## Overview: SURVEYFREQ Procedure

The SURVEYFREQ procedure produces one-way to  $n$ -way frequency and crosstabulation tables from sample survey data. These tables include estimates of population totals, population proportions, and their standard errors. Confidence limits, coefficients of variation, and design effects are also available. The procedure provides a variety of options to customize the table display.

For one-way frequency tables, PROC SURVEYFREQ provides Rao-Scott chi-square goodness-of-fit tests, which are adjusted for the sample design. You can test a null hypothesis of equal proportions for a one-way frequency table, or you can input custom null hypothesis proportions for the test. For two-way tables, PROC SURVEYFREQ provides design-adjusted tests of independence, or no association, between the row and column variables. These tests include the Rao-Scott chi-square test, the Rao-Scott likelihood ratio test, the Wald chi-square test, and the Wald log-linear chi-square test. For  $2 \times 2$  tables, PROC SURVEYFREQ computes estimates and confidence limits for risks (row proportions), the risk difference, the odds ratio, and relative risks.

PROC SURVEYFREQ computes variance estimates based on the sample design used to obtain the survey data. The design can be a complex multistage survey design with stratification, clustering, and unequal weighting. PROC SURVEYFREQ provides a choice of variance estimation methods, which include Taylor series linearization, balanced repeated replication (BRR), and the jackknife.

PROC SURVEYFREQ now uses ODS Graphics to create graphs as part of its output. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS](#).” For specific information about the statistical graphics available with the SURVEYFREQ procedure, see the [PLOTS](#) option in the TABLES statement and the section “[ODS Graphics](#)” on page 7129.

---

## Getting Started: SURVEYFREQ Procedure

The following example shows how you can use PROC SURVEYFREQ to analyze sample survey data. The example uses data from a customer satisfaction survey for a student information system (SIS), which is a software product that provides modules for student registration, class scheduling, attendance, grade reporting, and other functions.

The software company conducted a survey of school personnel who use the SIS. A probability sample of SIS users was selected from the study population, which included SIS users at middle schools and high schools in the three-state area of Georgia, South Carolina, and North Carolina. The sample design for this survey was a two-stage stratified design. A first-stage sample of schools was selected from the list of schools in the three-state area that use the SIS. The list of schools (the first-stage sampling frame) was stratified by state and by customer status (whether the school was a new user of the system or a renewal user). Within the first-stage strata, schools were selected with probability proportional to size and with replacement, where the size measure was school enrollment. From each sample school, five staff members were randomly selected to complete the SIS satisfaction questionnaire. These staff members included three teachers and two administrators or guidance department members.

The SAS data set `SIS_Survey` contains the survey results, as well as the sample design information needed to analyze the data. This data set includes an observation for each school staff member responding to the survey. The variable `Response` contains the staff member's response about overall satisfaction with the system.

The variable `State` contains the school's state, and the variable `NewUser` contains the school's customer status ('New Customer' or 'Renewal Customer'). These two variables determine the first-stage strata from which schools were selected. The variable `School` contains the school identification code and identifies the first-stage sampling units (clusters). The variable `SamplingWeight` contains the overall sampling weight for each respondent. Overall sampling weights were computed from the selection probabilities at each stage of sampling and were adjusted for nonresponse.

Other variables in the data set `SIS_Survey` include `SchoolType` and `Department`. The variable `SchoolType` identifies the school as a high school or a middle school. The variable `Department` identifies the staff member as a teacher, or an administrator or guidance department member.

The following PROC SURVEYFREQ statements request a one-way frequency table for the variable `Response`:

```
title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey;
  tables Response;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

The PROC SURVEYFREQ statement invokes the procedure and identifies the input data set to be analyzed. The TABLES statement requests a one-way frequency table for the variable `Response`.

The table request syntax for PROC SURVEYFREQ is very similar to the table request syntax for PROC FREQ. This example shows a request for a single one-way table, but you can also request two-way tables and multiway tables. As in PROC FREQ, you can request more than one table in the same TABLES statement, and you can use multiple TABLES statements in the same invocation of the procedure.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information for the procedure, so that the analysis is done according to the sample design used for the survey, and the estimates apply to the study population. The STRATA statement names the variables State and NewUser, which identify the first-stage strata. Note that the design for this example also includes stratification at the second stage of selection (by type of school personnel), but you specify only the first-stage strata for PROC SURVEYFREQ. The CLUSTER statement names the variable School, which identifies the clusters (primary sampling units). The WEIGHT statement names the sampling weight variable.

Figure 84.1 and Figure 84.2 display the output produced by PROC SURVEYFREQ, which includes the “Data Summary” table and the one-way table, “Table of Response.” The “Data Summary” table is produced by default unless you specify the NOSUMMARY option. This table shows there are 6 strata, 370 clusters or schools, and 1850 observations (respondents) in the SIS\_Survey data set. The sum of the sampling weights is approximately 39,000, which estimates the total number of school personnel in the study area that use the SIS.

**Figure 84.1** SIS\_Survey Data Summary

Student Information System Survey	
The SURVEYFREQ Procedure	
Data Summary	
Number of Strata	6
Number of Clusters	370
Number of Observations	1850
Sum of Weights	38899.6482

Figure 84.2 displays the one-way table of Response, which provides estimates of the population total (weighted frequency) and the population percentage for each category (level) of the variable Response. The response level ‘Very Unsatisfied’ has a frequency of 304, which means that 304 sample respondents fall into this category. It is estimated that 17.17% of all school personnel in the study population fall into this category, and the standard error of this estimate is 1.29%. Note that the estimates apply to the population of all SIS users in the study area, as opposed to describing only the sample of 1850 respondents. The estimate of the total number of school personnel that are ‘Very Unsatisfied’ is 6,678, with a standard deviation of 502. The standard errors computed by PROC SURVEYFREQ are based on the multistage stratified design of the survey. This differs from some of the traditional analysis procedures, which assume the design is simple random sampling from an infinite population.

**Figure 84.2** One-Way Table of Response

Table of Response					
Response	Frequency	Weighted Frequency	Std Dev of Wgt Freq	Percent	Std Err of Percent
Very Unsatisfied	304	6678	501.61039	17.1676	1.2872
Unsatisfied	326	6907	495.94101	17.7564	1.2712
Neutral	581	12291	617.20147	31.5965	1.5795
Satisfied	455	9309	572.27868	23.9311	1.4761
Very Satisfied	184	3714	370.66577	9.5483	0.9523
Total	1850	38900	129.85268	100.000	

The following PROC SURVEYFREQ statements request confidence limits for the percentages and a chi-square goodness-of-fit test for the one-way table of Response. The ODS GRAPHICS ON statement enables ODS Graphics.

```

title 'Student Information System Survey';
ods graphics on;
proc surveyfreq data=SIS_Survey nosummary;
  tables Response / clwt nopct chisq;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
ods graphics off;

```

The NOSUMMARY option in the PROC statement suppresses the “Data Summary” table. In the TABLES statement, the CLWT option requests confidence limits for the weighted frequencies (totals). The NOPCT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square goodness-of-fit test.

Figure 84.3 shows the one-way table of Response, which includes confidence limits for the weighted frequencies. The 95% confidence limits for the total number of users that are ‘Very Unsatisfied’ are 5692 and 7665. To change the  $\alpha$  level of the confidence limits, which equals 5% by default, you can use the ALPHA= option. Like the other estimates and standard errors produced by PROC SURVEYFREQ, these confidence limit computations take into account the complex survey design and apply to the entire study population.

Figure 84.4 displays the weighted frequency plot of Response. By default, PROC SURVEYFREQ produces a weighted frequency plot for each table request when you have enabled ODS Graphics. The plot displays weighted frequencies (totals) together with their confidence limits in the form of a vertical bar chart. You can use the PLOTS= option in the TABLES statement to request a dot plot instead of a bar chart or to plot percentages instead of weighted frequencies.

**Figure 84.3** Confidence Limits for Response Totals

Student Information System Survey					
The SURVEYFREQ Procedure					
Table of Response					
Response	Frequency	Weighted Frequency	Std Dev of Wgt Freq	95% Confidence Limits for Wgt Freq	
Very Unsatisfied	304	6678	501.61039	5692	7665
Unsatisfied	326	6907	495.94101	5932	7882
Neutral	581	12291	617.20147	11077	13505
Satisfied	455	9309	572.27868	8184	10435
Very Satisfied	184	3714	370.66577	2985	4443
Total	1850	38900	129.85268	38644	39155

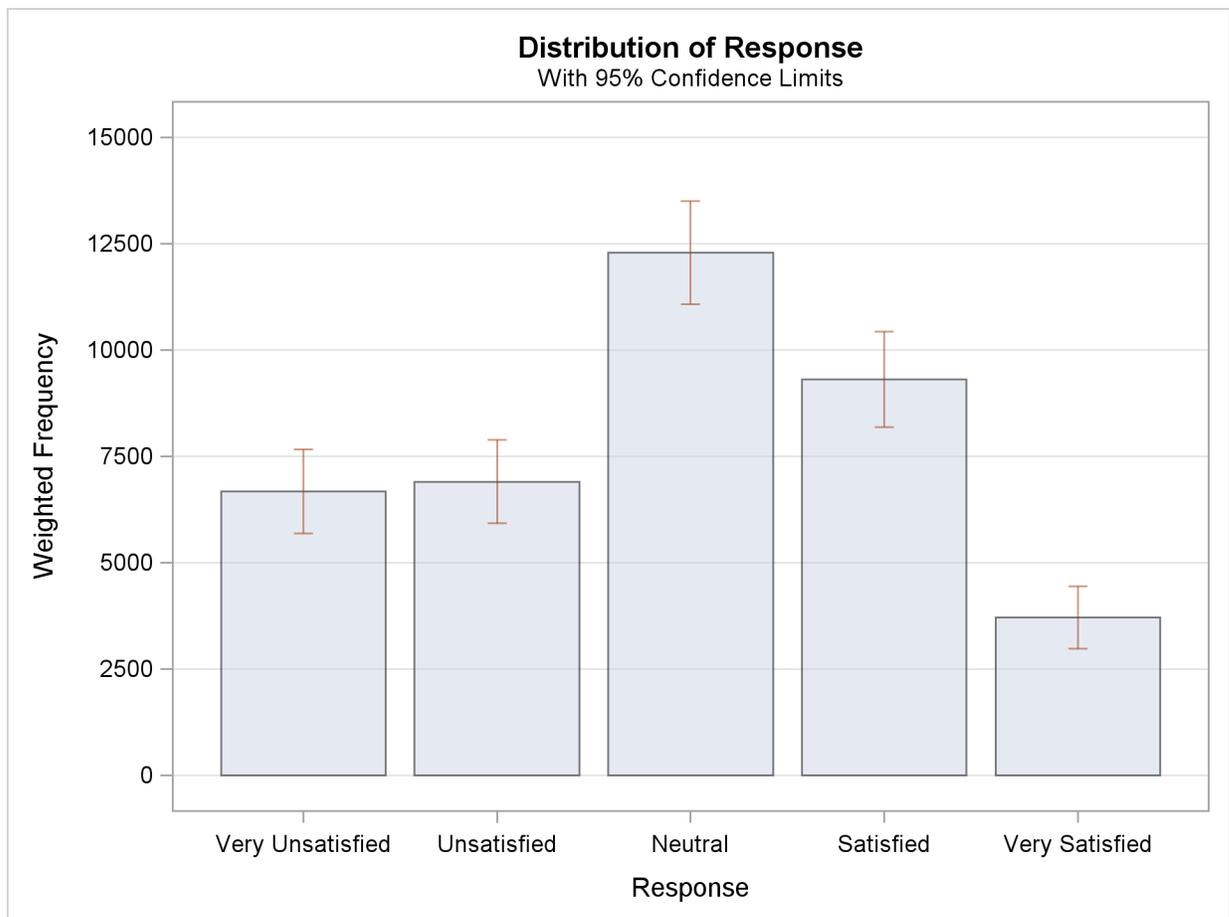

**Figure 84.4** Bar Chart of Response Totals

Figure 84.5 shows the chi-square goodness-of-fit results for the table of Response. The null hypothesis for this test is equal proportions for the levels of the one-way table. (To test a null hypothesis of specified proportions instead of equal proportions, you can use the TESTP= option to specify null hypothesis proportions.)

The chi-square test provided by the CHISQ option is the Rao-Scott design-adjusted chi-square test, which takes the sample design into account and provides inferences for the study population. To produce the Rao-Scott chi-square statistic, PROC SURVEYFREQ first computes the usual Pearson chi-square statistic based on the weighted frequencies, and then adjusts this value with a design correction. An  $F$  approximation is also provided. For the table of Response, the  $F$  value is 30.0972 with a  $p$ -value of  $<0.0001$ , which indicates rejection of the null hypothesis of equal proportions for all response levels.

**Figure 84.5** Chi-Square Goodness-of-Fit Test for Response

Rao-Scott Chi-Square Test	
Pearson Chi-Square	251.8105
Design Correction	2.0916
Rao-Scott Chi-Square	120.3889
DF	4
Pr > ChiSq	<.0001
F Value	30.0972
Num DF	4
Den DF	1456
Pr > F	<.0001
Sample Size = 1850	

Continuing to analyze the SIS\_Survey data, the following PROC SURVEYFREQ statements request a two-way table of SchoolType by Response:

```

title 'Student Information System Survey';
ods graphics on;
proc surveyfreq data=SIS_Survey nosummary;
  tables SchoolType * Response / plots=wtfreqplot(type=dot scale=percent);
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
ods graphics off;

```

The STRATA, CLUSTER, and WEIGHT statements do not change from the one-way table analysis, because the sample design and the input data set are the same. These SURVEYFREQ statements request a different table but specify the same sample design information.

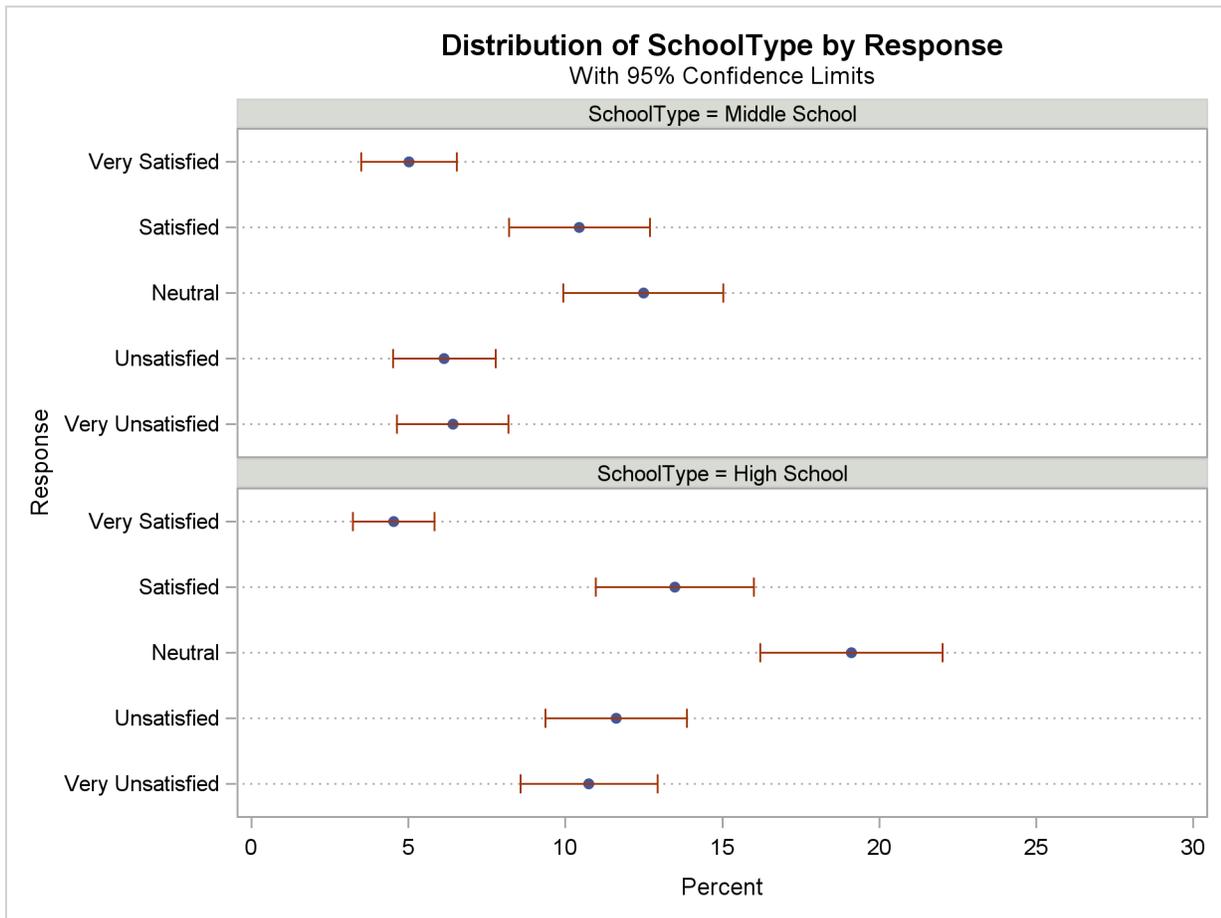

The ODS GRAPHICS ON statement enables ODS Graphics. The PLOTS= option in the TABLES statement requests a plot of SchoolType by Response, and the TYPE=DOT *plot-option* specifies a dot plot instead of the default bar chart. The SCALE=PERCENT *plot-option* requests a plot of percentages instead of totals.

Figure 84.6 shows the two-way table produced for SchoolType by Response. The first variable named in the two-way table request, SchoolType, is referred to as the *row variable*, and the second variable, Response, is referred to as the *column variable*. Two-way tables display all column variable levels for each row variable level. This two-way table lists all levels of the column variable Response for each level of the row variable SchoolType, ‘Middle School’ and ‘High School’. Also SchoolType = ‘Total’ shows the distribution of Response overall for both types of schools. And Response = ‘Total’ provides totals over all levels of response, for each type of school and overall. To suppress these totals, you can specify the NOTOTAL option.

**Figure 84.6** Two-Way Table of SchoolType by Response

Student Information System Survey

	Very Satisfied	90	1762	255.67158	4.5290	0.6579
	Total		1100	23142	1003	59.4911
Total	Very Unsatisfied	304	6678	501.61039	17.1676	1.2872
	Unsatisfied	326	6907	495.94101	17.7564	1.2712
	Neutral	581	12291	617.20147	31.5965	1.5795
	Satisfied	455	9309	572.27868	23.9311	1.4761
	Very Satisfied	184	3714	370.66577	9.5483	0.9523
	Total		1850	38900	129.85268	100.000

Figure 84.7 displays the weighted frequency dot plot that PROC SURVEYFREQ produces for the table of SchoolType by Response. You can plot percentages instead of weighted frequencies by specifying the SCALE=PERCENT *plot-option*. You can use other *plot-options* to change the orientation of the plot or to request a different two-way layout.

**Figure 84.7** Dot Plot of Percentages for SchoolType by Response

By default, without any other TABLES statement options, a two-way table displays the frequency, the weighted frequency and its standard deviation, and the percentage and its standard error for each table cell (combination of row and column variable levels). But there are several options available to customize your table display by adding more information or by suppressing some of the default information.

The following PROC SURVEYFREQ statements request a two-way table of SchoolType by Response that displays row percentages, and also request a chi-square test of association between the two variables:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey nosummary;
  tables SchoolType * Response / row nowt chisq;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;

```

The ROW option in the TABLES statement requests row percentages, which give the distribution of Response within each level of the row variable SchoolType. The NOWT option suppresses display of the weighted frequencies and their standard deviations. The CHISQ option requests a Rao-Scott chi-square test of association between SchoolType and Response.

Figure 84.8 displays the two-way table of SchoolType by Response. For middle schools, it is estimated that 25.79% of school personnel are satisfied with the student information system and 12.39% are very satisfied. For high schools, these estimates are 22.67% and 7.61%, respectively.

Figure 84.9 displays the chi-square test results. The Rao-Scott chi-square statistic equals 9.04, and the corresponding  $F$  value is 2.26 with a  $p$ -value of 0.0605. This indicates an association between school type (middle school or high school) and satisfaction with the student information system at the 10% significance level.

**Figure 84.8** Two-Way Table with Row Percentages

## Syntax: SURVEYFREQ Procedure

The following statements are available in PROC SURVEYFREQ:

```

PROC SURVEYFREQ < options > ;
  BY variables ;
  CLUSTER variables ;
  REPWEIGHTS variables < / options > ;
  STRATA variables < / option > ;
  TABLES requests < / options > ;
  WEIGHT variable ;

```

The PROC SURVEYFREQ statement invokes the procedure, identifies the data set to be analyzed, and specifies the variance estimation method. The PROC SURVEYFREQ statement is required.

The TABLES statement specifies frequency or crosstabulation tables and requests tests and statistics for those tables. The STRATA statement lists the variables that form the strata in a stratified sample design. The CLUSTER statement specifies cluster identification variables in a clustered sample design. The WEIGHT statement names the sampling weight variable. The REPWEIGHTS statement names replicate weight variables for BRR or jackknife variance estimation. The BY statement requests completely separate analyses of groups defined by the BY variables.

All statements can appear multiple times except the PROC SURVEYFREQ statement and the WEIGHT statement, which can appear only once.

The rest of this section gives detailed syntax information for the BY, CLUSTER, REPWEIGHTS, STRATA, TABLES, and WEIGHT statements in alphabetical order after the description of the PROC SURVEYFREQ statement.

---

## PROC SURVEYFREQ Statement

**PROC SURVEYFREQ** < options > ;

The PROC SURVEYFREQ statement invokes the procedure. In this statement, you identify the data set to be analyzed, specify the variance estimation method, and provide sample design information. The **DATA=** option names the input data set to be analyzed. The **VARMETHOD=** option specifies the variance estimation method, which is the Taylor series method by default. For Taylor series variance estimation, you can include a finite population correction factor in the analysis by providing either the sampling rate or population total with the **RATE=** or **TOTAL=** option. If your design is stratified, with different sampling rates or totals for different strata, then you can input these stratum rates or totals in a SAS data set that contains the stratification variables.

You can specify the following options in the PROC SURVEYFREQ statement:

### **DATA=SAS-data-set**

names the SAS data set to be analyzed by PROC SURVEYFREQ. If you omit the **DATA=** option, the procedure uses the most recently created SAS data set.

### **MISSING**

treats missing values as a valid (nonmissing) category for all categorical variables, which include **TABLES**, **STRATA**, and **CLUSTER** variables.

By default, if you do not specify the **MISSING** option, an observation is excluded from the analysis if it has a missing value for any **STRATA** or **CLUSTER** variable. Additionally, PROC SURVEYFREQ excludes an observation from a frequency or crosstabulation table if that observation has a missing value for any of the variables in the table request, unless you specify the **MISSING** option. For more information, see the section “[Missing Values](#)” on page 7087.

### **NOMCAR**

includes observations with missing values of **TABLES** variables in the variance computation as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. When you specify the **NOMCAR** option, PROC SURVEYFREQ computes variance estimates by analyzing the nonmissing values as a domain (subpopulation), where the entire population includes both nonmissing and missing domains. See the section “[Missing Values](#)” on page 7087 for details.

By default, PROC SURVEYFREQ completely excludes an observation from a frequency or crosstabulation table (and the corresponding variance computations) if that observation has a missing value for any of the variables in the table request, unless you specify the **MISSING** option. Note that the **NOMCAR** option has no effect when you specify the **MISSING** option, which treats missing values as a valid nonmissing level.

The **NOMCAR** option applies only to Taylor series variance estimation. The replication methods, which you request with the **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** options, do not use the **NOMCAR** option.

### **NOSUMMARY**

suppresses the display of the “Data Summary” table, which PROC SURVEYFREQ produces by default. For details about this table, see the section “[Data Summary Table](#)” on page 7122.

**ORDER=DATA | FORMATTED | FREQ | INTERNAL**

specifies the order of the variable levels in the frequency and crosstabulation tables, which you request in the **TABLES** statement. The **ORDER=** option also controls the order of the **STRATA** variable levels in the Stratum Information table.

The **ORDER=** option can take the following values:

<b>ORDER=</b>	<b>Levels Ordered By</b>
DATA	Order of appearance in the input data set
FORMATTED	External formatted value, except for numeric variables with no explicit format, which are sorted by their unformatted (internal) value
FREQ	Descending frequency count; levels with the most observations come first in the order
INTERNAL	Unformatted value

By default, **ORDER=INTERNAL**. The **FORMATTED** and **INTERNAL** orders are machine-dependent. Note that the frequency count used by **ORDER=FREQ** is the nonweighted frequency (sample size), rather than the weighted frequency.

For more information about sorting order, see the chapter on the **SORT** procedure in the *Base SAS Procedures Guide* and the discussion of BY-group processing in *SAS Language Reference: Concepts*.

**PAGE**

displays only one table per page. Otherwise, PROC SURVEYFREQ displays multiple tables per page as space permits.

**RATE=value | SAS-data-set****R=value | SAS-data-set**

specifies the sampling rate as a nonnegative *value*, or identifies an input data set that provides the stratum sampling rates in a variable named `_RATE_`. PROC SURVEYFREQ uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the **RATE=** option for **BRR** or jackknife variance estimation, which you request with the **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE** option.

