.20;
 samplesize model=twosamplesurvival
 (nullhazard=0.03466
 accrate=10);
run;
ods graphics off;
```

A Whitehead method creates boundaries that approximately satisfy the Type I and Type II error probability level specification. The BOUNDARYKEY=ALPHA option is used to adjust the boundary value at the last stage and to meet the specified Type I probability level.

The specified ACCRATE=10 option indicates that 10 mice will be accrued each week and the resulting minimum and maximum accrual times are displayed. With the BOUNDARYSCALE=SCORE option, the procedure displays the output boundaries with the score statistics.

The “Design Information” table in [Output 84.6.1](#) displays design specifications and derived statistics.

**Output 84.6.1** Design Information

| The SEQDESIGN Procedure                   |                    |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.6.3](#).

**Output 84.6.3** Boundary Plot

With the MODEL=TWOSAMPLESURVIVAL option in the SAMPLESIZE statement, the “Sample Size Summary” table in Output 84.6.4 displays the parameters for the sample size computation.

**Output 84.6.4** Required Sample Size Summary

| Sample Size Summary   |                     |
|-----------------------|---------------------|
| Test                  | Two-Sample Survival |
| Null Hazard Rate      | 0.03466             |
| Hazard Rate (Group A) | 0.01733             |
| Hazard Rate (Group B) | 0.03466             |
| Hazard Ratio          | 0.499999            |
| log(Hazard Ratio)     | -0.69315            |
| Reference Hazards     | Alt Ref             |
| Accrual               | Uniform             |
| Accrual Rate          | 10                  |
| Min Accrual Time      | 6.682498            |
| Min Sample Size       | 66.82498            |
| Max Accrual Time      | 25.401              |
| Max Sample Size       | 254.01              |
| Max Number of Events  | 66.82498            |

With a minimum accrual time of 6.6825 weeks and a maximum accrual time of 25.401 weeks, an accrual time of 20 weeks is used in the study.

The “Numbers of Events” table in [Output 84.6.5](#) displays the required number of events for the group sequential clinical trial.

**Output 84.6.5** Required Numbers of Events

| Numbers of Events (D)<br>Two-Sample Log-Rank Test |       |             |
|---------------------------------------------------|-------|-------------|
| _Stage_                                           | D     | Information |
| 1                                                 | 16.71 | 4.1766      |
| 2                                                 | 33.41 | 8.3531      |
| 3                                                 | 50.12 | 12.5297     |
| 4                                                 | 66.82 | 16.7062     |

The following statements invoke the SEQDESIGN procedure and provide more detailed sample size information:

```
proc seqdesign altref=0.69315
 boundaryscale=score
 ;
 OneSidedWhitehead: design method=whitehead
 nstages=4
 boundarykey=alpha
 alt=upper
 stop=both
 beta=0.20;
 samplesize model=twosamplesurvival
 (nullhazard=0.03466
 accrate=10 acctime=20);
 ods output Boundary=Bnd_Surv;
run;
```

The ODS OUTPUT statement with the BOUNDARY=BND\_SURV option creates an output data set named BND\_SURV which contains the resulting boundary information for the subsequent sequential tests.

With an accrual time of 20 weeks, the “Sample Size Summary” table in [Output 84.6.6](#) displays the follow-up time for the trial.

**Output 84.6.6** Required Sample Size Summary

| 1                                                                      | 60.00    | 4.1854      |
| 2                                                                      | 90.00    | 8.9322      |
| 3                                                                      | 100.00   | 12.7667     |
| 4                                                                      | 100.00   | 17.1377     |

Thus the study will perform three interim analyses after 12, 18, and 22 weeks and a final analysis after 27 weeks if the study does not stop at any of the interim analyses.

Note that the SEQDESIGN procedure does not compute numbers of events or sample sizes for all statistical models. If the number of events or sample size for a fixed-sample design is available, then the MODEL=INPUTNEVENTS or MODEL=INPUTNOBS option can be used to input fixed-sample information. For example, with a required fixed-sample number of events 51.4073, the following SAMPLESIZE statement can be used to produce the same sample size results:

```

samplesize model=inputnevents
 (d=51.47 sample=two
 hazard=0.03466 0.01733
 accrate=10 acctime=20);

```

Suppose that 120 mice are available after week 12 for the first interim analysis. [Output 84.6.8](#) lists the 10 observations in the data set weeks\_1.

**Output 84.6.8** Clinical Trial Data

| First 10 Obs in the Trial Data |           |       |       |
|--------------------------------|-----------|-------|-------|
| Obs                            | Trt<br>Gp | Event | Weeks |
| 1                              | 0         | 0     | 11    |
| 2                              | 1         | 0     | 11    |
| 3                              | 0         | 0     | 11    |
| 4                              | 1         | 0     | 11    |
| 5                              | 0         | 1     | 6     |
| 6                              | 1         | 0     | 11    |
| 7                              | 0         | 0     | 11    |
| 8                              | 1         | 0     | 11    |
| 9                              | 0         | 1     | 9     |
| 10                             | 1         | 0     | 11    |

The TrtGp variable is a grouping variable with the value 0 for a mouse in the placebo control group and the value 1 for a mouse in the treatment group. The Weeks variable is the survival time variable measured in weeks and the Event variable is the censoring variable with the value 0 indicating censoring. That is, the values of Weeks are considered censored if the corresponding values of Event are 0; otherwise, they are considered as event times.

The following statements use the LIFETEST procedure to estimate the log-rank statistic at stage 1:

```
proc lifetest data=Surv_1;
 time Weeks*Event(0);
 test TrtGp;
 ods output logunichisq=Parms_Surv1;
run;
```

The following statements create and display (in [Output 84.6.9](#)) the data set for the log-rank statistic and its associated standard error:

```
data Parms_Surv1;
 set Parms_Surv1(rename=(Statistic=Estimate));
 if Variable='TrtGp';
 Scale='Score';
 Stage= 1;
 keep Variable _Scale_ _Stage_ StdErr Estimate;
run;

proc print data=Parms_Surv1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.6.9** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | TrtGp    | 3.2004   | 1.9979 | Score   | 1       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Surv
 Parms (Testvar=TrtGp)=Parms_Surv1
 infoadj=none
 boundaryscale=score
 ;
 ods output Test=Test_Surv1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_SURV1 option specifies the input data set PARMS\_SURV1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRTGp option identifies the test variable TRTGp in the data set. The INFOADJ=NONE option maintains the information levels for future interim stages (2 and 3) at the values provided in the BOUNDARY= data set.

The ODS OUTPUT statement with the TEST=TEST\_SURV1 option creates an output data set named TEST\_SURV1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.6.10](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the maximum information and the Type I error level  $\alpha$  are preserved. Since the computed information level at stage 1 is not the same as the value provided in the BOUNDARY= data set, the power has been modified.

**Output 84.6.10** Design Information

| The SEQTEST Procedure                     |                    |
|-------------------------------------------|--------------------|
| Design Information                        |                    |

| Max Information (Percent of Fixed Sample) | 130.0335           |
| Max Information                           | 16.7062448         |
| Null Ref ASN (Percent of Fixed Sample)    | 62.80855           |
| Alt Ref ASN (Percent of Fixed Sample)     | 74.19155           |

The “Test Information” table in [Output 84.6.11](#) displays the boundary values for the test statistic with the SCORE statistic scale. Since only the information level at stage 1 is specified in the DATA= data set, the information levels at subsequent stages are derived proportionally from the corresponding information levels provided in the BOUNDARY= data set. At stage 1, the score statistic 3.2004 is between the upper  $\beta$  boundary value  $-1.0386$  and the upper  $\alpha$  boundary value  $4.7142$ , so the trial continues to the next stage.

**Output 84.6.11** Sequential Tests

| Test Information (Score Scale) |                        |          |                        |                          |         |

| 1                              | 3.20040  | Continue                  |
| 2                              | .        |                           |
| 3                              | .        |                           |
| 4                              | .        |                           |

Note that the observed information level 3.9917 corresponds to a proportion of 0.2389 in information level. If the observed information level is much smaller than the target proportion of 0.25, then you need to increase the accrual rate, accrual time, or follow-up time to achieve the target maximum information level for the trial. Scharfstein and Tsiatis (1998) use the simulation and bootstrap methods to modify the trial at interim stages to achieve the target maximum information level. These modifications should be specified in the study protocol or study plan before the study starts.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in [Output 84.6.12](#). As expected, the test statistic is in the continuation region between the upper  $\beta$  and  $\alpha$  boundary values.

**Output 84.6.12** Sequential Test Plot

Note that the input `DATA=` option can also be used for the test statistics. For example, the following statements create and display (in [Output 84.6.13](#)) the data set for the log-rank statistic and its associated standard error after the `LIFETEST` procedure. Since the log-rank statistic is a score statistic, the corresponding information level is the variance of the statistic.

```
proc lifetest data=Surv_1;
 time Weeks*Event(0);
 test TrtGp;
 ods output logunichisq=Parms_Surv1a;
run;
```

```

data Parms_Surv1a;
 set Parms_Surv1a(rename=(Statistic=TrtGp));
 keep _Scale_ _Stage_ _Info_ TrtGp;
 Scale='Score';
 Stage= 1;
 Info= StdErr * StdErr;
 if Variable='TrtGp';
run;

proc print data=Parms_Surv1a;
 title 'Statistics Computed at Stage 1';
run;

```

**Output 84.6.13** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |        |         |         |         |
|--------------------------------|--------|---------|---------|---------|
| Obs                            | TrtGp  | _Scale_ | _Stage_ | _Info_  |
| 1                              | 3.2004 | Score   | 1       | 3.99170 |

The following statements can be used to invoke the SEQTEST procedure to test for early stopping at stage 1:

```

ods graphics on;
proc seqtest Boundary=Bnd_Surv
 Data(Testvar=TrtGp)=Parms_Surv1a
 inoadj=none
 boundaryscale=score
 ;
 ods output Test=Test_Surv1;
run;
ods graphics off;

```

The following statements use the LIFETEST procedure to compute the log-rank statistic and its associated standard error at stage 2:

```

proc lifetest data=Surv_2;
 time Weeks*Event(0);
 test TrtGp;
 ods output logunichisq=Parms_Surv2;
run;

```

The following statements create and display (in [Output 84.6.14](#)) the data set for the log-rank statistic and its associated standard error for each of the first two stages:

```

data Parms_Surv2;
 set Parms_Surv2 (rename=(Statistic=Estimate));
 if Variable='TrtGp';
 Scale='Score';
 Stage= 2;
 keep Variable _Scale_ _Stage_ StdErr Estimate;
run;

```

```
proc print data=Parms_Surv2;
 title 'Statistics Computed at Stage 2';
run;
```

#### Output 84.6.14 Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | TrtGp    | 7.3136   | 2.9489 | Score   | 2       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Surv1
 Parms (Testvar=TrtGp) =Parms_Surv2
 infoadj=none
 boundaryscale=score
 cotype=lower
 ;
ods output Test=Test_Surv2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set. The INFOADJ=NONE option maintains the information level for stage 3 at the value provided in the BOUNDARY= data set.

The ODS OUTPUT statement with the TEST=TEST\_SURV2 option creates an output data set named TEST\_SURV2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage if the trial does not stop at the current stage.

The “Test Information” table in [Output 84.6.15](#) displays the boundary values for the test statistic. The test statistic 7.31365 is larger than the corresponding upper  $\alpha$  boundary 5.79886, so the study stops and rejects the null hypothesis. That is, there is evidence of reduction in hazard rate for the new treatment.

## Output 84.6.15 Sequential Tests

| The SEQTEST Procedure          |                        |          |                        |                          |         |

| Test Information (Score Scale) |                |             |
|--------------------------------|----------------|-------------|
| Null Reference = 0             |                |             |
| _Stage_                        | -----Test----- |             |
|                                | Estimate       | Action      |
| 1                              | 3.20040        | Continue    |
| 2                              | 7.31365        | Reject Null |
| 3                              | .              | .           |
| 4                              | .              | .           |

With ODS Graphics enabled, the “Test Plot” displays boundary values of the design and the test statistic at the first two stages, as shown in [Output 84.6.16](#). It also shows that the test statistic is in the “Rejection Region” above the upper  $\alpha$  boundary value at stage 2.

Output 84.6.16 Sequential Test Plot

After the stopping of a trial, the “Parameter Estimates” table in Output 84.6.17 displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and  $p$ -value under the null hypothesis  $H_0 : \theta = 0$ .

Output 84.6.17 Parameter Estimates

| Parameter Estimates<br>Stagewise Ordering |                |          |                                  |                 |              |
|-------------------------------------------|----------------|----------|----------------------------------|-----------------|--------------|
| Parameter                                 | Stopping Stage | MLE      | p-Value for $H_0: \text{Parm}=0$ | Median Estimate | Lower 95% CL |
| TrtGp                                     | 2              | 0.841024 | 0.0139                           | 0.810329        | 0.21615      |

As expected, the  $p$ -value 0.0139 is significant at the  $\alpha = 0.05$  level and the lower 95% confidence limit is larger than  $\theta_0 = 0$ . The  $p$ -value, unbiased median estimate, and lower confidence limit depend on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic. With

the specified stagewise ordering, the  $p$ -value is  $p_1 + p_2$ , where  $p_1$  is the  $\alpha$  spending at stage 1,

$$p_1 = P_{\theta=0}(Z_1\sqrt{I_1} \geq 4.71422) = 0.00915$$

$$p_2 = P_{\theta=0}(Z_2\sqrt{I_2} \geq 7.31365 \mid -1.04069 < Z_1\sqrt{I_1} < 4.71422)$$

where  $Z_k$  is a standardized normal variate and  $I_k$  is the information level at stage  $k$  for  $k = 1, 2$ .

### Example 84.7: Testing an Effect in a Proportional Hazards Regression Model

This example compares two survival distributions for the treatment effect. The example uses a power family method to generate two-sided asymmetric boundaries and then uses a proportional hazards regression model to test the hypothesis with a covariate.

A clinic is conducting a clinical study for the effect of a new cancer treatment. The study consists of mice exposed to a carcinogen and randomized to either the control group or the treatment group. The event of interest is the death from cancer induced by the carcinogen, and the response is the time from randomization to death.

Consider the proportional hazards regression model

$$h(t; \text{TrtGp}, \text{Wgt}) = h_0(t) \exp(\beta_g \text{TrtGp} + \beta_w \text{Wgt})$$

where  $h_0(t)$  is an arbitrary and unspecified baseline hazard function,  $\text{TrtGp}$  is the grouping variable for the two groups,  $\text{Wgt}$  is the initial weight of the mice, and  $\beta_g$  and  $\beta_w$  are the regression parameters associated with the variables  $\text{TrtGp}$  and  $\text{Wgt}$ , respectively. The grouping variable has the value 0 for each mouse in the control group and the value 1 for each mouse in the treatment group.

The hypothesis  $H_0 : \beta_g = 0$  with an alternative hypothesis  $H_1 : \beta_g \neq 0$  is used for the study.

Suppose that from past experience, the median survival time for the control group is  $t_0 = 20$  weeks. The study would like to detect a  $t_1 = 40$  weeks median survival time with a 80% power in the trial. Assuming exponential survival functions for the two groups, the hazard rates can be computed from

$$S_j(t_j) = e^{-h_j t_j} = \frac{1}{2}$$

where  $j = 0, 1$ .

Thus, with the hazard rates  $h_0 = 0.03466$  and  $h_1 = 0.01733$ , the hazard ratio  $\exp(\beta_g) = h_1/h_0 = 1/2$  and the alternative hypothesis

$$\beta_{g1} = \log\left(\frac{1}{2}\right) = -0.69315$$

Following the derivations in the section “Test for a Parameter in the Proportional Hazards Regression Model” in the chapter “The SEQDESIGN Procedure,” the required number of events for testing a parameter in  $\beta$  is given by

$$D_X = I_X \frac{1}{(1 - r_x^2) \sigma_x^2}$$

where  $\sigma_x^2$  is the variance of TrtGp and  $r_x^2$  is the proportion of variance of TrtGp explained by the variable Wgt.

If the two groups have the same number of mice in the study, then the MLE of the variance is  $\hat{\sigma}_x^2 = 0.25$ . Further, if  $r_x^2 = 0.10$ , then you can specify the MODEL=PHREG( XVARIANCE=0.25 XRSQUARE=0.10) option in the SAMPLESIZE statement in the SEQDESIGN procedure to compute the required number of events and the individual number of events at each stage.

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design for normally distributed data. The design uses a two-sided alternative hypothesis with early stopping to reject the null hypothesis  $H_0$ . A power family method is used to derive the boundaries.

```
ods graphics on;
proc seqdesign altref=0.69315;
 TwoSidedPowerFamily: design method=pow
 nstages=4
 alpha=0.075 (lower=0.025)
 beta=0.20;
 samplesize model=phreg(xvariance=0.25 xrsquare=0.10
 hazard=0.02451 accrate=10);
run;
ods graphics off;
```

The ALPHA=0.075(LOWER=0.025) option specifies a lower  $\alpha$  level 0.025 for the lower rejection boundary and an upper  $\alpha$  level  $0.05 = 0.075 - 0.025$  for the upper rejection boundary. The geometric average hazard  $\sqrt{h_0 \times h_1} = \sqrt{0.03466 \times 0.01733} = 0.02451$  is used in the HAZARD= option in the SAMPLESIZE statement to compute the required sample size. The specified ACCRATE=10 option indicates that 10 mice will be accrued each week and the resulting minimum and maximum accrual times will be displayed.

The “Design Information” table in [Output 84.7.1](#) displays the design specifications and the derived statistics.

**Output 84.7.1** Design Information

| The SEQDESIGN Procedure                   |                |

| 1                                           | -2.98871                  | 2.59149    |  |
| 2                                           | -2.51320                  | 2.17917    |  |
| 3                                           | -2.27093                  | 1.96910    |  |
| 4                                           | -2.11334                  | 1.83246    |  |

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.7.3](#).

**Output 84.7.3** Boundary Plot

With the MODEL=PHREG option in the SAMPLESIZE statement, the “Sample Size Summary” table in Output 84.7.4 displays the parameters used in the sample size computation for the proportional hazards regression model.

**Output 84.7.4** Required Sample Size Summary

| Sample Size Summary  |                  |
|----------------------|------------------|
| Test                 | PH Reg Parameter |
| Parameter            | 0.69315          |
| X Variance           | 0.25             |
| R Square (X)         | 0.1              |
| Hazard Rate          | 0.02451          |
| Accrual              | Uniform          |
| Accrual Rate         | 10               |
| Min Accrual Time     | 7.73017          |
| Min Sample Size      | 77.3017          |
| Max Accrual Time     | 27.97872         |
| Max Sample Size      | 279.7872         |
| Max Number of Events | 77.3017          |

With a minimum accrual time of 7.73 weeks and maximum accrual time of 27.98 weeks, an accrual time of 20 weeks is used in the study. The “Numbers of Events” table in [Output 84.7.5](#) displays the required numbers of events for the group sequential clinical trial.

**Output 84.7.5** Required Sample Sizes

| Numbers of Events (D)              |       |             |
|------------------------------------|-------|-------------|
| Z Test for PH Regression Parameter |       |             |
| <u>Stage</u>                       | D     | Information |
| 1                                  | 19.33 | 4.3482      |
| 2                                  | 38.65 | 8.6964      |
| 3                                  | 57.98 | 13.0447     |
| 4                                  | 77.30 | 17.3929     |

The following statements invoke the SEQDESIGN procedure and provide more detailed sample size information with a 20-week accrual time:

```
proc seqdesign altref=0.69315;
 TwoSidedPowerFamily: design method=pow
 nstages=4
 alpha=0.075 (lower=0.025)
 beta=0.20;
 samplesize model=phreg(xvariance=0.25 xrsquare=0.10
 hazard=0.02451
 accrate=10 acctime=20);
 ods output Boundary=Bnd_Time;
run;
```

The ODS OUTPUT statement with the BOUNDARY=BND\_TIME option creates an output data set named BND\_TIME which contains the resulting boundary information for the subsequent sequential tests.

With an accrual time of 20 weeks, the “Sample Size Summary” table in [Output 84.7.6](#) displays the follow-up time for the trial.

**Output 84.7.6** Sample Size Summary

| The SEQDESIGN Procedure         |                  |
|---------------------------------|------------------|
| Design: TwoSidedPowerFamily     |                  |
| Sample Size Summary             |                  |

Thus, the study will perform three interim analyses after 14, 20, and 25 weeks and a final analysis after 31 weeks if the study does not stop at any of the interim analyses.

Suppose 140 mice are available for the first interim analysis after week 14. [Output 84.7.8](#) lists the first 10 observations in the data set `weeks_1`.

**Output 84.7.8** Clinical Trial Data

| First 10 Obs in the Trial Data |           |       |         |       |  |
|--------------------------------|-----------|-------|---------|-------|--|
| Obs                            | Trt<br>Gp | Event | Wgt     | Weeks |  |
| 1                              | 0         | 0     | 22.1659 | 12    |  |
| 2                              | 1         | 0     | 28.4458 | 12    |  |
| 3                              | 0         | 0     | 26.2857 | 12    |  |

| 5                              | 0         | 0     | 21.5114 | 12    |  |
| 6                              | 1         | 0     | 23.2240 | 12    |  |
| 7                              | 0         | 1     | 22.6845 | 6     |  |
| 8                              | 1         | 0     | 27.9292 | 12    |  |
| 9                              | 0         | 0     | 22.5514 | 12    |  |
| 10                             | 1         | 1     | 27.3793 | 11    |  |

The `TrtGp` variable is a grouping variable with the value 0 for a mouse in the placebo control group and the value 1 for a mouse in the treatment group.

The `Weeks` variable is the survival time variable measured in weeks and the `Event` variable is the censoring variable with the value 0 indicating censoring. That is, the values of `Weeks` are considered censored if the corresponding values of `Event` are 0; otherwise, they are considered as event times.

The following statements use the PHREG procedure to estimate the treatment effect after adjusting for the `Wgt` variable at stage 1:

```
proc phreg data=Time_1;
 model Weeks*Event(0)= TrtGp Wgt;
 ods output parameterestimates=Parms_Time1;
run;
```

The following statements create and display (in [Output 84.7.9](#)) the data set for the treatment effect MLE statistic and its associated standard error. Note that for a MLE statistic, the inverse of the variance of the statistic is the information.

```
data Parms_Time1;
 set Parms_Time1;
 if Parameter='TrtGp';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Time1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.7.9** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |           |          |         |         |         |
|--------------------------------|-----------|----------|---------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | TrtGp     | 0.00836  | 0.46588 | MLE     | 1       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Time
 Parms (Testvar=TrtGp)=Parms_Time1
 infoadj=prop
 order=lr
 ;
ods output Test=Test_Time1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_TIME1 option specifies the input data set PARMS\_TIME1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRTGP option identifies the test variable TRTGP in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ORDER=LR option uses the LR ordering to derive the  $p$ -value, the unbiased median estimate, and the confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST\_TIME1 option creates an output data set named TEST\_TIME1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.7.10](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I  $\alpha$  level. The maximum information and the power have been modified for the new information levels.

**Output 84.7.10** Design Information

```

The SEQTEST Procedure

4 .

```

With the INFOADJ=PROP option (which is the default), the information levels at interim stages 2 and 3 are derived proportionally from the information levels in the BOUNDARY= data set. At stage 1, the standardized Z statistic 0.01795 is between the lower and upper  $\alpha$  boundary values of  $-2.92457$  and  $2.54086$ , so the trial continues to the next stage.

Note that the observed information level 4.6073 corresponds to a proportion of 0.2649 in the information level. If the observed information level is much larger than the target proportion of 0.25, then you can decrease the accrual rate, accrual time, or follow-up time to achieve target information levels for subsequent stages. These modifications should be specified in the study plan before the study begins.

With ODS Graphics enabled, a boundary plot with test statistics is displayed, as shown in [Output 84.7.12](#). As expected, the test statistic is in the continuation region between the lower and upper  $\alpha$  boundary values.

**Output 84.7.12** Sequential Test Plot

The following statements use the PHREG procedure to compute the MLE statistic and its associated standard error at stage 2:

```
proc phreg data=Time_2;
 model Weeks*Event(0) = TrtGp Wgt;
 ods output parameterestimates = ParmTime2;
run;
```

The following statements create the data set for the MLE statistic and its associated standard error at stage 2:

```
data Parms_Time2;
 set Parms_Time2;
 if Parameter='TrtGp';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;
```

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
proc seqtest Boundary=Test_Time1
 Parms(Testvar=TrtGp)=Parms_Time2
 infoadj=prop
 order=lr
 ;
 ods output Test=Test_Time2;
run;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_TIME2 option creates an output data set named TEST\_TIME2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Test Information” table in [Output 84.7.13](#) displays the boundary values for the test statistic with the MLE statistic scale. At stage 2, the standardized Z statistic  $-0.43552$  is between the lower  $\alpha$  and upper boundary values,  $-2.47689$  and  $2.14819$ , respectively, so the trial continues to the next stage.

## Output 84.7.13 Sequential Tests

| The SEQTEST Procedure                   |                       |          |                       |                     |                         |             |

| Test Information (Standardized Z Scale) |                |                 |          |
|-----------------------------------------|----------------|-----------------|----------|
| Null Reference = 0                      |                |                 |          |
| _Stage_                                 | -----Test----- |                 | Action   |
|                                         | Estimate       | -----TrtGp----- |          |
| 1                                       | 0.01795        |                 | Continue |
| 2                                       | -0.43552       |                 | Continue |
| 3                                       | .              |                 |          |
| 4                                       | .              |                 |          |

Since the data set PARMs\_Time2 contains the test information only at stage 2, the information level at stage 1 in the TEST\_Time1 data set is used to generate boundary values for the test.

Similarly, the test statistic at stage 3 is also between its corresponding lower and upper  $\alpha$  boundary values. The trial continues to the next stage.

The following statements use the PHREG procedure to compute the MLE statistic and its associated standard error at the final stage:

```
proc phreg data=Time_4;
 model Weeks*Event(0)= TrtGp Wgt;
 ods output parameterestimates= ParmS_Time4;
run;
```

The following statements create and display (in Output 84.7.14) the data set for the MLE statistic and its associated standard error at each stage of the study:

```
data ParmS_Time4;
 set ParmS_Time4;
 if Parameter='TrtGp';
 Scale='MLE';
 Stage= 4;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=ParmS_Time4;
 title 'Statistics Computed at Stage 4';
run;
```

**Output 84.7.14** Statistics Computed at Stage 4

| Statistics Computed at Stage 4 |           |          |         |         |         |
|--------------------------------|-----------|----------|---------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr  | _Scale_ | _Stage_ |
| 1                              | TrtGp     | -0.04451 | 0.23971 | MLE     | 4       |

The following statements invoke the SEQTEST procedure to test the hypothesis at stage 4:

```
ods graphics on;
proc seqtest Boundary=Test_Time3
 Parms (Testvar=TrtGp)=Parms_Time4
 order=lr
 ;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 4, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 4, and the TESTVAR= option identifies the test variable in the data set.

The “Test Information” table in [Output 84.7.15](#) displays the boundary values for the test statistic. The standardized test statistic  $-0.1857$  is between the lower and upper  $\alpha$  boundary values of  $-2.10447$  and  $1.82112$ , respectively, so the study stops and accepts the null hypothesis. That is, there is no evidence of reduction in hazard rate for the new treatment.

## Output 84.7.15 Sequential Tests

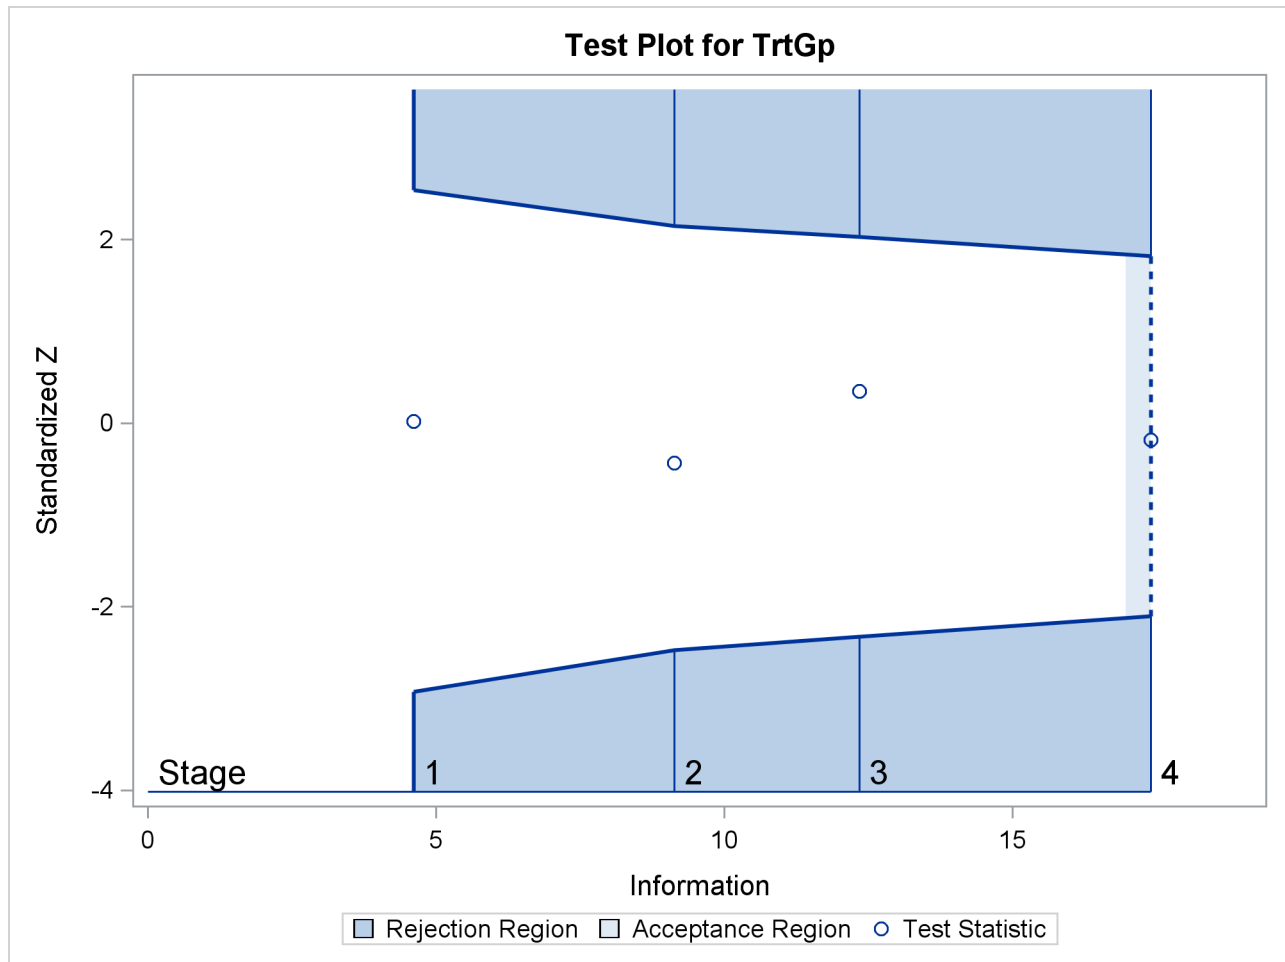

| The SEQTEST Procedure                   |                       |          |                       |                     |                         |             |

| 3                                       | 0.34864        | Continue    |
| 4                                       | -0.18570       | Accept Null |

The “Test Plot” displays boundary values of the design and the test statistic at the first two stages, as shown in [Output 84.7.16](#). It also shows that the test statistic is in the “Acceptance Region” between the lower and upper  $\alpha$  boundary values at stage 4.

**Output 84.7.16** Sequential Test Plot

After the stopping of a trial, the “Parameter Estimates” table in **Output 84.7.17** displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and  $p$ -value under the null hypothesis  $H_0 : \theta = 0$ .

**Output 84.7.17** Parameter Estimates

| Parameter Estimates<br>LR Ordering |                       |           |                                  |                 |
|------------------------------------|-----------------------|-----------|----------------------------------|-----------------|
| Parameter                          | Stopping Stage        | MLE       | p-Value for $H_0: \text{Parm}=0$ | Median Estimate |
| TrtGp                              | 4                     | -0.044514 | 0.8525                           | -0.044577       |
| Parameter Estimates<br>LR Ordering |                       |           |                                  |                 |
| Parameter                          | 95% Confidence Limits |           |                                  |                 |
| TrtGp                              | -0.51461      0.42538 |           |                                  |                 |

As expected, the two-sided  $p$ -value 0.8525 is not significant at the lower  $\alpha = 0.025$  level and the upper  $\alpha = 0.05$  level, and the two-sided 95% confidence interval contains the null value zero. The  $p$ -value, unbiased median estimate, and lower confidence limit depend on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the standardized  $Z$  statistic. With the specified LR ordering, the two-sided  $p$ -value is derived from the one-sided  $p$ -value

$$p_u = \sum_{k=1}^4 P_{\theta=0} (Z_k \geq z_4 \mid -a_{k'} < Z_{k'} < a_{k'}, k' < k)$$

where  $z_4 = -0.1857$  is the observed test statistic at stage 4,  $Z_k$  is a standardized normal variate at stage  $k$ , and  $-a_{k'}$  and  $a_{k'}$  are the stage  $k$  lower and upper rejection boundary values, respectively.

Thus,

$$p_u = \alpha_u + P_{\theta=0} (z_4 \leq Z_4 < a_4 \mid -a_{k'} < Z_{k'} < a_{k'}, k' < 4)$$

where  $\alpha_u = 0.05$  is the upper  $\alpha$  level and  $a_4 = 1.82112$ .

Since  $P_{\theta=0} (z_4 \leq Z_4 \leq a_4 \mid -a_{k'} < Z_{k'} < a_{k'}, k' < 4) = 0.52374$ ,  $p_u = 0.05 + 0.52374 = 0.57374$ , which is greater than 0.50. Thus, the two-sided  $p$ -value is given by  $2 \times (1.0 - p_u) = 0.8525$ .

---

### Example 84.8: Testing an Effect in a Logistic Regression Model

This example requests a two-sided test for the dose effect in a dose-response model (Whitehead 1997, pp. 262–263). Consider the logistic regression model

$$\text{logit}(p) = \log\left(\frac{p}{1-p}\right) = \beta_0 + \beta_1 \text{LDose}$$

where  $p = \text{Prob}(\text{Resp} = 1 \mid \text{LDose})$  is the response probability to be modeled for the binary response **Resp** and  $\text{LDose} = \log(\text{Dose} + 1)$  is the covariate. The dose levels are 0 for the control group, and they are 1, 3, and 6 for the three treatment groups.

Following the derivations in the section “Test for a Parameter in the Logistic Regression Model” in the chapter “The SEQDESIGN Procedure,” the required sample size can be derived from

$$N = I_X \frac{\sigma_y^2}{(1 - r_x^2) \sigma_x^2}$$

where  $\sigma_y^2$  is the variance of the response variable in the logistic regression model,  $r_x^2$  is the proportion of variance of **LDose** explained by other covariates, and  $\sigma_x^2$  is the variance of **LDose**.

Since **LDose** is the only covariate in the model,  $r_x^2 = 0$ . For a logistic model, the variance  $\sigma^2$  can be estimated by

$$\sigma_y^2 = \frac{1}{\hat{p}(1 - \hat{p})}$$

where  $\hat{p}$  is the estimated probability of the response variable **Resp**. Thus, the sample size can be computed as

$$N = I_X \frac{1}{p(1-p)} \frac{1}{\sigma_x^2}$$

The null hypothesis  $H_0 : \beta_1 = 0$  corresponds to no treatment effect. Suppose that the alternative hypothesis  $H_1 : \beta_1 = 0.5$  is the reference improvement that should be detected at a 0.90 level.

Note that  $\beta_1 = 0.5$  corresponds to an odds ratio of 2 between the treatment group with dose level 3 and the control group. The log odds ratio between the two groups is

$$\log\left(\frac{p_t(1-p_c)}{(1-p_t)p_0}\right) = \log\left(\frac{p_t}{1-p_t}\right) - \log\left(\frac{p_c}{1-p_c}\right)$$

which corresponds to

$$(\beta_0 + \beta_1 \log(3 + 1)) - (\beta_0 + \beta_1 \log(1)) = \beta_1 \log(4) = \log(2)$$

If the same number of patients are assigned in each of the four groups, then the MLE of the variance of LDose is  $\hat{\sigma}_x^2 = 0.5345$ . Further, if the response rate is 0.40, then the required sample size can be derived using the SAMPLESIZE statement in the SEQDESIGN procedure.

The following statements invoke the SEQDESIGN procedure and request a three-stage group sequential design for normally distributed data. The design has a null hypothesis of no treatment effect  $H_0 : \beta_1 = 0$  with early stopping to reject the null hypothesis with a two-sided alternative hypothesis  $H_1 : \beta_1 = \pm 0.5$ .

```
ods graphics on;
proc seqdesign altref=0.5;
 TwoSidedErrorSpending: design method=errfuncpow
 method(loweralpha)=errfuncpow(rho=1)
 method(upperalpha)=errfuncpow(rho=3)
 nstages=3
 stop=both;
 samplesize model=logistic(prop=0.4 xvariance=0.5345);
 ods output Boundary=Bnd_Dose;
run;
ods graphics off;
```

The ODS OUTPUT statement with the BOUNDARY=BND\_DOSE option creates an output data set named BND\_DOSE which contains the resulting boundary information for the subsequent sequential tests.

The “Design Information” table in [Output 84.8.1](#) displays design specifications and derived statistics. Since the alternative reference is specified, the maximum information 47.22445 is derived.

**Output 84.8.1** Error Spending Design Information

That is, 123 new patients are needed in each stage and the number is rounded up to 124 for each stage to have a multiple of four for the four dose levels in the trial. Note that since the sample sizes are derived from an estimated response probability and are rounded up, the actual information levels might not match the corresponding target information levels.

[Output 84.8.6](#) lists the first 10 observations of the trial data.

**Output 84.8.6** Clinical Trial Data

| First 10 Obs in the Trial Data |      |      |         |  |
|--------------------------------|------|------|---------|--|
| Obs                            | Resp | Dose | LDose   |  |
| 1                              | 0    | 0    | 0.00000 |  |

The following statements use the LOGISTIC procedure to estimate the slope  $\beta_1$  and its associated standard error at stage 1:

```
proc logistic data=Dose_1;
 model Resp(event='1')= LDose;
 ods output ParameterEstimates=Parms_Dose1;
run;
```

The following statements create and display (in [Output 84.8.7](#)) the input data set that contains slope  $\beta_1$  and its associated standard error for the SEQTEST procedure:

```
data Parms_Dose1;
 set Parms_Dose1;
 if Variable='LDose';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Dose1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.8.7** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | LDose    | 0.5741   | 0.2544 | MLE     | 1       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Dose
 Parms(testvar=LDose)=Parms_Dose1
 infoadj=prop
 order=mle
 boundaryscale=mle
 ;
 ods output Test=Test_Dose1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_DOSE1 option specifies the input data set PARMS\_DOSE1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=LDOSE option identifies the test variable LDOSE in the data set.

If the computed information level for stage 1 is not the same as the value provided in the BOUNDARY= data set, the INFOADJ=PROP option (which is the default) proportionally adjusts the information levels at future interim stages from the levels provided in the BOUNDARY= data set. The ORDER=MLE option uses the MLE ordering to derive the  $p$ -value, the unbiased median estimate, and the confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST\_DOSE1 option creates an output data set named TEST\_DOSE1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.8.8](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information

levels to maintain the Type I  $\alpha$  level. The maximum information remains the same as the design stored in the BOUNDARY= data set, but the derived Type II error probability  $\beta$  and power  $1 - \beta$  are different because of the new information levels.

**Output 84.8.8** Design Information

| The SEQTEST Procedure                       |                    |

| _Stage_                      | -----Boundary Values----- |          |         |         | -----Test----- |          |
|                              | Alpha                     | Beta     | Beta    | Alpha   | Estimate       | Action   |
| 1                            | -0.61078                  | .        | .       | 0.79337 | 0.57409        | Continue |
| 2                            | -0.40974                  | -0.18169 | 0.16222 | 0.44033 | .              |          |
| 3                            | -0.31633                  | -0.31633 | 0.28860 | 0.28860 | .              |          |

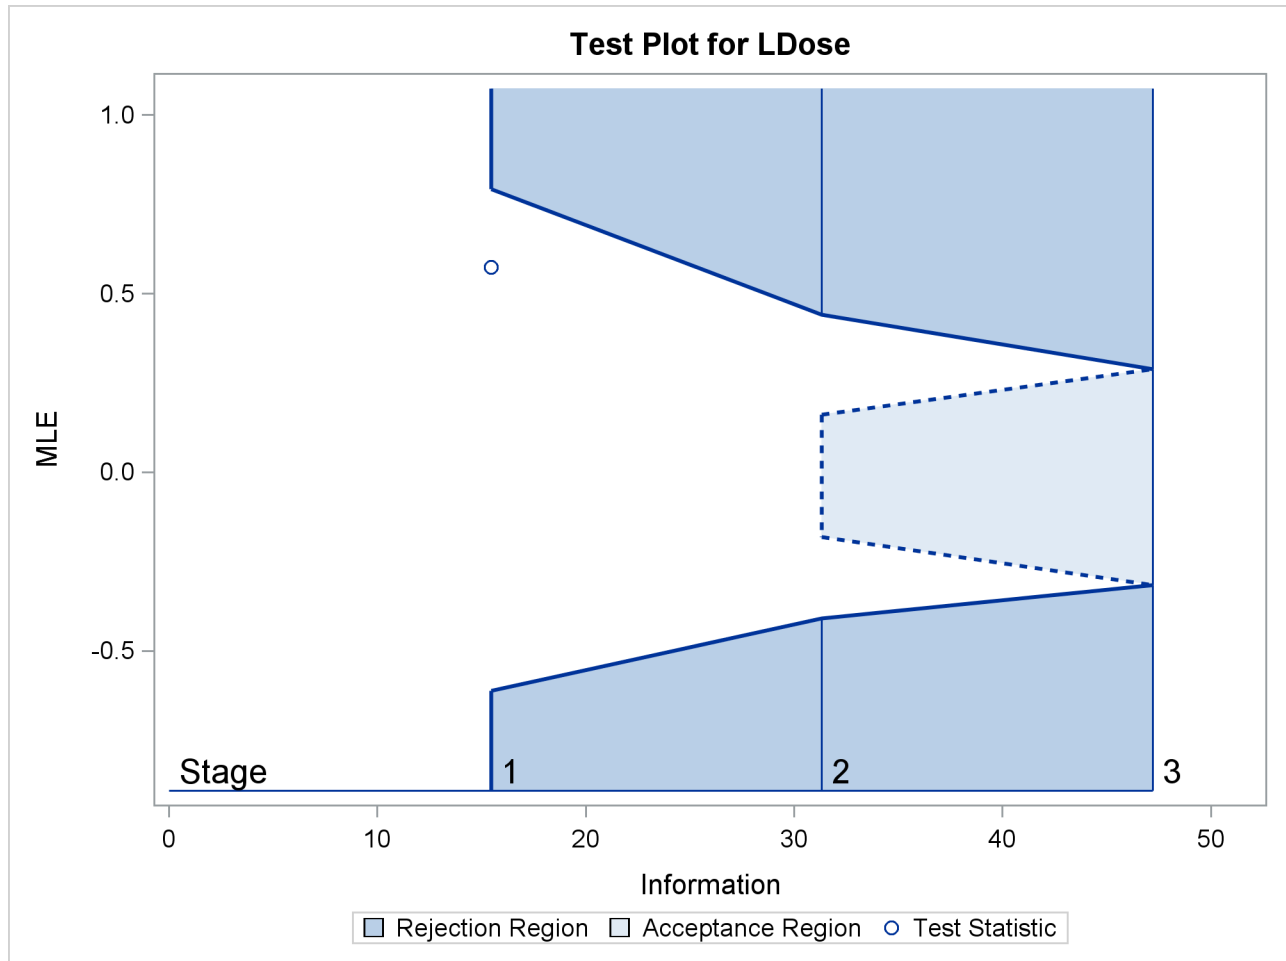

The information level at stage 1 is derived from the standard error  $s_1$  in the PARMS= data set,

$$I_1 = \frac{1}{s_1^2} = \frac{1}{0.2544^2} = 15.45$$

With the INFOADJ=PROP option (which is the default), the information level at stage 2 is derived proportionally from the observed information at stage 1 and the information levels in the BOUNDARY= data set. At stage 1, the  $\beta$  boundary values are missing and there is no early stopping to accept  $H_0$ . The MLE test statistic 0.57409 is between the lower and upper  $\alpha$  boundaries, so the trial continues to the next stage.

With ODS Graphics enabled, a boundary plot with the boundary values and test statistics is displayed, as shown in [Output 84.8.10](#). As expected, the test statistic is in the continuation region below the upper alpha boundary.

**Output 84.8.10** Sequential Test Plot

The following statements use the LOGISTIC procedure to estimate the slope  $\beta_1$  and its associated standard error at stage 2:

```
proc logistic data=dose_2;
 model Resp(event='1')=LDose;
 ods output ParameterEstimates=Parms_Dose2;
run;
```

The following statements create and display (in [Output 84.8.11](#)) the input data set that contains slope  $\beta_1$  and its associated standard error at stage 2 for the SEQTEST procedure:

```
data Parms_Dose2;
 set Parms_Dose2;
 if Variable='LDose';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Variable Estimate StdErr;
run;

proc print data=Parms_Dose2;
 title 'Statistics Computed at Stage 2';
run;
```

**Output 84.8.11** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |          |          |        |         |         |
|--------------------------------|----------|----------|--------|---------|---------|
| Obs                            | Variable | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | LDose    | 0.5213   | 0.1788 | MLE     | 2       |

The following statements invoke the SEQTEST procedure to test for early stopping at stage 2:

```
ods graphics on;
proc seqtest Boundary=Test_Dose1
 Parms (Testvar=LDose) =Parms_Dose2
 infoadj=prop
 order=mle
 boundaryscale=mle
 rci
 plots=rci
 ;
 ods output Test=Test_Dose2;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ORDER=MLE option uses the MLE ordering to derive the  $p$ -value, unbiased median estimate, and confidence limits for the regression slope estimate.

The ODS OUTPUT statement with the TEST=TEST\_DOSE2 option creates an output data set named TEST\_DOSE2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Design Information” table in [Output 84.8.12](#) displays design specifications. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the boundary values are modified for the new information levels to maintain the Type I  $\alpha$  level.

**Output 84.8.12** Design Information

| The SEQTEST Procedure                       |                    |
|---------------------------------------------|--------------------|
| Design Information                          |                    |
| BOUNDARY Data Set                           | WORK.TEST_DOSE1    |
| Data Set                                    | WORK.PARMS_DOSE2   |
| Statistic Distribution                      | Normal             |
| Boundary Scale                              | MLE                |
| Alternative Hypothesis                      | Two-Sided          |
| Early Stop                                  | Accept/Reject Null |
| Number of Stages                            | 3                  |
| Alpha                                       | 0.05               |
| Beta (Lower)                                | 0.0999             |
| Beta (Upper)                                | 0.07871            |
| Power (Lower)                               | 0.9001             |
| Power (Upper)                               | 0.92129            |
| Max Information (Percent of Fixed Sample)   | 103.7227           |
| Max Information                             | 47.2244524         |
| Null Ref ASN (Percent of Fixed Sample)      | 79.44086           |
| Lower Alt Ref ASN (Percent of Fixed Sample) | 66.04641           |
| Upper Alt Ref ASN (Percent of Fixed Sample) | 76.22739           |

The information is derived from the standard error associated with the slope estimate at the final stage and is larger than the target level. The derived Type II error probability  $\beta$  and power  $1 - \beta$  are different because of the new information levels.

The “Test Information” table in [Output 84.8.13](#) displays the boundary values for the test statistic with the specified MLE scale. The information levels are derived from the standard errors in the PARMS= data set. At stage 2, the slope estimate 0.52128 is larger than 0.44091, the upper  $\alpha$  boundary value, the trial stops to reject the null hypothesis of no treatment effect.

**Output 84.8.13** Sequential Tests

| Test Information (MLE Scale) |                         |          |                       |         |

| 2                            | -0.41028                  | -0.18112 | 0.16166         | 0.44091 | 0.52128         | Reject Null |
| 3                            | -0.31628                  | -0.31628 | 0.28861         | 0.28861 | .               |             |

With ODS Graphics enabled, a boundary plot with the boundary values and test statistics is displayed, as shown in [Output 84.8.14](#). As expected, the test statistic is above the upper  $\alpha$  boundary in the upper rejection region at stage 2.

Output 84.8.14 Sequential Test Plot

After a trial is stopped, the “Parameter Estimates” table in [Output 84.8.15](#) displays the stopping stage, parameter estimate, unbiased median estimate, confidence limits, and the  $p$ -value under the null hypothesis  $H_0 : \beta_1 = 0$ .

Output 84.8.15 Parameter Estimates

| Parameter Estimates<br>MLE Ordering |                       |          |                                  |                 |
|-------------------------------------|-----------------------|----------|----------------------------------|-----------------|
| Parameter                           | Stopping Stage        | MLE      | p-Value for $H_0: \text{Parm}=0$ | Median Estimate |
| LDose                               | 2                     | 0.521275 | 0.0050                           | 0.502647        |
| Parameter Estimates<br>MLE Ordering |                       |          |                                  |                 |
| Parameter                           | 95% Confidence Limits |          |                                  |                 |
| LDose                               | 0.15745               | 0.85154  |                                  |                 |

With the ORDER=MLE option, the MLE ordering is used to compute the  $p$ -value, unbiased median estimate, and confidence limits. As expected, the  $p$ -value 0.005 is significant at the  $\alpha = 0.05$  level and the confidence interval does not contain the null reference zero.

With the RCI option, the “Repeated Confidence Intervals” table in [Output 84.8.16](#) displays repeated confidence intervals for the parameter. For a two-sided test, since the rejection lower repeated confidence limit 0.0804 is greater than the null reference zero, the trial is stopped to reject the hypothesis.

**Output 84.8.16** Repeated Confidence Intervals

| Repeated Confidence Intervals |                   |                    |                         |                         |                          |                          |
|-------------------------------|-------------------|--------------------|-------------------------|-------------------------|--------------------------|--------------------------|
| _Stage_                       | Information Level | Parameter Estimate | -Rejection Boundary-    | -Rejection Boundary-    | -Acceptance Boundary-    | -Acceptance Boundary-    |
|                               |                   |                    | Lower 97.5% Repeated CL | Upper 97.5% Repeated CL | Lower 90.01% Repeated CL | Upper 92.13% Repeated CL |
| 1                             | 15.4506           | 0.57409            | -0.2193                 | 1.1849                  | .                        | .                        |
| 2                             | 31.2835           | 0.52128            | 0.0804                  | 0.9316                  | 0.2024                   | 0.8596                   |

With the PLOTS=RCI option, the “Repeated Confidence Intervals Plot” displays repeated confidence intervals for the parameter, as shown in [Output 84.8.17](#). It shows that the null reference zero is inside the rejection repeated confidence interval at stage 1 but outside the rejection repeated confidence interval at stage 2. This implies that the study stops at stage 2 to reject the hypothesis.

**Output 84.8.17** Repeated Confidence Intervals Plot

Note that the hypothesis is accepted if at any stage, the acceptance repeated confidence interval falls within the interval  $(-0.5, 0.5)$  of the alternative references.

### Example 84.9: Conducting a Trial with a Nonbinding Acceptance Boundary

This example demonstrates a trail with a nonbinding acceptance boundary. The design is similar to the design in Example 84.1, but has a nonbinding beta boundary.

A clinic is studying the effect of vitamin C supplements in treating flu symptoms. The study consists of patients in the clinic who have exhibited the first sign of flu symptoms within the last 24 hours. These patients are randomly assigned to either the control group (which receives placebo pills) or the treatment group (which receives large doses of vitamin C supplements). At the end of a five-day period, the flu symptoms of each patient are recorded.

Suppose that you know from past experience that flu symptoms disappear in five days for 60% of patients who experience flu symptoms. The clinic would like to detect a 75% symptom disappearance with a high probability. A test that compares the proportions directly specifies the null hypothesis  $H_0 : \theta = p_t - p_c = 0$

with a one-sided alternative  $H_1 : \theta > 0$  and a power of 0.90 at  $H_1 : \theta = 0.15$ , where  $p_t$  and  $p_c$  are the proportions of symptom disappearance in the treatment group and control group, respectively.

The following statements invoke the SEQDESIGN procedure and request a four-stage group sequential design by using an O'Brien-Fleming method for normally distributed data.

```
ods graphics on;
proc seqdesign altref=0.15 errspend
 ;
 NonbindingDesign: design nstages=4
 method=obf
 alt=upper
 stop=both(betaboundary=nonbinding)
 alpha=0.025
 ;
 samplesize model=twosamplefreq(nullprop=0.6 test=prop);
ods output Boundary=Bnd_Count;
run;
ods graphics off;
```

The ALT=UPPER option specifies a one-sided alternative hypothesis, and the STOP=BOTH option specifies early stopping to reject or accept the null hypothesis  $H_0$ . The BETABOUNDARY=NONBINDING suboption requests nonbinding beta boundary to have the flexibility to continue the trial when a test statistic falls in the acceptance region at interim stages (Zhu, Ni, and Yao 2011, pp. 132–133). The ODS OUTPUT statement with the BOUNDARY=BND\_COUNT option creates an output data set named BND\_COUNT which contains the resulting boundary information for the subsequent sequential tests.

The “Design Information” table in [Output 84.9.1](#) displays design specifications. With the specified alternative hypothesis  $H_1 : \theta = 0.15$ , the maximum information is derived to achieve a power of 0.90 at  $H_1$ . The derived fixed-sample information ratio 1.107 is the maximum information needed for a group sequential design relative to its corresponding fixed-sample design. Compare to the default BETABOUNDARY=BINDING option, the BETABOUNDARY=NONBINDING option requires a larger sample size for the design.

**Output 84.9.1** O'Brien-Fleming Design Information

With ODS Graphics enabled, a detailed boundary plot with the rejection and acceptance regions is displayed, as shown in [Output 84.1.3](#). The horizontal axis indicates the information levels for the design. The stages are indicated by vertical lines with accompanying stage numbers. If the test statistic at a stage is in a rejection region, the trial stops and the hypothesis is rejected. If the test statistic is in an acceptance region, then the trial either stops to accept the hypothesis or continues to the next stage. If the statistic is not in a rejection or an acceptance region, the trial continues to the next stage.

**Output 84.9.3** O'Brien-Fleming Boundary Plot

The boundary plot also displays the information level and critical value for the corresponding fixed-sample design. The solid and dashed lines at the fixed-sample information level correspond to the rejection and acceptance lines, respectively.

The “Error Spending Information (Nonbinding Beta Boundary)” in **Output 84.9.4** displays cumulative error spending at each stage for each boundary. With a nonbinding beta boundary, the  $\alpha$  spending at each stage is computed by using the  $\alpha$  boundary only.

**Output 84.9.4** Error Spending Information

| Error Spending Information (Nonbinding Beta Boundary) |                                   |                             |                          |  |
|-------------------------------------------------------|-----------------------------------|-----------------------------|--------------------------|--|

| 3                                                     | 0.7500                            | 0.06343                     | 0.01046                  |  |
| 4                                                     | 1.0000                            | 0.10000                     | 0.02500                  |  |

With the SAMPLESIZE statement, the maximum information is used to derive the required sample size for the study. The “Sample Size Summary” table in [Output 84.9.5](#) displays parameters for the sample size computation.

**Output 84.9.5** Required Sample Size Summary

| Sample Size Summary             |                        |
|---------------------------------|------------------------|
| Test                            | Two-Sample Proportions |
| Null Proportion                 | 0.6                    |
| Proportion (Group A)            | 0.75                   |
| Test Statistic                  | Z for Proportion       |
| Reference Proportions           | Alt Ref                |
| Max Sample Size                 | 442.0603               |
| Expected Sample Size (Null Ref) | 248.7446               |
| Expected Sample Size (Alt Ref)  | 313.5929               |

With the derived maximum information and the specified MODEL= option in the SAMPLESIZE statement, the total sample size in each group for testing the difference between two proportions under the alternative hypothesis is

$$N_1 = N_2 = (p_{1c}(1 - p_{1c}) + p_{1t}(1 - p_{1t})) I_X$$

where  $p_{1c} = 0.6$  and  $p_{1t} = p_{1c} + \theta_1 = 0.75$ . By default (or equivalently if you specify REF=PROP in the MODEL=TWOSAMPLEFREQ option), the required sample sizes are computed under the alternative hypothesis. See the section “Test for the Difference between Two Binomial Proportions” in the chapter “The SEQDESIGN Procedure” for a description of these parameters.

The “Sample Sizes (N)” table in [Output 84.9.6](#) displays the required sample sizes at each stage, in both fractional and integer numbers. The derived sample sizes under the heading Fractional N which correspond to the design are not integers. These sample sizes are rounded up to integers under the heading Ceiling N. In practice, integer sample sizes are used, and the information levels increase slightly. Thus, 56, 111, 166, and 222 patients are needed in each group for the four stages, respectively.

**Output 84.9.6** Required Sample Sizes

| Sample Sizes (N)                            |        |          |          |             |
|---------------------------------------------|--------|----------|----------|-------------|

| 10                             | 1   | 0    |  |

The `Trt` variable is a grouping variable with value 0 for a patient in the placebo control group and value 1 for a patient in the treatment group who is given vitamin C supplements. The `Resp` variable is an indicator variable with value 1 for a patient without flu symptoms after five days and value 0 for a patient with flu symptoms after five days.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 1:

```
proc genmod data=count_1;
 model Resp= Trt;
 ods output ParameterEstimates=Parms_Count1;
run;
```

Output 84.9.8 displays the treatment effect at stage 1.

**Output 84.9.8** Stage 1 Treatment Difference

| Intercept                                          | 1  | 0.6786   | 0.0619         | 0.5572                     | 0.7999 | 120.07          | <.0001     |
| Trt                                                | 1  | 0.0179   | 0.0876         | -0.1538                    | 0.1895 | 0.04            | 0.8384     |
| Scale                                              | 1  | 0.4634   | 0.0310         | 0.4065                     | 0.5283 |                 |            |

NOTE: The scale parameter was estimated by maximum likelihood.

The test statistic is  $\hat{\theta}_1 = \hat{p}_t - \hat{p}_c = 0.0179$ , and its associated standard error is

$$\sqrt{\text{Var}(\hat{\theta}_1)} = \sqrt{\frac{\hat{p}_c(1 - \hat{p}_c)}{56} + \frac{\hat{p}_t(1 - \hat{p}_t)}{56}} = 0.0876$$

The following statements create and display (in Output 84.9.9) the data set that contains the parameter estimate at stage 1,  $\hat{\theta}_1 = 0.0179$ , and its associated standard error  $\sqrt{\text{Var}(\hat{\theta}_1)} = 0.0876$  which are used in the SEQTEST procedure:

```
data Parms_Count1;
 set Parms_Count1;
 if Parameter='Trt';
 Scale='MLE';
 Stage= 1;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Count1;
 title 'Statistics Computed at Stage 1';
run;
```

**Output 84.9.9** Statistics Computed at Stage 1

| Statistics Computed at Stage 1 |           |          |        |         |         |
|--------------------------------|-----------|----------|--------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | Trt       | 0.0179   | 0.0876 | MLE     | 1       |

The initial required sample sizes are derived with the proportions  $p_c = 0.6$  and  $p_t = 0.75$ . If the observed proportions are different from these assumed values, or if the number of available patients is different from the study plan in one of the stages, then the information level that corresponds to the test statistic is estimated from

$$I_k = \frac{1}{\text{Var}(\hat{\theta}_k)}$$

The following statements invoke the SEQTEST procedure and test for early stopping at stage 1:

```
ods graphics on;
proc seqtest Boundary=Bnd_Count
 Parms (Testvar=Trt)=Parms_Count1
 betaboundary=nonbinding
 infoadj=none
 errspendmin=0.001
 errspend
 ;
ods output Test=Test_Count1;
run;
ods graphics off;
```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 1, which was generated in the SEQDESIGN procedure. The PARMS=PARMS\_COUNT1 option specifies the input data set PARMS\_COUNT1 that contains the test statistic and its associated standard error at stage 1, and the TESTVAR=TRT option identifies the test variable TRT in the data set.

The BETABOUNDARY=NONBINDING option requests nonbinding beta boundary to have the flexibility to continue the trial when the test statistic falls in the acceptance region at stage 1. The INFOADJ=NONE option maintains the information levels at future interim stages (2 and 3) as provided in the BOUNDARY= data set. The default BOUNDARYSCALE=STDZ option displays the output boundaries in terms of the standardized normal  $Z$  scale.

The O'Brien-Fleming design is conservative in early stages and might not be desirable in a clinical trial. The ERRSPENDMIN=0.001 option specifies the minimum error spending at each stage to be 0.001, and it might increase the corresponding nominal  $p$ -value in early stages for the trial. The default BOUNDARYSCALE=STDZ option uses the standardized normal  $Z$  scale to display test statistics in the boundary table and boundary plots.

The ODS OUTPUT statement with the TEST=TEST\_COUNT1 option creates an output data set named TEST\_COUNT1 which contains the updated boundary information for the test at stage 1. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The "Design Information" table in [Output 84.9.10](#) displays design specifications. The derived statistics, such as the overall  $\alpha$  and  $\beta$  levels, are derived from the specified maximum information and boundary values in the BOUNDARY= data set. Note that with a minor change in the information level at stage 1, the power also changes slightly from the design provided in the BOUNDARY= data set.

**Output 84.9.10** Design Information

With the ERRSPEND option, the “Error Spending Information” table in [Output 84.9.11](#) displays cumulative error spending at each stage for each boundary. By default (or equivalently if you specify BOUNDARYKEY=ALPHA), the Type I error level with nonbinding beta boundary  $\alpha = 0.025$  is maintained. Furthermore, with the ERRSPENDMIN=0.001 option, the  $\alpha$  spending at each stage is greater than or equal to 0.001.

**Output 84.9.11** Error Spending Information

| Error Spending Information (Nonbinding Beta Boundary) |                         |          |                             |         |
|-------------------------------------------------------|-------------------------|----------|-----------------------------|---------|

|                                                       | Proportion              | Actual   | Beta                        | Alpha   |
| 1                                                     | 0.2522                  | 130.3756 | 0.00302                     | 0.00100 |
| 2                                                     | 0.5000                  | 258.5148 | 0.02640                     | 0.00299 |
| 3                                                     | 0.7500                  | 387.7722 | 0.06433                     | 0.01101 |
| 4                                                     | 1.0000                  | 517.0296 | 0.10142                     | 0.02500 |

The “Test Information” table in [Output 84.9.12](#) displays the boundary values for the design, test statistic, and resulting action at each stage. With the default BOUNDARYSCALE=STDZ option, the standardized normal Z scale is used for the test statistic and boundary values. The table shows that the test statistic 0.2039 is between the upper  $\alpha$  and  $\beta$  boundaries, so the trial continues to the next stage.

## Output 84.9.12 Sequential Test

| Test Information (Standardized Z Scale)      |                         |          |                        |                           |         |

|----------------------------------------------|----------------|---------------|
| Nonbinding Beta Boundary, Null Reference = 0 |                |               |
| _Stage_                                      | -----Test----- |               |
|                                              | Estimate       | Trt<br>Action |
| 1                                            | 0.20390        | Continue      |
| 2                                            | .              | .             |
| 3                                            | .              | .             |
| 4                                            | .              | .             |

The information level at stage 1 is derived from the standard error,

$$I_1 = \frac{1}{\text{Var}(\hat{\theta}_1)} = \frac{1}{(\text{s.e.}(\hat{\theta}_1))^2} = 130.376$$

By default (or equivalently if you specify PLOTS=TEST), the “Test Plot” graph displays boundary values of the design and the test statistic at stage 1, as shown in [Output 84.9.13](#). It also shows that the observed statistic is in the continuation region.

Output 84.9.13 Sequential Test Plot

The observed information level at stage 1,  $I_1 = 130.376$ , is slightly larger than the target information level at the design. If an observed information level in the study is substantially different from its target level in the design, then the sample sizes should be adjusted in the subsequent stages to achieve the target information levels.

Suppose the trial continues to the next stage, and 111 patients are available in each group at stage 2. The data set COUNT\_2 contains these 222 patients.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 2:

```
proc genmod data=Count_2;
 model Resp= Trt;
 ods output ParameterEstimates=Parms_Count2;
run;
```

The following statements create the parameter estimate at stage 2,  $\hat{\theta}_2 = \hat{p}_2 - \hat{p}_1 = 0.027$ , and its associated standard error  $\sqrt{\text{Var}(\hat{\theta}_2)} = 0.0621$  into a test data set:

```

data Parms_Count2;
 set Parms_Count2;
 if Parameter='Trt';
 Scale='MLE';
 Stage= 2;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;

proc print data=Parms_Count2;
 title 'Statistics Computed at Stage 2';
run;

```

Output 84.9.14 displays the test statistics at stage 2.

**Output 84.9.14** Statistics Computed at Stage 2

| Statistics Computed at Stage 2 |           |          |        |         |         |
|--------------------------------|-----------|----------|--------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | Trt       | 0.0270   | 0.0621 | MLE     | 2       |

The following statements invoke the SEQTEST procedure and test for early stopping at stage 2:

```

ods graphics on;
proc seqtest Boundary=Test_Count1
 Parms(Testvar=Trt)=Parms_Count2
 betaboundary=nonbinding
 infoadj=none
 ;
ods output Test=Test_Count2;
run;
ods graphics off;

```

The BOUNDARY= option specifies the input data set that provides the boundary information for the trial at stage 2, which was generated by the SEQTEST procedure at the previous stage. The PARMS= option specifies the input data set that contains the test statistic and its associated standard error at stage 2, and the TESTVAR= option identifies the test variable in the data set.

The ODS OUTPUT statement with the TEST=TEST\_COUNT2 option creates an output data set named TEST\_COUNT2 which contains the updated boundary information for the test at stage 2. The data set also provides the boundary information that is needed for the group sequential test at the next stage.

The “Test Information” table in [Output 84.9.15](#) displays the boundary values, test statistic, and resulting action at each stage. The table shows that the test statistic 0.43522 is less than the corresponding upper beta boundary value, so the trial can be stopped to accept the hypothesis. With the BETABOUNDARY=NONBINDING option, The clinic has the option to continue the trial while still maintaining the Type I error level.

**Output 84.9.15** Sequential Test

| The SEQTEST Procedure                        |                        |          |                        |                          |         |

| 2                                            | 0.43522        | Accept Null (Nonbinding) |
| 3                                            | .              |                          |
| 4                                            | .              |                          |

With ODS Graphics enabled, the “Test Plot” is displayed, as shown in [Output 84.9.16](#). The plot displays boundary values of the design and the test statistics at the first two stages. As expected, the test statistic at stage 2 is in the “Upper Acceptance Region” below the upper beta boundary.

Output 84.9.16 Sequential Test Plot

Suppose the clinic decides to continue the trial, and at the next stage, 108 patients are available in each group at stage 3. The data set COUNT\_3 contains these 332 patients.

The following statements use the GENMOD procedure to estimate the treatment effect at stage 3:

```
proc genmod data=Count_3;
 model Resp= Trt;
 ods output ParameterEstimates=Parms_Count3;
run;
```

The following statements create the parameter estimate at stage 2,  $\hat{\theta}_2 = \hat{p}_2 - \hat{p}_1 = 0.1205$ , and its associated standard error  $\sqrt{\text{Var}(\hat{\theta}_2)} = 0.0507$  into a test data set:

```
data Parms_Count3;
 set Parms_Count3;
 if Parameter='Trt';
 Scale='MLE';
 Stage= 3;
 keep _Scale_ _Stage_ Parameter Estimate StdErr;
run;
```

```
proc print data=Parms_Count3;
 title 'Statistics Computed at Stage 3';
run;
```

Output 84.9.17 displays the test statistics at stage 3.