If your sample design has multiple stages, you should specify the *first-stage sampling rate*, which is the ratio of the number of primary sampling units (PSUs) that are selected to the total number of PSUs in the population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate in all strata, you should specify a nonnegative *value* for the **RATE=** option. If your design is stratified with different sampling rates in different strata, then you should name a SAS data set that contains the stratification variables and the stratum sampling rates. See the section “Population Totals and Sampling Rates” on page 7085 for details.

The sampling rate *value* must be a nonnegative number. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYFREQ converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you do not specify the `RATE=` or `TOTAL=` option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the `TOTAL=` option and the `RATE=` option in the same PROC SURVEYFREQ statement.

**TOTAL=***value* | *SAS-data-set*

**N=***value* | *SAS-data-set*

specifies the total number of primary sampling units (PSUs) in the study population as a positive *value*, or identifies an input data set that provides the stratum population totals in a variable named `_TOTAL_`. PROC SURVEYFREQ uses this information to compute a finite population correction for Taylor series variance estimation. The procedure does not use the `TOTAL=` option for BRR or jackknife variance estimation, which you request with the `VARMETHOD=BRR` or `VARMETHOD=JACKKNIFE` option.

For a nonstratified sample design, or for a stratified sample design with the same population total in all strata, you should specify a positive *value* for the `TOTAL=` option. If your sample design is stratified with different population totals in different strata, then you should name a SAS data set that contains the stratification variables and the stratum totals. See the section “Population Totals and Sampling Rates” on page 7085 for details.

If you do not specify the `TOTAL=` or `RATE=` option, then the Taylor series variance estimation does not include a finite population correction. You cannot specify both the `TOTAL=` option and the `RATE=` option in the same PROC SURVEYFREQ statement.

**VARHEADER=**`LABEL` | `NAME` | `NAMELABEL`

specifies the variable identification to use in the displayed output. By default `VARHEADER=NAME`, which displays variable names in the output. The `VARHEADER=` option affects the headers of the variable level columns in one-way frequency tables, crosstabulation tables, and the “Stratum Information” table. The `VARHEADER=` option also controls variable identification in the table headers.

The `VARHEADER=` option can take the following values:

<b>VARHEADER=</b>	<b>Variable Identification Displayed</b>
<code>LABEL</code>	Variable label
<code>NAME</code>	Variable name
<code>NAMELABEL</code>	Variable name and label, as <i>Name (Label)</i>

**VARMETHOD=BRR** <(method-options)>

**VARMETHOD=JACKKNIFE** | **JK** <(method-options)>

**VARMETHOD=TAYLOR**

specifies the variance estimation method. `VARMETHOD=TAYLOR` requests the Taylor series method, which is the default if you do not specify the `VARMETHOD=` option or the `REPWEIGHTS` statement. `VARMETHOD=BRR` requests variance estimation by balanced repeated replication (BRR), and `VARMETHOD=JACKKNIFE` requests variance estimation by the delete-1 jackknife method.

For `VARMETHOD=BRR` and `VARMETHOD=JACKKNIFE`, you can specify *method-options* in parentheses following the variance method name. Table 84.1 summarizes the available *method-options*.

**Table 84.1** Variance Estimation Options

<b>VARMETHOD=</b>	<b>Variance Estimation Method</b>	<b>Method-Options</b>
BRR	Balanced repeated replication	DFADJ FAY <=value> HADAMARD=SAS-data-set OUTWEIGHTS=SAS-data-set PRINTH REPS=number
JACKKNIFE	Jackknife	DFADJ OUTJKCOEFS=SAS-data-set OUTWEIGHTS=SAS-data-set
TAYLOR	Taylor series linearization	None

*Method-options* must be enclosed in parentheses following the variance method name. For example:

```
varmethod=BRR (reps=60 outweights=myReplicateWeights)
```

The following values are available for the VARMETHOD= option:

**BRR** < *method-options* > requests variance estimation by balanced repeated replication (BRR). The BRR method requires a stratified sample design with two primary sampling units (PSUs) in each stratum. If you specify the VARMETHOD=BRR option, you must also specify a **STRATA** statement unless you provide replicate weights with a **REPWEIGHTS** statement. See the section “Balanced Repeated Replication (BRR)” on page 7097 for details.

You can specify the following *method-options* in parentheses following VARMETHOD=BRR:

#### **DFADJ**

computes the degrees of freedom as the number of nonmissing strata for the individual table request. The degrees of freedom for VARMETHOD=BRR equal the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ *method-option*, PROC SURVEYFREQ does not count any empty strata that occur when observations with missing values of the **TABLES** variables are removed from the analysis of that table.

See the section “Degrees of Freedom” on page 7106 for more information. See the section “Data Summary Table” on page 7122 for details about valid observations.

The DFADJ *method-option* has no effect when you specify the **MISSING** option, which treats missing values as a valid nonmissing

level. The DFADJ *method-option* is not used when you specify the degrees of freedom in the DF= option in the TABLES statement.

The DFADJ *method-option* cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you use a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS or TABLES statement.

**FAY** <=*value*>

requests Fay's method, which is a modification of the BRR method. See the section "Fay's BRR Method" on page 7098 for details.

You can specify the *value* of the Fay coefficient, which is used in converting the original sampling weights to replicate weights. The Fay coefficient must be a nonnegative number less than 1. By default, the value of the Fay coefficient equals 0.5.

**HADAMARD=***SAS-data-set*

**H=***SAS-data-set*

names a SAS data set that contains the Hadamard matrix for BRR replicate construction. If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, PROC SURVEYFREQ generates an appropriate Hadamard matrix for replicate construction. See the sections "Balanced Repeated Replication (BRR)" on page 7097 and "Hadamard Matrix" on page 7100 for details.

If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the HADAMARD=*SAS-data-set method-option*.

In the HADAMARD= input data set, each variable corresponds to a column of the Hadamard matrix, and each observation corresponds to a row of the matrix. You can use any variable names in the HADAMARD= data set. All values in the data set must equal either 1 or -1. You must ensure that the matrix you provide is indeed a Hadamard matrix—that is,  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{A}$  is the Hadamard matrix of dimension  $R$  and  $\mathbf{I}$  is an identity matrix. PROC SURVEYFREQ does not check the validity of the Hadamard matrix that you provide.

The HADAMARD= input data set must contain at least  $H$  variables, where  $H$  denotes the number of first-stage strata in your design. If the data set contains more than  $H$  variables, PROC SURVEYFREQ uses only the first  $H$  variables. Similarly, the HADAMARD= input data set must contain at least  $H$  observations.

If you do not specify the REPS= *method-option*, then the number of replicates is taken to be the number of observations in

the HADAMARD= input data set. If you specify the number of replicates—for example, REPS=*nreps*—then the first *nreps* observations in the HADAMARD= data set are used to construct the replicates.

You can specify the PRINTH *method-option* to display the Hadamard matrix that the procedure uses to construct replicates for BRR.

#### **OUTWEIGHTS=SAS-data-set**

names a SAS data set to store the replicate weights that PROC SURVEYFREQ creates for BRR variance estimation. See the section “Balanced Repeated Replication (BRR)” on page 7097 for information about replicate weights. See the section “Replicate Weights Output Data Set” on page 7121 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with a REPWEIGHTS statement.

#### **PRINTH**

displays the Hadamard matrix used to construct replicates for BRR. When you provide the Hadamard matrix in the HADAMARD= *method-option*, PROC SURVEYFREQ displays only the rows and columns that are actually used to construct replicates. See the sections “Balanced Repeated Replication (BRR)” on page 7097 and “Hadamard Matrix” on page 7100 for more information.

The PRINTH *method-option* is not available when you provide replicate weights with a REPWEIGHTS statement because the procedure does not use a Hadamard matrix in this case.

#### **REPS=number**

specifies the number of replicates for BRR variance estimation. The value of *number* must be an integer greater than 1.

If you do not provide a Hadamard matrix with the HADAMARD= *method-option*, the number of replicates should be greater than the number of strata and should be a multiple of 4. See the section “Balanced Repeated Replication (BRR)” on page 7097 for more information. If a Hadamard matrix cannot be constructed for the REPS= value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the REPS= value that you specify.

If you provide a Hadamard matrix with the HADAMARD= *method-option*, the value of REPS= must not be less than the number of rows in the Hadamard matrix. If you provide a Hadamard matrix and do not specify the REPS= *method-option*, the number of replicates equals the number of rows in the Hadamard matrix.

If you do not specify the REPS= or HADAMARD= *method-option* and do not include a REPWEIGHTS statement, the number of replicates equals the smallest multiple of 4 that is greater than the number of strata.

If you provide replicate weights with a REPWEIGHTS statement, the procedure does not use the REPS= *method-option*. With a REPWEIGHTS statement, the number of replicates equals the number of REPWEIGHTS variables.

JACKKNIFE | JK < *method-options* > requests variance estimation by the delete-1 jackknife method. See the section “[The Jackknife Method](#)” on page 7100 for details. If you provide replicate weights with a REPWEIGHTS statement, VARMETHOD=JACKKNIFE is the default variance estimation method.

You can specify the following *method-options* in parentheses following VARMETHOD=JACKKNIFE:

#### DFADJ

computes the degrees of freedom by using the number of nonmissing strata and clusters for the individual table request. The degrees of freedom for VARMETHOD=JACKKNIFE equal the number of clusters minus the number of strata, which by default is based on all valid observations in the data set. But if you specify the DFADJ *method-option*, PROC SURVEYFREQ does not count any empty strata or clusters that occur when observations with missing values of the TABLES variables are removed from the analysis of that table.

See the section “[Degrees of Freedom](#)” on page 7106 for more information. See the section “[Data Summary Table](#)” on page 7122 for details about valid observations.

The DFADJ *method-option* has no effect when you specify the MISSING option, which treats missing values as a valid nonmissing level. The DFADJ *method-option* is not used when you specify the degrees of freedom in the DF= option in the TABLES statement.

The DFADJ *method-option* cannot be used when you provide replicate weights with a REPWEIGHTS statement. When you include a REPWEIGHTS statement, the degrees of freedom equal the number of REPWEIGHTS variables (or replicates), unless you specify an alternative value in the DF= option in the REPWEIGHTS or TABLES statement.

#### OUTJKCOEFS=SAS-data-set

names a SAS data set to store the jackknife coefficients. See the section “[The Jackknife Method](#)” on page 7100 for information about jackknife coefficients. See the section “[Jackknife Coefficients Output Data Set](#)” on page 7122 for details about the contents of the OUTJKCOEFS= data set.

**OUTWEIGHTS=SAS-data-set**

names a SAS data set to store the replicate weights that PROC SURVEYFREQ creates for jackknife variance estimation. See the section “[The Jackknife Method](#)” on page 7100 for information about replicate weights. See the section “[Replicate Weights Output Data Set](#)” on page 7121 for details about the contents of the OUTWEIGHTS= data set.

The OUTWEIGHTS= *method-option* is not available when you provide replicate weights with a REPWEIGHTS statement.

TAYLOR requests Taylor series variance estimation. This is the default method if you do not specify the VARMETHOD= option or a REPWEIGHTS statement. See the section “[Taylor Series Variance Estimation](#)” on page 7090 for details.

---

## BY Statement

### BY variables ;

You can specify a BY statement with PROC SURVEYFREQ to obtain separate analyses of observations in groups that are defined by the BY variables.

Note that using a BY statement provides completely separate analyses of the BY groups. It does not provide a statistically valid domain (subpopulation) analysis, where the total number of units in the subpopulation is not known with certainty. You should include the domain variable(s) in your TABLES request to obtain domain analysis. See the section “[Domain Analysis](#)” on page 7086 for more details.

If you specify more than one BY statement, the procedure uses only the last BY statement and ignores any previous BY statements.

When you use a BY statement, the procedure expects the input data set to be sorted in order of the BY variables. If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about the BY-group processing, see the discussion in *SAS Language Reference: Concepts*. For more information about the DATASETS procedure, see the *Base SAS Procedures Guide*.

---

## CLUSTER Statement

**CLUSTER** *variables* ;

The CLUSTER statement names variables that identify the first-stage clusters in a clustered sample design. First-stage clusters are also known as primary sampling units (PSUs). The combinations of categories of CLUSTER variables define the clusters in the sample. If there is a STRATA statement, clusters are nested within strata.

If your sample design has clustering at multiple stages, you should specify only the first-stage clusters (PSUs) in the CLUSTER statement. See the section “[Specifying the Sample Design](#)” on page 7084 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with the REPWEIGHTS statement, you do not need to specify a CLUSTER statement.

The CLUSTER *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the CLUSTER variables determine the CLUSTER variable levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

Note that an observation is excluded from the analysis if it has a missing value for any CLUSTER variable unless you specify the MISSING option in the PROC SURVEYFREQ statement. See the section “[Missing Values](#)” on page 7087 for more information.

You can use multiple CLUSTER statements to specify CLUSTER variables. The procedure uses variables from all CLUSTER statements to create clusters.

---

## REPWEIGHTS Statement

**REPWEIGHTS** *variables* < / *options* > ;

The REPWEIGHTS statement names variables that provide replicate weights for BRR or jackknife variance estimation, which you request with the VARMETHOD=BRR or VARMETHOD=JACKKNIFE option in the PROC SURVEYFREQ statement. If you do not provide replicate weights for these methods by using a REPWEIGHTS statement, then PROC SURVEYFREQ constructs replicate weights for the analysis. See the sections “[Balanced Repeated Replication \(BRR\)](#)” on page 7097 and “[The Jackknife Method](#)” on page 7100 for information about replicate weights.

Each REPWEIGHTS variable should contain the weights for a single replicate, and the number of replicates equals the number of REPWEIGHTS variables. The REPWEIGHTS variables must be numeric, and the variable values must be nonnegative numbers.

If you provide replicate weights with a REPWEIGHTS statement, you do not need to specify a CLUSTER or STRATA statement. If you use a REPWEIGHTS statement and do not specify the VARMETHOD= option in the PROC SURVEYFREQ statement, the procedure uses VARMETHOD=JACKKNIFE by default.

If you specify a REPWEIGHTS statement but do not include a WEIGHT statement, PROC SURVEYFREQ uses the average of each observation's replicate weights as the observation's weight.

You can specify the following options in the REPWEIGHTS statement after a slash (/):

**DF=***df*

specifies the degrees of freedom for the analysis. The value of *df* must be a positive number. By default, the degrees of freedom equals the number of REPWEIGHTS variables. See the section “Degrees of Freedom” on page 7106 for details.

PROC SURVEYFREQ uses the DF= value in computing confidence limits for proportions, totals, and other statistics. See the section “Confidence Limits for Proportions” on page 7102 for details. PROC SURVEYFREQ also uses the DF= value in computing the denominator degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. See the sections “Rao-Scott Chi-Square Test” on page 7113, “Rao-Scott Likelihood Ratio Chi-Square Test” on page 7116, “Wald Chi-Square Test” on page 7118, and “Wald Log-Linear Chi-Square Test” on page 7120 for more information.

**JKCOEFS=***value*

specifies the jackknife coefficient for VARMETHOD=JACKKNIFE. The coefficient *value* must be a nonnegative number. See the section “The Jackknife Method” on page 7100 for details about jackknife coefficients.

You can use this option to specify a single value of the jackknife coefficient, which the procedure uses for all replicates. To specify different coefficients for different replicates, use the JKCOEFS=(*values*) or JKCOEFS=SAS-*data-set* option.

**JKCOEFS=**(*values*)

specifies jackknife coefficients for VARMETHOD=JACKKNIFE, where each coefficient corresponds to an individual replicate identified by a REPWEIGHTS variable. You can separate *values* with blanks or commas. The coefficient *values* must be nonnegative numbers. The number of *values* must equal the number of replicate weight variables named in the REPWEIGHTS statement. List these values in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement.

See the section “The Jackknife Method” on page 7100 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=SAS-*data-set* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

**JKCOEFS=**SAS-*data-set*

names a SAS data set that contains the jackknife coefficients for VARMETHOD=JACKKNIFE. You provide the jackknife coefficients in the JKCOEFS= data set variable JKCoefficient. Each coefficient value must be a nonnegative number. The coefficients should correspond to the replicates that are identified by the REPWEIGHTS variables. Provide the coefficients as

observations in the JKCOEFS= data set and arrange them in the same order in which you list the corresponding replicate weight variables in the REPWEIGHTS statement. The number of observations in the JKCOEFS= data set must not be less than the number of REPWEIGHTS variables.

See the section “[The Jackknife Method](#)” on page 7100 for details about jackknife coefficients.

To specify different coefficients for different replicates, you can also use the JKCOEFS=*values* option. To specify a single jackknife coefficient for all replicates, use the JKCOEFS=*value* option.

---

## STRATA Statement

**STRATA** *variables* < / *option* > ;

The STRATA statement names variables that identify the first-stage strata in a stratified sample design. The combinations of levels of STRATA variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently.

If your sample design has stratification at multiple stages, you should specify only the first-stage strata in the STRATA statement. See the section “[Specifying the Sample Design](#)” on page 7084 for more information.

If you provide replicate weights for BRR or jackknife variance estimation with a REPWEIGHTS statement, you do not need to specify a STRATA statement.

The STRATA *variables* are one or more variables in the DATA= input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. The formatted values of the STRATA variables determine the STRATA variable levels. Thus, you can use formats to group values into levels. See the discussion of the FORMAT procedure in the *Base SAS Procedures Guide* and the discussions of the FORMAT statement and SAS formats in *SAS Language Reference: Dictionary*.

Note that an observation is excluded from the analysis if it has a missing value for any STRATA variable unless you specify the MISSING option in the PROC SURVEYFREQ statement. See the section “[Missing Values](#)” on page 7087 for more information.

You can use multiple STRATA statements to specify STRATA variables. The procedure uses variables from all STRATA statements to define strata.

You can specify the following option in the STRATA statement after a slash (/):

### LIST

displays a “Stratum Information” table, which lists all strata together with the corresponding values of the STRATA variables. This table provides the number of observations and the number of clusters in each stratum, as well as the sampling fraction if you specify the RATE= or TOTAL= option. See the section “[Stratum Information Table](#)” on page 7123 for more information.

## TABLES Statement

**TABLES** *requests* *</options>* ;

The TABLES statement requests one-way to  $n$ -way frequency and crosstabulation tables and statistics for these tables.

If you omit the TABLES statement, PROC SURVEYFREQ generates one-way frequency tables for all **DATA=** data set variables that are not listed in the other statements.

The following argument is required in the TABLES statement:

### *requests*

specify the frequency and crosstabulation tables to produce. A *request* is composed of one variable name or several variable names separated by asterisks. To request a one-way frequency table, use a single variable. To request a two-way crosstabulation table, use an asterisk between two variables. To request a multiway table (an  $n$ -way table, where  $n > 2$ ), separate the desired variables with asterisks. The unique values of these variables form the rows, columns, and layers of the table.

For two-way tables to multiway tables, the values of the last variable form the crosstabulation table columns, while the values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate crosstabulation table for each layer. For example, a specification of A\*B\*C\*D in a TABLES statement produces  $k$  tables, where  $k$  is the number of different combinations of levels for A and B. Each table lists the levels for D (columns) within each level of C (rows).

You can use multiple TABLES statements in a single PROC SURVEYFREQ step. You can also specify any number of table requests in a single TABLES statement. To specify multiple table requests quickly, use a grouping syntax by placing parentheses around several variables and joining other variables or variable combinations. Table 84.2 shows some examples of grouping syntax.

**Table 84.2** Grouping Syntax

Request	Equivalent to
tables A*(B C);	tables A*B A*C;
tables (A B)*(C D);	tables A*C B*C A*D B*D;
tables (A B C)*D;	tables A*D B*D C*D;
tables A -- C;	tables A B C;
tables (A -- C)*D;	tables A*D B*D C*D;

The TABLES statement variables are one or more variables from the **DATA=** input data set. These variables can be either character or numeric, but the procedure treats them as categorical variables. PROC SURVEYFREQ uses the formatted values of the TABLES variable to determine the categorical variable levels. So if you assign a format to a variable with a **FORMAT** statement, PROC SURVEYFREQ formats the values before dividing observations into the levels of a frequency or crosstabulation table. See the discussion of the **FORMAT**

procedure in the *Base SAS Procedures Guide* and the discussions of the `FORMAT` statement and SAS formats in *SAS Language Reference: Dictionary*.

The frequency or crosstabulation table lists the values of both character and numeric variables in ascending order based on internal (unformatted) variable values unless you change the order with the `ORDER=` option. To list the values in ascending order by formatted value, use `ORDER=FORMATTED` in the `PROC SURVEYFREQ` statement.

## Without Options

If you request a frequency or crosstabulation table without specifying options, `PROC SURVEYFREQ` produces the following for each table level or cell:

- frequency (sample size)
- weighted frequency, which estimates the population total
- standard deviation of the weighted frequency
- percentage, which estimates the population proportion
- standard error of the percentage

The table displays weighted frequencies if your analysis includes a `WEIGHT` statement, or if you specify the `WTFREQ` option in the `TABLES` statement. The table also displays the number of observations with missing values. See the sections “[One-Way Frequency Tables](#)” on page 7124 and “[Crosstabulation Tables](#)” on page 7125 for more information.

## Options

Table 84.3 lists the options available in the `TABLES` statement. Descriptions follow in alphabetical order.

**Table 84.3** TABLES Statement Options

Option	Description
<b>Control Statistical Analysis</b>	
<code>ALPHA=</code>	Sets the level for confidence limits
<code>CHISQ</code>	Requests Rao-Scott chi-square test
<code>CHISQ1</code>	Requests Rao-Scott modified chi-square test
<code>DF=</code>	Specifies degrees of freedom
<code>LRCHISQ</code>	Requests Rao-Scott likelihood ratio test
<code>LRCHISQ1</code>	Requests Rao-Scott modified likelihood ratio test
<code>OR</code>	Requests odds ratio and relative risks
<code>RISK</code>	Requests risks and risk difference
<code>TESTP=</code>	Specifies null proportions for one-way chi-square test
<code>WCHISQ</code>	Requests Wald chi-square test
<code>WLLCHISQ</code>	Requests Wald log-linear chi-square test

Table 84.3 *continued*

Option	Description
<b>Request Additional Table Information</b>	
CL	Displays confidence limits for percentages and specifies confidence limit type for percentages
CLWT	Displays confidence limits for weighted frequencies
COL	Displays column percentages and standard errors
CV	Displays coefficients of variation for percentages
CVWT	Displays coefficients of variation for weighted frequencies
DEFF	Displays design effects for percentages
EXPECTED	Displays expected weighted frequencies (two-way tables)
ROW	Displays row percentages and standard errors
VAR	Displays variances for percentages
VARWT	Displays variances for weighted frequencies
WTFREQ	Displays totals and standard errors when there is no WEIGHT statement
<b>Control Displayed Output</b>	
NOCELLPERCENT	Suppresses display of overall percentages
NOFREQ	Suppresses display of frequency counts
NOPERCENT	Suppresses display of all percentages
NOPRINT	Suppresses display of tables but displays statistical tests
NOSPARE	Suppresses display of zero rows and columns
NOSTD	Suppresses display of standard errors for all estimates
NOTOTAL	Suppresses display of row and column totals
NOWT	Suppresses display of weighted frequencies
<b>Produce Statistical Graphics</b>	
PLOTS=	Requests plots from ODS Graphics

You can specify the following options in a TABLES statement:

**ALPHA= $\alpha$** 

sets the level for confidence limits. The value of  $\alpha$  must be between 0 and 1, and the default is 0.05. A confidence level of  $\alpha$  produces  $100(1 - \alpha)\%$  confidence limits. The default of ALPHA=0.05 produces 95% confidence limits.

You request confidence limits for percentages with the CL option, and you request confidence limits for weighted frequencies with the CLWT option. See the sections “Confidence Limits for Proportions” on page 7102 and “Confidence Limits for Totals” on page 7102 for more information.

The ALPHA= option also applies to confidence limits for the risks and risk difference, which you request with the RISK option, and to confidence limits for the odds ratio and relative risks, which you request with the OR option. See the sections “Risks and Risk Difference” on page 7109 and “Odds Ratio and Relative Risks” on page 7110 for details.

**CHISQ**

requests the Rao-Scott chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies. See the section “Rao-Scott Chi-Square Test” on page 7113 for details.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the **TESTP=** option.

The CHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the **CHISQ1** option.

### **CHISQ1**

requests the Rao-Scott modified chi-square test. This test applies a design effect correction to the Pearson chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section “[Rao-Scott Chi-Square Test](#)” on page 7113 for details. To compute the design effect correction from proportion estimates instead of null proportions, specify the **CHISQ** option.

By default for one-way tables, the CHISQ option provides a design-based goodness-of-fit test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the **TESTP=** option.

### **CL** < (options) >

requests confidence limits for the percentages (proportions) in the crosstabulation table. By default, PROC SURVEYFREQ computes standard Wald (“linear”) confidence limits for proportions by using the variance estimates that are based on the sample design. See the section “[Confidence Limits for Proportions](#)” on page 7102 for more information. The procedure determines the confidence coefficient from the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits.

You can specify *options* in parentheses following the CL option to control the confidence limit computations. You can use the **TYPE=** option to request an alternative confidence limit type. In addition to Wald confidence limits, the following types of design-based confidence limits are available for proportions: modified Clopper-Pearson (exact), modified Wilson (score), and logit confidence limits.

If you specify the **PSMALL** option, PROC SURVEYFREQ uses the alternative confidence limit type for extreme (small or large) proportion estimates and uses Wald confidence limits for all other proportion estimates. If you do not specify the **PSMALL** option, PROC SURVEYFREQ computes the specified confidence limit type for all proportion values.

You can specify the following options in parentheses following the CL option:

### **ADJUST=NO | YES**

controls the degrees-of-freedom adjustment to the effective sample size for the modified Clopper-Pearson and Wilson confidence limits. By default, **ADJUST=YES**. If you specify **ADJUST=NO**, the confidence limit computations do not apply the degrees-of-freedom adjustment to the effective sample size. See the section “[Modified Confidence Limits](#)” on page 7103 for details.

The **ADJUST=** option is available for **TYPE=CLOPPERPEARSON** and **TYPE=WILSON** confidence limits.

### **PSMALL** <= *p* >

uses the alternative confidence limit type that you specify with the **TYPE=** option for extreme (small or large) proportion values.

The PSMALL value  $p$  defines the range of extreme proportion values, where those proportions less than or equal to  $p$  or greater than or equal to  $(1 - p)$  are considered to be extreme, and those proportions between  $p$  and  $(1 - p)$  are not extreme. If you do not specify a PSMALL value  $p$ , PROC SURVEYFREQ uses  $p = 0.25$  by default. For  $p = 0.25$ , the procedure computes Wald confidence limits for proportions between 0.25 and 0.75 and computes the alternative confidence limit type for proportions less than or equal to 0.25 or greater than or equal to 0.75.

The PSMALL value  $p$  must be a nonnegative number. You can specify  $p$  as a proportion between 0 and 0.5. Or you can specify  $p$  in percentage form as a number between 1 and 50, and PROC SURVEYFREQ converts that number to a proportion. The procedure treats the value 1 as the percentage form 1%.

The PSMALL option is available for TYPE=CLOPPERPEARSON, TYPE=LOGIT, and TYPE=WILSON confidence limits. See the section “[Confidence Limits for Proportions](#)” on page 7102 for details.

### TRUNCATE=NO | YES

controls the truncation of the effective sample size for the modified Clopper-Pearson and Wilson confidence limits. By default, TRUNCATE=YES truncates the effective sample size if it is larger than the original sample size. If you specify TRUNCATE=NO, the effective sample size is not truncated. See the section “[Modified Confidence Limits](#)” on page 7103 for details.

The TRUNCATE= option is available for TYPE=CLOPPERPEARSON and TYPE=WILSON confidence limits.

### TYPE=*name*

specifies the type of confidence limits to compute for proportions. If you do not specify the TYPE= option, PROC SURVEYFREQ computes Wald confidence limits (TYPE=WALD) by default.

If you specify the PSMALL option, the procedure uses the specified confidence limit type for extreme proportions (outside the PSMALL range) and uses Wald confidence limits for proportions that are not outside the range. If you do not specify the PSMALL option, the procedure uses the specified confidence limit type for all proportions.

The following values are available for the TYPE= option:

#### CLOPPERPEARSON | CP

requests modified Clopper-Pearson (exact) confidence limits for proportions. See the section “[Modified Clopper-Pearson Confidence Limits](#)” on page 7104 for details.

#### LOGIT

requests logit confidence limits for proportions. See the section “[Logit Confidence Limits](#)” on page 7105 for details.

#### WALD

requests standard Wald (“linear”) confidence limits for proportions. This is the default confidence limit type if you do not specify the TYPE= option. See the section “[Wald Confidence Limits](#)” on page 7103 for details.

**WILSON | SCORE**

requests modified Wilson (score) confidence limits for proportions. See the section “[Modified Wilson Confidence Limits](#)” on page 7105 for details.

**CLWT**

requests confidence limits for the weighted frequencies (totals) in the crosstabulation table. PROC SURVEYFREQ determines the confidence coefficient from the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits. See the section “[Confidence Limits for Totals](#)” on page 7102 for more information.

**COL < ( option ) >**

displays the column percentage (estimated proportion of the column total) for each cell in a two-way table. The COL option also provides the standard errors of the column percentages. See the section “[Row and Column Proportions](#)” on page 7096 for more information. This option has no effect for one-way tables.

You can specify the following option in parentheses following the COL option:

**DEFF**

displays the design effect for each column percentage in the crosstabulation table. See the section “[Design Effect](#)” on page 7107 for more information.

**CV**

displays the coefficient of variation for each percentage (proportion) estimate in the crosstabulation table. See the section “[Coefficient of Variation](#)” on page 7107 for more information.

**CVWT**

displays the coefficient of variation for each weighted frequency (estimated total), in the crosstabulation table. See the section “[Coefficient of Variation](#)” on page 7107 for more information.

**DEFF**

displays the design effect for each overall percentage (proportion) estimate in the crosstabulation table. See the section “[Design Effect](#)” on page 7107 for more information.

To request design effects for row or column percentages, specify the DEFF option in parentheses following the `ROW` or `COL` option.

**DF=*df***

specifies the degrees of freedom for the analysis. The value of *df* must be a nonnegative number. By default, PROC SURVEYFREQ computes the degrees of freedom as described in the section “[Degrees of Freedom](#)” on page 7106.

PROC SURVEYFREQ uses the `DF=` value in computing confidence limits for proportions, totals, and other statistics. See the section “[Confidence Limits for Proportions](#)” on page 7102 for details. PROC SURVEYFREQ also uses the `DF=` value in computing the denominator degrees of freedom for the *F* statistics in the Rao-Scott and Wald chi-square tests. See the sections “[Rao-Scott Chi-Square Test](#)” on page 7113, “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7116, “[Wald Chi-Square Test](#)” on page 7118, and “[Wald Log-Linear Chi-Square Test](#)” on page 7120 for more information.

**EXPECTED**

displays expected weighted frequencies (totals) for the table cells in a two-way table. The expected weighted frequencies are computed under the null hypothesis that the row and column variables are independent. See the section “[Expected Weighted Frequency](#)” on page 7108 for more information. This option has no effect for one-way tables.

**LRCHISQ**

requests the Rao-Scott likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies. See the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7116 for more information.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the `TESTP=` option.

The LRCHISQ option uses proportion estimates to compute the design effect correction. To use null hypothesis proportions instead, specify the `LRCHISQ1` option.

**LRCHISQ1**

requests the Rao-Scott modified likelihood ratio chi-square test. This test applies a design effect correction to the likelihood ratio chi-square statistic computed from the weighted frequencies, and bases the design effect correction on null hypothesis proportions. See the section “[Rao-Scott Likelihood Ratio Chi-Square Test](#)” on page 7116 for more information. To compute the design effect correction from proportion estimates instead of null proportions, specify the `LRCHISQ` option.

By default for one-way tables, the LRCHISQ option provides a design-based test for equal proportions. To compute the test for other null hypothesis proportions, specify the null proportions with the `TESTP=` option.

**NOCELLPERCENT**

suppresses the display of overall cell percentages in the crosstabulation table, as well as the standard errors of the percentages. The NOCELLPERCENT option does not suppress the display of row or column percentages, which you request with the `ROW` or `COL` option.

**NOFREQ**

suppresses the display of cell frequencies in the crosstabulation table. The NOFREQ option also suppresses the display of row, column, and overall table frequencies.

**NOPERCENT**

suppresses the display of all percentages in the crosstabulation table. The NOPERCENT option also suppresses the display of standard errors of the percentages. Use the `NOCELLPERCENT` option to suppress display of overall cell percentages but allow display of row or column percentages.

**NOPRINT**

suppresses the display of frequency and crosstabulation tables but displays all requested statistical tests. Note that this option disables the Output Delivery System (ODS) for the suppressed tables. For more information, see Chapter 20, “[Using the Output Delivery System.](#)”

**NOSPARSE**

suppresses the display of variable levels with zero frequency in two-way tables. By default, the procedure displays all levels of the column variable within each level of the row variable, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row variable levels with zero frequency for the layer.

**NOSTD**

suppresses the display of all standard errors in the crosstabulation table.

**NOTOTAL**

suppresses the display of row totals, column totals, and overall totals in the crosstabulation table.

**NOWT**

suppresses the display of weighted frequencies in the crosstabulation table. The NOWT option also suppresses the display of standard errors of the weighted frequencies.

**OR**

requests estimates of the odds ratio, the column 1 relative risk, and the column 2 relative risk for  $2 \times 2$  tables. The OR option also provides confidence limits for these statistics. See the section “[Odds Ratio and Relative Risks](#)” on page 7110 for details.

To compute confidence limits for the odds ratio and relative risks, PROC SURVEYFREQ determines the confidence coefficient from the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

**PLOTS** < ( *global-plot-options* ) > < = *plot-request* < ( *plot-options* ) > >

**PLOTS** < ( *global-plot-options* ) >

< = ( *plot-request* < ( *plot-options* ) > < ... *plot-request* < ( *plot-options* ) > > >

controls the plots that are produced through ODS Graphics. *Plot-requests* identify the plots, and *plot-options* control the appearance and content of the plots. You can specify *plot-options* in parentheses following a *plot-request*. A *global-plot-option* applies to all plots for which it is available, unless it is altered by a specific *plot-option*. You can specify *global-plot-options* in parentheses following the PLOTS option.

When you specify only one *plot-request*, you can omit the parentheses around the *plot-request*. For example:

```
plots=all
plots=wtfreqplot
plots=(wtfreqplot oddsratioplot)
plots(only)=(riskdiffplot relriskplot)
```

See [Figure 84.4](#) and [Figure 84.7](#) for examples of plots that PROC SURVEYFREQ produces. For general information about ODS Graphics, see Chapter 21, “[Statistical Graphics Using ODS.](#)”

You must enable ODS Graphics before requesting plots, as shown in the following example:

```
ods graphics on;
proc surveyfreq;
  tables treatment*response / chisq plots=wtfreqplot;
  weight wt;
run;
ods graphics off;
```

If you have enabled ODS graphics but do not specify the PLOTS= option, then PROC SURVEYFREQ produces all plots that are associated with the analyses that you request in the TABLES statement.

Table 84.4 lists the available *plot-requests* together with their required TABLES statement options.

**Table 84.4** *Plot-Requests*

<i>Plot-Request</i>	Description	Required TABLES Statement Option
ALL	All plots	None
NONE	No plots	None
ODDSRATIOPLOT	Odds ratio plot	OR ( $h \times 2 \times 2$ table)
RELRIKSPLOT	Relative risk plot	OR ( $h \times 2 \times 2$ table)
RISKDIFFPLOT	Risk difference plot	RISK, RISK1, or RISK2 ( $h \times 2 \times 2$ table)
WTFREQPLOT	Weighted frequency plot	Frequency or crosstabulation table request

Weighted frequency plots are available for frequency and crosstabulation tables. You can specify the SCALE=PERCENT *plot-option* for the WTFREQPLOT *plot-request* to plot percentages instead of weighted frequencies. Table 84.5 lists the available *plot-options* for weighted frequency plots.

**Table 84.5** *Plot-Options for WTFREQPLOT*

<i>Plot-Option</i>	Description	Values
CLBAR=	Confidence limit bars	YES* or NO
NPANELPOS=	Two-way rows per panel	Number
ORIENT=	Orientation	VERTICAL* or HORIZONTAL
SCALE=	Scale	WTFREQ* or PERCENT
TWOWAY=	Two-way plot layout	GROUPVERTICAL*, GROUPTHORIZONTAL, or STACKED
TYPE=	Type	BARCHART* or DOTPLOT

\* Default

Odds ratio, relative risk, and risk difference plots are available for multiway  $2 \times 2$  tables when you specify the corresponding analysis option in the TABLES statement. Table 84.6 lists the available *plot-options* for these plots.

**Table 84.6** *Plot-Options for ODDSRATIOPLOT, RELRISKPLOT, and RISKDIFFPLOT*

<i>Plot-Option</i>	<i>Description</i>	<i>Values</i>
COLUMN=*	Risk column	1 or 2
LOGBASE=**	Axis scale	2, E, or 10
NPANELPOS=	Statistics per graphic	Number
ORDER=	Order	ASCENDING or DESCENDING
RANGE=	Range	Values or CLIP
STATS	Displays statistic values	None

\* Available for RELRISKPLOT and RISKDIFFPLOT  
 \*\* Available for ODDSRATIOPLOT and RELRISKPLOT

### *Global-Plot-Options*

A *global-plot-option* applies to all plots for which the option is available, unless it is altered by a specific *plot-option*. All individual *plot-options* are available as *global-plot-options*. Table 84.5 and Table 84.6 list the individual *plot-options*. The ONLY option is also available as a *global-plot-option*.

*Global-plot-options* are specified in parentheses following the PLOTS option. For example:

```
plots (order=ascending stats)=(riskdiffplot oddsratioplot)
plots (only)=wtfreqplot
```

You can specify the following option as a *global-plot-option*:

#### **ONLY**

suppresses the default plots and requests only the plots that are specified as *plot-requests*.

### *Plot-Requests*

The following *plot-requests* are available with the PLOTS= option:

#### **ALL**

requests all plots that are associated with the specified analyses. This is the default if you do not specify the PLOTS(ONLY) option.

#### **NONE**

suppresses all plots.

**ODDSRATIOPLOT** < ( *plot-options* ) >

requests a plot of odds ratios with confidence limits. Odds ratio plots are available for multiway  $2 \times 2$  tables. To produce an odds ratio plot, you must also specify the **OR** option in the TABLES statement to compute odds ratios. The following *plot-options* are available for ODDSRATIOPLOT: **LOGBASE=**, **NPANELPOS=**, **ORDER=**, **RANGE=**, and **STATS**.

**RELRISKPLOT** < ( *plot-options* ) >

requests a plot of relative risks with confidence limits. Relative risk plots are available for multiway  $2 \times 2$  tables. To produce a relative risk plot, you must also specify the **OR** option in the TABLES statement to compute relative risks. The following *plot-options* are available for RELRISKPLOT: **COLUMN=**, **LOGBASE=**, **NPANELPOS=**, **ORDER=**, **RANGE=**, and **STATS**.

**RISKDIFFPLOT** < ( *plot-options* ) >

requests a plot of risk differences with confidence limits. Risk difference plots are available for multiway  $2 \times 2$  tables. To produce a risk difference plot, you must also specify the **RISK**, **RISK1**, or **RISK2** option in the TABLES statement to compute risk differences. The following *plot-options* are available for RISKDIFFPLOT: **COLUMN=**, **NPANELPOS=**, **ORDER=**, **RANGE=**, and **STATS**.

**WTFREQPLOT** < ( *plot-options* ) >

requests a weighted frequency plot. Weighted frequency plots are available for frequency and crosstabulation tables. For multiway tables, PROC SURVEYFREQ provides a two-way weighted frequency plot for each table layer. You can plot (weighted) percentages instead of frequencies by specifying the **SCALE=PERCENT** *plot-option*.

The following *plot-options* are available for WTFREQPLOT: **CLBAR=**, **ORIENT=**, **SCALE=**, and **TYPE=**. Additionally, the **TWOWAY=** and **NPANELPOS=** *plot-options* are available for weighted frequency plots of two-way and multiway tables. The **NPANELPOS=** *plot-option* and the **CLBAR=YES** *plot-option* are not available with the **TWOWAY=STACKED** layout. The **CLBAR=YES** *plot-option*, which displays confidence limits on the plots, is the default for all other weighted frequency plot layouts.

***Plot-Options for WTFREQPLOT***

You can specify the following *plot-options* in parentheses after the **WTFREQPLOT** *plot-request*:

**CLBAR=NO | YES**

controls the confidence limit error bars on the plots. **CLBAR=NO** suppresses the confidence limit error bars. **CLBAR=YES** is the default for all weighted frequency plots except the **TWOWAY=STACKED** layout. Confidence limit error bars are not available with the **TWOWAY=STACKED** layout.

**NPANELPOS=*n***

divides the two-way weighted frequency plot into multiple panels that display at most  $|n|$  levels of the row variable per panel. If  $n$  is positive, the number of table rows per panel is balanced; but if  $n$  is negative, the number of rows per panel is not balanced. By default,  $n = 0$  and all rows are displayed in a single plot. For example, suppose your two-way table has 21 levels of the row variable. Then NPANELPOS=20 displays two panels, the first with 11 rows and the second with 10; NPANELPOS=-20 displays 20 rows in the first panel but only one in the second.

The NPANELPOS= *plot-option* applies to two-way plots that are displayed with grouped layout, which you specify with the **TWOWAY=GROUPVERTICAL** or **TWOWAY=GROUPHORIZONTAL** *plot-option*. The NPANELPOS= *plot-option* does not apply to the **TWOWAY=STACKED** layout.

**ORIENT=HORIZONTAL | VERTICAL**

controls the orientation of the weighted frequency plot. The **ORIENT=HORIZONTAL** *plot-option* places the variable levels on the Y axis and the weighted frequencies or percentages on the X axis. **ORIENT=VERTICAL** places the variable levels on the X axis. The default orientation is **ORIENT=VERTICAL** for bar charts (**TYPE=BAR**) and **ORIENT=HORIZONTAL** for dot plots (**TYPE=DOT**).

**SCALE=WTFREQ | PERCENT**

specifies the scale of the frequencies to display. **SCALE=WTFREQ** displays weighted frequencies (totals), and **SCALE=PERCENT** displays percentages. The default is **SCALE=WTFREQ**.

**TWOWAY=GROUPVERTICAL | GROUPHORIZONTAL | STACKED**

specifies the layout for a two-way weighted frequency plot. The **TWOWAY=** *plot-option* applies to weighted frequency plots for two-way and multiway table requests; for multiway table requests, PROC SURVEYFREQ produces a two-way weighted frequency plot for each table layer.

**TWOWAY=GROUPVERTICAL** produces a grouped plot with a vertical common baseline. The plot is grouped by the row variable, which is the first variable that you specify in a two-way table request. **TWOWAY=GROUPHORIZONTAL** produces a grouped plot with a horizontal common baseline.

**TWOWAY=STACKED** produces stacked weighted frequency plots for two-way tables. In a stacked bar chart, the bars correspond to the column variable values, and the row frequencies are stacked within each column. In a stacked dot plot, the dotted lines correspond to the columns, and the row frequencies within columns are plotted as data dots on the same column line.

The default two-way layout is **TWOWAY=GROUPVERTICAL**. The **TYPE=** and **ORIENT=** *plot-options* are available for each **TWOWAY=** layout option.

**TYPE=BARCHART | DOTPLOT**

specifies the type of the weighted frequency plot. **TYPE=BARCHART** produces a bar chart, and **TYPE=DOTPLOT** produces a dot plot. The default type is **TYPE=BARCHART**.

**Plot-Options for ODDSRATIO PLOT, RELRISK PLOT, and RISKDIFF PLOT**

You can specify the following *plot-options* in parentheses after the **ODDSRATIO PLOT**, **RELRISK PLOT**, or **RISKDIFF PLOT** *plot-request*:

**COLUMN=1 | 2**

specifies the risk column for the relative risk and risk difference plots (**RELRISK PLOT** and **RISKDIFF PLOT**, respectively). If you specify the **COLUMN=1** *plot-option*, then the plot displays the column 1 relative risks or the column 1 risk differences. Similarly, **COLUMN=2** displays the column 2 relative risks or risk differences.

The **COLUMN=** *plot-option* does not apply to odds ratio plots. The default is **COLUMN=1** for relative risks plots.

If you request both column 1 and column 2 risk differences with the **RISK** option, then **COLUMN=1** is the default for the risk difference plot. If you request computation of only column 1 (or column 2) risk differences with the **RISK1** (or **RISK2**) option, then by default the risk difference plot displays the corresponding risk differences.

**LOGBASE=2 | E | 10**

applies to the **ODDSRATIO PLOT** and **RELRISK PLOT**. The **LOGBASE=** *plot-option* displays the odds ratio or relative risk axis on the specified log scale.

**NPANELPOS=*n***

divides the plot into multiple panels that display at most  $|n|$  statistics (odds ratios, relative risks, or risk differences) per panel. If  $n$  is positive, the number of statistics per panel is balanced; but if  $n$  is negative, the number of statistics per panel is not balanced. By default,  $n = 0$  and all statistics are displayed in a single plot. For example, suppose you want to display 21 odds ratios. Then **NPANELPOS=20** displays two panels, the first with 11 odds ratios and the second with 10; **NPANELPOS=-20** displays 20 odds ratios in the first panel but only one in the second.

**ORDER=ASCENDING | DESCENDING**

displays the statistics (odds ratios, relative risks, or risk differences) in sorted order. By default, the statistics are displayed in the order in which the two-way table layers appear in the multiway table.

**RANGE= ( <min> <,max> ) | CLIP**

specifies the range of values to display. If you specify **RANGE=CLIP**, the confidence limits are clipped and the display range is determined by the minimum and maximum values of the estimates. By default, the display range includes all confidence limits.

**STATS**

displays the values of the statistics and their confidence limits on the right side of the plot. If you do not request the **STATS** option, the statistic values are not displayed.

**RISK**

requests risk statistics for  $2 \times 2$  tables. The RISK option also provides standard errors and confidence limits for these statistics. Risk statistics include the row 1 risk (proportion), row 2 risk, overall risk, and risk difference. See the section “[Risks and Risk Difference](#)” on page 7109 for details.

The RISK option provides both column 1 and column 2 risks. To request only column 1 or column 2 risks, use the [RISK1](#) or [RISK2](#) option.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the [ALPHA=](#) option, which by default equals 0.05 and produces 95% confidence limits.

**RISK1**

requests column 1 risk statistics for  $2 \times 2$  tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk (proportion), row 2 risk, overall risk, and risk difference. See the section “[Risks and Risk Difference](#)” on page 7109 for details.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the [ALPHA=](#) option, which by default equals 0.05 and produces 95% confidence limits.

**RISK2**

requests column 2 risk statistics for  $2 \times 2$  tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk (proportion), row 2 risk, overall risk, and risk difference. See the section “[Risks and Risk Difference](#)” on page 7109 for details.

To compute confidence limits for the risks and risk difference, PROC SURVEYFREQ determines the confidence coefficient from the [ALPHA=](#) option, which by default equals 0.05 and produces 95% confidence limits.

**ROW** < option >

displays the row percentage (estimated proportion of the row total) for each cell in a two-way table. The ROW option also provides the standard errors of the row percentages. See the section “[Row and Column Proportions](#)” on page 7096 for more information. This option has no effect for one-way tables.

You can specify the following option in parentheses following the ROW option:

**DEFF**

displays the design effect for each row percentage in the crosstabulation table. See the section “[Design Effect](#)” on page 7107 for more information.

**TESTP=(values)**

specifies null hypothesis proportions (test percentages) for one-way chi-square tests. You can separate *values* with blanks or commas. Specify *values* in probability form as numbers between 0 and 1, where the proportions sum to 1. Or specify *values* in percentage form as numbers between 0 and 100, where the percentages sum to 100. PROC SURVEYFREQ treats the value 1 as the percentage form 1%. The number of TESTP= values must equal the number of variable levels in the one-way table. List these values in the same order in which the corresponding variable levels appear in the output.

When you specify the TESTP= option, PROC SURVEYFREQ displays the specified test percentages in the one-way frequency table. The TESTP= option has no effect for two-way tables.

PROC SURVEYFREQ uses the TESTP= values for all one-way chi-square tests you request in the TABLES statement. The available one-way chi-square tests include the Rao-Scott (Pearson) chi-square test and the Rao-Scott likelihood ratio chi-square test and their modified versions, which you request with the CHISQ, CHISQ1, LRCHISQ, and LRCHISQ1 options. See the sections “Rao-Scott Chi-Square Test” on page 7113 and “Rao-Scott Likelihood Ratio Chi-Square Test” on page 7116 for details.

#### **VAR**

displays the variance estimate for each percentage in the crosstabulation table. See the section “Proportions” on page 7094 for details. By default, PROC SURVEYFREQ displays the standard errors of the percentages.

#### **VARWT**

displays the variance estimate for each weighted frequency, or estimated total, in the crosstabulation table. See the section “Totals” on page 7092 for details. By default, PROC SURVEYFREQ displays the standard deviations of the weighted frequencies.

#### **WCHISQ**

requests the Wald chi-square test for two-way tables. See the section “Wald Chi-Square Test” on page 7118 for details.

#### **WLLCHISQ**

requests the Wald log-linear chi-square test for two-way tables. See the section “Wald Log-Linear Chi-Square Test” on page 7120 for details.

#### **WTFREQ**

displays totals (weighted frequencies) and their standard errors when you do not specify a WEIGHT or REPWEIGHTS statement. PROC SURVEYFREQ displays the weighted frequencies by default when you include a WEIGHT or REPWEIGHTS statement. Without a WEIGHT or REPWEIGHTS statement, PROC SURVEYFREQ assigns all observations a weight of one.