**Output 84.9.17** Statistics Computed at Stage 3

| Statistics Computed at Stage 3 |           |          |        |         |         |
|--------------------------------|-----------|----------|--------|---------|---------|
| Obs                            | Parameter | Estimate | StdErr | _Scale_ | _Stage_ |
| 1                              | Trt       | 0.1205   | 0.0507 | MLE     | 3       |

The following statements invoke the SEQTEST procedure and test for early stopping at stage 3:

```
ods graphics on;
proc seqtest Boundary=Test_Count2
 Parms (Testvar=Trt) =Parms_Count3
 betaboundary=nonbinding
;
ods output Test=Test_Count3;
run;
ods graphics off;
```

The “Test Information” table in [Output 84.9.18](#) displays the boundary values, test statistic, and resulting action at each stage. The table shows that the test statistic 2.37437 is greater than the corresponding upper alpha boundary value, so the trial stops to reject the hypothesis.

## Output 84.9.18 Sequential Test

| Nonbinding Beta Boundary, Null Reference = 0 |                |                          |
| _Stage_                                      | -----Test----- |                          |
|                                              | Estimate       | -----Trt-----<br>Action  |
| 1                                            | 0.20390        | Continue                 |
| 2                                            | 0.43522        | Accept Null (Nonbinding) |
| 3                                            | 2.37437        | Reject Null              |
| 4                                            | .              | .                        |

With ODS Graphics enabled, the “Test Plot” is displayed, as shown in [Output 84.9.19](#). The plot displays boundary values of the design and the test statistics at the first two stages. As expected, the test statistic at stage 3 is in the “Upper Rejection Region” above the upper alpha boundary.

**Output 84.9.19** Sequential Test Plot

After a trial is stopped, the “Parameter Estimates” table in [Output 84.9.20](#) displays the stopping stage and the maximum likelihood estimate of the parameter. It also displays the  $p$ -value, median estimate, and confidence limits for the parameter that correspond to the observed statistic by using the specified sample space ordering.

**Output 84.9.20** Parameter Estimates

| Parameter Estimates<br>Stagewise Ordering |                |          |                                  |                 |              |
|-------------------------------------------|----------------|----------|----------------------------------|-----------------|--------------|
| Parameter                                 | Stopping Stage | MLE      | p-Value for $H_0: \text{Parm}=0$ | Median Estimate | Lower 95% CL |
| Trt                                       | 3              | 0.120482 | 0.0103                           | 0.119371        | 0.03494      |

The MLE statistic at the stopping stage is the maximum likelihood estimate of the parameter and is biased. The computation of  $p$ -value, unbiased median estimate, and confidence limits depends on the ordering of the sample space  $(k, z)$ , where  $k$  is the stage number and  $z$  is the observed standardized  $Z$  statistic. By default

(or equivalently if you specify ORDER=STAGewise), the stagewise ordering that uses counterclockwise ordering around the continuation region is used to compute the  $p$ -value, unbiased median estimate, and confidence limits. As expected, the  $p$ -value is less than 0.025, and the confidence interval does not contain the null reference zero.

See the section “Available Sample Space Orderings in a Sequential Test” on page 7230 for a detailed description of the stagewise ordering.

## Overview: SIM2D Procedure

The SIM2D procedure uses an LU decomposition technique to produce a spatial simulation for a Gaussian random field with a specified mean and covariance structure in two dimensions.

The simulation can be conditional or unconditional. If it is conditional, a set of coordinates and associated field values are read from a SAS data set. The resulting simulation honors these data values.

You can specify the mean structure as a quadratic function in the coordinates. Specify the semivariance by naming the form and supplying the associated parameters, or by using the contents of an item store file that was previously created by PROC VARIOGRAM.

PROC SIM2D can handle anisotropic and nested semivariogram models. Seven covariance models are supported: Gaussian, exponential, spherical, cubic, pentaspherical, sine hole effect, and Matérn. A single nugget effect is also supported.

You can specify the locations of simulation points in a **GRID** statement, or they can be read from a SAS data set. The grid specification is most suitable for a regular grid; the data set specification can handle any irregular pattern of points.

The SIM2D procedure writes the simulated values for each grid point to an output data set. The SIM2D procedure uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS.](#)” For more information about the graphics available in PROC SIM2D, see the section “[ODS Graphics](#)” on page 7413.

---

## Introduction to Spatial Simulation

The purpose of spatial simulation is to produce a set of partial realizations of a spatial random field (SRF)  $Z(s), s \in D \subset \mathcal{R}^2$  in a way that preserves a specified mean  $\mu(s) = E[Z(s)]$  and covariance structure  $C_z(s_1 - s_2) = \text{Cov}(Z(s_1), Z(s_2))$ . The realizations are partial in the sense that they occur only at a finite set of locations  $(s_1, s_2, \dots, s_n)$ . These locations are typically on a regular grid, but they can be arbitrary locations in the plane.

PROC SIM2D produces simulations for continuous processes in two dimensions by using the lower-upper (LU) decomposition method. In these simulations the possible values of the measured quantity  $Z(s_0)$  at location  $s_0 = (x_0, y_0)$  can vary continuously over a certain range. An additional assumption, needed for computational purposes, is that the spatial random field  $Z(s)$  is Gaussian. The section “[Details: SIM2D Procedure](#)” on page 7408 provides more information about different types of spatial simulation and associated computational methods.

Spatial simulation is different from spatial prediction, where the emphasis is on predicting a point value at a given grid location. In this sense, spatial prediction is local. In contrast, spatial simulation is global; the emphasis is on the entire realization  $(Z(s_1), Z(s_2), \dots, Z(s_n))$ .

Given the correct mean  $\mu(s)$  and covariance structure  $C_z(s_1 - s_2)$ , SRF quantities that are difficult or impossible to calculate in a spatial prediction context can easily be approximated by functions of multiple simulations.

---

## Getting Started: SIM2D Procedure

Spatial simulation, just like spatial prediction, requires a model of spatial dependence, usually in terms of the covariance  $C_z(\mathbf{h})$ . For a given set of spatial data  $Z(s_i), i = 1, \dots, n$ , the covariance structure (both the form and parameter values) can be found by the VARIOGRAM procedure. This example uses the coal seam thickness data that are also used in the section “Getting Started: VARIOGRAM Procedure” on page 8561.

In this example, the data consist of coal seam thickness measurements (in feet) taken over an area of  $100 \times 100$  ( $10^6$  ft<sup>2</sup>). The coordinates are offsets from a point in the southwest corner of the measurement area, with the north and east distances in units of thousands of feet.

---

### Preliminary Spatial Data Analysis

A semivariance analysis of the coal seam thickness thick data set is performed in “Getting Started: VARIOGRAM Procedure” on page 8561 of the VARIOGRAM procedure. The analysis considers the spatial random field (SRF)  $Z(s)$  of the Thick variable to be free of surface trends. The expected value  $E[Z(s)]$  is then a constant  $\mu(s) = \mu$ , which suggests that you can work with the original thickness data rather than residuals from a trend surface fit. In fact, a reasonable approximation of the spatial process generating the coal seam data is given by

$$Z(s) = \mu + \varepsilon(s)$$

where  $\varepsilon(s)$  is a Gaussian SRF with Gaussian covariance structure

$$C_z(\mathbf{h}) = c_0 \exp\left(-\frac{h^2}{a_0^2}\right)$$

Of note, the term “Gaussian” is used in two ways in this description. For a set of locations  $s_1, s_2, \dots, s_n$ , the random vector

$$\mathbf{Z}(s) = \begin{bmatrix} Z(s_1) \\ Z(s_2) \\ \vdots \\ Z(s_n) \end{bmatrix}$$

has a multivariate Gaussian or normal distribution  $N_n(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ . The  $(i,j)$  element of  $\boldsymbol{\Sigma}$  is computed by  $C_z(s_i - s_j)$ , which happens to be a Gaussian functional form.

Any functional form for  $C_z(\mathbf{h})$  that yields a valid covariance matrix  $\Sigma$  can be used. Both the functional form of  $C_z(\mathbf{h})$  and the parameter values

$$\mu = 40.1173$$

$$c_0 = 7.4599$$

$$a_0 = 30.1111$$

are estimated by using PROC VARIOGRAM in section “[Theoretical Semivariogram Model Fitting](#)” on page 8571 in the VARIOGRAM procedure. Specifically, the expected value  $\mu$  is reported in the VARIOGRAM procedure OUTV output data set, and the parameters  $c_0$  and  $a_0$  are estimates derived from a weighted least squares fit.

The choice of a Gaussian functional form for  $C_z(\mathbf{h})$  is simply based on the data, and it is not at all crucial to the simulation. However, it *is* crucial to the simulation method used in PROC SIM2D that  $Z(s)$  be a Gaussian SRF. For details, see the section “[Computational and Theoretical Details of Spatial Simulation](#)” on page 7408.

## Investigating Variability by Simulation

The variability of  $Z(s)$ , as modeled by

$$Z(s) = \mu + \varepsilon(s)$$

with the Gaussian covariance structure  $C_z(\mathbf{h})$  found previously, is not obvious from the covariance model form and parameters. The variation around the mean of the surface is relatively small, making it difficult visually to pick up differences in surface plots of simulated realizations.

Instead, you can compute the mean for each location on a grid from a series of realizations in a simulation. Then, the standard deviation of all the simulated values at each grid location provides you with a measure of the variability of  $Z(s)$  for the given covariance structure. You can also investigate variations at selected grid points in more detail, as shown in the “[Example 85.2: Variability at Selected Locations](#)” on page 7419.

The present example shows how to use ODS Graphics with PROC SIM2D to investigate the mean and standard deviation of simulated values. You use the thick data set which is available from the SasHELP library. In the data set, the Thick variable represents simulated observations of coal seam thickness. For your goal, you produce 5,000 realizations of a simulation with PROC SIM2D, where you specify the Gaussian model with the parameters found previously. You want the simulated data to pass through the simulated values, so first you define the data with the following data step:

```

```

Since this is a conditional simulation, you can specify the **OBSERV** option in the **PLOTS** option in PROC SIM2D to see the locations and values of the measured points in the area where you want to perform spatial simulations.

Furthermore, the **SIM** suboption in the **PLOTS** option specifies that you want to create a plot that shows the means of the simulated values across the region. The **SIM** suboption with no other arguments produces a plot that shows the contours of the simulated means in the foreground and the gradient of the simulated standard deviations in the background.

You obtain these PROC SIM2D results at the nodes of an output grid that you specify according to your application needs. In the present analysis, a convenient area that encompasses all the Thick data points is a square with a side length of 100,000 feet. You define a regular grid for your simulation in this area. Assume a distance of 2,500 feet between grid nodes in both directions for a smooth contour plot. Based on this choice, your square grid has 41 nodes on each side. This means that PROC SIM2D computes the simulated values at a total of 1,681 grid points. You use the **GRID** statement of the PROC SIM2D to specify this grid.

The **SIMULATE** statement specifies the parameters of your simulation across the output grid. In particular, the **VAR=** option specifies the conditional simulation variable. The number of realizations in the simulation is specified with the **NUMREAL=** option. The **SEED=** option specifies the seed for the simulation random number generator.

The spatial correlation model for the simulation is also specified in the **SIMULATE** statement. You specify the model type by using the **FORM=** option. The options **SCALE=** and **RANGE=** specify the covariance structure sill  $c_0$  and range  $a_0$  parameters, respectively, as discussed in the previous section.

Although it is not included in the original spatial structure, note that a minimal nugget effect is specified with the **NUGGET=** option to avoid singularity issues. Singularity can appear in the present example as a result of the combined use of the Gaussian covariance model and relatively short distances between nodes, data, or nodes and data in the simulation area.

These steps are implemented using the following **DATA** step and statements:

```
ods graphics on;

proc sim2d data=thick outsim=sim plot=(observ sim);
 coordinates xc=East yc=North;
 simulate var=Thick numreal=5000 seed=79931
 scale=7.4599 range=30.1111 nugget=1e-8 form=gauss;
 mean 40.1173;
 grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;
```

The table in [Figure 85.1](#) shows the number of observations read and used in the conditional simulation. This table can provide you with useful information in case you have missing values in the input data.

**Figure 85.1** Number of Observations for the thick Data Set

| Using PROC SIM2D for Spatial Simulation     |    |
|---------------------------------------------|----|
| The SIM2D Procedure                         |    |
| Simulation: SIM1, Dependent Variable: Thick |    |
| Number of Observations Read                 | 75 |
| Number of Observations Used                 | 75 |

The sample locations are then plotted in [Figure 85.2](#). The figure clearly shows some small-scale variation that is typical of spatial data.

**Figure 85.2** Scatter Plot of the Observations Spatial Distribution

PROC SIM2D also produces the table shown in Figure 85.3, which contains information about the type of simulation you run and the number of realizations requested.

**Figure 85.3** Simulation Analysis Information

| Simulation Information |             |
|------------------------|-------------|
| Simulation Grid Points | 1681        |
| Type                   | Conditional |
| Number of Realizations | 5000        |

The table in Figure 85.4 displays the spatial correlation model information that is used by PROC SIM2D for the current simulation. If applicable, the table also provides the effective range. This is the distance  $r_\epsilon$  at which the covariance is 5% of its value at zero. Here you specified the Gaussian model, for which the effective range  $r_\epsilon$  is  $\sqrt{3}a_0$ .

**Figure 85.4** Simulation Covariance Model Information

| Covariance Model Information |           |
|------------------------------|-----------|
| Type                         | Gaussian  |
| Sill                         | 7.4599    |
| Range                        | 30.1111   |
| Effective Range              | 52.153955 |
| Nugget Effect                | 1E-8      |

Eventually, the SIM2D procedure produces the requested simulation plot shown in Figure 85.5. The contours of the mean of the simulated values show the average of the simulated realizations at each grid node; the average is based on the given spatial structure characteristics. In this case, these means are also conditioned by the Thick observations across the region.

**Figure 85.5** Contour Plot of Conditionally Simulated Coal Seam Thickness

Observe also the gradient that shows the standard deviation of the simulated values at each grid node. This gradient appears to be generally small throughout the region. A few exceptions are evident close to the region borders. In these areas the simulated realizations depend on a limited amount of neighboring data. The simulation at these locations relies mainly on the underlying spatial structure.

In addition to the simulation analysis, you can use the PROC SIM2D output to obtain statistical information about the simulated values at selected locations. Assume that you would like some basic statistics for the extreme southwest point at (East=0, North=0) and the point (East=75, North=75) toward the northeast corner of the region. You use the following DATA step to select the realizations for these points from the OUTSIM= output data set:

```
data selected;
 set sim(where=((gxc=0 and gyc=0) or (gxc=75 and gyc=75)));
 label gxc = "X-coord";
 label gyc = "Y-coord";
run;
```

Then, you use PROC SORT to sort the selected data set entries and PROC MEANS to produce the simulation statistics for the selected points. The following statements yield the mean, standard deviation, and maximum values of the 5,000 realizations of the Thick values at each one of the selected locations:

```
proc sort data=selected;
 by gxc gyc;
run;
proc means data=selected Mean Std Max;
 class gxc gyc;
 ways 2;
 where ((gxc = 0) & (gyc = 0)
 | ((gxc = 75) & (gyc = 75)));
 var SValue;
run;

ods graphics off;
```

The requested statistics for the grid points (East=0, North=0) and (East=75, North=75) are shown in [Figure 85.6](#).

**Figure 85.6** Simulation Statistics at Grid Points (East=0, North=0) and (East=75, North=75)

| Using PROC SIM2D for Spatial Simulation                  |         |       |            |           |            |  |
|----------------------------------------------------------|---------|-------|------------|-----------|------------|--|
| The MEANS Procedure                                      |         |       |            |           |            |  |
| Analysis Variable : SVALUE Simulated Value at Grid Point |         |       |            |           |            |  |
| X-coord                                                  | Y-coord | N Obs | Mean       | Std Dev   | Maximum    |  |
| 0                                                        | 0       | 5000  | 40.6968472 | 0.5328597 | 42.6616357 |  |
| 75                                                       | 75      | 5000  | 40.1090845 | 0.0024556 | 40.1197239 |  |

“[Example 85.2: Variability at Selected Locations](#)” on page 7419 shows you how to perform a simulation at a set of selected locations rather than on a domain-wide grid, and how to obtain more detailed statistics from the simulation.

## Syntax: SIM2D Procedure

The following statements are available in the SIM2D procedure:

```

PROC SIM2D options ;
 BY variables ;
 COORDINATES coordinate-variables ;
 GRID grid-options ;
 ID variable ;
 RESTORE store-options ;
 SIMULATE simulate-options ;
 MEAN mean-options ;

```

The **SIMULATE** and **MEAN** statements are hierarchical; you can specify any number of **SIMULATE** statements, but you must specify at least one. If you specify a **MEAN** statement, it refers to the preceding **SIMULATE** statement. If you omit the **MEAN** statement, a zero-mean model is simulated.

You must specify a single **COORDINATES** statement to identify the  $x$  and  $y$  coordinate variables in the input data set when you perform a conditional simulation. You must also specify a single **GRID** statement to specify the grid information.

Table 85.1 outlines the options available in PROC SIM2D classified by function.

**Table 85.1** Options Available in the SIM2D Procedure

| Task                                                                | Statement   | Option  |
|---------------------------------------------------------------------|-------------|---------|
| <b>Data Set Options</b>                                             |             |         |
| Specify an input data set                                           | PROC SIM2D  | DATA=   |
| Specify a grid data set                                             | GRID        | GDATA=  |

## PROC SIM2D Statement

**PROC SIM2D** *options* ;

The PROC SIM2D statement invokes the SIM2D procedure. Table 85.2 summarizes the options available in the PROC SIM2D statement.

**Table 85.2** PROC SIM2D Statement Options

| Option   | Description                                              |
|----------|----------------------------------------------------------|
| DATA=    | Specifies an input data set                              |
| IDGLOBAL | Uses ascending observation numbers across BY groups      |
| IDNUM    | Uses the observation number for the observation labels   |
| NARROW   | Restricts the variables included in the OUTSIM= data set |
| NOPRINT  | Suppresses the normal display of results                 |
| OUTSIM=  | Writes simulated values to a SAS data set                |
| PLOTS    | Specifies plot display and options                       |

You can specify the following options with the PROC SIM2D statement.

### **DATA=SAS-data-set**

specifies a SAS data set that contains the  $x$  and  $y$  coordinate variables and the VAR= variables that are used in the SIMULATE statements. This data set is required if you specify the BY statement or the COORDINATES statement or if any of the SIMULATE statements are conditional—that is, if you specify the VAR= option in any of those. Otherwise, you do not need the DATA= option, and this option is ignored if you specify it.

### **IDGLOBAL**

specifies that ascending observation numbers be used across BY groups for the observation labels in the appropriate output data sets and the OBSERVATIONS plot, instead of resetting the observation number in the beginning of each BY group. The IDGLOBAL option is ignored if no BY variables are specified. Also, if you specify the ID statement, then the IDGLOBAL option is ignored unless you also specify the IDNUM option in the PROC SIM2D statement.

### **IDNUM**

specifies that the observation number be used for the observation labels in the appropriate output data sets and the OBSERVATIONS plot. The IDNUM option takes effect when you specify the ID statement; otherwise, it is ignored.

### **NARROW**

restricts the variables included in the OUTSIM= data set. When you specify the NARROW option, only four variables are included. This option is useful when a large number of simulations are produced. Including only four variables reduces the memory required for the OUTSIM= data set. For details about the variables that are excluded with the NARROW option, see the section “Output Data Set” on page 7411.

**NOPRINT**

suppresses the normal display of results. The NOPRINT option is useful when you want only to create one or more output data sets with the procedure. **NOTE:** This option temporarily disables the Output Delivery System (ODS); see the section “[ODS Graphics](#)” on page 7413 for more information.

**OUTSIM=SAS-data-set**

specifies a SAS data set in which to store the simulation values, iteration number, simulate statement label, variable name, and grid location. For details, see the section “[Output Data Set](#)” on page 7411.

**PLOTS** <(global-plot-option)> <= plot-request <(options)>>**PLOTS** <(global-plot-option)> <= (plot-request <(options)> <... plot-request <(options)>>>

controls the plots produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request. Here are some examples:

```
plots=none
plots=observ
plots=(observ(out1) sim)
plots=(sim(fill=mean line=sd obs=grad) sim(fill=sd))
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;

proc sim2d data=thick outsim=sim;
 coordinates xc=East yc=North;
 simulate var=Thick numreal=5000 seed=79931
 scale=7.4599 range=30.1111 form=gauss;
 mean 40.1173;
 grid x=0 to 100 by 2.5 y=0 to 100 by 2.5;
run;

ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS](#).”

By default, no graphs are created; you must specify the PLOTS= option to make graphs.

The following *global-plot-option* is available:

**ONLY**

produces only plots that are specifically requested.

The following individual *plot-requests* and *plot options* are available:

**ALL**

produces all appropriate plots. You can specify other *options* with ALL. For example, to request all appropriate plots and an additional simulation plot, specify PLOTS=(ALL SIM).

**EQUATE**

specifies that all appropriate plots be produced in a way in which the axes coordinates have equal size units.

**NONE**

suppresses all plots.

**OBSERVATIONS** < (*observations-plot-options*) >**OBSERV** < (*observations-plot-options*) >**OBS** < (*observations-plot-options*) >

produces the observed data plot in conditional simulations. Only one observations plot is created if you specify the OBSERVATIONS option more than once within a PLOTS option.

The OBSERVATIONS option has the following suboptions:

**GRADIENT**

specifies that observations be displayed as circles colored by the observed measurement.

**LABEL** < (*label-option*) >

labels the observations. The label is the ID variable if the ID statement is specified; otherwise, it is the observation number. The *label-option* can be one of the following:

**EQ=number**

specifies that labels show for any observation whose value is equal to the specified *number*.

**MAX=number**

specifies that labels show for observations with values smaller than or equal to the specified *number*.

**MIN=number**

specifies that labels show for observations with values equal to or greater than the specified *number*.

If you specify multiple instances of the OBSERVATIONS option and you specify the LABEL suboption in any of those, then the resulting observations plot displays the observations labels. If more than one *label-option* is specified in multiple LABEL suboptions, then the prevailing *label-option* in the resulting OBSERVATIONS plot emerges by adhering to the choosing order: MIN, MAX, EQ.

**OUTLINE**

specifies that observations be displayed as circles with a border but with a completely transparent fill.

**OUTLINEGRADIENT**

is the same as OBSERVATIONS(GRADIENT) except that a border is shown around each observation.

**SHOWMISSING**

specifies that observations with missing values be displayed in addition to the observations with nonmissing values. By default, missing values locations are not shown on the

plot. If you specify multiple instances of the OBSERVATIONS option and you specify the SHOWMISSING suboption in any of those, then the resulting observations plot displays the observations with missing values.

If you omit any of the GRADIENT, OUTLINE, and OUTLINEGRADIENT suboptions, the OUTLINEGRADIENT is the default suboption. If you specify multiple instances of the OBSERVATIONS option or multiple suboptions for OBSERVATIONS, then the resulting observations plot honors the last specified GRADIENT, OUTLINE, or OUTLINEGRADIENT suboption.

### **SIMULATION** < (*sim-plot-options*) >

#### **SIM** < (*sim-plot-options*) >

specifies that simulation plots be produced. You can specify the SIM option multiple times in the same PLOTS option to request instances of plots with the following *sim-plot-options*:

#### **ALPHA=number**

specifies a parameter to obtain the confidence level for constructing confidence limits based on the simulation standard deviation. The value of *number* must be between 0 and 1, and the confidence level is  $1 - \text{number}$ . The default is ALPHA=0.05; this corresponds to the confidence level of 95%. The ALPHA= suboption is used only for simulation plots in one dimension, and it is incompatible with the FILL and LINE suboptions.

#### **CLONLY**

specifies that only the confidence limits be shown in a simulation plot without the simulation mean. This suboption can be useful for identifying confidence limits when the simulation standard deviation is small at the simulation locations. CLONLY is used only for simulation band plots of simulations on a linear grid, and it is incompatible with the FILL and LINE suboptions.

#### **CONNP**

specifies that grid points that you provide as individual simulation locations be connected with a line on the area map. This suboption is ignored when you have a single grid point, a prediction grid in two dimensions, or when you also specify the NOMAP suboption. The CONNP suboption is incompatible with the FILL and LINE suboptions.

#### **FILL=NONE | MEAN | SD**

produces a surface plot for either the values of the means or the standard deviations. FILL=SD is the default. However, if you omit the FILL suboption the behavior depends on the LINE suboption as follows: If you specify LINE=NONE or entirely omit the LINE suboption, then the FILL suboption is set to its default value. If LINE=PRED or LINE=SE, then the FILL suboption is set to the same value as the LINE suboption.

#### **LINE=NONE | MEAN | SD**

produces a contour line plot for either the values of the means or the standard deviations. LINE=MEAN is the default. However, if you omit the LINE suboption the behavior depends on the FILL suboption as follows: If you specify FILL=NONE or entirely omit the FILL suboption, then the LINE suboption is set to its default value. If FILL=PRED or FILL=SE, then the LINE suboption is set to the same value as the FILL suboption.

**NOMAP**

specifies that the simulation plot be produced without a map of the domain where you have observations. The NOMAP suboption is used in the case of simulation in one dimension or at individual points. It is ignored in the case of unconditional simulation, and it is incompatible with the FILL and LINE suboptions.

**OBS=obs-options**

produces an overlaid scatter plot of the observations in addition to the specified contour plots. The following *obs-options* are available:

**GRAD**

specifies that observations be displayed as circles colored by the observed measurement. The same color gradient displays the means surface and the observations. The conditional simulation honors the observed values, so the means surface at the observation locations has the same color as the corresponding observations.

**LINEGRAD**

is the same as OBS=GRAD except that a border is shown around each observation. This option is useful for identifying the location of observations where the standard deviations are small, because at these points the color of the observations and the color of the surface are indistinguishable.

**NONE**

specifies that no observations be displayed.

**OUTL**

specifies that observations be displayed as circles with a border but with a completely transparent fill.

OBS=NONE is the default when you have a grid in two dimensions, and OBS=LINEGRAD is the default used in the area map when you specify a conditional simulation in one dimension.

**SHOWD**

specifies that the horizontal axis in scatter plots of linear simulation grids show the distance between grid points instead of the grid points' coordinates. When the area map is displayed, the simulation locations are also connected with a line. In all other grid configurations the SHOWD suboption is ignored, and it is incompatible with the FILL and LINE suboptions.

**SHOWP**

specifies that the grid points in band plots of linear simulation grids be shown as marks on the band plot. In all other grid configurations the SHOWP suboption is ignored, and it is incompatible with the FILL and LINE suboptions.

**TYPE=BAND | BOX**

requests a particular type of plot when you have a linear grid, regardless of the default SIM plot behavior in this case. The TYPE suboption is incompatible with the FILL and LINE suboptions.

If you specify multiple instances of the ALPHA, FILL, LINE, OBS, or TYPE suboptions in the same SIM option, then the resulting simulation plot honors the last value specified for any

of the suboptions. Any combination where you specify FILL=NONE and LINE=NONE is not available. When the simulation grid is in two dimensions, only the FILL, LINE, and OBS suboptions apply. If you specify incompatible suboptions in the same SIM plot, then the plot instance is skipped.

The SIM option produces a surface or contour line plot for grids in two dimensions and a band plot or box plot for grids in one dimension or individual points. In two dimensions the plot illustrates the means and standard deviations of the simulation realizations at each grid point. By default, when you specify a linear grid with fewer than 10 points, PROC SIM2D produces a SIM box plot that depicts the simulation distribution at each point. For 10 or more points in a linear grid, the SIM plot is a band plot of the simulation means and the confidence limits at the 95% confidence level. You can override the default behavior in linear grids with the TYPE suboption. Simulation at individual locations always produces a SIM box plot.

In cases of conditional simulation in one dimension or at individual points an area map is produced that shows the observations and the grid points. Band plots of linear grids display the grid points as a line on the map. When you specify individual simulation locations, the grid points are indicated with marks on the area map. The area map appears on the side of conditional simulation band plots or box plots, unless you specify the NOMAP suboption. You can also label individual grid points or the ends of linear grid segments with the LABEL option of the GRID statement.

#### **SEMIVARIOGRAM** <(semivar-plot-option)>

##### **SEMIVAR** <(semivar-plot-option)>

specifies that the semivariogram used for the simulation be produced. You can use the following *semivar-plot-option*:

##### **MAXD=number**

specifies a positive value for the upper limit of the semivariogram horizontal axis of distance. The SEMIVARIOGRAM plot extends by default to a distance that depends on the correlation model range. You can use the MAXD= option to adjust the default maximum distance value for the plot.

The SEMIVARIOGRAM option produces a plot for each correlation model that you specify for your simulation tasks. In an anisotropic case, the plot is not produced if you assign different anisotropy angles for different model components. The only exception is when you specify zonal components at right angles with the nonzonal model components. Also, the SEMIVARIOGRAM option is ignored for models that consist of purely zonal components.

## **BY Statement**

### **BY variables ;**

You can specify a BY statement with PROC SIM2D to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SIM2D procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

In PROC SIM2D it makes sense to use the BY statement only in conditional simulations where observations are involved. In particular, using the BY statement assumes that you have specified an input data set with the DATA= option in the PROC SIM2D statement. In PROC SIM2D if you omit the VAR= option in the SIMULATE statement, then this is a request for unconditional simulation even if you have specified the DATA= option in the PROC SIM2D statement. Therefore, it is possible to specify the BY statement and request mixed types of simulations by specifying multiple SIMULATE statements in the same PROC SIM2D step.

A special case occurs when you omit the DATA= option in the PROC SIM2D statement, your unconditional simulation correlation model input comes from an item store in the RESTORE statement, and this store has its own BY groups. The SIM2D procedure exhibits then a BY-like behavior, even though you specified no BY statement. This behavior enables you to distinguish the simulation tasks that depend on models in the different store BY groups.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## COORDINATES Statement

**COORDINATES** *coordinate-variables* ;

The two options in the COORDINATES statement give the name of the variables in the DATA= data set that contains the values of the  $x$  and  $y$  coordinates of the conditioning data. You must specify the COORDINATES statement when you specify an input data set with the DATA= option in the PROC SIM2D statement.

Only one COORDINATES statement is allowed, and it is applied to all SIMULATE statements that have the VAR= specification. In other words, it is assumed that all the VAR= variables in all SIMULATE statements have the same  $x$  and  $y$  coordinates.

You can abbreviate the COORDINATES statement as COORD.

**XCOORD**=(*variable-name*)

**XC**=(*variable-name*)

gives the name of the variable that contains the  $x$  coordinate of the data in the DATA= data set.

**YCOORD**=(*variable-name*)

**YC=(variable-name)**

gives the name of the variable that contains the y coordinate of the data locations in the **DATA=** data set.

---

## GRID Statement

**GRID** *grid-options* </ option > ;

The GRID statement specifies the grid of spatial locations at which to perform the simulations. A single GRID statement is required and is applied to all **SIMULATE** statements. Specify the grid in one of the following three ways:

- Specify the *x* and *y* coordinates explicitly for a grid in two dimensions.
- Specify the **NPTS=** option in addition to the *x* and *y* coordinates to define a grid of individual points or in one dimension.
- Specify the coordinates by using a SAS data set for a grid of individual points or in one dimension.

The GRID statement has the following *grid-options*:

**NPTS=number**

**NPTS=ALL**

controls specification of a grid in one dimension or a grid of individual simulation locations.

When you specify the **NPTS=number** option and the coordinates of two points in the **GRIDDATA=** data set or in both the **X=** and **Y=** options, you request a linear simulation grid. Its direction is across the line defined by the specified points. The grid size is equal to the *number* of points that you specify in the **NPTS=** option, where *number*  $\geq 2$ .

When you specify the **NPTS=ALL** option and the coordinates for any number of points in the **GRIDDATA=** data set or in each of the **X=** and **Y=** options, the **SIM2D** procedure performs simulation only at the specified individual locations. Use the **NPTS=ALL** option to examine a set of individual points anywhere on the **XY** plane or to specify a custom grid in one dimension.

If the number of *x* coordinates and the number of *y* coordinates in the **X=** and **Y=** options, respectively, are different, then the **NPTS=** option is ignored; in that case, a two-dimensional grid is used according to the specified **X=** and **Y=** options.

If you specify a simulation grid with any number of points other than two in the **GRIDDATA=** data set, then the option **NPTS=ALL** has the same effect as omitting the **NPTS=** option.

**X=number**

**X= $x_1, \dots, x_m$**

**X= $x_1$  to  $x_m$**

**X= $x_1$  to  $x_m$  by  $\delta x$**

specifies the *x* coordinate of the grid locations.

**Y=number**

**Y=y<sub>1</sub>, . . . , y<sub>m</sub>**

**Y=y<sub>1</sub> to y<sub>m</sub>**

**Y=y<sub>1</sub> to y<sub>m</sub> by  $\delta y$**

specifies the y coordinate of the grid locations.

Use the X= and Y= options of the GRID statement to specify a grid in one or two dimensions, or a grid of individual simulation locations.

For example, the following two GRID statements are equivalent:

```
GRID X=1, 2, 3, 4, 5 Y=0, 2, 4, 6, 8, 10;
```

```
GRID X=1 TO 5 Y=0 to 10 by 2;
```

In the following example, the first GRID statement produces a grid in two dimensions. The second statement produces simulation output only for the four individual points at the locations (1,0), (2,5), (3,7), and (4,10) on the XY plane.

```
GRID X=1 TO 4 Y=0, 5, 7, 10;
```

```
GRID X=1 TO 4 Y=0, 5, 7, 10 NPTS=ALL;
```

In the next example, the first GRID statement specifies a 2-by-2 grid in two dimensions. The second GRID statement specifies a linear grid of eight points. The grid is in the direction of the line defined by the specified points (2,8) and (3,5) on the XY plane and it extends between these two points.

```
GRID X=2, 3 Y=8, 5;
```

```
GRID x=2, 3 Y=8, 5 NPTS=8;
```

The last example shows a GRID statement that specifies a linear grid made of seven points across the Y axis. In this case, the syntax is sufficient to fully define a linear grid without the NPTS= option.

```
GRID X=5 Y=3 TO 9;
```

To specify grid locations from a SAS data set, you must provide the name of the data set and the variables that contain the values of the x and y coordinates.

**GRIDDATA=SAS-data-set**

**GDATA=SAS-data-set**

specifies a SAS data set that contains the x and y grid coordinates. Use the GRIDDATA= option of the GRID statement to specify a grid in one dimension or a grid of individual simulation locations.

**XCOORD**=(*variable-name*)

**XC**=(*variable-name*)

gives the name of the variable that contains the *x* coordinate of the grid locations in the **GRIDDATA**= data set.

**YCOORD**=(*variable-name*)

**YC**=(*variable-name*)

gives the name of the variable that contains the *y* coordinate of the grid locations in the **GRIDDATA**= data set.

You can specify the following option in the **GRID** statement after a slash (/):

**LABEL** <(suboption)> = (*character-list*)

specifies labels to tag grid points in simulation plots when you use grids in one dimension. You can specify one or more such labels as quoted strings in the *character-list*.

When the number of labels in the *character-list* exceeds the number of points in your grid, the labels in the list are used sequentially and any labels in excess are ignored. When the number of labels in the *character-list* is smaller than the number of points in your grid, the behavior is as follows:

- If an area map is included in the simulation plot, then blank labels are assigned to the remaining nonlabeled grid points on the map.
- For the simulation band and box plots, the coordinates of nonlabeled grid points are automatically assigned as their labels.

If the grid points are collinear and the horizontal axis displays distance, then two labels appear by default in the simulation plot. These are assigned to the first and the last points of the grid to help identify the ends of the linear grid segment on the plot map. This label pair is shown only when the plot includes an area map. Specifically, the two labels appear when you request simulation band plots, or simulation box plots for which you specify the **SIM(SHOWD)** suboption, if applicable. The two labels do not appear if you specify explicitly the **NOMAP** suboption in the **PLOTS=SIM** option.

The two labels have default values, unless you choose to specify your own labels with the **LABEL**= option. If you specify more than two labels in the *character-list* under these conditions, then only the first and last labels in the list are used; any additional labels in between are ignored.

The **LABEL**= option has the following *suboption*:

#### **ALL**

specifies that all individual points in the grid are assigned sequentially the labels you specify in the **LABEL(ALL)**= option when the **SIM(SHOWD)** suboption is applicable and specified in a simulation box plot. In all other cases, the **ALL** suboption is ignored.

The **ALL** suboption enables you to override the default behavior when the **SIM(SHOWD)** suboption is specified (the default behavior is to display labels only for the first and last grid points). As a result, you can use the **ALL** suboption to label grid grid points in both conditional and unconditional simulation tasks regardless of whether you specify the **NOMAP** suboption in the **PLOTS=SIM** option.

The **LABEL**= option is ignored when you produce simulation plots of grids in two dimensions.

---

## ID Statement

**ID** *variable* ;

The ID statement specifies which variable to include for identification of the observations in the labels and tool tips of the **OBSERVATIONS** plot and the tool tips of the **SIM** plot. The ID statement has an effect only when you perform conditional simulation.

In the SIM2D procedure you can specify only one ID variable in the ID statement. If no ID statement is given, then PROC SIM2D uses the observation number in the plots.

---

## RESTORE Statement

**RESTORE IN=***store-name* </ *option*> ;

The RESTORE statement specifies an item store that provides spatial correlation model input for the PROC SIM2D simulation tasks. An item store is a binary file defined by the SAS System. You cannot modify the contents of an item store. The SIM2D procedure can use only item stores created by PROC VARIOGRAM.

Item stores enable you to use saved correlation models without having to repeat specification of these models in the **SIMULATE** statement. In principle, an item store contains the chosen model from a model fitting process in PROC VARIOGRAM. If more than one model form is fitted, then all successful fits are included in the item store. In this case, you can choose any of the available models to use for simulation with the **STORESELECT(MODEL=)** option in the **SIMULATE** statement. Successfully fitted models might include questionable fits, which are so flagged when you specify the **INFO** option to display model names.

The *store-name* is a usual one- or two-level SAS name, as for SAS data sets. If you specify a one-level name, then the item store resides in the WORK library and is deleted at the end of the SAS session. Since item stores are often used for postprocessing tasks, typical usage specifies a two-level name of the form *libname.membername*.

When you specify the RESTORE statement, the default output contains some general information about the input item store. This information includes the store name, label (if assigned), the data set that was used to create the store, BY group information, the procedure that created the store, and the creation date.

You can specify the following option in the RESTORE statement after a slash (/):

**INFO** <( *info-options* )>

specifies that additional information about the input item store be printed. This information is provided in two ODS tables. One table displays the variables in the item store, in addition to the mean and standard deviation for each of them. These statistics are based on the observations that were used to produce the store results. The second table shows the model on top of the list of all fitted models for each direction angle in the item store. The INFO option has the following *info-options*:

### DETAILS

#### DET

specifies that more detailed information be displayed about the input item store. This option produces the full list of models for each direction angle in the item store, in addition to the model equivalence class. For more information about classes of equivalence, see the section

“Classes of Equivalence” on page 8634 in the VARIOGRAM procedure. The DETAILS option is ignored if the input item store contains information about a single fitted model.

### ONLY

specifies that only information about the input item store without any simulation tasks be displayed.

Each variable in an item store has a mean value that is passed to PROC SIM2D and used in simulations. If the mean in the item store is a missing value, then a zero mean is used by default. Specify the “MEAN Statement” on page 7406MEAN statement to override the mean information in the item store. For example, if you want to use only the correlation model in the item store and exclude the accompanying mean, then explicitly specify a zero mean in the “MEAN Statement” on page 7406MEAN statement.

When you specify an input item store with the RESTORE statement in PROC SIM2D, all the DATA= input data set variables must match input item store variables. If there are BY groups in the input DATA= set or in the input RESTORE variables, then PROC SIM2D handles the different cases as follows:

- If both PROC SIM2D has BY groups and the RESTORE statement has BY groups, then the analysis variables must match. This matching assumes implicitly that in each BY group of PROC SIM2D and the item store, the corresponding set of observations and correlation model comes from the same random field. This assumption is valid if you use the same data set, first in PROC VARIOGRAM to fit a model and save it in the item store, and then in PROC SIM2D to run simulations with the resulting correlation models.
- If PROC SIM2D has BY groups but the item store does not, then the item store is accepted only if the procedure and the item store analysis variables match. In this case, the same item store model choice iterates across the BY groups of the input data. You are advised to proceed with caution: each BY group in the input DATA= set corresponds to a different realization of a random field. Hence, by using the same correlation model for simulation purposes, you implicitly assume that all these different realizations are instances of the same random field.
- If PROC SIM2D has an input DATA= set and no BY groups but the item store has BY groups, then the item store is rejected
- If PROC SIM2D has no input DATA= set and the item store has BY groups, then PROC SIM2D runs unconditional simulations for the models in the store BY groups. See also the BY statement for more about the behavior in this case.

---

## SIMULATE Statement

**SIMULATE** *simulate-options* ;

The SIMULATE statement specifies details on the simulation and the covariance model used in the simulation. You can specify the following *simulate-options* with a SIMULATE statement, which can be abbreviated by SIM.

Table 85.3 summarizes the options available in the SIMULATE statement.

**Table 85.3** SIMULATE Statement Options

| Option                                | Description                                               |
|---------------------------------------|-----------------------------------------------------------|
| <b>Simulate-Options</b>               |                                                           |
| NUMREAL=                              | Specifies the number of realizations to produce           |
| VAR=                                  | Specifies the conditioning variable                       |
| <b>Covariance Model Specification</b> |                                                           |
| ANGLE=                                | Specifies the angle of the major axis                     |
| FORM=                                 | Specifies the functional form                             |
| MDATA=                                | Specifies the input data set containing parameter values  |
| NUGGET=                               | Specifies the nugget effect for the model                 |
| RANGE=                                | Specifies the range parameter                             |
| RATIO=                                | Specifies the ratio of the minor axis to the major axis   |
| SCALE=                                | Specifies the scale (or <i>sill</i> ) parameter           |
| SEED=                                 | Specifies the seed to use for the random number generator |
| SINGULAR=                             | Gives the singularity criterion                           |
| SMOOTH=                               | Specifies the smoothness parameter                        |
| STORESELECT                           | Uses information from an input item store for prediction  |

**NUMREAL=***number*

**NUMR=***number*

**NR=***number*

specifies the number of realizations to produce for the spatial process specified by the covariance model. As a result, the number of observations in the **OUTSIM=** data set contributed by a given **SIMULATE** statement is the product of the **NUMREAL=** value and the number of grid points. This can cause the **OUTSIM=** data set to become large even for moderate values of the **NUMREAL=** option.

**VAR=**(*variable-name*)

specifies the single numeric variable used as the conditioning variable in the simulation. In other words, the simulation is conditional on the values of the **VAR=** variable found in the **DATA=** data set. If you omit the **VAR=** option or if all observations of the **VAR=** variable are missing values, then the simulation is *unconditional*. Since multiple **SIMULATE** statements are allowed, you can perform both unconditional and conditional simulations with a single **PROC SIM2D** statement.

### Covariance Model Specification

You can specify a semivariogram or covariance model in three ways:

- You specify the required parameters **SCALE**, **RANGE**, **FORM**, and **SMOOTH** (if you specify the **MATERN** form), and possibly the optional parameters **NUGGET**, **ANGLE**, and **RATIO**, explicitly in the **SIMULATE** statement.
- You specify an **MDATA=** data set. This data set contains variables that correspond to the required parameters **SCALE**, **RANGE**, **FORM**, and **SMOOTH** (if you specify the **MATERN** form), and, optionally, variables for the **NUGGET**, **ANGLE**, and **RATIO** parameters.

- You can specify an input item store in the **RESTORE** statement. The item store contains one or more correlation models for one or more direction angles. You can specify these models in the **STORESELECT** option of the **SIMULATE** statement to run a simulation.

The three methods are mutually exclusive: you specify all parameters explicitly, they are all are read from the **MDATA=** data set, or you select a model and its parameters from an input item store. The following *simulate-options* are related to model specification:

**ANGLE=***angle*

**ANGLE=**(*angle1*, . . . , *anglek*)

specifies the angle of the major axis for anisotropic models, measured in degrees clockwise from the N–S axis. The default is **ANGLE=0**.

In the case of a nested semivariogram model with *k* nestings, you have the following two ways to specify the anisotropy major axis: you can specify only one *angle* which is then applied to all nested forms, or you can specify one angle for each of the *k* nestings.

**NOTE:** The syntax makes it possible to specify different angles for different forms of the nested model, but this practice is rarely used.

**FORM=***form*

**FORM=**(*form1*, . . . , *formk*)

specifies the functional form (type) of the semivariogram model. Use the syntax with the single *form* to specify a non-nested model. Use the syntax with forms *form<sub>i</sub>*, *i* = 1, . . . , *k*, to specify a nested model with *k* structures. Each of the forms can be any of the following:

**CUBIC | EXPONENTIAL | GAUSSIAN | MATERN |  
PENTASPHERICAL | SINEHOLEEFFECT | SPHERICAL**

**CUB | EXP | GAU | MAT | PEN | SHE | SPH**

specify the functional form (type).

For example, the syntax

**FORM=GAU**

specifies a model with a single Gaussian structure. Also, the syntax

**FORM= (EXP, SHE, MAT)**

specifies a nested model with an exponential, a sine hole effect, and a Matérn structure. Finally

**FORM= (EXP, EXP)**

specifies a nested model with two structures both of which are exponential.

**NOTE:** In the documentation, models are named either by using their full names or by using the first three letters of their structures. Also, the names of different structures in a nested model are separated by a hyphen (-). According to this convention, the previous examples illustrate how to specify a GAU, an EXP-SHE-MAT, and an EXP-EXP model, respectively, with the **FORM=** option.

All the supported model forms have two parameters specified by the **SCALE=** and **RANGE=** options, except for the MATERN model which has a third parameter specified by the **SMOOTH=** option. A **FORM=** value is required, unless you specify the **MDATA=** option or the **STORESELECT** option.

Computation of the MATERN covariance is numerically demanding. As a result, simulations that use Matérn covariance structures can be time-consuming.

#### **MDATA=SAS-data-set**

specifies the input data set that contains parameter values for the covariance or semivariogram model. The **MDATA=** option cannot be combined with any of the **FORM=** or **STORESELECT** options.

The **MDATA=** data set must contain variables named **SCALE**, **RANGE**, and **FORM**, and it can optionally contain variables **NUGGET**, **ANGLE**, and **RATIO**. If you specify the MATERN form, then you must also include a variable named **SMOOTH** in the **MDATA=** data set.

The **FORM** variable must be a character variable, and it can assume only the values allowed in the explicit **FORM=** syntax described previously. The **RANGE**, **SCALE** and **SMOOTH** variables must be numeric. The optional variables **ANGLE**, **RATIO**, and **NUGGET** must also be numeric if present.

The number of observations present in the **MDATA=** data set corresponds to the level of nesting of the covariance or semivariogram model. For example, to specify a non-nested model that uses a spherical covariance, an **MDATA=** data set might contain the following statements:

```
data mdl;
 input scale range form $;
 datalines;
 25 10 SPH
 ;
```

The PROC SIM2D statement to use the **MDATA=** specification is of the form shown in the following:

```
proc sim2d data=...;
 sim var=... mdata=mdl;
run;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```
proc sim2d data=...;
 sim var=... scale=25 range=10 form=sph;
run;
```

The following **MDATA=** data set is an example of an anisotropic nested model:

```
data md2;
 input scale range form $ nugget angle ratio smooth;
 datalines;
 20 8 SPH 5 35 .7 .
 12 3 MAT 5 0 .8 2.8
 4 1 GAU 5 45 .5 .
 ;
```

```
proc sim2d data=...;
 sim var=.... mdata=md2;
run;
```

This is equivalent to the following explicit specification of the covariance model parameters:

```
proc sim2d data=...;
 sim var=.... scale=(20,12,4) range=(8,3,1) form=(SPH,MAT,GAU)
 angle=(35,0,45) ratio=(.7,.8,.5) nugget=5 smooth=2.8;
run;
```

This example is somewhat artificial in that it is usually hard to detect different anisotropy directions and ratios for different nestings by using an experimental semivariogram. **NOTE:** The NUGGET variable value is the same for all nestings. This is always the case; the nugget effect is a single additive term for all models. For further details, see the section “[The Nugget Effect](#)” on page 3830 in the KRIGE2D procedure.

The example also shows that if you specify a MATERN form in the nested model, then the SMOOTH variable must be specified for all nestings in the MDATA= data set. You simply specify the SMOOTH value as missing for nestings other than MATERN.

The **SIMULATE** statement can be given a label. This is useful for identification in the **OUTSIM=** data set when multiple **SIMULATE** statements are specified. For example:

```
proc sim2d data=...;
 gauss1: sim var=.... form=gau;
 mean;
 gauss2: sim var=.... form gau;
 mean;
 exp1: sim var=.... form=exp;
 mean;
 exp2: sim var=.... form=exp;
 mean;
run;
```

In the **OUTSIM=** data set, the values “GAUSS1,” “GAUSS2,” “EXP1,” and “EXP2” for the LABEL variable help to identify the realizations that correspond to the four **SIMULATE** statements. If you do not provide a label for a **SIMULATE** statement, a default label of SIM $n$  is given, where  $n$  is the number of unlabeled **SIMULATE** statements seen so far.

#### **NUGGET=***number*

specifies the nugget effect for the model. This effect is due to a discontinuity in the semivariogram as determined by plotting the sample semivariogram (see the section “[The Nugget Effect](#)” on page 3830 in the KRIGE2D procedure for details). For models without any nugget effect, the NUGGET= option is left out. The default is NUGGET=0.

#### **RANGE=***range*

#### **RANGE=**(*range1, ..., rangek*)

specifies the range parameter in the semivariogram models. In the case of a nested semivariogram model with  $k$  nestings, you must specify a range for each nesting.

The range parameter is the divisor in the exponent in all supported models. It has the units of distance or distance squared for these models, and it is related to the correlation scale for the underlying spatial process.

See the section “[Theoretical Semivariogram Models](#)” on page 3823 in the KRIGE2D procedure for details about how the RANGE= values are determined.

**RATIO=***ratio*

**RATIO=**(*ratio1*, . . . , *ratio**k*)

specifies the ratio of the length of the minor axis to the length of the major axis for anisotropic models. The value of the RATIO= option must be between 0 and 1. In the case of a nested semivariogram model with *k* nestings, you can specify a ratio for each nesting. The default is RATIO=1.

**SCALE=***scale*

**SCALE=**(*scale1*, . . . , *scale**k*)

specifies the scale (or *sill*) parameter in semivariogram models. In the case of a nested semivariogram model with *k* nestings, you must specify a scale for each nesting. The scale parameter is the multiplicative factor in all supported models; it has the same units as the variance of the VAR= variable.

See the section “[Theoretical Semivariogram Models](#)” on page 3823 in the KRIGE2D procedure for details about how the SCALE= values are determined.

**SEED=***seed-value*

specifies the seed to use for the random number generator. The SEED= option *seed-value* has to be an integer.

**SINGULAR=***number*

gives the singularity criterion for solving the set of linear equations involved in the computation of the mean and covariance of the conditional distribution associated with a given SIMULATE statement. The larger the value of the SINGULAR= option, the easier it is for the covariance matrix system to be declared singular. The default is SINGULAR=1E-8.

For more details about the use of the SINGULAR= option, see the section “[Computational and Theoretical Details of Spatial Simulation](#)” on page 7408.

**SMOOTH=***smooth*

**SMOOTH=**(*smooth1*, . . . , *smooth**m*)

specifies the smoothness parameter  $\nu > 0$  in the Matérn type of semivariance structures. The special case  $\nu = 0.5$  is equivalent to the exponential model, whereas  $\nu \rightarrow \infty$  gives the Gaussian model.

When you specify *m* different MATERN forms in the FORM= option, you must also provide *m* smoothness values in the SMOOTH option. If you must specify more than one smoothness value, the values are assigned sequentially to the MATERN nestings in the order the nestings are specified. If you specify more smoothness values than necessary, then values in excess are ignored.

**STORESELECT**(*sselect-options*)

**SSEL**(*sselect-options*)

specifies that information from an input item store be used for the prediction. You cannot combine the STORESELECT option with any of the FORM= or MDATA= options. The STORESELECT option has the following *sselect-options*:

**TYPE=***field-type*

specifies whether to perform isotropic or anisotropic simulation. You can choose the *field-type* from one of the following:

**ISO**

specifies isotropic field for the simulation.

**ANIGEO | GEO**

specifies a field with geometric anisotropy for the simulation.

**ANIZON**(*zonal-form1*, . . . , *zonal-formn*)**ZON**(*zonal-form1*, . . . , *zonal-formn*)

specifies a field with zonal anisotropy for the simulation. Each *zonal-formi*,  $i = 1, \dots, n$ , can be any of the following:

**CUB | EXP | GAU | MAT | PEN | SHE | SPH**

specify a form for the simulation.

Each *zonal-formi*,  $i = 1, \dots, n$ , is a structure in the purely zonal component of the correlation model in the direction angle of the minor anisotropy axis. For this reason, when you specify the TYPE=ANIZON suboption you must also specify the nonzonal component of the correlation model in the MODEL= suboption of the STORESELECT option. Assume the nonzonal component has  $k$  structures; these are common across all directions and each one has the same scale in all directions. In that sense, you use the TYPE=ANIZON suboption to specify only the  $n$  zonal anisotropy structures of an input store ( $k + n$ )-structure nested model in the direction angle of the minor anisotropy axis.

Given this specification,  $k + n$  must be up to the maximum number of nested model structures that is supported by the item store. See also the MODEL= suboption of the STORESELECT option.

In conclusion, you can use an input item store for prediction with zonal anisotropy if you know that every structure in the nonzonal model component has the same scale across all directions. When this condition does not apply for the item store models, specify the model parameters explicitly in the SIMULATE statement.

Computation of the MATERN covariance is numerically demanding. As a result, predictions that use Matérn covariance structures can be time-consuming.

If you omit the TYPE= option, the default behavior is TYPE=ISO when the input item store contains information for only one angle or for the omnidirectional case. If you specify an item store with information for more than one direction, then the default behavior is TYPE=ANIGEO.

When you specify TYPE=ISO to request isotropic analysis in the presence of an item store with information for multiple directions, you must specify the ANGLEID= suboption of the STORESELECT option with one argument. This argument specifies which of the direction angles information to use for the isotropic analysis.

When you indicate the presence of anisotropy with the TYPE=ANIGEO or TYPE=ANIZON suboptions of the STORESELECT option, the following conditions apply:

- You must specify the ANGLEID= suboption of the STORESELECT option to designate the major and minor anisotropy axes. See the ANGLEID= suboption of the STORESELECT option for details.

- – For TYPE=ANIGEO, ensure that you have the same scale in all anisotropy directions.
- For TYPE=ANIZON, ensure that the nonzonal component scale is the same in all anisotropy directions.

If you import a nested model, these rules also apply to each one of the nested structures.

- Model ranges in the major anisotropy axis must be longer than ranges in the minor anisotropy axis.
- Any Matérn covariance structure must maintain its smoothness parameter value in all anisotropy directions.

**ANGLEID=***angleid1*

**ANGLEID=**(*angleid1*, *angleid2*)

specifies which direction angles in the input item store be used for simulation. The angles are identified by the corresponding number in the AngleID column of the “Store Models Information” table, or by the AngleID parameter in the table title when you specify the **INFO(DETAILS)** option in the **RESTORE** statement.

If you request isotropic prediction in the **TYPE=** suboption of the **STORESELECT** option and the item store has omnidirectional contents or information about only one angle, then the **ANGLEID=** option is ignored. The simulation input comes from the omnidirectional information. In the case of a single angle, you still perform isotropic simulation and the model parameters are provided by the model in the single direction angle in the item store. However, if the item store contains information for more than one angle, then you must specify one angle ID in *angleid1*. The model information from the corresponding angle is then used in your isotropic simulation.

When you specify an anisotropic simulation in the **TYPE=** option of the **STORESELECT** option, you need to have information about two perpendicular direction angles. One of them is the major and the other is the minor anisotropy axis. You must always specify the major anisotropy axis angle ID in *angleid1* and the minor anisotropy axis angle ID in *angleid2*. This means that the range parameters of the model forms in the angle designated by the *angleid1* need to be larger than the corresponding ranges of the forms in the angle designated by the *angleid2*. Conveniently, if the item store has only two angles, then you only need to specify the ID *angleid1* of the major anisotropy axis angle. If the item store has only one angle, then you cannot perform anisotropic simulation with input from the item store.

**NOTE:** You can perform geometric anisotropic analysis even if the item store does not contain information about a direction that is perpendicular to the one specified by *angleid1*. This is possible due to the geometry of the ellipse. In particular, when you specify the major axis with *angleid1* and an angle ID for a second direction with a corresponding smaller range, then PROC SIM2D automatically computes the minor anisotropy axis range and the necessary range ratio parameter.

Anisotropic analysis is not possible when you specify instances of the same angle in the input item store. It is possible that PROC VARIOGRAM produces an item store where two or more directions can be the same if their corresponding correlation models were obtained for different angle tolerances or bandwidths in the VARIOGRAM procedure. Consequently, you cannot specify anisotropic simulation if the input store contains only two angles that are the same or if you specify *angleid1* and *angleid2* that correspond to equal angles.

**MODEL=***form*

**MODEL=**(*form1*, . . . , *formk*)

specifies the theoretical semivariogram model selection to use for the simulation. Use any combination of one, two, or three forms to describe a model in the input item store because up to three nested structures are supported. Each *form<sub>i</sub>*,  $i = 1, \dots, k$ , can be any of the following:

**CUB | EXP | GAU | MAT | PEN | SHE | SPH**

specify the selection model.

Computation of the MATERN covariance is numerically demanding. As a result, simulations that use Matérn covariance structures can be time-consuming.

All fitted models that are stored in the input item store contain information about their component parameters and also about the nugget effect if any. The SIM2D procedure retrieves this information when you make a model selection in the MODEL= option, and you do not need to individually specify a nugget effect or any other parameter of the model.

By default, the model that is ranked first among the models for a given angle in the item store is used for the simulation task. If more than one model is available in the item store, then you can specify the MODEL= option to use a different model for the simulation.

In an anisotropic simulation, the default selection is the model that is ranked first in the direction angle of the major anisotropy axis. If you specify the TYPE=ANIGEO option, then a model that consists of identical structures needs to be present in the selected minor anisotropy axis angle in the item store. If you specify the TYPE=ANIZON option, then a model with the exact same first  $k$  structures must be present in the selected minor anisotropy axis angle, and it must feature at least one more structure as a zonal component. The zonal component is specified separately in the TYPE=ANIZON suboption of the STORESELECT option. Consequently, remember that in zonal anisotropy the MODEL= suboption designates only the nonzonal component of the correlation model in the minor anisotropy axis direction. In all, if there are  $k$  common structures and  $n$  structures in the purely zonal component, then  $k + n$  must be up to the maximum number of nested model structures that is supported by the item store.

**SVAR=***store-var*

**SVAR=**(*store-varlist*)

specifies one *store-var* item store variable or a list *store-varlist* of variables that are present in the item store. This option selects one or more item store variables whose correlation models you want to use in the current simulation task.

If you are performing a conditional simulation, then PROC SIM2D searches the input item store for the variable that is specified in the VAR= option of the SIMULATE statement. Then, the procedure selects the appropriate correlation model for the task. In this case, if you specify the SVAR= option, it is ignored. However, when you request an unconditional simulation and specify input from an item store, then you must also use SVAR= to specify a source for your correlation model.

In comparison to the other two ways of specifying a correlation model in PROC SIM2D, the STORESELECT option is quite different because you can avoid explicit specification of all parameter values of a model. When you specify the STORESELECT option, then the corresponding scale, range, nugget effect, and smoothness (if appropriate) parameter values are invoked as saved attributes of the model that you select from the item store.

In the case of anisotropy, you specify the angles indirectly with the `ANGLEID=` option of the `STORESELECT` option, and the ratios are computed implicitly by using the selected model ranges. Explore how to specify valid anisotropical models imported from an input item store with the two examples that follow.

In the first example, assume the input item store `lnStoreGeo` contains exponential models in the angles  $\theta_1 = 0^\circ$ ,  $\theta_2 = 45^\circ$ , and  $\theta_3 = 90^\circ$ . You know in advance that all models have the same scale  $c_1 = c_2 = c_3$  across these directions and that the respective ranges are  $a_1 = 15$ ,  $a_2 = 20$ , and  $a_3 = 25$  in distance units. Hence, you have a case of geometric anisotropy where the major anisotropy axis is in the direction of angle  $\theta_3$  and the minor anisotropy axis is in the direction of angle  $\theta_1$ . The following statements in PROC SIM2D use the information in the item store `lnStoreGeo` to perform simulation under the assumption of geometric anisotropy:

```
proc sim2d data=...;
 restore in=lnStoreGeo;
 simulate storeselect(model=exp type=anigeo angleid=(3,1));
run;
```

For the second example, assume a case of zonal anisotropy. Consider the input item store `lnStoreZon`, which contains models in the two angles,  $\theta_1 = 30^\circ$  and  $\theta_2 = 120^\circ$ . Specifically, in  $\theta_1$  you have an exponential-spherical model: the exponential structure has scale  $c_{1E} = 3$  and range  $a_{1E} = 10$ ; the spherical structure has scale  $c_{1S} = 1$  and range  $a_{1S} = 6$ . In direction  $\theta_2$  you have an exponential model with scale  $c_{1E} = 3$  and range  $a_{1E} = 12$ . Hence, the zonal anisotropy major axis is in the direction of the lowest total variance, which is in angle  $\theta_2$ ; then, the minor axis is in the direction of angle  $\theta_1$ . The following statements in PROC SIM2D use the information in the store `lnStoreZon` to perform simulation under the assumption of zonal anisotropy:

```
proc sim2d data=...;
 restore in=lnStoreZon;
 simulate storeselect(model=exp type=anizon(sph) angleid=(2,1));
run;
```

---

## MEAN Statement

**MEAN** *spec1, ..., spec6* ;

**MEAN QDATA**=*SAS-data-set* **CONST**=*var1* **CX**=*var2* **CY**=*var3*  
**CXX**=*var4* **CYY**=*var5* **CXY**=*var6* ;

**MEAN QDATA**=*SAS-data-set* ;

A mean function  $\mu(s)$  that is a quadratic in the coordinates can be written as

$$\mu(s) = \mu(x, y) = \beta_0 + \beta_1 x + \beta_2 y + \beta_3 x^2 + \beta_4 y^2 + \beta_5 xy$$

The MEAN statement specifies the quadratic surface to use as the mean function for the simulated SRF. There are two ways to specify the MEAN statement. The MEAN statement allows the specification of the coefficients  $\beta_0, \dots, \beta_5$  either explicitly or through a QDATA= data set.

An example of an explicit specification is the following:

```
mean 1.4 + 2.5*x + 3.6*y + 0.47*x*x + 0.58*y*y + 0.69*x*y;
```

In this example, all terms have a nonzero coefficient. Any term with a zero coefficient is simply left out of the specification. For example,

```
mean 1.4;
```

is a valid quadratic form with all terms having zero coefficients except the constant term.

An equivalent way of specifying the mean function is through the QDATA= data set. For example, the MEAN statement

```
mean 1.4 + 2.5*x + 3.6*y + 0.47*x*x + 0.58*y*y + 0.69*x*y;
```

can be alternatively specified by the following DATA step and MEAN statement:

```
data q1;
 input c1 c2 c3 c4 c5 c6;
 datalines;
 1.4 2.5 3.6 0.47 0.58 0.69
 ;

proc sim2d data=...;
 simulate ...;
 mean qdata=q1 const=c1 cx=c2 cy=c3 cxx=c4 cyy=c5 cxy=c6;
run;
```

The QDATA= data set specifies the data set containing the coefficients. The parameters CONST=, CX=, CY=, CXX=, CYY=, and CYX= specify the variables in the QDATA= data set that correspond to the constant, linear x, linear y, and so on. For any coefficient not specified in this list, the QDATA= data set is checked for the presence of variables with default names of CONST, CX, CY, CXX, CYY, and CXY. If these variables are present, their values are taken as the corresponding coefficients. Hence, you can rewrite the previous example as follows:

```
data q1;
 input const cx cy cxx cyy cxy;
 datalines;
 1.4 2.5 3.6 0.47 0.58 0.69
 ;

proc sim2d data=...;
 simulate ...;
 mean qdata=q1;
run;
```

If a given coefficient does not appear in the list or in the data set with the default name, a value of zero is assumed.

If you run a simulation task with input from a [RESTORE](#) statement, then by default the simulation uses the mean of the item store variable in the simulation. You can override this default behavior if you explicitly specify the MEAN statement with a different mean function.

---

## Details: SIM2D Procedure

---

### Computational and Theoretical Details of Spatial Simulation

---

#### Introduction

There are a number of approaches to simulating spatial random fields or, more generally, simulating sets of dependent random variables. These include sequential indicator methods, turning bands, and the Karhunen-Loeve expansion. See Christakos (1992, Chapter 8) and Deutsch and Journel (1992, Chapter V) for details.

A particularly simple method available for Gaussian spatial random fields is the LU decomposition method. This method is computationally efficient. For a given covariance matrix, the  $LU = \mathbf{LL}'$  decomposition is computed once, and the simulation proceeds by repeatedly generating a vector of independent  $N(0, 1)$  random variables and multiplying by the  $\mathbf{L}$  matrix.

One problem with this technique is memory requirements; memory is required to hold the full data and grid covariance matrix in core. While this is especially limiting in the three-dimensional case, you can use PROC SIM2D, which handles only two-dimensional data, for moderately sized simulation problems.

#### Theoretical Development

It is a simple matter to produce an  $N(0, 1)$  random number, and by stacking  $k$   $N(0, 1)$  random numbers in a column vector, you can obtain a vector with independent standard normal components  $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$ . The meaning of the terms *independence* and *randomness* in the context of a deterministic algorithm required for the generation of these numbers is subtle; see Knuth (1981, Chapter 3) for details.

Rather than  $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$ , what is required is the generation of a vector  $\mathbf{Z} \sim N_k(\mathbf{0}, \mathbf{C})$ —that is,

$$\mathbf{Z} = \begin{bmatrix} Z_1 \\ Z_2 \\ \vdots \\ Z_k \end{bmatrix}$$

with covariance matrix

$$\mathbf{C} = \begin{pmatrix} C_{11} & C_{12} & \cdots & C_{1k} \\ C_{21} & C_{22} & \cdots & C_{2k} \\ & \ddots & & \\ C_{k1} & C_{k2} & \cdots & C_{kk} \end{pmatrix}$$

If the covariance matrix is symmetric and positive definite, it has a Cholesky root  $\mathbf{L}$  such that  $\mathbf{C}$  can be factored as

$$\mathbf{C} = \mathbf{LL}'$$

where  $\mathbf{L}$  is lower triangular. See Ralston and Rabinowitz (1978, Chapter 9, Section 3-3) for details. This vector  $\mathbf{Z}$  can be generated by the transformation  $\mathbf{Z} = \mathbf{LW}$ . Here is where the assumption of a Gaussian SRF is crucial. When  $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$ , then  $\mathbf{Z} = \mathbf{LW}$  is also Gaussian. The mean of  $\mathbf{Z}$  is

$$E(\mathbf{Z}) = \mathbf{L}(E(\mathbf{W})) = \mathbf{0}$$

and the variance is

$$\text{Var}(\mathbf{Z}) = \text{Var}(\mathbf{LW}) = E(\mathbf{LW}\mathbf{W}'\mathbf{L}') = \mathbf{L}E(\mathbf{W}\mathbf{W}')\mathbf{L}' = \mathbf{L}\mathbf{L}' = \mathbf{C}$$

Consider now an SRF  $Z(s), s \in D \subset \mathcal{R}^2$ , with spatial covariance function  $C(\mathbf{h})$ . Fix locations  $s_1, s_2, \dots, s_k$ , and let  $\mathbf{Z}$  denote the random vector

$$\mathbf{Z} = \begin{bmatrix} Z(s_1) \\ Z(s_2) \\ \vdots \\ Z(s_k) \end{bmatrix}$$

with corresponding covariance matrix

$$\mathbf{C}_Z = \begin{pmatrix} C(\mathbf{0}) & C(s_1 - s_2) & \cdots & C(s_1 - s_k) \\ C(s_2 - s_1) & C(\mathbf{0}) & \cdots & C(s_2 - s_k) \\ & & \ddots & \\ C(s_k - s_1) & C(s_k - s_2) & \cdots & C(\mathbf{0}) \end{pmatrix}$$

Since this covariance matrix is symmetric and positive definite, it has a Cholesky root, and the  $Z(s_i), i = 1, \dots, k$ , can be simulated as described previously. This is how the SIM2D procedure implements unconditional simulation in the zero-mean case. More generally,

$$Z(s) = \mu(s) + \varepsilon(s)$$

where  $\mu(s)$  is a quadratic form in the coordinates  $s = (x, y)$  and the  $\varepsilon(s)$  is an SRF that has the same covariance matrix  $\mathbf{C}_Z$  as previously. In this case, the  $\mu(s_i), i = 1, \dots, k$ , is computed once and added to the simulated vector  $\varepsilon(s_i), i = 1, \dots, k$ , for each realization.

For a conditional simulation, this distribution of

$$\mathbf{Z} = \begin{bmatrix} Z(s_1) \\ Z(s_2) \\ \vdots \\ Z(s_k) \end{bmatrix}$$

must be conditioned on the observed data. The relevant general result concerning conditional distributions of multivariate normal random variables is the following. Let  $\mathbf{X} \sim N_m(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , where

$$\mathbf{X} = \begin{bmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \end{bmatrix}$$

$$\boldsymbol{\mu} = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}$$

$$\boldsymbol{\Sigma} = \begin{pmatrix} \boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{pmatrix}$$

The subvector  $\mathbf{X}_1$  is  $k \times 1$ ,  $\mathbf{X}_2$  is  $n \times 1$ ,  $\boldsymbol{\Sigma}_{11}$  is  $k \times k$ ,  $\boldsymbol{\Sigma}_{22}$  is  $n \times n$ , and  $\boldsymbol{\Sigma}_{12} = \boldsymbol{\Sigma}'_{21}$  is  $k \times n$ , with  $k + n = m$ . The full vector  $\mathbf{X}$  is partitioned into two subvectors,  $\mathbf{X}_1$  and  $\mathbf{X}_2$ , and  $\boldsymbol{\Sigma}$  is similarly partitioned into covariances and cross covariances.

With this notation, the distribution of  $\mathbf{X}_1$  conditioned on  $\mathbf{X}_2 = \mathbf{x}_2$  is  $N_k(\tilde{\boldsymbol{\mu}}, \tilde{\boldsymbol{\Sigma}})$ , with

$$\tilde{\boldsymbol{\mu}} = \boldsymbol{\mu}_1 + \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}(\mathbf{x}_2 - \boldsymbol{\mu}_2)$$

and

$$\tilde{\boldsymbol{\Sigma}} = \boldsymbol{\Sigma}_{11} - \boldsymbol{\Sigma}_{12}\boldsymbol{\Sigma}_{22}^{-1}\boldsymbol{\Sigma}_{21}$$

See Searle (1971, pp. 46–47) for details. The correspondence with the conditional spatial simulation problem is as follows. Let the coordinates of the observed data points be denoted  $\tilde{s}_1, \tilde{s}_2, \dots, \tilde{s}_n$ , with values  $\tilde{z}_1, \tilde{z}_2, \dots, \tilde{z}_n$ . Let  $\tilde{\mathbf{Z}}$  denote the random vector

$$\tilde{\mathbf{Z}} = \begin{bmatrix} Z(\tilde{s}_1) \\ Z(\tilde{s}_2) \\ \vdots \\ Z(\tilde{s}_n) \end{bmatrix}$$

The random vector  $\tilde{\mathbf{Z}}$  corresponds to  $\mathbf{X}_2$ , while  $\mathbf{Z}$  corresponds to  $\mathbf{X}_1$ . Then  $(\mathbf{Z} \mid \tilde{\mathbf{Z}} = \tilde{\mathbf{z}}) \sim N_k(\tilde{\boldsymbol{\mu}}, \tilde{\mathbf{C}})$  as in the previous distribution. The matrix

$$\tilde{\mathbf{C}} = \mathbf{C}_{11} - \mathbf{C}_{12}\mathbf{C}_{22}^{-1}\mathbf{C}_{21}$$

is again positive definite, so a Cholesky factorization can be performed.

The dimension  $n$  for  $\tilde{\mathbf{Z}}$  is simply the number of nonmissing observations for the **VAR=** variable; the values  $\tilde{z}_1, \tilde{z}_2, \dots, \tilde{z}_n$  are the values of this variable. The coordinates  $\tilde{s}_1, \tilde{s}_2, \dots, \tilde{s}_n$  are also found in the **DATA=** data set, with the variables that correspond to the  $x$  and  $y$  coordinates identified in the **COORDINATES** statement. **NOTE:** All **VAR=** variables use the same set of conditioning coordinates; this fixes the matrix  $\mathbf{C}_{22}$  for all simulations.

The dimension  $k$  for  $\mathbf{Z}$  is the number of grid points specified in the **GRID** statement. Since there is a single **GRID** statement, this fixes the matrix  $\mathbf{C}_{11}$  for all simulations. Similarly,  $\mathbf{C}_{12}$  is fixed.

The Cholesky factorization  $\tilde{\mathbf{C}} = \mathbf{L}\mathbf{L}'$  is computed once, as is the mean correction

$$\tilde{\boldsymbol{\mu}} = \boldsymbol{\mu}_1 + \mathbf{C}_{12}\mathbf{C}_{22}^{-1}(\mathbf{x}_2 - \boldsymbol{\mu}_2)$$

The means  $\boldsymbol{\mu}_1$  and  $\boldsymbol{\mu}_2$  are computed using the grid coordinates  $s_1, s_2, \dots, s_k$ , the data coordinates  $\tilde{s}_1, \tilde{s}_2, \dots, \tilde{s}_n$ , and the quadratic form specification from the **MEAN** statement. The simulation is now performed exactly as in the unconditional case. A  $k \times 1$  vector of independent standard  $N(0, 1)$  random variables is generated and multiplied by  $\mathbf{L}$ , and  $\tilde{\boldsymbol{\mu}}$  is added to the transformed vector. This is repeated  $N$  times, where  $N$  is the value specified for the **NR=** option.

## Computational Details

In the computation of  $\tilde{\boldsymbol{\mu}}$  and  $\boldsymbol{\Sigma}$  described in the previous section, the inverse  $\boldsymbol{\Sigma}_{22}^{-1}$  is never actually computed; an equation of the form

$$\boldsymbol{\Sigma}_{22}\mathbf{A} = \mathbf{B}$$

is solved for  $\mathbf{A}$  by using a modified Gaussian elimination algorithm that takes advantage of the fact that  $\boldsymbol{\Sigma}_{22}$  is symmetric with constant diagonal  $C_z(0)$  that is larger than all off-diagonal elements. The **SINGULAR=** option pertains to this algorithm. The value specified for the **SINGULAR=** option is scaled by  $C_z(0)$  before comparison with the pivot element.

### Memory Usage

For conditional simulations, the largest matrix held in core memory at any one time depends on the number of grid points and data points. Using the previous notation, the data-data covariance matrix  $\mathbf{C}_{22}$  is  $n \times n$ , where  $n$  is the number of nonmissing observations for the **VAR=** variable in the **DATA=** data set. The grid-data cross covariance  $\mathbf{C}_{12}$  is  $n \times k$ , where  $k$  is the number of grid points. The grid-grid covariance  $\mathbf{C}_{11}$  is  $k \times k$ . The maximum memory required at any one time for storing these matrices is

$$\max(k(k + 1), n(n + 1) + 2(n \times k)) \times \text{sizeof}(\text{double})$$

There are additional memory requirements that add to the total memory usage, but usually these matrix calculations dominate, especially when the number of grid points is large.

---

## Output Data Set

The **SIM2D** procedure produces a single output data set: the **OUTSIM=SAS-data-set**. The **OUTSIM=** data set contains all the needed information to uniquely identify the simulated values.

The **OUTSIM=** data set contains the following variables:

- **LABEL**, which is the label for the current **SIMULATE** statement
- **VARNAME**, which is the name of the conditioning variable for the current **SIMULATE** statement
- **MODSVAR**, which is the name of the input item store variable associated with the current correlation model in an unconditional simulation

- `_ITER_`, which is the iteration number within the current `SIMULATE` statement
- `GXC`, which is the  $x$  coordinate for the current grid point
- `GYC`, which is the  $y$  coordinate for the current grid point
- `SVALUE`, which is the value of the simulated variable

If you specify the `NARROW` option in the `PROC SIM2D` statement, the `LABEL` and `VARNAME` variables are not included in the `OUTSIM=` data set. This option is useful in the case where the number of data points, grid points, and realizations are such that they generate a very large `OUTSIM=` data set. The size of the `OUTSIM=` data set is reduced when these variables are not included.

In unconditional simulation tasks where no input data set is specified, the `VARNAME` variable is excluded from the `OUTSIM=` data set. In unconditional simulation tasks where you have specified an input data set, the `VARNAME` variable is included but given a missing value. In the case of mixed conditional and unconditional simulations (that is, when multiple `SIMULATE` statements are specified, among which one or more contain a `VAR=` specification and one or more have no `VAR=` specification), the `VARNAME` variable is included but is given a missing value for those observations that correspond to an unconditional simulation.

The `MODSVAR` variable is included in the `OUTSIM=` data set only when you specify an input item store with the `RESTORE` statement, and it indicates the presence of that store. This variable helps you identify the output of different unconditional simulations when the model input comes from an item store; it is not suggesting that a simulation task is conditioned upon it.

Specifically, the `MODSVAR` variable has a missing value for conditional simulation tasks. The variable also has a missing value for unconditional simulations for which you specify a correlation model explicitly, either with the `FORM=` option or with the `MDATA=` data set in the `SIMULATE` statement. In all other cases, the `MODSVAR` variable indicates the input item store variable that is associated with the store model used for the current unconditional simulation task.

---

## Displayed Output

In addition to the output data set, the `SIM2D` procedure produces output objects as well. The `SIM2D` procedure output objects are the following:

- a default “Number of Observations” table that displays the number of observations read from the input data set and the number of observations used in the analysis.
- a map that shows the spatial distribution of the observations of the current `VAR` variable in the `SIMULATE` statement, in the case of conditional simulations. The observations are displayed by default with circled markers whose color indicates the `VAR` value at the corresponding location.
- a default table for each `SIMULATE` statement that summarizes the simulation specifications.
- a default table for each `SIMULATE` statement that shows the covariance model parameters for the corresponding simulation.
- plots of simulation outcome at each point of the specified output grid or at specified individual locations. You can produce more than one of these plots for every `SIMULATE` statement with styles that you can specify by using the available suboptions of the `PLOTS=SIM` option.

- a “Store Info” table with basic information about the input item store. This table is produced by default when you specify the **RESTORE** statement.
- a “Store Variables Information” table that describes the analysis variables of an input item store. The table is produced by default when you specify an item store with the **RESTORE** statement.
- a “Store Models Information” table with detailed information about the models and direction angles that are contained in an input item store. The table is produced by default when you specify an item store with the **RESTORE** statement.

---

## ODS Table Names

Each table created by PROC SIM2D has a name associated with it, and you must use this name to reference the table when using ODS Graphics. These names are listed in [Table 85.4](#).

**Table 85.4** ODS Tables Produced by PROC SIM2D

| ODS Table Name                 | Description                                                   | Statement | Option         |
|--------------------------------|---------------------------------------------------------------|-----------|----------------|
| <a href="#">ModelInfo</a>      | Parameters of the covariance model used in current simulation | PROC      | Default output |
| <a href="#">NObs</a>           | Number of observations read and used                          | PROC      | Default output |
| <a href="#">SimuInfo</a>       | General information about the simulation                      | PROC      | Default output |
| <a href="#">StoreInfo</a>      | Input item store identity information                         | RESTORE   | Default output |
| <a href="#">StoreModelInfo</a> | Input item store direction angles and models information      | RESTORE   | INFO           |
| <a href="#">StoreVarInfo</a>   | Input item store variables and their statistics               | RESTORE   | INFO           |

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “[Statistical Graphics Using ODS.](#)”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “[Enabling and Disabling ODS Graphics](#)” on page 600 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “[A Primer on ODS Statistical Graphics](#)” on page 599 in Chapter 21, “[Statistical Graphics Using ODS.](#)”

For additional control of the graphics that are displayed, see the **PLOTS** option in the section “[PROC SIM2D Statement](#)” on page 7386.

## ODS Graph Names

PROC SIM2D assigns a name to each graph it creates by using ODS Graphics. You can use these names to reference the graphs when using ODS Graphics. You must also specify the PLOTS= option indicated in Table 85.5.

**Table 85.5** Graphs Produced by PROC SIM2D

| ODS Graph Name   | Plot Description                                                                                                                                                                                                                                                       | Statement | Option        |
|------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-----------|---------------|
| SimulationPlot   | Outlines of the observation locations, and either a contour plot of the simulated means and surface of the standard deviation in areal grids, or a band plot of the simulated means or box plot of the simulation distribution in linear grids or individual locations | PROC      | PLOTS=SIM     |
| ObservationsPlot | Scatter plot of observed data and colored markers indicating observed values                                                                                                                                                                                           | PROC      | PLOTS=OBSERV  |
| Semivariogram    | Plots of the semivariogram models used for all simulation tasks                                                                                                                                                                                                        | PROC      | PLOTS=SEMIVAR |

## Examples: SIM2D Procedure

### Example 85.1: Simulation and Economic Feasibility

You can use simulations to investigate the expected behavior of a stochastic process. Simulations with PROC SIM2D can indicate spatial characteristics in your study that might be important for decision making or general assessment. The present example and the one in section “[Example 85.3: Risk Analysis with Simulation](#)” on page 7423 are two instances of this type of analysis in different fields.

Continuing with the coal seam thickness example from the section “[Getting Started: SIM2D Procedure](#)” on page 7377, this example asks a rather complicated question of economic nature. For illustration, an (approximate) answer is provided, which requires the use of simulation.

### Simulating a Subregion for Economic Feasibility

The coal seam must be of a minimum thickness, called a *cutoff value*, for a mining operation to be profitable. Suppose that, for a subregion of the measured area, the cost of mining is higher than in the remaining areas due to the geology of the overburden. This higher cost results in a higher thickness cutoff value for the subregion. Suppose also that it is determined from a detailed cost analysis that at least 60% of the subregion must exceed a seam thickness of 39.7 feet for profitability.

How can you use the SRF model ( $\mu$  and  $C_z(s)$ ) and the measured seam thickness values  $Z(s_i), i = 1, \dots, 75$ , to determine, in some approximate way, whether at least 60% of the subregion exceeds this minimum?

Spatial prediction does not appear to be helpful in answering this question. Although it is easy to determine whether a predicted value at a location in the subregion is above the 39.7-foot cutoff value, it is not clear how to incorporate the standard error associated with the predicted value. The standard error is what characterizes the stochastic nature of the prediction (and the underlying SRF). It is clear that it must be included in any realistic approach to the problem.

A conditional simulation, on the other hand, seems to be a natural way of obtaining an approximate answer. By simulating the SRF on a sufficiently fine grid in the subregion, you can determine the proportion of grid points in which the mean value over realizations exceeds the 39.7-foot cutoff and compare it with the 60% value needed for profitability.

It is desirable in any simulation study that the quantity being estimated (in this case, the proportion that exceeds the 39.7-foot cutoff) not depend on the number of simulations performed. For example, suppose that the maximum seam thickness is simulated. It is likely that the maximum value increases as the number of simulations performed increases. Hence, a simulation is not useful for such an estimate. A simulation is useful for determining the *distribution* of the maximum, but there are general theoretical results for such distributions, making such a simulation unnecessary. See Leadbetter, Lindgren, and Rootzen (1983) for details.

In the case of simulating the proportion that exceeds the 39.7-foot cutoff, it is expected that this quantity will settle down to a fixed value as the number of realizations increases. At a fixed grid point, the quantity being compared with the cutoff value is the mean over all simulated realizations; this mean value settles down to a fixed number as the number of realizations increases. In the same manner, the proportion of the grid where the mean values exceed the cutoff also becomes constant. This can be tested using PROC SIM2D.

A crucial, nonprovable assumption in applying SRF theory to the coal seam thickness data is that the values  $Z(s_i), i = 1, \dots, 75$ , represent a *single* realization from the set of all possible realizations consistent with the SRF model ( $\mu$  and  $C_z(\mathbf{h})$ ). A conditional simulation repeatedly produces other possible simulated realizations consistent with the model and data. However, the only concern of the mining company is this single unique realization. It is not concerned about similar coal fields to be mined sometime in the future; it might never see another coal field remotely similar to this one, or it might not be in business in the future.

Hence the proportion found by generating repeated simulated realizations must somehow relate back to the unique realization that is the coal field (seam thickness). This is done by interpreting the proportion found from a simulation to the spatial mean proportion for the unique realization. The term “spatial mean” is simply an appropriate integral over the fixed (but unknown) spatial function  $z(\mathbf{s})$ . (The SRF is denoted  $Z(\mathbf{s})$ ; a particular realization, a deterministic function of the spatial coordinates, is denoted  $z(\mathbf{s})$ .)

This interpretation requires an ergodic assumption, which is also needed in the original estimation of  $C_z(\mathbf{s})$ . See Cressie (1993, pp. 53–58) for a discussion of ergodicity and Gaussian SRFs.

## Implementation Using PROC SIM2D

The subregion to be considered is the southeast corner of the field, which is a square region with a length of 40 distance units (in thousands of feet). First, you input the thickness data as the following DATA step shows:

```

title 'Simulating a Subregion for Economic Feasibility';

data thick;
 input East North Thick @@;
 label Thick='Coal Seam Thickness';

```

```

datalines;
 0.7 59.6 34.1 2.1 82.7 42.2 4.7 75.1 39.5

;

```

PROC SIM2D is run on the entire data set for conditioning, while the simulation grid covers only this subregion. It is convenient to be able to vary the seed, the grid increment, and the number of simulations performed. The following macro implements the computation of the percent area that exceeds the cutoff value by using the seed, the grid increment, and the number of simulated realizations as macro arguments.

Within the macro, the data set produced by PROC SIM2D is transposed with PROC TRANSPOSE so that each grid location is a separate variable. The MEANS procedure averages then the simulated value at each grid point over all realizations. It is this average that is compared to the cutoff value. The last DATA step does the comparison, uses an appropriate loop to determine the percent of the grid locations that exceed this cutoff value, and writes the results to the listing file in the form of a report. This sequence is implemented with the following statements:

```

/* Construct macro for conditional simulation -----*/
%let cc0=7.4599;
%let aa0=30.1111;
%let ngt=1e-8;
%let form=gauss;
%let cut=39.7;

%macro area_sim(seed=,nr=,ginc=);
 %let ngrid=%eval(40/&ginc+1);
 %let tgrid=%eval(&ngrid*&ngrid);

 proc sim2d data=thick outsim=sim1;
 coordinates xc=east yc=north;
 simulate var=thick numreal=&nr seed=&seed

```

```

 scale=&cc0 range=&aa0 nugget=&ngt form=&form;
 mean 40.1173;
 grid x=60 to 100 by &ginc
 y= 0 to 40 by &ginc;
run;

proc transpose data=sim1 out=sim2 prefix=sims;
 by _iter_;
 var svalue;
run;

proc means data=sim2 noprint n mean;
 var sims1-sims&tgrid;
 output out=msim n=numsim mean=ms1-ms&tgrid;
run;

data _null_;
 file print;
 array simss ms1-ms&tgrid;
 set msim;
 cflag=0;
 do ss=1 to &tgrid;
 tempv=simss[ss];
 if simss[ss] > &cut then do;
 cflag + 1;
 end;
 end;
 area_per=100*(cflag/&tgrid);
 put // +5 'Conditional Simulation of Coal Seam'
 ' Thickness for Subregion';
 put / +5 'Subregion is South-East Corner 40 by 40 distance units';
 put / +5 "Seed:&seed" +2 "Grid Increment:&ginc";
 put / +5 "Total Number of Grid Points:&tgrid" +2
 "Number of Simulations:&nr";
 put / +5 "Percent of Subregion Exceeding Cutoff of %left(&cut) ft.:"
 +2 area_per 5.2;
run;
%mend area_sim;

```

In the following statement, you invoke the macro three times. Each time, the macro is invoked with a different seed and combination of the grid increment and number of simulations. The macro is first invoked with a relatively coarse grid (grid increment of 10 distance units) and a small number of realizations (5). The output of this conditional simulation is shown in [Output 85.1.1](#).

```

/* Execute macro for coarse grid -----*/
%area_sim(seed=12345,nr=5,ginc=10);

```

**Output 85.1.1** Conditional Simulation of Coal Seam Thickness on a Coarse Grid

```

 Simulating a Subregion for Economic Feasibility

 Conditional Simulation of Coal Seam Thickness for Subregion

 Subregion is South-East Corner 40 by 40 distance units

 Seed:12345 Grid Increment:10

 Total Number of Grid Points:25 Number of Simulations:5

 Percent of Subregion Exceeding Cutoff of 39.7 ft.: 76.00

```

The next invocation, in the following statement, uses a finer grid and 50 realizations. The output of the second conditional simulation is shown in [Output 85.1.2](#).

```

/* Execute macro for fine grid and fewer simulations -----*/
%area_sim(seed=54321,nr=50,ginc=1);

```

**Output 85.1.2** Conditional Simulation of Coal Seam Thickness on a Fine Grid

```

 Simulating a Subregion for Economic Feasibility

 Conditional Simulation of Coal Seam Thickness for Subregion

 Subregion is South-East Corner 40 by 40 distance units

 Seed:54321 Grid Increment:1

 Total Number of Grid Points:1681 Number of Simulations:50

 Percent of Subregion Exceeding Cutoff of 39.7 ft.: 76.09

```

The final invocation, in the following statement, uses the same grid increment and 500 realizations. The output of this conditional simulation is shown in [Output 85.1.3](#).

```

/* Execute macro for fine grid and more simulations -----*/
%area_sim(seed=655311,nr=500,ginc=1);

```

**Output 85.1.3** Conditional Simulation of Coal Seam Thickness on a Fine Grid

```

Simulating a Subregion for Economic Feasibility

Conditional Simulation of Coal Seam Thickness for Subregion

Subregion is South-East Corner 40 by 40 distance units

Seed:655311 Grid Increment:1

Total Number of Grid Points:1681 Number of Simulations:500

Percent of Subregion Exceeding Cutoff of 39.7 ft.: 76.09

```

The results from the preceding simulations indicate that about 76% of the subregion exceeds the cutoff value.

**NOTE:** The number of grid points in the simulation increases with the square of the decrease in the grid increment, leading to long CPU processing times. Increasing the number of realizations results in a linear increase in processing times. Hence, using as coarse a grid as possible allows for more realizations and experimentation with different seeds.

---

## Example 85.2: Variability at Selected Locations

This example exhibits a more detailed investigation of the variation of simulated Thick variable values. You use the same thick data set from the section “Getting Started: SIM2D Procedure” on page 7377, and you are interested in the simulated values statistics at two selected grid points.

Specifically, you perform a simulation asking for 5,000 realizations (iterations) at two points of the region defined in the section “Preliminary Spatial Data Analysis” on page 7377. These are the extreme southwest point and a point toward the northeast corner of the region. Since you want to avoid performing the simulation across the whole region, you need to produce a `GDATA=` data set to specify the coordinates of the selected points. These steps are implemented using the following DATA step and statements:

```

title 'Investigation of Random Field Variability';

data thick;
 input East North Thick @@;
 label Thick='Coal Seam Thickness';
 datalines;

 ;

data grid;
 input xc yc;
 datalines;
 0 0
 75 75
 ;

```

Then, you run PROC SIM2D with the same parameters and characteristics as those shown in the section “Preliminary Spatial Data Analysis” on page 7377. This time, however, you ask for simulated values only at the two locations you specified in the previous DATA step. The following statements execute the requested simulation:

```

proc sim2d data=thick outsim=sim1;
 coordinates xc=East yc=North;
 simulate var=Thick numreal=5000 seed=79931
 scale=7.4599 range=30.1111 form=gauss;
 mean 40.1173;
 grid gdata=grid xc=xc yc=yc;
run;

```

After the simulation is performed, summary statistics are computed for each of the specified grid points. In particular, you use PROC UNIVARIATE and a BY statement to request the quantiles and the extreme observations at these locations, as the following statements show:

```
proc sort data=sim1;
 by gxc gyc;
run;

proc univariate data=sim1;
 var svalue;
 by gxc gyc;
 ods select Quantiles ExtremeObs;
 title 'Simulation Statistics at Selected Grid Points';
run;
```

The summary statistics for the first grid point (East=0, North=0) are presented in [Output 85.2.1](#).

**Output 85.2.1** Simulation Statistics at Grid Point (East=0, North=0)

For each simulation location, a single realization might result in values that differ significantly from the random field mean at that location. However, the averages of progressively larger numbers of realizations tend to shorten this gap and reduce the simulation variability, as exhibited in the results for the two example locations in [Output 85.2.1](#) and [Output 85.2.2](#). At the limit of an infinite number of realizations, the simulation mean recovers the mean and covariance structure of the random field.

---

## Example 85.3: Risk Analysis with Simulation

This example is in the field of environmental risk assessment. A square region of size 500 km × 500 km has been sampled for arsenic in drinking water. The `logAsData` data set consists of 138 simulated arsenic logarithm concentration observations represented by the `logAs` variable. Section “[Example 102.1: Aspects of Semivariogram Model Fitting](#)” on page 8648 in the VARIOGRAM procedure treats these observations as actual data in order to determine the spatial continuity structure for illustration in the examples.

A preliminary analysis indicates that the population exposure to the pollutant is currently at a relatively low level, as shown in the section “[Example 49.1: Spatial Prediction of Pollutant Concentration](#)” on page 3846 in the KRIGE2D procedure. In particular, spatial prediction with kriging suggests that less than 1% of the region is affected by arsenic concentration in water that exceeds the World Health Organization (WHO) standard of 10  $\mu\text{g}/\text{lt}$ .

You want to simulate the random field of the arsenic logarithm concentration so that you can gain insight into the characteristics of this field. Your objective is to assess whether the occurrence of above-threshold arsenic concentrations is a localized phenomenon, and whether you might expect more such occurrences across the region. For the simulation you need the outcome of the spatial continuity analysis in section “[Example 102.1: Aspects of Semivariogram Model Fitting](#)” on page 8648 in the VARIOGRAM procedure. These results are the fitted semivariance models that are stored in the `SemivAsStore` item store by PROC VARIOGRAM.

Based on the discussion in the section “[Example 85.1: Simulation and Economic Feasibility](#)” on page 7414, you simulate the arsenic logarithm concentration on the premise of the ergodicity assumption. In brief, this assumption relates the mean and covariances of each individual realization to the corresponding values of the random field; see also the section “[Ergodicity](#)” on page 8615 in the VARIOGRAM procedure. In the present case you are interested in the average of a large size of realizations, rather than individual ones. A single realization could suggest possible locations where the WHO regulatory standard might be violated. The average of multiple realizations has a smoothing effect on individual excessive-concentration episodes in single realizations. The smoothing enables you to see general characteristics of the arsenic concentration field behavior on the basis of its spatial correlation description.

For illustration, assume a rectangular grid of nodes with an equal spacing of 10 km between neighboring nodes in the north and east directions. Then, simulated values are produced at a total of  $51 \times 51 = 2601$  locations.

You begin by reading the `logAsData` data set with the following DATA step:

```

;

```

For this simulation you use the spatial correlation information that is saved in the SemivAsStore item store in the section “[Example 102.1: Aspects of Semivariogram Model Fitting](#)” on page 8648 in the VARIOGRAM procedure with the following statements:

```
ods graphics on;

proc variogram data=logAsData plots=none;
 store out=SemivAsStore / label='LogAs Concentration Models';
 compute lagd=5 maxlag=40;
 coord xc=East yc=North;
 model form=auto(mlist=(exp,gau,mat) nest=1 to 2);
 var logAs;
run;
```

In PROC SIM2D you specify the container item store with the **IN=** option of the **RESTORE** statement. You request correlation input from an item store by specifying the **STORESELECT** option in the **SIMULATE** statement. You request 5,000 realizations for this simulation by specifying the number in the **NUMREAL=** option of the **SIMULATE** statement.

Assume that you first want to review the saved models in the item store. Use the **INFO** option of the **RESTORE** statement to produce a table with information about the top-ranking fitted model in the item store. Use the **DET** and **ONLY** suboptions of the **INFO** option to request details about all fitted models included in the item store. The **ONLY** suboption suppresses the simulation tasks and produces only the tables about the item store. You specify the following statements:

```
proc sim2d data=logAsData outsim=Outsim plots=none;
 restore in=SemivAsStore / info(det only);
 coordinates xc=East yc=North;
 simulate var=logAs numreal=5000 storeselect seed=39841;
 grid x=0 to 500 by 10 y=0 to 500 by 10;
run;
```

PROC SIM2D produces a table with general information about the input item store identity, as shown in [Output 85.3.1](#).

### Output 85.3.1 PROC SIM2D and Input Item Store General Information

| Risk Assessment with Simulation          |                            |
|------------------------------------------|----------------------------|
| The SIM2D Procedure                      |                            |
| Correlation Model Item Store Information |                            |
| Input Item Store                         | WORK.SEMIVASSTORE          |
| Item Store Label                         | LogAs Concentration Models |
| Data Set Created From                    | WORK.LOGASDATA             |
| By-group Information                     | No By-groups Present       |
| Created By                               | PROC VARIOGRAM             |
| Date Created                             | 07JUN12:14:11:33           |

Output 85.3.2 displays the item store variables, in addition to the mean and standard deviation of their data set of origin. In this case, the logAs values come from the logAsData data set. By default, the SIM2D procedure uses the variable mean in the item store for the simulation, unless you explicitly specify the MEAN statement.

**Output 85.3.2** Variables in the Input Item Store

| Item Store Variables |          |               |
|----------------------|----------|---------------|
| Variable             | Mean     | Std Deviation |
| logAs                | 0.084309 | 1.527707      |

The models in the SemivAsStore item store that have been fitted to the arsenic logarithm logAs empirical semivariance are shown in Output 85.3.3. The default item store model selection is the model on top of the list in Output 85.3.3.

**Output 85.3.3** Angle and Models Information in the Input Item Store

| Item Store Models For logAs |                                      |
|-----------------------------|--------------------------------------|
| Class                       | Model                                |
| 1                           | Gau-Gau<br>Gau-Mat                   |
| 2                           | Exp-Gau                              |
| 3                           | Exp-Mat                              |
| 4                           | Mat                                  |
| 5                           | Gau                                  |
| 6                           | Exp<br>Exp-Exp<br>Mat-Exp<br>Gau-Exp |

You run again the SIM2D procedure without the INFO option in the RESTORE statement. This action prompts PROC SIM2D to run the simulation tasks that you specify with the SIMULATE statement. You specify the STORESELECT option in the SIMULATE statement without any suboptions, so that the simulation uses the default model selection in the SemivAsStore item store. You save the simulation output in the Outsims output data set. You also specify the SIM and the SEMIVAR suboptions in the PLOTS option of the PROC SIM2D statement to obtain output plots. You use the following statements:

```
proc sim2d data=logAsData outsims=Outsims plots=(sim semivar);
 restore in=SemivAsStore;
 coordinates xc=East yc=North;
 simulate var=logAs numreal=5000 storeselect seed=89702;
 grid x=0 to 500 by 10 y=0 to 500 by 10;
run;
```

**NOTE:** This step can take several minutes to run, and it produces a data set with over 10 million observations. When you run these statements, PROC SIM2D again produces a table about the input item store identity. This output is followed by a number of observations table and information about the simulation task, as shown in [Output 85.3.4](#).

**Output 85.3.4** Number of Observations and Simulation Information Tables

| Risk Assessment with Simulation             |             |
|---------------------------------------------|-------------|
| The SIM2D Procedure                         |             |
| Simulation: SIM1, Dependent Variable: logAs |             |
| Number of Observations Read                 | 138         |
| Number of Observations Used                 | 138         |
| Simulation Information                      |             |
| Simulation Grid Points                      | 2601        |
| Type                                        | Conditional |
| Number of Realizations                      | 5000        |

The SIM2D procedure uses the selected fitted Gaussian-Gaussian model in the SemivAsStore item store. [Output 85.3.5](#) shows the saved parameter values of the model that are used in the simulation.

**Output 85.3.5** Information about the Gaussian-Gaussian Model

| Covariance Model Information       |           |
|------------------------------------|-----------|
| Nested Structure 1 Type            | Gaussian  |
| Nested Structure 1 Sill            | 0.3276646 |
| Nested Structure 1 Range           | 62.312728 |
| Nested Structure 1 Effective Range | 107.92881 |
| Nested Structure 2 Type            | Gaussian  |
| Nested Structure 2 Sill            | 1.261545  |
| Nested Structure 2 Range           | 21.459563 |
| Nested Structure 2 Effective Range | 37.169053 |
| Nugget Effect                      | 0.0830758 |

[Output 85.3.6](#) shows a plot of the correlation model used in the simulation. Its parameters come from the stored information in the SemivAsStore item store.

**Output 85.3.6** Gaussian-Gaussian Semivariogram Model Used in Simulation

The PLOTS=SIM option produces contours of the mean value of the 5,000 realizations for each one of the output grid locations, and a surface of the associated standard deviation. The resulting plot is shown in Output 85.3.7. The mean value contours exhibit reduced variation compared to a SIM plot of one single realization. In fact, Output 85.3.7 is very similar to the prediction plot of the same Gaussian model in the section “Example 49.1: Spatial Prediction of Pollutant Concentration” on page 3846 in the KRIGE2D procedure.

Clearly, there appears to be a small area of increased arsenic concentration values, which is located in the central-eastern part of the domain. The WHO threshold of  $10 \mu\text{g}/\text{lt}$  for the maximum allowed arsenic concentration in water translates into about 2.3 in the log scale. The indicated area is the only one within the region where the simulated means exceed the value 3. In addition, there appear to be two smaller areas of simulated means values at or above 2 in the southern part of the region.

**Output 85.3.7** Simulated Arsenic Logarithm Values with Gaussian-Gaussian Covariance

The simulation plot indicates that arsenic concentration values in excess of the WHO health standard is a rather localized phenomenon. If it were not so, then the plot would suggest that increased arsenic concentrations extend across larger areas. In turn, this means that individual realizations would tend to produce systematically higher arsenic concentrations at different neighboring locations, and their average would appear as higher logAs values in the **SIM** plot. Instead, you conclude that the Gaussian-Gaussian correlation that describes the spatial continuity for the arsenic logarithm observations leads to only localized occurrence of the WHO standard violation.

Now you want to find out whether additional localized occurrences might take place on the basis of the Gaussian-Gaussian spatial continuity behavior. The distribution of the simulation standard deviation values in **Output 85.3.7** offers important feedback about this issue. Observe the areas in the plot where the means gradient indicates increasing values. The means contours create several pools where the values increase to simulated means higher than 1.

With the clear exceptions of the isolated area in the central-eastern part of the domain and the pool in the south-west that exhibit logAs values above 2, the simulation standard deviation seems to be around 1 or less in almost all other pools with logAs values above 1. Due to those relatively low standard deviations, this visual inspection suggests that even in individual realizations you might rarely expect the arsenic logarithm to exceed the threshold value of around 2.3.

However, in the few pools of logAs values above 1, there can be patches of increased standard deviation. In these cases, you suspect that arsenic concentration could exceed occasionally the WHO regulatory standard, even if the plot of the simulated means does not explicitly portray so.

Based on these remarks, you want to quantify the percentage of the region that could be affected by excessive arsenic concentration. You begin with a DATA step that takes as input the simulation Outsim output data set. The DATA step marks the simulated arsenic logarithm means values that are in excess of the WHO concentration threshold of 10  $\mu\text{g}/\text{lt}$ , and saves the outcome into an indicator variable OverLimit. At the same time, the arsenic logarithm values are transformed back into arsenic concentration values so that they can be compared to the threshold value. The simulated means in the Outsim data set are stored in the svalue variable. You use the following statements:

```
data AsOverLimit;
 set Outsim;
 OverLimit = (exp(svalue) > 10) * 100;
run;
```

Then, you use the MEANS procedure to express the selected nodes population (where the WHO standard violation occurs) as a percentage of the entire domain area. You invoke PROC MEANS twice. The first time, you average over each realization in the PROC SIM2D output. For that purpose, you use the variable `_ITER_` in the simulation sim1 output data set as a BY variable in PROC MEANS. You save the iteration-averaged indicator values in the PctOverLimit variable. The second time, PROC MEANS averages the PctOverLimit variable to obtain the percentage you want. You also specify the P5 and P95 options in the PROC MEANS statement to request the lower and upper confidence limits, respectively, in this computation. The interval between those limits expresses the 90% interval for the true area percentage based on the stochastic simulation. You use the following statements:

```
proc means data=AsOverLimit noprint;
 by _ITER_;
 var OverLimit;
 output out=OverLimitData mean=PctOverLimit;
run;
proc means data=OverLimitData mean p5 p95;
 var PctOverLimit;
 label PctOverLimit="Percent above threshold";
run;
```

The result is shown in [Output 85.3.8](#). PROC MEANS accounts for all individual occurrences throughout the simulation where the WHO arsenic concentration threshold is exceeded. This happens at about 3.9% of the total area in 5,000 realizations. Compare this value to the less than 1% percentage in the PROC KRIGE2D prediction, as reported in the beginning of this section. On one hand, the prediction outcome tells you what goes on currently across the region within a degree of certainty given by the prediction error. On the other hand, the simulation provides you with an indicator that under the given spatial continuity estimate a relatively larger area is in potential danger of being affected by above-threshold arsenic concentration.

In fact, the 5% and 95% confidence limits in [Output 85.3.8](#) show the area percentage limits within which you can expect excessive arsenic concentration. Based on the stochastic simulation, at the 90% confidence level the arsenic concentration in drinking water is expected to violate the WHO regulatory standard in anywhere from about 2.6% to 5.4% of the study region.

**Output 85.3.8** Violation of Arsenic Concentration Threshold Using Gaussian-Gaussian Model

| Risk Assessment with Simulation                          |           |           |
|----------------------------------------------------------|-----------|-----------|
| The MEANS Procedure                                      |           |           |
| Analysis Variable : PctOverLimit Percent above threshold |           |           |
| Mean                                                     | 5th Pctl  | 95th Pctl |
| 3.9308727                                                | 2.6143791 | 5.4209919 |

You also want to compute the probability that individual areas in the region are expected to violate the WHO arsenic concentration standard. Start by identifying again the simulated arsenic logarithm means values in excess of the WHO concentration threshold of 10  $\mu\text{g}/\text{lt}$ . The following DATA step saves the outcome into the variable LocalOverLimit:

```
data LocalAsOverLimit;
 set Outsim;
 LocalOverLimit = (exp(svalue) > 10);
run;
```

Then you use the SORT procedure to sort the information based on location coordinates. This intermediate step is necessary so that you can use the MEANS procedure with the LocalAsOverLimit data set. In the following statements, PROC MEANS computes the expected violations of the WHO standard for each location in the region across all realizations of the simulation:

```
proc sort data=LocalAsOverLimit;
 by gxc gyc;
run;
proc means data=LocalAsOverLimit noprint;
 by gxc gyc;
 var LocalOverLimit;
 output out=OverLimLocI mean=ProbOverLimit;
run;
```

The output is the probability that the WHO standard is violated at each one of the simulation locations across the region. You create a plot of this probability with the help of the TEMPLATE and the SGRENDER procedures. You use the following statements:

```

proc template;
 define statgraph surfacePlot;
 dynamic _VARX _VARY _VAR _TITLE _LEGENDLABEL;
 BeginGraph;
 entrytitle _TITLE;
 layout overlay /
 xaxisopts = (offsetmax=0)
 yaxisopts = (offsetmax=0);
 contourplotparm x=_VARX y=_VARY z=_VAR /
 nhint=10 name='probplot';
 continuouslegend 'probplot' / title=_LEGENDLABEL;
 endlayout;
 EndGraph;
 end;
run;

proc sgrender data=OverLimLoc1 template=surfacePlot;
 dynamic _VARX = 'gxc'
 _VARY = 'gyc'
 _VAR = 'ProbOverLimit'
 _TITLE='Arsenic WHO Standard Violation'
 _LEGENDLABEL='Violation Probability';
 label gyc='North' gxc='East';
run;

ods graphics off;

```

Output 85.3.9 shows the map of probability that the arsenic concentration WHO standard is violated in the region for the selected spatial correlation model of the pollutant. Based on the preceding analysis, the probability is very close to 1 in the area where the simulation mean values are above the standard limit. A few more areas that were indicated earlier in the analysis suggest a violation probability between 20% and 40%. The remaining areas in the region exhibit very low probability, which is notably nonzero at a few scattered locations. These findings suggest that throughout the simulation there have been realizations where the arsenic WHO standard was exceeded at locations whose simulated mean is well below that standard.

From the environmental risk assessment perspective, the preceding analysis can trigger a more detailed investigation into areas in the region where the health standard might be violated. Although the original observations in the logAsData data set indicate no existing problem in some of these areas, the present example illustrates that spatial analysis and simulation can raise flags of caution. This type of analysis can help to focus scientific, management, and policy efforts on these particular areas of the region and to monitor closely the pollutant concentration for potential health risks.

**Output 85.3.9** Map of Violation of the Arsenic WHO Standard Probability

### Overview: SIMNORMAL Procedure

The SIMNORMAL procedure can perform conditional and unconditional simulation for a set of correlated normal or Gaussian random variables.

The means, variances, and covariances (or correlations) are read from an input TYPE=CORR or TYPE=COV data set. This data set is typically produced by the CORR procedure. Conditional simulations are performed by appending a special observation, identified by the value of 'COND' for the \_TYPE\_ variable, which contains the conditioning value.

The output data set from PROC SIMNORMAL contains simulated values for each of the analysis variables. Optionally, the output data set also contains the seed stream and the values of the conditioning variables. PROC SIMNORMAL produces no printed output.

---

### Getting Started: SIMNORMAL Procedure

The following example illustrates the use of PROC SIMNORMAL to generate variable values conditioned on a set of related or correlated variables.

Suppose you are given a sample of size 50 from ten normally distributed, correlated random variables,  $IN_{1,i}, \dots, IN_{5,i}, OUT_{1,i}, \dots, OUT_{5,i}, i = 1, \dots, 50$ . The first five variables represent input variables for a chemical manufacturing process, and the last five are output variables.

First, the data are input and the correlation structure is determined by using PROC CORR, as in the following statements. The results are shown in Figure 86.1.

```
data a ;
 input in1-in5 out1-out5 ;
 datalines ;
 9.3500 10.0964 7.3177 10.3617 10.3444 9.4612

After the mean and correlation structure are determined, any subset of these variables can be simulated. Suppose you are interested in a particular function of the output variables for two sets of values of the input variables for the process. In particular, you are interested in the mean and variability of the following function over 500 runs of the process conditioned on each set of input values:

$$f(out_1, \dots, out_5) = \frac{out_1 - out_3}{out_1 + out_2 + out_3 + out_4 + out_5}$$

Although the distribution of these quantities could be determined theoretically, it is simpler to perform a conditional simulation by using PROC SIMNORMAL.

To do this, you first append a `_TYPE_='COND'` observation to the covariance data set produced by PROC CORR for each group of input values:

```

data cond1 ;
 TYPE='COND' ;
 in1 = 8 ;
 in2 = 10.5 ;
 in3 = 12 ;
 in4 = 13.5 ;
 in5 = 14.4 ;
 output ;
run ;

data cond2 ;
 TYPE='COND' ;
 in1 = 15.4 ;
 in2 = 13.7 ;
 in3 = 11 ;
 in4 = 7.9 ;
 in5 = 5.5 ;
 output ;
run ;

```

Next, each of these conditioning observations is appended to a copy of the `OUTP=OUTCOV` data from the CORR procedure, as in the following statements. A new variable, `INPUT`, is added to distinguish the sets of input values. This variable is used as a `BY` variable in subsequent steps.

```

data outcov1 ;
 input=1 ;
 set outcov cond1 ;
run ;

data outcov2 ;
 input=2 ;
 set outcov cond2 ;
run ;

```

Finally, these two data sets are concatenated:

```

data outcov ;
 set outcov1 outcov2 ;
run ;
proc print data=outcov ;
 where (_type_ ne 'COV') ;
run ;

```

Figure 86.2 shows the added observations.

| 14  | 14.4000 | .       | .       | .       | .       | .       |
| 25  | 10.2259 | 9.8535  | 9.9686  | 10.2959 | 10.1586 | 10.2602 |
| 26  | 1.2676  | 0.8983  | 0.9641  | 1.3555  | 0.9126  | 0.8353  |
| 27  | 50.0000 | 50.0000 | 50.0000 | 50.0000 | 50.0000 | 50.0000 |
| 28  | 5.5000  | .       | .       | .       | .       | .       |

You now run PROC SIMNORMAL, specifying the input data set and the VAR and COND variables. Note that you must specify a `TYPE=COV` or `TYPE=CORR` for the input data set. PROC CORR automatically assigns a `TYPE=COV` or `TYPE=CORR` attribute for the OUTP= data set. However, since the intermediate DATA steps that appended the `_TYPE_='COND'` observations turned off this attribute, an explicit `TYPE=CORR` in the DATA= option in the PROC SIMNORMAL statement is needed.

The specification of PROC SIMNORMAL now follows from the problem description. The condition variables are IN1–IN5, the analysis variables are OUT1–OUT5, and 500 realizations are required. A seed value can be chosen arbitrarily, or the system clock can be used. Note that in the following statements, the simulation is done for each of the values of the BY variable INPUT:

```
proc simnormal data=outcov(type=cov)
 out = osim
 numreal = 500
 seed = 33179
 ;
 by input ;
 var out1-out5 ;
 cond in1-in5 ;
run;

data b;
 set osim ;
 denom = sum(of out1-out5) ;
 if abs(denom) < 1e-8 then ff = . ;
 else ff = (out1-out3)/denom ;
run ;
```

The DATA step that follows the simulation computes the function  $f(out_1, \dots, out_5)$ ; in the following statements the UNIVARIATE procedure computes the simple statistics for this function for each set of conditioning input values. This is shown in Figure 86.3, and Figure 86.4 shows the distribution of the function values for each set of input values by using the SG PANEL procedure.

```
proc univariate data=b ;
 by input ;
 var ff ;
run ;
title ;
proc sgpanel data=b ;
 panelby input ;
 REFLINE 0 / axis= x ;
 density ff ;
run ;
```

## Syntax: SIMNORMAL Procedure

The following statements are available in the SIMNORMAL procedure:

```

PROC SIMNORMAL DATA=SAS-data-set < options > ;
 VAR variables ;
 BY variables ;
 CONDITION variables ;

```

Both the PROC SIMNORMAL and VAR statements are required. The following statements can be used with the SIMNORMAL procedure:

---

## PROC SIMNORMAL Statement

```

PROC SIMNORMAL DATA=SAS-data-set < options > ;

```

The PROC SIMNORMAL statement invokes the SIMNORMAL procedure. Table 86.1 summarizes the options available in the PROC SIMNORMAL statement.

**Table 86.1** Summary of PROC SIMNORMAL Statement Options

| Option                                    | Description                                                                         |
|-------------------------------------------|-------------------------------------------------------------------------------------|
| <b>Specify Input and Output Data Sets</b> |                                                                                     |
| DATA=                                     | Specifies input data set (TYPE=CORR, COV, and so on)                                |
| OUT=                                      | Creates output data set that contains simulated values                              |
| <b>Seed Values</b>                        |                                                                                     |
| SEED=                                     | Specifies seed value (integer)                                                      |
| SEEDBY                                    | Requests reinitialization of seed for each BY group                                 |
| <b>Control Contents of OUT= Data Set</b>  |                                                                                     |
| OUTSEED                                   | Requests seed values written to OUT= data set                                       |
| OUTCOND                                   | Requests conditioning variable values written to OUT=data set                       |
| <b>Control Number of Simulated Values</b> |                                                                                     |
| NUMREAL=                                  | Specifies the number of realizations for each BY group written to the OUT= data set |
| <b>Singularity Criteria</b>               |                                                                                     |
| SINGULAR1=                                | Sets the singularity criterion for Cholesky decomposition                           |
| SINGULAR2=                                | Sets the singularity criterion for covariance matrix sweeping                       |

The following options can be used with the PROC SIMNORMAL statement.

**DATA=SAS-data-set**

specifies the input data set that must be a specially structured TYPE=CORR, COV, UCORR, UCOV, or SSCP SAS data set. If the DATA= option is omitted, the most recently created SAS data set is used.

**SEED=seed-value**

specifies the seed to use for the random number generator. If the SEED= value is omitted, the system clock is used. If the system clock is used, a note is written to the log; the note gives the seed value based on the system clock. In addition, the random seed stream is copied to the OUT= data set if the OUTSEED option is specified.

**SEEDBY**

specifies that the seed stream be reinitialized for each BY group. By default, a single random stream is used over all BY groups. If you specify SEEDBY, the random stream starts again at the initial seed value. This initial value is from the SEED= value that you specify. If you do not specify a SEED=value, the system clock generates this initial seed.

For example, suppose you had a TYPE=CORR data set with BY groups, and the mean, variances, and covariance or correlation values were identical for each BY group. Then if you specified SEEDBY, the simulated values in each BY group in the OUT= data set would be identical.

**OUT=SAS-data-set**

specifies a SAS data set in which to store the simulated values for the VAR variables. If you omit the OUT=option, the output data set is created and given a default name by using the DATA $n$  convention.

See the section “OUT= Output Data Set” on page 7446 for details.

**NUMREAL= $n$** 

specifies the number of realizations to generate. A value of NUMREAL=500 generates 500 observations in the OUT=dataset, or 500 observations within each BY group if a BY statement is given.

NUMREAL can be abbreviated as NUMR or NR.

**OUTSEED**

requests that the seed values be included in the OUT= data set. The variable Seed is added to the OUT= data set. The first value of Seed is the SEED= value specified in the PROC SIMNORMAL statement (or obtained from the system clock); subsequent values are produced by the random number generator.

**OUTCOND**

requests that the values of the conditioning variables be included in the OUT= data set. These values are constant for the data set or within a BY group. Note that specifying OUTCOND can greatly increase the size of the OUT= data set. This increase depends on the number of conditioning variables.

**SINGULAR1= $number$** 

specifies the first singularity criterion, which is applied to the Cholesky decomposition of the covariance matrix. The SINGULAR1= value must be in the range (0, 1). The default value is  $10^{-8}$ . SINGULAR1 can be abbreviated SING1.

**SINGULAR2= $number$** 

specifies the second singularity criterion, which is applied to the sweeping of the covariance or correlation matrix to obtain the conditional covariance. The SINGULAR2=option is applicable only when a CONDITION statement is given. The SINGULAR2= value must be in the range (0, 1). The default value is  $10^{-8}$ . SINGULAR2 can be abbreviated SING2.

## BY Statement

**BY variables ;**

A BY statement can be used with the SIMNORMAL procedure to obtain separate simulations for each covariance structure defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in the order of the BY variables. If a CONDITION statement is used along with a BY statement, there must be a \_TYPE\_='COND' observation within each BY group. Note that if a BY statement is specified, the number of realizations specified by the NUMREAL= option are produced for each BY group.

## CONDITION Statement

**CONDITION | COND variables ;**

A `CONDITION` statement specifies the conditioning variables. The presence of a `CONDITION` statement requests that a conditional simulation be performed.

The lack of a `CONDITIONAL` statement simply means that an unconditional simulation for the `VAR` variables is to be performed.

If a `CONDITION` statement is given, the variables listed must be numeric variables in the `DATA=` data set. This requires a conditioning value for each of the `CONDITION` variables. This value is supplied by adding a `_TYPE_='COND'` observation for each `CONDITION` variable. Such observations are added to the `DATA=` data set by a `DATA` step.

Note that a data set created by the `CORR` procedure is automatically given the `TYPE=COV`, `UCOV`, `CORR`, or `UCORR` attribute, so you do not have to specify the `TYPE=` option in the `DATA=` option in the `PROC SIMNORMAL` statement. However, when adding the conditioning values by using a `DATA` step with a `SET` statement, you must use the `TYPE=COV`, `UCOV`, `CORR`, or `UCORR` attribute in the new data set. See the section “Getting Started: [SIMNORMAL Procedure](#)” on page 7435 for an example in which the `TYPE` is set.

## VAR Statement

**VAR** *variables* ;

Use the `VAR` statement to specify the analysis variables. Only numeric variables can be specified. If a `VAR` statement is not given, all numeric variables in the `DATA=` data set that are not in the `CONDITION` or `BY` statement are used.

## OUT= Output Data Set

The `SIMNORMAL` procedure produces a single output data set: the `OUT=SAS-data-set`.

The `OUT=` data set contains the following variables:

- all variables listed in the `VAR` statement
- all variables listed in the `BY` statement, if one is given
- `Rnum`, which is the realization number within the current `BY` group
- `Seed`, which is current seed value, if the `OUTSEED` option is specified
- all variables listed in the `CONDITION` statement, if a `CONDITION` statement is given and the `OUTCOND` option is specified

The number of observations is determined by the value of the `NUMREAL=` option. If there are no `BY` groups, the number of observations in the `OUT=` data set is equal to the value of the `NUMREAL=` option. If there are `BY` groups, there are number of observations equals the value of the `NUMREAL=` option for each `BY` group.

---

## Computational Details: SIMNORMAL Procedure

---

### Introduction

There are a number of approaches to simulating a set of dependent random variables. In the context of spatial random fields, these include sequential indicator methods, turning bands, and the Karhunen-Loeve expansion. See Christakos (1992, Chapter 8) and Deutsch and Journel (1992, Chapter 5) for details.

In addition, there is the LU decomposition method, a particularly simple and computationally efficient for normal or Gaussian variates. For a given covariance matrix, the  $\mathbf{LU} = \mathbf{LL}'$  decomposition is computed once, and the simulation proceeds by repeatedly generating a vector of independent  $N(0, 1)$  random variables and multiplying by the  $\mathbf{L}$  matrix.

One problem with this technique is that memory is required to hold the covariance matrix of all the analysis and conditioning variables in core.

---

### Unconditional Simulation

It is a simple matter to produce an  $N(0, 1)$  random number, and by stacking  $k$  such numbers in a column vector you obtain a vector with independent standard normal components  $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$ . The meaning of the terms *independence* and *randomness* in the context of a deterministic algorithm required for the generation of these numbers is somewhat subtle; see Knuth (1973, Vol. 2, Chapter 3) for a discussion of these issues.

Rather than  $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I})$ , what is required is the generation of a vector  $\mathbf{Z} \sim N_k(\mathbf{0}, \mathbf{V})$ —that is,

$$\mathbf{Z} = \begin{bmatrix} Z_1 \\ Z_2 \\ \vdots \\ Z_k \end{bmatrix}$$

with covariance matrix

$$\mathbf{V} = \begin{pmatrix} \sigma_{11} & \sigma_{12} & \cdots & \sigma_{1k} \\ \sigma_{21} & \sigma_{22} & \cdots & \sigma_{2k} \\ & \ddots & & \\ \sigma_{k1} & \sigma_{k2} & \cdots & \sigma_{kk} \end{pmatrix}$$

where

$$\sigma_{ij} = \text{Cov}(Z_i, Z_j)$$

If the covariance matrix is symmetric and positive definite, it has a Cholesky root  $\mathbf{L}$  such that  $\mathbf{V}$  can be factored as

$$\mathbf{V} = \mathbf{L}\mathbf{L}'$$

where  $\mathbf{L}$  is lower triangular. See Ralston and Rabinowitz (1978, Chapter 9, Section 3-3) for details. This vector  $\mathbf{Z}$  can be generated by the transformation  $\mathbf{Z} = \mathbf{L}\mathbf{W}$ . Note that this is where the assumption of multivariate normality is crucial. If  $\mathbf{W} \sim N_k(\mathbf{0}, \mathbf{I}_k)$ , then  $\mathbf{Z} = \mathbf{L}\mathbf{W}$  is also normal or Gaussian. The mean of  $\mathbf{Z}$  is

$$E(\mathbf{Z}) = \mathbf{L}(E(\mathbf{W})) = \mathbf{0}$$

and the variance is

$$\text{Var}(\mathbf{Z}) = \text{Var}(\mathbf{L}\mathbf{W}) = E(\mathbf{L}\mathbf{W}\mathbf{W}'\mathbf{L}') = \mathbf{L} E(\mathbf{W}\mathbf{W}') \mathbf{L}' = \mathbf{L}\mathbf{L}' = \mathbf{V}$$

Finally, let  $Y_k = Z_k + \mu_k$ ; that is, you add a mean term to each variable  $Z_k$ . The covariance structure of the  $Y_k$ 's remains the same. Unconditional simulation is done by simply repeatedly generating  $k$   $N(0, 1)$  random numbers, stacking them, and performing the transformation

$$\mathbf{W} \mapsto \mathbf{Z} = \mathbf{L}\mathbf{W} \mapsto \mathbf{Y} = \mathbf{Z} + \boldsymbol{\mu}$$

## Conditional Simulation

For a conditional simulation, this distribution of

$$\mathbf{Y} = \begin{bmatrix} Y_1 \\ Y_2 \\ \vdots \\ Y_k \end{bmatrix}$$

must be conditioned on the values of the CONDITION variables. The relevant general result concerning conditional distributions of multivariate normal random variables is the following. Let  $\mathbf{X} \sim N_m(\boldsymbol{\mu}, \boldsymbol{\Sigma})$ , where

$$\mathbf{X} = \begin{bmatrix} \mathbf{X}_1 \\ \mathbf{X}_2 \end{bmatrix}$$

$$\boldsymbol{\mu} = \begin{bmatrix} \mu_1 \\ \mu_2 \end{bmatrix}$$

$$\boldsymbol{\Sigma} = \begin{pmatrix} \boldsymbol{\Sigma}_{11} & \boldsymbol{\Sigma}_{12} \\ \boldsymbol{\Sigma}_{21} & \boldsymbol{\Sigma}_{22} \end{pmatrix}$$

and where  $bX_1$  is  $k \times 1$ ,  $X_2$  is  $n \times 1$ ,  $\Sigma_{11}$  is  $k \times k$ ,  $\Sigma_{22}$  is  $n \times n$ , and  $\Sigma_{12} = \Sigma'_{21}$  is  $k \times n$ , with  $k + n = m$ . The full vector  $\mathbf{X}$  has simply been partitioned into two subvectors,  $\mathbf{X}_1$  and  $\mathbf{X}_2$ , and  $\Sigma$  has been similarly partitioned into covariances and cross covariances.

With this notation, the distribution of  $\mathbf{X}_1$  conditioned on  $\mathbf{X}_2 = x_2$  is  $N_k(\tilde{\mu}, \tilde{\Sigma})$ , with

$$\tilde{\mu} = \mu_1 + \Sigma_{12}\Sigma_{22}^{-1}(x_2 - \mu_2)$$

and

$$\tilde{\Sigma} = \Sigma_{11} - \Sigma_{12}\Sigma_{22}^{-1}\Sigma_{21}$$

See Searle (1971, pp. 46–47) for details.

Using the SIMNORMAL procedure corresponds with the conditional simulation as follows. Let  $Y_1, \dots, Y_k$  be the VAR variables as before ( $k$  is the number of variables in the VAR list). Let the mean vector for  $\mathbf{Y}$  be denoted by  $\mu_1 = E(\mathbf{Y})$ . Let the CONDITION variables be denoted by  $C_1, \dots, C_n$  (where  $n$  is the number of variables in the COND list). Let the mean vector for  $\mathbf{C}$  be denoted by  $\mu_2 = E(\mathbf{C})$  and the conditioning values be denoted by

$$\mathbf{c} = \begin{bmatrix} c_1 \\ c_2 \\ \vdots \\ c_n \end{bmatrix}$$

Then stacking

$$\mathbf{X} = \begin{bmatrix} \mathbf{Y} \\ \mathbf{C} \end{bmatrix}$$

the variance of  $\mathbf{X}$  is

$$\mathbf{V} = \text{Var}(\mathbf{X}) = \Sigma = \begin{pmatrix} \mathbf{V}_{11} & \mathbf{V}_{12} \\ \mathbf{V}_{21} & \mathbf{V}_{22} \end{pmatrix}$$

where  $\mathbf{V}_{11} = \text{Var}(\mathbf{Y})$ ,  $\mathbf{V}_{12} = \text{Cov}(\mathbf{Y}, \mathbf{C})$ , and  $\mathbf{V}_{22} = \text{Var}(\mathbf{C})$ . By using the preceding general result, the relevant covariance matrix is

$$\tilde{\mathbf{V}} = \mathbf{V}_{11} - \mathbf{V}_{12}\mathbf{V}_{22}^{-1}\mathbf{V}_{21}$$

and the mean is

$$\tilde{\mu} = \mu_1 + \mathbf{V}_{12}\mathbf{V}_{22}^{-1}(\mathbf{c} - \mu_2)$$

By using  $\tilde{\mathbf{V}}$  and  $\tilde{\mu}$ , simulating  $(\mathbf{Y}|\mathbf{C} = \mathbf{c}) \sim N_k(\tilde{\mu}, \tilde{\mathbf{V}})$  now proceeds as in the unconditional case.

### Overview: STDIZE Procedure

The STDIZE procedure standardizes one or more numeric variables in a SAS data set by subtracting a location measure and dividing by a scale measure. A variety of location and scale measures are provided, including estimates that are resistant to outliers and clustering. Some of the well-known standardization methods such as mean, median, standard deviation, range, Huber's estimate, Tukey's biweight estimate, and Andrew's wave estimate are available in the STDIZE procedure.

In addition, you can multiply each standardized value by a constant and add a constant. Thus, the final output value is

$$result = add + multiply \times \frac{original - location}{scale}$$

where

*result* = final output value  
*add* = constant to add (ADD= option)  
*multiply* = constant to multiply by (MULT= option)  
*original* = original input value  
*location* = location measure  
*scale* = scale measure

PROC STDIZE can also find quantiles in one pass of the data, a capability that is especially useful for very large data sets. With such data sets, the UNIVARIATE procedure might have high or excessive memory or time requirements.

## Getting Started: STDIZE Procedure

The following example demonstrates how you can use the STDIZE procedure to obtain location and scale measures of your data.

In the following hypothetical data set, a random sample of grade twelve students is selected from a number of coeducational schools. Each school is classified as one of two types: Urban or Rural. There are 40 observations.

The variables are id (student identification), Type (type of school attended: 'urban'=urban area and 'rural'=rural area), and total (total assessment scores in History, Geometry, and Chemistry).

The following DATA step creates the SAS data set TotalScores.

```
data TotalScores;
 title 'High School Scores Data';
 input id Type $ total @@;
 datalines;
 1 rural 135 2 rural 125 3 rural 223 4 rural 224 5 rural 133
 6 rural 253 7 rural 144 8 rural 193 9 rural 152 10 rural 178
 11 rural 120 12 rural 180 13 rural 154 14 rural 184 15 rural 187
 16 rural 111 17 rural 190 18 rural 128 19 rural 110 20 rural 217
 21 urban 192 22 urban 186 23 urban 64 24 urban 159 25 urban 133
 26 urban 163 27 urban 130 28 urban 163 29 urban 189 30 urban 144
 31 urban 154 32 urban 198 33 urban 150 34 urban 151 35 urban 152
 36 urban 151 37 urban 127 38 urban 167 39 urban 170 40 urban 123
 ;
```

Suppose you now want to standardize the total scores in different types of schools prior to any further analysis. Before standardizing the total scores, you can use the box plot from PROC BOXPLOT to summarize the total scores for both types of schools.

```
ods graphics on;
proc boxplot data=TotalScores;
 plot total*Type / boxstyle=schematic noserifs;
run;
```

The PLOT statement in the PROC BOXPLOT statement creates the schematic plots (without the serifs) when you specify `boxstyle=schematic noserifs`. Figure 87.1 displays a box plot for each type of school.

**Figure 87.1** Schematic Plots from PROC BOXPLOT

Inspection reveals that one urban score is a low outlier. Also, if you compare the lengths of two box plots, there seems to be twice as much dispersion for the rural scores as for the urban scores.

The following PROC UNIVARIATE statement reports the information about the extreme values of the Score variable for each type of school:

```
proc univariate data=TotalScores;
 var total;
 by Type;
run;
```

Figure 87.2 displays the table from PROC UNIVARIATE for the lowest and highest five total scores for urban schools. The outlier (Obs = 23), marked in Figure 87.2 by the symbol '0', has a score of 64.

**Figure 87.2** Table for Extreme Observations When Type=urban

| High School Scores Data  |     |                |     |
|--------------------------|-----|----------------|-----|
| ----- Type=urban -----   |     |                |     |
| The UNIVARIATE Procedure |     |                |     |
| Variable: total          |     |                |     |
| Extreme Observations     |     |                |     |
| ----Lowest----           |     | ----Highest--- |     |
| Value                    | Obs | Value          | Obs |
| 64                       | 23  | 170            | 39  |
| 123                      | 40  | 186            | 22  |
| 127                      | 37  | 189            | 29  |
| 130                      | 27  | 192            | 21  |
| 133                      | 25  | 198            | 32  |

The following PROC STDIZE procedure requests the METHOD=STD option for computing the location and scale measures:

```
proc stdize data=totalscores method=std pstat;
 title2 'METHOD=STD';
 var total;
 by Type;
run;
```

Figure 87.3 displays the table of location and scale measures from the PROC STDIZE statement. PROC STDIZE uses the sample mean as the location measure and the sample standard deviation as the scale measure for standardizing. The PSTAT option displays a table containing these two measures.

**Figure 87.3** Location and Scale Measures Table When METHOD=STD

| High School Scores Data<br>METHOD=STD |            |                            |    |
|---------------------------------------|------------|----------------------------|----|
| ----- Type=rural -----                |            |                            |    |
| The STDIZE Procedure                  |            |                            |    |
| Location and Scale Measures           |            |                            |    |
| Location = mean                       |            | Scale = standard deviation |    |
| Name                                  | Location   | Scale                      | N  |
| total                                 | 167.050000 | 41.956713                  | 20 |
| High School Scores Data<br>METHOD=STD |            |                            |    |
| ----- Type=urban -----                |            |                            |    |
| The STDIZE Procedure                  |            |                            |    |
| Location and Scale Measures           |            |                            |    |
| Location = mean                       |            | Scale = standard deviation |    |
| Name                                  | Location   | Scale                      | N  |
| total                                 | 153.300000 | 30.066768                  | 20 |

The ratio of the scale of rural scores to the scale of urban scores is approximately 1.4 (41.96/30.07). This ratio is smaller than the dispersion ratio observed in the previous schematic plots.