---

## **WEIGHT Statement**

**WEIGHT** *variable* ;

The WEIGHT statement names the variable that contains the sampling weights. This variable must be numeric, and the sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “Missing Values” on page 7087 for more information. If you specify more than one WEIGHT statement, the procedure uses only the first WEIGHT statement and ignores the rest.

If you do not specify a `WEIGHT` statement but provide replicate weights with a `REPWEIGHTS` statement, PROC SURVEYFREQ uses the average of each observation's replicate weights as the observation's weight.

If you do not specify a `WEIGHT` statement or a `REPWEIGHTS` statement, PROC SURVEYFREQ assigns all observations a weight of one.

---

## Details: SURVEYFREQ Procedure

---

### Specifying the Sample Design

PROC SURVEYFREQ produces tables and statistics that are based on the sample design used to obtain the survey data. PROC SURVEYFREQ can be used for single-stage or multistage designs, with or without stratification, and with or without unequal weighting. To analyze your survey data with PROC SURVEYFREQ, you need to provide sample design information for the procedure. This information can include design strata, clusters, and sampling weights. You provide sample design information with the `STRATA`, `CLUSTER`, and `WEIGHT` statements, and with the `RATE=` or `TOTAL=` option in the PROC SURVEYFREQ statement.

If you provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a `STRATA` or `CLUSTER` statement. Otherwise, you should specify `STRATA` and `CLUSTER` statements whenever your design includes stratification and clustering.

When there are clusters (PSUs) in the sample design, the procedure estimates variance by using the PSUs, as described in the section “[Statistical Computations](#)” on page 7090. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. Therefore, the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling.

### Stratification

If your sample design is stratified at the first stage of sampling, use the `STRATA` statement to name the variables that form the strata. The combinations of categories of `STRATA` variables define the strata in the sample, where strata are nonoverlapping subgroups that were sampled independently. If your sample design has stratification at multiple stages, you should identify only the first-stage strata in the `STRATA` statement.

If you use a `REPWEIGHTS` statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a `STRATA` statement. Otherwise, you should specify a `STRATA` statement whenever your design includes stratification. If you do not specify a `STRATA` statement or a `REPWEIGHTS` statement, then PROC SURVEYFREQ assumes there is no stratification at the first stage.

## Clustering

If your sample design selects clusters at the first stage of sampling, use the **CLUSTER** statement to name the variables that identify the first-stage clusters, which are also called primary sampling units (PSUs). The combinations of categories of **CLUSTER** variables define the clusters in the sample. If there is a **STRATA** statement, clusters are nested within strata. If your sample design has clustering at multiple stages, you should specify only the first-stage clusters (PSUs) in the **CLUSTER** statement. **PROC SURVEYFREQ** assumes that each cluster that is defined by the **CLUSTER** statement variables represents a PSU in the sample, and that each observation belongs to one PSU.

If you use a **REPWEIGHTS** statement to provide replicate weights for BRR or jackknife variance estimation, you do not need to specify a **CLUSTER** statement. Otherwise, you should specify a **CLUSTER** statement whenever your design includes clustering at the first stage of sampling. If you do not specify a **CLUSTER** statement, then **PROC SURVEYFREQ** treats each observation as a PSU.

## Weighting

If your sample design includes unequal weighting, use the **WEIGHT** statement to name the variable that contains the sampling weights. Sampling weights must be positive numbers. If an observation has a weight that is nonpositive or missing, then the procedure omits that observation from the analysis. See the section “**Missing Values**” on page 7087 for more information.

If you do not specify a **WEIGHT** statement but include a **REPWEIGHTS** statement, **PROC SURVEYFREQ** uses the average of each observation’s replicate weights as the observation’s weight. If you do not specify a **WEIGHT** statement or a **REPWEIGHTS** statement, **PROC SURVEYFREQ** assigns all observations a weight of one.

## Population Totals and Sampling Rates

To include a finite population correction (*fpc*) in Taylor series variance estimation, you can input either the sampling rate or the population total by using the **RATE=** or **TOTAL=** option in the **PROC SURVEYFREQ** statement. (You cannot specify both of these options in the same **PROC SURVEYFREQ** statement.) The **RATE=** and **TOTAL=** options apply only to Taylor series variance estimation. The procedure does not use a finite population correction for BRR or jackknife variance estimation.

If you do not specify the **RATE=** or **TOTAL=** option, the Taylor series variance estimation does not include a finite population correction. For fairly small sampling fractions, it is appropriate to ignore this correction. See Cochran (1977) and Kish (1965) for more information.

If your design has multiple stages of selection and you are specifying the **RATE=** option, you should input the first-stage sampling rate, which is the ratio of the number of PSUs in the sample to the total number of PSUs in the study population. If you are specifying the **TOTAL=** option for a multistage design, you should input the total number of PSUs in the study population.

For a nonstratified sample design, or for a stratified sample design with the same sampling rate or the same population total in all strata, you can use the **RATE=value** or **TOTAL=value** option. If your sample design is stratified with different sampling rates or population totals in different strata,

use the `RATE=SAS-data-set` or `TOTAL=SAS-data-set` option to name a SAS data set that contains the stratum sampling rates or totals. This data set is called a *secondary data set*, as opposed to the *primary data set* that you specify with the `DATA=` option.

The secondary data set must contain all the stratification variables listed in the `STRATA` statement and all the variables in the `BY` statement. Furthermore, the `BY` groups must appear in the same order as in the primary data set. If there are formats that are associated with the `STRATA` variables and the `BY` variables, then the formats must be consistent in the primary and the secondary data sets. If you specify the `TOTAL=SAS-data-set` option, the secondary data set must have a variable named `_TOTAL_` that contains the stratum population totals. If you specify the `RATE=SAS-data-set` option, the secondary data set must have a variable named `_RATE_` that contains the stratum sampling rates. If the secondary data set contains more than one observation for any one stratum, the procedure uses the first value of `_TOTAL_` or `_RATE_` for that stratum and ignores the rest.

The *value* in the `RATE=` option or the values of `_RATE_` in the secondary data set must be nonnegative numbers. You can specify *value* as a number between 0 and 1. Or you can specify *value* in percentage form as a number between 1 and 100, and PROC SURVEYFREQ converts that number to a proportion. The procedure treats the value 1 as 100% instead of 1%.

If you specify the `TOTAL=value` option, *value* must not be less than the sample size. If you provide stratum population totals in a secondary data set, these values must not be less than the corresponding stratum sample sizes.

---

## Domain Analysis

PROC SURVEYFREQ provides domain analysis through its multiway table capability. *Domain analysis* refers to the computation of statistics for domains (subpopulations), in addition to the computation of statistics for the entire study population. Formation of subpopulations can be unrelated to the sample design, and so the domain sample sizes can actually be random variables. Domain analysis takes this variability into account by using the entire sample in estimating the variance of domain estimates. Domain analysis is also known as subgroup analysis, subpopulation analysis, and subdomain analysis. For more information about domain analysis, see Lohr (2009), Cochran (1977), and Fuller et al. (1989).

To request domain analysis with PROC SURVEYFREQ, you should include the domain variable(s) in your `TABLES` statement request. For example, specifying `DOMAIN * A * B` in a `TABLES` statement produces separate two-way tables of A by B for each level of `DOMAIN`. If your domains are formed by more than one variable, you can specify `DomainVariable_1 * DomainVariable_2 * A * B`, for example, to obtain two-way tables of A by B for each domain formed by the different combinations of levels for `DomainVariable_1` and `DomainVariable_2`. See [Example 84.2](#) for an example of domain analysis.

If you specify `DOMAIN * A` in a `TABLES` statement, the values of the variable `DOMAIN` form the table rows. The two-way table lists levels of the variable A within each level of the row variable `DOMAIN`. Specify the `ROW` option in the `TABLES` statement to obtain the row percentages and their standard errors. This provides the one-way distribution of A for each domain (level of the variable `DOMAIN`).

Including the domain variables in a `TABLES` statement request provides a different analysis from that obtained by using a `BY` statement, which provides completely separate analyses of the `BY` groups. The `BY` statement can also be used to analyze the data set by subgroups, but it is critical to

note that this does *not* produce a valid domain analysis. The BY statement is appropriate only when the number of units in each subgroup is known with certainty. For example, the BY statement can be used to obtain stratum level estimates when you have fixed sample sizes for the strata. When the subgroup sample size is a random variable, include the domain variables in your TABLES statement request.

---

## Missing Values

### WEIGHT Variable

If an observation has a missing value or a nonpositive value for the **WEIGHT** variable, then PROC SURVEYFREQ excludes that observation from the analysis.

### REPWEIGHTS Variables

If you provide replicate weights with a **REPWEIGHTS** statement for BRR or jackknife variance estimation, all **REPWEIGHTS** variable values must be nonmissing. Similarly, if you provide jackknife coefficients with the **JKCOEFS=** option in the **REPWEIGHTS** statement, all values of the **JKCoefficient** variable must be nonmissing. The procedure does not perform the analysis when any replicate weight or jackknife coefficient value is missing.

### STRATA and CLUSTER Variables

An observation is excluded from the analysis if it has a missing value for any **STRATA** or **CLUSTER** variable, unless you specify the **MISSING** option in the PROC SURVEYFREQ statement. If you specify the **MISSING** option, the procedure treats missing values as a valid (nonmissing) category for all categorical variables, which include **STRATA** variables, **CLUSTER** variables, and **TABLES** variables.

### TABLES Variables

By default, PROC SURVEYFREQ excludes an observation from a crosstabulation table (and all associated analyses) if the observation has a missing value for any of the variables in the **TABLES** request, unless you specify the **MISSING** or **NOMCAR** option in the PROC SURVEYFREQ statement. When the procedure excludes observations with missing values from a table, it displays the total frequency of missing observations below the table.

If you specify the **MISSING** option, the procedure treats missing values as a valid (nonmissing) level for each **TABLES** variable. These levels are displayed in the crosstabulation table and included in computations of totals, percentages, and all other table statistics.

If you specify the **NOMCAR** option, which is available for Taylor series variance estimation, the procedure includes observations with missing values of **TABLES** variables in the variance computations. The **NOMCAR** option does not display missing levels in the crosstabulation table or compute percentages and totals for missing levels.

## The NOMCAR Option

The **NOMCAR** option includes observations with missing values of **TABLES** variables in the variance computations as *not missing completely at random* (NOMCAR) for Taylor series variance estimation. By default, observations are completely excluded from the analysis if they have missing values for any of the variables in the current **TABLES** request. This default treatment is based on the assumption that the values are *missing completely at random* (MCAR), and assumes that the analysis results should not be substantially different between the missing and nonmissing groups. See the section “[Analysis Considerations](#)” on page 7089 for more information.

When you specify the **NOMCAR** option, PROC SURVEYFREQ computes variance estimates by analyzing the nonmissing values as a domain (subpopulation), where the entire population includes both nonmissing and missing domains.

Note that the **NOMCAR** option has no effect when you specify the **MISSING** option, which treats missing values as a valid nonmissing level. The **NOMCAR** option does not affect the inclusion of observations with missing values of the **WEIGHT**, **CLUSTER**, or **STRATA** variables. Observations with missing values of the **WEIGHT** variable are always excluded from the analysis. Observations with missing values of the **CLUSTER** or **STRATA** variables are excluded unless you specify the **MISSING** option.

The **NOMCAR** option applies only to Taylor series variance estimation. The replication methods, which you request with the **VARMETHOD=BRR** and **VARMETHOD=JACKKNIFE** options, do not use the **NOMCAR** option.

## Degrees of Freedom

PROC SURVEYFREQ computes degrees of freedom to obtain the  $t$ -percentile for confidence limits for proportions, totals, and other statistics. The procedure also uses degrees of freedom for the  $F$  statistics in the Rao-Scott and Wald chi-square tests. The degrees of freedom computation depends on the variance estimation method that you request. See the section “[Degrees of Freedom](#)” on page 7106 for details. Missing values can affect the degrees of freedom computation.

### **Taylor Series Variance Estimation**

The degrees of freedom can depend on the number of clusters, the number of strata, and the number of observations. For Taylor series variance estimation, these numbers are based on the observations included in the analysis of the individual table. These numbers do not count observations that are excluded from the table due to missing values. If all values in a stratum are excluded from the analysis of a table as missing values, then that stratum is called an *empty stratum*. Empty strata are not counted in the total number of strata for the table. Similarly, empty clusters and missing observations are not included in the total counts of clusters and observations that are used to compute the degrees of freedom for the analysis.

If you specify the **MISSING** option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the **NOMCAR** option for Taylor series variance estimation, observations with missing values of the **TABLES** variables are included in computing degrees of freedom.

### Replicate-Based Variance Estimation

For BRR or jackknife variance estimation, by default PROC SURVEYFREQ computes the degrees of freedom by using all valid observations in the input data set. A valid observation is an observation that has a positive value of the **WEIGHT** variable and nonmissing values of the **STRATA** and **CLUSTER** variables unless you specify the **MISSING** option. See the section “Data Summary Table” on page 7122 for details about valid observations.

If you specify the *DFADJ method-option* for **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE**, the procedure computes the degrees of freedom based on the nonmissing observations included in the individual table analysis. This excludes any empty strata or clusters that occur when observations with missing values of the **TABLES** variables are removed from the analysis for that table.

### Table Summary Output Data Set

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the individual table. If there are missing observations, empty strata, or empty clusters excluded from the analysis, the “Table Summary” data set also contains this information. If you request any confidence limits or chi-square tests for the table, which require degrees of freedom, the “Table Summary” data set provides the degrees of freedom.

Due to missing values, the number of observations used for an individual table analysis can differ from the number of valid observations in the input data set, which is reported in the “Data Summary” table. Similarly, a difference can also occur for the number of clusters or strata. See [Example 84.3](#) for more information about the “Table Summary” output data set.

If you specify the **NOMCAR** option for Taylor series variance estimation, the “Table Summary” data set reflects all observations used for variance estimation, which includes those observations with missing values of the **TABLES** variables.

### Analysis Considerations

If you have missing values in your survey data for any reason (such as nonresponse), this can compromise the quality of your survey results. An observation without missing values is called a *complete respondent*, and an observation with missing values is called an *incomplete respondent*. If the complete respondents are different from the incomplete respondents with regard to a survey effect or outcome, then survey estimates will be biased and will not accurately represent the survey population. There are a variety of techniques in sample design and survey operations that can reduce nonresponse. After data collection is complete, you can use imputation to replace missing values with acceptable values, and you can use sampling weight adjustments to compensate for nonresponse. You should complete this data preparation and adjustment before you analyze your data with PROC SURVEYFREQ. See Cochran (1977), Kalton and Kaspyzyk (1986), and Brick and Kalton (1996) for more details.

---

## Statistical Computations

### Variance Estimation

PROC SURVEYFREQ provides a choice of variance estimation methods for complex survey data. In addition to the Taylor series linearization method, the procedures offer two replication-based (resampling) methods—balanced repeated replication (BRR) and the delete-1 jackknife. These variance estimation methods usually give similar, satisfactory results (Lohr 2009; Särndal, Swensson, and Wretman 1992; Wolter 1985). The choice of a variance estimation method can depend on the sample design used, the sample design information available, the parameters to be estimated, and computational issues. See Lohr (2009) for more details.

#### *Taylor Series Variance Estimation*

The Taylor series linearization method can be used to estimate standard errors of proportions and other statistics for crosstabulation tables. For sample survey data, the proportion estimator is a ratio estimator formed from estimators of totals. For example, to estimate the proportion in a crosstabulation table cell, the procedure uses the ratio of the estimator of the cell total frequency to the estimator of the overall population total, where these totals are linear statistics computed from the survey data. The Taylor series expansion method obtains a first-order linear approximation for the ratio estimator and then uses the variance estimate for this approximation to estimate the variance of the estimate itself (Woodruff 1971; Fuller 1975). For more information about Taylor series variance estimation for sample survey data, see Lohr (2009), Särndal, Swensson, and Wretman (1992), Lee, Forthoffer, and Lorimor (1989), and Wolter (1985).

When there are clusters (PSUs) in the sample design, the Taylor series method estimates variance from the variance among PSUs. When the design is stratified, the procedure combines stratum variance estimates to compute the overall variance estimate. For a multistage sample design, the variance estimation depends only on the first stage of the sample design. So the required input includes only first-stage cluster (PSU) and first-stage stratum identification. You do not need to input design information about any additional stages of sampling. This variance estimation method assumes that the first-stage sampling fraction is small, or the first-stage sample is drawn with replacement, as it often is in practice.

See the sections “Proportions” on page 7094, “Row and Column Proportions” on page 7096, “Risks and Risk Difference” on page 7109, and “Odds Ratio and Relative Risks” on page 7110 for details and formulas for Taylor series variance estimates.

#### *Replication-Based Variance Estimation*

Replication-based methods for variance estimation draw multiple replicates (subsamples) from the full sample by following a specific resampling scheme. Commonly used resampling schemes include *balanced repeated replication* (BRR) and the *jackknife*. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (2009) for more information.

The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. Each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix and adjusting the original weights of the remaining PSUs. The adjusted weights are called *replicate weights*. PROC SURVEYFREQ also provides Fay’s method, which is a modification of the BRR method. See the section “Balanced Repeated Replication (BRR)” on page 7097 for details.

The jackknife method deletes one PSU at a time from the full sample to create replicates, and modifies the original weights to obtain replicate weights. The total number of replicates equals the number of PSUs. If the sample design is stratified, each stratum must contain at least two PSUs, and the jackknife is applied separately within each stratum. See the section “The Jackknife Method” on page 7100 for details.

Instead of having PROC SURVEYFREQ generate replicate weights for the analysis, you can input your own replicate weights with a REPWEIGHTS statement. This can be useful if you need to do multiple analyses with the same set of replicate weights, or if you have access to replicate weights instead of design information. See the section “Replicate Weights Output Data Set” on page 7121 for more information.

## Definitions and Notation

For a stratified clustered sample design, define the following:

$h = 1, 2, \dots, H$	is the stratum number, with a total of $H$ strata
$i = 1, 2, \dots, n_h$	is the cluster number within stratum $h$ , with a total of $n_h$ sample clusters in stratum $h$
$j = 1, 2, \dots, m_{hi}$	is the unit number within cluster $i$ of stratum $h$ , with a total of $m_{hi}$ sample units from cluster $i$ of stratum $h$
$n = \sum_{h=1}^H \sum_{i=1}^{n_h} m_{hi}$	is the total number of observations in the sample
$f_h$	= first-stage sampling rate for stratum $h$
$W_{hij}$	= sampling weight of unit $j$ in cluster $i$ of stratum $h$

The sampling rate  $f_h$ , which is used in Taylor series variance estimation, is the fraction of first-stage units (PSUs) selected for the sample. You can specify the stratum sampling rates with the RATE= option. Or if you specify population totals with the TOTAL= option, PROC SURVEYFREQ computes  $f_h$  as the ratio of stratum sample size to the stratum total, in terms of PSUs. See the section “Population Totals and Sampling Rates” on page 7085 for details. If you do not specify the RATE= option or the TOTAL= option, then the procedure assumes that the stratum sampling rates  $f_h$  are negligible and does not use a finite population correction when computing variances.

This notation is also applicable to other sample designs. For example, for a design without stratification, you can let  $H = 1$ ; for a sample design without clustering, you can let  $m_{hi} = 1$  for every  $h$  and  $i$ , which replaces clusters with individual sampling units.

For a two-way table representing the crosstabulation of two variables, define the following, where there are  $R$  levels of the row variable and  $C$  levels of the column variable:

$$\begin{aligned}
 r &= 1, 2, \dots, R && \text{is the row number, with a total of } R \text{ rows} \\
 c &= 1, 2, \dots, C && \text{is the column number, with a total of } C \text{ columns} \\
 N_{rc} &&& \text{is the population total in row } r \text{ and column } c \\
 N_{r\cdot} &= \sum_{c=1}^C N_{rc} && \text{is the total in row } r \\
 N_{\cdot c} &= \sum_{r=1}^R N_{rc} && \text{is the total in column } c \\
 N &= \sum_{r=1}^R \sum_{c=1}^C N_{rc} && \text{is the overall total} \\
 P_{rc} &= N_{rc} / N && \text{is the population proportion in row } r \text{ and column } c \\
 P_{r\cdot} &= N_{r\cdot} / N && \text{is the proportion in row } r \\
 P_{\cdot c} &= N_{\cdot c} / N && \text{is the proportion in column } c \\
 P_{rc}^r &= N_{rc} / N_{r\cdot} && \text{is the row proportion for table cell } (r, c) \\
 P_{rc}^c &= N_{rc} / N_{\cdot c} && \text{is the column proportion for table cell } (r, c)
 \end{aligned}$$

For a specified observation (identified by stratum, cluster, and unit number within the cluster), define the following to indicate whether or not that observation belongs to cell  $(r, c)$ , row  $r$  and column  $c$ , of the two-way table, for  $r = 1, 2, \dots, R$  and  $c = 1, 2, \dots, C$ :

$$\delta_{hij}(r, c) = \begin{cases} 1 & \text{if observation } (hij) \text{ is in cell } (r, c) \\ 0 & \text{otherwise} \end{cases}$$

Similarly, define the following functions to indicate the observation's row and column classification:

$$\begin{aligned}
 \delta_{hij}(r \cdot) &= \begin{cases} 1 & \text{if observation } (hij) \text{ is in row } r \\ 0 & \text{otherwise} \end{cases} \\
 \delta_{hij}(\cdot c) &= \begin{cases} 1 & \text{if observation } (hij) \text{ is in column } c \\ 0 & \text{otherwise} \end{cases}
 \end{aligned}$$

## Totals

PROC SURVEYFREQ estimates population frequency totals for the specified crosstabulation tables, including totals for two-way table cells, rows, columns, and overall totals. The procedure computes the estimate of the total frequency in table cell  $(r, c)$  as the weighted frequency sum,

$$\hat{N}_{rc} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}$$

Similarly, PROC SURVEYFREQ computes estimates of row totals, column totals, and overall totals as

$$\hat{N}_{r\cdot} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r \cdot) W_{hij}$$

$$\widehat{N}_{\cdot c} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(\cdot c) W_{hij}$$

$$\widehat{N} = \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij}$$

PROC SURVEYFREQ estimates the variances of totals by using the variance estimation method that you request. If you request BRR variance estimation (by specifying the `VARMETHOD=BRR` option in the PROC SURVEYFREQ statement), the procedure estimates the variances as described in the section “Balanced Repeated Replication (BRR)” on page 7097. If you request jackknife variance estimation (by specifying the `VARMETHOD=JACKKNIFE` option), the procedure estimates the variances as described in the section “The Jackknife Method” on page 7100.

If you do not specify the `VARMETHOD=` option or a `REPWEIGHTS` statement, the default variance estimation method is Taylor series, which you can also request with the `VARMETHOD=TAYLOR` option. Since totals are linear statistics, their variances can be estimated directly, without the approximation that is used for proportions and other nonlinear statistics. PROC SURVEYFREQ estimates the variance of the total frequency in table cell  $(r, c)$  as

$$\widehat{\text{Var}}(\widehat{N}_{rc}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{N}_{rc})$$

where if  $n_h > 1$ ,

$$\widehat{\text{Var}}_h(\widehat{N}_{rc}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^h)^2$$

$$n_{rc}^{hi} = \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij}$$

$$\bar{n}_{rc}^h = \sum_{i=1}^{n_h} n_{rc}^{hi} / n_h$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{N}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard deviation of the total is computed as

$$\text{Std}(\widehat{N}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{N}_{rc})}$$

The variances and standard deviations are computed in a similar manner for row totals, column totals, and overall table totals.

## Covariance of Totals

The covariance matrix of the table cell totals  $\widehat{N}_{rc}$  is an  $rc \times rc$  matrix  $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$ , which contains the pairwise table cell covariances  $\widehat{\text{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab})$ , for  $r = 1, \dots, R$ ;  $c = 1, \dots, C$ ;  $a = 1, \dots, R$ ; and  $b = 1, \dots, C$ .

PROC SURVEYFREQ estimates the covariances by using the variance estimation method that you request. If you request BRR variance estimation (by specifying the `VARMETHOD=BRR` option in the PROC SURVEYFREQ statement), the procedure estimates the covariances by the method described in the section “Balanced Repeated Replication (BRR)” on page 7097. If you request jackknife variance estimation (by specifying the `VARMETHOD=JACKKNIFE` option), the procedure uses the method described in the section “The Jackknife Method” on page 7100.

Otherwise (by default, or if you request the Taylor series method), PROC SURVEYFREQ estimates the covariance between total frequency estimates for table cells  $(r, c)$  and  $(a, b)$  as

$$\widehat{\text{Cov}}(\widehat{N}_{rc}, \widehat{N}_{ab}) = \sum_{h=1}^H \left( \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (n_{rc}^{hi} - \bar{n}_{rc}^h) (n_{ab}^{hi} - \bar{n}_{ab}^h) \right)$$

## Proportions

PROC SURVEYFREQ computes the estimate of the proportion in table cell  $(r, c)$  as the ratio of the estimated total for the table cell to the estimated overall total,

$$\begin{aligned} \widehat{P}_{rc} &= \widehat{N}_{rc} / \widehat{N} \\ &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} W_{hij} \end{aligned}$$

If you request BRR variance estimation (by specifying the `VARMETHOD=BRR` option in the PROC SURVEYFREQ statement), the procedure estimates the variances of proportion estimates as described in the section “Balanced Repeated Replication (BRR)” on page 7097. If you request jackknife variance estimation (by specifying the `VARMETHOD=JACKKNIFE` option), the procedure estimates the variances as described in the section “The Jackknife Method” on page 7100.

If you do not specify the `VARMETHOD=` option or a `REPWEIGHTS` statement, the default variance estimation method is Taylor series, which you can also request with the `VARMETHOD=TAYLOR` option. By using Taylor series linearization, the variance of a proportion estimate can be expressed as

$$\widehat{\text{Var}}(\widehat{P}_{rc}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{rc})$$

where if  $n_h > 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{rc}^{hi} - \bar{e}_{rc}^h)^2$$

$$e_{rc}^{hi} = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}) W_{hij} \right) / \widehat{N}$$

$$\bar{e}_{rc}^h = \sum_{i=1}^{n_h} e_{rc}^{hi} / n_h$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc})}$$

Similarly, the estimate of the proportion in row  $r$  is

$$\widehat{P}_{r\cdot} = \widehat{N}_{r\cdot} / \widehat{N}$$

And its variance estimate is

$$\widehat{\text{Var}}(\widehat{P}_{r\cdot}) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{r\cdot})$$

where if  $n_h > 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{r\cdot}) = \frac{n_h(1 - f_h)}{n_h - 1} \sum_{i=1}^{n_h} (e_{r\cdot}^{hi} - \bar{e}_{r\cdot}^h)^2$$

$$e_{r\cdot}^{hi} = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r \cdot) - \widehat{P}_{r\cdot}) W_{hij} \right) / \widehat{N}$$

$$\bar{e}_{r\cdot}^h = \sum_{i=1}^{n_h} e_{r\cdot}^{hi} / n_h$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{r\cdot}) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the proportion in row  $r$  is computed as

$$\text{StdErr}(\widehat{P}_{r\cdot}) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{r\cdot})}$$

Computations for the proportion in column  $c$  are done in the same way.

## Row and Column Proportions

PROC SURVEYFREQ computes the estimate of the row proportion for table cell  $(r, c)$  as the ratio of the estimated total for the table cell to the estimated total for row  $r$ ,

$$\begin{aligned}\widehat{P}_{rc}^r &= \widehat{N}_{rc} / \widehat{N}_r \\ &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r \cdot) W_{hij}\end{aligned}$$

Similarly, PROC SURVEYFREQ estimates the column proportion for table cell  $(r, c)$  as the ratio of the estimated total for the table cell to the estimated total for column  $c$ ,

$$\begin{aligned}\widehat{P}_{rc}^c &= \widehat{N}_{rc} / \widehat{N}_{\cdot c} \\ &= \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(r, c) W_{hij} / \sum_{h=1}^H \sum_{i=1}^{n_h} \sum_{j=1}^{m_{hi}} \delta_{hij}(\cdot c) W_{hij}\end{aligned}$$

If you request BRR variance estimation (**VARMETHOD=BRR**), PROC SURVEYFREQ estimates the variances of the row and column proportions as described in the section “Balanced Repeated Replication (BRR)” on page 7097. If you request jackknife variance estimation (**VARMETHOD=JACKKNIFE**), the procedure estimates the variances as described in the section “The Jackknife Method” on page 7100.

If you do not specify the **VARMETHOD=** option or a **REPWEIGHTS** statement, the default variance estimation method is Taylor series (**VARMETHOD=TAYLOR**). By using Taylor series linearization, the variance of the row proportion estimate can be expressed as

$$\widehat{\text{Var}}(\widehat{P}_{rc}^r) = \sum_{h=1}^H \widehat{\text{Var}}_h(\widehat{P}_{rc}^r)$$

where if  $n_h > 1$ ,

$$\begin{aligned}\widehat{\text{Var}}_h(\widehat{P}_{rc}^r) &= \frac{n_h(1-f_h)}{n_h-1} \sum_{i=1}^{n_h} (g_{rc}^{hi} - \bar{g}_{rc}^h)^2 \\ g_{rc}^{hi} &= \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}^r \delta_{hij}(r \cdot)) W_{hij} \right) / \widehat{N}_r \\ \bar{g}_{rc}^h &= \sum_{i=1}^{n_h} g_{rc}^{hi} / n_h\end{aligned}$$

and if  $n_h = 1$ ,

$$\widehat{\text{Var}}_h(\widehat{P}_{rc}^r) = \begin{cases} \text{missing} & \text{if } n_{h'} = 1 \text{ for } h' = 1, 2, \dots, H \\ 0 & \text{if } n_{h'} > 1 \text{ for some } 1 \leq h' \leq H \end{cases}$$

The standard error of the row proportion is computed as

$$\text{StdErr}(\widehat{P}_{rc}^r) = \sqrt{\widehat{\text{Var}}(\widehat{P}_{rc}^r)}$$

The Taylor series variance estimate for the column proportion is computed as described previously for the row proportion, but with

$$g_{rc}^{hi} = \left( \sum_{j=1}^{m_{hi}} (\delta_{hij}(r, c) - \widehat{P}_{rc}^c \delta_{hij}(\cdot, c)) W_{hij} \right) / \widehat{N}_{\cdot c}$$

### Balanced Repeated Replication (BRR)

If you specify the `VARMETHOD=BRR` option, then PROC SURVEYFREQ uses balanced repeated replication (BRR) for variance estimation. The BRR variance estimation method requires a stratified sample design with two PSUs in each stratum. You can provide replicate weights for BRR variance estimation by using a `REPWEIGHTS` statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (2009) for more information about BRR variance estimation.

If you do not provide replicate weights with a `REPWEIGHTS` statement, PROC SURVEYFREQ constructs replicates based on the stratified design with two PSUs in each stratum. This section describes replicate construction by the traditional BRR method. If you specify the `FAY method-option` for `VARMETHOD=BRR`, the procedure uses Fay's modified BRR method, which is described in the section "Fay's BRR Method" on page 7098.

With the traditional BRR method, each replicate is obtained by deleting one PSU per stratum according to the corresponding Hadamard matrix of dimension  $R$ , where  $R$  is the number of replicates. The number of replicates equals the smallest multiple of 4 that is greater than the number of strata  $H$ . Alternatively, you can specify the number of replicates with the `REPS= method-option`. If a Hadamard matrix cannot be constructed for the `REPS=` value that you specify, the value is increased until a Hadamard matrix of that dimension can be constructed. Therefore, it is possible for the actual number of replicates used to be larger than the `REPS=` value that you specify.

You can provide a Hadamard matrix for BRR replicate construction by using the `HADAMARD= method-option`. Otherwise, PROC SURVEYFREQ generates an appropriate Hadamard matrix. See the section "Hadamard Matrix" on page 7100 for more information. You can display the Hadamard matrix by specifying the `PRINTH method-option`.

PROC SURVEYFREQ constructs replicates by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $H$  denotes the number of strata. The  $r$ th replicate ( $r = 1, 2, \dots, R$ ) is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$ th element of the Hadamard matrix equals 1, then the first PSU of stratum  $h$  is included in the  $r$ th replicate, and the second PSU of stratum  $h$  is excluded.

- If the  $(r, h)$ th element of the Hadamard matrix equals  $-1$ , then the second PSU of stratum  $h$  is included in the  $r$ th replicate, and the first PSU of stratum  $h$  is excluded.

For the PSUs included in replicate  $r$ , the original weights are doubled to form the replicate  $r$  weights. For the PSUs not included in replicate  $r$ , the replicate  $r$  weights equal zero. You can use the `OUTWEIGHTS=method-option` to store the replicate weights in a SAS data set. See the section “Replicate Weights Output Data Set” on page 7121 for details about the contents of the `OUTWEIGHTS=` data set. You can provide these replicate weights to the procedure for subsequent analyses by using a `REPWEIGHTS` statement.

Let  $\theta$  denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let  $\hat{\theta}$  denote the estimate of  $\theta$  from the full sample, and let  $\hat{\theta}_r$  denote the estimate from the  $r$ th BRR replicate, which is computed by using the replicate weights. The BRR variance estimate for  $\hat{\theta}$  is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2$$

where  $R$  is the total number of replicates.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column  $j$  for table cell  $(i, j)$ . If a replicate  $r$  contains no observations in column  $j$ , then the column  $j$  proportion is not estimable from replicate  $r$ . In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'} \sum_{r=1}^{R'} (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  is estimable, and  $R'$  is the number of those replicates.

### Fay's BRR Method

If you specify the `FAY` *method-option* for `VARMETHOD=BRR`, then PROC SURVEYFREQ uses Fay's BRR method, which is a modification of the traditional BRR variance estimation method. As for traditional BRR, Fay's method requires a stratified sample design with two PSUs in each stratum. You can provide replicate weights by using a `REPWEIGHTS` statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate.

If you do not provide replicate weights with a `REPWEIGHTS` statement, PROC SURVEYFREQ constructs replicates based on the stratified design with two PSUs in each stratum. As for traditional BRR, the number of replicates  $R$  equals the smallest multiple of 4 that is greater than the number of strata  $H$ , or you can specify the number of replicates with the `REPS=method-option`. You can provide a Hadamard matrix for replicate construction by using the `HADAMARD=method-option`, or PROC SURVEYFREQ generates an appropriate Hadamard matrix.

The traditional BRR method constructs half-sample replicates by deleting one PSU per stratum according to the Hadamard matrix and doubling the original weights to form replicate weights. Fay's BRR method adjusts the original weights by a coefficient  $\epsilon$ , where  $0 \leq \epsilon < 1$ . You can specify the value of  $\epsilon$  with the `FAY=method-option`. If you do not specify the value of  $\epsilon$ , PROC SURVEYFREQ uses  $\epsilon = 0.5$  by default. See Judkins (1990) and Rao and Shao (1999) for information about the value of the Fay coefficient. When  $\epsilon = 0$ , Fay's method becomes the traditional BRR method. See Dippo, Fay, and Morganstein (1984), Fay (1989), and Judkins (1990) for more information.

PROC SURVEYFREQ constructs Fay BRR replicates by using the first  $H$  columns of the  $R \times R$  Hadamard matrix, where  $H$  denotes the number of strata. The  $r$ th replicate ( $r = 1, 2, \dots, R$ ) is drawn from the full sample according to the  $r$ th row of the Hadamard matrix as follows:

- If the  $(r, h)$ th element of the Hadamard matrix equals 1, the sampling weight of the first PSU in stratum  $h$  is multiplied by  $\epsilon$ , and the sampling weight of the second PSU is multiplied by  $(2 - \epsilon)$  to form the  $r$ th replicate weights.
- If the  $(r, h)$ th element of the Hadamard matrix equals  $-1$ , then the sampling weight of the second PSU in stratum  $h$  is multiplied by  $\epsilon$ , and the sampling weight of the first PSU is multiplied by  $(2 - \epsilon)$  to form the  $r$ th replicate weights.

You can use the `OUTWEIGHTS=method-option` to store the replicate weights in a SAS data set. See the section “Replicate Weights Output Data Set” on page 7121 for details about the contents of the `OUTWEIGHTS=` data set. You can provide these replicate weights to the procedure for subsequent analyses by using a `REPWEIGHTS` statement.

Let  $\theta$  denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let  $\hat{\theta}$  denote the estimate of  $\theta$  from the full sample, and let  $\hat{\theta}_r$  denote the estimate from the  $r$ th BRR replicate, which is computed by using the replicate weights. The Fay BRR variance estimate for  $\hat{\theta}$  is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R(1 - \epsilon)^2} \sum_{r=1}^R (\hat{\theta}_r - \hat{\theta})^2$$

where  $R$  is the total number of replicates and  $\epsilon$  is the Fay coefficient.

If you request Fay's BRR method and also include a `REPWEIGHTS` statement, PROC SURVEYFREQ uses the replicate weights that you provide and includes the Fay coefficient  $\epsilon$  in the denominator of the variance estimate in the preceding expression.

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column  $j$  for table cell  $(i, j)$ . If a replicate  $r$  contains no observations in column  $j$ , then the column  $j$  proportion is not estimable from replicate  $r$ . In this case, the BRR variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{1}{R'(1 - \epsilon)^2} \sum_{r=1}^{R'} (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  is estimable, and  $R'$  is the number of those replicates.

### Hadamard Matrix

PROC SURVEYFREQ uses a Hadamard matrix to construct replicates for BRR variance estimation. You can provide a Hadamard matrix for replicate construction by using the `HADAMARD=method-option` for `VARMETHOD=BRR`. Otherwise, PROC SURVEYFREQ generates an appropriate Hadamard matrix. You can display the Hadamard matrix by specifying the `PRINTH method-option`.

A Hadamard matrix  $\mathbf{A}$  of dimension  $R$  is a square matrix that has all elements equal to 1 or  $-1$ . A Hadamard matrix must satisfy the requirement that  $\mathbf{A}'\mathbf{A} = R\mathbf{I}$ , where  $\mathbf{I}$  is an identity matrix. The dimension of a Hadamard matrix must equal 1, 2, or a multiple of 4.

For example, the following matrix is a Hadamard matrix of dimension  $k = 8$ :

1	1	1	1	1	1	1	1
1	-1	1	-1	1	-1	1	-1
1	1	-1	-1	1	1	-1	-1
1	-1	-1	1	1	-1	-1	1
1	1	1	1	-1	-1	-1	-1
1	-1	1	-1	-1	1	-1	1
1	1	-1	-1	-1	-1	1	1
1	-1	-1	1	-1	1	1	-1

For BRR replicate construction, the dimension of the Hadamard matrix must be at least  $H$ , where  $H$  denotes the number of first-stage strata in your design. If a Hadamard matrix of a given dimension exists, it is not necessarily unique. Therefore, if you want to use a specific Hadamard matrix, you must provide the matrix as a SAS data set in the `HADAMARD=SAS-data-set method-option`. You must ensure that the matrix that you provide is actually a Hadamard matrix; PROC SURVEYFREQ does not check the validity of your Hadamard matrix.

See the section “Balanced Repeated Replication (BRR)” on page 7097 and “Fay’s BRR Method” on page 7098 for details about how the Hadamard matrix is used to construct replicates for BRR variance estimation.

### The Jackknife Method

If you specify the `VARMETHOD=JACKKNIFE` option, PROC SURVEYFREQ uses the delete-1 jackknife method for variance estimation. The jackknife method can be used for stratified sample designs and for designs with no stratification. If your design is stratified, the jackknife method requires at least two PSUs in each stratum. You can provide replicate weights for jackknife variance estimation by using a `REPWEIGHTS` statement, or the procedure can construct replicate weights for the analysis. PROC SURVEYFREQ estimates the parameter of interest (a proportion, total, odds ratio, or other statistic) from each replicate, and then uses the variability among replicate estimates to estimate the overall variance of the parameter estimate. See Wolter (1985) and Lohr (2009) for more information about jackknife variance estimation.

If you do not provide replicate weights with a `REPWEIGHTS` statement, PROC SURVEYFREQ constructs the replicates. The number of replicates  $R$  equals the number of PSUs, and the procedure deletes one PSU from the full sample to form each replicate. The sampling weights are modified by the jackknife coefficient for the replicate to create the replicate weights.

If your design is not stratified (no **STRATA** statement), the jackknife coefficient has the same value for each replicate  $r$ . The jackknife coefficient equals

$$\alpha_r = \frac{R-1}{R} \text{ for } r = 1, 2, \dots, R$$

where  $R$  is the total number of replicates (or total number of PSUs). For the PSUs included in a replicate, the replicate weights are computed by dividing the original sampling weights by the jackknife coefficient. For the deleted PSU, which is not included in the replicate, the replicate weights equal zero. The replicate weight for the  $j$ th member of the  $i$ th PSU can be expressed as follows when the design is not stratified:

$$W_{ij}^r = \begin{cases} W_{ij}/\alpha_r & \text{if PSU } i \text{ is included in replicate } r \\ 0 & \text{otherwise} \end{cases}$$

where  $W_{ij}$  is the original sampling weight of unit  $(ij)$ ,  $r$  is the replicate number, and  $\alpha_r$  is the jackknife coefficient.

If your design is stratified, the jackknife method requires at least two PSUs in each stratum. Let stratum  $\tilde{h}_r$  be the stratum from which a PSU is deleted to form the  $r$ th replicate. Stratum  $\tilde{h}_r$  is called the *donor stratum*. The jackknife coefficients are defined as

$$\alpha_r = \frac{n_{\tilde{h}_r} - 1}{n_{\tilde{h}_r}} \text{ for } r = 1, 2, \dots, R$$

where  $n_{\tilde{h}_r}$  is the total number of PSUs in the donor stratum for replicate  $r$ . For all strata other than the donor stratum, the replicate  $r$  weights equal the original sampling weights. For PSUs included from the donor stratum, the replicate weights are computed by dividing the original sampling weights by the jackknife coefficient. For the deleted PSU, which is not included in the replicate, the replicate weights equal zero. The replicate weight for the  $j$ th member of the  $i$ th PSU in stratum  $h$  can be expressed as

$$W_{hij}^r = \begin{cases} W_{hij} & \text{if } h \neq \tilde{h}_r \\ W_{hij}/\alpha_r & \text{if } h = \tilde{h}_r \text{ and PSU } (hi) \text{ is included in replicate } r \\ 0 & \text{if } h = \tilde{h}_r \text{ and PSU } (hi) \text{ is not included in replicate } r \end{cases}$$

You can use the **OUTWEIGHTS=** *method-option* to store the replicate weights in a SAS data set. You can also use the **OUTJKCOEFS=** *method-option* to store the jackknife coefficients in a SAS data set. See the sections “**Jackknife Coefficients Output Data Set**” on page 7122 and “**Replicate Weights Output Data Set**” on page 7121 for details about the contents of these output data sets. You can provide replicate weights and jackknife coefficients to the procedure for subsequent analyses by using a **REPWEIGHTS** statement. If you provide replicate weights but do not provide jackknife coefficients, PROC SURVEYFREQ uses  $\alpha_r = (R-1)/R$  as the jackknife coefficient for all replicates.

Let  $\theta$  denote the population parameter to be estimated—for example, a proportion, total, odds ratio, or other statistic. Let  $\hat{\theta}$  denote the estimate of  $\theta$  from the full sample, and let  $\hat{\theta}_r$  be the estimate from

the  $r$ th jackknife replicate, which is computed by using the replicate weights. The jackknife variance estimate for  $\hat{\theta}$  is computed as

$$\widehat{V}(\hat{\theta}) = \sum_{r=1}^R \alpha_r (\hat{\theta}_r - \hat{\theta})^2$$

where  $R$  is the total number of replicates and  $\alpha_r$  is the jackknife coefficient for replicate  $r$ .

If a parameter cannot be estimated from some replicate(s), then the variance estimate is computed by using those replicates from which the parameter can be estimated. For example, suppose the parameter is a column proportion—the proportion of column  $j$  for table cell  $(i, j)$ . If a replicate  $r$  contains no observations in column  $j$ , then the column  $j$  proportion is not estimable from replicate  $r$ . In this case, the jackknife variance estimate is computed as

$$\widehat{V}(\hat{\theta}) = \frac{R}{R'} \sum_{r=1}^{R'} \alpha_r (\hat{\theta}_r - \hat{\theta})^2$$

where the summation is over the replicates where the parameter  $\theta$  is estimable, and  $R'$  is the number of those replicates.

### Confidence Limits for Totals

If you specify the **CLWT** option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the weighted frequencies (totals) in the crosstabulation tables.

For the total in table cell  $(r, c)$ , the confidence limits are computed as

$$\widehat{N}_{rc} \pm (t_{df, \alpha/2} \times \text{StdErr}(\widehat{N}_{rc}))$$

where  $\widehat{N}_{rc}$  is the estimate of the total frequency in table cell  $(r, c)$ ,  $\text{StdErr}(\widehat{N}_{rc})$  is the standard error of the estimate, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “Degrees of Freedom” on page 7106. The confidence level  $\alpha$  is determined by the value of the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits.

The confidence limits for row totals, column totals, and the overall total are computed similarly to the confidence limits for table cell totals.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, the “Table Summary” data set also contains the degrees of freedom  $df$  and the value of  $t_{df, \alpha/2}$  that is used to compute the confidence limits. See [Example 84.3](#) for more information about this output data set.

### Confidence Limits for Proportions

If you specify the **CL** option in the TABLES statement, PROC SURVEYFREQ computes confidence limits for the proportions in the frequency and crosstabulation tables.

By default, PROC SURVEYFREQ computes Wald (“linear”) confidence limits if you do not specify an alternative confidence limit type with the `TYPE=` option. In addition to Wald confidence limits, the following types of design-based confidence limits are available for proportions: modified Clopper-Pearson (exact), modified Wilson (score), and logit confidence limits.

PROC SURVEYFREQ also provides the `PSMALL` option, which uses the alternative confidence limit type for extreme (small or large) proportions and uses the Wald confidence limits for all other proportions (not extreme). For the default `PSMALL=` value of 0.25, the procedure computes Wald confidence limits for proportions between 0.25 and 0.75 and computes the alternative confidence limit type for proportions that are outside of this range. See Curtin et al. (2006).

See Korn and Graubard (1999), Korn and Graubard (1998), Curtin et al. (2006), and Sukasih and Jang (2005) for details about confidence limits for proportions based on complex survey data, including comparisons of their performance. See also Brown, Cai, and DasGupta (2001), Agresti and Coull (1998) and the other references cited in the following sections for information about binomial confidence limits.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of observations, strata, and clusters that are included in the analysis of the requested table. When you request confidence limits, the “Table Summary” data set also contains the degrees of freedom  $df$  and the value of  $t_{df,\alpha/2}$  that is used to compute the confidence limits. See [Example 84.3](#) for more information about this output data set.

### Wald Confidence Limits

PROC SURVEYFREQ computes standard Wald (“linear”) confidence limits for proportions by default. These confidence limits use the variance estimates that are based on the sample design. For the proportion in table cell  $(r, c)$ , the Wald confidence limits are computed as

$$\hat{P}_{rc} \pm \left( t_{df,\alpha/2} \times \text{StdErr}(\hat{P}_{rc}) \right)$$

where  $\hat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\text{StdErr}(\hat{P}_{rc})$  is the standard error of the estimate, and  $t_{df,\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “Degrees of Freedom” on page 7106. The confidence level  $\alpha$  is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

The confidence limits for row proportions and column proportions are computed similarly to the confidence limits for table cell proportions.

### Modified Confidence Limits

PROC SURVEYFREQ uses the modification described in Korn and Graubard (1998) to compute design-based Clopper-Pearson (exact) and Wilson (score) confidence limits. This modification substitutes the degrees-of-freedom adjusted effective sample size for the original sample size in the confidence limit computations.

The effective sample size  $n_e$  is computed as

$$n_e = n / \text{DEFF}$$

where  $n$  is the original sample size (unweighted frequency) that corresponds to the total domain of the proportion estimate, and DEFF is the design effect.

If the proportion is computed for a table cell of a two-way table, then the domain is the two-way table, and the sample size  $n$  is the frequency of the two-way table. If the proportion is a row proportion, which is based on a two-way table row, then the domain is the row, and the sample size  $n$  is the frequency of the row.

The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. See the section “[Design Effect](#)” on page 7107 for details about how PROC SURVEYFREQ computes the design effect.

If you do not specify the `ADJUST=NO` option, the procedure applies a degrees-of-freedom adjustment to the effective sample size to compute the modified sample size. If you specify `ADJUST=NO`, the procedure does not apply the adjustment and uses the effective sample size  $n_e$  in the confidence limit computations.

The modified sample size  $n_e^*$  is computed by applying a degrees-of-freedom adjustment to the effective sample size  $n_e$  as

$$n_e^* = n_e \left( \frac{t_{(n-1), \alpha/2}}{t_{df, \alpha/2}} \right)^2$$

where  $df$  is the degrees of freedom and  $t_{df, \alpha/2}$  is the  $100(1-\alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom. The section “[Degrees of Freedom](#)” on page 7106 describes the computation of the degrees of freedom  $df$ , which is based on the variance estimation method and the sample design. The confidence level  $\alpha$  is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

The design effect is usually greater than 1 for complex survey designs, and in that case the effective sample size is less than the actual sample size. If the adjusted effective sample size  $n_e^*$  is greater than the actual sample size  $n$ , then the procedure truncates the value of  $n_e^*$  to  $n$ , as recommended by Korn and Graubard (1998). If you specify the `TRUNCATE=NO` option, the procedure does not truncate the value of  $n_e^*$ .

**Modified Clopper-Pearson Confidence Limits** Clopper-Pearson (exact) confidence limits for the binomial proportion are constructed by inverting the equal-tailed test based on the binomial distribution. This method is attributed to Clopper and Pearson (1934). See Leemis and Trivedi (1996) for a derivation of the  $F$  distribution expression for the confidence limits.