The STDIZE procedure provides several location and scale measures that are resistant to outliers. The following statements invoke three different standardization methods and display the tables for the location and scale measures:

```
proc stdize data=totalscores method=mad pstat;
 title2 'METHOD=MAD';
 var total;
 by Type;
run;
```

```
proc stdize data=totalscores method=iqr pstat;
 title2 'METHOD=IQR';
 var total;
 by Type;
run;
```

```

proc stdize data=totalscores method=abw(4) pstat;
 title2 'METHOD=ABW(4)';
 var total;
 by Type;
run;

```

Figure 87.4 displays the table of location and scale measures when the standardization method is median absolute deviation (MAD). The location measure is the median, and the scale measure is the median absolute deviation from the median. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.06 (32.0/15.5) and is close to the dispersion ratio observed in the previous schematic plots.

**Figure 87.4** Location and Scale Measures Table When METHOD=MAD

| High School Scores Data<br>METHOD=MAD |            |                                    |    |
|---------------------------------------|------------|------------------------------------|----|
| ----- Type=rural -----                |            |                                    |    |
| The STDIZE Procedure                  |            |                                    |    |
| Location and Scale Measures           |            |                                    |    |
| Location = median                     |            | Scale = median abs dev from median |    |
| Name                                  | Location   | Scale                              | N  |
| total                                 | 166.000000 | 32.000000                          | 20 |
| High School Scores Data<br>METHOD=MAD |            |                                    |    |
| ----- Type=urban -----                |            |                                    |    |
| The STDIZE Procedure                  |            |                                    |    |
| Location and Scale Measures           |            |                                    |    |
| Location = median                     |            | Scale = median abs dev from median |    |
| Name                                  | Location   | Scale                              | N  |
| total                                 | 153.000000 | 15.500000                          | 20 |

Figure 87.5 displays the table of location and scale measures when the standardization method is IQR. The location measure is the median, and the scale measure is the interquartile range. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.03 (61/30) and is, in fact, the dispersion ratio observed in the previous schematic plots.

**Figure 87.5** Location and Scale Measures Table When METHOD=IQR

| total                                 | 166.000000 | 61.000000                   | 20 |
| High School Scores Data<br>METHOD=IQR |            |                             |    |
| ----- Type=urban -----                |            |                             |    |
| The STDIZE Procedure                  |            |                             |    |
| Location and Scale Measures           |            |                             |    |
| Location = median                     |            | Scale = interquartile range |    |
| Name                                  | Location   | Scale                       | N  |
| total                                 | 153.000000 | 30.000000                   | 20 |

Figure 87.6 displays the table of location and scale measures when the standardization method is ABW, for which the location measure is the biweight one-step M-estimate, and the scale measure is the biweight A-estimate. Note that the initial estimate for ABW is MAD. The following steps help to decide the value of the tuning constant:

1. For rural scores, the location estimate for MAD is 166.0, and the scale estimate for MAD is 32.0. The maximum of the rural scores is 253 (not shown), and the minimum is 110 (not shown). Thus, the tuning constant needs to be 3 so that it does not reject any observation that has a score between 110 to 253.
2. For urban scores, the location estimate for MAD is 153.0, and the scale estimate for MAD is 15.5. The maximum of the rural scores is 198, and the minimum (also an outlier) is 64. Thus, the tuning constant needs to be 4 so that it rejects the outlier (64) but includes the maximum (198) as a normal observation.
3. The maximum of the tuning constants, obtained in steps 1 and 2, is 4.

See Goodall (1983, Chapter 11) for details about the tuning constant. The ratio of the scale of rural scores to the scale of urban scores is approximately 2.06 (32.0/15.5). It is also close to the dispersion ratio observed in the previous schematic plots.

**Figure 87.6** Location and Scale Measures Table When METHOD=ABW

| High School Scores Data<br>METHOD=ABW(4) |            |                             |    |

| Name                                     | Location   | Scale                       | N  |
| total                                    | 162.889603 | 56.662855                   | 20 |
| High School Scores Data<br>METHOD=ABW(4) |            |                             |    |
| ----- Type=urban -----                   |            |                             |    |
| The STDIZE Procedure                     |            |                             |    |
| Location and Scale Measures              |            |                             |    |
| Location = biweight 1-step M-estimate    |            | Scale = biweight A-estimate |    |
| Name                                     | Location   | Scale                       | N  |
| total                                    | 156.014608 | 28.615980                   | 20 |

The preceding analysis shows that METHOD=MAD, METHOD=IQR, and METHOD=ABW all provide better dispersion ratios than METHOD=STD does.

You can recompute the standard deviation after deleting the outlier from the original data set for comparison. The following statements create a data set NoOutlier that excludes the outlier from the TotalScores data set and invoke PROC STDIZE with METHOD=STD.

```
data NoOutlier;
 set totalscores;
 if (total = 64) then delete;
run;

proc stdize data=NoOutlier method=std pstat;
 title2 'After Removing Outlier, METHOD=STD';
 var total;
 by Type;
run;
```

Figure 87.7 displays the location and scale measures after deleting the outlier. The lack of resistance of the standard deviation to outliers is clearly illustrated: if you delete the outlier, the sample standard deviation of urban scores changes from 30.07 to 22.09. The new ratio of the scale of rural scores to the scale of urban scores is approximately 1.90 (41.96/22.09).

**Figure 87.7** Location and Scale Measures Table When METHOD=STD without the Outlier

| High School Scores Data<br>After Removing Outlier, METHOD=STD |            |                            |    |
|---------------------------------------------------------------|------------|----------------------------|----|
| ----- Type=rural -----                                        |            |                            |    |

## Syntax: STDIZE Procedure

The following statements are available in the STDIZE procedure:

```

PROC STDIZE < options > ;
 BY variables ;
 FREQ variable ;
 LOCATION variables ;
 SCALE variables ;
 VAR variables ;
 WEIGHT variable ;

```

The PROC STDIZE statement is required. The BY, LOCATION, FREQ, VAR, SCALE, and WEIGHT statements are described in alphabetical order following the PROC STDIZE statement.

## PROC STDIZE Statement

**PROC STDIZE** < options > ;

The PROC STDIZE statement invokes the STDIZE procedure. You can specify the following options in the PROC STDIZE statement. Table 87.1 summarizes the options available in the PROC STDIZE statement.

**Table 87.1** Summary of PROC STDIZE Statement Options

| Option                                 | Description                                                                                                                |
|----------------------------------------|----------------------------------------------------------------------------------------------------------------------------|
| <b>Specify standardization methods</b> |                                                                                                                            |
| METHOD=                                | Specifies the name of the standardization method                                                                           |
| INITIAL=                               | Specifies the method for computing initial estimates for the A estimates                                                   |
| <b>Unstandardize variables</b>         |                                                                                                                            |
| UNSTD                                  | Unstandardizes variables when you also specify the METHOD=IN option                                                        |
| <b>Process missing values</b>          |                                                                                                                            |
| NOMISS                                 | Omits observations with any missing values from computation                                                                |
| MISSING=                               | Specifies the method or a numeric value for replacing missing values                                                       |
| REPLACE                                | Replaces missing data with zero in the standardized data                                                                   |
| REONLY                                 | Replaces missing data with the location measure (does not standardize the data)                                            |
| <b>Specify data set details</b>        |                                                                                                                            |
| DATA=                                  | Specifies the input data set                                                                                               |
| KEEPLN                                 | Specifies that output variables inherit the length of the analysis variable                                                |
| OUT=                                   | Specifies the output data set                                                                                              |
| OPREFIX=                               | Specifies that original variables appear in the OUT= data set                                                              |
| SPREFIX=                               | Specifies a prefix for the standardized variable names                                                                     |
| OUTSTAT=                               | Specifies the output statistic data set                                                                                    |
| <b>Specify computational settings</b>  |                                                                                                                            |
| VARDEF=                                | Specifies the variances divisor                                                                                            |
| NMARKERS=                              | Specifies the number of markers when you also specify PCTLMTD=ONEPASS                                                      |
| MULT=                                  | Specifies the constant to multiply each value by after standardizing                                                       |
| ADD=                                   | Specifies the constant to add to each value after standardizing and multiplying by the value specified in the MULT= option |
| FUZZ=                                  | Specifies the relative fuzz factor for writing the output                                                                  |
| <b>Specify percentiles</b>             |                                                                                                                            |
| PCTLDEF=                               | Specifies the definition of percentiles when you also specify the PCTLMTD=ORD_STAT option                                  |

Table 87.1 continued

| Option                            | Description                                                                                                 |
|-----------------------------------|-------------------------------------------------------------------------------------------------------------|
| PCTLMTD=                          | Specifies the method used to estimate percentiles                                                           |
| PCTLPTS=                          | Writes observations containing percentiles to the data set specified in the OUTSTAT= option                 |
| <b>Normalize scale estimators</b> |                                                                                                             |
| NORM                              | Normalizes the scale estimator to be consistent for the standard deviation of a normal distribution         |
| SNORM                             | Normalizes the scale estimator to have an expectation of approximately 1 for a standard normal distribution |
| <b>Specify output</b>             |                                                                                                             |
| PSTAT                             | Displays the location and scale measures                                                                    |

These options and their abbreviations are described (in alphabetical order) in the remainder of this section.

**ADD=c**

specifies a constant, *c*, to add to each value after standardizing and multiplying by the value you specify in the MULT= option. The default value is 0.

**DATA=SAS-data-set**

specifies the input data set to be standardized. If you omit the DATA= option, the most recently created data set is used.

**FUZZ=c**

specifies the relative fuzz factor. The default value is 1E-14. For the OUT= data set, the score is computed as follows:

$$\text{if } |result| < m \times c \text{ then } result = 0$$

where *m* is the constant specified in the MULT= option, or 1 if MULT= option is not specified.

For the OUTSTAT= data set and the location and scale table, the *scale* and *location* values are computed as follows:

$$\text{if } scale < |location| \times c \text{ then } scale = 0$$

Otherwise,

$$\text{if } |location| < m \times c \text{ then } location = 0$$

**INITIAL=method**

specifies the method for computing initial estimates for the A estimates (ABW, AWAVE, and AHUBER). You cannot specify the following methods for initial estimates: INITIAL=ABW, INITIAL=AHUBER, INITIAL=AWAVE, and INITIAL=IN. The default is INITIAL=MAD.

**KEEPLN**

specifies that the standardized variables inherit the lengths of the analysis variables that PROC STDIZE uses to derive them. PROC STDIZE stores numbers in double-precision without this option.

*Caution:* The KEEPLEN option causes the standardized variables to permanently lose numeric precision by truncating or rounding the values. However, the precision of the output variables will match that of the input.

**METHOD=*name***

specifies the name of the method for computing location and scale measures. Valid values for *name* are as follows: MEAN, MEDIAN, SUM, EUCLEN, USTD, STD, RANGE, MIDRANGE, MAXABS, IQR, MAD, ABW, AHUBER, AWAVE, AGK, SPACING, L, and IN.

For details about these methods, see the descriptions in the section “[Standardization Methods](#)” on page 7468. The default is METHOD=STD.

**MISSING=*method* | *value***

specifies the method (or a numeric value) for replacing missing values. If you omit the MISSING= option, the REPLACE option replaces missing values with the location measure given by the METHOD= option. Specify the MISSING= option when you want to replace missing values with a different value. You can specify any name that is valid in the METHOD= option except the name IN. The corresponding location measure is used to replace missing values.

If a numeric value is given, the value replaces missing values after standardizing the data. However, you can specify the REONLY option with the MISSING= option to suppress standardization for cases in which you want only to replace missing values.

**MULT=*c***

specifies a constant, *c*, by which to multiply each value after standardizing. The default value is 1.

**NMARKERS=*n***

specifies the number of markers used when you specify the one-pass algorithm (PCTLMTD=ONEPASS). The value *n* must be greater than or equal to 5. The default value is 105.

**NOMISS**

omits observations with missing values for any of the analyzed variables from calculation of the location and scale measures. If you omit the NOMISS option, all nonmissing values are used.

**NORM**

normalizes the scale estimator to be consistent for the standard deviation of a normal distribution when you specify the option METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING.

**OPREFIX<=*o-prefix*>**

specifies that the original variables should appear in the OUT= data set. You can optionally specify an equal sign and a prefix. For example, if OPREFIX=Original, then the names of the variables are OriginalVAR1, OriginalVAR2, and so on, where VAR1 and VAR2 are the original variable names. The value of OPREFIX= must be different from the value of SPREFIX=. If you specify OPREFIX, without an equal sign and a prefix, then the default prefix is null and you must specify SPREFIX=*s-prefix*.

**OUT=SAS-data-set**

specifies the name of the SAS data set created by PROC STDIZE. By default, the output data set is a copy of the DATA= data set except that the analyzed variables have been standardized. Analyzed variables are those specified in the VAR statement or, if there is no VAR statement, all numeric variables not listed in any other statement. However, you can use the OPREFIX option to request that both the original and standardized variables be included in the output data set. You can change variable names by specifying prefixes with the OPREFIX= and SPREFIX= options. See the section “[Output Data Sets](#)” on page 7473 for more information.

If you want to create a SAS data set in a permanent library, you must specify a two-level name. For more information about permanent libraries and SAS data sets, see *SAS Language Reference: Concepts*.

If you omit the OUT= option, PROC STDIZE creates an output data set named according to the DATA $n$  convention.

**OUTSTAT=SAS-data-set**

specifies the name of the SAS data set containing the location and scale measures and other computed statistics. See the section “[Output Data Sets](#)” on page 7473 for more information.

**PCTLDEF=percentiles**

specifies which of five definitions is used to calculate percentiles when you specify the option PCTLMTD=ORD\_STAT. By default, PCTLDEF=5. Note that the option PCTLMTD=ONEPASS implies PCTLDEF=5. See the section “[Computational Methods for the PCTLDEF= Option](#)” on page 7471 for details about percentile definition.

You cannot use PCTLDEF= when you compute weighted quantiles.

**PCTLMTD=ORD\_STAT | ONEPASS | P2**

specifies the method used to estimate percentiles. Specify the PCTLMTD=ORD\_STAT option to compute the percentiles by the order statistics method.

The PCTLMTD=ONEPASS option modifies an algorithm invented by Jain and Chlamtac (1985). See the section “[Computing Quantiles](#)” on page 7471 for more details about this algorithm.

**PCTLPTS= $n$** 

writes percentiles to the OUTSTAT= data set. Values of  $n$  can be any decimal number between 0 and 100, inclusive.

A requested percentile is identified by the \_TYPE\_ variable in the OUTSTAT= data set with a value of P $n$ . For example, suppose you specify the option PCTLPTS=10, 30. The corresponding observations in the OUTSTAT= data set that contain the 10th and the 30th percentiles would then have values \_TYPE\_=P10 and \_TYPE\_=P30, respectively.

**PSTAT**

displays the location and scale measures.

**REPLACE**

replaces missing data with the value 0 in the standardized data (this value corresponds to the location measure before standardizing). To replace missing data by other values, see the preceding description of the MISSING= option. You cannot specify both the REPLACE and REONLY options.

**REONLY**

replaces missing data only; PROC STDIZE does not standardize the data. Missing values are replaced with the location measure unless you also specify the `MISSING=value` option, in which case missing values are replaced with *value*. You cannot specify both the `REPLACE` and `REONLY` options.

**SNORM**

normalizes the scale estimator to have an expectation of approximately 1 for a standard normal distribution when you specify the `METHOD=SPACING` option.

**SPREFIX=<s-prefix>**

specifies a prefix for the standardized variables. For example, if `SPREFIX=Std`, then the names of the standardized variables are `StdVAR1`, `StdVAR2`, and so on, where `VAR1` and `VAR2` are the original variable names. The value of `SPREFIX=` must be different from the value of `OPREFIX=`. The default prefix is null. If you omit the `SPREFIX` option, the standardized variables still appear in the `OUT=` data set by default and the variable names remain the same. If you want to have the variable names changed, you need to specify a prefix with `SPREFIX=s-prefix`.

**UNSTD****UNSTDIZE**

unstandardizes variables when you specify the `METHOD=IN(ds)` option. The location and scale measures, along with constants for addition and multiplication that the unstandardization is based on, are identified by the `_TYPE_` variable in the `ds` data set.

The `ds` data set must have a `_TYPE_` variable and contain the following two observations: a `_TYPE_ = 'LOCATION'` observation and a `_TYPE_ = 'SCALE'` observation. The variable `_TYPE_` can also contain the optional observations, `'ADD'` and `'MULT'`; if these observations are not found in the `ds` data set, the constants specified in the `ADD=` and `MULT=` options (or their default values) are used for unstandardization.

See the section “`OUTSTAT= Data Set`” on page 7473 for details about the statistics that each value of `_TYPE_` represents. The formula used for unstandardization is as follows: If the final output value from the previous standardization is calculated as

$$result = add + multiply \times \frac{original - location}{scale}$$

The unstandardized variable is computed as

$$original = scale \times \frac{result - add}{multiply} + location$$

**VARDEF=DF | N | WDF | WEIGHT | WGT**

specifies the divisor to be used in the calculation of variances. By default, `VARDEF=DF`. The values and associated divisors are as follows.

| Value        | Divisor                | Formula            |
|--------------|------------------------|--------------------|
| DF           | Degrees of freedom     | $n - 1$            |
| N            | Number of observations | $n$                |
| WDF          | Sum of weights minus 1 | $(\sum_i w_i) - 1$ |
| WEIGHT   WGT | Sum of weights         | $\sum_i w_i$       |

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC STDIZE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the STDIZE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

When you specify the option METHOD=IN(ds), the following rules are applied to BY-group processing:

- If the ds data set does not contain any of the BY variables, the entire DATA= data set is standardized by the location and scale measures (along with the constants for addition and multiplication) in the ds data set.
- If the ds data set contains some, but not all, of the BY variables or if some BY variables do not have the same type or length in the ds data set that they have in the DATA= data set, PROC STDIZE displays an error message and stops.
- If all of the BY variables appear in the ds data set with the same type and length as in the DATA= data set, each BY group in the DATA= data set is standardized using the location and scale measures (along with the constants for addition and multiplication) from the corresponding BY group in the ds data set. The BY groups in the ds data set must be in the same order in which they appear in the DATA= data set. All BY groups in the DATA= data set must also appear in the ds data set. If you do not specify the NOTSORTED option, some BY groups can appear in the ds data set but not in the DATA= data set; such BY groups are not used in standardizing data.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## FREQ Statement

**FREQ** *variable* ;

If one variable in the input data set represents the frequency of occurrence for other values in the observation, specify the variable name in a FREQ statement. PROC STDIZE treats the data set as if each observation appeared  $n$  times, where  $n$  is the value of the FREQ variable for the observation. Nonintegral values of the FREQ variable are truncated to the largest integer less than the FREQ value. If the FREQ variable has a value that is less than 1 or is missing, the observation is not used in the analysis.

### NOTRUNCATE

#### NOTRUNC

specifies that frequency values are not truncated to integers.

The nonintegral values of the FREQ variable can be used for the following standardization methods: AGK, ABW, AHUBER, AWAVE, EUCLLEN, IQR, L, MAD, MEAN, MEDIAN, SPACING, STD, SUM, and USTD. The nonintegral frequency values are used for the MAD, MEDIAN, or IQR method only when PCTLMTD=ORD\_STAT is specified. If PCTLMTD=ONEPASS is specified, the NOTRUNCATE option is ignored.

---

## LOCATION Statement

**LOCATION** *variables* ;

The LOCATION statement specifies a list of numeric variables that contain location measures in the input data set specified by the METHOD=IN option.

---

## SCALE Statement

**SCALE** *variables* ;

The SCALE statement specifies the list of numeric variables that contain scale measures in the input data set specified by the METHOD=IN option.

---

## VAR Statement

**VAR** *variable* ;

The VAR statement lists numeric variables to be standardized. If you omit the VAR statement, all numeric variables not listed in the BY, FREQ, and WEIGHT statements are used.

## WEIGHT Statement

**WEIGHT** *variable* ;

The WEIGHT statement specifies a numeric variable in the input data set with values that are used to weight each observation. Only one variable can be specified.

The WEIGHT variable values can be nonintegers. An observation is used in the analysis only if the value of the WEIGHT variable is greater than zero.

The WEIGHT variable applies only when you specify the following standardization methods: AGK, EUCLEN, IQR, L, MAD, MEAN, MEDIAN, STD, SUM, and USTD. Weights are used for the METHOD=MAD, MEDIAN, or IQR only when PCTLMTD=ORD\_STAT is specified; if PCTLMTD=ONEPASS is specified, the WEIGHT statement is ignored.

PROC STDIZE uses the value of the WEIGHT variable to calculate the sample mean and sample variances:

$$\bar{x}_w = \sum_i w_i x_i / \sum_i w_i \quad (\text{sample mean})$$

$$us_w^2 = \sum_i w_i x_i^2 / d \quad (\text{uncorrected sample variances})$$

$$s_w^2 = \sum_i w_i (x_i - \bar{x}_w)^2 / d \quad (\text{sample variances})$$

where  $w_i$  is the weight value of the  $i$ th observation,  $x_i$  is the value of the  $i$ th observation, and  $d$  is the divisor controlled by the VARDEF= option (see the VARDEF= option for details).

The following weighted statistics are defined accordingly:

|        |                                                                                                        |
|--------|--------------------------------------------------------------------------------------------------------|
| MEAN   | the weighted mean, $\bar{x}_w$                                                                         |
| SUM    | the weighted sum, $\sum_i w_i x_i$                                                                     |
| USTD   | the weighted uncorrected standard deviation, $\sqrt{us_w^2}$                                           |
| STD    | the weighted standard deviation, $\sqrt{s_w^2}$                                                        |
| EUCLEN | the weighted Euclidean length, computed as the square root of the weighted uncorrected sum of squares: |

$$\sqrt{\sum_i w_i x_i^2}$$

|        |                                                                                                                                                                           |
|--------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| MEDIAN | the weighted median. See the section “ <a href="#">Weighted Percentiles</a> ” on page 7472 for the formulas and descriptions.                                             |
| MAD    | the weighted median absolute deviation from the weighted median. See the section “ <a href="#">Weighted Percentiles</a> ” on page 7472 for the formulas and descriptions. |
| IQR    | the weighted median, 25th percentile, and the 75th percentile. See the section “ <a href="#">Weighted Percentiles</a> ” on page 7472 for the formulas and descriptions.   |

- AGK the AGK estimate. This estimate is documented further in the ACECLUS procedure as the METHOD=COUNT option. See the discussion of the WEIGHT statement in Chapter 23, “The ACECLUS Procedure,” for information about how the WEIGHT variable is applied to the AGK estimate.
- L the  $L_p$  estimate. This estimate is documented further in the FASTCLUS procedure as the LEAST= option. See the discussion of the WEIGHT statement in Chapter 36, “The FASTCLUS Procedure,” for information about how the WEIGHT variable is used to compute weighted cluster means. The number of clusters is always 1.

---

## Details: STDIZE Procedure

---

### Standardization Methods

The following table lists standardization methods and their corresponding location and scale measures available with the METHOD= option.

**Table 87.2** Available Standardization Methods

| Method              | Location                     | Scale                                 |
|---------------------|------------------------------|---------------------------------------|
| MEAN                | Mean                         | 1                                     |
| MEDIAN              | Median                       | 1                                     |
| SUM                 | 0                            | Sum                                   |
| EUCLEN              | 0                            | Euclidean length                      |
| USTD                | 0                            | Standard deviation about origin       |
| STD                 | Mean                         | Standard deviation                    |
| RANGE               | Minimum                      | Range                                 |
| MIDRANGE            | Midrange                     | Range/2                               |
| MAXABS              | 0                            | Maximum absolute value                |
| IQR                 | Median                       | Interquartile range                   |
| MAD                 | Median                       | Median absolute deviation from median |
| ABW( <i>c</i> )     | Biweight one-step M-estimate | Biweight A-estimate                   |
| AHUBER( <i>c</i> )  | Huber one-step M-estimate    | Huber A-estimate                      |
| AWAVE( <i>c</i> )   | Wave one-step M-estimate     | Wave A-estimate                       |
| AGK( <i>p</i> )     | Mean                         | AGK estimate (ACECLUS)                |
| SPACING( <i>p</i> ) | Mid-minimum spacing          | Minimum spacing                       |
| L( <i>p</i> )       | L( <i>p</i> )                | L( <i>p</i> )                         |
| IN(ds)              | Read from data set           | Read from data set                    |

For METHOD=ABW( $c$ ), METHOD=AHUBER( $c$ ), or METHOD=AWAVE( $c$ ),  $c$  is a positive numeric tuning constant.

For METHOD=AGK( $p$ ),  $p$  is a numeric constant that gives the proportion of pairs to be included in the estimation of the within-cluster variances.

For METHOD=SPACING( $p$ ),  $p$  is a numeric constant that gives the proportion of data to be contained in the spacing.

For METHOD=L( $p$ ),  $p$  is a numeric constant greater than or equal to 1 that specifies the power to which differences are to be raised in computing an L( $p$ ) or Minkowski metric.

For METHOD=IN(ds), ds is the name of a SAS data set that meets either of the following two conditions:

- The data set contains a `_TYPE_` variable. The observation that contains the location measure corresponds to the value `_TYPE_ = 'LOCATION'`, and the observation that contains the scale measure corresponds to the value `_TYPE_ = 'SCALE'`. You can also use a data set created by the `OUTSTAT=` option from another PROC STDIZE statement as the ds data set. See the section “Output Data Sets” on page 7473 for the contents of the `OUTSTAT=` data set.
- The data set contains the location and scale variables specified by the `LOCATION` and `SCALE` statements.

PROC STDIZE reads in the location and scale variables in the ds data set by first looking for the `_TYPE_` variable in the ds data set. If it finds this variable, PROC STDIZE continues to search for all variables specified in the `VAR` statement. If it does not find the `_TYPE_` variable, PROC STDIZE searches for the location variables specified in the `LOCATION` statement and the scale variables specified in the `SCALE` statement.

The variable `_TYPE_` can also contain the optional observations, ‘ADD’ and ‘MULT’. If these observations are found in the ds data set, the values in the observation of `_TYPE_ = 'MULT'` are the multiplication constants, and the values in the observation of `_TYPE_ = 'ADD'` are the addition constants; otherwise, the constants specified in the `ADD=` and `MULT=` options (or their default values) are used.

For robust estimators, see Goodall (1983) and Iglewicz (1983). The MAD method has the highest breakdown point (50%), but it is somewhat inefficient. The ABW, AHUBER, and AWAVE methods provide a good compromise between breakdown and efficiency. The L( $p$ ) location estimates are increasingly robust as  $p$  drops from 2 (which corresponds to least squares, or mean estimation) to 1 (which corresponds to least absolute value, or median estimation). However, the L( $p$ ) scale estimates are not robust.

The SPACING method is robust to both outliers and clustering (Jannsen et al. 1995) and is, therefore, a good choice for cluster analysis or nonparametric density estimation. The mid-minimum spacing method estimates the mode for small  $p$ . The AGK method is also robust to clustering and more efficient than the SPACING method, but it is not as robust to outliers and takes longer to compute. If you expect  $g$  clusters, the argument to METHOD=SPACING or METHOD=AGK should be  $\frac{1}{g}$  or less. The AGK method is less biased than the SPACING method for small samples. As a general guide, it is reasonable to use AGK for samples of size 100 or less and SPACING for samples of size 1,000 or more, with the treatment of intermediate sample sizes depending on the available computer resources.

## Computation of the Statistics

Formulas for statistics of METHOD=MEAN, METHOD=MEDIAN, METHOD=SUM, METHOD=USTD, METHOD=STD, METHOD=RANGE, and METHOD=IQR are given in the chapter “Elementary Statistics Procedures” (*Base SAS Procedures Guide*).

Note that the computations of median and upper and lower quartiles depend on the PCTLMTD= option.

The other statistics listed in Table 87.2, except for METHOD=IN, are described as follows:

|                |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EUCLEN         | Euclidean length.<br>$\sqrt{\sum_{i=1}^n x_i^2}$ , where $x_i$ is the $i$ th observation and $n$ is the total number of observations in the sample.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| L( $p$ )       | Minkowski metric. This metric is documented as the LEAST= $p$ option in the PROC FASTCLUS statement of the FASTCLUS procedure (see Chapter 36, “The FASTCLUS Procedure”).<br><br>If you specify METHOD=L( $p$ ) in the PROC STDIZE statement, your results are similar to those obtained from PROC FASTCLUS if you specify the LEAST= $p$ option with MAXCLUS=1 (and use the default values of the MAXITER= option). The difference between the two types of calculations concerns the maximum number of iterations. In PROC STDIZE, it is a criterion for convergence on all variables; in PROC FASTCLUS, it is a criterion for convergence on a single variable.<br><br>The location and scale measures for L( $p$ ) are output to the OUTSEED= data set in PROC FASTCLUS. |
| MIDRANGE       | $(\text{maximum} + \text{minimum})/2$                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| ABW( $c$ )     | Tukey’s biweight. See Goodall (1983, pp. 376–378, p. 385) for the biweight one-step M-estimate. | AGK( $p$ )     | The noniterative univariate form of the estimator described by Art, Gnanadesikan, and Kettenring (1982).<br><br>The AGK estimate is documented in the section on the METHOD= option in the PROC ACECLUS statement of the ACECLUS procedure (also see the section “Background” on page 814 in Chapter 23, “The ACECLUS Procedure”). Specifying METHOD=AGK( $p$ ) in the PROC STDIZE statement is the same as specifying METHOD=COUNT and P= $p$ in the PROC ACECLUS statement.                                                                                                                                                                                                                                                                                                |
| SPACING( $p$ ) | The absolute difference between two data values. The minimum spacing for a proportion $p$ is the minimum absolute difference between two data values that contain a proportion $p$ of the data between them. The mid-minimum spacing is the mean of these two data values.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Computing Quantiles

PROC STDIZE offers two methods for computing quantiles: the one-pass approach and the order-statistics approach (like that used in the UNIVARIATE procedure).

The one-pass approach used in PROC STDIZE modifies the  $P^2$  algorithm for histograms proposed by Jain and Chlamtac (1985). The primary difference comes from the movement of markers. The one-pass method allows a marker to move to the right (or left) by more than one position (to the largest possible integer) as long as it does not result in two markers being in the same position. The modification is necessary in order to incorporate the `FREQ` variable.

You might obtain inaccurate results if you use the one-pass approach to estimate quantiles beyond the quartiles (that is, when you estimate quantiles  $< P25$  or quantiles  $> P75$ ). A large sample size (10,000 or more) is often required if the tail quantiles (quantiles  $\leq P10$  or quantiles  $\geq P90$ ) are requested. Note that, for variables with highly skewed or heavy-tailed distributions, tail quantile estimates might be inaccurate.

The order-statistics approach for estimating quantiles is faster than the one-pass method but requires that the entire data set be stored in memory. The accuracy in estimating the quantiles is comparable for both methods when the requested percentiles are between the lower and upper quartiles. The default is `PCTLMTD=ORD_STAT` if enough memory is available; otherwise, `PCTLMTD=ONEPASS`.

### Computational Methods for the `PCTLDEF=` Option

You can specify one of five methods for computing quantile statistics when you use the order-statistics approach (`PCTLMTD=ORD_STAT`); otherwise, the `PCTLDEF=5` method is used when you use the one-pass approach (`PCTLMTD=ONEPASS`).

**Percentile Definitions** Let  $n$  be the number of nonmissing values for a variable, and let  $x_1, x_2, \dots, x_n$  represent the ordered values of the variable. For the  $t$ th percentile, let  $p = t/100$ . In the following definitions numbered 1, 2, 3, and 5, let

$$np = j + g$$

where  $j$  is the integer part and  $g$  is the fractional part of  $np$ . For definition 4, let

$$(n + 1)p = j + g$$

Given the preceding definitions, the  $t$ th percentile,  $y$ , is defined as follows:

`PCTLDEF=1`      weighted average at  $x_{np}$

$$y = (1 - g)x_j + gx_{j+1}$$

where  $x_0$  is taken to be  $x_1$

`PCTLDEF=2`      observation numbered closest to  $np$

$$y = x_i$$

where  $i$  is the integer part of  $np + 1/2$  if  $g \neq 1/2$ . If  $g = 1/2$ , then

$y = x_j$  if  $j$  is even, or

$y = x_{j+1}$  if  $j$  is odd

|           |                                                |
|-----------|------------------------------------------------|
| PCTLDEF=3 | empirical distribution function                |
|           | $y = x_j$ if $g = 0$                           |
|           | $y = x_{j+1}$ if $g > 0$                       |
| PCTLDEF=4 | weighted average aimed at $x_{p(n+1)}$         |
|           | $y = (1 - g)x_j + gx_{j+1}$                    |
|           | where $x_{n+1}$ is taken to be $x_n$           |
| PCTLDEF=5 | empirical distribution function with averaging |
|           | $y = (x_j + x_{j+1})/2$ if $g = 0$             |
|           | $y = x_{j+1}$ if $g > 0$                       |

### Weighted Percentiles

When you specify a WEIGHT statement, or specify the NOTRUNCATE option in a FREQ statement, the percentiles are computed differently. The 100 $p$ th weighted percentile  $y$  is computed from the empirical distribution function with averaging

$$y = \begin{cases} \frac{1}{2}(x_i + x_{i+1}) & \text{if } \sum_{j=1}^i w_j = pW \\ x_{i+1} & \text{if } \sum_{j=1}^i w_j < pW < \sum_{j=1}^{i+1} w_j \end{cases}$$

where  $w_i$  is the weight associated with  $x_i$ , and where  $W = \sum_{i=1}^n w_i$  is the sum of the weights.

For PCTLMTD= ORD\_STAT, the PCTLDEF= option is not applicable when a WEIGHT statement is used, or when a NOTRUNCATE option is specified in a FREQ statement. However, in this case, if all the weights are identical, the weighted percentiles are the same as the percentiles that would be computed without a WEIGHT statement and with PCTLDEF=5.

For PCTLMTD= ONEPASS, the quantile computation currently does not use any weights.

---

### Constant Data

Constant variables are not standardized. The scale value is set to missing when the data are constant.

---

### Missing Values

Missing values can be replaced by the location measure or by any specified constant (see the REPLACE option and the MISSING= option). You can also suppress standardization if you want only to replace missing values (see the REONLY option).

If you specify the NOMISS option, PROC STDIZE omits observations with any missing values in the analyzed variables from computation of the location and scale measures.

## Output Data Sets

### OUT= Data Set

By default, the output data set is a copy of the DATA= data set except that the analyzed variables have been standardized. Analyzed variables are those specified in the VAR statement or, if there is no VAR statement, all numeric variables not listed in any other statement. However, you can use the OPREFIX option to request that both the original and standardized variables be included in the output data set. You can change variable names by specifying prefixes with the OPREFIX=*o-prefix* and SPREFIX=*s-prefix* options, but keep in mind that the two prefixes must be different. See [OPREFIX](#) and [SPREFIX](#) for more information.

### OUTSTAT= Data Set

The new data set contains the following variables:

- the BY variables, if any
- `_TYPE_`, a character variable
- the analyzed variables

Each observation in the new data set contains a type of statistic as indicated by the `_TYPE_` variable. The values of the `_TYPE_` variable are as follows:

|                |                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| LOCATION       | location measure of each variable                                                                                                                                                                                      |
| SCALE          | scale measure of each variable                                                                                                                                                                                         |
| ADD            | constant specified in the ADD= option. This value is the same for each variable.                                                                                                                                       |
| MULT           | constant specified in the MULT= option. This value is the same for each variable.                                                                                                                                      |
| N              | total number of nonmissing positive frequencies of each variable                                                                                                                                                       |
| NORM           | norm measure of each variable. This observation is produced only when you specify the NORM option with METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING or when you specify the SNORM option with METHOD=SPACING. |
| NObsRead       | number of physical records read                                                                                                                                                                                        |
| NObsUsed       | number of physical records used in the analysis                                                                                                                                                                        |
| NObsMiss       | number of physical records containing missing values                                                                                                                                                                   |
| $P_n$          | percentiles of each variable, as specified by the PCTLPTS= option. The argument $n$ is any real number such that $0 \leq n \leq 100$                                                                                   |
| SumFreqsRead   | sum of the frequency variable (or the sum of NObsUsed ones when there is no frequency variable) for all observations read                                                                                              |
| SumFreqsUsed   | sum of the frequency variable (or the sum of NObsUsed ones when there is no frequency variable) for all observations used in the analysis                                                                              |
| SumWeightsRead | sum of the weight variable (or the sum of NObsUsed ones when there is no weight variable) for all observations read                                                                                                    |

SumWeightsUsed      sum of the weight variable (or the sum of NObsUsed ones when there is no weight variable) for all observations used in the analysis

---

## Displayed Output

If you specify the PSTAT option, PROC STDIZE displays the following statistics for each variable:

- the name of the variable, Name
- the location estimate, Location
- the scale estimate, Scale
- the norm estimate, Norm (when you specify the NORM option with METHOD=AGK, METHOD=IQR, METHOD=MAD, or METHOD=SPACING or when you specify the SNORM option with METHOD=SPACING)
- sum of nonmissing positive frequencies, N
- sum of nonmissing positive weights if the WEIGHT statement is specified, Sum of Weights

---

## ODS Table Names

PROC STDIZE assigns a name to the single table it creates. You can use this name to reference the table when using the Output Delivery System (ODS) to select a table or create an output data set. This name is listed in Table 87.3. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 87.3** ODS Table Produced by PROC STDIZE

| ODS Table Name | Description                 | Statement | Option |
|----------------|-----------------------------|-----------|--------|
| Statistics     | Location and Scale Measures | PROC      | PSTAT  |

## Example: STDIZE Procedure

---

### Example 87.1: Standardization of Variables in Cluster Analysis

To illustrate the effect of standardization in cluster analysis, this example uses the Fish data set described in the “Getting Started” section of Chapter 36, “The FASTCLUS Procedure.” The numbers are measurements taken on 159 fish caught from the same lake (Laengelmavesi) near Tampere in Finland (Puranen 1917). The fish data set is available from the Sashelp library.

The species (bream, parkki, pike, perch, roach, smelt, and whitefish), weight, three different length measurements (measured from the nose of the fish to the beginning of its tail, the notch of its tail, and the end of its tail), height, and width of each fish are recorded.

A couple of new variables are created in the Fish data set: `Weight3` and `logLengthRatio`. The weight of a fish indicates its size—a heavier pike tends to be larger than a lighter pike. To get a one-dimensional measure of the size of a fish, take the cubic root of the weight (`Weight3`). The variables `Height`, `Width`, `Length1`, `Length2`, and `Length3` are rescaled in order to adjust for dimensionality. The `logLengthRatio` variable measures the tail length.

Because the new variables `Weight3`–`logLengthRatio` depend on the variable `Weight`, observations with missing values for `Weight` are not added to the data set. Consequently, there are 157 observations in the SAS data set `Sashelp.Fish`.

Before you perform a cluster analysis on coordinate data, it is necessary to consider scaling or transforming the variables since variables with large variances tend to have a larger effect on the resulting clusters than variables with small variances do.

This example uses three different approaches to standardize or transform the data prior to the cluster analysis. The first approach uses several standardization methods provided in the `STDIZE` procedure. However, since standardization is not always appropriate prior to the clustering (see Milligan and Cooper (1987) for a Monte Carlo study on various methods of variable standardization), the second approach performs the cluster analysis with no standardization. The third approach invokes the `ACECLUS` procedure to transform the data into a within-cluster covariance matrix.

The clustering is performed by the `FASTCLUS` procedure to find seven clusters. Note that the variables `Length2` and `Length3` are eliminated from this analysis since they both are significantly and highly correlated with the variable `Length1`. The correlation coefficients are 0.9958 and 0.9604, respectively. An output data set is created, and the `FREQ` procedure is invoked to compare the clusters with the species classification.

The DATA step is as follows:

```

title 'Fish Measurement Data';

data Fish;
 set sashelp.fish;
 if Weight <= 0 or Weight = . then delete;
 Weight3 = Weight ** (1/3);
 Height = Height / Weight3;
 Width = Width / Weight3;
 Length1 = Length1 / Weight3;
 Length2 = Length2 / Weight3;
 Length3 = Length3 / Weight3;
 LogLengthRatio = log(Length3 / Length1);
run;

```

The following macro, Std, standardizes the Fish data. The macro reads a single argument, mtd, which selects the METHOD= specification to be used in PROC STDIZE.

```

/*--- macro for standardization ---*/

%macro Std(mtd);
 title2 "Data are Standardized by PROC STDIZE with METHOD= &mtd";
 proc stdize data=fish out=sdzout method=&mtd;
 var Length1 logLengthRatio Height Width Weight3;
 run;
%mend Std;

```

The following macro, FastFreq, includes a PROC FASTCLUS statement for performing cluster analysis and a PROC FREQ statement for crosstabulating species with the cluster membership information that is derived from the previous PROC FASTCLUS statement. The macro reads a single argument, ds, which selects the input data set to be used in PROC FASTCLUS.

```

/*--- macro for clustering and crosstabulating ---*/
/*--- cluster membership with species ---*/

%macro FastFreq(ds);
 proc fastclus data=&ds out=clust maxclusters=7 maxiter=100 noprint;
 var Length1 logLengthRatio Height Width Weight3;
 run;

 proc freq data=clust;
 tables species*cluster;
 run;
%mend FastFreq;

```

The following analysis (labeled 'Approach 1') includes 18 different methods of standardization followed by clustering. Since there is a large amount of output from this approach, only results from METHOD=STD, METHOD=RANGE, METHOD=AGK(0.14), and METHOD=SPACING(0.14) are shown. The following statements produce [Output 87.1.1](#) through [Output 87.1.4](#).

```
/* Approach 1: data are standardized by PROC STDIZE */

The following analysis (labeled 'Approach 3') transforms the original data with the ACECLUS procedure and creates a TYPE=ACE output data set that is used as an input data set for the cluster analysis. The following statements produce [Output 87.1.6](#).

```
/* Approach 3: data are transformed by PROC ACECLUS */

title2 'Data are Transformed by PROC ACECLUS';
proc aceclus data=fish out=ace p=.02 noprint;
 var Length1 logLengthRatio Height Width Weight3;
run;
%FastFreq(ace);
```

Table 87.4 displays a table summarizing each classification results. In this table, the first column represents the standardization method, the second column represents the number of clusters that the seven species are classified into, and the third column represents the total number of observations that are misclassified.

**Table 87.4** Summary of Clustering Results

| Method of Standardization | Number of Clusters | Misclassification |
|---------------------------|--------------------|-------------------|
| MEAN                      | 5                  | 71                |

Consider the results displayed in Output 87.1.1. In that analysis, the method of standardization is STD, and the number of clusters and the number of misclassifications are computed as shown in Table 87.5.

**Table 87.5** Computations of Numbers of Clusters and Misclassification When Standardization Method Is STD

| Species   | Cluster Number | Misclassification in Each Species |
|-----------|----------------|-----------------------------------|
| Bream     | 6              | 0                                 |
| Parkki    | 5              | 0                                 |
| Perch     | 7              | 29                                |
| Pike      | 1              | 0                                 |
| Roach     | 7              | 0                                 |
| Smelt     | 3              | 1                                 |
| Whitefish | 7              | 3                                 |

In Output 87.1.1, the bream species is classified as cluster 6 since all 34 bream are categorized into cluster 6 with no misclassification. A similar pattern is seen with the roach, parkki, pike, and smelt species.

For the whitefish species, two fish are categorized into cluster 2, one fish is categorized into cluster 4, and three fish are categorized into cluster 7. Because the majority of this species is categorized into cluster 7, it is recorded in Table 87.5 as being classified as cluster 7 with 3 misclassifications. A similar pattern is seen with the perch species: it is classified as cluster 7 with 29 misclassifications.

In summary, when the standardization method is STD, seven species of fish are classified into only five clusters and the total number of misclassified observations is 33.

The result of this analysis demonstrates that when variables are standardized by the STDIZE procedure with methods including RANGE, MIDRANGE, MAXABS, AGK(0.14), and SPACING(0.14), the FASTCLUS procedure produces the correct number of clusters and less misclassification than it does when other standardization methods are used. The SPACING method attains the best result, probably because the variables Length1 and Height both exhibit marked groupings (bimodality) in their distributions.

### Overview: STDRATE Procedure

Epidemiology is the study of the occurrence and distribution of health-related states or events in specified populations. Epidemiology also includes the study of the determinants that influence these states, and the application of this knowledge to control health problems (Porta 2008). It is a discipline that describes, quantifies, and postulates causal mechanisms for health phenomena in populations (Friss and Sellers 2009).

A common goal is to establish relationships between various factors (such as exposure to a specific chemical) and the event outcomes (such as incidence of disease). But the measure of an association between an exposure and an event outcome can be biased due to confounding. That is, the association of the exposure to some other variables, such as age, influences the occurrence of the event outcome. With confounding, the usual effect between an exposure and an event outcome can be biased because some of the effect might be accounted for by other variables. For example, with an event rate discrepancy among different age groups of a population, the overall crude rate might not provide a useful summary statistic to compare populations.

One strategy to control confounding is stratification. In stratification, a population is divided into several subpopulations according to specific criteria for the confounding variables, such as age and sex groups. The effect of the exposure on the event outcome is estimated within each stratum, and then these stratum-specific effect estimates are combined into an overall estimate.

Two commonly used event frequency measures are rate and risk:

- A rate is a measure of the frequency with which an event occurs in a defined population in a specified period of time. It measures the change in one quantity per unit of another quantity. For example, an event rate measures how fast the events are occurring. That is, an event rate of a population over a specified time period can be defined as the number of new events divided by population-time (Kleinbaum, Kupper, and Morgenstern 1982, p. 100) over the same time period.
- A risk is the probability that an event occurs in a specified time period. It is assumed that only one event can occur in the time period for each subject or item. The overall crude risk of a population over a specified time period is the number of new events in the time period divided by the population size at the beginning of the time period.

Standardized overall rate and risk estimates based on stratum-specific estimates can be derived with the effects of confounding variables removed. These estimates provide useful summary statistics and allow valid comparison of the populations. There are two types of standardization:

- Direct standardization computes the weighted average of stratum-specific estimates in the study population, using the weights from a standard or reference population. This standardization is applicable when the study population is large enough to provide stable stratum-specific estimates. The directly standardized estimate is the overall crude rate in the study population if it has the same strata distribution as the reference population. When standardized estimates for different populations are derived by using the same reference population, the resulting estimates can also be compared by using the estimated difference and estimated ratio statistics.
- Indirect standardization computes the weighted average of stratum-specific estimates in the reference population, using the weights from the study population. The ratio of the overall crude rate or risk in the study population and the corresponding weighted estimate in the reference population is the standardized morbidity ratio (SMR). This ratio is also the standardized mortality ratio if the event is death. SMR is used to compare rates or risks in the study and reference populations. With SMR, the indirectly standardized estimate is then computed as the product of the SMR and the overall crude estimate for the reference population. SMR and indirect standardization are applicable even when the study population is so small that the resulting stratum-specific rates are not stable.

Assuming that an effect, such as the rate difference between two populations, is homogeneous across strata, each stratum provides an estimate of the same effect. A pooled estimate of the effect can then be derived

from these stratum-specific effect estimates. One way to estimate a homogeneous effect is the Mantel-Haenszel method (Greenland and Rothman 2008, p. 271). For a homogeneous rate difference effect between two populations, the Mantel-Haenszel estimate is identical to the difference between two directly standardized rates, but with weights derived from the two populations instead of from an explicitly specified reference population. The Mantel-Haenszel method can also be applied to other homogeneous effects between populations, such as the rate ratio, risk difference, and risk ratio.

The STDRATE procedure computes directly standardized rates and risks for study populations. For two study populations with the same reference population, PROC STDRATE compares directly standardized rates or risks from these two populations. For homogeneous effects across strata, PROC STDRATE computes Mantel-Haenszel estimates. The STDRATE procedure also computes indirectly standardized rates and risks, including SMR.

The attributable fraction measures the excess event rate or risk fraction in the exposed population that can be attributed to the exposure. The rate or risk ratio statistic is required in the attributable fraction computation, and the STDRATE procedure estimates the ratio by using either SMR or the rate ratio statistic in the Mantel-Haenszel estimates.

Although the STDRATE procedure provides useful summary standardized statistics, standardization is not a substitute for individual comparisons of stratum-specific estimates. PROC STDRATE provides summary statistics, such as rate and risk estimates and their confidence limits, in each stratum. In addition, PROC STDRATE also displays these stratum-specific statistics by using ODS Graphics.

Note that the term standardization has different meanings in other statistical applications. For example, the STDIZE procedure standardizes numeric variables in a SAS data set by subtracting a location measure and dividing by a scale measure.

---

## Getting Started: STDRATE Procedure

This example illustrates indirect standardization and uses the standardized mortality ratio to compare the death rate from skin cancer between people who live in the state of Florida and people who live in the United States as a whole.

The Florida\_C43 data set contains the stratum-specific mortality information for skin cancer in year 2000 for the state of Florida (Florida Department of Health 2000, 2012). The variable Age is a grouping variable that forms the strata in the standardization, and the variables Event and PYear identify the number of events and total person-years, respectively. The COMMA11. format is specified in the DATA step to input numerical values that contain commas in PYear.

```
data Florida_C43;
 input Age $1-5 Event PYear comma11.;
 datalines;
00-04 0 953,785
05-14 0 1,997,935
15-24 4 1,885,014
25-34 14 1,957,573
35-44 43 2,356,649
45-54 72 2,088,000
55-64 70 1,548,371
65-74 126 1,447,432
```

```

75-84 136 1,087,524
85+ 73 335,944
;

```

The US\_C43 data set contains the corresponding stratum-specific mortality information for the United States in year 2000 (Miniño et al. 2002; U.S. Bureau of Census 2011). The variable `Age` is the grouping variable, and the variables `Event` and `PYear` identify the number of events and the total person-years, respectively.

```

data US_C43;
 input Age $1-5 Event comma7. PYear comma12.;
 datalines;
00-04 0 19,175,798
05-14 1 41,077,577
15-24 41 39,183,891
25-34 186 39,892,024
35-44 626 45,148,527
45-54 1,199 37,677,952
55-64 1,303 24,274,684
65-74 1,637 18,390,986
75-84 1,624 12,361,180
85+ 803 4,239,587
;

```

The following statements invoke the STD RATE procedure and request indirect standardization to compare death rates between the state of Florida and the United States:

```

ods graphics on;
proc stdrate data=Florida_C43 refdata=US_C43
 method=indirect
 stat=rate(mult=100000)
 plots=all
 ;
 population event=Event total=PYear;
 reference event=Event total=PYear;
 strata Age / stats smr;
run;
ods graphics off;

```

The `DATA=` and `REFDATA=` options name the study data set and reference data set, respectively. The `METHOD=INDIRECT` option requests indirect standardization. The `STAT=RATE` option specifies the rate as the frequency measure for standardization, and the `MULT=100000` suboption (which is the default) displays the rates per 100,000 person-years in the table output and graphics output. The `PLOTS=ALL` option requests all appropriate plots with indirect standardization.

The POPULATION statement specifies the options that are related to the study population, and the EVENT= and TOTAL= options specify variables for the number of events and person-years in the study population, respectively.

The REFERENCE statement specifies the options related to the reference population, and the EVENT= and TOTAL= options specify variables for the number of events and person-years in the reference population, respectively.

The STRATA statement lists the variable Age that forms the strata. The STATS option requests a strata information table that contains stratum-specific statistics such as rates, and the SMR option requests a table of stratum-specific SMR estimates.

The “Standardization Information” table in [Figure 88.1](#) displays the standardization information.

**Figure 88.1** Standardization Information

| The STDRATE Procedure       |                          |
|-----------------------------|--------------------------|
| Standardization Information |                          |
| Data Set                    | WORK.FLORIDA_C43         |
| Reference Data Set          | WORK.US_C43              |
| Method                      | Indirect Standardization |
| Statistic                   | Rate                     |
| Number of Strata            | 10                       |
| Rate Multiplier             | 100000                   |

The STATS option in the STRATA statement requests that the “Indirectly Standardized Strata Statistics” table in [Figure 88.2](#) display the strata information and expected number of events at each stratum. The MULT=100000 suboption in the STAT=RATE option requests that crude rates per 100,000 person-years be displayed. The Expected Events column displays the expected number of events when the stratum-specific rates in the reference data set are applied to the corresponding person-years in the study data set.

With ODS Graphics enabled, the PLOTS=ALL option displays all appropriate plots. With indirect standardization and a rate statistic, these plots include the strata distribution plot, the strata rate plot, and the strata SMR plot. By default, strata levels are displayed on the vertical axis for these plots.

The strata distribution plot displays proportions for stratum-specific person-years in the study and reference populations, as shown in Figure 88.3.

Figure 88.3 Strata Distribution Plot

The strata distribution plot displays the proportions in the “Indirectly Standardized Strata Statistics” table in Figure 88.2. In the plot, the proportions of the study population are identified by the blue lines, and the proportions of the reference population are identified by the red lines. The plot shows that the study population has higher proportions in older age groups and lower proportions in younger age groups than the reference population.

The strata rate plot displays stratum-specific rate estimates in the study and reference populations, as shown in Figure 88.4. This plot displays the rate estimates in the “Indirectly Standardized Strata Statistics” table in Figure 88.2. In addition, the plot displays the confidence limits for the rate estimates in the study population and the overall crude rates for the two populations.

Figure 88.4 Strata Rate Plot

The SMR option in the STRATA statement requests that the “Strata SMR Estimates” table in Figure 88.5 display the strata SMR at each stratum. The MULT=100000 suboption in the STAT=RATE option requests that the reference rates per 100,000 person-years be displayed.

| 4                        | 0.7304                       | 2.3373 |
| 5                        | 0.9226                       | 1.7093 |
| 6                        | 0.8333                       | 1.3339 |
| 7                        | 0.6449                       | 1.0395 |
| 8                        | 0.8072                       | 1.1487 |
| 9                        | 0.7919                       | 1.1118 |
| 10                       | 0.8841                       | 1.4104 |

The “Strata SMR Estimates” table shows that although SMR is less than 1 only at three age strata (55–64, 65–74, and 75–84), these three strata contain about 60% of the total events.

The strata SMR plot displays stratum-specific SMR estimates with confidence limits, as shown in Figure 88.6. The plot displays the SMR estimates in the “Strata SMR Estimates” table in Figure 88.5.

Figure 88.6 Strata SMR Plot

The METHOD=INDIRECT option requests that the “Standardized Morbidity/Mortality Ratio” table in Figure 88.7 be displayed. The table displays the SMR, its confidence limits, and the test for the null hypothesis  $H_0 : SMR = 1$ . The default ALPHA=0.05 option requests that 95% confidence limits be constructed.

Figure 88.7 Standardized Morbidity/Mortality Ratio

| Standardized Morbidity/Mortality Ratio |                 |              |                |                              |        |      |         |
|----------------------------------------|-----------------|--------------|----------------|------------------------------|--------|------|---------|
| Observed Events                        | Expected Events | Standard SMR | Standard Error | 95% Normal Confidence Limits |        | Z    | Pr >  Z |
| 538                                    | 528.726         | 1.0175       | 0.0439         | 0.9316                       | 1.1035 | 0.40 | 0.6893  |

The 95% normal confidence limits contain the null hypothesis value  $SMR = 1$ , and the hypothesis of  $SMR = 1$  is not rejected at the  $\alpha = 0.05$  level from the normal test.

The “Indirectly Standardized Rate Estimates” table in Figure 88.8 displays the indirectly standardized rate and related statistics.

| 2.6829                                 | 0.1157      | 2.4562            | 2.9096     |          |        |  |

The indirectly standardized rate estimate is the product of the SMR and the crude rate estimate for the reference population. The table shows that although the crude rate in the state of Florida (3.4359) is 30% higher than the crude rate in the U.S. (2.6366), the resulting standardized rate (2.6829) is close to the crude rate in the U.S.

---

## Syntax: STD RATE Procedure

The following statements are available in PROC STD RATE:

```

PROC STD RATE < options > ;
 BY variables ;
 POPULATION options ;
 REFERENCE options ;
 STRATA variables < / option > ;

```

The PROC STD RATE statement invokes the procedure, names the data sets, specifies the standardization method, and identifies the statistic for standardization. The BY statement requests separate analyses of groups defined by the BY variables. The required POPULATION statement specifies the rate or risk information in study populations, and the REFERENCE statement specifies the rate or risk information in the reference population. The STRATA statement lists the variables that form the strata.

The following sections describe the PROC STD RATE statement and then describe the other statements in alphabetical order.

## PROC STD RATE Statement

**PROC STD RATE** < options > ;

Table 88.1 summarizes the *options* in the PROC STD RATE statement.

**Table 88.1** Summary of PROC STD RATE Options

| Option                         | Description                                                                                               |

| <b>Input Data Sets</b>         |                                                                                                           |
| <b>DATA=</b>                   | Names the SAS data set that contains the study populations                                                |
| <b>REFDATA=</b>                | Names the SAS data set that contains the reference population                                             |
| <b>Standardization Methods</b> |                                                                                                           |
| <b>METHOD=</b>                 | Specifies the method for standardization                                                                  |
| <b>STAT=</b>                   | Specifies the statistic for standardization                                                               |
| <b>EFFECT</b>                  | Specifies the test to compare study populations for direct standardization and Mantel-Haenszel estimation |
| <b>Displayed Output</b>        |                                                                                                           |
| <b>ALPHA=</b>                  | Specifies the significance level for confidence intervals                                                 |
| <b>CL=</b>                     | Requests the confidence limits for the standardized estimates                                             |
| <b>PLOTS</b>                   | Requests stratum-specific plots                                                                           |

You can specify the following *options* in the PROC STD RATE statement to compute standardized rates and risks in the procedure. They are listed in alphabetical order.

### **ALPHA=** $\alpha$

requests that confidence limits be constructed with confidence level  $100(1 - \alpha)\%$ , where  $0 < \alpha < 1$ . The default is ALPHA=0.05. These confidence limits include confidence limits for the stratum-specific rates or risks, standardized rate and risk, standardized morbidity/mortality ratio, and population attributable rate and risk.

### **CL=GAMMA** < (TYPE=AVERAGE | CONSERVATIVE) > | LOGNORMAL | NONE | NORMAL | POISSON

specifies the method to construct confidence limits for SMR and standardized rate and risk. You can specify the following values for this option:

#### **GAMMA**

requests confidence limits based on a gamma distribution for METHOD=DIRECT and METHOD=MH. This value applies only when STAT=RATE. You can specify the TYPE=CONSERVATIVE suboption to request conservative confidence limits that are based on a gamma distribution and were developed by Fay and Feuer (1997), or you can specify the TYPE=AVERAGE suboption to request modified confidence limits proposed by Tiwari, Clegg, and Zou (2006).

**LOGNORMAL**

requests confidence limits based on a lognormal distribution.

**NONE**

suppresses construction of confidence limits.

**NORMAL**

requests confidence limits based on a normal distribution.

**POISSON**

requests confidence limits based on a Poisson distribution. This value applies only when METHOD=INDIRECT.

The default is CL=NORMAL.

**DATA=SAS-data-set**

names the required SAS data set that contains the event information in the study populations.

**EFFECT <=DIFF | RATIO >**

displays a table of the effect estimate and associated confidence limits. This option applies only when METHOD=DIRECT with two study populations and when METHOD=MH, where two study populations are required.

EFFECT and EFFECT=RATIO display a test on the ratio effect of estimates between the study populations, and the EFFECT=DIFF option displays a test on the difference effect.

**METHOD= DIRECT | INDIRECT <(AF)> | MH <(AF)>****M= DIRECT | INDIRECT <(AF)> | MH <(AF)>**

specifies the required method for standardization. METHOD=DIRECT requests direct standardization, METHOD=INDIRECT requests indirect standardization, and METHOD=MH requests Mantel-Haenszel estimation.

The AF suboption requests the attributable fraction that measures the excess event rate or risk fraction in the exposed population that is attributable to the exposure. This suboption also requests the population attributable fraction that measures the excess event rate or risk fraction in the total population that is attributable to the exposure.

**PLOTS <( global-options )> <= plot-request >****PLOTS <( global-options )> <= ( plot-request <... plot-request > ) >**

specifies options that control the details of the plots. The default is PLOTS=RATE for STAT=RATE and PLOTS=RISK for STAT=RISK.

You can specify the following *global-options*:

**DISPLAY=INDEX | LEVEL**

specifies tick mark values for the strata axis. DISPLAY=LEVEL displays strata levels on the strata axis, and DISPLAY=INDEX displays strata indices of sequential strata identification numbers on the strata axis. The default is DISPLAY=LEVEL.

**ONLY**

suppresses the default plots and displays only plots that are specifically requested.

**STRATUM=HORIZONTAL | VERTICAL**

controls the orientation of the plots. STRATUM=VERTICAL places the strata information on the vertical axis, and STRATUM=HORIZONTAL places the strata information on the horizontal axis. The default is STRATUM=VERTICAL.

You can specify the following *plot-requests*:

**ALL**

produces all appropriate plots.

**DIST | DISTRIBUTION**

displays a plot of the proportions for stratum-specific exposed time or sample size.

**EFFECT**

displays a plot of the stratum-specific effect estimates and associated confidence limits. This option applies only when METHOD=DIRECT with two study populations and when METHOD=MH, where two study populations are required. If the EFFECT=DIFF option is specified, the stratum-specific rate or risk difference effects are displayed. Otherwise, the stratum-specific rate or risk ratio effects are displayed.

**NONE**

suppresses all plots.

**RATE**

displays a plot of the stratum-specific rates and associated confidence limits. This option applies only when STAT=RATE. If a confidence limits method is specified in the STATS(CL=) option in the STRATA statement, that method is used to compute the confidence limits. Otherwise, the normal approximation is used.

**RISK**

displays a plot of the stratum-specific risks and associated confidence limits. This option applies only when STAT=RISK. If a confidence limits method is specified in the STATS(CL=) option in the STRATA statement, that method is used to compute the confidence limits. Otherwise, the normal approximation is used.

**SMR**

displays a plot of the stratum-specific SMR estimates and associated confidence limits. This option applies only when METHOD=INDIRECT. If a method is specified in the SMR(CL=) option in the STRATA statement, that method is used to compute the confidence limits. Otherwise, the normal approximation is used.

**REFDATA=SAS-data-set**

names the required SAS data set that contains the event information in the reference population.

**STAT=RATE** < ( **MULT =c** ) >

**STAT=RISK**

specifies the statistic for standardization. **STAT=RATE** computes standardized rates, and **STAT=RISK** computes standardized risks. The default is **STAT=RATE**.

The **MULT=** suboption in the **STAT=RATE** option specifies a power of 10 constant *c*, and requests that rates per *c* population-time units be displayed in the output tables and graphics. The default is **MULT=100000**, which specifies rates per 100,000 population-time units.

## BY Statement

**BY** *variables* ;

You can specify a **BY** statement with **PROC STDRATE** to obtain separate analyses of observations in groups that are defined by the **BY** variables. When a **BY** statement appears, the procedure expects the input data set to be sorted in order of the **BY** variables. If you specify more than one **BY** statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the **SORT** procedure with a similar **BY** statement.
- Specify the **NOTSORTED** or **DESCENDING** option in the **BY** statement for the **STDRATE** procedure. The **NOTSORTED** option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the **BY** variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the **BY** variables by using the **DATASETS** procedure (in Base SAS software).

For more information about **BY**-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the **DATASETS** procedure, see the discussion in the *Base SAS Procedures Guide*.

## POPULATION Statement

**POPULATION** < *options* > ;

The required **POPULATION** statement specifies the information in the study data set. You can specify the following *options* in the **POPULATION** statement:

**EVENT=***variable*

specifies the *variable* for the number of events in the study data set.

**GROUP** < ( **ORDER=DATA** | **FORMATTED** | **INTERNAL** ) > =*variable*

specifies the *variable* whose values identify the various populations. This option is required when **METHOD=MH** and also applies when **METHOD=DIRECT** in the **PROC STDRATE** statement.

The optional ORDER= suboption specifies the order in which the values of the *variable* are to be displayed. You can specify the following values for the ORDER= suboption:

|                  |                                                                                            |
|------------------|--------------------------------------------------------------------------------------------|
| <b>DATA</b>      | sorts by the order in which the values appear in the input data set.                       |
| <b>FORMATTED</b> | sorts by their external formatted values.                                                  |
| <b>INTERNAL</b>  | sorts by the unformatted values, which yields the same order that the SORT procedure does. |

By default, ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

**POPEVENT=***number*

specifies the total number of events in the study data set. This option applies only when METHOD=INDIRECT is specified in the PROC STDRATE statement and the total number of events is not available in the study data set.

**RATE < ( MULT=*c* ) > =** *variable*

specifies the *variable* for the observed rate in the study data set. This option applies only when STAT=RATE is specified in the PROC STDRATE statement. The MULT=*c* suboption specifies a power of 10 constant *c* and requests that the rates per *c* population-time units be read from the data set. The default is the value of the MULT= suboption used in the STAT=RATE option in the PROC STDRATE statement.

**RISK=***variable*

specifies the *variable* for the observed risk in the study data set. This option applies only when STAT=RISK is specified in the PROC STDRATE statement.

**TOTAL=***variable*

specifies the *variable* for either the population-time (STAT=RATE) or the number of observations (STAT=RISK) in the study data set.

---

## REFERENCE Statement

**REFERENCE** < *options* > ;

The REFERENCE statement specifies the information in the reference data set. This statement is required when METHOD=DIRECT or METHOD=INDIRECT is specified in the PROC STDRATE statement.

You can specify the following *options* in the REFERENCE statement:

**EVENT=***variable*

specifies the *variable* for the number of events in the reference data set.

**RATE < ( MULT=*c* ) > =** *variable*

specifies the *variable* for the observed rate in the reference data set. This option applies only when STAT=RATE is specified in the PROC STDRATE statement. The MULT=*c* suboption specifies a power of 10 constant *c* and requests that the rates per *c* population-time units be read from the data set. The default is the value of the MULT= suboption used in the STAT=RATE option in the PROC STDRATE statement.

**RISK=***variable*

specifies the *variable* for the observed risk in the reference data set. This option applies only when STAT=RISK is specified in the PROC STDRATE statement.

**TOTAL=***variable*

specifies the *variable* for either the population-time (STAT=RATE) or the number of observations (STAT=RISK) in the reference data set.

When METHOD=INDIRECT is specified in the PROC STDRATE statement, the overall reference population rate and risk are needed to compute indirect standardized rate and risk, respectively. If the information is not available in the reference data set, you can specify the following *options* for overall reference population rate and risk.

**REFEVENT=***number*

specifies the total *number* of events in the reference data set.

**REFRATE <( MULT=*c* )> =** *number*

specifies the crude rate in the reference data set. This option applies only when STAT=RATE is specified in the PROC STDRATE statement. The MULT=*c* suboption specifies a power of 10 constant *c*, and the *number* is the crude rate per *c* population-time units in the data set. The default is the value of the MULT= suboption in the STAT=RATE option in the PROC STDRATE statement.

**REFRISK=***number*

specifies the crude risk in the reference data set. This option applies only when STAT=RISK is specified in the PROC STDRATE statement.

**REFTOTAL=***number*

specifies either the total population-time (STAT=RATE) or the total number of observations (STAT=RISK) in the reference data set.

When STAT=RATE, the REFRATE= option specifies the crude reference rate for the indirect standardized rate. If the REFRATE= option is not specified, the REFEVENT= and REFTOTAL options can be used to compute the crude reference rate. Similarly, when STAT=RISK, the REFRISK= option specifies the crude reference risk for the indirect standardized rate. If the REFRISK= option is not specified, the REFEVENT= and REFTOTAL options can be used to compute the crude reference risk.

---

## STRATA Statement

**STRATA** *variables* </ *options*> ;

The STRATA statement names *variables* that form the strata in the standardization. The combinations of categories of STRATA variables define the strata in the population.

The STRATA variables are one or more variables in all input data sets. These variables can be either character or numeric. The formatted values of the STRATA variables determine the levels. Thus, you can use formats to group values into levels. See the FORMAT procedure in the *Base SAS Procedures Guide* and the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary* for more information.

When the STRATA statement is not specified or the statement is specified without variables, all observations in a data set are treated as though they are from a single stratum.

You can specify the following *options* in the STRATA statement after a slash (/):

**EFFECT**

displays a table of the stratum-specific effect estimates and associated confidence limits. This option applies only when METHOD=DIRECT with two study populations and when METHOD=MH, where two study populations are required. If the EFFECT=DIFF option in the PROC STDRATE statement is specified, the stratum-specific rate or risk difference effects are displayed. Otherwise, the stratum-specific rate or risk ratio effects are displayed.

**MISSING**

treats missing values as a valid (nonmissing) category for all STRATA variables. When PROC STDRATE determines levels of a STRATA variable, an observation with missing values for that STRATA variable is excluded, unless the MISSING option is specified.

**ORDER=DATA | FORMATTED | INTERNAL**

specifies the order in which the values of the categorical variables are to be displayed. You can specify the following values for the ORDER= option:

|                  |                                                                                            |
|------------------|--------------------------------------------------------------------------------------------|
| <b>DATA</b>      | sorts by the order in which the values appear in the input data set.                       |
| <b>FORMATTED</b> | sorts by their external formatted values.                                                  |
| <b>INTERNAL</b>  | sorts by the unformatted values, which yields the same order that the SORT procedure does. |

By default, ORDER=INTERNAL. For ORDER=FORMATTED and ORDER=INTERNAL, the sort order is machine-dependent.

**STATS < ( CL=LOGNORMAL | NONE | NORMAL | POISSON ) >**

displays tables for stratum-specific statistics such as stratum-specific rates and risks. You can specify the following values of the CL= suboption to request confidence limits for the rate or risk estimate in each stratum:

**LOGNORMAL**

requests confidence limits based on a lognormal approximation.

**NONE**

suppresses confidence limits.

**NORMAL**

requests confidence limits based on a normal approximation and also displays the standard error for the rate estimate in each stratum.

**POISSON**

requests confidence limits based on a Poisson distribution for stratum-specific rates. This values applies only when STAT=RATE in the PROC STDRATE statement.

The default is CL=NORMAL.

**SMR < ( CL=LOGNORMAL | NONE | NORMAL | POISSON ) >**

displays tables for stratum-specific SMR estimates. This option applies only when METHOD=INDIRECT is specified in the PROC STDRATE statement. You can specify the following values of the CL= suboption to request confidence limits for the SMR estimate in each stratum:

**LOGNORMAL**

requests confidence limits based on a lognormal approximation.

**NONE**

suppresses confidence limits.

**NORMAL**

requests confidence limits based on a normal approximation and also displays the standard error for the SMR estimate in each stratum.

**POISSON**

requests confidence limits based on a Poisson distribution for stratum-specific SMR estimates. This values applies only when STAT=RATE in the PROC STDRATE statement.

The default is CL=NORMAL.

## Details: STDRATE Procedure

### Rate

A major task in epidemiology is to compare event frequencies for groups of people. Both rate and risk are commonly used to measure event frequency in the comparison. Rate is a measure of change in one quantity per unit of another quantity. An event rate measures how fast the events are occurring. In contrast, an event risk is the probability that an event occurs over a specified follow-up time period.

An event rate of a population over a specified time period can be defined as the number of new events divided by the population-time of the population over the same time period,

$$\hat{\lambda} = \frac{d}{\mathcal{T}}$$

where  $d$  is the number of events and  $\mathcal{T}$  is the population-time that is computed by adding up the time contributed by each subject in the population over the specified time period.

For a general population, the subsets (strata) might not be homogeneous enough to have a similar rate. Thus, the rate for each stratum should be computed separately to reflect this discrepancy. For a population that consists of  $K$  homogeneous strata (such as different age groups), the stratum-specific rate for the  $j$ th stratum in a population is computed as

$$\hat{\lambda}_j = \frac{d_j}{\mathcal{T}_j}$$

where  $d_j$  is the number of events and  $\mathcal{T}_j$  is the population-time for subjects in the  $j$ th stratum of the population.

Assuming the number of events in the  $j$ th stratum,  $d_j$ , has a Poisson distribution, the variance of  $\hat{\lambda}_j$  is

$$V(\hat{\lambda}_j) = V\left(\frac{d_j}{\mathcal{T}_j}\right) = \frac{1}{\mathcal{T}_j^2} V(d_j) = \frac{d_j}{\mathcal{T}_j^2} = \frac{\hat{\lambda}_j}{\mathcal{T}_j}$$

By using the method of statistical differentials (Elandt-Johnson and Johnson 1980, pp. 70–71), the variance of the logarithm of rate can be estimated by

$$V(\log(\hat{\lambda}_j)) = \frac{1}{\hat{\lambda}_j^2} V(\hat{\lambda}_j) = \frac{1}{\hat{\lambda}_j^2} \frac{\hat{\lambda}_j}{\mathcal{T}_j} = \frac{1}{\hat{\lambda}_j \mathcal{T}_j} = \frac{1}{d_j}$$

Because the rate value can be very small, especially for rare events, it is sometimes expressed in terms of the product of a multiplier and the rate itself. For example, a rate can be expressed as the number of events per 100,000 person-years.

### Normal Distribution Confidence Interval for Rate

A  $(1 - \alpha)$  confidence interval for  $\hat{\lambda}_j$  based on a normal distribution is given by

$$\left( \hat{\lambda}_j - z \sqrt{V(\hat{\lambda}_j)}, \hat{\lambda}_j + z \sqrt{V(\hat{\lambda}_j)} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution.

### Lognormal Distribution Confidence Interval for Rate

A  $(1 - \alpha)$  confidence interval for  $\log(\hat{\lambda}_j)$  based on a normal distribution is given by

$$\left( \log(\hat{\lambda}_j) - z \sqrt{V(\log(\hat{\lambda}_j))}, \log(\hat{\lambda}_j) + z \sqrt{V(\log(\hat{\lambda}_j))} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution and the variance  $V(\log(\hat{\lambda}_j)) = 1/d_j$ .

Thus, a  $(1 - \alpha)$  confidence interval for  $\hat{\lambda}_j$  based on a lognormal distribution is given by

$$\left( \hat{\lambda}_j e^{-\frac{z}{\sqrt{d_j}}}, \hat{\lambda}_j e^{\frac{z}{\sqrt{d_j}}} \right)$$

### Poisson Distribution Confidence Interval for Rate

Denote the  $(\alpha/2)$  quantile for the  $\chi^2$  distribution with  $2d_j$  degrees of freedom by

$$q_{lj} = (\chi_{2d_j}^2)^{-1}(\alpha/2)$$

Denote the  $(1 - \alpha/2)$  quantiles for the  $\chi^2$  distribution with  $2(d_j + 1)$  degrees of freedom by

$$q_{uj} = (\chi_{2(d_j+1)}^2)^{-1}(1 - \alpha/2)$$

Then a  $(1 - \alpha)$  confidence interval for  $\hat{\lambda}_j$  based on the  $\chi^2$  distribution is given by

$$\left( \frac{q_{lj}}{2\mathcal{T}_j}, \frac{q_{uj}}{2\mathcal{T}_j} \right)$$

### Confidence Interval for Rate Difference Statistic

For rate estimates from two independent samples,  $\hat{\lambda}_{1j}$  and  $\hat{\lambda}_{2j}$ , a  $(1 - \alpha)$  confidence interval for the rate difference  $\hat{\lambda}_{dj} = \hat{\lambda}_{1j} - \hat{\lambda}_{2j}$  is

$$\left( \hat{\lambda}_{dj} - z \sqrt{V(\hat{\lambda}_{dj})}, \hat{\lambda}_{dj} + z \sqrt{V(\hat{\lambda}_{dj})} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution and the variance

$$V(\hat{\lambda}_{dj}) = V(\hat{\lambda}_{1j}) + V(\hat{\lambda}_{2j})$$

### Confidence Interval for Rate Ratio Statistic

For rate estimates from two independent samples,  $\hat{\lambda}_{1j}$  and  $\hat{\lambda}_{2j}$ , a  $(1 - \alpha)$  confidence interval for the log rate ratio statistic  $\log(\hat{\lambda}_{rj}) = \log(\hat{\lambda}_{1j}/\hat{\lambda}_{2j})$  is

$$\left( \log(\hat{\lambda}_{rj}) - z \sqrt{V(\log(\hat{\lambda}_{rj}))}, \log(\hat{\lambda}_{rj}) + z \sqrt{V(\log(\hat{\lambda}_{rj}))} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution and the variance

$$V(\log(\hat{\lambda}_{rj})) = V(\log(\hat{\lambda}_{1j})) + V(\log(\hat{\lambda}_{2j}))$$

Thus, a  $(1 - \alpha)$  confidence interval for the rate ratio statistic  $\hat{\lambda}_{rj}$  is given by

$$\left( \frac{\hat{\lambda}_{1j}}{\hat{\lambda}_{2j}} e^{-z \sqrt{V(\log(\hat{\lambda}_{rj}))}}, \frac{\hat{\lambda}_{1j}}{\hat{\lambda}_{2j}} e^{z \sqrt{V(\log(\hat{\lambda}_{rj}))}} \right)$$

### Confidence Interval for Rate SMR

At stratum  $j$ , a stratum-specific standardized morbidity/mortality ratio is

$$\mathcal{R}_j = \frac{d_j}{\mathcal{E}_j}$$

where  $\mathcal{E}_j$  is the expected number of events.

With the rate

$$\hat{\lambda}_j = \frac{d_j}{\mathcal{T}_j}$$

SMR can be expressed as

$$\mathcal{R}_j = \frac{\mathcal{T}_j}{\mathcal{E}_j} \hat{\lambda}_j$$

Thus, a  $(1 - \alpha)$  confidence interval for  $\mathcal{R}_j$  is given by

$$\left( \frac{\mathcal{T}_j}{\mathcal{E}_j} \hat{\lambda}_{jl}, \frac{\mathcal{T}_j}{\mathcal{E}_j} \hat{\lambda}_{ju} \right)$$

where  $(\hat{\lambda}_{jl}, \hat{\lambda}_{ju})$  is a  $(1 - \alpha)$  confidence interval for the rate  $\hat{\lambda}_j$ .

## Risk

An event risk of a population over a specified time period can be defined as the number of new events in the follow-up time period divided by the event-free population size at the beginning of the time period,

$$\hat{\gamma} = \frac{d}{\mathcal{N}}$$

where  $\mathcal{N}$  is the population size.

For a general population, the subsets (strata) might not be homogeneous enough to have a similar risk. Thus, the risk for each stratum should be computed separately to reflect this discrepancy. For a population that consists of  $K$  homogeneous strata (such as different age groups), the stratum-specific risk for the  $j$ th stratum in a population is computed as

$$\hat{\gamma}_j = \frac{d_j}{\mathcal{N}_j}$$

where  $\mathcal{N}_j$  is the population size in the  $j$ th stratum of the population.

Assuming the number of events,  $d_j$ , has a binomial distribution, then a variance estimate of  $\hat{\gamma}_j$  is

$$V(\hat{\gamma}_j) = \frac{\hat{\gamma}_j(1 - \hat{\gamma}_j)}{\mathcal{N}_j}$$

By using the method of statistical differentials (Elandt-Johnson and Johnson 1980, pp. 70–71), the variance of the logarithm of risk can be estimated by

$$V(\log(\hat{\gamma}_j)) = \frac{1}{\hat{\gamma}_j^2} V(\hat{\gamma}_j) = \frac{1}{\hat{\gamma}_j^2} \frac{\hat{\gamma}_j(1 - \hat{\gamma}_j)}{\mathcal{N}_j} = \frac{1 - \hat{\gamma}_j}{\hat{\gamma}_j \mathcal{N}_j} = \frac{1}{d_j} - \frac{1}{\mathcal{N}_j}$$

### Normal Distribution Confidence Interval for Risk

A  $(1 - \alpha)$  confidence interval for  $\hat{\gamma}_j$  based on a normal distribution is given by

$$\left( \hat{\gamma}_j - z \sqrt{V(\hat{\gamma}_j)}, \hat{\gamma}_j + z \sqrt{V(\hat{\gamma}_j)} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution.

### Lognormal Distribution Confidence Interval for Risk

A  $(1 - \alpha)$  confidence interval for  $\log(\hat{\gamma}_j)$  based on a normal distribution is given by

$$\left( \log(\hat{\gamma}_j) - z \sqrt{V(\log(\hat{\gamma}_j))}, \log(\hat{\gamma}_j) + z \sqrt{V(\log(\hat{\gamma}_j))} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution and the variance  $V(\log(\hat{\gamma}_j)) = 1/d_j - 1/\mathcal{N}_j$ .

Thus, a  $(1 - \alpha)$  confidence interval for  $\hat{\gamma}_j$  based on a lognormal distribution is given by

$$\left( \hat{\gamma}_j e^{-z \sqrt{\frac{1}{d_j} - \frac{1}{\mathcal{N}_j}}}, \hat{\gamma}_j e^{z \sqrt{\frac{1}{d_j} - \frac{1}{\mathcal{N}_j}}} \right)$$

### Confidence Interval for Risk Difference Statistic

For rate estimates from two independent samples,  $\hat{\gamma}_{1j}$  and  $\hat{\gamma}_{2j}$ , a  $(1 - \alpha)$  confidence interval for the risk difference  $\hat{\gamma}_{dj} = \hat{\gamma}_{1j} - \hat{\gamma}_{2j}$  is

$$\left( \hat{\gamma}_{dj} - z \sqrt{V(\hat{\gamma}_{dj})}, \hat{\gamma}_{dj} + z \sqrt{V(\hat{\gamma}_{dj})} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution and the variance

$$V(\hat{\gamma}_{dj}) = V(\hat{\gamma}_{1j}) + V(\hat{\gamma}_{2j})$$

### Confidence Interval for Risk Ratio Statistic

For rate estimates from two independent samples,  $\hat{\gamma}_{1j}$  and  $\hat{\gamma}_{2j}$ , a  $(1 - \alpha)$  confidence interval for the log risk ratio statistic  $\log(\hat{\gamma}_{rj}) = \log(\hat{\gamma}_{1j}/\hat{\gamma}_{2j})$  is

$$\left( \log(\hat{\gamma}_{rj}) - z \sqrt{V(\log(\hat{\gamma}_{rj}))}, \log(\hat{\gamma}_{rj}) + z \sqrt{V(\log(\hat{\gamma}_{rj}))} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution and the variance

$$V(\log(\hat{\gamma}_{rj})) = V(\log(\hat{\gamma}_{1j})) + V(\log(\hat{\gamma}_{2j}))$$

Thus, a  $(1 - \alpha)$  confidence interval for the risk ratio statistic  $\hat{\gamma}_{rj}$  is given by

$$\left( \frac{\hat{\gamma}_{1j}}{\hat{\gamma}_{2j}} e^{-z \sqrt{V(\log(\hat{\gamma}_{rj}))}}, \frac{\hat{\gamma}_{1j}}{\hat{\gamma}_{2j}} e^{z \sqrt{V(\log(\hat{\gamma}_{rj}))}} \right)$$

### Confidence Interval for Risk SMR

At stratum  $j$ , a stratum-specific standardized morbidity/mortality ratio is

$$\mathcal{R}_j = \frac{d_j}{\mathcal{E}_j}$$

where  $\mathcal{E}_j$  is the expected number of events.

With the risk

$$\hat{\gamma}_j = \frac{d_j}{\mathcal{N}_j}$$

SMR can be expressed as

$$\mathcal{R}_j = \frac{\mathcal{N}_j}{\mathcal{E}_j} \hat{\gamma}_j$$

Thus, a  $(1 - \alpha)$  confidence interval for  $\mathcal{R}_j$  is given by

$$\left( \frac{\mathcal{N}_j}{\mathcal{E}_j} \hat{\gamma}_{jl}, \frac{\mathcal{N}_j}{\mathcal{E}_j} \hat{\gamma}_{ju} \right)$$

where  $(\hat{\gamma}_{jl}, \hat{\gamma}_{ju})$  is a  $(1 - \alpha)$  confidence interval for the risk  $\hat{\gamma}_j$ .

## Direct Standardization

Direct standardization uses the weights from a reference population to compute the standardized rate of a study group as the weighted average of stratum-specific rates in the study population. The standardized rate is computed as

$$\hat{\lambda}_{ds} = \frac{\sum_j \mathcal{T}_{rj} \hat{\lambda}_{sj}}{\mathcal{T}_r}$$

where  $\hat{\lambda}_{sj}$  is the rate in the  $j$ th stratum of the study population,  $\mathcal{T}_{rj}$  is the population-time in the  $j$ th stratum of the reference population, and  $\mathcal{T}_r = \sum_k \mathcal{T}_{rk}$  is the population-time in the reference population.

Similarly, direct standardization uses the weights from a reference population to compute the standardized risk of a study group as the weighted average of stratum-specific risks in the study population. The standardized risk is computed as

$$\hat{\gamma}_{ds} = \frac{\sum_j \mathcal{N}_{rj} \hat{\gamma}_{sj}}{\mathcal{N}_r}$$

where  $\hat{\gamma}_{sj}$  is the risk in the  $j$ th stratum of the study population,  $\mathcal{N}_{rj}$  is the number of observations in the  $j$ th stratum of the reference population, and  $\mathcal{N}_r = \sum_k \mathcal{N}_{rk}$  is the total number of observations in the reference population.

That is, the directly standardized rate and risk of a study population are weighted averages of the stratum-specific rates and risks, respectively, where the weights are the corresponding strata population sizes in the reference population. The direct standardization can be used when the study population is large enough to provide stable stratum-specific rates or risks. When the same reference population is used for multiple study populations, directly standardized rates and risks provide valid comparisons between study populations.

The variances of the directly standardized rate and risk are

$$V(\hat{\lambda}_{ds}) = V\left(\frac{\sum_j \mathcal{T}_{rj} \hat{\lambda}_{sj}}{\mathcal{T}_r}\right) = \frac{\sum_j \mathcal{T}_{rj}^2 V(\hat{\lambda}_{sj})}{\mathcal{T}_r^2}$$

$$V(\hat{\gamma}_{ds}) = V\left(\frac{\sum_j \mathcal{N}_{rj} \hat{\gamma}_{sj}}{\mathcal{N}_r}\right) = \frac{\sum_j \mathcal{N}_{rj}^2 V(\hat{\gamma}_{sj})}{\mathcal{N}_r^2}$$

By using the method of statistical differentials (Elandt-Johnson and Johnson 1980, pp. 70–71), the variance of the logarithm of directly standardized rate and risk can be estimated by

$$V(\log(\hat{\lambda}_{ds})) = \frac{1}{\hat{\lambda}_{ds}^2} V(\hat{\lambda}_{ds})$$

$$V(\log(\hat{\gamma}_{ds})) = \frac{1}{\hat{\gamma}_{ds}^2} V(\hat{\gamma}_{ds})$$

The confidence intervals for  $\hat{\lambda}_{ds}$  and  $\hat{\gamma}_{ds}$  can be constructed based on normal and lognormal distributions. A gamma distribution confidence interval can also be constructed for  $\hat{\lambda}_{ds}$ .

In the next four subsections,  $\beta = \lambda$  denotes the rate statistic and  $\beta = \gamma$  denotes the risk statistic.

### Normal Distribution Confidence Intervals for Standardized Rate and Risk

A  $(1 - \alpha)$  confidence interval for  $\hat{\beta}_{ds}$  based on a normal distribution is then given by

$$\left( \hat{\beta}_{ds} - z \sqrt{V(\hat{\beta}_{ds})}, \hat{\beta}_{ds} + z \sqrt{V(\hat{\beta}_{ds})} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution.

### Lognormal Distribution Confidence Intervals for Standardized Rate and Risk

A  $(1 - \alpha)$  confidence interval for  $\log(\hat{\beta}_{ds})$  based on a normal distribution is given by

$$\left( \log(\hat{\beta}_{ds}) - z \sqrt{V(\log(\hat{\beta}_{ds}))}, \log(\hat{\beta}_{ds}) + z \sqrt{V(\log(\hat{\beta}_{ds}))} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution.

Thus, a  $(1 - \alpha)$  confidence interval for  $\hat{\beta}_{ds}$  based on a lognormal distribution is given by

$$\left( \hat{\beta}_{ds} e^{-z \sqrt{V(\log(\hat{\beta}_{ds}))}}, \hat{\beta}_{ds} e^{z \sqrt{V(\log(\hat{\beta}_{ds}))}} \right)$$

### Gamma Distribution Confidence Interval for Standardized Rate

Fay and Feuer (1997) use the relationship between the Poisson and gamma distributions to derive approximate confidence intervals for the standardized rate  $\hat{\lambda}_{ds}$  based on the gamma distribution. As in the construction of the asymptotic normal confidence intervals, it is assumed that the number of events has a Poisson distribution, and the standardized rate is a weighted sum of independent Poisson random variables. A confidence interval for  $\hat{\lambda}_{ds}$  is then given by

$$\left( \frac{v}{2\hat{\lambda}_{ds}} (\chi^2)^{-1}_{\frac{2\hat{\lambda}_{ds}^2}{v}} \left( \frac{\alpha}{2} \right), \frac{v + w_x^2}{2(\hat{\lambda}_{ds} + w_x)} (\chi^2)^{-1}_{\frac{2(\hat{\lambda}_{ds} + w_x)^2}{v + w_x^2}} \left( 1 - \frac{\alpha}{2} \right) \right)$$

where

$$v = \sum_j w_j^2 \frac{\hat{\lambda}_{sj}}{\bar{T}_{sj}}$$

$$w_j = \frac{\bar{T}_{rj}}{\bar{T}_r} \frac{1}{\bar{T}_{sj}}$$

and  $w_x$  is the maximum  $w_j$ .

Tiwari, Clegg, and Zou (2006) propose a less conservative confidence interval for  $\hat{\lambda}_{ds}$  with a different upper confidence limit,

$$\left( \frac{v}{2\hat{\lambda}_{ds}} (\chi^2)^{-1}_{\frac{2\hat{\lambda}_{ds}^2}{v}} \left( \frac{\alpha}{2} \right), \frac{v + w_{2m}}{2(\hat{\lambda}_{ds} + w_m)} (\chi^2)^{-1}_{\frac{2(\hat{\lambda}_{ds} + w_m)^2}{v + w_{2m}}} \left( 1 - \frac{\alpha}{2} \right) \right)$$

where  $w_m$  is the average  $w_j$  and  $w_{2m}$  is the average  $w_j^2$ .

## Comparing Standardized Rates and Comparing Standardized Risks

By using the same reference population, two directly standardized rates or risks from different populations can be compared. Both the difference and ratio statistics can be used in the comparison. Assume that  $\hat{\beta}_1$  and  $\hat{\beta}_2$  are directly standardized rates or risks for two populations with variances  $V(\hat{\beta}_1)$  and  $V(\hat{\beta}_2)$ , respectively. The difference test assumes that the difference statistic

$$\hat{\beta}_1 - \hat{\beta}_2$$

has a normal distribution with mean 0 under the null hypothesis  $H_0 : \beta_1 = \beta_2$ . The variance is given by

$$V(\hat{\beta}_1 - \hat{\beta}_2) = V(\hat{\beta}_1) + V(\hat{\beta}_2)$$

The ratio test assumes that the log ratio statistic,

$$\log\left(\frac{\hat{\beta}_1}{\hat{\beta}_2}\right)$$

has a normal distribution with mean 0 under the null hypothesis  $H_0 : \beta_1 = \beta_2$ , or equivalently,  $\log(\beta_1/\beta_2) = 0$ . An estimated variance is given by

$$V\left(\log\left(\frac{\hat{\beta}_1}{\hat{\beta}_2}\right)\right) = V(\log(\hat{\beta}_1)) + V(\log(\hat{\beta}_2)) = \frac{1}{\hat{\beta}_1^2} V(\hat{\beta}_1) + \frac{1}{\hat{\beta}_2^2} V(\hat{\beta}_2)$$

## Mantel-Haenszel Effect Estimation

In direct standardization, the derived standardized rates and risks in a study population are the weighted average of the stratum-specific rates and risks in the population, respectively, where the weights are given by the population-time for standardized rate and the number of observations for standardized risk in a reference population.

Assuming that an effect, such as rate difference, rate ratio, risk difference, and risk ratio between two populations, is homogeneous across strata, the Mantel-Haenszel estimates of this effect can be constructed from directly standardized rates or risks in the two populations, where the weights are constructed from the stratum-specific population-times for rate and number of observations for risk of the two populations.

That is, for population  $k$ ,  $k=1$  and  $2$ , the standardized rate and risk are

$$\hat{\lambda}_k = \frac{\sum_j w_j \hat{\lambda}_{kj}}{\sum_j w_j} \quad \text{and} \quad \hat{\gamma}_k = \frac{\sum_j w_j \hat{\gamma}_{kj}}{\sum_j w_j}$$

where the weights are

$$w_j = \frac{\mathcal{T}_{1j} \mathcal{T}_{2j}}{\mathcal{T}_{1j} + \mathcal{T}_{2j}}$$

for standardized rate, and

$$w_j = \frac{\mathcal{N}_{1j} \mathcal{N}_{2j}}{\mathcal{N}_{1j} + \mathcal{N}_{2j}}$$

for standardized risk.

### Rate and Risk Difference Statistics

Denote  $\beta = \lambda$  for rate and  $\beta = \gamma$  for risk. The variance is

$$V(\hat{\beta}_k) = V\left(\frac{\sum_j w_j \hat{\beta}_{kj}}{\sum_j w_j}\right) = \frac{1}{(\sum_j w_j)^2} \sum_j w_j^2 V(\hat{\beta}_{kj})$$

The Mantel-Haenszel difference statistic is

$$\hat{\beta}_1 - \hat{\beta}_2$$

with variance

$$V(\hat{\beta}_1 - \hat{\beta}_2) = V(\hat{\beta}_1) + V(\hat{\beta}_2)$$

Under the null hypothesis  $H_0 : \beta_1 = \beta_2$ , the difference statistic  $\hat{\beta}_1 - \hat{\beta}_2$  has a normal distribution with mean 0.

### Rate Ratio Statistic

The Mantel-Haenszel rate ratio statistic is  $\hat{\lambda}_1/\hat{\lambda}_2$ , and the log ratio statistic is

$$\log\left(\frac{\hat{\lambda}_1}{\hat{\lambda}_2}\right)$$

Under the null hypothesis  $H_0 : \lambda_1 = \lambda_2$  (or equivalently,  $\log(\lambda_1/\lambda_2) = 0$ ), the log ratio statistic has a normal distribution with mean 0 and variance

$$V\left(\log\left(\frac{\hat{\lambda}_1}{\hat{\lambda}_2}\right)\right) = \frac{\sum_j w_j \hat{\lambda}_{pj}}{(\sum_j w_j \hat{\lambda}_{1j})(\sum_j w_j \hat{\lambda}_{2j})}$$

where

$$\hat{\lambda}_{pj} = \frac{d_{1j} + d_{2j}}{T_{1j} + T_{2j}}$$

is the combined rate estimate in stratum  $j$  under the null hypothesis of equal rates (Greenland and Robins 1985; Greenland and Rothman 2008, p. 273).

### Risk Ratio Statistic

The Mantel-Haenszel risk ratio statistic is  $\hat{\gamma}_1/\hat{\gamma}_2$ , and the log ratio statistic is

$$\log\left(\frac{\hat{\gamma}_1}{\hat{\gamma}_2}\right)$$

Under the null hypothesis  $H_0 : \gamma_1 = \gamma_2$  (or equivalently,  $\log(\gamma_1/\gamma_2) = 0$ ), the log ratio statistic has a normal distribution with mean 0 and variance

$$V\left(\log\left(\frac{\hat{\gamma}_1}{\hat{\gamma}_2}\right)\right) = \frac{\sum_j w_j (\hat{\gamma}_{pj} - \hat{\gamma}_{1j}\hat{\gamma}_{2j})}{(\sum_j w_j \hat{\gamma}_{1j})(\sum_j w_j \hat{\gamma}_{2j})}$$

where

$$\hat{\gamma}_{pj} = \frac{d_{1j} + d_{2j}}{N_{1j} + N_{2j}}$$

is the combined risk estimate in stratum  $j$  under the null hypothesis of equal risks (Greenland and Robins 1985; Greenland and Rothman 2008, p. 275).

## Indirect Standardization and Standardized Morbidity/Mortality Ratio

Indirect standardization compares the rates of the study and reference populations by applying the stratum-specific rates in the reference population to the study population, where the stratum-specific rates might not be reliable.

The expected number of events in the study population is

$$\mathcal{E} = \sum_j \mathcal{T}_{sj} \hat{\lambda}_{rj}$$

where  $\mathcal{T}_{sj}$  is the population-time in the  $j$ th stratum of the study population and  $\hat{\lambda}_{rj}$  is the rate in the  $j$ th stratum of the reference population.

With the expected number of events,  $\mathcal{E}$ , the standardized morbidity ratio or standardized mortality ratio can be expressed as

$$\mathcal{R}_{sm} = \frac{\mathcal{D}}{\mathcal{E}}$$

where  $\mathcal{D}$  is the observed number of events (Breslow and Day 1987, p. 65).

The ratio  $\mathcal{R}_{sm} > 1$  indicates that the mortality rate or risk in the study population is larger than the estimate in the reference population, and  $\mathcal{R}_{sm} < 1$  indicates that the mortality rate or risk in the study population is smaller than the estimate in the reference population.

With the ratio  $\mathcal{R}_{sm}$ , an indirectly standardized rate for the study population is computed as

$$\hat{\lambda}_{is} = \mathcal{R}_{sm} \hat{\lambda}_r$$

where  $\hat{\lambda}_r$  is the overall crude rate in the reference population.

Similarly, to compare the risks of the study and reference populations, the stratum-specific risks in the reference population are used to compute the expected number of events in the study population

$$\mathcal{E} = \sum_j N_{sj} \hat{\gamma}_{rj}$$

where  $N_{sj}$  is the number of observations in the  $j$ th stratum of the study population and  $\hat{\gamma}_{rj}$  is the risk in the  $j$ th stratum of the reference population.

Also, with the standardized morbidity ratio  $\mathcal{R}_{sm} = \mathcal{D}/\mathcal{E}$ , an indirectly standardized risk for the study population is computed as

$$\hat{\gamma}_{is} = \mathcal{R}_{sm} \hat{\gamma}_r$$

where  $\hat{\gamma}_r$  is the overall crude risk in the reference population.

The observed number of events in the study population is  $\mathcal{D} = \sum_j d_{sj}$ , where  $d_{sj}$  is the number of events in the  $j$ th stratum of the population. For the rate estimate, if  $d_{sj}$  has a Poisson distribution, then the variance of the standardized mortality ratio  $\mathcal{R}_{sm} = \mathcal{D} / \mathcal{E}$  is

$$V(\mathcal{R}_{sm}) = \frac{1}{\mathcal{E}^2} \sum_j V(d_{sj}) = \frac{1}{\mathcal{E}^2} \sum_j d_{sj} = \frac{\mathcal{D}}{\mathcal{E}^2} = \frac{\mathcal{R}_{sm}}{\mathcal{E}}$$

For the risk estimate, if  $d_{sj}$  has a binomial distribution, then the variance of  $\mathcal{R}_{sm} = \mathcal{D} / \mathcal{E}$  is

$$V(\mathcal{R}_{sm}) = V\left(\frac{1}{\mathcal{E}} \sum_j d_{sj}\right) = \frac{1}{\mathcal{E}^2} \sum_j V(d_{sj}) = \frac{1}{\mathcal{E}^2} \sum_j \mathcal{N}_{sj}^2 V(\hat{\gamma}_{sj})$$

where

$$V(\hat{\gamma}_{sj}) = \frac{\hat{\gamma}_{sj}(1 - \hat{\gamma}_{sj})}{\mathcal{N}_{sj}}$$

By using the method of statistical differentials (Elandt-Johnson and Johnson 1980, pp. 70–71), the variance of the logarithm of  $\mathcal{R}_{sm}$  can be estimated by

$$V(\log(\mathcal{R}_{sm})) = \frac{1}{\mathcal{R}_{sm}^2} V(\mathcal{R}_{sm})$$

For the rate estimate,

$$V(\log(\mathcal{R}_{sm})) = \frac{1}{\mathcal{R}_{sm}^2} V(\mathcal{R}_{sm}) = \frac{1}{\mathcal{R}_{sm}^2} \frac{\mathcal{R}_{sm}}{\mathcal{E}} = \frac{1}{\mathcal{R}_{sm}} \frac{1}{\mathcal{E}} = \frac{1}{\mathcal{D}}$$

The confidence intervals for  $\mathcal{R}_{sm}$  can be constructed based on normal, lognormal, and Poisson distributions.

### Normal Distribution Confidence Interval for SMR

A  $(1 - \alpha)$  confidence interval for  $\mathcal{R}_{sm}$  based on a normal distribution is given by

$$(\mathcal{R}_l, \mathcal{R}_u) = \left( \mathcal{R}_{sm} - z \sqrt{V(\mathcal{R}_{sm})}, \mathcal{R}_{sm} + z \sqrt{V(\mathcal{R}_{sm})} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution.

A test statistic for the null hypothesis  $H_0 : \text{SMR} = 1$  is then given by

$$\frac{\mathcal{R}_{sm} - 1}{\sqrt{V(\mathcal{R}_{sm})}}$$

The test statistic has an approximate standard normal distribution under  $H_0$ .

### Lognormal Distribution Confidence Interval for SMR

A  $(1 - \alpha)$  confidence interval for  $\log(\mathcal{R}_{sm})$  based on a normal distribution is given by

$$\left( \log(\mathcal{R}_{sm}) - z \sqrt{V(\log(\mathcal{R}_{sm}))}, \log(\mathcal{R}_{sm}) + z \sqrt{V(\log(\mathcal{R}_{sm}))} \right)$$

where  $z = \Phi^{-1}(1 - \alpha/2)$  is the  $(1 - \alpha/2)$  quantile of the standard normal distribution.

Thus, a  $(1 - \alpha)$  confidence interval for  $\mathcal{R}_{sm}$  based on a lognormal distribution is given by

$$\left( \mathcal{R}_{sm} e^{-z \sqrt{V(\log(\mathcal{R}_{sm}))}}, \mathcal{R}_{sm} e^{z \sqrt{V(\log(\mathcal{R}_{sm}))}} \right)$$

A test statistic for the null hypothesis  $H_0 : \text{SMR} = 1$  is then given by

$$\frac{\log(\mathcal{R}_{sm})}{\sqrt{V(\log(\mathcal{R}_{sm}))}}$$

The test statistic has an approximate standard normal distribution under  $H_0$ .

### Poisson Distribution Confidence Interval for Rate SMR

Denote the  $(\alpha/2)$  quantile for the  $\chi^2$  distribution with  $2\mathcal{D}$  degrees of freedom by

$$q_l = (\chi_{2\mathcal{D}}^2)^{-1}(\alpha/2)$$

Denote the  $(1 - \alpha/2)$  quantiles for the  $\chi^2$  distribution with  $2(\mathcal{D} + 1)$  degrees of freedom by

$$q_u = (\chi_{2(\mathcal{D}+1)}^2)^{-1}(1 - \alpha/2)$$

Then a  $(1 - \alpha)$  confidence interval for  $\mathcal{R}_{sm}$  based on the  $\chi^2$  distribution is given by

$$(\mathcal{R}_l, \mathcal{R}_u) = \left( \frac{q_l}{2\mathcal{E}}, \frac{q_u}{2\mathcal{E}} \right)$$

A  $p$ -value for the test of the null hypothesis  $H_0 : \text{SMR} = 1$  is given by

$$2 \min \left( \sum_{k=0}^{\mathcal{D}} \frac{e^{-\mathcal{E}} \mathcal{E}^k}{k!}, \sum_{k=\mathcal{D}}^{\infty} \frac{e^{-\mathcal{E}} \mathcal{E}^k}{k!} \right)$$

### Indirectly Standardized Rate and Its Confidence Interval

With a rate-standardized mortality ratio  $\mathcal{R}_{sm}$ , an indirectly standardized rate for the study population is computed as

$$\hat{\lambda}_{is} = \mathcal{R}_{sm} \hat{\lambda}_r$$

where  $\hat{\lambda}_r$  is the overall crude rate in the reference population.

The  $(1 - \alpha/2)$  confidence intervals for  $\hat{\lambda}_{is}$  can be constructed as

$$(\mathcal{R}_l \hat{\lambda}_r, \mathcal{R}_u \hat{\lambda}_r)$$

where  $(\mathcal{R}_l, \mathcal{R}_u)$  is the confidence interval for  $\mathcal{R}_{sm}$ .

## Indirectly Standardized Risk and Its Confidence Interval

With a risk-standardized mortality ratio  $\mathcal{R}_{sm}$ , an indirectly standardized risk for the study population is computed as

$$\hat{\gamma}_{is} = \mathcal{R}_{sm} \hat{\gamma}_r$$

where  $\hat{\gamma}_r$  is the overall crude risk in the reference population.

The  $(1 - \alpha/2)$  confidence intervals for  $\hat{\gamma}_{is}$  can be constructed as

$$(\mathcal{R}_l \hat{\gamma}_r, \mathcal{R}_u \hat{\gamma}_r)$$

where  $(\mathcal{R}_l, \mathcal{R}_u)$  is the confidence interval for  $\mathcal{R}_{sm}$ .

## Attributable Fraction and Population Attributable Fraction

The attributable fraction measures the excess event rate or risk fraction in the exposed population that is attributable to the exposure. That is, it is the proportion of event rate or risk in the exposed population that would be reduced if the exposure were not present. In contrast, the population attributable fraction measures the excess event rate or risk fraction in the total population that is attributable to the exposure.

In the STDRATE procedure, you can compute the attributable fraction by using either indirect standardization or Mantel-Haenszel estimation.

### Indirect Standardization

With indirect standardization, you specify a study population that consists of subjects who are exposed to a factor, such as smoking, and a reference population that consists of subjects who are not exposed to the factor. Denote the numbers of events in the study and reference populations by  $\mathcal{D}_s$  and  $\mathcal{D}_r$ , respectively.

For the rate estimate, denote the population-times in the study and reference populations by  $\mathcal{T}_s$  and  $\mathcal{T}_r$ , respectively. Then the event rates in the two populations can be expressed as the following equations, respectively:

$$\hat{\lambda}_s = \frac{\mathcal{D}_s}{\mathcal{T}_s} \quad \text{and} \quad \hat{\lambda}_r = \frac{\mathcal{D}_r}{\mathcal{T}_r}$$

Similarly, for the risk estimate, denote the numbers of observations in the study and reference populations by  $\mathcal{N}_s$  and  $\mathcal{N}_r$ , respectively. Then the event risks in the two populations can be expressed as the following equations, respectively:

$$\hat{\gamma}_s = \frac{\mathcal{D}_s}{\mathcal{N}_s} \quad \text{and} \quad \hat{\gamma}_r = \frac{\mathcal{D}_r}{\mathcal{N}_r}$$

In the next two subsections,  $\beta = \lambda$  denotes the rate statistic and  $\beta = \gamma$  denotes the risk statistic.

### Attributable Fraction with Indirect Standardization

The attributable fraction is the fraction of event rate or risk in the exposed population that is attributable to exposure:

$$\mathcal{R}_a = \frac{\hat{\beta}_s - \hat{\beta}_r}{\hat{\beta}_s}$$

With a standardized mortality ratio  $\mathcal{R}_{sm}$ , the attributable fraction is estimated by

$$\mathcal{R}_a = \frac{\mathcal{R}_{sm} - 1}{\mathcal{R}_{sm}}$$

The confidence intervals for the attributable fraction can be computed using the confidence intervals for  $\mathcal{R}_{sm}$ . That is, with a confidence interval  $(\mathcal{R}_l, \mathcal{R}_u)$  for  $\mathcal{R}_{sm}$ , the corresponding  $\mathcal{R}_a$  confidence interval is given by

$$\left( \frac{\mathcal{R}_l - 1}{\mathcal{R}_l}, \frac{\mathcal{R}_u - 1}{\mathcal{R}_u} \right)$$

### Population Attributable Fraction with Indirect Standardization

The population attributable fraction for a population is the fraction of event rate or risk in a given time period that is attributable to exposure. The population attributable fraction is

$$\mathcal{R}_{pa} = \frac{\hat{\beta}_0 - \hat{\beta}_r}{\hat{\beta}_0}$$

where

$$\hat{\beta}_0 = \frac{\mathcal{D}_s + \mathcal{D}_r}{\mathcal{T}_s + \mathcal{T}_r}$$

is the combined rate in the total population for the rate statistic and where

$$\hat{\beta}_0 = \frac{\mathcal{D}_s + \mathcal{D}_r}{\mathcal{N}_s + \mathcal{N}_r}$$

is the combined risk in the total population for the risk statistic.

Denote  $\rho = \mathcal{D}_s / (\mathcal{D}_s + \mathcal{D}_r)$ , the proportion of exposure among events, then  $\mathcal{R}_{pa}$  can also be expressed as

$$\mathcal{R}_{pa} = \rho \frac{\mathcal{R}_{sm} - 1}{\mathcal{R}_{sm}}$$

where  $\mathcal{R}_{sm}$  is the standardized mortality ratio.

An approximate confidence interval for the population attributable rate  $\mathcal{R}_{pa}$  can be derived by using the complementary log transformation (Greenland 2008, p. 296). That is, with

$$\mathcal{H} = \log(1 - \mathcal{R}_{pa})$$

a variance estimator for the estimated  $\mathcal{H}$  is given by

$$\text{Var}(\hat{\mathcal{H}}) = \frac{\mathcal{R}_{pa}^2}{(1 - \mathcal{R}_{pa})^2} \left( \frac{\hat{V}}{(\mathcal{R}_{sm} - 1)^2} + \frac{2}{\mathcal{D}_s (\mathcal{R}_{sm} - 1)} + \frac{\mathcal{D}_r}{\mathcal{D}_s (\mathcal{D}_s + \mathcal{D}_r)} \right)$$

where  $\hat{V}$  is a variance estimate for  $\log(\mathcal{R}_{sm})$ .

## Mantel-Haenszel Estimation

With Mantel-Haenszel estimation, you specify one study population that consists of subjects who are exposed to a factor and another study population that consists of subjects who are not exposed to the factor. Denote the numbers of events in the exposed and nonexposed study populations by  $\mathcal{D}_1$  and  $\mathcal{D}_2$ , respectively.

For the rate estimate, denote the population-times in the two populations by  $\mathcal{T}_1$  and  $\mathcal{T}_2$ , respectively. Then the event rates in the two populations can be expressed as the following equations, respectively:

$$\hat{\lambda}_1 = \frac{\mathcal{D}_1}{\mathcal{T}_1} \quad \text{and} \quad \hat{\lambda}_2 = \frac{\mathcal{D}_2}{\mathcal{T}_2}$$

Similarly, for the risk estimate, denote the numbers of observations in the two populations by  $\mathcal{N}_1$  and  $\mathcal{N}_2$ , respectively. Then the event risks in the two populations can be expressed as the following equations, respectively:

$$\hat{\gamma}_1 = \frac{\mathcal{D}_1}{\mathcal{N}_1} \quad \text{and} \quad \hat{\gamma}_2 = \frac{\mathcal{D}_2}{\mathcal{N}_2}$$

In the next two subsections,  $\beta = \lambda$  denotes the rate statistic and  $\beta = \gamma$  denotes the risk statistic.

## Attributable Fraction with Mantel-Haenszel Estimation

The attributable fraction is the fraction of event rate or risk in the exposed population that is attributable to exposure:

$$\mathcal{R}_a = \frac{\hat{\beta}_1 - \hat{\beta}_2}{\hat{\beta}_1}$$

Denote the rate or risk ratio by  $\mathcal{R} = \hat{\beta}_1/\hat{\beta}_2$ . The attributable fraction is given by

$$\mathcal{R}_a = \frac{\mathcal{R} - 1}{\mathcal{R}}$$

The confidence intervals for the attributable fraction can be computed using the confidence intervals for the rate or risk ratio  $\mathcal{R}$ . That is, with a confidence interval  $(\mathcal{R}_l, \mathcal{R}_u)$  for  $\mathcal{R}$ , the corresponding  $\mathcal{R}_a$  confidence interval is given by

$$\left( \frac{\mathcal{R}_l - 1}{\mathcal{R}_l}, \frac{\mathcal{R}_u - 1}{\mathcal{R}_u} \right)$$

For Mantel-Haenszel estimation, you can use the Mantel-Haenszel rate or risk ratio to estimate  $\mathcal{R}$ .

## Population Attributable Fraction with Mantel-Haenszel Estimation

The population attributable fraction for a population is the fraction of event rate or risk in a given time period that is attributable to exposure. The population attributable fraction is

$$\mathcal{R}_{pa} = \frac{\hat{\beta}_0 - \hat{\beta}_2}{\hat{\beta}_0}$$

where

$$\hat{\beta}_0 = \frac{\mathcal{D}_1 + \mathcal{D}_2}{\mathcal{T}_1 + \mathcal{T}_2}$$

is the combined rate in the total population for the rate statistic and where

$$\hat{\beta}_0 = \frac{\mathcal{D}_1 + \mathcal{D}_2}{\mathcal{N}_1 + \mathcal{N}_2}$$

is the combined risk in the total population for the risk statistic.

Denote the proportion of exposure among events as  $\rho = \mathcal{D}_1 / (\mathcal{D}_1 + \mathcal{D}_2)$ . Then  $\mathcal{R}_{pa}$  can also be expressed as

$$\mathcal{R}_{pa} = \rho \frac{\mathcal{R} - 1}{\mathcal{R}}$$

where  $\mathcal{R} = \hat{\beta}_1 / \hat{\beta}_2$  is the rate or risk ratio.

An approximate confidence interval for the population attributable rate  $\mathcal{R}_{pa}$  can be derived by using the complementary log transformation (Greenland 2008, p. 296). That is, with

$$\mathcal{H} = \log(1 - \mathcal{R}_{pa})$$

a variance estimator for the estimated  $\mathcal{H}$  is given by

$$\text{Var}(\hat{\mathcal{H}}) = \frac{\mathcal{R}_{pa}^2}{(1 - \mathcal{R}_{pa})^2} \left( \frac{\hat{V}}{(\mathcal{R} - 1)^2} + \frac{2}{\mathcal{D}_1 (\mathcal{R} - 1)} + \frac{\mathcal{D}_2}{\mathcal{D}_1 (\mathcal{D}_1 + \mathcal{D}_2)} \right)$$

where  $\hat{V}$  is a variance estimate for  $\log(\mathcal{R})$ .

For Mantel-Haenszel estimation, you can use the Mantel-Haenszel rate or risk ratio to estimate  $\mathcal{R}$ .

---

## Applicable Data Sets and Required Variables for Method Specifications

The METHOD= and DATA= options are required in the STDRATE procedure. The METHOD= option specifies the standardization method, and the DATA= and REFDATA= options specify the study populations and reference population, respectively. You can use the GROUP= option in the POPULATION statement to identify various study populations. Table 88.2 lists applicable data sets for each method.

**Table 88.2** Applicable Data Sets for Method Specifications

| METHOD=  | Number of Populations |                   |
|----------|-----------------------|-------------------|
|          | in DATA= Data Set     | REFDATA= Data Set |
| DIRECT   | 1                     | X                 |
|          | 2                     | X                 |
| MH       | 2                     |                   |
| INDIRECT | 1                     | X                 |

Table 88.3 lists the required variables for each method.

**Table 88.3** Required Variables for Method Specifications

| METHOD=  | STAT= | DATA= Data Set |      |       | REFDATA= Data Set |      |       |
|----------|-------|----------------|------|-------|-------------------|------|-------|
|          |       | RATE           | RISK | TOTAL | RATE              | RISK | TOTAL |
| DIRECT   | RATE  | X              |      |       |                   |      | X     |
|          | RISK  |                | X    |       |                   |      | X     |
| MH       | RATE  | X              |      | X     |                   |      |       |
|          | RISK  |                | X    | X     |                   |      |       |
| INDIRECT | RATE  |                |      | X     | X                 |      |       |
|          | RISK  |                |      | X     |                   | X    |       |

The symbol “X” indicates that the variable is either explicitly specified or implicitly available from other variables. For example, when STAT=RATE, the variable RATE is available if the corresponding variables EVENT and TOTAL are specified.

## Applicable Confidence Limits for Rate and Risk Statistics

In the STD RATE procedure, the METHOD= option specifies the standardization method, and the STAT= option specifies either either rate or risk for standardization. Table 88.4 lists applicable confidence limits for different methods with standardized rate, rate SMR, standardized risk, and risk SMR.

**Table 88.4** Applicable Confidence Limits for Standardized Rate and Risk Statistics

| Statistic | METHOD=  | Confidence Limits |           |       |         |
|-----------|----------|-------------------|-----------|-------|---------|
|           |          | Normal            | Lognormal | Gamma | Poisson |
| Rate      | DIRECT   | X                 | X         | X     |         |
|           | MH       | X                 | X         | X     |         |
|           | INDIRECT | X                 | X         |       | X       |
| Rate SMR  | INDIRECT | X                 | X         |       | X       |
| Risk      | DIRECT   | X                 | X         |       |         |
|           | MH       | X                 | X         |       |         |
|           | INDIRECT | X                 | X         |       | X       |
| Risk SMR  | INDIRECT | X                 | X         |       | X       |

Table 88.5 lists applicable confidence limits for stratum-specific rate, rate SMR, risk, and risk SMR.

**Table 88.5** Applicable Confidence Limits for Strata Rate and Risk Statistics

| Statistic | Confidence Limits |           |         |
|-----------|-------------------|-----------|---------|
|           | Normal            | Lognormal | Poisson |
| Rate      | X                 | X         | X       |
| Rate SMR  | X                 | X         | X       |
| Risk      | X                 | X         |         |
| Risk SMR  | X                 | X         |         |

## Table Output

The STD RATE procedure displays the “Standardization Information” table by default. In addition, the procedure also displays the “Standardized Rate Estimates” table (with the default STAT=RATE option in the PROC STD RATE statement) and the “Standardized Risk Estimates” table (with the STAT=RISK option) by default. The rest of this section describes the output tables in alphabetical order.

### Attributable Fraction Estimates

The “Attributable Fraction Estimates” table displays the following information:

- Parameter: attributable rate and population attributable rate for the rate statistic, and attributable risk and population attributable risk for the risk statistic
- Estimate: estimate of the parameter
- Method: method to construct confidence limits
- Lower and Upper: lower and upper confidence limits

### Effect Estimates

The “Effect Estimates” table displays the following information:

- Standardized Rate: directly standardized rates for study populations
- Standardized Risk: directly standardized risks for study populations

When EFFECT=RATIO, the table displays the following:

- Estimate: the rate or risk ratio estimate
- Log Ratio: the logarithm of rate ratio or risk ratio estimate

- Standard Error: standard error of the logarithm of the ratio estimate
- Z: the standard Z statistic
- $\text{Pr} > |Z|$ : the  $p$ -value for the test

When EFFECT=DIFF, the table displays the following:

- Estimate: the rate or risk difference estimate
- Standard Error: standard error of the difference estimate
- Z: the standard Z statistic
- $\text{Pr} > |Z|$ : the  $p$ -value for the test

### Standardization Information

The “Standardization Information” table displays the input data sets, type of statistic to be standardized, standardization method, and number of strata. The table also displays the variance divisor for the risk estimate, and the rate multiplier for the rate estimate. With a rate multiplier  $c$ , the rates per  $c$  population-time units are displayed in the output tables.

### Standardized Morbidity/Mortality Ratio

The “Standardized Morbidity/Mortality Ratio” table displays the following information:

- SMR: standardized morbidity/mortality ratio
- Standard Error: standard error for SMR
- Lower and Upper: lower and upper confidence limits for SMR
- Test Statistic:  $\text{SMR}-1$ , for the test of  $\text{SMR}=1$
- Estimate: value of test statistic
- Standard Error: standard error of the estimate
- Z: the standard Z statistic
- $\text{Pr} > |Z|$ : the  $p$ -value for the test

## Standardized Rate Estimates

The “Standardized Rate Estimates” table displays the following information:

- Population: study populations, and reference population for indirect standardization
- Number of Events: number of events in population
- Population-Time: total contributed time in population, for the rate statistic
- Crude Rate: event rate in the population
- Expected Number of Events
- SMR: standardized morbidity/mortality ratio, for indirect standardization
- Standardized Rate: for the rate statistic
- Standard Error: standard error of the standardized estimate of rate
- Confidence Limits: lower and upper confidence limits for standardized estimate

## Standardized Risk Estimates

The “Standardized Risk Estimates” table displays the following information:

- Population: study populations, and reference population for indirect standardization
- Number of Events: number of events in population
- Number of Observations: number of observations in population
- Crude Risk: event risk in the population
- Expected Number of Events
- SMR: standardized morbidity/mortality ratio, for indirect standardization
- Standardized Risk
- Standard Error: standard error of the standardized estimate of risk
- Confidence Limits: lower and upper confidence limits for standardized estimate

## Strata Effect Estimates

The “Strata Effect Estimates” table displays the following information for each stratum:

- Stratum Index: a sequential stratum identification number
- STRATA variables: the levels of STRATA variables
- Rate: rates for the study populations, for the rate statistic
- Risk: risks for the study populations, for the risk statistic

When EFFECT=DIFF, the table displays the following information for each stratum:

- Estimate: rate or risk difference estimate of the study populations
- Standard Error: the standard error of the difference estimate
- Confidence Limits: confidence limits for the difference estimate

When EFFECT=RATIO, the table displays the following information for each stratum:

- Estimate: rate or risk ratio estimate of the study populations
- Confidence Limits: confidence limits for the ratio estimate

## Strata Statistics

For each POPULATION statement, the “Strata Information” table displays the following information for each stratum:

- Stratum Index: a sequential stratum identification number
- STRATA variables: the levels of STRATA variables

If the REFERENCE statement is specified, the table displays the following information for each stratum in the reference population:

- Population-Time Value: population-time for the rate statistic for direct standardization
- Population-Time Proportion: proportion for the population-time
- Number of Observations Value: number of observations for the risk statistic for direct standardization
- Number of Observations Proportion: proportion for the number of observations
- Rate: for the rate statistic for indirect standardization
- Risk: for the risk statistic for indirect standardization

For the rate statistic, the table displays the following information for each stratum in the specified study data set:

- Number of Events
- Population-Time Value
- Population-Time Proportion
- Rate Estimate
- Standard Error: standard error for the rate estimate if the `CL=NORMAL` suboption is specified in the `STATS` option in the `STRATA` statement
- Confidence Limits: confidence limits for the risk estimate if the `CL` suboption is specified in the `STATS` option in the `STRATA` statement
- Expected Number of Events: expected number of events that use the reference population population-time for direct standardization, Mantel-Haenszel weight for Mantel-Haenszel estimation, or reference population rate for indirect standardization

For the risk statistic, the table displays the following information for each stratum in the specified study data set:

- Number of Events
- Number of Observations Value
- Number of Observations Proportion
- Risk
- Standard Error: standard error for the risk estimate, if the `CL=NORMAL` suboption is specified in the `STATS` option in the `STRATA` statement
- Confidence Limits: confidence limits for the risk estimate, if the `CL` suboption is specified in the `STATS` option in the `STRATA` statement
- Expected Number of Events: expected number of events that uses the reference population number of observations for direct standardization, Mantel-Haenszel weight for Mantel-Haenszel estimation, or reference population risk for indirect standardization

### Strata SMR Estimates

The “Strata SMR Estimates” table displays the following information for each stratum:

- Stratum Index: a sequential stratum identification number
- `STRATA` variables: the levels of `STRATA` variables
- Number of Events

- Expected Number of Observations
- SMR Estimate
- Standard Error: standard error for the SMR estimate, if the CL=NORMAL suboption is specified in the SMR option in the STRATA statement
- Confidence Limits: confidence limits for the SMR estimate, if the CL suboption is specified in the SMR option in the STRATA statement

For the rate statistic, the table also displays the following information for each stratum:

- Population-Time
- Reference Rate

For the risk statistic, the table also displays the following information for each stratum:

- Number of Observations
- Reference Risk

---

## ODS Table Names

PROC STD RATE assigns a name to each table it creates. You must use these names to refer to tables when you use the Output Delivery System (ODS). These names are listed in [Table 88.6](#). For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 88.6** ODS Tables Produced by PROC STD RATE

| ODS Table Name | Description                            | Statement     | Option              |
|----------------|----------------------------------------|---------------|---------------------|
| AttrFraction   | Attributable fraction                  | PROC STD RATE | METHOD=INDIRECT(AF) |
|                |                                        | PROC STD RATE | METHOD=MH(AF)       |
| Effect         | Effect estimates                       | PROC STD RATE | EFFECT              |
| SMR            | Standardized morbidity/mortality ratio | PROC STD RATE | METHOD=INDIRECT     |
| StdInfo        | Standardization information            | PROC STD RATE |                     |
| StdRate        | Standardized rate estimates            | PROC STD RATE | STAT=RATE           |
| StdRisk        | Standardized risk estimates            | PROC STD RATE | STAT=RISK           |
| StrataEffect   | Strata effect estimates                | STRATA        | EFFECT              |
| StrataStats    | Strata statistics                      | STRATA        | STATS               |
| StrataSMR      | Strata SMR estimates                   | STRATA        | SMR                 |

---

## Graphics Output

This section describes the use of ODS for creating graphics with the STD RATE procedure. To request these graphs, ODS Graphics must be enabled and you must specify the associated graphics options in the PROC STD RATE statement. For more information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

### Strata Distribution Plot

The PLOTS=DIST option displays the proportion of exposed time or sample size for each stratum in the populations.

### Strata Effect Plot

The PLOTS=EFFECT option displays the stratum-specific effect measure of rate difference, rate ratio, risk difference, or risk ratio. In addition, the crude effect measure and confidence limits of these stratum-specific effect estimates are also displayed.

### Strata Rate Plot

The PLOTS=RATE option displays the stratum-specific rate estimates and their confidence limits of populations. In addition, the overall crude rates of populations are also displayed.

### Strata Risk Plot

The PLOTS=RISK option displays the stratum-specific risk estimates and their confidence limits of populations. In addition, the overall crude risks of populations are also displayed.

### Strata SMR Plot

The PLOTS=SMR option displays the SMR for each stratum in the populations.

---

## ODS Graphics

Statistical procedures use ODS Graphics to create graphs as part of their output. ODS Graphics is described in detail in Chapter 21, “Statistical Graphics Using ODS.”

Before you create graphs, ODS Graphics must be enabled (for example, by specifying the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” on page 599 in Chapter 21, “Statistical Graphics Using ODS.”

PROC STD RATE assigns a name to each graph it creates. You can use these names to refer to the graphs when you use ODS. To request the graph, ODS Graphics must be enabled and you must use the PLOTS option in the PROC STD RATE statement to specify the *plot-request* indicated in Table 88.7.

**Table 88.7** Graphs Produced by PROC STDRATE

| ODS Graph Name   | Plot Description                                                                     | <i>plot-request</i> in PLOTS Option |
|------------------|--------------------------------------------------------------------------------------|-------------------------------------|
| StrataDistPlot   | Strata proportion of exposed time or sample size                                     | DIST                                |
| StrataEffectPlot | Strata effect measure of rate difference, rate ratio, risk difference, or risk ratio | EFFECT                              |
| StrataRatePlot   | Strata rate estimates                                                                | RATE                                |
| StrataRiskPlot   | Strata risk estimates                                                                | RISK                                |
| StrataSMRPlot    | Strata SMR of rates or risks                                                         | SMR                                 |

## Examples: STDRATE Procedure

### Example 88.1: Comparing Directly Standardized Rates

This example computes directly standardized mortality rates for populations in the states of Alaska and Florida, and then compares these two standardized rates with a rate ratio statistic.

The Alaska data set contains the stratum-specific mortality information in a given period of time for the state of Alaska (Alaska Bureau of Vital Statistics 2000a, b). Variables `Sex` and `Age` are the grouping variables that form the strata in the standardization, and variables `Death` and `PYear` indicate the number of events and person-years, respectively. The `COMMA9.` format is specified in the `DATA` step to input numerical values that contain commas in `PYear`.

```

data Alaska;
 State='Alaska';
 input Sex $ Age $ Death PYear comma9.;
 datalines;
Male 00-14 37 81,205
Male 15-34 68 93,662
Male 35-54 206 108,615
Male 55-74 369 35,139
Male 75+ 556 5,491
Female 00-14 78 77,203
Female 15-34 181 85,412
Female 35-54 395 100,386
Female 55-74 555 32,118
Female 75+ 479 7,701
;

```

The Florida data set contains the corresponding stratum-specific mortality information for the state of Florida (Florida Department of Health 2000, 2012). Variables `Sex` and `Age` are the grouping variables that form the strata in the standardization, and variables `Death` and `PYear` indicate the number of events and person-years, respectively.

```

data Florida;
 State='Florida';
 input Sex $ Age $ Death comma8. PYear comma11.;
 datalines;
Male 00-14 1,189 1,505,889
Male 15-34 2,962 1,972,157
Male 35-54 10,279 2,197,912
Male 55-74 26,354 1,383,533
Male 75+ 42,443 554,632
Female 00-14 906 1,445,831
Female 15-34 1,234 1,870,430
Female 35-54 5,630 2,246,737
Female 55-74 18,309 1,612,270
Female 75+ 53,489 868,838
;

```

The TwoStates data set contains the data sets Alaska and Florida:

```

data TwoStates;
 length State $ 7.;
 set Alaska Florida;
run;

```

The US data set contains the corresponding stratum-specific person-years information for the United States (U.S. Bureau of Census 2011). Variables Sex and Age are the grouping variables that form the strata in the standardization, and the variable PYear indicates the person-years.

```

data US;
 input Sex $ Age $ PYear comma12.;
 datalines;
Male 00-14 30,854,207
Male 15-34 40,199,647
Male 35-54 40,945,028
Male 55-74 19,948,630
Male 75+ 6,106,351
Female 00-14 29,399,168
Female 15-34 38,876,268
Female 35-54 41,881,451
Female 55-74 22,717,040
Female 75+ 10,494,416
;

```

The following statements invoke the STDRATE procedure and compute the direct standardized rates for the states of Florida and Alaska by using the United States as the reference population. The DATA= option names the data set for the study populations, and the REFDATA= option names the data set for the reference population.

```

ods graphics on;
proc stdrate data=TwoStates
 refdata=US
 method=direct
 stat=rate(mult=1000)
 effect

```

```

plots(only)=(dist effect)
;
population group=State event=Death total=PYear;
reference total=PYear;
strata Sex Age / effect;
run;
ods graphics off;

```

The METHOD=DIRECT option requests direct standardization, and the STAT=RATE option specifies the rate statistic for standardization. With the EFFECT option, the procedure computes the rate effect between the study populations with the default rate ratio statistics.

The “Standardization Information” table in [Output 88.1.1](#) displays the standardization information.

### Output 88.1.1 Standardization Information

| The STD RATE Procedure      |                        |
|-----------------------------|------------------------|
| Standardization Information |                        |
| Data Set                    | WORK.TWOSTATES         |
| Group Variable              | State                  |
| Reference Data Set          | WORK.US                |
| Method                      | Direct Standardization |
| Statistic                   | Rate                   |
| Number of Strata            | 10                     |
| Rate Multiplier             | 1000                   |

With ODS Graphics enabled, the PLOTS(ONLY)=(DIST EFFECT) option displays the strata distribution plot and the strata effect plot, but does not display the default strata rate plot.

The strata distribution plot displays proportions for stratum-specific person-years in the study populations and reference population, as shown in [Output 88.1.2](#).

Output 88.1.2 Strata Distribution Plot

The EFFECT option in the STRATA statement and the STAT=RATE option request that the “Strata Rate Effect Estimates” table in [Output 88.1.3](#) display the stratum-specific rate effect statistics between the two study populations. The default EFFECT=RATIO in the PROC STD RATE statement requests that the stratum-specific rate ratio statistics be displayed.

**Output 88.1.3** Strata Effect Estimates

| Strata Rate Effect Estimates (Rate Multiplier = 1000) |        |       |                 |         |               |                                    |         |
|-------------------------------------------------------|--------|-------|-----------------|---------|---------------|------------------------------------|---------|
| Stratum<br>Index                                      | Sex    | Age   | -----State----- |         | Rate<br>Ratio | 95% Lognormal<br>Confidence Limits |         |

| 7                                                     | Male   | 15-34 | 0.726           | 1.5019  | 0.4834        | 0.3801                             | 0.6148  |
| 8                                                     | Male   | 35-54 | 1.897           | 4.6767  | 0.4055        | 0.3533                             | 0.4655  |
| 9                                                     | Male   | 55-74 | 10.501          | 19.0483 | 0.5513        | 0.4975                             | 0.6109  |
| 10                                                    | Male   | 75+   | 101.257         | 11.9394 | 8.4809        | 7.7634                             | 9.2647  |

The “Strata Rate Effect Estimates” table shows that except for the age group 75+, Alaska has lower mortality rates for male groups and higher mortality rates for female groups than Florida. For age group 75+, Alaska has much higher mortality rates than Florida for both male and female groups.

With ODS Graphics enabled and two study populations, the PLOTS=EFFECT option displays the stratum-specific effect measures and their associated confidence limits, as shown in [Output 88.1.4](#). The STAT=RATE option and the default EFFECT=RATIO option request that the strata rate ratios be displayed. By default, confidence limits are generated with 95% confidence level. This plot displays the stratum-specific rate ratios in the “Strata Rate Effect Estimates” table in [Output 88.1.3](#).

Output 88.1.4 Strata Effect Measure Plot

The “Directly Standardized Rate Estimates” table in [Output 88.1.5](#) displays directly standardized rates and related statistics.

**Output 88.1.5** Directly Standardized Rate Estimates

| Directly Standardized Rate Estimates |                            |                 |            |                        |                 |
|--------------------------------------|----------------------------|-----------------|------------|------------------------|-----------------|
| Rate Multiplier = 1000               |                            |                 |            |                        |                 |
| State                                | -----Study Population----- |                 | Crude Rate | -Reference Population- |                 |
|                                      | Observed Events            | Population-Time |            | Expected Events        | Population-Time |
| Alaska                               | 2924                       | 626932          | 4.6640     | 1126924                | 266481515       |
| Florida                              | 76455                      | 15577105        | 4.9082     | 1076187                | 266481515       |

| Directly Standardized Rate Estimates |                             |                |            |                   |
|--------------------------------------|-----------------------------|----------------|------------|-------------------|
| Rate Multiplier = 1000               |                             |                |            |                   |
| State                                | -----Standardized Rate----- |                |            |                   |
|                                      | Estimate                    | Standard Error | 95% Normal | Confidence Limits |
| Alaska                               | 4.2289                      | 0.0901         | 4.0522     | 4.4056            |
| Florida                              | 4.0385                      | 0.0156         | 4.0079     | 4.0691            |

The MULT=1000 suboption in the STAT=RATE option requests that rates per 1,000 person-years be displayed. The table shows that although the crude rate in the Florida population (4.908) is higher than the crude rate in the Alaska population (4.664), the resulting standardized rate in the Florida population (4.0385) is lower than the crude rate in the Alaska population (4.2289).

The EFFECT option requests that the “Rate Effect Estimates” table in [Output 88.1.6](#) display the log rate ratio statistics of the two directly standardized rates by default.

**Output 88.1.6** Effect Estimates

| Rate Effect Estimates (Rate Multiplier = 1000) |         |            |                |                |      |         |
|------------------------------------------------|---------|------------|----------------|----------------|------|---------|
| -----State-----                                |         | Rate Ratio | Log Rate Ratio | Standard Error | Z    | Pr >  Z |
| Alaska                                         | Florida |            |                |                |      |         |
| 4.2289                                         | 4.0385  | 1.0471     | 0.0461         | 0.0217         | 2.13 | 0.0335  |

The table shows that with a log rate ratio statistic 1.047, the resulting *p*-value is 0.0335, which indicates that the death rate is significantly higher in Alaska than in Florida at the 5% significance level.

---

**Example 88.2: Computing Mantel-Haenszel Risk Estimation**

This example uses Mantel-Haenszel method to estimate the effect of household smoking on respiratory symptoms of school children, after adjusting for the effects of the student’s grade and household pets.

Suppose that the School data set contains the stratum-specific numbers of cases of respiratory symptoms in a given school year for a school district. Variables Pet and Grade are the grouping variables that form

the strata in the standardization, and the variable Smoking identifies students who have smokers in their households. The variables Case and Student indicate the number of cases with respiratory symptoms and the total number of students, respectively.