PROC SURVEYFREQ computes modified Clopper-Pearson confidence limits according to the approach of Korn and Graubard (1998). The degrees-of-freedom adjusted effective sample size  $n_e^*$  is substituted for the sample size in the Clopper-Pearson computation, and the adjusted effective sample size times the proportion estimate  $n_e^* \hat{p}$  is substituted for the number of positive responses. (Or if you specify the `ADJUST=NO` option, the procedure uses the unadjusted effective sample size  $n_e$  instead of  $n_e^*$ .)

The modified Clopper-Pearson confidence limits for a proportion ( $P_L$  and  $P_U$ ) are computed as

$$P_L = \left( 1 + \frac{n_e^* - \hat{p}n_e^* + 1}{\hat{p}n_e^* F(1 - \alpha/2, 2\hat{p}n_e^*, 2(n_e^* - \hat{p}n_e^* + 1))} \right)^{-1}$$

$$P_U = \left( 1 + \frac{n_e^* - \hat{p}n_e^*}{(\hat{p}n_e^* + 1) F(\alpha/2, 2(\hat{p}n_e^* + 1), 2(n_e^* - \hat{p}n_e^*))} \right)^{-1}$$

where  $F(\alpha, b, c)$  is the  $\alpha$ th percentile of the  $F$  distribution with  $b$  and  $c$  degrees of freedom,  $n_e^*$  is the adjusted effective sample size, and  $\hat{p}$  is the proportion estimate.

**Modified Wilson Confidence Limits** Wilson confidence limits for the binomial proportion are also known as score confidence limits and are attributed to Wilson (1927). The confidence limits are based on inverting the normal test that uses the null proportion in the variance (the score test). See Newcombe (1998) and Korn and Graubard (1999) for details.

PROC SURVEYFREQ computes modified Wilson confidence limits by substituting the degrees-of-freedom adjusted effective sample size  $n_e^*$  for the original sample size in the standard Wilson computation. (Or if you specify the `ADJUST=NO` option, the procedure substitutes the unadjusted effective sample size  $n_e$ .)

The modified Wilson confidence limits for a proportion are computed as

$$\left( \hat{p} + (\kappa)^2/2n_e^* \right) \pm \left( \kappa \sqrt{(\hat{p}(1 - \hat{p}) + (\kappa)^2)/4n_e^* / (1 + (\kappa)^2/n_e^*)} \right)$$

where  $n_e^*$  is the adjusted effective sample size and  $\hat{p}$  is the estimate of the proportion. With the degrees-of-freedom adjusted effective sample size  $n_e^*$ , the computation uses  $\kappa = z_{\alpha/2}$ . With the unadjusted effective sample size, which you request with the `ADJUST=NO` option, the computation uses  $\kappa = t_{df, \alpha/2}$ . See Curtin et al. (2006) for details.

### Logit Confidence Limits

If you specify the `TYPE=LOGIT` option, PROC SURVEYFREQ computes logit confidence limits for proportions. See Agresti (2002) and Korn and Graubard (1998) for more information.

Logit confidence limits for proportions are based on the logit transformation  $Y = \log(\hat{p}/(1 - \hat{p}))$ . The logit confidence limits  $P_L$  and  $P_U$  are computed as

$$P_L = \exp(Y_L) / (1 + \exp(Y_L))$$

$$P_U = \exp(Y_U) / (1 + \exp(Y_U))$$

where

$$(Y_L, Y_U) = \log(\hat{p}/(1 - \hat{p})) \pm (t_{df, \alpha/2} \times \text{StdErr}(\hat{p}) / (\hat{p}(1 - \hat{p})))$$

where  $\hat{p}$  is the estimate of the proportion,  $\text{StdErr}(\hat{p})$  is the standard error of the estimate, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom. The degrees

of freedom are calculated as described in the section “Degrees of Freedom” on page 7106. The confidence level  $\alpha$  is determined by the value of the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits.

## Degrees of Freedom

PROC SURVEYFREQ uses the degrees of freedom of the variance estimator to obtain the  $t$ -percentile for confidence limits for proportions, totals, and other statistics. The procedure also uses the degrees of freedom in computing the  $F$  statistics for the Rao-Scott and Wald chi-square tests.

PROC SURVEYFREQ computes the degrees of freedom based on the variance estimation method and the sample design. Alternatively, you can specify the degrees of freedom in the `DF=` option in the `TABLES` statement instead of having the procedure compute it.

For Taylor series variance estimation, PROC SURVEYFREQ calculates the degrees of freedom ( $df$ ) as the number of clusters minus the number of strata. If there are no clusters, then  $df$  equals the number of observations minus the number of strata. If the design is not stratified, then  $df$  equals the number of clusters minus one. These numbers are based on the observations included in the analysis of the individual table request. These numbers do not count observations that are excluded from the table due to missing values. See the section “Missing Values” on page 7087 for details. If you specify the `MISSING` option, missing values are treated as valid nonmissing levels and are included in computing degrees of freedom. If you specify the `NOMCAR` option for Taylor series variance estimation, observations with missing values of the `TABLES` variables are included in computing degrees of freedom.

If you provide replicate weights with a `REPWEIGHTS` statement, the degrees of freedom is equal the number of replicates, which is the number of `REPWEIGHTS` variables that you provide. Alternatively, you can specify the degrees of freedom in the `DF=` option in the `REPWEIGHTS` or `TABLES` statement.

For BRR variance estimation (when you do not use a `REPWEIGHTS` statement), PROC SURVEYFREQ calculates the degrees of freedom as the number of strata. PROC SURVEYFREQ bases the number of strata on all valid observations in the data set, unless you specify the `DFADJ method-option` for `VARMETHOD=BRR`. When you specify the `DFADJ` option, the procedure computes the degrees of freedom as the number of nonmissing strata for the individual table request. This excludes any empty strata that occur when observations with missing values of the `TABLES` variables are removed from the analysis for that table.

For jackknife variance estimation (when you do not use a `REPWEIGHTS` statement), PROC SURVEYFREQ calculates the degrees of freedom as the number of clusters minus the number of strata. If there are no clusters, then  $df$  equals the number of observations minus the number of strata. If the design is not stratified, then  $df$  equals the number of clusters minus one. For jackknife variance estimation, PROC SURVEYFREQ bases the number of strata and clusters on all valid observations in the data set, unless you specify the `DFADJ method-option` for `VARMETHOD=JACKKNIFE`. When you specify the `DFADJ` option, the procedure computes the degrees of freedom from the number of nonmissing strata and clusters for the individual table request. This excludes any empty strata or clusters that occur when observations with missing values of the `TABLES` variables are removed from the analysis for that table.

For each table request, PROC SURVEYFREQ produces a nondisplayed ODS table, “Table Summary,” which contains the number of (nonmissing) observations, strata, and clusters that are included in the analysis of the table. If there are missing observations, empty strata, or empty clusters excluded from the analysis, the “Table Summary” data set also contains this information. If you request confidence limits or chi-square tests, which depend on the degrees of freedom of the variance estimator, the “Table Summary” data set provides the degrees of freedom  $df$ . See [Example 84.3](#) for more information about this output data set.

## Coefficient of Variation

If you specify the **CV** option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the proportion estimates in the frequency and crosstabulation tables. The coefficient of variation is the ratio of the standard error to the estimate.

For the proportion in table cell  $(r, c)$ , the coefficient of variation is computed as

$$CV(\hat{P}_{rc}) = \text{StdErr}(\hat{P}_{rc}) / \hat{P}_{rc}$$

where  $\hat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$  and  $\text{StdErr}(\hat{P}_{rc})$  is the standard error of the estimate. The coefficients of variation for row proportions and column proportions are computed similarly.

If you specify the **CVWT** option in the TABLES statement, PROC SURVEYFREQ computes the coefficients of variation for the weighted frequencies (estimated totals) in the crosstabulation tables. For the total in table cell  $(r, c)$ , the coefficient of variation is computed as

$$CV(\hat{N}_{rc}) = \text{StdErr}(\hat{N}_{rc}) / \hat{N}_{rc}$$

where  $\hat{N}_{rc}$  is the estimate of the total in table cell  $(r, c)$  and  $\text{StdErr}(\hat{N}_{rc})$  is the standard error of the estimate. The coefficients of variation for row totals, column totals, and the overall total are computed similarly.

## Design Effect

If you specify the **DEFF** option in the TABLES statement, PROC SURVEYFREQ computes design effects for the overall proportion estimates in the frequency and crosstabulation tables. If you specify the **ROW(DEFF)** or **COL(DEFF)** option, the procedure provides design effects for the row or column proportion estimates, respectively. The design effect for an estimate is the ratio of the actual variance (estimated based on the sample design) to the variance of a simple random sample with the same number of observations. See Lohr (2009) and Kish (1965) for details.

For Taylor series variance estimation, PROC SURVEYFREQ computes the design effect for the proportion in table cell  $(r, c)$  as

$$\begin{aligned} \text{DEFF}(\hat{P}_{rc}) &= \widehat{\text{Var}}(\hat{P}_{rc}) / \widehat{\text{Var}}_{\text{SRS}}(\hat{P}_{rc}) \\ &= \widehat{\text{Var}}(\hat{P}_{rc}) / \left\{ (1-f) \hat{P}_{rc} (1 - \hat{P}_{rc}) / (n-1) \right\} \end{aligned}$$

where  $\widehat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\widehat{\text{Var}}(\widehat{P}_{rc})$  is the variance of the estimate,  $f$  is the overall sampling fraction, and  $n$  is the sample size (unweighted frequency) for the two-way table.

For Taylor series variance estimation, PROC SURVEYFREQ determines the value of  $f$ , the overall sampling fraction, based on the **RATE=** or **TOTAL=** option. If you do not specify either of these options, then PROC SURVEYFREQ assumes the value of  $f$  is negligible and does not use a finite population correction in the analysis, as described in the section “Population Totals and Sampling Rates” on page 7085. If you specify **RATE=value**, then PROC SURVEYFREQ uses this value as the overall sampling fraction  $f$ . If you specify **TOTAL=value**, then PROC SURVEYFREQ computes  $f$  as the ratio of the number of PSUs in the sample to the specified total.

If you specify stratum sampling rates with the **RATE=SAS-data-set** option, then PROC SURVEYFREQ computes stratum totals based on these stratum sampling rates and the number of sample PSUs in each stratum. The procedure sums the stratum totals to form the overall total, and computes  $f$  as the ratio of the number of sample PSUs to the overall total. Alternatively, if you specify stratum totals with the **TOTAL=SAS-data-set** option, then PROC SURVEYFREQ sums these totals to compute the overall total. The overall sampling fraction  $f$  is then computed as the ratio of the number of sample PSUs to the overall total.

For BRR and jackknife variance estimation, PROC SURVEYFREQ computes the design effect for the proportion in table cell  $(r, c)$  as

$$\begin{aligned} \text{DEFF}(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \widehat{\text{Var}}_{\text{SRS}}(\widehat{P}_{rc}) \\ &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \left\{ \widehat{P}_{rc} (1 - \widehat{P}_{rc}) / (n - 1) \right\} \end{aligned}$$

where  $\widehat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\widehat{\text{Var}}(\widehat{P}_{rc})$  is the variance of the estimate, and  $n$  is the sample size (unweighted frequency) for the two-way table. This computation does not include the overall sampling fraction.

The procedure computes design effects similarly for proportions in one-way frequency tables, and also for row and column proportions in two-way tables. In these design effect computations, the value of  $n$  is the sample size (unweighted frequency) that corresponds to the total domain of the proportion estimate. For table cell proportions of a two-way table, the domain is the two-way table and the sample size  $n$  is the frequency of the two-way table. For row proportions, which are based on a two-way table row, the domain is the row and the sample size  $n$  is the frequency of the row.

### Expected Weighted Frequency

If you specify the **EXPECTED** option in the TABLES statement, PROC SURVEYFREQ computes expected weighted frequencies for the table cells in two-way tables. The expected weighted frequencies are computed under the null hypothesis that the row and column variables are independent. The expected weighted frequency for table cell  $(r, c)$  equals

$$E_{rc} = \widehat{N}_r \cdot \widehat{N}_{\cdot c} / \widehat{N}$$

where  $\widehat{N}_{r.}$  is the estimated total for row  $r$ ,  $\widehat{N}_{.c}$  is the estimated total for column  $c$ , and  $\widehat{N}$  is the estimated overall total. Equivalently, the expected weighted frequency can be expressed as

$$E_{rc} = \widehat{P}_{r.} \widehat{P}_{.c} \widehat{N}$$

These expected values are used in the design-based chi-square tests of independence, as described in the sections “[Rao-Scott Chi-Square Test](#)” on page 7113 and “[Wald Chi-Square Test](#)” on page 7118.

## Risks and Risk Difference

The **RISK** option provides estimates of risks (binomial proportions) and risk differences for  $2 \times 2$  tables, together with their standard errors and confidence limits. Risk statistics include the row 1 risk, row 2 risk, overall risk, and risk difference. If you specify the RISK option, PROC SURVEYFREQ provides both column 1 and column 2 risks. You can request only column 1 (or only column 2) risks by specifying the **RISK1** (or **RISK2**) option.

The column 1 risk for row 1 is the row 1 proportion for table cell (1,1). The column 1 risk estimate is computed as the ratio of the estimated total for table cell (1,1) to the estimated total for row 1,

$$\widehat{P}_{11}^{(1)} = \widehat{N}_{11} / \widehat{N}_{1.}$$

where the total estimates are computed as described in the section “[Totals](#)” on page 7092. The column 1 risk for row 2 is the row 2 proportion for table cell (2,1), which is estimated as

$$\widehat{P}_{21}^{(2)} = \widehat{N}_{21} / \widehat{N}_{2.}$$

The overall column 1 risk is the overall proportion in column 1, and its estimate is computed as

$$\widehat{P}_{.1} = \widehat{N}_{.1} / \widehat{N}$$

The column 2 risk estimates are computed similarly.

The row 1 and row 2 risks are the same as the row proportions for a  $2 \times 2$  table, and their variances are computed as described in the section “[Row and Column Proportions](#)” on page 7096. The overall risk is the overall proportion in the column, and its variance computation is described in the section “[Proportions](#)” on page 7094. Confidence limits for the column 1 risk for row 1 are computed as

$$\widehat{P}_{11}^{(1)} \pm \left( t_{df, \alpha/2} \times \text{StdErr}(\widehat{P}_{11}^{(1)}) \right)$$

where  $\text{StdErr}(\widehat{P}_{11}^{(1)})$  is the standard error of the risk estimate, and  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “[Degrees of Freedom](#)” on page 7106. The value of the confidence coefficient  $\alpha$  is determined by the **ALPHA=** option, which by default equals 0.05 and produces 95% confidence limits. Confidence limits for the other risks are computed similarly.

The risk difference is defined as the row 1 risk minus the row 2 risk. The estimate of the column 1 risk difference  $\widehat{RD}_1$  is computed as

$$\begin{aligned}\widehat{RD}_1 &= \widehat{P}_{11}^{(1)} - \widehat{P}_{21}^{(2)} \\ &= \left( \widehat{N}_{11} / \widehat{N}_{1\cdot} \right) - \left( \widehat{N}_{21} / \widehat{N}_{2\cdot} \right)\end{aligned}$$

The column 2 risk difference is computed similarly.

PROC SURVEYFREQ estimates the variance of the risk difference by using the variance estimation method that you request. If you request BRR variance estimation (`VARMETHOD=BRR`), the procedure estimates the variance as described in the section “Balanced Repeated Replication (BRR)” on page 7097. If you request jackknife variance estimation (`VARMETHOD=JACKKNIFE`), the procedure estimates the variance as described in the section “The Jackknife Method” on page 7100.

If you do not specify the `VARMETHOD=` option or a `REPWEIGHTS` statement, the default variance estimation method is Taylor series (`VARMETHOD=TAYLOR`). By using Taylor series linearization, the variance estimate for the column 1 risk difference  $\widehat{\text{Var}}(\widehat{RD}_1)$  can be expressed as

$$\widehat{\text{Var}}(\widehat{RD}_1) = \widehat{\mathbf{D}} \widehat{\mathbf{V}}(\widehat{\mathbf{X}}) \widehat{\mathbf{D}}'$$

where  $\widehat{\mathbf{V}}(\widehat{\mathbf{X}})$  is the covariance matrix of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{X}} = ( \widehat{N}_{11}, \widehat{N}_{1\cdot}, \widehat{N}_{21}, \widehat{N}_{2\cdot} )$$

and  $\widehat{\mathbf{D}}$  is an array containing the partial derivatives of the risk difference with respect to the elements of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{D}} = ( 1/\widehat{N}_{1\cdot}, -\widehat{N}_{11}/\widehat{N}_{1\cdot}^2, -1/\widehat{N}_{2\cdot}, -\widehat{N}_{21}/\widehat{N}_{2\cdot}^2 )$$

See Wolter (1985, pp. 239–242) for details. The variance estimate for the column 2 risk difference is computed similarly.

The standard error of the column 1 risk difference is

$$\text{StdErr}(\widehat{RD}_1) = \sqrt{\widehat{\text{Var}}(\widehat{RD}_1)}$$

Confidence limits for the column 1 risk difference are computed as

$$\widehat{RD}_1 \pm \left( t_{df, \alpha/2} \times \text{StdErr}(\widehat{RD}_1) \right)$$

where  $t_{df, \alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom calculated as described in the section “Degrees of Freedom” on page 7106. The value of the confidence coefficient  $\alpha$  is determined by the `ALPHA=` option, which by default equals 0.05 and produces 95% confidence limits. Confidence limits for the column 2 risk difference are computed in the same way.

## Odds Ratio and Relative Risks

The `OR` option provides estimates of the odds ratio, the column 1 relative risk, and the column 2 relative risk for  $2 \times 2$  tables, together with their confidence limits.

**Odds Ratio**

For a  $2 \times 2$  table, the odds of a positive (column 1) response in row 1 is  $N_{11}/N_{12}$ . Similarly, the odds of a positive response in row 2 is  $N_{21}/N_{22}$ . The odds ratio is formed as the ratio of the row 1 odds to the row 2 odds. The estimate of the odds ratio is computed as

$$\widehat{OR} = \frac{\widehat{N}_{11} / \widehat{N}_{12}}{\widehat{N}_{21} / \widehat{N}_{22}} = \frac{\widehat{N}_{11} \widehat{N}_{22}}{\widehat{N}_{12} \widehat{N}_{21}}$$

The value of the odds ratio can be any nonnegative number. When the row and column variables are independent, the true value of the odds ratio equals 1. An odds ratio greater than 1 indicates that the odds of a positive response are higher in row 1 than in row 2. An odds ratio less than 1 indicates that the odds of positive response are higher in row 2. The strength of association increases with the deviation from 1. See Stokes, Davis, and Koch (2000) and Agresti (2007) for details.

PROC SURVEYFREQ constructs confidence limits for the odds ratio by using the log transform. The  $100(1 - \alpha)\%$  confidence limits for the odds ratio are computed as

$$\left( \widehat{OR} \times \exp(-t_{df,\alpha/2} \sqrt{v}), \widehat{OR} \times \exp(t_{df,\alpha/2} \sqrt{v}) \right)$$

where

$$v = \widehat{\text{Var}}(\ln \widehat{OR}) = \widehat{\text{Var}}(\widehat{OR}) / \widehat{OR}^2$$

is the estimate of the variance of the log odds ratio, and where  $t_{df,\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom. The computation of  $df$  is described in the section “Degrees of Freedom” on page 7106. The value of the confidence coefficient  $\alpha$  is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variance of the odds ratio as described in the section “Balanced Repeated Replication (BRR)” on page 7097. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section “The Jackknife Method” on page 7100.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the odds ratio can be expressed as

$$\widehat{\text{Var}}(\widehat{OR}) = \widehat{\mathbf{D}} \widehat{\mathbf{V}}(\widehat{\mathbf{N}}) \widehat{\mathbf{D}}'$$

where  $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$  is the covariance matrix of the estimates of the cell totals  $\widehat{\mathbf{N}}$ ,

$$\widehat{\mathbf{N}} = ( \widehat{N}_{11}, \widehat{N}_{12}, \widehat{N}_{21}, \widehat{N}_{22} )$$

and  $\widehat{\mathbf{D}}$  is an array containing the partial derivatives of the odds ratio with respect to the elements of  $\widehat{\mathbf{N}}$ . The section “Covariance of Totals” on page 7094 describes the computation of  $\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$ . The array  $\widehat{\mathbf{D}}$  is computed as

$$\widehat{\mathbf{D}} = \left( \begin{array}{cc} \widehat{N}_{22}/\widehat{N}_{12}\widehat{N}_{21}, & -\widehat{N}_{11}\widehat{N}_{22}/\widehat{N}_{21}\widehat{N}_{12}^2, \\ -\widehat{N}_{11}\widehat{N}_{22}/\widehat{N}_{12}\widehat{N}_{21}^2, & \widehat{N}_{11}/\widehat{N}_{12}\widehat{N}_{21} \end{array} \right)$$

See Wolter (1985, pp. 239–242) for more information.

### Relative Risks

For a  $2 \times 2$  table, the column 1 relative risk is the ratio of the column 1 risks for row 1 to row 2. As described in the section “[Risks and Risk Difference](#)” on page 7109, the column 1 risk for row 1 is the proportion of row 1 observations classified in column 1, and the column 1 risk for row 2 is the proportion of row 2 observations classified in column 1. The estimate of the column 1 relative risk is computed as

$$\widehat{RR}_1 = \frac{\widehat{N}_{11} / \widehat{N}_{1.}}{\widehat{N}_{21} / \widehat{N}_{2.}}$$

Similarly, the estimate of the column 2 relative risk is computed as

$$\widehat{RR}_2 = \frac{\widehat{N}_{12} / \widehat{N}_{1.}}{\widehat{N}_{22} / \widehat{N}_{2.}}$$

A relative risk greater than 1 indicates that the probability of positive response is greater in row 1 than in row 2. Similarly, a relative risk less than 1 indicates that the probability of positive response is less in row 1 than in row 2. The strength of association increases with the deviation from 1. See Stokes, Davis, and Koch (2000) and Agresti (2007) for more information.

PROC SURVEYFREQ constructs confidence limits for the relative risk by using the log transform, which is similar to the odds ratio computations described previously. The  $100(1 - \alpha)\%$  confidence limits for the column 1 relative risk are computed as

$$\left( \widehat{RR}_1 \times \exp(-t_{df,\alpha/2} \sqrt{v}), \widehat{RR}_1 \times \exp(t_{df,\alpha/2} \sqrt{v}) \right)$$

where

$$v = \widehat{\text{Var}}(\ln \widehat{RR}_1) = \widehat{\text{Var}}(\widehat{RR}_1) / \widehat{RR}_1^2$$

is the estimate of the variance of the log column 1 relative risk, and where  $t_{df,\alpha/2}$  is the  $100(1 - \alpha/2)$ th percentile of the  $t$  distribution with  $df$  degrees of freedom. The computation of  $df$  is described in the section “[Degrees of Freedom](#)” on page 7106. The value of the confidence coefficient  $\alpha$  is determined by the ALPHA= option, which by default equals 0.05 and produces 95% confidence limits.

If you request BRR variance estimation (VARMETHOD=BRR), PROC SURVEYFREQ estimates the variance of the column 1 relative risk as described in the section “[Balanced Repeated Replication \(BRR\)](#)” on page 7097. If you request jackknife variance estimation (VARMETHOD=JACKKNIFE), the procedure estimates the variance as described in the section “[The Jackknife Method](#)” on page 7100.

If you do not specify the VARMETHOD= option or a REPWEIGHTS statement, the default variance estimation method is Taylor series (VARMETHOD=TAYLOR). By using Taylor series linearization, the variance estimate for the column 1 relative risk can be expressed as

$$\widehat{\text{Var}}(\widehat{RR}_1) = \widehat{\mathbf{D}} \widehat{\mathbf{V}}(\widehat{\mathbf{X}}) \widehat{\mathbf{D}}'$$

where  $\widehat{\mathbf{V}}(\widehat{\mathbf{X}})$  is the covariance matrix of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{X}} = (\widehat{N}_{11}, \widehat{N}_{1.}, \widehat{N}_{21}, \widehat{N}_{2.})$$

and  $\widehat{\mathbf{D}}$  is an array containing the partial derivatives of the column 1 relative risk with respect to the elements of  $\widehat{\mathbf{X}}$ ,

$$\widehat{\mathbf{D}} = \left( \begin{array}{cc} \widehat{N}_{2\cdot}/\widehat{N}_{21}\widehat{N}_{1\cdot}, & -\widehat{N}_{11}\widehat{N}_{2\cdot}/\widehat{N}_{21}\widehat{N}_{1\cdot}^2, \\ -\widehat{N}_{11}\widehat{N}_{2\cdot}/\widehat{N}_{1\cdot}\widehat{N}_{21}^2, & \widehat{N}_{11}/\widehat{N}_{21}\widehat{N}_{1\cdot} \end{array} \right)$$

See Wolter (1985, pp. 239–242) for more information.

Confidence limits for the column 2 relative risk are computed similarly.