```
data School;
 input Smoking $ Pet $ Grade $ Case Student;
 datalines;
Yes Yes K-1 109 807
Yes Yes 2-3 106 791
Yes Yes 4-5 112 868
Yes No K-1 168 1329
Yes No 2-3 162 1337
Yes No 4-5 183 1594
No Yes K-1 284 2403
No Yes 2-3 266 2237
No Yes 4-5 273 2279
No No K-1 414 3398
No No 2-3 372 3251
No No 4-5 382 3270
;
```

The following statements invoke the STDRATE procedure and compute the Mantel-Haenszel rate difference statistic between students with household smokers and students without household smokers:

```
ods graphics on;
proc stdrate data=School
 method=mh
 stat=risk
 effect=diff
 plots=all
 ;
 population group=Smoking event=Case total=Student;
 strata Pet Grade / order=data stats(cl=none) effect;
run;
ods graphics off;
```

The ORDER=DATA option in the STRATA statement sorts the strata by the order of appearance in the input data set.

The “Standardization Information” table in [Output 88.2.1](#) displays the standardization information.

**Output 88.2.1** Standardization Information

| The STDRATE Procedure       |                 |
|-----------------------------|-----------------|
| Standardization Information |                 |
| Data Set                    | WORK.SCHOOL     |
| Group Variable              | Smoking         |
| Method                      | Mantel-Haenszel |
| Statistic                   | Risk            |
| Number of Strata            | 6               |

The `STATS` option in the `STRATA` statement requests that the `STD RATE` procedure display a “Mantel-Haenszel Standardized Strata Statistics” table for study populations, as shown in [Output 88.2.2](#). The table displays the strata information and the expected number of events in each stratum. The Expected Events column shows the expected number of events when the Mantel-Haenszel weights are applied to the corresponding stratum-specific risks in the study populations. The `CL=NONE` suboption requests that confidence limits for strata risks not be displayed.

## Output 88.2.2 Mantel-Haenszel Standardized Strata Statistics

| The STDRATE Procedure                          |               |     |       |  |

With ODS Graphics enabled, the PLOTS=ALL option displays all appropriate plots. With the METHOD=MH and STAT=RISK options, these plots include the strata distribution plot, strata risk plot, and strata effect plot.

The strata distribution plot displays proportions for stratum-specific numbers of students in the study populations, as shown in Output 88.2.3.

**Output 88.2.3** Strata Distribution Plot

The strata risk plot displays stratum-specific risk estimates with confidence limits in the study populations, as shown in Output 88.2.4. This plot displays stratum-specific risk estimates in the “Mantel-Haenszel Standardized Strata Statistics” table in Output 88.2.2. In addition, the overall crude risks for the two study populations are also displayed. By default, strata levels are displayed on the vertical axis.

Output 88.2.4 Strata Risk Plot

The EFFECT option in the STRATA statement requests that the “Strata Risk Effect Estimates” table be displayed, as shown in Output 88.2.5. The EFFECT=DIFF option in the PROC STDRA TE statement requests that strata risk differences be displayed.

**Output 88.2.5** Strata Effect Estimates

| Strata Risk Effect Estimates |     |       |                   |         |                 |                |

| 6                            | -.017120                     | 0.021148 |

The “Strata Risk Effect Estimates” table shows that for the stratum of students without household pets in Grade 4–5, the risk is higher for students without household smokers than for students with household smokers. For all other strata, the risk is lower for students without household smokers than for students with household smokers. The difference is not significant in each stratum because the null value 0 is between the lower and upper confidence limits.

With ODS Graphics enabled, the PLOTS=EFFECT option displays the plot with the stratum-specific risk effect measures and their associated confidence limits, as shown in [Output 88.2.6](#). The EFFECT=DIFF option requests that the risk difference be displayed. By default, confidence limits are generated with 95% confidence level. This plot displays the stratum-specific risk differences in the “Strata Risk Effect Estimates” table in [Output 88.2.5](#).

Output 88.2.6 Strata Risk Plot

The “Mantel-Haenszel Standardized Risk Estimates” table in [Output 88.2.7](#) displays the Mantel-Haenszel standardized risks and related statistics.

**Output 88.2.7** Standardized Risk Estimates (Mantel-Haenszel Estimation)

| Mantel-Haenszel Standardized Risk Estimates |                            |                           |               |                     |         |

| Mantel-Haenszel Standardized Risk Estimates |                             |                   |                                 |        |
|---------------------------------------------|-----------------------------|-------------------|---------------------------------|--------|
| Smoking                                     | -----Standardized Risk----- |                   |                                 |        |
|                                             | Estimate                    | Standard<br>Error | 95% Normal<br>Confidence Limits |        |
| No                                          | 0.1182                      | 0.00250           | 0.1133                          | 0.1231 |
| Yes                                         | 0.1251                      | 0.00404           | 0.1172                          | 0.1331 |

The EFFECT=DIFF option requests that the “Risk Effect Estimates” table display the risk difference statistic for the two directly standardized risks, as shown in [Output 88.2.8](#).

**Output 88.2.8** Mantel-Haenszel Effect Estimates

| Risk Effect Estimates |        |                    |                   |       |         |
|-----------------------|--------|--------------------|-------------------|-------|---------|
| -----Smoking-----     |        | Risk<br>Difference | Standard<br>Error | Z     | Pr >  Z |
| No                    | Yes    |                    |                   |       |         |
| 0.1182                | 0.1251 | -0.00698           | 0.00475           | -1.47 | 0.1418  |

The table shows that although the standardized risk for students without household smokes is lower than the standardized risk for students with household smokes, the difference (-0.00698) is not significant at the 5% significance level, (*p*-value 0.1418).

---

**Example 88.3: Computing Attributable Fraction Estimates**

This example computes the excess event risk fraction that is attributable to a specific chemical exposure for workers in a factory.

Suppose that the Factory data set contains the stratum-specific event information for exposure to a specific chemical agent. The variable Age is the grouping variable that forms the strata. The variables Event\_E and Count\_E indicate the number of events and number of workers for workers with the specific chemical exposure, respectively. The variables Event\_NE and Count\_NE indicate the number of events and number of workers for workers without the specific chemical exposure, respectively.

```

data Factory;
 input Age $ Event_E Count_E Event_NE Count_NE;
 datalines;
20-29 31 352 143 2626
30-39 57 486 392 4124
40-49 62 538 459 4662
50-59 50 455 337 3622
60-69 38 322 199 2155
70+ 9 68 35 414
;

```

The following statements invoke the STDRATE procedure and compute the attributable risk and population attributable risk for the chemical exposure:

```

ods graphics on;
proc stdrate data=Factory
 reldata=Factory
 method=indirect (af)
 stat=risk
 plots (stratum=horizontal)
;
 population event=Event_E total=Count_E;
 reference event=Event_NE total=Count_NE;
 strata Age / stats;
run;
ods graphics off;

```

The “Standardization Information” table in [Output 88.3.1](#) displays the standardization information.

### Output 88.3.1 Standardization Information

| The STDRATE Procedure       |                          |
|-----------------------------|--------------------------|
| Standardization Information |                          |
| Data Set                    | WORK.FACTORY             |
| Reference Data Set          | WORK.FACTORY             |
| Method                      | Indirect Standardization |
| Statistic                   | Risk                     |
| Number of Strata            | 6                        |

The STATS option in the STRATA statement requests that the “Indirectly Standardized Strata Statistics” table in [Output 88.3.2](#) display the strata information and the expected number of events at each stratum. The Expected Events column shows the expected numbers of events when the stratum-specific risks in the reference data set are applied to the corresponding numbers of workers in the study data set.

**Output 88.3.2** Strata Information (Indirect Standardization)

| The STDRATE Procedure                     |       |                            |                                   |            |               |                   |

| 4                                         | 0.081153                        | 0.138627 | 3622                              | 0.2058     | 0.09304       | 42.3343            |
| 5                                         | 0.082774                        | 0.153251 | 2155                              | 0.1224     | 0.09234       | 29.7346            |
| 6                                         | 0.051809                        | 0.212897 | 414                               | 0.0235     | 0.08454       | 5.7488             |

With ODS Graphics enabled and the specified STAT=RISK option, the default PLOTS=RISK option displays the stratum-specific risk estimates in the study and reference populations, as shown in [Output 88.3.3](#). The STRATUM=HORIZONTAL global option in the PLOTS option displays the strata information on the horizontal axis. The plot displays the stratum-specific risk estimates in the “Indirect Standardized Strata Statistics” table in [Output 88.3.2](#). In addition, confidence limits for the risk estimates in the study population and the overall crude risks for the two populations are also displayed

Output 88.3.3 Strata Risk Plot

The METHOD=INDIRECT option requests that the “Standardized Morbidity/Mortality Ratio” table in [Output 88.3.4](#) display the SMR, its 95% confidence limits, and the test for the null hypothesis  $H_0 : \text{SMR} = 1$ .

Output 88.3.4 Standardized Morbidity/Mortality Ratio

| Standardized Morbidity/Mortality Ratio |                 |        |                |                              |        |      |         |
|----------------------------------------|-----------------|--------|----------------|------------------------------|--------|------|---------|
| Observed Events                        | Expected Events | SMR    | Standard Error | 95% Normal Confidence Limits |        | Z    | Pr >  Z |
| 247                                    | 196.151         | 1.2592 | 0.0755         | 1.1113                       | 1.4072 | 3.43 | 0.0006  |

The “Standardized Morbidity/Mortality Ratio” table shows that  $\text{SMR}=1.259$ , the 95% confidence limits do not contain the null value  $\text{SMR}=1$ , and the null hypothesis of  $\text{SMR}=1$  is rejected at  $\alpha = 0.05$  level from the normal test.

The “Indirectly Standardized Risk Estimates” table in [Output 88.3.5](#) displays the standardized risks and related statistics.

**Output 88.3.5** Standardized Risks (Indirect Standardization)

| Indirectly Standardized Risk Estimates |                           |                                 |               |                    |        |  |
|----------------------------------------|---------------------------|---------------------------------|---------------|--------------------|--------|--|
| -----Study Population-----             |                           |                                 | Reference     |                    |        |  |
| Observed<br>Events                     | Number of<br>Observations | Crude<br>Risk                   | Crude<br>Risk | Expected<br>Events | SMR    |  |
| 247                                    | 2221                      | 0.1112                          | 0.0889        | 196.151            | 1.2592 |  |
| Indirectly Standardized Risk Estimates |                           |                                 |               |                    |        |  |
| -----Standardized Risk-----            |                           |                                 |               |                    |        |  |
| Estimate                               | Standard<br>Error         | 95% Normal<br>Confidence Limits |               |                    |        |  |
| 0.1120                                 | 0.00671                   | 0.0988                          | 0.1251        |                    |        |  |

The AF suboption in the METHOD=INDIRECT option requests that the “Attributable Fraction Estimates” table display the attributable risk and population attributable risk, as shown in [Output 88.3.6](#)

**Output 88.3.6** Attributable Fraction Estimates

| Attributable Fraction Estimates |          |                         |         |
|---------------------------------|----------|-------------------------|---------|
| Parameter                       | Estimate | -95% Confidence Limits- |         |
| Attributable Risk               | 0.20587  | 0.10013                 | 0.28937 |
| Population Attributable Risk    | 0.02806  | 0.01159                 | 0.04426 |

The attributable risk fraction 0.206 indicates that 20.6% of all events in the chemical exposure group are attributed to the chemical exposure, and the population attributable risk fraction 0.028 indicates that about 2.8% of all events in the total population are attributed to the chemical exposure.

The Attributable fraction can also be computed by using Mantel-Haenszel method.

Suppose that the Factory1 data set contains the stratum-specific event information for exposure to a specific chemical agent. The variable Age is the grouping variable that forms the strata, and the variable Exposure identifies workers with chemical exposure. The variables Event and Count indicate the number of events and number of workers, respectively.

```

data Factory1;
 input Exposure $ Age $ Event Count;
 datalines;
Yes 20-29 31 352
Yes 30-39 57 486
Yes 40-49 62 538
Yes 50-59 50 455
Yes 60-69 38 322
Yes 70+ 9 68
No 20-29 143 2626

```

```

No 30-39 392 4124
No 40-49 459 4662
No 50-59 337 3622
No 60-69 199 2155
No 70+ 35 414
;

```

The following statements invoke the STDRATE procedure and compute the attributable risk and population attributable risk for the chemical exposure:

```

proc stdrate data=Factory1
 method=mh (af)
 stat=risk
 effect
;
 population group(order=data)=Exposure event=Event total=Count;
 strata Age;
run;

```

The “Standardization Information” table in [Output 88.3.7](#) displays the standardization information.

#### Output 88.3.7 Standardization Information

| The STDRATE Procedure       |                 |
|-----------------------------|-----------------|
| Standardization Information |                 |
| Data Set                    | WORK.FACTORY1   |
| Group Variable              | Exposure        |

| Mantel-Haenszel Standardized Risk Estimates |                             |                   |                                 |        |
|---------------------------------------------|-----------------------------|-------------------|---------------------------------|--------|
| Exposure                                    | -----Standardized Risk----- |                   |                                 |        |
|                                             | Estimate                    | Standard<br>Error | 95% Normal<br>Confidence Limits |        |
| Yes                                         | 0.1112                      | 0.00667           | 0.0981                          | 0.1243 |
| No                                          | 0.0884                      | 0.00214           | 0.0842                          | 0.0926 |

The EFFECT option requests that the “Risk Effect Estimates” table display the risk ratio statistic for the two directly standardized risks, as shown in [Output 88.3.9](#).

**Output 88.3.9** Mantel-Haenszel Effect Estimates

| Risk Effect Estimates |        |               |                      |                   |      |         |
|-----------------------|--------|---------------|----------------------|-------------------|------|---------|
| -----Exposure-----    |        | Risk<br>Ratio | Log<br>Risk<br>Ratio | Standard<br>Error | Z    | Pr >  Z |
| Yes                   | No     |               |                      |                   |      |         |
| 0.1112                | 0.0884 | 1.2584        | 0.2298               | 0.0647            | 3.55 | 0.0004  |

The AF suboption in the METHOD=MH option requests that the “Attributable Fraction Estimates” table display the attributable risk and population attributable risk, as shown in [Output 88.3.10](#)

**Output 88.3.10** Attributable Fraction Estimates

| Attributable Fraction Estimates |          |                         |         |
|---------------------------------|----------|-------------------------|---------|
| Parameter                       | Estimate | -95% Confidence Limits- |         |
| Attributable Risk               | 0.20531  | 0.09789                 | 0.29994 |
| Population Attributable Risk    | 0.02799  | 0.01070                 | 0.04497 |

Similar to the results of using the SMR estimates, the attributable risk fraction (0.205) indicates that 20.5% of all events in the chemical exposure group are attributed to the chemical exposure, and the population attributable risk fraction (0.028) indicates that about 2.8% of all events in the total population are attributed to the chemical exposure.

## Example 88.4: Displaying SMR Results from BY Groups

This example illustrates the use of ODS OUTPUT statement to save standardized mortality ratios for different causes and to display these statistics together in a table and in a plot.

The Florida\_Cs data set contains the stratum-specific mortality information for stomach cancer and skin cancer in year 2000 for the state of Florida (Florida Department of Health 2000, 2012). The variable Age is the grouping variable that forms the strata in the standardization. The variables Event\_C16, Event\_C43, and PYear identify the number of events for stomach cancer, the number of events for skin cancer, and the person-years, respectively. The COMMA12. format is specified in the DATA step to input numerical values that contain commas in PYear.

```
data Florida_Cs;
 input Age $1-5 Event_C16 Event_C43 PYear comma12.;
 datalines;
00-04 0 0 953,785
05-14 0 0 1,997,935
15-24 0 4 1,885,014
25-34 1 14 1,957,573
35-44 19 43 2,356,649
45-54 64 72 2,088,000
55-64 114 70 1,548,371
65-74 201 126 1,447,432
75-84 294 136 1,087,524
85+ 136 73 335,944
;
```

The following statements construct and list the mortality information by cancer cause:

```
data Florida_Cs;
 set Florida_Cs;
 Cause='Stomach'; Event=Event_C16; output;
 Cause='Skin'; Event=Event_C43; output;
 drop Event_C16 Event_C43;
run;

proc sort data=Florida_Cs;
 by Cause;
run;

proc print data=Florida_Cs;
 var Cause Age Event PYear;
run;
```

**Output 88.4.1** Florida Data

| Obs | Cause   | Age   | Event | PYear   |
|-----|---------|-------|-------|---------|
| 1   | Skin    | 00-04 | 0     | 953785  |
| 2   | Skin    | 05-14 | 0     | 1997935 |
| 3   | Skin    | 15-24 | 4     | 1885014 |
| 4   | Skin    | 25-34 | 14    | 1957573 |
| 5   | Skin    | 35-44 | 43    | 2356649 |
| 6   | Skin    | 45-54 | 72    | 2088000 |
| 7   | Skin    | 55-64 | 70    | 1548371 |
| 8   | Skin    | 65-74 | 126   | 1447432 |
| 9   | Skin    | 75-84 | 136   | 1087524 |
| 10  | Skin    | 85+   | 73    | 335944  |
| 11  | Stomach | 00-04 | 0     | 953785  |
| 12  | Stomach | 05-14 | 0     | 1997935 |
| 13  | Stomach | 15-24 | 0     | 1885014 |
| 14  | Stomach | 25-34 | 1     | 1957573 |
| 15  | Stomach | 35-44 | 19    | 2356649 |
| 16  | Stomach | 45-54 | 64    | 2088000 |
| 17  | Stomach | 55-64 | 114   | 1548371 |
| 18  | Stomach | 65-74 | 201   | 1447432 |
| 19  | Stomach | 75-84 | 294   | 1087524 |
| 20  | Stomach | 85+   | 136   | 335944  |

The US\_Cs data set contains the corresponding stratum-specific mortality information for the United States (Miniño et al. 2002; U.S. Bureau of Census 2011). The variable Age is the grouping variable that forms the strata in the standardization. The variables Event\_C16, Event\_C43, and PYear identify the number of events for stomach cancer, the number of events for skin cancer, and the person-years, respectively.

```
data US_Cs;
 input Age $1-5 Event_C16 Event_C43 PYear comma12.;
 datalines;
00-04 0 0 19,175,798
05-14 1 1 41,077,577
15-24 14 41 39,183,891
25-34 124 186 39,892,024
35-44 484 626 45,148,527
45-54 1097 1199 37,677,952
55-64 1804 1303 24,274,684
65-74 3054 1637 18,390,986
75-84 3833 1624 12,361,180
85+ 2234 803 4,239,587
;
```

The following statements construct and list the mortality information by cancer cause:

```
data US_Cs;
 set US_Cs;
 Cause='Stomach'; Event=Event_C16; output;
 Cause='Skin'; Event=Event_C43; output;
 drop Event_C16 Event_C43;
run;
```

```

proc sort data=US_Cs;
 by Cause;
run;

proc print data=US_Cs;
 var Cause Age Event PYear;
run;

```

Output 88.4.2 lists the mortality information by cancer cause.

**Output 88.4.2** Florida Data

| Obs | Cause   | Age   | Event | PYear    |
|-----|---------|-------|-------|----------|
| 1   | Skin    | 00-04 | 0     | 19175798 |
| 2   | Skin    | 05-14 | 1     | 41077577 |
| 3   | Skin    | 15-24 | 41    | 39183891 |

| 20  | Stomach | 85+   | 2234  | 4239587  |

The following statements invoke the STDRATE procedure and request indirect standardization to compute the skin and stomach SMR estimates for the state of Florida. The BY statement requests separate analyses of causes that are defined by the Cause variable.

```

ods graphics on;
ods select StdInfo StrataSmrPlot Smr;
proc stdrate data=Florida_Cs refdata=US_Cs
 stat=rate
 method=indirect
 plots=smr
 ;
 population event=Event total=PYear;
 reference event=Event total=PYear;
 strata Age;
 by Cause;
ods output smr=Smr_Cs;
run;
ods graphics off;

```

Only the tables and plots that are specified in the ODS SELECT statement are displayed.

The STDINFO option in the ODS SELECT statement requests that the “Standardization Information” table display the standardization information for the first BY group, skin cancer, as shown in [Output 88.4.3](#)

### Output 88.4.3 Standardization Information

| ----- Cause=Skin -----      |                          |
|-----------------------------|--------------------------|
| The STDRATE Procedure       |                          |
| Standardization Information |                          |
| Data Set                    | WORK.FLORIDA_CS          |
| Reference Data Set          | WORK.US_CS               |
| Method                      | Indirect Standardization |
| Statistic                   | Rate                     |
| Number of Strata            | 10                       |
| Rate Multiplier             | 100000                   |

The STRATASMRPLOT option in the ODS SELECT statement requests that the strata SMR plot display stratum-specific SMR estimates for skin cancer with confidence limits, as shown in [Output 88.4.4](#).

Output 88.4.4 Strata SMR Plot

The SMR option in the ODS SELECT statement requests that the “Standardized Morbidity/Mortality Ratio” table display the SMR, its confidence limits, and the test for the null hypothesis  $H_0 : SMR = 1$  for skin cancer, as shown in Output 88.4.5. With the default ALPHA=0.05, 95% confidence limits are constructed.

Output 88.4.5 Standardized Morbidity/Mortality Ratio

| ----- Cause=Skin -----                 |                    |                 |                   |                                 |        |      |         |
|----------------------------------------|--------------------|-----------------|-------------------|---------------------------------|--------|------|---------|
| Standardized Morbidity/Mortality Ratio |                    |                 |                   |                                 |        |      |         |
| Observed<br>Events                     | Expected<br>Events | Standard<br>SMR | Standard<br>Error | 95% Normal<br>Confidence Limits |        | Z    | Pr >  Z |
| 538                                    | 528.726            | 1.0175          | 0.0439            | 0.9316                          | 1.1035 | 0.40 | 0.6893  |

Similarly, the “Standardization Information” table in Output 88.4.6 displays the standardization information for the second BY group, stomach cancer.

**Output 88.4.6** Standardization Information

```

----- Cause=Stomach -----
 The STDRATE Procedure
 Standardization Information

Data Set WORK.FLORIDA_CS
Reference Data Set WORK.US_CS
Method Indirect Standardization
Statistic Rate
Number of Strata 10
Rate Multiplier 100000

```

The “Strata SMR Plot” displays stratum-specific SMR estimates with confidence limits for stomach cancer, as shown in [Output 88.4.7](#).

**Output 88.4.7** Strata SMR Plot

The “Standardized Morbidity/Mortality Ratio” table displays the SMR, its confidence limits, and the test for the null hypothesis  $H_0 : \text{SMR} = 1$  for stomach cancer, as shown in [Output 88.4.8](#).

**Output 88.4.8** Standardized Morbidity/Mortality Ratio

| ----- Cause=Stomach -----              |                    |                 |                   |                                 |        |       |         |
|----------------------------------------|--------------------|-----------------|-------------------|---------------------------------|--------|-------|---------|
| Standardized Morbidity/Mortality Ratio |                    |                 |                   |                                 |        |       |         |
| Observed<br>Events                     | Expected<br>Events | Standard<br>SMR | Standard<br>Error | 95% Normal<br>Confidence Limits |        | Z     | Pr >  Z |
| 829                                    | 962.537            | 0.8613          | 0.0299            | 0.8026                          | 0.9199 | -4.64 | <.0001  |

The ODS OUTPUT SMR=SMR\_CS statement requests that the “Standardized Morbidity/Mortality Ratio” tables for the two cancer causes be saved in the data set Smr\_Cs. The following statements display the selected output variables for the data set:

```
proc print data=Smr_Cs;
 var Cause ObservedEvents ExpectedEvents Smr SmrLcl SmrUcl;
run;
```

**Output 88.4.9** SMR Results from BY Groups

| Obs | Cause   | Observed<br>Events | Expected<br>Events | Smr    | SmrLcl | SmrUcl |
|-----|---------|--------------------|--------------------|--------|--------|--------|
| 1   | Skin    | 538                | 528.726            | 1.0175 | 0.9316 | 1.1035 |
| 2   | Stomach | 829                | 962.537            | 0.8613 | 0.8026 | 0.9199 |

The table in [Output 88.4.9](#) shows that the study population (state of Florida) has a higher skin cancer rate and a lower stomach cancer rate than the reference population (United States), but only the lower stomach cancer rate is significant because its corresponding SMR upper confidence limit (0.9199) is less than 1.

The following statements display the standardized morbidity/mortality ratios for the two causes in a plot:

```
proc sgplot data=Smr_Cs;
 scatter y=Cause x=Smr / group=Cause;
 highlow y=Cause high=SmrUcl low=SmrLcl / highcap=serif lowcap=serif;
 yaxis type=discrete;
 xaxis label="SMR";
 refline 1 / axis=x transparency=0.5;
run;
```

Output 88.4.10 SMR Results

Alternatively, you can also use the following statements to obtain separate analyses for the two cancer causes, and then to display these standardized mortality ratios together in a table and in a plot:

```

/*----- Perform Separate Analyses for Different Causes -----*/
ods graphics on;
ods select StdInfo StrataSmrPlot Smr;
proc stdrate data=Florida-Cs refdata=US-Cs
 stat=rate
 method=indirect
 plots=smr
 ;
 population event=Event_C43 total=PYear;
 reference event=Event_C43 total=PYear;
 strata Age;
ods output smr=Smr_c43;
run;

```

```

ods select StdInfo StrataSmrPlot Smr;
proc stdrate data=Florida-Cs reldata=US-Cs
 stat=rate
 method=indirect
 plots=smr
 ;
 population event=Event_C16 total=PYear;
 reference event=Event_C16 total=PYear;
 strata Age;
ods output smr=Smr_c16;
run;
ods graphics off;

/*----- Combine SMRs -----*/
data Smr_C43;
 set Smr_C43;
 length Cause $ 7.;
 Cause='Skin';
run;

data Smr_C16;
 set Smr_C16;
 length Cause $ 7.;
 Cause='Stomach';
run;

data Smr-Cs;
 set Smr_C43 Smr_C16;
run;

/*----- Display the Cause-Specific SMRs -----*/
proc print data=Smr-Cs;
 var Cause ObservedEvents ExpectedEvents Smr SmrLcl SmrUcl;
run;

proc sgplot data=Smr-Cs;
 scatter y=Cause x=Smr / group=Cause;
 highlow y=Cause high=SmrUcl low=SmrLcl / highcap=serif lowcap=serif;
 yaxis type=discrete;
 xaxis label="SMR";
 refline 1 / axis=x transparency=0.5;
run;

```

### Overview: STEPDISC Procedure

Given a classification variable and several quantitative variables, the STEPDISC procedure performs a stepwise discriminant analysis to select a subset of the quantitative variables for use in discriminating among the classes. The set of variables that make up each class is assumed to be multivariate normal with a common covariance matrix. The STEPDISC procedure can use forward selection, backward elimination, or stepwise selection (Klecka 1980). The STEPDISC procedure is a useful prelude to further analyses with the CANDISC procedure or the DISCRIM procedure.

With PROC STEPDISC, variables are chosen to enter or leave the model according to one of two criteria:

- the significance level of an  $F$  test from an analysis of covariance, where the variables already chosen act as covariates and the variable under consideration is the dependent variable
- the squared partial correlation for predicting the variable under consideration from the CLASS variable, controlling for the effects of the variables already selected for the model

Forward selection begins with no variables in the model. At each step, PROC STEPDISC enters the variable that contributes most to the discriminatory power of the model as measured by Wilks' lambda, the likelihood ratio criterion. When none of the unselected variables meet the entry criterion, the forward selection process stops.

Backward elimination begins with all variables in the model except those that are linearly dependent on previous variables in the VAR statement. At each step, the variable that contributes least to the discriminatory power of the model as measured by Wilks' lambda is removed. When all remaining variables meet the criterion to stay in the model, the backward elimination process stops.

Stepwise selection begins, like forward selection, with no variables in the model. At each step, the model is examined. If the variable in the model that contributes least to the discriminatory power of the model as measured by Wilks' lambda fails to meet the criterion to stay, then that variable is removed. Otherwise, the variable not in the model that contributes most to the discriminatory power of the model is entered. When all variables in the model meet the criterion to stay and none of the other variables meet the criterion to enter, the stepwise selection process stops. Stepwise selection is the default method of variable selection.

It is important to realize that, in the selection of variables for entry, only one variable can be entered into the model at each step. The selection process does not take into account the relationships between variables that have not yet been selected. Thus, some important variables could be excluded in the process. Also, Wilks' lambda might not be the best measure of discriminatory power for your application. However, if you use PROC STEPDISC carefully, in combination with your knowledge of the data and careful cross validation, it can be a valuable aid in selecting variables for a discrimination model.

As with any stepwise procedure, it is important to remember that when many significance tests are performed, each at a level of, for example, 5% (0.05), the overall probability of rejecting at least one true null hypothesis is much larger than 5%. If you want to prevent including any variables that do not contribute to the discriminatory power of the model in the population, you should specify a very small significance level. In most applications, all variables considered have some discriminatory power, however small. To choose the model that provides the best discrimination by using the sample estimates, you need only to guard against estimating more parameters than can be reliably estimated with the given sample size.

Costanza and Afifi (1979) use Monte Carlo studies to compare alternative stopping rules that can be used with the forward selection method in the two-group multivariate normal classification problem. Five different numbers of variables, ranging from 10 to 30, are considered in the studies. The comparison is based on conditional and estimated unconditional probabilities of correct classification. They conclude that the use of a moderate significance level, in the range of 10 to 25 percent, often performs better than the use of a much larger or a much smaller significance level.

The significance level and the squared partial correlation criteria select variables in the same order, although they might select different numbers of variables. Increasing the sample size tends to increase the number of variables selected when you are using significance levels, but it has little effect on the number selected by using squared partial correlations.

See Chapter 10, "Introduction to Discriminant Procedures," for more information about discriminant analysis.

## Getting Started: STEPDISC Procedure

The data in this example are measurements of 159 fish caught in Finland's lake Laengelmavesi; this data set is available from the Puranen. For each of the seven species (bream, roach, whitefish, parkki, perch, pike, and smelt) the weight, length, height, and width of each fish are tallied. Three different length measurements are recorded: from the nose of the fish to the beginning of its tail, from the nose to the notch of its tail, and from the nose to the end of its tail. The height and width are recorded as percentages of the third length variable. The fish data set is available from the Sashelp library. PROC STEPDISC will select a subset of the six quantitative variables that might be useful for differentiating between the fish species. This subset is used in conjunction with PROC CANDISC and PROC DISCRIM to develop discrimination models.

The following steps use PROC STEPDISC to select a subset of potential discriminator variables. By default, PROC STEPDISC uses stepwise selection on all numeric variables that are not listed in other statements, and the significance levels for a variable to enter the subset and to stay in the subset are set to 0.15. The following statements produce [Figure 89.1](#) through [Figure 89.5](#):

```

title 'Fish Measurement Data';

proc stepdisc data=sashelp.fish;
 class Species;
run;

```

PROC STEPDISC begins by displaying summary information about the analysis (see [Figure 89.1](#)). This information includes the number of observations with nonmissing values, the number of classes in the classification variable (specified by the CLASS statement), the number of quantitative variables under consideration, the significance criteria for variables to enter and to stay in the model, and the method of variable selection being used. The frequency of each class is also displayed.

**Figure 89.1** Summary Information

| Bream                   | Bream         | 34        | 34.0000 | 0.215190   |
| Parkki                  | Parkki        | 11        | 11.0000 | 0.069620   |
| Perch                   | Perch         | 56        | 56.0000 | 0.354430   |
| Pike                    | Pike          | 17        | 17.0000 | 0.107595   |
| Roach                   | Roach         | 20        | 20.0000 | 0.126582   |
| Smelt                   | Smelt         | 14        | 14.0000 | 0.088608   |
| Whitefish               | Whitefish     | 6         | 6.0000  | 0.037975   |

For each entry step, the statistics for entry are displayed for all variables not currently selected (see Figure 89.2). The variable selected to enter at this step (if any) is displayed, as well as all the variables currently selected. Next are multivariate statistics that take into account all previously selected variables and the newly entered variable.

Figure 89.2 Step 1: Variable HEIGHT Selected for Entry

| Average Squared Canonical Correlation | 0.125888 |         |        |           |        |

For each removal step (Figure 89.3), the statistics for removal are displayed for all variables currently entered. The variable to be removed at this step (if any) is displayed. If no variable meets the criterion to be removed and the maximum number of steps as specified by the MAXSTEP= option has not been attained, then the procedure continues with another entry step.

**Figure 89.3** Step 2: No Variable Is Removed; Variable Length2 Added

```

```

All the variables in the data set are found to have potential discriminatory power. These variables are used to develop discrimination models in both the CANDISC and DISCRIM procedure chapters.

---

## Syntax: STEPDISC Procedure

The following statements are available in the STEPDISC procedure:

```

PROC STEPDISC < options > ;
 CLASS variable ;
 BY variables ;
 FREQ variable ;
 VAR variables ;
 WEIGHT variable ;

```

The BY, CLASS, FREQ, VAR, and WEIGHT statements are described after the PROC STEPDISC statement.

---

## PROC STEPDISC Statement

```

PROC STEPDISC < options > ;

```

The PROC STEPDISC statement invokes the STEPDISC procedure. Table 89.1 summarizes the options available in the PROC STEPDISC statement.

**Table 89.1** STEPDISC Procedure Options

| Option                            | Description                                  |
|-----------------------------------|----------------------------------------------|
| <b>Input Data Set</b>             |                                              |
| DATA=                             | Specifies input SAS data set                 |
| <b>Method Details</b>             |                                              |
| MAXMACRO=                         | Specifies maximum macro variable lists       |
| METHOD=                           | Specifies method                             |
| SINGULAR=                         | Specifies singularity                        |
| <b>Control Stepwise Selection</b> |                                              |
| SLENTY=                           | Specifies entry significance                 |
| SLSTAY=                           | Specifies staying significance               |
| PR2ENTRY=                         | Specifies entry partial R square             |
| PR2STAY=                          | Specifies staying partial R square           |
| INCLUDE=                          | Forces inclusion of variables                |
| MAXSTEP=                          | Specifies maximum number of steps            |
| START=                            | Specifies variables to begin                 |
| STOP=                             | Specifies number of variables in final model |
| <b>Control Displayed Output</b>   |                                              |
| ALL                               | Displays all                                 |
| BCORR                             | Displays between correlations                |
| BCOV                              | Displays between covariances                 |
| BSSCP                             | Displays between SSCPs                       |
| PCORR                             | Displays pooled correlations                 |
| PCOV                              | Displays pooled covariances                  |

Table 89.1 *continued*

| Option  | Description                       |
|---------|-----------------------------------|
| PSSCP   | Displays pooled SSCPs             |
| SHORT   | Suppresses output                 |
| SIMPLE  | Displays descriptive statistics   |
| STDMEAN | Displays standardized class means |
| TCORR   | Displays total correlations       |
| TCOV    | Displays total covariances        |
| TSSCP   | Displays total SSCPs              |
| WCORR   | Displays within correlations      |
| WCOV    | Displays within covariances       |
| WSSCP   | Displays within SSCPs             |

**ALL**

activates all of the display options.

**BCORR**

displays between-class correlations.

**BCOV**

displays between-class covariances. The between-class covariance matrix equals the between-class SSCP matrix divided by  $n(c - 1)/c$ , where  $n$  is the number of observations and  $c$  is the number of classes. The between-class covariances should be interpreted in comparison with the total-sample and within-class covariances, not as formal estimates of population parameters.

**BSSCP**

displays the between-class SSCP matrix.

**DATA=SAS-data-set**

specifies the data set to be analyzed. The data set can be an ordinary SAS data set or one of several specially structured data sets created by statistical procedures available with SAS/STAT software. These specially structured data sets include TYPE=CORR, COV, CSSCP, and SSCP. If the DATA= option is omitted, the procedure uses the most recently created SAS data set.

**INCLUDE=n**

includes the first  $n$  variables in the VAR statement in every model. By default, INCLUDE=0.

**MAXMACRO=n**

specifies the maximum number of macro variables with independent variable lists to create. By default, MAXMACRO=100. PROC STEPDISC saves the list of selected variables in a macro variable, &\_StdVar. Suppose your input variable list consists of x1-x10; then &\_StdVar would be set to x1 x3 x4 x10 if, for example, the first, third, fourth, and tenth variables were selected for the model. This list can be used, for example, in a subsequent procedure's VAR statement as follows:

```
var &_stdvar;
```

With BY processing, one macro variable is created for each BY group, and the macro variables are indexed by the BY-group number. The MAXMACRO= option can be used to either limit or

increase the number of these macro variables in processing data sets with many BY groups. The macro variables are created as follows:

With no BY processing, PROC STEPDISC creates the following:

|                              |                                                                   |
|------------------------------|-------------------------------------------------------------------|
| <code>_StdVar</code>         | selected variables                                                |
| <code>_StdVar1</code>        | selected variables                                                |
| <code>_StdNumBys</code>      | number of BY groups (1)                                           |
| <code>_StdNumMacroBys</code> | number of <code>_StdVari</code> macro variables actually made (1) |

With BY processing, PROC STEPDISC creates the following:

|                              |                                                                                                                                                                                                      |
|------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <code>_StdVar</code>         | selected variables for BY group 1                                                                                                                                                                    |
| <code>_StdVar1</code>        | selected variables for BY group 1                                                                                                                                                                    |
| <code>_StdVar2</code>        | selected variables for BY group 2                                                                                                                                                                    |
| .                            |                                                                                                                                                                                                      |
| .                            |                                                                                                                                                                                                      |
| .                            |                                                                                                                                                                                                      |
| <code>_StdVarm</code>        | selected variables for BY group $m$ , where a number is substituted for $m$                                                                                                                          |
| <code>_StdNumBys</code>      | $n$ , the number of BY groups                                                                                                                                                                        |
| <code>_StdNumMacroBys</code> | the number $m$ of <code>_StdVari</code> macro variables actually made. This value might be less than <code>_StdNumBys = n</code> , and it is less than or equal to the <code>MAXMACRO=</code> value. |

#### **MAXSTEP= $n$**

specifies the maximum number of steps. By default, `MAXSTEP=` two times the number of variables in the VAR statement.

#### **METHOD=BACKWARD | BW**

#### **METHOD=FORWARD | FW**

#### **METHOD=STEPWISE | SW**

specifies the method used to select the variables in the model. The `BACKWARD` method specifies backward elimination, `FORWARD` specifies forward selection, and `STEPWISE` specifies stepwise selection. By default, `METHOD=STEPWISE`.

#### **PCORR**

displays pooled within-class correlations (partial correlations based on the pooled within-class covariances).

#### **PCOV**

displays pooled within-class covariances.

#### **PR2ENTRY= $\rho$**

#### **PR2E= $\rho$**

specifies the partial R square for adding variables in the forward selection mode, where  $\rho \leq 1$ .

#### **PR2STAY= $\rho$**

#### **PR2S= $\rho$**

specifies the partial R square for retaining variables in the backward elimination mode, where  $\rho \leq 1$ .

**PSSCP**

displays the pooled within-class corrected SSCP matrix.

**SHORT**

suppresses the displayed output from each step.

**SIMPLE**

displays simple descriptive statistics for the total sample and within each class.

**SINGULAR= $\rho$** 

specifies the singularity criterion for entering variables, where  $0 < \rho < 1$ . PROC STEPDISC precludes the entry of a variable if the squared multiple correlation of the variable with the variables already in the model exceeds  $1 - \rho$ . With more than one variable already in the model, PROC STEPDISC also excludes a variable if it would cause any of the variables already in the model to have a squared multiple correlation (with the entering variable and the other variables in the model) exceeding  $1 - \rho$ . By default, SINGULAR= 1E-8.

**SLENTRY= $\rho$** **SLE= $\rho$** 

specifies the significance level for adding variables in the forward selection mode, where  $0 \leq \rho \leq 1$ . The default value is 0.15.

**SLSTAY= $\rho$** **SLS= $\rho$** 

specifies the significance level for retaining variables in the backward elimination mode, where  $0 \leq \rho \leq 1$ . The default value is 0.15.

**START= $n$** 

specifies that the first  $n$  variables in the VAR statement be used to begin the selection process. When you specify METHOD=FORWARD or METHOD=STEPWISE, the default value is 0; when you specify METHOD=BACKWARD, the default value is the number of variables in the VAR statement.

**STDMEAN**

displays total-sample and pooled within-class standardized class means.

**STOP= $n$** 

specifies the number of variables in the final model. The STEPDISC procedure stops the selection process when a model with  $n$  variables is found. This option applies only when you specify METHOD=FORWARD or METHOD=BACKWARD. When you specify METHOD=FORWARD, the default value is the number of variables in the VAR statement; when you specify METHOD=BACKWARD, the default value is 0.

**TCORR**

displays total-sample correlations.

**TCOV**

displays total-sample covariances.

**TSSCP**

displays the total-sample corrected SSCP matrix.

**WCORR**

displays within-class correlations for each class level.

**WCOV**

displays within-class covariances for each class level.

**WSSCP**

displays the within-class corrected SSCP matrix for each class level.

---

## BY Statement

**BY variables ;**

You can specify a BY statement with PROC STEPDISC to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the STEPDISC procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

## CLASS Statement

**CLASS** *variable* ;

The values of the CLASS variable define the groups for analysis. Class levels are determined by the formatted values of the CLASS variable. The CLASS variable can be numeric or character. A CLASS statement is required.

---

## FREQ Statement

**FREQ** *variable* ;

If a variable in the data set represents the frequency of occurrence for the other values in the observation, include the name of the variable in a FREQ statement. The procedure then treats the data set as if each observation appears  $n$  times, where  $n$  is the value of the FREQ variable for the observation. The total number of observations is considered to be equal to the sum of the FREQ variable when the procedure determines degrees of freedom for significance probabilities.

If the value of the FREQ variable is missing or is less than one, the observation is not used in the analysis. If the value is not an integer, the value is truncated to an integer.

---

## VAR Statement

**VAR** *variables* ;

The VAR statement specifies the quantitative variables eligible for selection. The default is all numeric variables not listed in other statements.

---

## WEIGHT Statement

**WEIGHT** *variable* ;

To use relative weights for each observation in the input data set, place the weights in a variable in the data set and specify the name in a WEIGHT statement. This is often done when the variance associated with each observation is different and the values of the WEIGHT variable are proportional to the reciprocals of the variances. If the value of the WEIGHT variable is missing or is less than zero, then a value of zero for the weight is assumed.

The WEIGHT and FREQ statements have a similar effect except that the WEIGHT statement does not alter the degrees of freedom.

---

## Details: STEPDISC Procedure

---

### Missing Values

Observations containing missing values are omitted from the analysis.

---

### Input Data Sets

The input data set can be an ordinary SAS data set or one of several specially structured data sets created by statistical procedures available with SAS/STAT software. For more information about these data sets, see Appendix A, “[Special SAS Data Sets](#).” The BY variable in these data sets becomes the CLASS variable in PROC STEPDISC. These specially structured data sets include the following:

- TYPE=CORR data sets created by PROC CORR by using a BY statement
- TYPE=COV data sets created by PROC PRINCOMP by using both the COV option and a BY statement
- TYPE=CSSCP data sets created by PROC CORR by using the CSSCP option and a BY statement, where the OUT= data set is assigned TYPE=CSSCP with the TYPE= data set option
- TYPE=SSCP data sets created by PROC REG by using both the OUTSSCP= option and a BY statement

When the input data set is TYPE=CORR, TYPE=COV, or TYPE=CSSCP, the STEPDISC procedure reads the number of observations for each class from the observations with `_TYPE_='N'` and the variable means in each class from the observations with `_TYPE_='MEAN'`. The procedure then reads the within-class correlations from the observations with `_TYPE_='CORR'`, the standard deviations from the observations with `_TYPE_='STD'` (data set TYPE=CORR), the within-class covariances from the observations with `_TYPE_='COV'` (data set TYPE=COV), or the within-class corrected sums of squares and crossproducts from the observations with `_TYPE_='CSSCP'` (data set TYPE=CSSCP).

When the data set does not include any observations with `_TYPE_='CORR'` (data set TYPE=CORR), `_TYPE_='COV'` (data set TYPE=COV), or `_TYPE_='CSSCP'` (data set TYPE=CSSCP) for each class, PROC STEPDISC reads the pooled within-class information from the data set. In this case, the STEPDISC procedure reads the pooled within-class correlations from the observations with `_TYPE_='PCORR'`, the pooled within-class standard deviations from the observations with `_TYPE_='PSTD'` (data set TYPE=CORR), the pooled within-class covariances from the observations with `_TYPE_='PCOV'` (data set TYPE=COV), or the pooled within-class corrected SSCP matrix from the observations with `_TYPE_='PSSCP'` (data set TYPE=CSSCP).

When the input data set is TYPE=SSCP, the STEPDISC procedure reads the number of observations for each class from the observations with `_TYPE_='N'`, the sum of weights of observations from the variable INTERCEPT in observations with `_TYPE_='SSCP'` and `_NAME_='INTERCEPT'`, the variable sums from the analysis variables in observations with `_TYPE_='SSCP'` and `_NAME_='INTERCEPT'`, and the uncorrected sums of squares and crossproducts from the analysis variables in observations with `_TYPE_='SSCP'` and `_NAME_=variable-names`.

---

## Computational Resources

In the following discussion, let

- $n$  = number of observations
- $c$  = number of class levels
- $v$  = number of variables in the VAR list
- $l$  = length of the CLASS variable
- $t$  =  $v + c - 1$

## Memory Requirements

The amount of memory in bytes for temporary storage needed to process the data is

$$c(4v^2 + 28v + 3l + 4c + 72) + 16v^2 + 92v + 4t^2 + 20t + 4l$$

Additional temporary storage of 72 bytes at each step is also required to store the results.

## Time Requirements

The following factors determine the time requirements of a stepwise discriminant analysis:

- The time needed for reading the data and computing covariance matrices is proportional to  $nv^2$ . The STEPDISC procedure must also look up each class level in the list. This is faster if the data are sorted by the CLASS variable. The time for looking up class levels is proportional to a value ranging from  $n$  to  $n \ln(c)$ .
- The time needed for stepwise discriminant analysis is proportional to the number of steps required to select the set of variables in the discrimination model. The number of steps required depends on the data set itself and the selection method and criterion used in the procedure. Each forward or backward step takes time proportional to  $(v + c)^2$ .

---

## Displayed Output

The displayed output from PROC STEPDISC includes the class level information table. For each level of the classification variable, the following information is provided: the output data set variable name, frequency sum, weight sum, and the proportion of the total sample.

The optional output from PROC STEPDISC includes the following:

The optional output includes the following:

- Within-class SSCP matrices for each group
- Pooled within-class SSCP matrix
- Between-class SSCP matrix
- Total-sample SSCP matrix
- Within-class covariance matrices for each group
- Pooled within-class covariance matrix
- Between-class covariance matrix, equal to the between-class SSCP matrix divided by  $n(c - 1)/c$ , where  $n$  is the number of observations and  $c$  is the number of classes
- Total-sample covariance matrix
- Within-class correlation coefficients and  $\text{Pr} > |r|$  to test the hypothesis that the within-class population correlation coefficients are zero
- Pooled within-class correlation coefficients and  $\text{Pr} > |r|$  to test the hypothesis that the partial population correlation coefficients are zero
- Between-class correlation coefficients and  $\text{Pr} > |r|$  to test the hypothesis that the between-class population correlation coefficients are zero
- Total-sample correlation coefficients and  $\text{Pr} > |r|$  to test the hypothesis that the total population correlation coefficients are zero
- Simple statistics, including  $N$  (the number of observations), sum, mean, variance, and standard deviation for the total sample and within each class
- Total-sample standardized class means, obtained by subtracting the grand mean from each class mean and dividing by the total-sample standard deviation
- Pooled within-class standardized class means, obtained by subtracting the grand mean from each class mean and dividing by the pooled within-class standard deviation

At each step, the following statistics are displayed:

- for each variable considered for entry or removal: partial R-square, the squared (partial) correlation, the  $F$  statistic, and  $\text{Pr} > F$ , the probability level, from a one-way analysis of covariance
- the minimum tolerance for entering each variable. A variable is entered only if its tolerance and the tolerances for all variables already in the model are greater than the value specified in the SINGULAR= option. The tolerance for the entering variable is  $1 - R^2$  from regressing the entering variable on the other variables already in the model. The tolerance for a variable already in the model is  $1 - R^2$  from regressing that variable on the entering variable and the other variables already in the model. With  $m$  variables already in the model, for each entering variable,  $m + 1$  multiple regressions are performed by using the entering variable and each of the  $m$  variables already in the model as a dependent variable. These  $m + 1$  tolerances are computed for each entering variable, and the minimum tolerance is displayed for each.

The tolerance is computed by using the total-sample correlation matrix. It is customary to compute tolerance by using the pooled within-class correlation matrix (Jennrich 1977), but it is possible for a variable with excellent discriminatory power to have a high total-sample tolerance and a low pooled within-class tolerance. For example, PROC STEPDISC enters a variable that yields perfect discrimination (that is, produces a canonical correlation of one), but a program that uses pooled within-class tolerance does not.

- the variable label, if any
- the name of the variable chosen
- the variables already selected or removed
- Wilks' lambda and the associated  $F$  approximation with degrees of freedom and  $\text{Pr} < F$ , the associated probability level after the selected variable has been entered or removed. Wilks' lambda is the likelihood ratio statistic for testing the hypothesis that the means of the classes on the selected variables are equal in the population (see the section "[Multivariate Tests](#)" on page 92 in Chapter 4, "[Introduction to Regression Procedures](#)."). Lambda is close to zero if any two groups are well separated.
- Pillai's trace and the associated  $F$  approximation with degrees of freedom and  $\text{Pr} > F$ , the associated probability level after the selected variable has been entered or removed. Pillai's trace is a multivariate statistic for testing the hypothesis that the means of the classes on the selected variables are equal in the population (see the section "[Multivariate Tests](#)" on page 92 in Chapter 4, "[Introduction to Regression Procedures](#)").
- Average squared canonical correlation (ASCC). The ASCC is Pillai's trace divided by the number of groups minus 1. The ASCC is close to 1 if all groups are well separated and if all or most directions in the discriminant space show good separation for at least two groups.
- Summary to give statistics associated with the variable chosen at each step. The summary includes the following:
  - Step number
  - Variable entered or removed

- Number in, the number of variables in the model
- Partial R-square
- the  $F$  value for entering or removing the variable
- $\text{Pr} > F$ , the probability level for the  $F$  statistic
- Wilks' lambda
- $\text{Pr} < \text{Lambda}$  based on the  $F$  approximation to Wilks' lambda
- Average squared canonical correlation
- $\text{Pr} > \text{ASCC}$  based on the  $F$  approximation to Pillai's trace
- the variable label, if any

## ODS Table Names

PROC STEPDISC assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 89.2 along with the PROC STEPDISC statement options needed to produce the table. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

**Table 89.2** ODS Tables Produced by PROC STEPDISC

| ODS Table Name   | Description                                     | Option          |
|------------------|-------------------------------------------------|-----------------|
| BCorr            | Between-class correlations                      | BCORR           |
| BCov             | Between-class covariances                       | BCOV            |
| BSSCP            | Between-class SSCP matrix                       | BSSCP           |
| Counts           | Number of observations, variables, classes, df  | default         |
| CovDF            | Nonprinting table of df for covariance matrices | any *COV option |
| Levels           | Class level information                         | default         |
| Messages         | Entry/removal messages                          | default         |
| Multivariate     | Multivariate statistics                         | default         |
| NObs             | Number of observations                          | default         |
| PCorr            | Pooled within-class correlations                | PCORR           |
| PCov             | Pooled within-class covariances                 | PCOV            |
| PSSCP            | Pooled within-class SSCP matrix                 | PSSCP           |
| PStdMeans        | Pooled standardized class means                 | STDMEAN         |
| SimpleStatistics | Simple statistics                               | SIMPLE          |
| Steps            | Stepwise selection entry/removal                | default         |
| Summary          | Stepwise selection summary                      | default         |
| TCorr            | Total-sample correlations                       | TCORR           |
| TCov             | Total-sample covariances                        | TCOV            |
| TSSCP            | Total-sample SSCP matrix                        | TSSCP           |
| TStdMeans        | Total standardized class means                  | STDMEAN         |
| Variables        | Variable lists                                  | default         |
| WCorr            | Within-class correlations                       | WCORR           |
| WCov             | Within-class covariances                        | WCOV            |
| WSSCP            | Within-class SSCP matrices                      | WSSCP           |

## Example: STEPDISC Procedure

### Example 89.1: Performing a Stepwise Discriminant Analysis

The iris data published by Fisher (1936) have been widely used for examples in discriminant analysis and cluster analysis. The sepal length, sepal width, petal length, and petal width are measured in millimeters on 50 iris specimens from each of three species: *Iris setosa*, *I. versicolor*, and *I. virginica*. The iris data set is available from the Sashelp library.

A stepwise discriminant analysis is performed by using stepwise selection.

In the PROC STEPDISC statement, the BSSCP and TSSCP options display the between-class SSCP matrix and the total-sample corrected SSCP matrix. By default, the significance level of an  $F$  test from an analysis of covariance is used as the selection criterion. The variable under consideration is the dependent variable, and the variables already chosen act as covariates. The following SAS statements produce [Output 89.1.1](#) through [Output 89.1.8](#):

```

title 'Fisher (1936) Iris Data';

%let _stdvar = ;
proc stepdisc data=sashelp.iris bsscp tsscp;
 class Species;
 var SepalLength SepalWidth PetalLength PetalWidth;
run;

```

**Output 89.1.1** Iris Data: Summary Information

| Fisher (1936) Iris Data                        |               |                              |         |            |
|------------------------------------------------|---------------|------------------------------|---------|------------|
| The STEPDISC Procedure                         |               |                              |         |            |
| The Method for Selecting Variables is STEPWISE |               |                              |         |            |
| Total Sample Size                              | 150           | Variable(s) in the Analysis  | 4       |            |
| Class Levels                                   | 3             | Variable(s) Will Be Included | 0       |            |
|                                                |               | Significance Level to Enter  | 0.15    |            |
|                                                |               | Significance Level to Stay   | 0.15    |            |
| Number of Observations Read                    |               | 150                          |         |            |
| Number of Observations Used                    |               | 150                          |         |            |
| Class Level Information                        |               |                              |         |            |
| Species                                        | Variable Name | Frequency                    | Weight  | Proportion |
| Setosa                                         | Setosa        | 50                           | 50.0000 | 0.333333   |
| Versicolor                                     | Versicolor    | 50                           | 50.0000 | 0.333333   |
| Virginica                                      | Virginica     | 50                           | 50.0000 | 0.333333   |

**Output 89.1.2** Iris Data: Between-Class and Total-Sample SSCP Matrices

| Fisher (1936) Iris Data   |                   |             |             |             |             |
|---------------------------|-------------------|-------------|-------------|-------------|-------------|
| The STEPDISC Procedure    |                   |             |             |             |             |
| Between-Class SSCP Matrix |                   |             |             |             |             |
| Variable                  | Label             | SepalLength | SepalWidth  | PetalLength | PetalWidth  |
| Sepal Length              | Sepal Length (mm) | 6321.21333  | -1995.26667 | 16524.84000 | 7127.93333  |
| SepalWidth                | Sepal Width (mm)  | -1995.26667 | 1134.49333  | -5723.96000 | -2293.26667 |
| Petal Length              | Petal Length (mm) | 16524.84000 | -5723.96000 | 43710.28000 | 18677.40000 |
| PetalWidth                | Petal Width (mm)  | 7127.93333  | -2293.26667 | 18677.40000 | 8041.33333  |
| Total-Sample SSCP Matrix  |                   |             |             |             |             |
| Variable                  | Label             | SepalLength | SepalWidth  | PetalLength | PetalWidth  |
| Sepal Length              | Sepal Length (mm) | 10216.83333 | -632.26667  | 18987.30000 | 7692.43333  |
| SepalWidth                | Sepal Width (mm)  | -632.26667  | 2830.69333  | -4911.88000 | -1812.42667 |
| Petal Length              | Petal Length (mm) | 18987.30000 | -4911.88000 | 46432.54000 | 19304.58000 |
| PetalWidth                | Petal Width (mm)  | 7692.43333  | -1812.42667 | 19304.58000 | 8656.99333  |

In step 1, the tolerance is 1.0 for each variable under consideration because no variables have yet entered the model. The variable `PetalLength` is selected because its  $F$  statistic, 1180.161, is the largest among all variables.

### Output 89.1.3 Iris Data: Stepwise Selection Step 1

| Fisher (1936) Iris Data                            |                   |          |         |        |           |
|----------------------------------------------------|-------------------|----------|---------|--------|-----------|
| The STEPDISC Procedure                             |                   |          |         |        |           |

In step 2, with the variable `PetalLength` already in the model, `PetalLength` is tested for removal before a new variable is selected for entry. Since `PetalLength` meets the criterion to stay, it is used as a covariate in the analysis of covariance for variable selection. The variable `SepalWidth` is selected because its  $F$  statistic, 43.035, is the largest among all variables not in the model and because its associated tolerance, 0.8164, meets the criterion to enter. The process is repeated in steps 3 and 4. The variable `PetalWidth` is entered in step 3, and the variable `SepalLength` is entered in step 4.

**Output 89.1.4** Iris Data: Stepwise Selection Step 2

```

Fisher (1936) Iris Data

PROC STEPDISC automatically creates a list of the selected variables and stores it in a macro variable. You can submit the following statement to see the list of selected variables:

```
* print the macro variable list;
%put &_stdvar;
```

The macro variable `_StdVar` contains the following variable list:

```
SepalLength SepalWidth PetalLength PetalWidth
```

You could use this macro variable if you want to analyze these variables in subsequent steps as follows:

```
proc discrim data=sashelp.iris;
 class Species;
 var &_stdvar;
run;
```

The results of this step are not shown.

## Overview: SURVEYFREQ Procedure

The SURVEYFREQ procedure produces one-way to  $n$ -way frequency and crosstabulation tables from sample survey data. These tables include estimates of population totals, population proportions, and their standard errors. Confidence limits, coefficients of variation, and design effects are also available. The procedure provides a variety of options to customize the table display.

For one-way frequency tables, PROC SURVEYFREQ provides Rao-Scott chi-square goodness-of-fit tests, which are adjusted for the sample design. You can test a null hypothesis of equal proportions for a one-way frequency table, or you can input custom null hypothesis proportions for the test. For two-way tables, PROC SURVEYFREQ provides design-adjusted tests of independence, or no association, between the row and column variables. These tests include the Rao-Scott chi-square test, the Rao-Scott likelihood ratio test, the Wald chi-square test, and the Wald log-linear chi-square test. For  $2 \times 2$  tables, PROC SURVEYFREQ computes estimates and confidence limits for risks (row proportions), the risk difference, the odds ratio, and relative risks.

PROC SURVEYFREQ computes variance estimates based on the sample design used to obtain the survey data. The design can be a complex multistage survey design with stratification, clustering, and unequal weighting. PROC SURVEYFREQ provides a choice of variance estimation methods, which include Taylor series linearization, balanced repeated replication (BRR), and the jackknife.

PROC SURVEYFREQ uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the SURVEYFREQ procedure, see the `PLOTS=` option in the TABLES statement and the section “[ODS Graphics](#)” on page 7669.

## Getting Started: SURVEYFREQ Procedure

The following example shows how you can use PROC SURVEYFREQ to analyze sample survey data. The example uses data from a customer satisfaction survey for a student information system (SIS), which is a software product that provides modules for student registration, class scheduling, attendance, grade reporting, and other functions.

The software company conducted a survey of school personnel who use the SIS. A probability sample of SIS users was selected from the study population, which included SIS users at middle schools and high schools

in the three-state area of Georgia, South Carolina, and North Carolina. The sample design for this survey was a two-stage stratified design. A first-stage sample of schools was selected from the list of schools in the three-state area that use the SIS. The list of schools (the first-stage sampling frame) was stratified by state and by customer status (whether the school was a new user of the system or a renewal user). Within the first-stage strata, schools were selected with probability proportional to size and with replacement, where the size measure was school enrollment. From each sample school, five staff members were randomly selected to complete the SIS satisfaction questionnaire. These staff members included three teachers and two administrators or guidance department members.

The SAS data set `SIS_Survey` contains the survey results, as well as the sample design information needed to analyze the data. This data set includes an observation for each school staff member responding to the survey. The variable `Response` contains the staff member's response about overall satisfaction with the system.

The variable `State` contains the school's state, and the variable `NewUser` contains the school's customer status ('New Customer' or 'Renewal Customer'). These two variables determine the first-stage strata from which schools were selected. The variable `School` contains the school identification code and identifies the first-stage sampling units (clusters). The variable `SamplingWeight` contains the overall sampling weight for each respondent. Overall sampling weights were computed from the selection probabilities at each stage of sampling and were adjusted for nonresponse.

Other variables in the data set `SIS_Survey` include `SchoolType` and `Department`. The variable `SchoolType` identifies the school as a high school or a middle school. The variable `Department` identifies the staff member as a teacher, or an administrator or guidance department member.

The following PROC SURVEYFREQ statements request a one-way frequency table for the variable `Response`:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey;
 tables Response;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;

```

The PROC SURVEYFREQ statement invokes the procedure and identifies the input data set to be analyzed. The TABLES statement requests a one-way frequency table for the variable `Response`. The table request syntax for PROC SURVEYFREQ is very similar to the table request syntax for PROC FREQ. This example shows a request for a single one-way table, but you can also request two-way tables and multiway tables. As in PROC FREQ, you can request more than one table in the same TABLES statement, and you can use multiple TABLES statements in the same invocation of the procedure.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information for the procedure, so that the analysis is done according to the sample design used for the survey, and the estimates apply to the study population. The STRATA statement names the variables `State` and `NewUser`, which identify the first-stage strata. Note that the design for this example also includes stratification at the second stage of selection (by type of school personnel), but you specify only the first-stage strata for PROC SURVEYFREQ. The CLUSTER statement names the variable `School`, which identifies the clusters (primary sampling units). The WEIGHT statement names the sampling weight variable.

Figure 90.1 and Figure 90.2 display the output produced by PROC SURVEYFREQ, which includes the “Data Summary” table and the one-way table, “Table of Response.” The “Data Summary” table is produced by default unless you specify the NOSUMMARY option. This table shows there are 6 strata, 370 clusters or schools, and 1850 observations (respondents) in the SIS\_Survey data set. The sum of the sampling weights is approximately 39,000, which estimates the total number of school personnel in the study area that use the SIS.

**Figure 90.1** SIS\_Survey Data Summary

| Student Information System Survey |            |
|-----------------------------------|------------|
| The SURVEYFREQ Procedure          |            |
| Data Summary                      |            |
| Number of Strata                  | 6          |
| Number of Clusters                | 370        |
| Number of Observations            | 1850       |
| Sum of Weights                    | 38899.6482 |

Figure 90.2 displays the one-way table of Response, which provides estimates of the population total (weighted frequency) and the population percentage for each category (level) of the variable Response. The response level ‘Very Unsatisfied’ has a frequency of 304, which means that 304 sample respondents fall into this category. It is estimated that 17.17% of all school personnel in the study population fall into this category, and the standard error of this estimate is 1.29%. Note that the estimates apply to the population of all SIS users in the study area, as opposed to describing only the sample of 1850 respondents. The estimate of the total number of school personnel that are ‘Very Unsatisfied’ is 6,678, with a standard deviation of 502. The standard errors computed by PROC SURVEYFREQ are based on the multistage stratified design of the survey. This differs from some of the traditional analysis procedures, which assume the design is simple random sampling from an infinite population.

**Figure 90.2** One-Way Table of Response

| Table of Response |           |                    |                     |         |                    |
|-------------------|-----------|--------------------|---------------------|---------|--------------------|
| Response          | Frequency | Weighted Frequency | Std Dev of Wgt Freq | Percent | Std Err of Percent |
| Very Unsatisfied  | 304       | 6678               | 501.61039           | 17.1676 | 1.2872             |
| Unsatisfied       | 326       | 6907               | 495.94101           | 17.7564 | 1.2712             |
| Neutral           | 581       | 12291              | 617.20147           | 31.5965 | 1.5795             |
| Satisfied         | 455       | 9309               | 572.27868           | 23.9311 | 1.4761             |
| Very Satisfied    | 184       | 3714               | 370.66577           | 9.5483  | 0.9523             |
| Total             | 1850      | 38900              | 129.85268           | 100.000 |                    |

The following PROC SURVEYFREQ statements request confidence limits for the percentages, a chi-square goodness-of-fit test, and a weighted frequency plot for the one-way table of Response. The ODS GRAPHICS ON statement enables ODS Graphics.