## Rao-Scott Chi-Square Test

The Rao-Scott chi-square test is a design-adjusted version of the Pearson chi-square test, which involves differences between observed and expected frequencies. For two-way tables, the null hypothesis for this test is no association between the row and column variables. For one-way tables, the null hypothesis is equal proportions for the variable levels. Or you can specify null hypothesis proportions for one-way tables by using the `TESTP=` option.

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott chi-square test with the `CHISQ` option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified chi-square test, with the `CHISQ1` option.

See Lohr (2009), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987) for details about design-adjusted chi-square tests.

### Two-Way Tables

The Rao-Scott chi-square statistic is computed from the Pearson chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association between the row and column variables, this statistic approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom, where the two-way table has  $R$  rows and  $C$  columns. PROC SURVEYFREQ also computes an  $F$  statistic that can provide a better approximation.

The Rao-Scott chi-square  $Q_{RS}$  is computed as

$$Q_{RS} = Q_P / D$$

where  $D$  is the design correction described in the section “[Design Correction for Two-Way Tables](#)” on page 7114, and  $Q_P$  is the Pearson chi-square based on the estimated totals. The Pearson chi-square is computed as

$$Q_P = (n/\widehat{N}) \sum_r \sum_c (\widehat{N}_{rc} - E_{rc})^2 / E_{rc}$$

where  $n$  is the sample size,  $\widehat{N}$  is the estimated overall total,  $\widehat{N}_{rc}$  is the estimated total for table cell  $(r, c)$ , and  $E_{rc}$  is the expected total for table cell  $(r, c)$  under the null hypothesis of no association,

$$E_{rc} = \widehat{N}_{r\cdot} \widehat{N}_{\cdot c} / \widehat{N}$$

Under the null hypothesis of no association, the Rao-Scott chi-square  $Q_{RS}$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom. A better approximation can be obtained by the  $F$  statistic,

$$F = Q_{RS} / (R - 1)(C - 1)$$

which has an  $F$  distribution with  $(R - 1)(C - 1)$  and  $(R - 1)(C - 1)\kappa$  degrees of freedom under the null hypothesis. The value  $\kappa$  is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section “Degrees of Freedom” on page 7106 describes the computation of  $\kappa$ .

### Design Correction for Two-Way Tables

If you specify the **CHISQ** or **LRCHISQ** option, the design correction  $D$  is computed by using the estimated proportions as

$$D = \left\{ \sum_r \sum_c (1 - \hat{P}_{rc}) \text{DEFF}(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_{r.}) \text{DEFF}(\hat{P}_{r.}) - \sum_c (1 - \hat{P}_{.c}) \text{DEFF}(\hat{P}_{.c}) \right\} / (R - 1)(C - 1)$$

where

$$\begin{aligned} \text{DEFF}(\hat{P}_{rc}) &= \widehat{\text{Var}}(\hat{P}_{rc}) / \text{Var}_{\text{SRS}}(\hat{P}_{rc}) \\ &= \text{Var}(\hat{P}_{rc}) / \left\{ (1 - f) \hat{P}_{rc} (1 - \hat{P}_{rc}) / (n - 1) \right\} \end{aligned}$$

as described in the section “Design Effect” on page 7107.  $\hat{P}_{rc}$  is the estimate of the proportion in table cell  $(r, c)$ ,  $\widehat{\text{Var}}(\hat{P}_{rc})$  is the variance of the estimate,  $f$  is the overall sampling fraction, and  $n$  is the number of observations in the sample.  $\text{DEFF}(\hat{P}_{r.})$ , the design effect for the estimate of the proportion in row  $r$ , and  $\text{DEFF}(\hat{P}_{.c})$ , the design effect for the estimate of the proportion in column  $c$ , are computed similarly.

If you specify the **CHISQ1** or **LRCHISQ1** option for the Rao-Scott modified test, the design correction uses the null hypothesis cell proportions instead of the estimated cell proportions. For two-way tables, the null hypothesis cell proportions are computed as the products of the corresponding row and column proportion estimates. The modified design correction  $D_0$  (based on null hypothesis proportions) is computed as

$$D_0 = \left\{ \sum_r \sum_c (1 - P_{rc}^0) \text{DEFF}_0(\hat{P}_{rc}) - \sum_r (1 - \hat{P}_{r.}) \text{DEFF}(\hat{P}_{r.}) - \sum_c (1 - \hat{P}_{.c}) \text{DEFF}(\hat{P}_{.c}) \right\} / (R - 1)(C - 1)$$

where

$$P_{rc}^0 = \hat{P}_{r.} \times \hat{P}_{.c}$$

and

$$\begin{aligned} \text{DEFF}_0(\widehat{P}_{rc}) &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \text{Var}_{\text{SRS}}(P_{rc}^0) \\ &= \widehat{\text{Var}}(\widehat{P}_{rc}) / \{(1-f) P_{rc}^0 (1 - P_{rc}^0) / (n-1)\} \end{aligned}$$

### One-Way Tables

For one-way tables, the Rao-Scott chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the `TESTP=` option, the Rao-Scott chi-square provides a design-based goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott chi-square statistic approximately follows a chi-square distribution with  $(C - 1)$  degrees of freedom for a table with  $C$  levels. PROC SURVEYFREQ also computes an  $F$  statistic that can provide a better approximation.

The Rao-Scott chi-square  $Q_{RS}$  is computed as

$$Q_{RS} = Q_P / D$$

where  $D$  is the design correction described in the section “[Design Correction for One-Way Tables](#)” on page 7116, and  $Q_P$  is the Pearson chi-square based on the estimated totals. The Pearson chi-square is computed as

$$Q_P = (n/\widehat{N}) \sum_c (\widehat{N}_c - E_c)^2 / E_c$$

where  $n$  is the sample size,  $\widehat{N}$  is the estimated overall total,  $\widehat{N}_c$  is the estimated total for level  $c$ , and  $E_c$  is the expected total for level  $c$  under the null hypothesis. For the null hypothesis of equal proportions, the expected total for level  $c$  equals

$$E_c = \widehat{N} / C$$

For specified null proportions, the expected total for level  $c$  equals

$$E_c = \widehat{N} \times P_c^0$$

where  $P_c^0$  is the null proportion for level  $c$ .

Under the null hypothesis, the Rao-Scott chi-square  $Q_{RS}$  approximately follows a chi-square distribution with  $(C - 1)$  degrees of freedom. A better approximation can be obtained by the  $F$  statistic,

$$F = Q_{RS} / (C - 1)$$

which has an  $F$  distribution with  $(C - 1)$  and  $(C - 1)\kappa$  degrees of freedom under the null hypothesis. The value  $\kappa$  is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section “[Degrees of Freedom](#)” on page 7106 describes the computation of  $\kappa$ .

**Design Correction for One-Way Tables**

If you specify the **CHISQ** or **LRCHISQ** option, the design correction  $D$  is computed by using the estimated proportions as

$$D = \sum_c (1 - \hat{P}_c) \text{DEFF}(\hat{P}_c) / (C - 1)$$

where

$$\begin{aligned} \text{DEFF}(\hat{P}_c) &= \widehat{\text{Var}}(\hat{P}_c) / \text{Var}_{\text{SRS}}(\hat{P}_c) \\ &= \widehat{\text{Var}}(\hat{P}_c) / \left\{ (1 - f) \hat{P}_c (1 - \hat{P}_c) / (n - 1) \right\} \end{aligned}$$

as described in the section “**Design Effect**” on page 7107.  $\hat{P}_c$  is the proportion estimate for table level  $c$ ,  $\widehat{\text{Var}}(\hat{P}_c)$  is the variance of the estimate,  $f$  is the overall sampling fraction, and  $n$  is the number of observations in the sample.

If you specify the **CHISQ1** or **LRCHISQ1** option for the Rao-Scott modified test, the design correction uses the null hypothesis proportions—either equal proportions for all levels, or the proportions that you specify with the **TESTP=** option. The modified design correction  $D_0$  is computed as

$$D_0 = \sum_c (1 - P_c^0) \text{DEFF}_0(\hat{P}_c) / (C - 1)$$

where

$$\begin{aligned} \text{DEFF}_0(\hat{P}_c) &= \widehat{\text{Var}}(\hat{P}_c) / \text{Var}_{\text{SRS}}(P_c^0) \\ &= \widehat{\text{Var}}(\hat{P}_c) / \left\{ (1 - f) P_c^0 (1 - P_c^0) / (n - 1) \right\} \end{aligned}$$

and  $P_c^0 = 1/C$  for equal proportions, or  $P_c^0$  equals the null proportion for level  $c$  if you specify the **TESTP=** option.

**Rao-Scott Likelihood Ratio Chi-Square Test**

The Rao-Scott likelihood ratio chi-square test is a design-adjusted version of the likelihood ratio test, which involves ratios between observed and expected frequencies. For two-way tables, the null hypothesis for this test is no association between the row and column variables. For one-way tables, the null hypothesis is equal proportions for the variable levels. Or you can specify null hypothesis proportions for one-way tables by using the **TESTP=** option.

Two forms of the design correction are available for the Rao-Scott tests. One form of the design correction uses the proportion estimates, and you request the corresponding Rao-Scott likelihood ratio test with the **LRCHISQ** option. The other form of the design correction uses the null hypothesis proportions. You request this test, called the Rao-Scott modified likelihood ratio test, with the **LRCHISQ1** option.

See Lohr (2009), Thomas, Singh, and Roberts (1996), and Rao and Scott (1981, 1984, 1987) for details about design-adjusted chi-square tests.

### Two-Way Tables

The Rao-Scott likelihood ratio statistic is computed from the likelihood ratio chi-square statistic and a design correction based on the design effects of the proportions. Under the null hypothesis of no association between the row and column variables, this statistic approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom. PROC SURVEYFREQ also computes an  $F$  statistic that can provide a better approximation.

The Rao-Scott likelihood ratio chi-square  $G_{RS}^2$  is computed as

$$G_{RS}^2 = G^2 / D$$

where  $D$  is the design correction described in the section “[Design Correction for Two-Way Tables](#)” on page 7114, and  $G^2$  is the likelihood ratio chi-square based on the estimated totals. The likelihood ratio chi-square is computed as

$$G^2 = 2 (n / \hat{N}) \sum_r \sum_c \hat{N}_{rc} \ln (\hat{N}_{rc} / E_{rc})$$

where  $n$  is the sample size,  $\hat{N}$  is the estimated overall total,  $\hat{N}_{rc}$  is the estimated total for table cell  $(r, c)$ , and  $E_{rc}$  is the expected total for cell  $(r, c)$  under the null hypothesis of no association. The expected total for cell  $(r, c)$  equals

$$E_{rc} = \hat{N}_r \cdot \hat{N}_{\cdot c} / \hat{N}$$

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square  $G_{RS}^2$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom. A better approximation can be obtained by the  $F$  statistic,

$$F = G_{RS}^2 / (R - 1)(C - 1)$$

which has an  $F$  distribution with  $(R - 1)(C - 1)$  and  $(R - 1)(C - 1)\kappa$  degrees of freedom under the null hypothesis. The value  $\kappa$  is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section “[Degrees of Freedom](#)” on page 7106 describes the computation of  $\kappa$ .

### One-Way Tables

For one-way tables, the Rao-Scott likelihood ratio chi-square statistic provides a design-based goodness-of-fit test for equal proportions. Or if you specify null proportions with the `TESTP=` option, the Rao-Scott likelihood ratio chi-square provides a design-based goodness-of-fit test for the specified proportions. Under the null hypothesis, the Rao-Scott likelihood ratio statistic approximately follows a chi-square distribution with  $(C - 1)$  degrees of freedom for a table with  $C$  levels. PROC SURVEYFREQ also computes an  $F$  statistic that can provide a better approximation.

The Rao-Scott likelihood ratio chi-square  $G_{RS}^2$  is computed as

$$G_{RS}^2 = G^2 / D$$

where  $D$  is the design correction described in the section “[Design Correction for One-Way Tables](#)” on page 7116, and  $G^2$  is the likelihood ratio chi-square based on the estimated totals. The likelihood ratio chi-square is computed as

$$G^2 = 2 (n / \hat{N}) \sum_c \hat{N}_c \ln (\hat{N}_c / E_c)$$

where  $n$  is the sample size,  $\widehat{N}$  is the estimated overall total,  $\widehat{N}_c$  is the estimated total for level  $c$ , and  $E_c$  is the expected total for level  $c$  under the null hypothesis. For the null hypothesis of equal proportions, the expected total for each level equals

$$E_c = \widehat{N} / C$$

For specified null proportions, the expected total for level  $c$  equals

$$E_c = \widehat{N} \times P_c^0$$

where  $P_c^0$  is the null proportion for level  $c$ .

Under the null hypothesis of no association, the Rao-Scott likelihood ratio chi-square  $G_{RS}^2$  approximately follows a chi-square distribution with  $(C - 1)$  degrees of freedom. A better approximation can be obtained by the  $F$  statistic,

$$F = G_{RS}^2 / (C - 1)$$

which has an  $F$  distribution with  $(C - 1)$  and  $(C - 1)\kappa$  degrees of freedom under the null hypothesis. The value  $\kappa$  is the degrees of freedom for the variance estimator and depends on the sample design and the variance estimation method. The section “Degrees of Freedom” on page 7106 describes the computation of  $\kappa$ .

## Wald Chi-Square Test

PROC SURVEYFREQ provides two Wald chi-square tests for independence of the row and column variables in a two-way table: a Wald chi-square test based on the difference between observed and expected weighted cell frequencies, and a Wald log-linear chi-square test based on the log odds ratios. These statistics test for independence of the row and column variables in two-way tables, taking into account the complex survey design. See Bedrick (1983), Koch, Freeman, and Freeman (1975), and Wald (1943) for information about Wald statistics and their applications to categorical data analysis.

For these two tests, PROC SURVEYFREQ computes the generalized Wald chi-square statistic, the corresponding Wald  $F$  statistic, and also an adjusted Wald  $F$  statistic for tables larger than  $2 \times 2$ . Under the null hypothesis of independence, the Wald chi-square statistic approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom for large samples. However, it has been shown that this test can perform poorly in terms of actual significance level and power, especially for tables with a large number of cells or for samples with a relatively small number of clusters. See Thomas and Rao (1984 and 1985) and Lohr (2009) for more information. See Felligi (1980) and Hidioglou, Fuller, and Hickman (1980) for information about the adjusted Wald  $F$  statistic. Thomas and Rao (1984) found that the adjusted Wald  $F$  statistic provides a more stable test than the chi-square statistic, although its power can be low when the number of sample clusters is not large. See also Korn and Graubard (1990) and Thomas, Singh, and Roberts (1996).

If you specify the **WCHISQ** option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence in the two-way table based on the differences between the observed (weighted) cell frequencies and the expected frequencies.

Under the null hypothesis of independence of the row and column variables, the expected cell frequencies are computed as

$$E_{rc} = \widehat{N}_{r.} \widehat{N}_{.c} / \widehat{N}$$

where  $\widehat{N}_{r\cdot}$  is the estimated total for row  $r$ ,  $\widehat{N}_{\cdot c}$  is the estimated total for column  $c$ , and  $\widehat{N}$  is the estimated overall total, as described in the section “Expected Weighted Frequency” on page 7108. The null hypothesis that the population weighted frequencies equal the expected frequencies can be expressed as

$$H_0: Y_{rc} = N_{rc} - E_{rc} = 0$$

for all  $r = 1, \dots, (R - 1)$  and  $c = 1, \dots, (C - 1)$ . This null hypothesis can be stated equivalently in terms of cell proportions, with the expected cell proportions computed as the products of the marginal row and column proportions.

The generalized Wald chi-square statistic  $Q_W$  is computed as

$$Q_W = \widehat{\mathbf{Y}}' (\mathbf{H} \widehat{\mathbf{V}}(\widehat{\mathbf{N}}) \mathbf{H}')^{-1} \widehat{\mathbf{Y}}$$

where  $\widehat{\mathbf{Y}}$  is the  $(R - 1)(C - 1)$  array of differences between the observed and expected weighted frequencies ( $\widehat{N}_{rc} - E_{rc}$ ), and  $(\mathbf{H} \widehat{\mathbf{V}}(\widehat{\mathbf{N}}) \mathbf{H}')$  estimates the variance of  $\widehat{\mathbf{Y}}$ .

$\widehat{\mathbf{V}}(\widehat{\mathbf{N}})$  is the covariance matrix of the estimates  $\widehat{N}_{rc}$ , and its computation is described in the section “Covariance of Totals” on page 7094.

$\mathbf{H}$  is an  $(R - 1)(C - 1)$  by  $RC$  matrix containing the partial derivatives of the elements of  $\widehat{\mathbf{Y}}$  with respect to the elements of  $\widehat{\mathbf{N}}$ . The elements of  $\mathbf{H}$  are computed as follows, where  $a$  denotes a row different from row  $r$ , and  $b$  denotes a column different from column  $c$ :

$$\partial \widehat{Y}_{rc} / \partial \widehat{N}_{rc} = 1 - (\widehat{N}_{r\cdot} + \widehat{N}_{\cdot c} - \widehat{N}_{\cdot c} \widehat{N}_{r\cdot} / \widehat{N}) / \widehat{N}$$

$$\partial \widehat{Y}_{rc} / \partial \widehat{N}_{ac} = - (\widehat{N}_{r\cdot} - \widehat{N}_{r\cdot} \widehat{N}_{\cdot c} / \widehat{N}) / \widehat{N}$$

$$\partial \widehat{Y}_{rc} / \partial \widehat{N}_{rb} = - (\widehat{N}_{\cdot c} - \widehat{N}_{r\cdot} \widehat{N}_{\cdot c} / \widehat{N}) / \widehat{N}$$

$$\partial \widehat{Y}_{rc} / \partial \widehat{Y}_{ab} = \widehat{N}_{r\cdot} \widehat{N}_{\cdot c} / \widehat{N}^2$$

Under the null hypothesis of independence, the statistic  $Q_W$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom for large samples.

PROC SURVEYFREQ computes the Wald  $F$  statistic as

$$F_W = Q_W / (R - 1)(C - 1)$$

Under the null hypothesis of independence,  $F_W$  approximately follows an  $F$  distribution with  $(R - 1)(C - 1)$  numerator degrees of freedom. The denominator degrees of freedom are the degrees of freedom for the variance estimator and depend on the sample design and the variance estimation method. The section “Degrees of Freedom” on page 7106 describes the computation of the denominator degrees of freedom. Alternatively, you can specify the denominator degrees of freedom with the `DF=` option in the TABLES statement.

For tables larger than  $2 \times 2$ , PROC SURVEYFREQ also computes the adjusted Wald  $F$  statistic as

$$F_{Adj\_W} = \frac{s - k + 1}{k s} Q_W$$

where  $k = (R - 1)(C - 1)$ , and  $s$  is the degrees of freedom, which are computed as described in the section “[Degrees of Freedom](#)” on page 7106. Alternatively, you can specify the value of  $s$  with the `DF=` option in the TABLES statement. Note that for  $2 \times 2$  tables,  $k = (R - 1)(C - 1) = 1$ , so the adjusted Wald  $F$  statistic equals the (unadjusted) Wald  $F$  statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis,  $F_{Adj\_W}$  approximately follows an  $F$  distribution with  $k$  numerator degrees of freedom and  $(s - k + 1)$  denominator degrees of freedom.

## Wald Log-Linear Chi-Square Test

If you specify the `WLLCHISQ` option in the TABLES statement, PROC SURVEYFREQ computes a Wald test for independence based on the log odds ratios. See the section “[Wald Chi-Square Test](#)” on page 7118 for more information about Wald tests.

For a two-way table of  $R$  rows and  $C$  columns, the Wald log-linear test is based on the  $(R - 1)(C - 1)$  array of elements  $\hat{Y}_{rc}$ ,

$$\hat{Y}_{rc} = \log \hat{N}_{rc} - \log \hat{N}_{rC} - \log \hat{N}_{Rc} + \log \hat{N}_{RC}$$

where  $\hat{N}_{rc}$  is the estimated total for table cell  $(r, c)$ . The null hypothesis of independence between the row and column variables can be expressed as  $H_0: Y_{rc} = 0$  for all  $r = 1, \dots, (R - 1)$  and  $c = 1, \dots, (C - 1)$ . This null hypothesis can be stated equivalently in terms of cell proportions.

The generalized Wald log-linear chi-square statistic is computed as

$$Q_{WLL} = \hat{\mathbf{Y}}' \hat{\mathbf{V}}(\hat{\mathbf{Y}})^{-1} \hat{\mathbf{Y}}$$

where  $\hat{\mathbf{Y}}$  is the  $(R - 1)(C - 1)$  array of the  $\hat{Y}_{rc}$ , and  $\hat{\mathbf{V}}(\hat{\mathbf{Y}})$  estimates the variance of  $\hat{\mathbf{Y}}$ ,

$$\hat{\mathbf{V}}(\hat{\mathbf{Y}}) = \mathbf{A} \mathbf{D}^{-1} \hat{\mathbf{V}}(\hat{\mathbf{N}}) \mathbf{D}^{-1} \mathbf{A}'$$

where  $\hat{\mathbf{V}}(\hat{\mathbf{N}})$  is the covariance matrix of the estimates  $\hat{N}_{rc}$ , which is computed as described in the section “[Covariance of Totals](#)” on page 7094.  $\mathbf{D}$  is a diagonal matrix with the estimated totals  $\hat{N}_{rc}$  on the diagonal, and  $\mathbf{A}$  is the  $(R - 1)(C - 1)$  by  $RC \times RC$  linear contrast matrix.

Under the null hypothesis of independence, the statistic  $Q_{WLL}$  approximately follows a chi-square distribution with  $(R - 1)(C - 1)$  degrees of freedom for large samples.

PROC SURVEYFREQ computes the Wald log-linear  $F$  statistic as

$$F_{WLL} = Q_{WLL} / (R - 1)(C - 1)$$

Under the null hypothesis of independence,  $F_{WLL}$  approximately follows an  $F$  distribution with  $(R - 1)(C - 1)$  numerator degrees of freedom. PROC SURVEYFREQ computes the denominator degrees of freedom as described in the section “[Degrees of Freedom](#)” on page 7106. Alternatively, you can specify the denominator degrees of freedom with the `DF=` option in the TABLES statement.

For tables larger than  $2 \times 2$ , PROC SURVEYFREQ also computes the adjusted Wald log-linear  $F$  statistic as

$$F_{Adj\_WLL} = \frac{s - k + 1}{k s} Q_{WLL}$$

where  $k = (R - 1)(C - 1)$ , and  $s$  is the denominator degrees of freedom computed as described in the section “Degrees of Freedom” on page 7106. Alternatively, you can specify the value of  $s$  with the `DF=` option in the `TABLES` statement. Note that for  $2 \times 2$  tables,  $k = (R - 1)(C - 1) = 1$ , so the adjusted Wald  $F$  statistic equals the (unadjusted) Wald  $F$  statistic, with the same numerator and denominator degrees of freedom.

Under the null hypothesis,  $F_{Adj\_WLL}$  approximately follows an  $F$  distribution with  $k$  numerator degrees of freedom and  $(s - k + 1)$  denominator degrees of freedom.

---

## Output Data Sets

You can use the Output Delivery System to create a SAS data set from any piece of PROC SURVEYFREQ output. See the section “ODS Table Names” on page 7128 for more information.

PROC SURVEYFREQ also provides an output data set that stores the replicate weights for BRR or jackknife variance estimation and an output data set that stores the jackknife coefficients for jackknife variance estimation.

### Replicate Weights Output Data Set

If you specify the `OUTWEIGHTS=method-option` for `VARMETHOD=BRR` or `JACKKNIFE`, PROC SURVEYFREQ stores the replicate weights in an output data set. The `OUTWEIGHTS=` output data set contains all observations from the `DATA=` input data set that are valid (used in the analysis). A valid observation must have a positive value of the `WEIGHT` variable, and also nonmissing values of the `STRATA` and `CLUSTER` variables, unless you specify the `MISSING` option. See the section “Data Summary Table” on page 7122 for details about valid observations.

The `OUTWEIGHTS=` data set contains the following variables:

- all variables in the `DATA=` input data set
- `RepWt_1`, `RepWt_2`, . . . , `RepWt_n`, which are the replicate weight variables, where  $n$  is the total number of replicates in the analysis

Each replicate weight variable contains the replicate weights for the corresponding replicate. Replicate weights equal zero for those observations not included in the replicate.

After the procedure creates replicate weights for a particular input data set and survey design, you can use the `OUTWEIGHTS=method-option` to store these replicate weights and then use them again in subsequent analyses, either in PROC SURVEYFREQ or in the other survey procedures. You can use a `REPWEIGHTS` statement to provide replicate weights for the procedure.

## Jackknife Coefficients Output Data Set

If you specify the `OUTJKCOEFS= method-option` for `VARMETHOD=JACKKNIFE`, PROC SURVEYFREQ stores the jackknife coefficients in an output data set. The `OUTJKCOEFS=` output data set contains one observation for each replicate. The `OUTJKCOEFS=` data set contains the following variables:

- Replicate, which is the replicate number for the jackknife coefficient
- JKCoefficient, which is the jackknife coefficient
- DonorStratum, which is the stratum of the PSU that was deleted to construct the replicate, if you specify a `STRATA` statement

After the procedure creates jackknife coefficients for a particular input data set and survey design, you can use the `OUTJKCOEFS= method-option` to store these coefficients and then use them again in subsequent analyses, either in PROC SURVEYFREQ or in the other survey procedures. You can use the `JKCOEFS=` option in the `REPWEIGHTS` statement to provide jackknife coefficients for the procedure.