```

title 'Student Information System Survey';
ods graphics on;
proc surveyfreq data=SIS_Survey nosummary;
 tables Response / clwt nopct chisq
 plots=WtFreqPlot;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;
ods graphics off;

```

The NOSUMMARY option in the PROC SURVEYFREQ statement suppresses the “Data Summary” table. In the TABLES statement, the CLWT option requests confidence limits for the weighted frequencies (totals). The NOPCT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square goodness-of-fit test, and the PLOTS= option requests a weighted frequency plot. ODS Graphics must be enabled before producing plots.

Figure 90.3 shows the one-way table of Response, which includes confidence limits for the weighted frequencies. The 95% confidence limits for the total number of users that are ‘Very Unsatisfied’ are 5692 and 7665. To change the  $\alpha$  level of the confidence limits, which equals 5% by default, you can use the ALPHA= option. Like the other estimates and standard errors produced by PROC SURVEYFREQ, these confidence limit computations take into account the complex survey design and apply to the entire study population.

**Figure 90.3** Confidence Limits for Response Totals

| Student Information System Survey |           |                       |                        |                                       |       |
|-----------------------------------|-----------|-----------------------|------------------------|---------------------------------------|-------|
| The SURVEYFREQ Procedure          |           |                       |                        |                                       |       |
| Table of Response                 |           |                       |                        |                                       |       |

| Very Unsatisfied                  | 304       | 6678                  | 501.61039              | 5692                                  | 7665  |
| Unsatisfied                       | 326       | 6907                  | 495.94101              | 5932                                  | 7882  |
| Neutral                           | 581       | 12291                 | 617.20147              | 11077                                 | 13505 |
| Satisfied                         | 455       | 9309                  | 572.27868              | 8184                                  | 10435 |
| Very Satisfied                    | 184       | 3714                  | 370.66577              | 2985                                  | 4443  |
| Total                             | 1850      | 38900                 | 129.85268              | 38644                                 | 39155 |

Figure 90.4 displays the weighted frequency plot of Response. The plot displays weighted frequencies (totals) together with their confidence limits in the form of a vertical bar chart. You can use the PLOTS= option to request a dot plot instead of a bar chart or to plot percentages instead of weighted frequencies.

**Figure 90.4** Bar Chart of Response Totals

Figure 90.5 shows the chi-square goodness-of-fit results for the table of Response. The null hypothesis for this test is equal proportions for the levels of the one-way table. (To test a null hypothesis of specified proportions instead of equal proportions, you can use the TESTP= option to specify null hypothesis proportions.)

The chi-square test provided by the CHISQ option is the Rao-Scott design-adjusted chi-square test, which takes the sample design into account and provides inferences for the study population. To produce the Rao-Scott chi-square statistic, PROC SURVEYFREQ first computes the usual Pearson chi-square statistic based on the weighted frequencies, and then adjusts this value with a design correction. An  $F$  approximation is also provided. For the table of Response, the  $F$  value is 30.0972 with a  $p$ -value of  $<0.0001$ , which indicates rejection of the null hypothesis of equal proportions for all response levels.

**Figure 90.5** Chi-Square Goodness-of-Fit Test for Response

| Rao-Scott Chi-Square Test |          |
|---------------------------|----------|
| Pearson Chi-Square        | 251.8105 |
| Design Correction         | 2.0916   |
| Rao-Scott Chi-Square      | 120.3889 |
| DF                        | 4        |
| Pr > ChiSq                | <.0001   |
| F Value                   | 30.0972  |
| Num DF                    | 4        |
| Den DF                    | 1456     |
| Pr > F                    | <.0001   |
| Sample Size = 1850        |          |

Continuing to analyze the SIS\_Survey data, the following PROC SURVEYFREQ statements request a two-way table of SchoolType by Response:

```

title 'Student Information System Survey';
ods graphics on;
proc surveyfreq data=SIS_Survey nosummary;
 tables SchoolType * Response /
 plots=wtfreqplot (type=dot scale=percent groupby=row);
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;
ods graphics off;

```

The STRATA, CLUSTER, and WEIGHT statements do not change from the one-way table analysis, because the sample design and the input data set are the same. These SURVEYFREQ statements request a different table but specify the same sample design information.

The ODS GRAPHICS ON statement enables ODS Graphics. The PLOTS= option in the TABLES statement requests a plot of SchoolType by Response, and the TYPE=DOT *plot-option* specifies a dot plot instead of the default bar chart. The SCALE=PERCENT *plot-option* requests a plot of percentages instead of totals. The GROUPBY=ROW *plot-option* groups the graph cells by the row variable (SchoolType).

Figure 90.6 shows the two-way table produced for SchoolType by Response. The first variable named in the two-way table request, SchoolType, is referred to as the *row variable*, and the second variable, Response, is referred to as the *column variable*. Two-way tables display all column variable levels for each row variable level. This two-way table lists all levels of the column variable Response for each level of the row variable SchoolType, 'Middle School' and 'High School'. Also SchoolType = 'Total' shows the distribution of Response overall for both types of schools. And Response = 'Total' provides totals over all levels of response, for each type of school and overall. To suppress these totals, you can specify the NOTOTAL option.

**Figure 90.6** Two-Way Table of SchoolType by Response

| Student Information System Survey |                  |           |                       |                        |           |                       |

|                                   | Total            |           | 1850                  | 38900                  | 129.85268 | 100.000               |

Figure 90.7 displays the weighted frequency dot plot that PROC SURVEYFREQ produces for the table of SchoolType and Response. The GROUPBY=ROW *plot-option* groups the graph cells by the row variable (SchoolType). If you do not specify GROUPBY=ROW, the procedure groups the graph cells by the column variable by default. You can plot percentages instead of weighted frequencies by specifying the SCALE=PERCENT *plot-option*. You can use other *plot-options* to change the orientation of the plot or to request a different two-way layout.

**Figure 90.7** Dot Plot of Percentages for SchoolType by Response

By default, without any other TABLES statement options, a two-way table displays the frequency, the weighted frequency and its standard deviation, and the percentage and its standard error for each table cell (combination of row and column variable levels). But there are several options available to customize your table display by adding more information or by suppressing some of the default information.

The following PROC SURVEYFREQ statements request a two-way table of SchoolType by Response that displays row percentages, and also request a chi-square test of association between the two variables:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey nosummary;
 tables SchoolType * Response / row nowt chisq;
 strata State NewUser;
 cluster School;
 weight SamplingWeight;
run;

```

The ROW option in the TABLES statement requests row percentages, which give the distribution of Response within each level of the row variable SchoolType. The NOWT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square test of association between SchoolType and Response.

Figure 90.8 displays the two-way table of SchoolType by Response. For middle schools, it is estimated that 25.79% of school personnel are satisfied with the student information system and 12.39% are very satisfied. For high schools, these estimates are 22.67% and 7.61%, respectively.

Figure 90.9 displays the chi-square test results. The Rao-Scott chi-square statistic equals 9.04, and the corresponding  $F$  value is 2.26 with a  $p$ -value of 0.0605. This indicates an association between school type (middle school or high school) and satisfaction with the student information system at the 10% significance level.

## Syntax: SURVEYFREQ Procedure

The following statements are available in the SURVEYFREQ procedure:

```

PROC SURVEYFREQ < options > ;
 BY variables ;
 CLUSTER variables ;
 REPWEIGHTS variables < / options > ;
 STRATA variables < / option > ;
 TABLES requests < / options > ;
 WEIGHT variable ;

```

The PROC SURVEYFREQ statement invokes the procedure, identifies the data set to be analyzed, and specifies the variance estimation method to use. The PROC SURVEYFREQ statement is required.

The TABLES statement specifies frequency or crosstabulation tables and requests tests and statistics for those tables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The WEIGHT statement names the sampling weight variable. The REPWEIGHTS statement names replicate weight variables for BRR or jackknife variance estimation. The BY statement requests completely separate analyses of groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYFREQ statement and the WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLUSTER, REPWEIGHTS, STRATA, TABLES, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYFREQ statement.

## PROC SURVEYFREQ Statement

**PROC SURVEYFREQ** < options > ;

The PROC SURVEYFREQ statement invokes the SURVEYFREQ procedure. It also identifies the data set to be analyzed, specifies the variance estimation method to use, and provides sample design information. The **DATA=** option names the input data set to be analyzed. The **VARMETHOD=** option specifies the variance estimation method, which is the Taylor series method by default. For Taylor series variance estimation, you can include a finite population correction factor in the analysis by providing either the sampling rate or population total with the **RATE=** or **TOTAL=** option. If your design is stratified with different sampling rates or totals for different strata, you can input these stratum rates or totals in a SAS data set that contains the stratification variables.

Table 90.1 summarizes the options available in the PROC SURVEYFREQ statement.

**Table 90.1** PROC SURVEYFREQ Statement Options

| Option            | Description                                                      |
|-------------------|------------------------------------------------------------------|
| <b>DATA=</b>      | Names the input SAS data set                                     |
| <b>MISSING</b>    | Treats missing values as a valid level                           |
| <b>NOMCAR</b>     | Treats missing values as <i>not missing completely at random</i> |
| <b>NOSUMMARY</b>  | Suppresses the display of the “Data Summary” table               |
| <b>ORDER=</b>     | Specifies the order of variable levels                           |
| <b>PAGE</b>       | Displays only one table per page                                 |
| <b>RATE=</b>      | Specifies the first-stage sampling rate                          |
| <b>TOTAL=</b>     | Specifies the total number of primary sampling units             |
| <b>VARHEADER=</b> | Specifies the variable identification to display                 |
| <b>VARMETHOD=</b> | Specifies the variance estimation method                         |

You can specify the following *options* in the PROC SURVEYFREQ statement:

### **DATA=SAS-data-set**

names the SAS data set to be analyzed by PROC SURVEYFREQ. If you omit the **DATA=** option, the procedure uses the most recently created SAS data set.

### **MISSING**

treats missing values as a valid (nonmissing) category for all categorical variables, which include **TABLES**, **STRATA**, and **CLUSTER** variables.

By default, if you do not specify the **MISSING** option, an observation is excluded from the analysis if it has a missing value for any **STRATA** or **CLUSTER** variable. Additionally, PROC SURVEYFREQ excludes an observation from a frequency or crosstabulation table if that observation has a missing value for any of the variables in the table request, unless you specify the **MISSING** option. For more information, see the section “Missing Values” on page 7627.

### **NOMCAR**

includes observations with missing values of **TABLES** variables in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the **NOMCAR** option, PROC SURVEYFREQ computes variance estimates by analyzing the non-

missing values as a domain (subpopulation), where the entire population includes both nonmissing and missing domains. See the section “[Missing Values](#)” on page 7627 for details.

By default, PROC SURVEYFREQ completely excludes an observation from a frequency or crosstabulation table (and the corresponding variance computations) if that observation has a missing value for any of the variables in the table request, unless you specify the [MISSING](#) option. Note that the [NOMCAR](#) option has no effect when you specify the [MISSING](#) option, which treats missing values as a valid nonmissing level.

The [NOMCAR](#) option applies only to Taylor series variance estimation. The replication methods, which you request with the [VARMETHOD=BRR](#) and [VARMETHOD=JACKKNIFE](#) options, do not use the [NOMCAR](#) option.

### **NOSUMMARY**

suppresses the display of the “Data Summary” table, which PROC SURVEYFREQ produces by default. For details about this table, see the section “[Data Summary Table](#)” on page 7663.

### **ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the order of the variable levels in the frequency and crosstabulation tables, which you request in the [TABLES](#) statement. The [ORDER=](#) option also controls the order of the [STRATA](#) variable levels in the “Stratum Information” table.

The [ORDER=](#) option can take the following values:

| <b>ORDER=</b> | <b>Levels Ordered By</b>                                                                                                               |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------|
| DATA          | Order of appearance in the input data set                                                                                              |
| FORMATTED     | External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value |
| FREQ          | Descending frequency count; levels with the most observations come first in the order                                                  |
| INTERNAL      | Unformatted value                                                                                                                      |

By default, [ORDER=INTERNAL](#). The [FORMATTED](#) and [INTERNAL](#) orders are machine-dependent. Note that the frequency count used by [ORDER=FREQ](#) is the nonweighted frequency (sample size), rather than the weighted frequency.

For more information about sort order, see the chapter on the [SORT](#) procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

### **PAGE**

displays only one table per page. Otherwise, PROC SURVEYFREQ displays multiple tables per page as space permits.

**RATE=***value* | *SAS-data-set*

**R=***value* | *SAS-data-set*

specifies the sampling rate as a nonnegative *value*, or identifies an input data set that provides the stratum sampling rates in a variable named `_RATE_`. PROC SURVEYFREQ uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the [RATE=](#) option for [BRR](#) or jackknife variance estimation, which you request with the [VARMETHOD=BRR](#) or [VARMETHOD=JACKKNIFE](#) option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of primary sampling units (PSUs) that are selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the RATE= option. If your design is stratified with different sampling rates in different strata, then you should name a SAS data set that contains the stratification variables and the stratum sampling rates. See the section “Population Totals and Sampling Rates” on page 7626 for details.

The sampling rate *value* must be a nonnegative number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYFREQ converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you do not specify the RATE= or TOTAL= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option in the same PROC SURVEYFREQ statement.

**TOTAL=***value* | *SAS-data-set*

**N=***value* | *SAS-data-set*

specifies the total number of primary sampling units (PSUs) in the study population as a positive *value*, or identifies an input data set that provides the stratum population totals in a variable named `_TOTAL_`. PROC SURVEYFREQ uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the TOTAL= option for BRR or jackknife variance estimation, which you request with the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the TOTAL= option. If your sample design is stratified with different population totals in different strata, then you should name a SAS data set that contains the stratification variables and the stratum totals. See the section “Population Totals and Sampling Rates” on page 7626 for details.

If you do not specify the TOTAL= or RATE= option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the TOTAL= option and the RATE= option in the same PROC SURVEYFREQ statement.

**VARHEADER=**LABEL | NAME | NAMELABEL

specifies the variable identification to use in the displayed output. By default VARHEADER=NAME, which displays variable names in the output. The VARHEADER= option affects the headers of the variable level columns in one-way frequency tables, crosstabulation tables, and the “Stratum Information” table. The VARHEADER= option also controls variable identification in the table headers.

The VARHEADER= option can take the following values:

| <b>VARHEADER=</b> | <b>Variable Identification Displayed</b>        |
|-------------------|-------------------------------------------------|
| LABEL             | Variable label                                  |
| NAME              | Variable name                                   |
| NAMELABEL         | Variable name and label, as <i>Name (Label)</i> |

**VARMETHOD=BRR** <(method-options)>

**VARMETHOD=JACKKNIFE** | **JK** <(method-options)>

**VARMETHOD=TAYLOR**

specifies the variance estimation method. **VARMETHOD=TAYLOR** requests the Taylor series method, which is the default if you do not specify the **VARMETHOD=** option or the **REPWEIGHTS** statement. **VARMETHOD=BRR** requests variance estimation by balanced repeated replication (BRR), and **VARMETHOD=JACKKNIFE** requests variance estimation by the delete-1 jackknife method.

For **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE**, you can specify *method-options* in parentheses after the variance method name. [Table 90.2](#) summarizes the available *method-options*.

**Table 90.2** Variance Estimation Options

| <b>VARMETHOD=</b> | <b>Variance Estimation Method</b> | <b>Method Options</b>                                                                        |
|-------------------|-----------------------------------|----------------------------------------------------------------------------------------------|
| BRR               | Balanced repeated replication     | DFADJ<br>FAY<=value><br>HADAMARD=SAS-data-set<br>OUTWEIGHTS=SAS-data-set<br>PRINTH<br>REPS=n |
| JACKKNIFE         | Jackknife                         | DFADJ<br>OUTJKCOEFS=SAS-data-set<br>OUTWEIGHTS=SAS-data-set                                  |
| TAYLOR            | Taylor series linearization       | None                                                                                         |

*Method-options* must be enclosed in parentheses after the variance method name. For example:

```
varmethod=BRR(reps=60 outweights=myReplicateWeights)
```

The following values are available for the **VARMETHOD=** option:

**BRR** < *method-options* >

requests variance estimation by balanced repeated replication (BRR). The BRR method requires a stratified sample design with two primary sampling units (PSUs) in each stratum. If you specify the **VARMETHOD=BRR** option, you must also specify a **STRATA** statement unless you provide replicate weights with a **REPWEIGHTS** statement. See the section “Balanced Repeated Replication (BRR)” on page 7637 for details.

You can specify the following *method-options* in parentheses after **VARMETHOD=BRR**:

**DFADJ**

computes the degrees of freedom as the number of nonmissing strata for the individual table request. The degrees of freedom for **VARMETHOD=BRR** equal the number of strata, which by default is based on all valid observations in the data set. But if you specify the **DFADJ** *method-option*, PROC SURVEYFREQ does not count any empty strata that occur when observations with missing values of the **TABLES** variables are removed from the analysis of that table.

See the section “Degrees of Freedom” on page 7645 for more information. See the section “Data Summary Table” on page 7663 for details about valid observations.

The DFADJ *method-option* has no effect when you specify the MISSING option, which treats missing values as a valid nonmissing level. The DFADJ *method-option* is not used when you specify the degrees of freedom in the DF= option in the TABLES statement.

The DFADJ *method-option* cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you use a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS or TABLES statement.

#### FAY <=value>

requests Fay’s method, which is a modification of the BRR method. See the section “Fay’s BRR Method” on page 7638 for details.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

#### HADAMARD=SAS-data-set

##### H=SAS-data-set

names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, PROC SURVEYFREQ generates an appropriate Hadamard matrix for replicate construction. See the sections “Balanced Repeated Replication (BRR)” on page 7637 and “Hadamard Matrix” on page 7639 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD=SAS-data-set *method-option*.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or –1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is,  $\mathbf{A}'\mathbf{A} = \mathbf{R}\mathbf{I}$ , where  $\mathbf{A}$  is the Hadamard matrix of dimension  $R$  and  $\mathbf{I}$  is an identity matrix. PROC SURVEYFREQ does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least  $H$  variables, where  $H$  denotes the number of first-stage strata in your design. If the data set contains more than  $H$  variables, PROC SURVEYFREQ uses only the first  $H$  variables. Similarly, the HADAMARD= input data set must contain at least  $H$  observations.

If you do not specify the REPS= *method-option*, then the number of replicates is taken to be the number of observations in the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH *method-option* to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

**OUTWEIGHTS=SAS-data-set**

names a SAS data set to store the replicate weights that PROC SURVEYFREQ creates for BRR variance estimation. See the section “[Balanced Repeated Replication \(BRR\)](#)” on page 7637 for information about replicate weights. See the section “[Replicate Weight Output Data Set](#)” on page 7662 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with a [REPWEIGHTS](#) statement.

**PRINTH**

displays the Hadamard matrix used to construct replicates for BRR. When you provide the Hadamard matrix in the [HADAMARD= method-option](#), PROC SURVEYFREQ displays only the rows and columns that are actually used to construct replicates. See the sections “[Balanced Repeated Replication \(BRR\)](#)” on page 7637 and “[Hadamard Matrix](#)” on page 7639 for more information.

The PRINTH *method-option* is not available when you provide replicate weights with a [REPWEIGHTS](#) statement because the procedure does not use a Hadamard matrix in this case.

**REPS=*n***

specifies the number of replicates for BRR variance estimation. The value of *n* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the [HADAMARD= method-option](#), the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section “[Balanced Repeated Replication \(BRR\)](#)” on page 7637 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the [HADAMARD= method-option](#), the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= *method-option*, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or [HADAMARD= method-option](#) and do not include a [REPWEIGHTS](#) statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with a [REPWEIGHTS](#) statement, the procedure does not use the REPS= *method-option*. With a [REPWEIGHTS](#) statement, the number of replicates equals the number of [REPWEIGHTS](#) variables.

**JACKKNIFE | JK < method-options >**

requests variance estimation by the delete-1 jackknife method. See the section “[The Jackknife Method](#)” on page 7640 for details. If you provide replicate weights with a [REPWEIGHTS](#) statement, [VARMETHOD=JACKKNIFE](#) is the default variance estimation method.

The jackknife method requires at least two primary sampling units (PSUs) in each stratum for stratified designs unless you provide replicate weights with a [REPWEIGHTS](#) statement.

You can specify the following *method-options* in parentheses after VARMETHOD=JACKKNIFE:

#### DFADJ

computes the degrees of freedom by using the number of nonmissing strata and clusters for the individual table request. The degrees of freedom for VARMETHOD=JACKKNIFE equal the number of clusters minus the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ *method-option*, PROC SURVEYFREQ does not count any empty strata or clusters that occur when observations with missing values of the TABLES variables are removed from the analysis of that table.

See the section “Degrees of Freedom” on page 7645 for more information. See the section “Data Summary Table” on page 7663 for details about valid observations.

The DFADJ *method-option* has no effect when you specify the MISSING option, which treats missing values as a valid nonmissing level. The DFADJ *method-option* is not used when you specify the degrees of freedom in the DF= option in the TABLES statement.

The DFADJ *method-option* cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you include a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS or TABLES statement.

#### OUTJKCOEFS=SAS-data-set

names a SAS data set to store the jackknife coefficients. See the section “The Jackknife Method” on page 7640 for information about jackknife coefficients. See the section “Jackknife Coefficient Output Data Set” on page 7662 for details about the contents of the OUTJKCOEFS= data set.

#### OUTWEIGHTS=SAS-data-set

names a SAS data set to store the replicate weights that PROC SURVEYFREQ creates for jackknife variance estimation. See the section “The Jackknife Method” on page 7640 for information about replicate weights. See the section “Replicate Weight Output Data Set” on page 7662 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with a REPWEIGHTS statement.

#### TAYLOR

requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option or a REPWEIGHTS statement. See the section “Taylor Series Variance Estimation” on page 7630 for details.

---

## BY Statement

**BY** *variables* ;

You can specify a BY statement with PROC SURVEYFREQ to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the SURVEYFREQ procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid domain (subpopulation) analysis, where the total number of units in the subpopulation is not known with certainty. You should include the domain variable(s) in your TABLES request to obtain domain analysis. See the section “[Domain Analysis](#)” on page 7626 for more details.

For more information about BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the discussion in the *Base SAS Procedures Guide*.

---

## CLUSTER Statement

**CLUSTER** *variables* ;

The CLUSTER statement names variables that identify the first-stage clusters in a clustered sample design. First-stage clusters are also known as primary sampling units (PSUs). The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters (PSUs) in the CLUSTER statement. See the section “[Specifying the Sample Design](#)” on page 7624 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

The CLUSTER variables are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*.

An observation is excluded from the analysis if it has a missing value for any CLUSTER variable unless you specify the MISSING option in the PROC SURVEYFREQ statement. See the section “[Missing Values](#)” on page 7627 for more information.

You can use multiple CLUSTER statements to specify CLUSTER variables. The procedure uses variables from all CLUSTER statements to create clusters.

## REPWEIGHTS Statement

**REPWEIGHTS** *variables* </ options > ;

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option in the PROC SURVEYFREQ statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then PROC SURVEYFREQ constructs replicate weights for the analysis. See the sections “Balanced Repeated Replication (BRR)” on page 7637 and “The Jackknife Method” on page 7640 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a **CLUSTER** or **STRATA** statement. If you use a REPWEIGHTS statement and do not specify the **VARMETHOD=** option in the PROC SURVEYFREQ statement, the procedure uses **VARMETHOD=JACKKNIFE** by default.

If you specify a REPWEIGHTS statement but do not include a **WEIGHT** statement, PROC SURVEYFREQ uses the average of each observation’s replicate weights as the observation’s weight.

You can specify the following *options* in the REPWEIGHTS statement after a slash (/):

### **DF=***df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables. See the section “Degrees of Freedom” on page 7645 for details.

PROC SURVEYFREQ uses the DF= value in computing confidence limits for proportions, totals, and other statistics. See the section “Confidence Limits for Proportions” on page 7642 for details. PROC SURVEYFREQ also uses the DF= value in computing the denominator degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. See the sections “Rao-Scott Chi-Square Test” on page 7652, “Rao-Scott Likelihood Ratio Chi-Square Test” on page 7657, “Wald Chi-Square Test” on page 7659, and “Wald Log-Linear Chi-Square Test” on page 7660 for more information.

### **JKCOEFS=***value*

specifies the jackknife coefficient for **VARMETHOD=JACKKNIFE**. The coefficient *value* must be a nonnegative number. See the section “The Jackknife Method” on page 7640 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the **JKCOEFS=(values)** or **JKCOEFS=SAS-data-set** option.

### **JKCOEFS=**< (>*values*< )>

specifies jackknife coefficients for **VARMETHOD=JACKKNIFE**, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section “The Jackknife Method” on page 7640 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the `JKCOEFS=SAS-data-set` option. To specify a single jackknife coefficient for all replicates, use the `JKCOEFS=value` option.

#### **JKCOEFS=SAS-data-set**

names a SAS data set that contains the jackknife coefficients for `VARMETHOD=JACKKNIFE`. You provide the jackknife coefficients in the `JKCOEFS=` data set variable `JKCoefficient`. Each coefficient value must be a nonnegative number. The coefficients should correspond to the replicates that are identified by the `REPWEIGHTS` variables. Provide the coefficients as observations in the `JKCOEFS=` data set and order them to match the order in which you list the corresponding replicate weight variables in the `REPWEIGHTS` statement. The number of observations in the `JKCOEFS=` data set must not be less than the number of `REPWEIGHTS` variables.

See the section “[The Jackknife Method](#)” on page 7640 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the `JKCOEFS=values` option. To specify a single jackknife coefficient for all replicates, use the `JKCOEFS=value` option.

## **STRATA Statement**

**STRATA** *variables* *</ option >* ;

The `STRATA` statement names variables that identify the first-stage strata in a stratified sample design. The combinations of levels of `STRATA` variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently.

If your sample design has stratification at multiple stages, you should specify only the first-stage strata in the `STRATA` statement. See the section “[Specifying the Sample Design](#)” on page 7624 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with a `REPWEIGHTS` statement, you do not need to specify a `STRATA` statement.

The `STRATA` variables are one or more variables in the `DATA=` input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the `STRATA` variables determine the `STRATA` variable levels. Thus, you can use formats to group values into levels. See the discussion of the `FORMAT` procedure in the *Base SAS Procedures Guide* and the discussions of the `FORMAT` statement and SAS formats in *SAS Formats and Informats: Reference*.

Note that an observation is excluded from the analysis if it has a missing value for any `STRATA` variable unless you specify the `MISSING` option in the `PROC SURVEYFREQ` statement. See the section “[Missing Values](#)” on page 7627 for more information.

You can use multiple `STRATA` statements to specify `STRATA` variables. The procedure uses variables from all `STRATA` statements to define strata.

You can specify the following *option* in the `STRATA` statement after a slash (/):

#### **LIST**

displays the “Stratum Information” table, which lists all strata together with the corresponding values of the `STRATA` variables. This table provides the number of observations and the number of clusters in each stratum, as well as the sampling fraction if you specify the `RATE=` or `TOTAL=` option in the `PROC SURVEYFREQ` statement. See the section “[Stratum Information Table](#)” on page 7663 for more information.

## TABLES Statement

**TABLES** *requests* *</ options >* ;

The TABLES statement requests one-way to  $n$ -way frequency and crosstabulation tables and statistics for these tables.

If you omit the TABLES statement, PROC SURVEYFREQ generates one-way frequency tables for all **DATA=** data set variables that are not listed in the other statements.

The following argument is required in the TABLES statement:

### *requests*

specify the frequency and crosstabulation tables to produce. A *request* is composed of one variable name or several variable names separated by asterisks. To request a one-way frequency table, use a single variable. To request a two-way crosstabulation table, use an asterisk between two variables. To request a multiway table (an  $n$ -way table, where  $n > 2$ ), separate the desired variables with asterisks. The unique values of these variables form the rows, columns, and layers of the table.

For two-way tables to multiway tables, the values of the last variable form the crosstabulation table columns, while the values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate crosstabulation table for each layer. For example, a specification of  $A*B*C*D$  in a TABLES statement produces  $k$  tables, where  $k$  is the number of different combinations of levels for A and B. Each table lists the levels for D (columns) within each level of C (rows).

You can use multiple TABLES statements in a single PROC SURVEYFREQ step. You can also specify any number of table requests in a single TABLES statement. To specify multiple table requests quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. Table 90.3 shows some examples of grouping syntax.

**Table 90.3** Grouping Syntax

| TABLES Request  | Equivalent to        |
|-----------------|----------------------|
| $A*(B\ C)$      | $A*B\ A*C$           |
| $(A\ B)*(C\ D)$ | $A*C\ B*C\ A*D\ B*D$ |
| $(A\ B\ C)*D$   | $A*D\ B*D\ C*D$      |
| $A\ --\ C$      | $A\ B\ C$            |
| $(A\ --\ C)*D$  | $A*D\ B*D\ C*D$      |

The TABLES statement variables are one or more variables from the **DATA=** input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. PROC SURVEYFREQ uses the formatted values of the TABLES variable to determine the categorical variable levels. So if you assign a format to a variable with a FORMAT statement, PROC SURVEYFREQ formats the values before dividing observations into the levels of a frequency or crosstabulation table. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Formats and Informats: Reference*.

By default, the frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values. You can change the order of the values in the table by specifying the **ORDER=** option in the **PROC SURVEYFREQ** statement. To list the values in ascending order by formatted value, use **ORDER=FORMATTED**.

## Without Options

If you request a frequency or crosstabulation table without specifying options, **PROC SURVEYFREQ** produces the following for each table level or cell:

- frequency (sample size)
- weighted frequency, which estimates the population total
- standard deviation of the weighted frequency
- percentage, which estimates the population proportion
- standard error of the percentage

The table displays weighted frequencies if your analysis includes a **WEIGHT** statement, or if you specify the **WTFREQ** option in the **TABLES** statement. The table also displays the number of observations with missing values. See the sections “**One-Way Frequency Tables**” on page 7664 and “**Crosstabulation Tables**” on page 7665 for more information.

## Options

Table 90.4 summarizes the *options* available in the **TABLES** statement. Descriptions of the *options* follow the table in alphabetical order.

**Table 90.4** TABLES Statement Options

| Option                              | Description                                            |
|-------------------------------------|--------------------------------------------------------|
| <b>Control Statistical Analysis</b> |                                                        |
| ALPHA=                              | Sets the level for confidence limits                   |
| CHISQ                               | Requests Rao-Scott chi-square test                     |
| DF=                                 | Specifies degrees of freedom                           |
| LRCHISQ                             | Requests Rao-Scott likelihood ratio test               |
| OR                                  | Requests odds ratio and relative risks                 |
| RISK                                | Requests risks and risk difference                     |
| TESTP=                              | Specifies null proportions for one-way chi-square test |
| WCHISQ                              | Requests Wald chi-square test                          |
| WLLCHISQ                            | Requests Wald log-linear chi-square test               |

Table 90.4 continued

| Option                                      | Description                                                                                    |
|---------------------------------------------|------------------------------------------------------------------------------------------------|
| <b>Request Additional Table Information</b> |                                                                                                |
| CL                                          | Displays confidence limits for percentages and specifies confidence limit type for percentages |
| CLWT                                        | Displays confidence limits for weighted frequencies                                            |
| COLUMN                                      | Displays column percentages and standard errors                                                |
| CV                                          | Displays coefficients of variation for percentages                                             |
| CVWT                                        | Displays coefficients of variation for weighted frequencies                                    |
| DEFF                                        | Displays design effects for percentages                                                        |
| EXPECTED                                    | Displays expected weighted frequencies (two-way tables)                                        |
| ROW                                         | Displays row percentages and standard errors                                                   |
| VAR                                         | Displays variances for percentages                                                             |
| VARWT                                       | Displays variances for weighted frequencies                                                    |
| WTFREQ                                      | Displays totals and standard errors when there is no WEIGHT statement                          |
| <b>Control Displayed Output</b>             |                                                                                                |
| NOCELLPERCENT                               | Suppresses display of overall percentages                                                      |
| NOFREQ                                      | Suppresses display of frequency counts                                                         |
| NOPERCENT                                   | Suppresses display of all percentages                                                          |
| NOPRINT                                     | Suppresses display of tables but displays statistical tests                                    |
| NOSPARE                                     | Suppresses display of zero rows and columns                                                    |
| NOSTD                                       | Suppresses display of standard errors for all estimates                                        |
| NOTOTAL                                     | Suppresses display of row and column totals                                                    |
| NOWT                                        | Suppresses display of weighted frequencies                                                     |
| <b>Produce Statistical Graphics</b>         |                                                                                                |
| PLOTS=                                      | Requests plots from ODS Graphics                                                               |

You can specify the following *options* in a TABLES statement:

**ALPHA= $\alpha$** 

sets the level for confidence limits. The value of  $\alpha$  must be between 0 and 1, and the default is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

You request confidence limits for percentages with the CL option, and you request confidence limits for weighted frequencies with the CLWT option. See the sections “Confidence Limits for Proportions” on page 7642 and “Confidence Limits for Totals” on page 7642 for more information.

The ALPHA= option also applies to confidence limits for the risks and risk difference, which you request with the RISK option, and to confidence limits for the odds ratio and relative risks, which you request with the OR option. See the sections “Risks and Risk Difference” on page 7648 and “Odds Ratio and Relative Risks” on page 7650 for details.

**CHISQ <(options)>**

requests the Rao-Scott chi-square test. This is a design-adjusted test that is computed by applying a design correction to the weighted Pearson chi-square statistic. By default, PROC SURVEYFREQ provides a first-order Rao-Scott chi-square test. If you specify CHISQ(SECONDORDER), the pro-

cedure provides a second-order (Satterthwaite) Rao-Scott chi-square test. See the section “[Rao-Scott Chi-Square Test](#)” on page 7652 for details.

For one-way tables, the CHISQ option produces a design-based goodness-of-fit test. By default, this is a goodness-of-fit test for equal proportions. If you specify the null hypothesis proportions in the `TESTP=` option, the CHISQ option produces a chi-square goodness-of-fit test for the specified proportions.

By default for one-way tables, and for first-order tests for two-way tables, the design correction is computed from proportion estimates. If you specify `CHISQ(MODIFIED)`, the design correction is computed from null hypothesis proportions. For second-order tests for two-way tables, the design correction is always computed from null hypothesis proportions.

You can specify the following *options* in parentheses after the CHISQ option:

#### **FIRSTORDER**

requests a first-order Rao-Scott chi-square test. This is the default for the CHISQ option; if you do not specify `CHISQ(SECONDORDER)`, the procedure provides a first-order Rao-Scott test.

#### **MODIFIED**

uses the null hypothesis proportions to compute the Rao-Scott design correction. By default (if you do not specify `CHISQ(MODIFIED)`), the procedure uses proportion estimates to compute the design correction for all first-order tests and for second-order tests for one-way tables. For second-order tests for two-way tables, the procedure always uses null hypothesis proportions to compute the design correction.

#### **SECONDORDER**

requests a second-order (Satterthwaite) Rao-Scott chi-square test. See the section “[Rao-Scott Chi-Square Test](#)” on page 7652 for details.

#### **CL** <(options)>

requests confidence limits for the percentages (proportions) in the crosstabulation table. By default, PROC SURVEYFREQ computes standard Wald (“linear”) confidence limits for proportions by using the variance estimates that are based on the sample design. See the section “[Confidence Limits for Proportions](#)” on page 7642 for more information. The procedure determines the confidence coefficient from the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

You can specify *options* in parentheses after the CL option to control the confidence limit computations. You can use the `TYPE=` option to request an alternative confidence limit type. In addition to Wald confidence limits, the following types of design-based confidence limits are available for proportions: modified Clopper-Pearson (exact), modified Wilson (score), and logit confidence limits.

If you specify the `PSMALL` option, PROC SURVEYFREQ uses the alternative confidence limit type for extreme (small or large) proportion estimates and uses Wald confidence limits for all other proportion estimates. If you do not specify the `PSMALL` option, PROC SURVEYFREQ computes the specified confidence limit type for all proportion values.

You can specify the following *options* in parentheses after the CL option:

#### **ADJUST=NO | YES**

controls the degrees-of-freedom adjustment to the effective sample size for the modified Clopper-Pearson and Wilson confidence limits. By default, `ADJUST=YES`. If you specify `ADJUST=NO`, the confidence limit computations do not apply the degrees-of-freedom adjustment to the effective sample size. See the section “[Modified Confidence Limits](#)” on page 7643 for details.

The ADJUST= option is available for **TYPE=CLOPPERPEARSON** and **TYPE=WILSON** confidence limits.

#### **PSMALL <=p>**

uses the alternative confidence limit type that you specify with the TYPE= option for extreme (small or large) proportion values.

The PSMALL value  $p$  defines the range of extreme proportion values, where those proportions less than or equal to  $p$  or greater than or equal to  $(1 - p)$  are considered to be extreme, and those proportions between  $p$  and  $(1 - p)$  are not extreme. If you do not specify a PSMALL value  $p$ , PROC SURVEYFREQ uses  $p = 0.25$  by default. For  $p = 0.25$ , the procedure computes Wald confidence limits for proportions between 0.25 and 0.75 and computes the alternative confidence limit type for proportions less than or equal to 0.25 or greater than or equal to 0.75.

The PSMALL value  $p$  must be a nonnegative number. You can specify  $p$  as a proportion between 0 and 0.5. Or you can specify  $p$  in percentage form as a number between 1 and 50, and PROC SURVEYFREQ converts that number to a proportion. The procedure treats the value 1 as the percentage form 1%.

The PSMALL option is available for **TYPE=CLOPPERPEARSON**, **TYPE=LOGIT**, and **TYPE=WILSON** confidence limits. See the section “Confidence Limits for Proportions” on page 7642 for details.

#### **TRUNCATE=NO | YES**

controls the truncation of the effective sample size for the modified Clopper-Pearson and Wilson confidence limits. By default, TRUNCATE=YES truncates the effective sample size if it is larger than the original sample size. If you specify TRUNCATE=NO, the effective sample size is not truncated. See the section “Modified Confidence Limits” on page 7643 for details.

The TRUNCATE= option is available for **TYPE=CLOPPERPEARSON** and **TYPE=WILSON** confidence limits.

#### **TYPE=name**

specifies the type of confidence limits to compute for proportions. If you do not specify the TYPE= option, PROC SURVEYFREQ computes Wald confidence limits (TYPE=WALD) by default.

If you specify the **CL(PSMALL)** option, the procedure uses the specified confidence limit type for extreme proportions (outside the PSMALL range) and uses Wald confidence limits for proportions that are not outside the range. If you do not specify the **CL(PSMALL)** option, the procedure uses the specified confidence limit type for all proportions.

The following *names* are available for the TYPE= option:

#### **CLOPPERPEARSON | CP**

requests modified Clopper-Pearson (exact) confidence limits for proportions. See the section “Modified Clopper-Pearson Confidence Limits” on page 7644 for details.

#### **LOGIT**

requests logit confidence limits for proportions. See the section “Logit Confidence Limits” on page 7645 for details.

**WALD**

requests standard Wald (“linear”) confidence limits for proportions. This is the default confidence limit type if you do not specify the TYPE= option. See the section “[Wald Confidence Limits](#)” on page 7643 for details.

**WILSON | SCORE**

requests modified Wilson (score) confidence limits for proportions. See the section “[Modified Wilson Confidence Limits](#)” on page 7644 for details.

**CLWT**

requests confidence limits for the weighted frequencies (totals) in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits. See the section “[Confidence Limits for Totals](#)” on page 7642 for more information.

**COLUMN <(option)>**

displays the column percentage (estimated proportion of the column total) for each cell in a two-way table. The COLUMN option also provides the standard errors of the column percentages. See the section “[Row and Column Proportions](#)” on page 7635 for more information. This option has no effect for one-way tables.

You can specify the following *option* in parentheses after the COLUMN option:

**DEFF**

displays the design effect for each column percentage in the crosstabulation table. See the section “[Design Effect](#)” on page 7646 for more information.

**CV**

displays the coefficient of variation for each percentage (proportion) estimate in the crosstabulation table. See the section “[Coefficient of Variation](#)” on page 7646 for more information.

**CVWT**

displays the coefficient of variation for each weighted frequency (estimated total), in the crosstabulation table. See the section “[Coefficient of Variation](#)” on page 7646 for more information.

**DEFF**

displays the design effect for each overall percentage (proportion) estimate in the crosstabulation table. See the section “[Design Effect](#)” on page 7646 for more information.

To request design effects for row or column percentages, specify the DEFF option in parentheses after the ROW or COLUMN option.

**DF=*df***

specifies the degrees of freedom for the analysis. The value of *df* must be a nonnegative number. By default, PROC SURVEYFREQ computes the degrees of freedom as described in the section “[Degrees of Freedom](#)” on page 7645.

PROC SURVEYFREQ uses the DF= value in computing confidence limits for proportions, totals, and other statistics. See the section “[Confidence Limits for Proportions](#)” on page 7642 for details. PROC SURVEYFREQ also uses the DF= value in computing the denominator degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. See the sections “[Rao-Scott Chi-Square Test](#)” on page 7652, “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7657, “[Wald Chi-Square Test](#)” on page 7659, and “[Wald Log-Linear Chi-Square Test](#)” on page 7660 for more information.

**EXPECTED**

displays expected weighted frequencies (totals) for the table cells in a two-way table. The expected weighted frequencies are computed under the null hypothesis that the row and column variables are independent. See the section “[Expected Weighted Frequency](#)” on page 7647 for more information. This option has no effect for one-way tables.

**LRCHISQ <(options)>**

requests the Rao-Scott likelihood ratio chi-square test. This is a design-adjusted test that is computed by applying a design correction to the weighted likelihood ratio chi-square statistic. By default, PROC SURVEYFREQ provides a first-order Rao-Scott likelihood ratio test. If you specify [LRCHISQ\(SECONDORDER\)](#), the procedure provides a second-order (Satterthwaite) Rao-Scott likelihood ratio test. See the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7657 for details.

For one-way tables, the LRCHISQ option produces a design-based likelihood ratio goodness-of-fit test. By default, the null hypothesis is equal proportions. If you specify null hypothesis proportions in the [TESTP=](#) option, the LRCHISQ option produces a design-based likelihood ratio test for the specified proportions.

By default for one-way tables, and for first-order tests for two-way tables, the design correction is computed from proportion estimates. If you specify [LRCHISQ\(MODIFIED\)](#), the design correction is computed from null hypothesis proportions. For second-order tests for two-way tables, the design correction is always computed from null hypothesis proportions.

You can specify the following *options* in parentheses after the LRCHISQ option:

**FIRSTORDER**

requests a first-order Rao-Scott likelihood ratio test. This is the default for the LRCHISQ option; if you do not specify [LRCHISQ\(SECONDORDER\)](#), the procedure provides a first-order Rao-Scott test.

**MODIFIED**

uses the null hypothesis proportions to compute the Rao-Scott design correction. By default (if you do not specify [LRCHISQ\(MODIFIED\)](#)), the procedure uses proportion estimates to compute the design correction for all first-order tests and for second-order tests for one-way tables. For second-order tests for two-way tables, the procedure always uses null hypothesis proportions to compute the design correction.

**SECONDORDER**

requests a second-order (Satterthwaite) Rao-Scott likelihood ratio test. See the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7657 for details.

**NOCELLPERCENT**

suppresses the display of overall cell percentages in the crosstabulation table, as well as the standard errors of the percentages. The NOCELLPERCENT option does not suppress the display of row or column percentages, which you request with the [ROW](#) or [COLUMN](#) option.

**NOFREQ**

suppresses the display of cell frequencies in the crosstabulation table. The NOFREQ option also suppresses the display of row, column, and overall table frequencies.

**NOPERCENT**

suppresses the display of all percentages in the crosstabulation table. The NOPERCENT option also suppresses the display of standard errors of the percentages. Use the **NOCELLPERCENT** option to suppress display of overall cell percentages but allow display of row or column percentages.

**NOPRINT**

suppresses the display of frequency and crosstabulation tables but displays all requested statistical tests. Note that this option disables the Output Delivery System (ODS) for the suppressed tables. For more information, see Chapter 20, “Using the Output Delivery System.”

**NOSPARSE**

suppresses the display of variable levels with zero frequency in two-way tables. By default, the procedure displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row variable levels with zero frequency for the layer.

**NOSTD**

suppresses the display of all standard errors in the crosstabulation table.

**NOTOTAL**

suppresses the display of row totals, column totals, and overall totals in the crosstabulation table.

**NOWT**

suppresses the display of weighted frequencies in the crosstabulation table. The NOWT option also suppresses the display of standard errors of the weighted frequencies.

**OR | RELRISK**

requests estimates of the odds ratio, the column 1 relative risk, and the column 2 relative risk for  $2 \times 2$  tables. The OR option also provides confidence limits for these statistics. See the section “Odds Ratio and Relative Risks” on page 7650 for details.

To compute confidence limits for the odds ratio and relative risks, PROC SURVEYFREQ determines the confidence coefficient from the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits.

**PLOTS** <(global-plot-options)> <=plot-request <(plot-options)>>

**PLOTS** <(global-plot-options)>

<=(plot-request <(plot-options)> <...plot-request <(plot-options)>>>

controls the plots that are produced through ODS Graphics. *Plot-requests* identify the plots, and *plot-options* control the appearance and content of the plots. You can specify *plot-options* in parentheses after a *plot-request*. A *global-plot-option* applies to all plots for which it is available unless it is altered by a specific *plot-option*. You can specify *global-plot-options* in parentheses after the PLOTS option.

When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. For example:

```
plots=all
plots=wtfreqplot
plots=(wtfreqplot oddsratioplot)
plots(only)=(riskdiffplot relriskplot)
```

ODS Graphics must be enabled before plots can be requested. For example:

```
ods graphics on;
proc surveyfreq;
 tables treatment*response / chisq plots=wtfreqplot;
 weight wt;
run;
ods graphics off;
```

For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” on page 600 in Chapter 21, “Statistical Graphics Using ODS.”

If ODS Graphics is enabled but you do not specify the PLOTS= option, PROC SURVEYFREQ produces all plots that are associated with the analyses that you request with the exception of weighted frequency plots and mosaic plots. To produce a weighted frequency plot or mosaic plot when ODS Graphics is enabled, you must specify the **WTFREQPLOT** or **MOSAICPLOT** *plot-request*, respectively, in the PLOTS= option, or you must specify the **PLOTS=ALL** option. PROC SURVEYFREQ produces the remaining plots (listed in Table 90.5) by default when you request the corresponding TABLES statement options. You can suppress default plots and request specific plots by using the **PLOTS(ONLY)=** option; **PLOTS(ONLY)=(*plot-requests*)** produces only the plots that are specified as *plot-requests*. You can suppress all plots by specifying the **PLOTS=NONE** option.

See Figure 90.4 and Figure 90.7 for examples of plots that PROC SURVEYFREQ produces. For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS.”

### Plot Requests

Table 90.5 lists the available *plot-requests* together with their required TABLES statement options. Descriptions of the *plot-requests* follow the table in alphabetical order.

**Table 90.5** Plot Requests

| Plot Request         | Description             | Required TABLES Statement Option                                            |
|----------------------|-------------------------|-----------------------------------------------------------------------------|
| <b>ALL</b>           | All plots               | None                                                                        |
| <b>MOSAICPLOT</b>    | Mosaic plot             | Crosstabulation table request                                               |
| <b>NONE</b>          | No plots                | None                                                                        |
| <b>ODDSRATIOPLOT</b> | Odds ratio plot         | <b>OR</b> ( $h \times 2 \times 2$ table)                                    |
| <b>RELRIKSPLOT</b>   | Relative risk plot      | <b>OR</b> ( $h \times 2 \times 2$ table)                                    |
| <b>RISKDIFFPLOT</b>  | Risk difference plot    | <b>RISK</b> , <b>RISK1</b> , or <b>RISK2</b> ( $h \times 2 \times 2$ table) |
| <b>WTFREQPLOT</b>    | Weighted frequency plot | Frequency or crosstabulation table request                                  |

The following *plot-requests* are available with the PLOTS= option:

#### **ALL**

requests all plots that are associated with the specified analyses. If you specify the PLOTS=ALL option, PROC SURVEYFREQ produces the weighted frequency and mosaic plots that are associated with the tables that you request. (PROC SURVEYFREQ does not produce weighted frequency and mosaic plots by default when ODS Graphics is enabled.)

**MOSAICPLOT** <(plot-option)>

requests a mosaic plot. Mosaic plots are available for crosstabulation tables. For multiway tables, PROC SURVEYFREQ provides a mosaic plot for each two-way table layer.

To produce a mosaic plot, you must specify the MOSAICPLOT *plot-request* in the PLOTS= option, or you must specify the PLOTS=ALL option. PROC SURVEYFREQ does not produce mosaic plots by default when ODS Graphics is enabled.

Mosaic plots display tiles that correspond to the crosstabulation table cells. The areas of the tiles are proportional to the weighted frequencies of the table cells. The column variable is displayed on the X axis, and the tile widths are proportional to the relative weighted frequencies of the column variable levels. The row variable is displayed on the Y axis, and the tile heights are proportional to the relative weighted frequencies of the row levels within column levels. The colors of the tiles correspond to the row variable levels. See Friendly (2000) for more information.

You can specify the following *plot-option* in parentheses after the MOSAICPLOT *plot-request*:

**SQUARE**

produces a square mosaic plot, where the height of the Y axis equals the width of the X axis. In a square mosaic plot, the scale of the relative weighted frequencies is the same on both axes. By default, PROC SURVEYFREQ produces a rectangular mosaic plot.

**NONE**

suppresses all plots.

**ODDSRATIOPLOT** <(plot-options)>

requests a plot of odds ratios with confidence limits. Odds ratio plots are available for multiway  $2 \times 2$  tables and display the odds ratio (with confidence limits) for each  $2 \times 2$  table layer. To produce an odds ratio plot, you must also specify the OR option in the TABLES statement for a multiway  $2 \times 2$  table.

Table 90.6 lists the *plot-options* that are available for odds ratio plots. See the subsection “Plot Options for ODDSRATIOPLOT, RELRISKPLOT, and RISKDIFFPLOT” for descriptions of the *plot-options*.

**Table 90.6** Plot Options for ODDSRATIOPLOT, RELRISKPLOT, and RISKDIFFPLOT

| Plot Option | Description             | Values                  |
|-------------|-------------------------|-------------------------|
| CLDISPLAY=  | Error bar type          | SERIF*, LINE, or BAR    |
| COLUMN=**   | Risk column             | 1* or 2                 |
| LOGBASE=*** | Axis scale              | 2, E, or 10             |
| NPANELPOS=  | Statistics per graphic  | Number (All*)           |
| ORDER=      | Order of two-way levels | ASCENDING or DESCENDING |
| RANGE=      | Range to display        | Values or CLIP          |
| STATS       | Displays statistics     | None                    |

\*Default

\*\* Available for RELRISKPLOT and RISKDIFFPLOT

\*\*\* Available for ODDSRATIOPLOT and RELRISKPLOT

**RELRIKSPLOT** <(plot-options)>

requests a plot of relative risks with confidence limits. Relative risk plots are available for multiway  $2 \times 2$  tables and display the relative risk (with confidence limits) for each  $2 \times 2$  table layer. To produce a relative risk plot, you must also specify the **OR** option in the TABLES statement for a multiway  $2 \times 2$  table.

Table 90.6 lists the *plot-options* that are available for relative risk plots. See the subsection “Plot Options for ODDSRATIO PLOT, RELRIKSPLOT, and RISKDIFF PLOT” for descriptions of the *plot-options*.

**RISKDIFFPLOT** <(plot-options)>

requests a plot of risk differences with confidence limits. Risk difference plots are available for multiway  $2 \times 2$  tables and display the risk difference (with confidence limits) for each  $2 \times 2$  table layer. To produce a risk difference plot, you must also specify the **RISK**, **RISK1**, or **RISK2** option in the TABLES statement for a multiway  $2 \times 2$  table.

Table 90.6 lists the *plot-options* that are available for risk difference plots. See the subsection “Plot Options for ODDSRATIO PLOT, RELRIKSPLOT, and RISKDIFF PLOT” for descriptions of the *plot-options*.

**WTFREQPLOT** <(plot-options)>

requests a weighted frequency plot. Weighted frequency plots are available for frequency and crosstabulation tables. For multiway tables, PROC SURVEYFREQ provides a two-way weighted frequency plot for each two-way table layer.

To produce a weighted frequency plot, you must specify the WTFREQPLOT *plot-request* in the PLOTS= option, or you must specify the **PLOTS=ALL** option. PROC SURVEYFREQ does not produce weighted frequency plots by default when ODS Graphics is enabled.

By default, PROC SURVEYFREQ displays weighted frequency plots as bar charts. You can specify the **TYPE=DOTPLOT** *plot-option* to display frequency plots as dot plots. You can plot weighted percentages instead of frequencies by specifying the **SCALE=PERCENT** *plot-option*. There are four frequency plot layouts available, which you can request by specifying the **TWOWAY=** *plot-option*. See the subsection “Plot Options for WTFREQPLOT” for more information.

By default, the primary grouping of graph cells in a two-way layout is by column variable. Row variable levels are then displayed within column variable levels. You can specify the **GROUPBY=ROW** *plot-option* to group first by row variable.

Weighted frequency plots for one-way tables display confidence limits by default. For two-way tables, weighted frequency plots display confidence limits by default in the **TWOWAY=GROUPVERTICAL** and **TWOWAY=GROUPHORIZONTAL** layouts. You can suppress confidence limits by specifying the **CLBAR=NO** *plot-option*. Confidence limits are not available for two-way plots in the **TWOWAY=CLUSTER** and **TWOWAY=STACKED** layouts.

Table 90.7 lists the *plot-options* that are available for weighted frequency plots. See the subsection “Plot Options for WTFREQPLOT” for descriptions of the *plot-options*.

**Table 90.7** Plot Options for WTFREQPLOT

| Plot Option  | Description           | Values                                                |
|--------------|-----------------------|-------------------------------------------------------|
| CLBAR=       | Confidence limit bars | YES* or NO                                            |
| GROUPBY=**   | Primary group         | COLUMN* or ROW                                        |
| NPANELPOS=** | Sections per panel    | Number (4*)                                           |
| ORIENT=      | Orientation           | VERTICAL* or HORIZONTAL                               |
| SCALE=       | Scale                 | WTFREQ* or PERCENT                                    |
| TWOWAY=**    | Two-way layout        | CLUSTER, GROUPTHORIZONTAL, GROUPVERTICAL*, or STACKED |
| TYPE=        | Type                  | BARCHART* or DOTPLOT                                  |

\*Default

\*\*For two-way tables

### Global Plot Options

A *global-plot-option* applies to all plots for which the option is available unless it is altered by an individual *plot-option*. All *plot-options* that are listed in Table 90.7 and Table 90.6 are available as *global-plot-options*. The **ONLY** option is also available as a *global-plot-option*.

You can specify *global-plot-options* in parentheses after the PLOTS option. For example:

```
plots(order=ascending stats)=(riskdiffplot oddsratioplot)
plots(only)=wtfreqplot
```

In addition to the *plot-options* that are listed in Table 90.7 and Table 90.6, you can specify the following *global-plot-option* in parentheses after the PLOTS option:

#### **ONLY**

suppresses the default plots and requests only the plots that are specified as *plot-requests*.

### Plot Options for ODDSATIOPLOTT, RELRISKPLOTT, and RISKDIFFPLOTT

You can specify the following *plot-options* in parentheses after the **ODDSATIOPLOTT**, **RELRISKPLOTT**, or **RISKDIFFPLOTT** *plot-request*:

#### **CLDISPLAY=SERIF | LINE | BAR < width >**

controls the appearance of the confidence limit error bars. The default value is **CLDISPLAY=SERIF**, which displays the confidence limits as lines with serifs. **CLDISPLAY=LINE** displays the confidence limits as plain lines without serifs.

**CLDISPLAY=BAR** displays the confidence limits as bars. By default, the width of the bars equals the size of the marker for the estimate. You can control the width of the bars and the size of the marker by specifying the value of *width* as a percentage of the distance between bars,  $0 < width \leq 1$ . The bar might disappear when the value of *width* is very small.

**COLUMN=1 | 2**

specifies the  $2 \times 2$  table column to use to compute the risk (proportion). The **COLUMN=** *plot-option* is available for the relative risk plot (**RELRISKPLOT**) and the risk difference plot (**RISKDIFFPLOT**). If you specify **COLUMN=1**, the plot displays the column 1 relative risks or the column 1 risk differences. Similarly, if you specify **COLUMN=2**, the plot displays the column 2 relative risks or risk differences.

The **COLUMN=** *plot-option* does not apply to odds ratio plots. The default is **COLUMN=1** for relative risks plots.

If you request both column 1 and column 2 risk differences with the **RISK** option, **COLUMN=1** is the default for the risk difference plot. If you request computation of only column 1 (or only column 2) risk differences with the **RISK1** (or **RISK2**) option, by default the risk difference plot displays the corresponding risk differences.

**LOGBASE=2 | E | 10**

applies to the odds ratio plot (**ODDSRATIOPLOT**) and the relative risk plot (**RELRISKPLOT**). The **LOGBASE=** *plot-option* displays the odds ratio or relative risk axis on the log scale that you specify.

**NPANELPOS=*n***

divides the plot into multiple panels that display at most  $|n|$  statistics (odds ratios, relative risks, or risk differences) per panel. If  $n$  is positive, the number of statistics per panel is balanced; if  $n$  is negative, the number of statistics per panel is not balanced. For example, suppose you want to display 21 odds ratios. **NPANELPOS=20** displays two panels, the first with 11 odds ratios and the second with 10 odds ratios; **NPANELPOS=-20** displays 20 odds ratios in the first panel but only one in the second panel.

By default,  $n = 0$  and all statistics are displayed in a single panel.

**ORDER=ASCENDING | DESCENDING**

displays the statistics (odds ratios, relative risks, or risk differences) in sorted order. By default, the statistics are displayed in the order in which the two-way table layers appear in the multiway table.

**RANGE=(*< min >* *<, max >*) | CLIP**

specifies the range of values to display. If you specify **RANGE=CLIP**, the confidence limits are clipped and the display range is determined by the minimum and maximum values of the estimates. By default, the display range includes all confidence limits.

**STATS**

displays the values of the statistics and their confidence limits on the right side of the plot. If you do not specify the **STATS** option, the statistic values are not displayed.

**Plot Options for WTFREQPLOT**

You can specify the following *plot-options* in parentheses after the **WTFREQPLOT** *plot-request*:

**CLBAR=NO | YES**

controls the confidence limit error bars in the plots. CLBAR=NO suppresses confidence limit error bars. CLBAR=YES is the default for all weighted frequency plots except two-way plots that are displayed in the **TWOWAY=CLUSTER** or **TWOWAY=STACKED** layout. Confidence limit error bars are not available in the **TWOWAY=CLUSTER** and **TWOWAY=STACKED** layouts.

**GROUPBY=COLUMN | ROW**

specifies the primary grouping for two-way weighted frequency plots. The default is **GROUPBY=COLUMN**, which groups graph cells first by column variable and displays row variable levels within column variable levels. You can specify **GROUPBY=ROW** to group first by row variable. In two-way and multiway table requests, the column variable is the last variable specified and forms the columns of the crosstabulation table. The row variable is the next-to-last variable specified and forms the rows of the table.

By default for a bar chart that is displayed in the **TWOWAY=STACKED** layout, bars correspond to the column variable levels and row levels are displayed (stacked) within each column bar. By default for a bar chart that is displayed in the **TWOWAY=CLUSTER** layout, bars are first grouped by column variable levels, and row levels are displayed as adjacent bars within each column-level group. You can reverse the default row and column variable groupings by specifying **GROUPBY=ROW**.

**NPANELPOS=*n***

divides a two-way weighted frequency plot into multiple panels that display at most  $|n|$  sections per panel. Sections correspond to row or column variable levels, depending on the type of plot and the grouping.

The **NPANELPOS= *plot-option*** applies to two-way plots that are displayed in the **TWOWAY=GROUPVERTICAL** or **TWOWAY=GROUPHORIZONTAL** layout. The **NPANELPOS= *plot-option*** does not apply to the **TWOWAY=CLUSTER** and **TWOWAY=STACKED** layouts, which are always displayed in a single panel.

If  $n$  is positive, the number of sections per panel is balanced; if  $n$  is negative, the number of sections per panel is not balanced. For example, suppose your two-way table has 21 sections. **NPANELPOS=20** displays two panels, the first with 11 sections and the second with 10 sections; **NPANELPOS=-20** displays 20 sections in the first panel but only 1 section in the second panel.

By default,  $n = 4$  and each panel includes at most four sections.

**ORIENT=HORIZONTAL | VERTICAL**

controls the orientation of the weighted frequency plot. The **ORIENT=HORIZONTAL** *plot-option* places the variable levels on the Y axis and the weighted frequencies or percentages on the X axis. **ORIENT=VERTICAL** places the variable levels on the X axis. The default is **ORIENT=VERTICAL** for bar charts (**TYPE=BARCHART**) and **ORIENT=HORIZONTAL** for dot plots (**TYPE=DOTPLOT**).

**SCALE=WTFREQ | PERCENT**

specifies the scale of the frequencies to display. **SCALE=WTFREQ** displays weighted frequencies (totals), and **SCALE=PERCENT** displays percentages. The default is **SCALE=WTFREQ**.

**TWOWAY=CLUSTER | GROUPTHORIZONTAL | GROUPVERTICAL | STACKED**

specifies the layout for two-way weighted frequency plots.

All TWOWAY= layouts are available for bar charts (**TYPE=BARCHART**). All TWOWAY= layouts except TWOWAY=CLUSTER are available for dot plots (**TYPE=DOTPLOT**). Confidence limits (**CLBAR=**) can be displayed in the GROUPVERTICAL and GROUPTHORIZONTAL layouts. Confidence limits are not available in the STACKED and CLUSTER layouts. The **ORIENT=** and **GROUPBY=** *plot-options* are available for all TWOWAY= layouts.

The default two-way layout is TWOWAY=GROUPVERTICAL, which produces a grouped plot that has a vertical common baseline. By default for bar charts (**TYPE=BARCHART**, **ORIENT=VERTICAL**), the X axis displays column variable levels, and the Y axis displays weighted frequencies. The plot includes a vertical (Y-axis) block for each row variable level. The relative positions of the graph cells in this plot layout are the same as the relative positions of the table cells in the crosstabulation table. You can reverse the default row and column grouping by specifying the **GROUPBY=ROW** *plot-option*.

The TWOWAY=GROUPTHORIZONTAL layout produces a grouped plot that has a horizontal common baseline. By default (**GROUPBY=COLUMN**), the plot displays a block on the X axis for each column variable level. Within each column-level block, the plot displays row variable levels.

The TWOWAY=STACKED layout produces stacked displays of weighted frequencies. By default (**GROUPBY=COLUMN**) in a stacked bar chart, the bars correspond to column variable levels, and row levels are stacked within each column level. By default in a stacked dot plot, the dotted lines correspond to column levels, and cell weighted frequencies are plotted as data dots on the corresponding column line. The dot color identifies the row level.

The TWOWAY=CLUSTER layout, which is available only for bar charts, displays groups of adjacent bars. By default, the primary grouping is by column variable level, and row levels are displayed within each column level.

You can reverse the default row and column grouping in any layout by specifying the **GROUPBY=ROW** *plot-option*. The default is **GROUPBY=COLUMN**, which groups first by column variable.

**TYPE=BARCHART | DOTPLOT**

specifies the type of the weighted frequency plot. **TYPE=BARCHART** produces a bar chart and **TYPE=DOTPLOT** produces a dot plot. The default type is **TYPE=BARCHART**.

**RISK | RISKDIFF**

requests risk statistics for  $2 \times 2$  tables. The RISK option also provides standard errors and confidence limits for these statistics. Risk statistics include the row 1 risk (proportion), row 2 risk, overall risk, and risk difference. See the section “[Risks and Risk Difference](#)” on page 7648 for details.

The RISK option provides both column 1 and column 2 risks. To request only column 1 or column 2 risks, use the **RISK1** or **RISK2** option.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits.

**RISK1**

requests column 1 risk statistics for  $2 \times 2$  tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk (proportion), row 2 risk, overall risk, and risk difference. See the section “[Risks and Risk Difference](#)” on page 7648 for details.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

**RISK2**

requests column 2 risk statistics for  $2 \times 2$  tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk (proportion), row 2 risk, overall risk, and risk difference. See the section “[Risks and Risk Difference](#)” on page 7648 for details.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

**ROW** < option >

displays the row percentage (estimated proportion of the row total) for each cell in a two-way table. The ROW option also provides the standard errors of the row percentages. See the section “[Row and Column Proportions](#)” on page 7635 for more information. This option has no effect for one-way tables.

You can specify the following *option* in parentheses after the ROW option:

**DEFF**

displays the design effect for each row percentage in the crosstabulation table. See the section “[Design Effect](#)” on page 7646 for more information.

**TESTP=**(values)

specifies null hypothesis proportions (test percentages) for chi-square tests for one-way tables (goodness-of-fit tests). You can separate *values* with blanks or commas. Specify *values* in probability form as numbers between 0 and 1, where the proportions sum to 1. Or specify *values* in percentage form as numbers between 0 and 100, where the percentages sum to 100. PROC SURVEYFREQ treats the value 1 as the percentage form 1%. The number of TESTP= values must equal the number of variable levels in the one-way table. List these values in the same order in which the corresponding variable levels appear in the output.

When you specify the TESTP= option, PROC SURVEYFREQ displays the specified test percentages in the one-way frequency table. The TESTP= option has no effect for two-way tables.

PROC SURVEYFREQ uses the TESTP= values for the one-way Rao-Scott chi-square test (**CHISQ**) and for the one-way Rao-Scott likelihood ratio chi-square test (**LRCHISQ**). See the sections “[Rao-Scott Chi-Square Test](#)” on page 7652 and “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7657 for details.

**VAR**

displays the variance estimate for each percentage in the crosstabulation table. See the section “[Proportions](#)” on page 7634 for details. By default, PROC SURVEYFREQ displays the standard errors of the percentages.

**VARWT**

displays the variance estimate for each weighted frequency, or estimated total, in the crosstabulation table. See the section “Totals” on page 7632 for details. By default, PROC SURVEYFREQ displays the standard deviations of the weighted frequencies.

**WCHISQ**

requests the Wald chi-square test for two-way tables. See the section “Wald Chi-Square Test” on page 7659 for details.

**WLLCHISQ**

requests the Wald log-linear chi-square test for two-way tables. See the section “Wald Log-Linear Chi-Square Test” on page 7660 for details.

**WTFREQ**

displays totals (weighted frequencies) and their standard errors when you do not specify a **WEIGHT** or **REPWEIGHTS** statement. PROC SURVEYFREQ displays the weighted frequencies by default when you include a **WEIGHT** or **REPWEIGHTS** statement. Without a **WEIGHT** or **REPWEIGHTS** statement, PROC SURVEYFREQ assigns all observations a weight of one.

---

## WEIGHT Statement

**WEIGHT** *variable* ;

The **WEIGHT** statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7627 for more information. If you specify more than one **WEIGHT** statement, the procedure uses only the first **WEIGHT** statement and ignores the rest.

If you do not specify a **WEIGHT** statement but provide replicate weights with a **REPWEIGHTS** statement, PROC SURVEYFREQ uses the average of each observation’s replicate weights as the observation’s weight.

If you do not specify a **WEIGHT** statement or a **REPWEIGHTS** statement, PROC SURVEYFREQ assigns all observations a weight of one.

---

## Details: SURVEYFREQ Procedure

### Specifying the Sample Design

PROC SURVEYFREQ produces tables and statistics that are based on the sample design used to obtain the survey data. PROC SURVEYFREQ can be used for single-stage or multistage designs, with or without stratification, and with or without unequal weighting. To analyze your survey data with PROC SURVEYFREQ, you need to provide sample design information for the procedure. This information can include design strata, clusters, and sampling weights. You can provide sample design information with the **STRATA**, **CLUSTER**, and **WEIGHT** statements, and with the **RATE=** or **TOTAL=** option in the PROC SURVEYFREQ statement.

If you provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a STRATA or CLUSTER statement. Otherwise, you should specify STRATA and CLUSTER statements whenever your design includes stratification and clustering.

When there are clusters (PSUs) in the sample design, the procedure estimates variance by using the PSUs, as described in the section “[Statistical Computations](#)” on page 7630. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. Therefore, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

## Stratification

If your sample design is stratified at the first stage of sampling, use the [STRATA](#) statement to name the variables that form the strata. The combinations of categories of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently. If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the STRATA statement.

If you use a [REPWEIGHTS](#) statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a STRATA statement. Otherwise, you should specify a STRATA statement whenever your design includes stratification. If you do not specify a STRATA statement or a REPWEIGHTS statement, then PROC SURVEYFREQ assumes there is no stratification at the first stage.

## Clustering

If your sample design selects clusters at the first stage of sampling, use the [CLUSTER](#) statement to name the variables that identify the first-stage clusters, which are also called primary sampling units (PSUs). The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata. If your sample design has clustering at multiple stages, you should specify only the first-stage clusters (PSUs) in the CLUSTER statement. PROC SURVEYFREQ assumes that each cluster that is defined by the CLUSTER statement variables represents a PSU in the sample, and that each observation belongs to one PSU.

If you use a [REPWEIGHTS](#) statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a CLUSTER statement. Otherwise, you should specify a CLUSTER statement whenever your design includes clustering at the first stage of sampling. If you do not specify a CLUSTER statement, then PROC SURVEYFREQ treats each observation as a PSU.

## Weighting

If your sample design includes unequal weighting, use the [WEIGHT](#) statement to name the variable that contains the sampling weights. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “[Missing Values](#)” on page 7627 for more information.

If you do not specify a WEIGHT statement but include a [REPWEIGHTS](#) statement, PROC SURVEYFREQ uses the average of each observation’s replicate weights as the observation’s weight. If you do not specify a WEIGHT statement or a REPWEIGHTS statement, PROC SURVEYFREQ assigns all observations a weight of one.

## Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the `RATE=` or `TOTAL=` option in the `PROC SURVEYFREQ` statement. (You cannot specify both of these options in the same `PROC SURVEYFREQ` statement.) The `RATE=` and `TOTAL=` options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the `RATE=` or `TOTAL=` option, Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the `RATE=` option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the `TOTAL=` option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the `RATE=value` or `TOTAL=value` option. If your sample design is stratified with different sampling rates or population totals in different strata, use the `RATE=SAS-data-set` or `TOTAL=SAS-data-set` option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the `DATA=` option.

The secondary data set must contain all the stratification variables listed in the `STRATA` statement and all the variables in the `BY` statement. Furthermore, the `BY` groups must appear in the same order as in the primary data set. If there are formats that are associated with the `STRATA` variables and the `BY` variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the `TOTAL=SAS-data-set` option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. If you specify the `RATE=SAS-data-set` option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the `RATE=` option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and `PROC SURVEYFREQ` converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

---

## Domain Analysis

`PROC SURVEYFREQ` provides domain analysis through its multiway table capability. *Domain analysis* refers to the computation of statistics for domains (subpopulations), in addition to the computation of statistics for the entire study population. Formation of subpopulations can be unrelated to the sample design, and so the domain sample sizes can actually be random variables. Domain analysis takes this variability into account by using the entire sample in estimating the variance of domain estimates. Domain analysis is also

known as subgroup analysis, subpopulation analysis, and subdomain analysis. For more information about domain analysis, see Lohr (2010); Cochran (1977); Fuller et al. (1989).

To request domain analysis with PROC SURVEYFREQ, you should include the domain variable(s) in your TABLES statement request. For example, specifying DOMAIN \* A \* B in a TABLES statement produces separate two-way tables of A by B for each level of DOMAIN. If your domains are formed by more than one variable, you can specify DomainVariable\_1 \* DomainVariable\_2 \* A \* B, for example, to obtain two-way tables of A by B for each domain formed by the different combinations of levels for DomainVariable\_1 and DomainVariable\_2. See [Example 90.2](#) for an example of domain analysis.

If you specify DOMAIN \* A in a TABLES statement, the values of the variable DOMAIN form the table rows. The two-way table lists levels of the variable A within each level of the row variable DOMAIN. Specify the ROW option in the TABLES statement to obtain the row percentages and their standard errors. This provides the one-way distribution of A for each domain (level of the variable DOMAIN).

Including the domain variables in a TABLES statement request provides a different analysis from that obtained by using a BY statement, which provides completely separate analyses of the BY groups. The BY statement can also be used to analyze the data set by subgroups, but it is critical to note that this does *not* produce a valid domain analysis. The BY statement is appropriate only when the number of units in each subgroup is known with certainty. For example, the BY statement can be used to obtain stratum level estimates when you have fixed sample sizes for the strata. When the subgroup sample size is a random variable, include the domain variables in your TABLES statement request.

## Missing Values

### WEIGHT Variable

If an observation has a missing value or a nonpositive value for the WEIGHT variable, then PROC SURVEYFREQ excludes that observation from the analysis.

### REPWEIGHTS Variables

If you provide replicate weights with a REPWEIGHTS statement for BRR or jackknife variance estimation, all REPWEIGHTS variable values must be nonmissing. Similarly, if you provide jackknife coefficients with the JKCOEFS= option in the REPWEIGHTS statement, all values of the JKCoefficient variable must be nonmissing. The procedure does not perform the analysis when any replicate weight or jackknife coefficient value is missing.

### STRATA and CLUSTER Variables

An observation is excluded from the analysis if it has a missing value for any STRATA or CLUSTER variable, unless you specify the MISSING option in the PROC SURVEYFREQ statement. If you specify the MISSING option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables, which include STRATA variables, CLUSTER variables, and TABLES variables.

### TABLES Variables

By default, PROC SURVEYFREQ excludes an observation from a crosstabulation table (and all associated analyses) if the observation has a missing value for any of the variables in the TABLES request, unless

you specify the **MISSING** or **NOMCAR** option in the **PROC SURVEYFREQ** statement. When the procedure excludes observations with missing values from a table, it displays the total frequency of missing observations below the table.

If you specify the **MISSING** option, the procedure treats missing values as a valid (nonmissing) level for each **TABLES** variable. These levels are displayed in the crosstabulation table and included in computations of totals, percentages, and all other table statistics.

If you specify the **NOMCAR** option in the **PROC SURVEYFREQ** statement for Taylor series variance estimation, the procedure includes observations with missing values of **TABLES** variables in the variance computations. The **NOMCAR** option does not display missing levels in the crosstabulation table or compute percentages and totals for missing levels.

### The **NOMCAR** Option

The **NOMCAR** option in the **PROC SURVEYFREQ** statement includes observations with missing values of **TABLES** variables in the variance computations as *not missing completely at random* (**NOMCAR**) for Taylor series variance estimation. By default, observations are completely excluded from the analysis if they have missing values for any of the variables in the current **TABLES** request. This default treatment is based on the assumption that the values are *missing completely at random* (**MCAR**), and assumes that the analysis results should not be substantially different between the missing and nonmissing groups. See the section “**Analysis Considerations**” on page 7629 for more information.

When you specify the **NOMCAR** option, **PROC SURVEYFREQ** computes variance estimates by analyzing the nonmissing values as a domain (subpopulation), where the entire population includes both nonmissing and missing domains.

Note that the **NOMCAR** option has no effect when you specify the **MISSING** option, which treats missing values as a valid nonmissing level. The **NOMCAR** option does not affect the inclusion of observations with missing values of the **WEIGHT**, **CLUSTER**, or **STRATA** variables. Observations with missing values of the **WEIGHT** variable are always excluded from the analysis. Observations with missing values of the **CLUSTER** or **STRATA** variables are excluded unless you specify the **MISSING** option.

The **NOMCAR** option applies only to Taylor series variance estimation **VARMETHOD=TAYLOR**. The replication methods, which you request with the **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** options, do not use the **NOMCAR** option.

### Degrees of Freedom

**PROC SURVEYFREQ** computes degrees of freedom to obtain the *t*-percentile for confidence limits for proportions, totals, and other statistics. The procedure also uses degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. The degrees of freedom computation depends on the variance estimation method that you request. See the section “**Degrees of Freedom**” on page 7645 for details. Missing values can affect the degrees of freedom computation.

#### **Taylor Series Variance Estimation**

The degrees of freedom can depend on the number of clusters, the number of strata, and the number of observations. For Taylor series variance estimation, these numbers are based on the observations included in the analysis of the individual table. These numbers do not count observations that are excluded from the table due to missing values. If all values in a stratum are excluded from the analysis of a table as missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of

strata for the table. Similarly, empty clusters and missing observations are not included in the total counts of clusters and observations that are used to compute the degrees of freedom for the analysis.

If you specify the **MISSING** option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the **NOMCAR** option for Taylor series variance estimation, observations with missing values of the **TABLES** variables are included in computing degrees of freedom.

### **Replicate-Based Variance Estimation**

For BRR or jackknife variance estimation, by default PROC SURVEYFREQ computes the degrees of freedom by using all valid observations in the input data set. A valid observation is an observation that has a positive value of the **WEIGHT** variable and nonmissing values of the **STRATA** and **CLUSTER** variables unless you specify the **MISSING** option. See the section “Data Summary Table” on page 7663 for details about valid observations.

If you specify the **DFADJ** *method-option* for **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE**, the procedure computes the degrees of freedom based on the nonmissing observations included in the individual table analysis. This excludes any empty strata or clusters that occur when observations with missing values of the **TABLES** variables are removed from the analysis for that table.

## **Table Summary Output Data Set**

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the individual table. If there are missing observations, empty strata, or empty clusters excluded from the analysis, the “Table Summary” data set also contains this information. If you request any confidence limits or chi-square tests for the table, which require degrees of freedom, the “Table Summary” data set provides the degrees of freedom.

Due to missing values, the number of observations used for an individual table analysis can differ from the number of valid observations in the input data set, which is reported in the “Data Summary” table. Similarly, a difference can also occur for the number of clusters or strata. See [Example 90.3](#) for more information about the “Table Summary” output data set.

If you specify the **NOMCAR** option for Taylor series variance estimation, the “Table Summary” data set reflects all observations used for variance estimation, which includes those observations with missing values of the **TABLES** variables.

## **Analysis Considerations**

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. An observation without missing values is called a *complete respondent*, and an observation with missing values is called an *incomplete respondent*. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYFREQ. For more details, see Cochran (1977); Kalton and Kaspyzyk (1986); Brick and Kalton (1996).

---

## Statistical Computations

### Variance Estimation

PROC SURVEYFREQ provides a choice of variance estimation methods for complex survey data. In addition to the Taylor series linearization method, the procedures offer two replication-based (resampling) methods—balanced repeated replication (BRR) and the delete-1 jackknife. These variance estimation methods usually give similar, satisfactory results (Lohr 2010; Särndal, Swensson, and Wretman 1992; Wolter 1985). The choice of a variance estimation method can depend on the sample design used, the sample design information available, the parameters to be estimated, and computational issues. See Lohr (2010) for more details.

#### **Taylor Series Variance Estimation**

The Taylor series linearization method can be used to estimate standard errors of proportions and other statistics for crosstabulation tables. For sample survey data, the proportion estimator is a ratio estimator formed from estimators of totals. For example, to estimate the proportion in a crosstabulation table cell, the procedure uses the ratio of the estimator of the cell total frequency to the estimator of the overall population total, where these totals are linear statistics computed from the survey data. The Taylor series expansion method obtains a first-order linear approximation for the ratio estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971; Fuller 1975). For more information about Taylor series variance estimation for sample survey data, see Lohr (2010); Särndal, Swensson, and Wretman (1992); Lee, Forthoffer, and Lorimor (1989); Wolter (1985).

When there are clusters (PSUs) in the sample design, the Taylor series method estimates variance from the variance among PSUs. When the design is stratified, the procedure combines stratum variance estimates to compute the overall variance estimate. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. So the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

See the sections “Proportions” on page 7634, “Row and Column Proportions” on page 7635, “Risks and Risk Difference” on page 7648, and “Odds Ratio and Relative Risks” on page 7650 for details and formulas for Taylor series variance estimates.

#### **Replication-Based Variance Estimation**

Replication-based methods for variance estimation draw multiple replicates (subsamples) from the full sample by following a specific resampling scheme. Commonly used resampling schemes include *balanced repeated replication* (BRR) and the *jackknife*. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (2010) for more information.

The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights of the remaining PSUs. The adjusted weights are called *replicate weights*. PROC SURVEYFREQ also provides Fay’s method, which is a modification of the BRR method. See the section “Balanced Repeated Replication (BRR)” on page 7637 for details.

The jackknife method deletes one PSU at a time from the full sample to create replicates, and modifies the original weights to obtain replicate weights. The total number of replicates equals the number of PSUs. If the sample design is stratified, each stratum must contain at least two PSUs, and the jackknife is applied separately within each stratum. See the section “[The Jackknife Method](#)” on page 7640 for details.

Instead of having PROC SURVEYFREQ generate replicate weights for the analysis, you can input your own replicate weights with a [REPWEIGHTS](#) statement. This can be useful if you need to do multiple analyses with the same set of replicate weights, or if you have access to replicate weights instead of design information. See the section “[Replicate Weight Output Data Set](#)” on page 7662 for more information.

## Definitions and Notation

For a stratified clustered sample design, define the following:

|                                            |                                                                                                                                 |
|--------------------------------------------|---------------------------------------------------------------------------------------------------------------------------------|
| $h = 1, 2, \dots, H$                       | is the stratum number,<br>with a total of $H$ strata                                                                            |
| $i = 1, 2, \dots, n_h$                     | is the cluster number within stratum $h$ ,<br>with a total of $n_h$ sample clusters in stratum $h$                              |
| $j = 1, 2, \dots, m_{hi}$                  | is the unit number within cluster $i$ of stratum $h$ ,<br>with a total of $m_{hi}$ sample units from cluster $i$ of stratum $h$ |
| $n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$ | is the total number of observations in the sample                                                                               |
| $f_h$                                      | first-stage sampling rate for stratum $h$                                                                                       |
| $W_{hij}$                                  | sampling weight of unit $j$ in cluster $i$ of stratum $h$                                                                       |

The sampling rate  $f_h$ , which is used in Taylor series variance estimation, is the fraction of first-stage units (PSUs) selected for the sample. You can specify the stratum sampling rates with the [RATE=](#) option. Or if you specify population totals with the [TOTAL=](#) option, PROC SURVEYFREQ computes  $f_h$  as the ratio of stratum sample size to the stratum total, in terms of PSUs. See the section “[Population Totals and Sampling Rates](#)” on page 7626 for details. If you do not specify the [RATE=](#) option or the [TOTAL=](#) option, then the procedure assumes that the stratum sampling rates  $f_h$  are negligible and does not use a finite population correction when computing variances.

This notation is also applicable to other sample designs. For example, for a design without stratification, you can let  $H = 1$ ; for a sample design without clustering, you can let  $m_{hi} = 1$  for every  $h$  and  $i$ , which replaces clusters with individual sampling units.

For a two-way table representing the crosstabulation of two variables, define the following, where there are  $R$  levels of the row variable and  $C$  levels of the column variable:

|                                        |                                                   |
|----------------------------------------|---------------------------------------------------|
| $r = 1, 2, \dots, R$                   | is the row number, with a total of $R$ rows       |
| $c = 1, 2, \dots, C$                   | is the column number, with a total of $C$ columns |
| $N_{rc}$                               | is the population total in row $r$ and column $c$ |
| $N_{r\cdot} = \sum_{c=1}^C N_{rc}$     | is the total in row $r$                           |
| $N_{\cdot c} = \sum_{r=1}^R N_{rc}$    | is the total in column $c$                        |
| $N = \sum_{r=1}^R \sum_{c=1}^C N_{rc}$ | is the overall total                              |

$P_{rc} = N_{rc} / N$  is the population proportion in row  $r$  and column  $c$

$P_{r.} = N_{r.} / N$  is the proportion in row  $r$

$P_{.c} = N_{.c} / N$  is the proportion in column  $c$

$P_{rc}^r = N_{rc} / N_{r.}$  is the row proportion for table cell  $(r, c)$

$P_{rc}^c = N_{rc} / N_{.c}$  is the column proportion for table cell  $(r, c)$

For a specified observation (identified by stratum, cluster, and unit number within the cluster), define the following to indicate whether or not that observation belongs to cell  $(r, c)$ , row  $r$  and column  $c$ , of the two-way table, for  $r = 1, 2, \dots, R$  and  $c = 1, 2, \dots, C$ :

$$\delta_{hij}(r, c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in cell } (r, c) \\ 0 & \text{otherwise} \end{cases}$$

Similarly, define the following functions to indicate the observation's row and column classification:

$$\delta_{hij}(r \cdot) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in row } r \\ 0 & \text{otherwise} \end{cases}$$

$$\delta_{hij}(\cdot c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in column } c \\ 0 & \text{otherwise} \end{cases}$$

## Totals

PROC SURVEYFREQ estimates population frequency totals for the specified crosstabulation tables, including totals for two-way table cells, rows, columns, and overall totals. The procedure computes the estimate of the total frequency in table cell  $(r, c)$  as the weighted frequency sum,

$$\widehat{N}_{rc} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}$$

Similarly, PROC SURVEYFREQ computes estimates of row totals, column totals, and overall totals as

$$\widehat{N}_{r.} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r \cdot) W_{hij}$$

$$\widehat{N}_{.c} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(\cdot c) W_{hij}$$

$$\widehat{N} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij}$$

PROC SURVEYFREQ estimates the variances of totals by using the variance estimation method that you request. If you request BRR variance estimation (by specifying the `VARMETHOD=BRR` option in the PROC SURVEYFREQ statement), the procedure estimates the variances as described in the section “Balanced

Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (by specifying the `VARMETHOD=JACKKNIFE` option), the procedure estimates the variances as described in the section “The Jackknife Method” on page 7640.

If you do not specify the `VARMETHOD=` option or a `REPWEIGHTS` statement, the default variance estimation method is Taylor series, which you can also request with the `VARMETHOD=TAYLOR` option. Since totals are linear statistics, their variances can be estimated directly, without the approximation that is used for proportions and other nonlinear statistics. PROC SURVEYFREQ estimates the variance of the total frequency in table cell  $(r, c)$  as

$$\widehat{\text{Var}}(\widehat{N}_{rc}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{N}_{rc})$$

where if  $n_h > 1$ ,

$$\begin{aligned} \widehat{\text{Var}}_h(\widehat{N}_{rc}) &= \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^h)^2 \\ n_{rc}^{hi} &= \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} \\ \bar{n}_{rc}^h &= \left( \sum_{i=1}^{n_h} n_{rc}^{hi} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{N}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard deviation of the total is computed as

$$\text{Std}(\widehat{N}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{N}_{rc})}$$

The variances and standard deviations are computed in a similar manner for row totals, column totals, and overall table totals.

### Covariance of Totals

The covariance matrix of the table cell totals  $\widehat{N}_{rc}$  is an  $rc \times rc$  matrix  $\widehat{\text{V}}(\widehat{\mathbf{N}})$ , which contains the pairwise table cell covariances  $\widehat{\text{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab})$ , for  $r = 1, \dots, R; c = 1, \dots, C; a = 1, \dots, R; \text{ and } b = 1, \dots, C$ .

PROC SURVEYFREQ estimates the covariances by using the variance estimation method that you request. If you request BRR variance estimation (by specifying the `VARMETHOD=BRR` option in the PROC SURVEYFREQ statement), the procedure estimates the covariances by the method described in the section “Balanced Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (by specifying the `VARMETHOD=JACKKNIFE` option), the procedure uses the method described in the section “The Jackknife Method” on page 7640.

Otherwise (by default, or if you request the Taylor series method), PROC SURVEYFREQ estimates the covariance between total frequency estimates for table cells  $(r, c)$  and  $(a, b)$  as

$$\widehat{\text{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab}) = \sum_{h=1}^H \left( \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^h) (n_{ab}^{hi} - \bar{n}_{ab}^h) \right)$$

## Proportions

PROC SURVEYFREQ computes the estimate of the proportion in table cell  $(r, c)$  as the ratio of the estimated total for the table cell to the estimated overall total,

$$\begin{aligned} \widehat{P}_{rc} &= \widehat{N}_{rc} / \widehat{N} \\ &= \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} \right) / \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij} \right) \end{aligned}$$

If you request BRR variance estimation (by specifying the `VARMETHOD=BRR` option in the PROC SURVEYFREQ statement), the procedure estimates the variances of proportion estimates as described in the section “Balanced Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (by specifying the `VARMETHOD=JACKKNIFE` option), the procedure estimates the variances as described in the section “The Jackknife Method” on page 7640.

If you do not specify the `VARMETHOD=` option or a `REPWEIGHTS` statement, the default variance estimation method is Taylor series, which you can also request with the `VARMETHOD=TAYLOR` option. By using Taylor series linearization, the variance of a proportion estimate can be expressed as

$$\widehat{\text{Var}}(\widehat{P}_{rc}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{rc})$$

where if  $n_h > 1$ ,

$$\begin{aligned} \widehat{\text{Var}}_h(\widehat{P}_{rc}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{rc}^{hi} - \bar{e}_{rc}^h)^2 \\ e_{rc}^{hi} &= \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}) W_{hij} \right) / \widehat{N} \\ \bar{e}_{rc}^h &= \left( \sum_{i=1}^{n_h} e_{rc}^{hi} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc})}$$

Similarly, the estimate of the proportion in row  $r$  is

$$\widehat{P}_{r.} = \widehat{N}_{r.} / \widehat{N}$$

And its variance estimate is

$$\widehat{\text{Var}}(\widehat{P}_{r.}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{r.})$$

where if  $n_h > 1$ ,

$$\begin{aligned} \widehat{\text{Var}}_h(\widehat{P}_{r.}) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (e_{r.}^{hi} - \bar{e}_{r.}^h)^2 \\ e_{r.}^{hi} &= \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r \cdot) - \widehat{P}_{r.}) W_{hij} \right) / \widehat{N} \\ \bar{e}_{r.}^h &= \left( \sum_{i=1}^{n_h} e_{r.}^{hi} \right) / n_h \end{aligned}$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{r.}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the proportion in row  $r$  is computed as

$$\text{StdErr}(\widehat{P}_{r.}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{r.})}$$

Computations for the proportion in column  $c$  are done in the same way.

## Row and Column Proportions

PROC SURVEYFREQ computes the estimate of the row proportion for table cell  $(r, c)$  as the ratio of the estimated total for the table cell to the estimated total for row  $r$ ,

$$\begin{aligned} \widehat{P}_{rc}^r &= \widehat{N}_{rc} / \widehat{N}_{r.} \\ &= \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} \right) / \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r \cdot) W_{hij} \right) \end{aligned}$$

Similarly, PROC SURVEYFREQ estimates the column proportion for table cell  $(r, c)$  as the ratio of the estimated total for the table cell to the estimated total for column  $c$ ,

$$\begin{aligned}\widehat{P}_{rc}^c &= \widehat{N}_{rc} / \widehat{N}_{\cdot c} \\ &= \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} \right) / \left( \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(\cdot, c) W_{hij} \right)\end{aligned}$$

If you request BRR variance estimation (**VARMETHOD=BRR**), PROC SURVEYFREQ estimates the variances of the row and column proportions as described in the section “Balanced Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (**VARMETHOD=JACKKNIFE**), the procedure estimates the variances as described in the section “The Jackknife Method” on page 7640.

If you do not specify the **VARMETHOD=** option or a **REPWEIGHTS** statement, the default variance estimation method is Taylor series (**VARMETHOD=TAYLOR**). By using Taylor series linearization, the variance of the row proportion estimate can be expressed as

$$\widehat{\text{Var}}(\widehat{P}_{rc}^r) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{rc}^r)$$

where if  $n_h > 1$ ,

$$\begin{aligned}\widehat{\text{Var}}_h(\widehat{P}_{rc}^r) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (g_{rc}^{hi} - \bar{g}_{rc}^h)^2 \\ g_{rc}^{hi} &= \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}^r \delta_{hij}(r, \cdot)) W_{hij} \right) / \widehat{N}_{r\cdot} \\ \bar{g}_{rc}^h &= \left( \sum_{i=1}^{n_h} g_{rc}^{hi} \right) / n_h\end{aligned}$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}^r) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the row proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}^r) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc}^r)}$$

The Taylor series variance estimate for the column proportion is computed as described previously for the row proportion, but with

$$g_{rc}^{hi} = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}^c \delta_{hij}(\cdot, c)) W_{hij} \right) / \widehat{N}_{\cdot c}$$

## Balanced Repeated Replication (BRR)

If you specify the `VARMETHOD=BRR` option, then PROC SURVEYFREQ uses balanced repeated replication (BRR) for variance estimation. The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. You can provide replicate weights for BRR variance estimation by using a `REPWEIGHTS` statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (2010) for more information about BRR variance estimation.

If you do not provide replicate weights with a `REPWEIGHTS` statement, PROC SURVEYFREQ constructs replicates based on the stratified design with two PSUs in each stratum. This section describes replicate construction by the traditional BRR method. If you specify the `FAY method-option` for `VARMETHOD=BRR`, the procedure uses Fay's modified BRR method, which is described in the section “Fay's BRR Method” on page 7638.

With the traditional BRR method, each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix of dimension  $R$ , where  $R$  is the number of replicates. The number of replicates equals the smallest multiple of 4 that is greater than the number of strata  $H$ . Alternatively, you can specify the number of replicates with the `REPS= method-option`. If a Hadamard matrix cannot be constructed for the `REPS=` value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the `REPS=` value that you specify.

You can provide a Hadamard matrix for BRR replicate construction by using the `HADAMARD= method-option`. Otherwise, PROC SURVEYFREQ generates an appropriate Hadamard matrix. See the section “Hadamard Matrix” on page 7639 for more information. You can display the Hadamard matrix by specifying the `PRINTH method-option`.

PROC SURVEYFREQ constructs replicates by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $H$  denotes the number of strata. The  $r$ th replicate ( $r = 1, 2, \dots, R$ ) is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If element  $(r, h)$  of the Hadamard matrix equals 1, then the first PSU of stratum  $h$  is included in the  $r$ th replicate, and the second PSU of stratum  $h$  is excluded.
- If element  $(r, h)$  of the Hadamard matrix equals  $-1$ , then the second PSU of stratum  $h$  is included in the  $r$ th replicate, and the first PSU of stratum  $h$  is excluded.

For the PSUs included in replicate  $r$ , the original weights are doubled to form the replicate  $r$  weights. For the PSUs not included in replicate  $r$ , the replicate  $r$  weights equal zero. You can use the `OUTWEIGHTS=SAS-data-set method-option` to store the replicate weights in a SAS data set. See the section “Replicate Weight Output Data Set” on page 7662 for details about the contents of the `OUTWEIGHTS=` data set. You can provide these replicate weights to the procedure for subsequent analyses by using a `REPWEIGHTS` statement.

Let  $\theta$  denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let  $\hat{\theta}$  denote the estimate of  $\theta$  from the full sample, and let  $\hat{\theta}_r$  denote the estimate from the  $r$ th BRR

replicate, which is computed by using the replicate weights. The BRR variance estimate for  $\hat{\theta}$  is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2$$

where  $R$  is the total number of replicates.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column  $j$  for table cell  $(i, j)$ . If a replicate  $r$  contains no observations in column  $j$ , then the column  $j$  proportion is not estimable from replicate  $r$ . In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'} \sum_{r=1}^{R'} (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  is estimable, and  $R'$  is the number of those replicates.

#### **Fay's BRR Method**

If you specify the **FAY** *method-option* for **VARMETHOD=BRR**, then PROC SURVEYFREQ uses Fay's BRR method, which is a modification of the traditional BRR variance estimation method. As for traditional BRR, Fay's method requires a stratified sample design with two PSUs in each stratum. You can provide replicate weights by using a **REPWEIGHTS** statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate.

If you do not provide replicate weights with a **REPWEIGHTS** statement, PROC SURVEYFREQ constructs replicates based on the stratified design with two PSUs in each stratum. As for traditional BRR, the number of replicates  $R$  equals the smallest multiple of 4 that is greater than the number of strata  $H$ , or you can specify the number of replicates with the **REPS=** *method-option*. You can provide a Hadamard matrix for replicate construction by using the **HADAMARD=** *method-option*, or PROC SURVEYFREQ generates an appropriate Hadamard matrix.

The traditional BRR method constructs half-sample replicates by deleting one PSU per stratum according to the Hadamard matrix and doubling the original weights to form replicate weights. Fay's BRR method adjusts the original weights by a coefficient  $\epsilon$ , where  $0 \leq \epsilon < 1$ . You can specify the value of  $\epsilon$  with the **FAY=** *method-option*. If you do not specify the value of  $\epsilon$ , PROC SURVEYFREQ uses  $\epsilon = 0.5$  by default. See Judkins (1990) and Rao and Shao (1999) for information about the value of the Fay coefficient. When  $\epsilon = 0$ , Fay's method becomes the traditional BRR method. For more information, see Dipppo, Fay, and Morganstein (1984); Fay (1989); Judkins (1990).

PROC SURVEYFREQ constructs Fay BRR replicates by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $H$  denotes the number of strata. The  $r$ th replicate ( $r = 1, 2, \dots, R$ ) is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If element  $(r, h)$  of the Hadamard matrix equals 1, the sampling weight of the first PSU in stratum  $h$  is multiplied by  $\epsilon$ , and the sampling weight of the second PSU is multiplied by  $(2 - \epsilon)$  to form the  $r$ th replicate weights.
- If element  $(r, h)$  of the Hadamard matrix equals  $-1$ , then the sampling weight of the second PSU in stratum  $h$  is multiplied by  $\epsilon$ , and the sampling weight of the first PSU is multiplied by  $(2 - \epsilon)$  to form the  $r$ th replicate weights.

You can use the `OUTWEIGHTS= method-option` to store the replicate weights in a SAS data set. See the section “Replicate Weight Output Data Set” on page 7662 for details about the contents of the `OUTWEIGHTS=` data set. You can provide these replicate weights to the procedure for subsequent analyses by using a `REPWEIGHTS` statement.

Let  $\theta$  denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let  $\hat{\theta}$  denote the estimate of  $\theta$  from the full sample, and let  $\hat{\theta}_r$  denote the estimate from the  $r$ th BRR replicate, which is computed by using the replicate weights. The Fay BRR variance estimate for  $\hat{\theta}$  is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R(1 - \epsilon)^2} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2$$

where  $R$  is the total number of replicates and  $\epsilon$  is the Fay coefficient.

If you request Fay’s BRR method and also include a `REPWEIGHTS` statement, `PROC SURVEYFREQ` uses the replicate weights that you provide and includes the Fay coefficient  $\epsilon$  in the denominator of the variance estimate in the preceding expression.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column  $j$  for table cell  $(i, j)$ . If a replicate  $r$  contains no observations in column  $j$ , then the column  $j$  proportion is not estimable from replicate  $r$ . In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'(1 - \epsilon)^2} \sum_{r=1}^{R'} (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  is estimable, and  $R'$  is the number of those replicates.

### **Hadamard Matrix**

`PROC SURVEYFREQ` uses a Hadamard matrix to construct replicates for BRR variance estimation. You can provide a Hadamard matrix for replicate construction by using the `HADAMARD= method-option` for `VARMETHOD=BRR`. Otherwise, `PROC SURVEYFREQ` generates an appropriate Hadamard matrix. You can display the Hadamard matrix by specifying the `PRINTH method-option`.

A Hadamard matrix  $\mathbf{A}$  of dimension  $R$  is a square matrix that has all elements equal to 1 or  $-1$ . A Hadamard matrix must satisfy the requirement that  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{I}$  is an identity matrix. The dimension of a Hadamard matrix must equal 1, 2, or a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension  $k = 8$ :

```

1 1 1 1 1 1 1 1
1 -1 1 -1 1 -1 1 -1
1 1 -1 -1 1 1 -1 -1
1 -1 -1 1 1 -1 -1 1
1 1 1 1 -1 -1 -1 -1
1 -1 1 -1 -1 1 -1 1
1 1 -1 -1 -1 -1 1 1
1 -1 -1 1 -1 1 1 -1

```

For BRR replicate construction, the dimension of the Hadamard matrix must be at least  $H$ , where  $H$  denotes the number of first-stage strata in your design. If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the `HADAMARD=SAS-data-set method-option`. You must ensure that the matrix that you provide is actually a Hadamard matrix; PROC SURVEYFREQ does not check the validity of your Hadamard matrix.

See the section “Balanced Repeated Replication (BRR)” on page 7637 and “Fay’s BRR Method” on page 7638 for details about how the Hadamard matrix is used to construct replicates for BRR variance estimation.

## The Jackknife Method

If you specify the `VARMETHOD=JACKKNIFE` option, PROC SURVEYFREQ uses the delete-1 jackknife method for variance estimation. The jackknife method can be used for stratified sample designs and for designs with no stratification. If your design is stratified, the jackknife method requires at least two PSUs in each stratum. You can provide replicate weights for jackknife variance estimation by using a `REPWEIGHTS` statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (2010) for more information about jackknife variance estimation.

If you do not provide replicate weights with a `REPWEIGHTS` statement, PROC SURVEYFREQ constructs the replicates. The number of replicates  $R$  equals the number of PSUs, and the procedure deletes one PSU from the full sample to form each replicate. The sampling weights are modified by the jackknife coefficient for the replicate to create the replicate weights.

If your design is not stratified (no `STRATA` statement), the jackknife coefficient has the same value for each replicate  $r$ . The jackknife coefficient equals

$$\alpha_r = (R - 1)/R \quad \text{for } r = 1, 2, \dots, R$$

where  $R$  is the total number of replicates (or total number of PSUs). For the PSUs included in a replicate, the replicate weights are computed by dividing the original sampling weights by the jackknife coefficient. For the deleted PSU, which is not included in the replicate, the replicate weights equal zero. The replicate weight for the  $j$ th member of the  $i$ th PSU can be expressed as follows when the design is not stratified:

$$W_{ij}^r = \begin{cases} W_{ij}/\alpha_r & \text{if PSU } i \text{ is included in replicate } r \\ 0 & \text{otherwise} \end{cases}$$

where  $W_{ij}$  is the original sampling weight of unit  $(ij)$ ,  $r$  is the replicate number, and  $\alpha_r$  is the jackknife coefficient.

If your design is stratified, the jackknife method requires at least two PSUs in each stratum. Let stratum  $h_r'$  be the stratum from which a PSU is deleted to form the  $r$ th replicate. Stratum  $h_r'$  is called the *donor stratum*. The jackknife coefficients are defined as

$$\alpha_r = (n_{h_r'} - 1)/n_{h_r'} \quad \text{for } r = 1, 2, \dots, R$$

where  $n_{h_r'}$  is the total number of PSUs in the donor stratum for replicate  $r$ . For all strata other than the donor stratum, the replicate  $r$  weights equal the original sampling weights. For PSUs included from the donor stratum, the replicate weights are computed by dividing the original sampling weights by the jackknife coefficient. For the deleted PSU, which is not included in the replicate, the replicate weights equal zero. The replicate weight for the  $j$ th member of the  $i$ th PSU in stratum  $h$  can be expressed as

$$W_{hij}^r = \begin{cases} W_{hij} & \text{if } h \neq h_r' \\ W_{hij}/\alpha_r & \text{if } h = h_r' \text{ and PSU } (hi) \text{ is included in replicate } r \\ 0 & \text{if } h = h_r' \text{ and PSU } (hi) \text{ is not included in replicate } r \end{cases}$$

You can use the `OUTWEIGHTS=method-option` to store the replicate weights in a SAS data set. You can also use the `OUTJKCOEFS=method-option` to store the jackknife coefficients in a SAS data set. See the sections “[Jackknife Coefficient Output Data Set](#)” on page 7662 and “[Replicate Weight Output Data Set](#)” on page 7662 for details about the contents of these output data sets. You can provide replicate weights and jackknife coefficients to the procedure for subsequent analyses by using a `REPWEIGHTS` statement. If you provide replicate weights but do not provide jackknife coefficients, PROC SURVEYFREQ uses  $\alpha_r = (R - 1)/R$  as the jackknife coefficient for all replicates.

Let  $\theta$  denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let  $\hat{\theta}$  denote the estimate of  $\theta$  from the full sample, and let  $\hat{\theta}_r$  be the estimate from the  $r$ th jackknife replicate, which is computed by using the replicate weights. The jackknife variance estimate for  $\hat{\theta}$  is computed as

$$\widehat{V}(\hat{\theta}) = \sum_{r=1}^R \alpha_r (\hat{\theta}_r - \hat{\theta})^2$$

where  $R$  is the total number of replicates and  $\alpha_r$  is the jackknife coefficient for replicate  $r$ .

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column  $j$  for table cell  $(i, j)$ . If a replicate  $r$  contains no observations in column  $j$ , then the column  $j$  proportion is not estimable from replicate  $r$ . In this case, the jackknife variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{R}{R'} \sum_{r=1}^{R'} \alpha_r (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  is estimable, and  $R'$  is the number of those replicates.

## Confidence Limits for Totals

If you specify the **CLWT** option in the **TABLES** statement, PROC SURVEYFREQ computes confidence limits for the weighted frequencies (totals) in the crosstabulation tables.

For the total in table cell  $(r, c)$ , the confidence limits are computed as

$$\hat{N}_{rc} \pm \left( t_{df, \alpha/2} \times \text{StdErr}(\hat{N}_{rc}) \right)$$

where  $\hat{N}_{rc}$  is the estimate of the total frequency in table cell  $(r, c)$ ,  $\text{StdErr}(\hat{N}_{rc})$  is the standard error of the estimate, and  $t_{df, \alpha/2}$  is the  $100(1-\alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “**Degrees of Freedom**” on page 7645. The confidence level  $\alpha$  is determined by the value of the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits.

The confidence limits for row totals, column totals, and the overall total are computed similarly to the confidence limits for table cell totals.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, the “Table Summary” data set also contains the degrees of freedom  $df$  and the value of  $t_{df, \alpha/2}$  that is used to compute the confidence limits. See [Example 90.3](#) for more information about this output data set.

## Confidence Limits for Proportions

If you specify the **CL** option in the **TABLES** statement, PROC SURVEYFREQ computes confidence limits for the proportions in the frequency and crosstabulation tables.

By default, PROC SURVEYFREQ computes Wald (“linear”) confidence limits if you do not specify an alternative confidence limit type with the **CL(TYPE=)** option. In addition to Wald confidence limits, the following types of design-based confidence limits are available for proportions: modified Clopper-Pearson (exact), modified Wilson (score), and logit confidence limits.

PROC SURVEYFREQ also provides the **CL(PSMALL)** option, which uses the alternative confidence limit type for extreme (small or large) proportions and uses the Wald confidence limits for all other proportions (not extreme). For the default **PSMALL=** value of 0.25, the procedure computes Wald confidence limits for proportions between 0.25 and 0.75 and computes the alternative confidence limit type for proportions that are outside of this range. See Curtin et al. (2006).

For details about confidence limits for proportions based on complex survey data, including comparisons of their performance, see Korn and Graubard (1999, 1998); Curtin et al. (2006); Sukasih and Jang (2005). Also, in addition to the other references cited in the following sections, for information about binomial confidence limits see Brown, Cai, and DasGupta (2001); Agresti and Coull (1998).

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, the “Table Summary” data set also contains the degrees of freedom  $df$  and the value of  $t_{df, \alpha/2}$  that is used to compute the confidence limits. See [Example 90.3](#) for more information about this output data set.

**Wald Confidence Limits**

PROC SURVEYFREQ computes standard Wald (“linear”) confidence limits for proportions by default. These confidence limits use the variance estimates that are based on the sample design. For the proportion in table cell  $(r, c)$ , the Wald confidence limits are computed as

$$\widehat{P}_{rc} \pm \left( t_{df, \alpha/2} \times \text{StdErr}(\widehat{P}_{rc}) \right)$$

where  $\widehat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\text{StdErr}(\widehat{P}_{rc})$  is the standard error of the estimate, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “[Degrees of Freedom](#)” on page 7645. The confidence level  $\alpha$  is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

The confidence limits for row proportions and column proportions are computed similarly to the confidence limits for table cell proportions.

**Modified Confidence Limits**

PROC SURVEYFREQ uses the modification described in Korn and Graubard (1998) to compute design-based Clopper-Pearson (exact) and Wilson (score) confidence limits. This modification substitutes the degrees-of-freedom adjusted effective sample size for the original sample size in the confidence limit computations.

The effective sample size  $n_e$  is computed as

$$n_e = n / \text{Deff}$$

where  $n$  is the original sample size (unweighted frequency) that corresponds to the total domain of the proportion estimate, and `Deff` is the design effect.

If the proportion is computed for a table cell of a two-way table, then the domain is the two-way table, and the sample size  $n$  is the frequency of the two-way table. If the proportion is a row proportion, which is based on a two-way table row, then the domain is the row, and the sample size  $n$  is the frequency of the row.

The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. See the section “[Design Effect](#)” on page 7646 for details about how PROC SURVEYFREQ computes the design effect.

If you do not specify the `CL(ADJUST=NO)` option, the procedure applies a degrees-of-freedom adjustment to the effective sample size to compute the modified sample size. If you specify `CL(ADJUST=NO)`, the procedure does not apply the adjustment and uses the effective sample size  $n_e$  in the confidence limit computations.

The modified sample size  $n_e^*$  is computed by applying a degrees-of-freedom adjustment to the effective sample size  $n_e$  as

$$n_e^* = n_e \left( \frac{t_{(n-1), \alpha/2}}{t_{df, \alpha/2}} \right)^2$$

where  $df$  is the degrees of freedom and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom. The section “[Degrees of Freedom](#)” on page 7645 describes the computation of

the degrees of freedom  $df$ , which is based on the variance estimation method and the sample design. The confidence level  $\alpha$  is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

The design effect is usually greater than 1 for complex survey designs, and in that case the effective sample size is less than the actual sample size. If the adjusted effective sample size  $n_e^*$  is greater than the actual sample size  $n$ , then the procedure truncates the value of  $n_e^*$  to  $n$ , as recommended by Korn and Graubard (1998). If you specify the `CL(TRUNCATE=NO)` option, the procedure does not truncate the value of  $n_e^*$ .

**Modified Clopper-Pearson Confidence Limits** Clopper-Pearson (exact) confidence limits for the binomial proportion are constructed by inverting the equal-tailed test based on the binomial distribution. This method is attributed to Clopper and Pearson (1934). See Leemis and Trivedi (1996) for a derivation of the  $F$  distribution expression for the confidence limits.

PROC SURVEYFREQ computes modified Clopper-Pearson confidence limits according to the approach of Korn and Graubard (1998). The degrees-of-freedom adjusted effective sample size  $n_e^*$  is substituted for the sample size in the Clopper-Pearson computation, and the adjusted effective sample size times the proportion estimate  $n_e^* \hat{p}$  is substituted for the number of positive responses. (Or if you specify the `CL(ADJUST=NO)` option, the procedure uses the unadjusted effective sample size  $n_e$  instead of  $n_e^*$ .)

The modified Clopper-Pearson confidence limits for a proportion ( $P_L$  and  $P_U$ ) are computed as

$$P_L = \left( 1 + \frac{n_e^* - \hat{p}n_e^* + 1}{\hat{p}n_e^* F(\alpha/2, 2\hat{p}n_e^*, 2(n_e^* - \hat{p}n_e^* + 1))} \right)^{-1}$$

$$P_U = \left( 1 + \frac{n_e^* - \hat{p}n_e^*}{(\hat{p}n_e^* + 1) F(1 - \alpha/2, 2(\hat{p}n_e^* + 1), 2(n_e^* - \hat{p}n_e^*))} \right)^{-1}$$

where  $F(\alpha/2, b, c)$  is the  $\alpha/2$  percentile of the  $F$  distribution with  $b$  and  $c$  degrees of freedom,  $n_e^*$  is the adjusted effective sample size, and  $\hat{p}$  is the proportion estimate.

**Modified Wilson Confidence Limits** Wilson confidence limits for the binomial proportion are also known as score confidence limits and are attributed to Wilson (1927). The confidence limits are based on inverting the normal test that uses the null proportion in the variance (the score test). See Newcombe (1998) and Korn and Graubard (1999) for details.

PROC SURVEYFREQ computes modified Wilson confidence limits by substituting the degrees-of-freedom adjusted effective sample size  $n_e^*$  for the original sample size in the standard Wilson computation. (Or if you specify the `CL(ADJUST=NO)` option, the procedure substitutes the unadjusted effective sample size  $n_e$ .)

The modified Wilson confidence limits for a proportion are computed as

$$\left( \hat{p} + (\kappa)^2/2n_e^* \right) \pm \left( \kappa \sqrt{(\hat{p}(1 - \hat{p}) + (\kappa)^2)/4n_e^* / (1 + (\kappa)^2/n_e^*)} \right)$$

where  $n_e^*$  is the adjusted effective sample size and  $\hat{p}$  is the estimate of the proportion. With the degrees-of-freedom adjusted effective sample size  $n_e^*$ , the computation uses  $\kappa = z_{\alpha/2}$ . With the unadjusted effective sample size, which you request with the `ADJUST=NO` option, the computation uses  $\kappa = t_{df, \alpha/2}$ . See Curtin et al. (2006) for details.

### Logit Confidence Limits

If you specify the `CL(TYPE=LOGIT)` option, PROC SURVEYFREQ computes logit confidence limits for proportions. See Agresti (2002) and Korn and Graubard (1998) for more information.

Logit confidence limits for proportions are based on the logit transformation  $Y = \log(\hat{p}/(1 - \hat{p}))$ . The logit confidence limits  $P_L$  and  $P_U$  are computed as

$$P_L = \exp(Y_L) / (1 + \exp(Y_L))$$

$$P_U = \exp(Y_U) / (1 + \exp(Y_U))$$

where

$$(Y_L, Y_U) = \log(\hat{p}/(1 - \hat{p})) \pm (t_{df, \alpha/2} \times \text{StdErr}(\hat{p}) / (\hat{p}(1 - \hat{p})))$$

where  $\hat{p}$  is the estimate of the proportion,  $\text{StdErr}(\hat{p})$  is the standard error of the estimate, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom. The degrees of freedom are calculated as described in the section “Degrees of Freedom” on page 7645. The confidence level  $\alpha$  is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

### Degrees of Freedom

PROC SURVEYFREQ uses the degrees of freedom of the variance estimator to obtain the  $t$ -percentile for confidence limits for proportions, totals, and other statistics. The procedure also uses the degrees of freedom in computing the  $F$  statistics for the Rao-Scott and Wald chi-square tests.

PROC SURVEYFREQ computes the degrees of freedom based on the variance estimation method and the sample design. Alternatively, you can specify the degrees of freedom in the `DF=` option in the `TABLES` statement instead of having the procedure compute it.

For Taylor series variance estimation, PROC SURVEYFREQ calculates the degrees of freedom ( $df$ ) as the number of clusters minus the number of strata. If there are no clusters, then  $df$  equals the number of observations minus the number of strata. If the design is not stratified, then  $df$  equals the number of clusters minus one. These numbers are based on the observations included in the analysis of the individual table request. These numbers do not count observations that are excluded from the table due to missing values. See the section “Missing Values” on page 7627 for details. If you specify the `MISSING` option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the `NOMCAR` option for Taylor series variance estimation, observations with missing values of the `TABLES` variables are included in computing degrees of freedom.

If you provide replicate weights with a `REPWEIGHTS` statement, the degrees of freedom is equal the number of replicates, which is the number of `REPWEIGHTS` variables that you provide. Alternatively, you can specify the degrees of freedom in the `DF=` option in the `REPWEIGHTS` or `TABLES` statement.

For BRR variance estimation (when you do not use a `REPWEIGHTS` statement), PROC SURVEYFREQ calculates the degrees of freedom as the number of strata. PROC SURVEYFREQ bases the number of strata on all valid observations in the data set, unless you specify the `DFADJ method-option` for `VARMETHOD=BRR`. When you specify the `DFADJ` option, the procedure computes the degrees of freedom as the number of nonmissing strata for the individual table request. This excludes any empty strata that occur when observations with missing values of the `TABLES` variables are removed from the analysis for that table.

For jackknife variance estimation (when you do not use a REPWEIGHTS statement), PROC SURVEYFREQ calculates the degrees of freedom as the number of clusters minus the number of strata. If there are no clusters, then  $df$  equals the number of observations minus the number of strata. If the design is not stratified, then  $df$  equals the number of clusters minus one. For jackknife variance estimation, PROC SURVEYFREQ bases the number of strata and clusters on all valid observations in the data set, unless you specify the DFADJ *method-option* for VARMETHOD=JACKKNIFE. When you specify the DFADJ option, the procedure computes the degrees of freedom from the number of nonmissing strata and clusters for the individual table request. This excludes any empty strata or clusters that occur when observations with missing values of the TABLES variables are removed from the analysis for that table.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the table. If there are missing observations, empty strata, or empty clusters excluded from the analysis, the “Table Summary” data set also contains this information. If you request confidence limits or chi-square tests, which depend on the degrees of freedom of the variance estimator, the “Table Summary” data set provides the degrees of freedom  $df$ . See Example 90.3 for more information about this output data set.

### Coefficient of Variation

If you specify the CV option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the proportion estimates in the frequency and crosstabulation tables. The coefficient of variation is the ratio of the standard error to the estimate.

For the proportion in table cell  $(r, c)$ , the coefficient of variation is computed as

$$CV(\hat{P}_{rc}) = \text{StdErr}(\hat{P}_{rc}) / \hat{P}_{rc}$$

where  $\hat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ , and  $\text{StdErr}(\hat{P}_{rc})$  is the standard error of the estimate. The coefficients of variation for row proportions and column proportions are computed similarly.

If you specify the CVWT option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the weighted frequencies (estimated totals) in the crosstabulation tables. For the total in table cell  $(r, c)$ , the coefficient of variation is computed as

$$CV(\hat{N}_{rc}) = \text{StdErr}(\hat{N}_{rc}) / \hat{N}_{rc}$$

where  $\hat{N}_{rc}$  is the estimate of the total in table cell  $(r, c)$ , and  $\text{StdErr}(\hat{N}_{rc})$  is the standard error of the estimate. The coefficients of variation for row totals, column totals, and the overall total are computed similarly.

### Design Effect

If you specify the DEFF option in the TABLES statement, PROC SURVEYFREQ computes design effects for the overall proportion estimates in the frequency and crosstabulation tables. If you specify the ROW(DEFF) or COLUMN(DEFF) option, the procedure provides design effects for the row or column proportion estimates, respectively. The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. See Lohr (2010) and Kish (1965) for details.

For Taylor series variance estimation, PROC SURVEYFREQ computes the design effect for the proportion in table cell  $(r, c)$  as

$$\begin{aligned} \text{Deff}(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \widehat{\text{Var}}_{\text{srs}}(\widehat{P}_{rc}) \\ &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \left( (1 - f) \widehat{P}_{rc} (1 - \widehat{P}_{rc}) / (n - 1) \right) \end{aligned}$$

where  $\widehat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\widehat{\text{Var}}(\widehat{P}_{rc})$  is the variance of the estimate,  $f$  is the overall sampling fraction, and  $n$  is the sample size (unweighted frequency) for the two-way table.

For Taylor series variance estimation, PROC SURVEYFREQ determines the value of  $f$ , the overall sampling fraction, based on the **RATE=** or **TOTAL=** option. If you do not specify either of these options, PROC SURVEYFREQ assumes the value of  $f$  is negligible and does not use a finite population correction in the analysis, as described in the section “Population Totals and Sampling Rates” on page 7626. If you specify **RATE=value**, PROC SURVEYFREQ uses this value as the overall sampling fraction  $f$ . If you specify **TOTAL=value**, PROC SURVEYFREQ computes  $f$  as the ratio of the number of PSUs in the sample to the specified total.

If you specify stratum sampling rates with the **RATE=SAS-data-set** option, then PROC SURVEYFREQ computes stratum totals based on these stratum sampling rates and the number of sample PSUs in each stratum. The procedure sums the stratum totals to form the overall total, and computes  $f$  as the ratio of the number of sample PSUs to the overall total. Alternatively, if you specify stratum totals with the **TOTAL=SAS-data-set** option, then PROC SURVEYFREQ sums these totals to compute the overall total. The overall sampling fraction  $f$  is then computed as the ratio of the number of sample PSUs to the overall total.

For BRR and jackknife variance estimation, PROC SURVEYFREQ computes the design effect for the proportion in table cell  $(r, c)$  as

$$\begin{aligned} \text{Deff}(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \widehat{\text{Var}}_{\text{srs}}(\widehat{P}_{rc}) \\ &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \left( \widehat{P}_{rc} (1 - \widehat{P}_{rc}) / (n - 1) \right) \end{aligned}$$

where  $\widehat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\widehat{\text{Var}}(\widehat{P}_{rc})$  is the variance of the estimate, and  $n$  is the sample size (unweighted frequency) for the two-way table. This computation does not include the overall sampling fraction.

The procedure computes design effects similarly for proportions in one-way frequency tables, and also for row and column proportions in two-way tables. In these design effect computations, the value of  $n$  is the sample size (unweighted frequency) that corresponds to the total domain of the proportion estimate. For table cell proportions of a two-way table, the domain is the two-way table and the sample size  $n$  is the frequency of the two-way table. For row proportions, which are based on a two-way table row, the domain is the row and the sample size  $n$  is the frequency of the row.

## Expected Weighted Frequency

If you specify the **EXPECTED** option in the **TABLES** statement, PROC SURVEYFREQ computes expected weighted frequencies for the table cells in two-way tables. The expected weighted frequencies are computed

under the null hypothesis that the row and column variables are independent. The expected weighted frequency for table cell  $(r, c)$  equals

$$E_{rc} = \hat{N}_{r.} \hat{N}_{.c} / \hat{N}$$

where  $\hat{N}_{r.}$  is the estimated total for row  $r$ ,  $\hat{N}_{.c}$  is the estimated total for column  $c$ , and  $\hat{N}$  is the estimated overall total. Equivalently, the expected weighted frequency can be expressed as

$$E_{rc} = \hat{P}_{r.} \hat{P}_{.c} \hat{N}$$

These expected values are used in the design-based chi-square tests of independence, as described in the sections “Rao-Scott Chi-Square Test” on page 7652 and “Wald Chi-Square Test” on page 7659.

## Risks and Risk Difference

The **RISK** option provides estimates of risks (binomial proportions) and risk differences for  $2 \times 2$  tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk, row 2 risk, overall risk, and risk difference. If you specify the **RISK** option, PROC SURVEYFREQ provides both column 1 and column 2 risks. You can request only column 1 (or only column 2) risks by specifying the **RISK1** (or **RISK2**) option.

The column 1 risk for row 1 is the row 1 proportion for table cell (1,1). The column 1 risk estimate is computed as the ratio of the estimated total for table cell (1,1) to the estimated total for row 1,

$$\hat{P}_{11}^{(1)} = \hat{N}_{11} / \hat{N}_{1.}$$

where the total estimates are computed as described in the section “Totals” on page 7632. The column 1 risk for row 2 is the row 2 proportion for table cell (2,1), which is estimated as

$$\hat{P}_{21}^{(2)} = \hat{N}_{21} / \hat{N}_{2.}$$

The overall column 1 risk is the overall proportion in column 1, and its estimate is computed as

$$\hat{P}_{.1} = \hat{N}_{.1} / \hat{N}$$

The column 2 risk estimates are computed similarly.

The row 1 and row 2 risks are the same as the row proportions for a  $2 \times 2$  table, and their variances are computed as described in the section “Row and Column Proportions” on page 7635. The overall risk is the overall proportion in the column, and its variance computation is described in the section “Proportions” on page 7634. Confidence limits for the column 1 risk for row 1 are computed as

$$\hat{P}_{11}^{(1)} \pm \left( t_{df, \alpha/2} \times \text{StdErr}(\hat{P}_{11}^{(1)}) \right)$$

where  $\text{StdErr}(\hat{P}_{11}^{(1)})$  is the standard error of the risk estimate, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “Degrees of Freedom” on page 7645. The value of the confidence coefficient  $\alpha$  is determined by the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits. Confidence limits for the other risks are computed similarly.

The risk difference is defined as the row 1 risk minus the row 2 risk. The estimate of the column 1 risk difference  $\widehat{RD}_1$  is computed as

$$\begin{aligned}\widehat{RD}_1 &= \widehat{P}_{11}^{(1)} - \widehat{P}_{21}^{(2)} \\ &= \left( \widehat{N}_{11} / \widehat{N}_{1\cdot} \right) - \left( \widehat{N}_{21} / \widehat{N}_{2\cdot} \right)\end{aligned}$$

The column 2 risk difference is computed similarly.

PROC SURVEYFREQ estimates the variance of the risk difference by using the variance estimation method that you request. If you request BRR variance estimation (**VARMETHOD=BRR**), the procedure estimates the variance as described in the section “Balanced Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (**VARMETHOD=JACKKNIFE**), the procedure estimates the variance as described in the section “The Jackknife Method” on page 7640.

If you do not specify the **VARMETHOD=** option or a **REPWEIGHTS** statement, the default variance estimation method is Taylor series (**VARMETHOD=TAYLOR**). By using Taylor series linearization, the variance estimate for the column 1 risk difference  $\widehat{\text{Var}}(\widehat{RD}_1)$  can be expressed as

$$\widehat{\text{Var}}(\widehat{RD}_1) = \widehat{\mathbf{D}} \widehat{\mathbf{V}}(\widehat{\mathbf{X}}) \widehat{\mathbf{D}}'$$

where  $\widehat{\mathbf{V}}(\widehat{\mathbf{X}})$  is the covariance matrix of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{X}} = \left( \widehat{N}_{11}, \widehat{N}_{1\cdot}, \widehat{N}_{21}, \widehat{N}_{2\cdot} \right)$$

and  $\widehat{\mathbf{D}}$  is an array that contains the partial derivatives of the risk difference with respect to the elements of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{D}} = \left( 1/\widehat{N}_{1\cdot}, -\widehat{N}_{11}/\widehat{N}_{1\cdot}^2, -1/\widehat{N}_{2\cdot}, -\widehat{N}_{21}/\widehat{N}_{2\cdot}^2 \right)$$

See Wolter (1985, pp. 239–242) for details. The variance estimate for the column 2 risk difference is computed similarly.

The standard error of the column 1 risk difference is

$$\text{StdErr}(\widehat{RD}_1) = \sqrt{\widehat{\text{Var}}(\widehat{RD}_1)}$$

Confidence limits for the column 1 risk difference are computed as

$$\widehat{RD}_1 \pm \left( t_{df, \alpha/2} \times \text{StdErr}(\widehat{RD}_1) \right)$$

where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “Degrees of Freedom” on page 7645. The value of the confidence coefficient  $\alpha$  is determined by the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits. Confidence limits for the column 2 risk difference are computed in the same way.

## Odds Ratio and Relative Risks

The OR option provides estimates of the odds ratio, the column 1 relative risk, and the column 2 relative risk for  $2 \times 2$  tables, together with their confidence limits.

### Odds Ratio

For a  $2 \times 2$  table, the odds of a positive (column 1) response in row 1 is  $N_{11}/N_{12}$ . Similarly, the odds of a positive response in row 2 is  $N_{21}/N_{22}$ . The odds ratio is formed as the ratio of the row 1 odds to the row 2 odds. The estimate of the odds ratio is computed as

$$\widehat{OR} = \frac{\widehat{N}_{11} / \widehat{N}_{12}}{\widehat{N}_{21} / \widehat{N}_{22}} = \frac{\widehat{N}_{11} \widehat{N}_{22}}{\widehat{N}_{12} \widehat{N}_{21}}$$

The value of the odds ratio can be any nonnegative number. When the row and column variables are independent, the true value of the odds ratio equals 1. An odds ratio greater than 1 indicates that the odds of a positive response are higher in row 1 than in row 2. An odds ratio less than 1 indicates that the odds of positive response are higher in row 2. The strength of association increases with the deviation from 1. For details, see Stokes, Davis, and Koch (2000); Agresti (2007).

PROC SURVEYFREQ constructs confidence limits for the odds ratio by using the log transform. The  $100(1 - \alpha)\%$  confidence limits for the odds ratio are computed as

$$\left( \widehat{OR} \times \exp(-t_{df, \alpha/2} \sqrt{v}), \widehat{OR} \times \exp(t_{df, \alpha/2} \sqrt{v}) \right)$$

where

$$v = \widehat{\text{Var}}(\ln \widehat{OR}) = \widehat{\text{Var}}(\widehat{OR}) / \widehat{OR}^2$$

is the estimate of the variance of the log odds ratio, and where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom. The computation of  $df$  is described in the section “Degrees of Freedom” on page 7645. The value of the confidence coefficient  $\alpha$  is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variance of the odds ratio as described in the section “Balanced Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section “The Jackknife Method” on page 7640.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the odds ratio can be expressed as

$$\widehat{\text{Var}}(\widehat{OR}) = \widehat{\mathbf{D}} \widehat{\mathbf{V}}(\widehat{\mathbf{N}}) \widehat{\mathbf{D}}'$$

where  $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$  is the covariance matrix of the estimates of the cell totals  $\widehat{\mathbf{N}}$ ,

$$\widehat{\mathbf{N}} = \begin{pmatrix} \widehat{N}_{11} & \widehat{N}_{12} & \widehat{N}_{21} & \widehat{N}_{22} \end{pmatrix}$$

and  $\widehat{\mathbf{D}}$  is an array that contains the partial derivatives of the odds ratio with respect to the elements of  $\widehat{\mathbf{N}}$ . The section “Covariance of Totals” on page 7633 describes the computation of  $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$ . The array  $\widehat{\mathbf{D}}$  is computed as

$$\widehat{\mathbf{D}} = \left( \widehat{N}_{22}/(\widehat{N}_{12}\widehat{N}_{21}), \quad -\widehat{N}_{11}\widehat{N}_{22}/(\widehat{N}_{21}\widehat{N}_{12}^2), \quad -\widehat{N}_{11}\widehat{N}_{22}/(\widehat{N}_{12}\widehat{N}_{21}^2), \quad \widehat{N}_{11}/(\widehat{N}_{12}\widehat{N}_{21}) \right)$$

See Wolter (1985, pp. 239–242) for more information.

### Relative Risks

For a  $2 \times 2$  table, the column 1 relative risk is the ratio of the column 1 risks for row 1 to row 2. As described in the section “Risks and Risk Difference” on page 7648, the column 1 risk for row 1 is the proportion of row 1 observations classified in column 1, and the column 1 risk for row 2 is the proportion of row 2 observations classified in column 1. The estimate of the column 1 relative risk is computed as

$$\widehat{RR}_1 = \frac{\widehat{N}_{11} / \widehat{N}_{1.}}{\widehat{N}_{21} / \widehat{N}_{2.}}$$

Similarly, the estimate of the column 2 relative risk is computed as

$$\widehat{RR}_2 = \frac{\widehat{N}_{12} / \widehat{N}_{1.}}{\widehat{N}_{22} / \widehat{N}_{2.}}$$

A relative risk greater than 1 indicates that the probability of positive response is greater in row 1 than in row 2. Similarly, a relative risk less than 1 indicates that the probability of positive response is less in row 1 than in row 2. The strength of association increases with the deviation from 1. For more information, see Stokes, Davis, and Koch (2000); Agresti (2007).

PROC SURVEYFREQ constructs confidence limits for the relative risk by using the log transform, which is similar to the odds ratio computations described previously. The  $100(1 - \alpha)\%$  confidence limits for the column 1 relative risk are computed as

$$\left( \widehat{RR}_1 \times \exp(-t_{df, \alpha/2} \sqrt{v}), \widehat{RR}_1 \times \exp(t_{df, \alpha/2} \sqrt{v}) \right)$$

where

$$v = \widehat{\text{Var}}(\ln \widehat{RR}_1) = \widehat{\text{Var}}(\widehat{RR}_1) / \widehat{RR}_1^2$$

is the estimate of the variance of the log column 1 relative risk, and where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$  percentile of the  $t$  distribution with  $df$  degrees of freedom. The computation of  $df$  is described in the section “Degrees of Freedom” on page 7645. The value of the confidence coefficient  $\alpha$  is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variance of the column 1 relative risk as described in the section “Balanced Repeated Replication (BRR)” on page 7637. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section “The Jackknife Method” on page 7640.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the column 1 relative risk can be expressed as

$$\widehat{\text{Var}}(\widehat{RR}_1) = \widehat{\mathbf{D}} \widehat{\mathbf{V}}(\widehat{\mathbf{X}}) \widehat{\mathbf{D}}'$$

where  $\widehat{\mathbf{V}}(\widehat{\mathbf{X}})$  is the covariance matrix of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{X}} = \left( \widehat{N}_{11}, \widehat{N}_{1.}, \widehat{N}_{21}, \widehat{N}_{2.} \right)$$

and  $\widehat{\mathbf{D}}$  is an array that contains the partial derivatives of the column 1 relative risk with respect to the elements of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{D}} = \left( \widehat{N}_{2.}/(\widehat{N}_{21}\widehat{N}_{1.}), -\widehat{N}_{11}\widehat{N}_{2.}/(\widehat{N}_{21}\widehat{N}_{1.}^2), -\widehat{N}_{11}\widehat{N}_{2.}/(\widehat{N}_{1.}\widehat{N}_{21}^2), \widehat{N}_{11}/(\widehat{N}_{21}\widehat{N}_{1.}) \right)$$

See Wolter (1985, pp. 239–242) for more information.

Confidence limits for the column 2 relative risk are computed similarly.

## Rao-Scott Chi-Square Test

The Rao-Scott chi-square test is a design-adjusted version of the Pearson chi-square test, which involves differences between observed and expected frequencies. For information about design-adjusted chi-square tests, see Lohr (2010, Section 10.3.2), Rao and Scott (1981, 1984, 1987); Thomas, Singh, and Roberts (1996).

PROC SURVEYFREQ provides a first-order Rao-Scott chi-square test by default. If you specify the **CHISQ(SECONDORDER)** option, PROC SURVEYFREQ provides a second-order (Satterthwaite) Rao-Scott chi-square test. The first-order design correction depends only on the design effects of the table cell proportion estimates and, for two-way tables, the design effects of the marginal proportion estimates. The second-order design correction requires computation of the full covariance matrix of the proportion estimates. The second-order test requires more computational resources than the first-order test, but it can provide some performance advantages (for Type I error and power), particularly when the design effects are variable (Thomas and Rao 1987; Rao and Thomas 1989).

### One-Way Tables

For one-way tables, the CHISQ option provides a Rao-Scott (design-based) goodness-of-fit test for one-way tables. By default, this is a test for the null hypothesis of equal proportions. If you specify null hypothesis proportions in the **TESTP=** option, the goodness-of-fit test uses the specified proportions.

**First-Order Test** The first-order Rao-Scott chi-square statistic for the goodness-of-fit test is computed as

$$Q_{RS1} = Q_P / D$$

where  $Q_P$  is the Pearson chi-square based on the estimated totals and  $D$  is the first-order design correction described in the section “[First-Order Design Correction](#)” on page 7653. See Rao and Scott (1979, 1981, 1984) for details.

For a one-way table with  $C$  levels, the Pearson chi-square is computed as

$$Q_P = (n/\hat{N}) \sum_c (\hat{N}_c - E_c)^2 / E_c$$

where  $n$  is the sample size,  $\hat{N}$  is the estimated overall total,  $\hat{N}_c$  is the estimated total for level  $c$ , and  $E_c$  is the expected total for level  $c$  under the null hypothesis. For the null hypothesis of equal proportions, the expected total for each level is

$$E_c = \hat{N} / C$$

For specified null proportions, the expected total for level  $c$  equals

$$E_c = \hat{N} \times P_c^0$$

where  $P_c^0$  is the null proportion that you specify for level  $c$ .

Under the null hypothesis, the first-order Rao-Scott chi-square  $Q_{RS1}$  approximately follows a chi-square distribution with  $(C - 1)$  degrees of freedom. A better approximation can be obtained by the  $F$  statistic,

$$F_1 = Q_{RS1} / (C - 1)$$

which has an  $F$  distribution with  $(C - 1)$  and  $\kappa(C - 1)$  degrees of freedom under the null hypothesis (Thomas and Rao 1984, 1987). The value of  $\kappa$  is the degrees of freedom for the variance estimator, which depends on the sample design and the variance estimation method. The section “[Degrees of Freedom](#)” on page 7645 describes the computation of  $\kappa$ .

**First-Order Design Correction** By default for one-way tables, the first-order design correction is computed from the proportion estimates as

$$D = \sum_c (1 - \hat{P}_c) \text{Deff}(\hat{P}_c) / (C - 1)$$

where

$$\begin{aligned} \text{Deff}(\hat{P}_c) &= \widehat{\text{Var}}(\hat{P}_c) / \text{Var}_{\text{srs}}(\hat{P}_c) \\ &= \widehat{\text{Var}}(\hat{P}_c) / \left( (1 - f) \hat{P}_c (1 - \hat{P}_c) / (n - 1) \right) \end{aligned}$$