---

## Displayed Output

### Data Summary Table

The “Data Summary” table provides information about the input data set and the sample design. PROC SURVEYFREQ displays this table unless you specify the `NOSUMMARY` option in the PROC SURVEYFREQ statement.

The “Data Summary” table displays the total number of valid observations. To be considered *valid*, an observation must have a nonmissing, positive sampling weight value if you specify a `WEIGHT` statement. If you do not specify the `MISSING` option, a valid observation must also have nonmissing values for all `STRATA` and `CLUSTER` variables. The number of valid observations can differ from the number of nonmissing observations for an individual table request, which the procedure displays in the frequency or crosstabulation tables. See the section “Missing Values” on page 7087 for more information.

PROC SURVEYFREQ displays the following information in the “Data Summary” table:

- Number of Strata, if you specify a `STRATA` statement
- Number of Clusters, if you specify a `CLUSTER` statement
- Number of Observations, which is the total number of valid observations
- Sum of Weights, which is the sum over all valid observations, if you specify a `WEIGHT` or `REPWEIGHTS` statement

## Stratum Information Table

If you specify the **LIST** option in the **STRATA** statement, PROC SURVEYFREQ displays a “Stratum Information” table. This table provides the following information for each stratum:

- Stratum Index, which is a sequential stratum identification number
- STRATA variables, which list the levels of **STRATA** variables for the stratum
- Number of Observations, which is the number of valid observations in the stratum
- Population Total for the stratum, if you specify the **TOTAL=** option
- Sampling Rate for the stratum, if you specify the **TOTAL=** or **RATE=** option. If you specify the **TOTAL=** option, the sampling rate is based on the number of valid observations in the stratum.
- Number of Clusters, which is the number of clusters in the stratum, if you specify a **CLUSTER** statement

## Variance Estimation Table

If you specify the **VARMETHOD=BRR**, **VARMETHOD=JACKKNIFE**, or **NOMCAR** option in the PROC SURVEYFREQ statement, the procedure displays a “Variance Estimation” table. If you do not specify any of these options, the procedure creates a “Variance Estimation” table but does not display it. You can store this nondisplayed table in an output data set by using the Output Delivery System (ODS). See the section “ODS Table Names” on page 7128 for more information.

The “Variance Estimation” table provides the following information:

- Method, which is the variance estimation method—Taylor Series, Balanced Repeated Replication, or Jackknife
- Replicate Weights input data set name, if you provide replicate weights with a **REPWEIGHTS** statement
- Number of Replicates, for **VARMETHOD=BRR** or **VARMETHOD=JACKKNIFE**
- Hadamard Data Set name, if you specify the **HADAMARD= method-option** for **VARMETHOD=BRR**
- Fay Coefficient, if you specify the **FAY method-option** for **VARMETHOD=BRR**
- Missing Levels Included (MISSING), if you specify the **MISSING** option
- Missing Levels Included (NOMCAR), if you specify the **NOMCAR** option

## Hadamard Matrix

If you specify the `PRINTH` *method-option* for `VARMETHOD=BRR`, PROC SURVEYFREQ displays the Hadamard matrix used to construct replicates for BRR variance estimation. If you provide a Hadamard matrix with the `HADAMARD=` *method-option* for `VARMETHOD=BRR` but the procedure does not use the entire matrix, the procedure displays only the rows and columns that are actually used to construct replicates.

## One-Way Frequency Tables

PROC SURVEYFREQ displays one-way frequency tables for all one-way table requests in the `TABLES` statements, unless you specify the `NOPRINT` option in the `TABLES` statement. A one-way table shows the sample frequency distribution of a single variable, and provides estimates for its population distribution in terms of totals and proportions.

If you request a one-way table without specifying options, PROC SURVEYFREQ displays the following information for each level of the variable:

- Frequency count, which is the number of sample observations in the level
- Weighted Frequency, which estimates the population total for the level
- Standard Deviation of Weighted Frequency
- Percent, which estimates the population proportion for the level
- Standard Error of Percent

The one-way table displays weighted frequencies if your analysis includes a `WEIGHT` or `REPWEIGHTS` statement, or if you specify the `WTFREQ` option in the `TABLES` statement.

The one-way table also displays the Frequency Missing, which is the number of observations with missing values.

You can suppress the frequency counts by specifying the `NOFREQ` option in the `TABLES` statement. Also, the `NOWT` option suppresses the weighted frequencies and their standard deviations. The `NOPERCENT` option suppresses the percentages and their standard errors. The `NOSTD` option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The `NOTOTAL` option suppresses the total row of the one-way table.

PROC SURVEYFREQ optionally displays the following information in a one-way table:

- Variance of Weighted Frequency, if you specify the `VARWT` option
- Confidence Limits for Weighted Frequency, if you specify the `CLWT` option
- Coefficient of Variation for Weighted Frequency, if you specify the `CVWT` option
- Test Percent, if you specify the `TESTP=` option

- Variance of Percent, if you specify the **VAR** option
- Confidence Limits for Percent, if you specify the **CL** option
- Coefficient of Variation for Percent, if you specify the **CV** option
- Design Effect for Percent, if you specify the **DEFF** option

## Crosstabulation Tables

PROC SURVEYFREQ displays all table requests in the **TABLES** statements, unless you specify the **NOPRINT** option in the **TABLES** statement. For two-way to multiway crosstabulation tables, the values of the last variable in the table request form the table columns. The values of the next-to-last variable form the rows. Each level (or combination of levels) of the other variables forms one layer. PROC SURVEYFREQ produces a separate two-way crosstabulation table for each layer of a multiway table.

For each layer, the crosstabulation table displays the row and column variable names and values (levels). Each two-way table lists levels of the column variable within each level of the row variable.

By default, the procedure displays all levels of the column variable within each level of the row variables, including any column variable levels with zero frequency for that row. For multiway tables, the procedure displays all levels of the row variable for each layer of the table by default, including any row levels with zero frequency for that layer. You can suppress the display of zero frequency levels by specifying the **NOSPARSE** option.

If you request a crosstabulation table without specifying options, the table displays the following information for each combination of variable levels (table cell):

- Frequency, which is the number of sample observations in the table cell
- Weighted Frequency, which estimates the population total for the table cell
- Standard Deviation of Weighted Frequency
- Percent, which estimates the population proportion for the table cell
- Standard Error of Percent

The two-way table displays weighted frequencies if your analysis includes a **WEIGHT** or **REPWEIGHTS** statement, or if you specify the **WTFREQ** option in the **TABLES** statement.

The two-way table also displays the Frequency Missing, which is the number of observations with missing values.

You can suppress the frequency counts by specifying the **NOFREQ** option in the **TABLES** statement. Also, the **NOWT** option suppresses the weighted frequencies and their standard deviations. The **NOPERCENT** option suppresses all percentages and their standard errors. The **NOCELLPERCENT** option suppresses overall cell percentages and their standard errors, but displays any other percentages

(and standard errors) that you request, such as row or column percentages. The **NOSTD** option suppresses the standard errors of the percentages and the standard deviations of the weighted frequencies. The **NOTOTAL** option suppresses the row totals and column totals, as well as the overall total.

PROC SURVEYFREQ optionally displays the following information in a two-way table:

- Expected Weighted Frequency, if you specify the **EXPECTED** option
- Variance of Weighted Frequency, if you specify the **VARWT** option
- Confidence Limits for Weighted Frequency, if you specify the **CLWT** option
- Coefficient of Variation for Weighted Frequency, if you specify the **CVWT** option
- Variance of Percent, if you specify the **VAR** option
- Confidence Limits for Percent, if you specify the **CL** option
- Coefficient of Variation for Percent, if you specify the **CV** option
- Design Effect for Percent, if you specify the **DEFF** option
- Row Percent, which estimates the population proportion of the row total, if you specify the **ROW** option
- Standard Error of Row Percent, if you specify the **ROW** option
- Variance of Row Percent, if you specify the **VAR** option and the **ROW** option
- Confidence Limits for Row Percent, if you specify the **CL** option and the **ROW** option
- Coefficient of Variation for Row Percent, if you specify the **CV** option and the **ROW** option
- Design Effect for Row Percent, if you specify the **ROW(DEFF)** option
- Column Percent, which estimates the population proportion of the column total, if you specify the **COL** option
- Standard Error of Column Percent, if you specify the **COL** option
- Variance of Column Percent, if you specify the **VAR** option and the **COL** option
- Confidence Limits for Column Percent, if you specify the **CL** option and the **COL** option
- Coefficient of Variation for Column Percent, if you specify the **CV** option and the **COL** option
- Design Effects for Column Percent, if you specify the **COL(DEFF)** option

## Statistical Tests

If you specify the **CHISQ** option for the Rao-Scott chi-square test, the **CHISQ1** option for the modified test, the **LRCHISQ** option for the Rao-Scott likelihood ratio chi-square test, or the **LRCHISQ1** option for the modified test, PROC SURVEYFREQ displays the following information:

- Pearson Chi-Square, if you specify the **CHISQ** or **CHISQ1** option
- Likelihood Ratio Chi-Square, if you specify the **LRCHISQ** or **LRCHISQ1** option
- Design Correction
- Rao-Scott Chi-Square, if you specify the **CHISQ** or **CHISQ1** option
- Rao-Scott Likelihood Ratio Chi-Square, if you specify the **LRCHISQ** or **LRCHISQ1** option
- DF, which is the degrees of freedom for the chi-square test
- Pr > ChiSq, which is the  $p$ -value for the chi-square test
- F Value
- Num DF, which is the numerator degrees of freedom for F
- Den DF, which is the denominator degrees of freedom for F
- Pr > F, which is the  $p$ -value for the  $F$  test

If you specify the **WCHISQ** option for the Wald chi-square test or the **WLLCHISQ** option for the Wald log-linear chi-square test, PROC SURVEYFREQ displays the following information:

- Wald Chi-Square, if you specify the **WCHISQ** option
- Wald Log-Linear Chi-Square, if you specify the **WLLCHISQ** option
- F Value
- Num DF, which is the numerator degrees of freedom for F
- Den DF, which is the denominator degrees of freedom for F
- Pr > F, which is the  $p$ -value for the  $F$  test
- Adjusted F Value, for tables larger than  $2 \times 2$
- Num DF, which is the numerator degrees of freedom for Adjusted F
- Den DF, which is the denominator degrees of freedom for Adjusted F
- Pr > Adj F, which is the  $p$ -value for the Adjusted  $F$  test

## Risks and Risk Difference

If you specify the **RISK** option in the TABLES statement for a  $2 \times 2$  table, PROC SURVEYFREQ displays “Column 1 Risk Estimates” and “Column 2 Risk Estimates” tables. You can display only column 1 or column 2 risks by specifying the **RISK1** or **RISK2** option, respectively.

The “Risk Estimates” table displays the following information for Row 1, Row 2, Total, and Difference:

- Row, which identifies the risk as Row 1, Row 2, Total, or Difference
- Risk estimate
- Standard Error
- Confidence Limits

In the “Column 1 Risk Estimates” table, the row 1 risk is the column 1 percentage of row 1. The row 2 risk is the column 1 percentage of row 2, and the total risk is the column 1 percentage of the entire table. The risk difference is the row 1 risk minus the row 2 risk. In the “Column 2 Risk Estimates” table, these computations are based on column 2.

## Odds Ratio and Relative Risks

If you specify the **OR** option in the TABLES statement for a  $2 \times 2$  table, PROC SURVEYFREQ displays the “Odds Ratio” table. This table includes the following information:

- Statistic, which identifies the statistic as the Odds Ratio, the Column 1 Relative Risk, or the Column 2 Relative Risk
- Estimate
- Confidence Limits

---

## ODS Table Names

PROC SURVEYFREQ assigns a name to each table that it creates. You can use these names to refer to tables when you use the Output Delivery System (ODS) to select tables and create output data sets. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

Table 84.7 lists the ODS table names together with their descriptions and the options required to produce the tables.

**Table 84.7** ODS Tables Produced by PROC SURVEYFREQ

ODS Table Name	Description	Statement	Option
ChiSq	Chi-square test	TABLES	CHISQ
ChiSq1	Modified chi-square test	TABLES	CHISQ1
CrossTabs	Crosstabulation table	TABLES	( <i>n</i> -way table, <i>n</i> > 1)
HadamardMatrix	Hadamard matrix	PROC	VARMETHOD=BRR(PRINTH)
LRChiSq	Likelihood ratio test	TABLES	LRCHISQ
LRChiSq1	Modified likelihood ratio test	TABLES	LRCHISQ1
OddsRatio	Odds ratio and relative risks	TABLES	OR (2 × 2 table)
OneWay	One-way frequency table	PROC or TABLES	(with no TABLES stmt) (one-way table)
Risk1	Column 1 risk estimates	TABLES	RISK or RISK1 (2 × 2 table)
Risk2	Column 2 risk estimates	TABLES	RISK or RISK2 (2 × 2 table)
StrataInfo	Stratum information	STRATA	LIST
Summary	Data summary	PROC	default
TableSummary	Table summary (not displayed)	TABLES	default
VarianceEstimation	Variance estimation	PROC	VARMETHOD=JK   BRR or NOMCAR
WChiSq	Wald chi-square test	TABLES	WCHISQ (two-way table)
WLLChiSq	Wald log-linear chi-square test	TABLES	WLLCHISQ (two-way table)

## ODS Graphics

PROC SURVEYFREQ assigns a name to each graph that it creates with ODS Graphics. You can use these names to refer to the graphs. Table 84.8 lists the names of the graphs that PROC SURVEYFREQ generates together with their descriptions, their PLOTS= options (*plot-requests*), and the TABLES statement options that are required to produce the graphs.

To request graphics with PROC SURVEYFREQ, you must first enable ODS Graphics by specifying the ODS GRAPHICS ON statement. See Chapter 21, “Statistical Graphics Using ODS,” for more information. When you have enabled ODS Graphics, you can request specific plots with the PLOTS= option in the TABLES statement. If you do not specify the PLOTS= option but have enabled ODS Graphics, then PROC SURVEYFREQ produces all plots that are associated with the analyses that you request.

**Table 84.8** ODS Graphics Produced by PROC SURVEYFREQ

ODS Graph Name	Plot Description	PLOTS= Option	TABLES Statement Option
WtFreqPlot	Weighted frequency plot	WTFREQPLOT	Any table request
ORPlot	Odds ratio plot	ODDSRATIOPLOT	OR ( <i>h</i> × 2 × 2 table)
RelRiskPlot	Relative risk plot	RELRISKPLOT	OR ( <i>h</i> × 2 × 2 table)
RiskDiffPlot	Risk difference plot	RISKDIFFPLOT	RISK ( <i>h</i> × 2 × 2 table)

---

## Examples: SURVEYFREQ Procedure

---

### Example 84.1: Two-Way Tables

This example uses the `SIS_Survey` data set from the section “Getting Started: SURVEYFREQ Procedure” on page 7049. The data set contains results from a customer satisfaction survey for a student information system (SIS).

The following PROC SURVEYFREQ statements request a two-way table for Department by Response and customize the crosstabulation table display:

```
title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey;
  tables Department * Response / cv deff nowt nostd nototal;
  strata State NewUser / list;
  cluster School;
  weight SamplingWeight;
run;
```

The TABLES statement requests a two-way table of Department by Response. The CV option requests coefficients of variation for the percentage estimates. The DEFF option requests design effects for the percentage estimates. The NOWT option suppresses display of the weighted frequencies, and the NOSTD option suppresses display of standard errors for the estimates. The NOTOTAL option suppresses the row totals, column totals, and overall totals.

The STRATA, CLUSTER, and WEIGHT statements provide sample design information for the procedure, so that the analysis is done according to the sample design used for the survey. The STRATA statement names the variables `State` and `NewUser`, which identify the first-stage strata. The LIST option in the STRATA statement requests a “Stratum Information” table. The CLUSTER statement names the variable `School`, which identifies the clusters (primary sampling units). The WEIGHT statement names the sampling weight variable.

Output 84.1.1 displays the “Data Summary” and “Stratum Information” tables produced by PROC SURVEYFREQ. The “Stratum Information” table lists the six strata in the survey and shows the number of observations and the number of clusters (schools) in each stratum.

**Output 84.1.1** Data Summary and Stratum Information

```

Student Information System Survey

The SURVEYFREQ Procedure

Data Summary

Number of Strata          6
Number of Clusters       370
Number of Observations   1850
Sum of Weights           38899.6482

Stratum Information

Stratum Index   State   NewUser          Number of   Number of
                State   NewUser          Obs        Clusters
-----
1      GA      Renewal Customer    315         63
2      GA      New Customer       355         71
3      NC      Renewal Customer    280         56
4      NC      New Customer       420         84
5      SC      Renewal Customer    210         42
6      SC      New Customer       270         54
-----

```

Output 84.1.2 displays the two-way table of Department by Response. According to the TABLES statement options that are specified, this two-way table includes coefficients of variation and design effects for the percentage estimates, and it does not show the weighted frequencies or the standard errors of the estimates. It also does not show the row, column, and overall totals.

**Output 84.1.2** Two-Way Table of Department by Response

```

Table of Department by Response

Department   Response          Frequency   Percent   CV for   Design
                Response          Frequency   Percent   Percent   Effect

Faculty      Very Unsatisfied    209    13.4987    0.0865    2.1586
              Unsatisfied         203    13.0710    0.0868    2.0962
              Neutral             346    22.4127    0.0629    2.1157
              Satisfied           254    16.2006    0.0806    2.3232
              Very Satisfied       98     6.2467    0.1362    2.2842
-----
Admin/Guidance Very Unsatisfied    95     3.6690    0.1277    1.1477
              Unsatisfied        123    4.6854    0.1060    1.0211
              Neutral            235    9.1838    0.0700    0.9166
              Satisfied           201    7.7305    0.0756    0.8848
              Very Satisfied       86     3.3016    0.1252    0.9892
-----

```

The following PROC SURVEYFREQ statements request a two-way table of Department by Response that includes row percentages, and also a Wald chi-square test of association between the two table variables:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey nosummary;
  tables Department * Response / row nowt wchisq;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;

```

Output 84.1.3 displays the two-way table. The row percentages show the distribution of Response for Department = 'Faculty' and for Department = 'Admin/Guidance'. This is equivalent to a domain (subpopulation) analysis of Response, where the domains are Department = 'Faculty' and Department = 'Admin/Guidance'.

Output 84.1.4 displays the Wald chi-square test of association between Department and Response. The Wald chi-square is 11.44, and the corresponding adjusted  $F$  value is 2.84 with a  $p$ -value of 0.0243. This indicates a significant association between department (faculty or admin/guidance) and satisfaction with the student information system.

**Output 84.1.3** Table of Department by Response with Row Percentages

Student Information System Survey						
The SURVEYFREQ Procedure						
Table of Department by Response						
Department	Response	Frequency	Percent	Std Err of Percent	Row Percent	Std Err of Row Percent

Pr > Adj F	0.0243
Sample Size = 1850	

**Example 84.2: Multiway Tables (Domain Analysis)**

Continuing to use the SIS\_Survey data set from the section “Getting Started: SURVEYFREQ Procedure” on page 7049, this example shows how to produce multiway tables. The following PROC SURVEYFREQ statements request a table of Department by SchoolType by Response for the student information system survey:

```

title 'Student Information System Survey';
proc surveyfreq data=SIS_Survey;
  tables Department * SchoolType * Response
         SchoolType * Response;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;

```

The TABLES statement requests a multiway table with SchoolType as the row variable, Response as the column variable, and Department as the layer variable. This request produces a separate two-way table of SchoolType by Response for each level of the variable Department. The TABLES statement also requests a two-way table of SchoolType by Response, which totals the multiway table over both levels of Department. As in the previous examples, the STRATA, CLUSTER, and WEIGHT statements provide sample design information, so that the analysis will be done according to the design used for this survey.

Output 84.2.1 displays the multiway table produced by PROC SURVEYFREQ, which includes a table of SchoolType by Response for Department = ‘Faculty’ and for Department = ‘Admin/Guidance’. This is equivalent to a domain (subpopulation) analysis of SchoolType by Response, where the domains are Department = ‘Faculty’ and Department = ‘Admin/Guidance’.

## Output 84.2.1 Multiway Table of Department by SchoolType by Response

## Student Information System Survey

## Example 84.3: Output Data Sets

PROC SURVEYFREQ uses the Output Delivery System (ODS) to create output data sets. This is a departure from older SAS procedures that provide OUTPUT statements for similar functionality. By using ODS, you can create a SAS data set from any piece of PROC SURVEYFREQ output. For more information about ODS, see Chapter 20, “Using the Output Delivery System.”

When selecting tables for ODS output data sets, you refer to tables by their ODS table names. Each table created by PROC SURVEYFREQ is assigned a name. See the section “ODS Table Names” on page 7128 for a list of the table names provided by PROC SURVEYFREQ.

To save the one-way table of Response from Figure 84.3 in an output data set, use an ODS OUTPUT statement as follows:

```
proc surveyfreq data=SIS_Survey;
  tables Response / cl nowt;
  ods output OneWay=ResponseTable;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

Output 84.3.1 displays the output data set ResponseTable, which contains the one-way table of Response. This data set has six observations, and each of these observations corresponds to a row of the one-way table. The first five observations correspond to the five levels of Response, as they are ordered in the one-way table display, and the last observation corresponds to the overall total, which is the last row of the one-way table. The data set ResponseTable includes a variable corresponding to each column of the one-way table. For example, the variable Percent contains the percentage estimates, and the variables LowerCL and UpperCL contain the lower and upper confidence limits for the percentage estimates.

**Output 84.3.1** ResponseTable Output Data Set

Obs	Table	Response	Frequency	Percent	StdErr	LowerCL	UpperCL
1	Table Response	Very Unsatisfied	304	17.1676	1.2872	14.6364	19.6989
2	Table Response	Unsatisfied	326	17.7564	1.2712	15.2566	20.2562
3	Table Response	Neutral	581	31.5965	1.5795	28.4904	34.7026
4	Table Response	Satisfied	455	23.9311	1.4761	21.0285	26.8338
5	Table Response	Very Satisfied	184	9.5483	0.9523	7.6756	11.4210
6	Table Response	.	1850	100.000	—	—	—

PROC SURVEYFREQ also creates a table summary that is not displayed. Some of the information in this table is similar to that contained in the “Data Summary” table, but the table summary describes the data that are used to analyze the specified table, while the data summary describes the entire input data set. Due to missing values, for example, the number of observations (or strata or clusters) used to analyze a particular table can differ from the number of observations (or strata or clusters) reported for the input data set in the “Data Summary” table. See the section “Missing Values” on page 7087 for more details. If you request confidence limits, the “Table Summary” table also contains the degrees of freedom and the *t*-value used to compute the confidence limits.

The following statements store the nondisplayed “Table Summary” table in the output data set ResponseSummary:

```
proc surveyfreq data=SIS_Survey;
  tables Response / cl nowt;
  ods output TableSummary=ResponseSummary;
  strata State NewUser;
  cluster School;
  weight SamplingWeight;
run;
```

Output 84.3.2 displays the output data set ResponseSummary.

#### Output 84.3.2 ResponseSummary Output Data Set

Obs	Table	Number of Observations	Number of Strata	Number of Clusters	Degrees of Freedom	t Percentile
1	Table Response	1850	6	370	364	1.966503

## Your Turn

---

We welcome your feedback.

- If you have comments about this book, please send them to **[yourturn@sas.com](mailto:yourturn@sas.com)**. Include the full title and page numbers (if applicable).
- If you have comments about the software, please send them to **[suggest@sas.com](mailto:suggest@sas.com)**.

# SAS® Publishing Delivers!

Whether you are new to the work force or an experienced professional, you need to distinguish yourself in this rapidly changing and competitive job market. SAS® Publishing provides you with a wide range of resources to help you set yourself apart. Visit us online at [support.sas.com/bookstore](http://support.sas.com/bookstore).

## SAS® Press

Need to learn the basics? Struggling with a programming problem? You'll find the expert answers that you need in example-rich books from SAS Press. Written by experienced SAS professionals from around the world, SAS Press books deliver real-world insights on a broad range of topics for all skill levels.

[support.sas.com/saspress](http://support.sas.com/saspress)

## SAS® Documentation

To successfully implement applications using SAS software, companies in every industry and on every continent all turn to the one source for accurate, timely, and reliable information: SAS documentation. We currently produce the following types of reference documentation to improve your work experience:

- Online help that is built into the software.
- Tutorials that are integrated into the product.
- Reference documentation delivered in HTML and PDF – free on the Web.
- Hard-copy books.

[support.sas.com/publishing](http://support.sas.com/publishing)

## SAS® Publishing News

Subscribe to SAS Publishing News to receive up-to-date information about all new SAS titles, author podcasts, and new Web site features via e-mail. Complete instructions on how to subscribe, as well as access to past issues, are available at our Web site.
