Introduction to the SAS/ACCESS Interface to Microsoft SQL Server

This document includes details only about the SAS/ACCESS interface to Microsoft SQL Server. It should be used as a supplement to the generic SAS/ACCESS documentation, *SAS/ACCESS for Relational Databases: Reference*.

The SAS/ACCESS interface to Microsoft SQL Server under UNIX hosts has been tested and certified against Data Direct Technologies Connect ODBC and Data Direct Sequelink ODBC products.

LIBNAME Statement Specifics for Microsoft SQL Server

This section describes the LIBNAME statement as supported in the SAS/ACCESS interface to Microsoft SQL Server. For a complete description of this feature, see the LIBNAME statement section in *SAS/ACCESS for Relational Databases: Reference*. The Microsoft SQL Server specific syntax for the LIBNAME statement is:

```
LIBNAME libref sqlsvr <connection-options> <LIBNAME-options>;
```
Arguments

libref
is any SAS name that serves as an alias to associate SAS with a database, schema, server, or group of tables and views.

sqlsvr
is the SAS/ACCESS engine name for the interface to Microsoft SQL Server.

connection-options
provide connection information and control how SAS manages the timing and concurrence of the connection to the DBMS. There are multiple ways that you can connect to Microsoft SQL Server when using the LIBNAME statement. Use only one of the following methods for each connection since they are mutually exclusive:
- specify USER=, PASSWORD=, and DATASRC=
- specify COMPLETE=
- specify NOPROMPT=
- specify PROMPT=
- specify REQUIRED=.

The connection options are defined as follows:

USER=<user-name>
enables you to connect to Microsoft SQL Server with a user ID that is different from the default ID.
USER= is optional. UID= is an alias for this option.

PASSWORD=<password>
specifies the Microsoft SQL Server password that is associated with your user ID.
PASSWORD= is optional. PWD= is an alias for this option.

DATASRC=<SQL-Server-data-source>
specifies the Microsoft SQL Server data source to which you want to connect.
For PC platforms, data sources must be configured by using the Microsoft SQL Server icon in the Windows Control Panel. For UNIX platforms, data sources must be configured by modifying the .ODBC.ini file.
DSN= is an alias for this option that indicates that the connection is attempted using the ODBC SQLConnect API, which requires a data source name. Optionally, a user ID and password can be used in conjunction with DSN=. This API is guaranteed to be present in all drivers.

COMPLETE=<SQL-Server-connection-options>
specifies connection options for your data source or database. Separate multiple options with a semicolon. When a successful connection is made, the complete connection string is returned in the SYSDBMSG macro variable.
If you do not specify enough correct connection options, you are prompted with a dialog box that displays the values from the COMPLETE= connection string. You can edit any field before you connect to the data source.
See your driver documentation for more details.

NOPROMPT=<SQL-Server-connection-options>
specifies connection options for your data source or database. Separate multiple options with a semicolon.
If you do not specify enough correct connection options, an error is returned. No dialog box is displayed to help you with the connection string.
PROMPT=<\'> SQL-Server-connection-options<\'>$ specifies connection options for your data source or database. Separate multiple options with a semicolon. When a successful connection is made, the complete connection string is returned in the SYSDBMSG macro variable.

PROMPT= does not immediately attempt to connect to the DBMS. Instead, it displays a dialog box that contains the values that you entered in the PROMPT= connection string. You can edit values or enter additional values in any field before you connect to the data source.

REQUIRED=<\'> SQL-Server-connection-options<\'>$ specifies connection options for your data source or database. Separate multiple options with a semicolon. When a successful connection is made, the complete connection string is returned in the SYSDBMSG macro variable.

If you do not specify enough correct connection options, a dialog box prompts you for the connection options. REQUIRED= allows you to modify only required fields in the dialog box.

The following Microsoft SQL Server connection options are not supported on UNIX:

- REQUIRED=
- BULKCOPY=
- PROMPT=
- COMPLETE=

LIBNAME-options define how DBMS objects are processed by SAS. Some LIBNAME options can enhance performance; others determine locking or naming behavior. The following table describes the LIBNAME options that are supported for Microsoft SQL Server, and presents default values where applicable. See the section about the SAS/ACCESS LIBNAME statement in SAS/ACCESS for Relational Databases: Reference for detailed information about these options.

### Table 1.1 SAS/ACCESS LIBNAME Options for Microsoft SQL Server

<table>
<thead>

</tbody>
</table>

---

**Microsoft SQL Server LIBNAME Statement Examples**

In following example, USER= and PASSWORD= are connection options.

```sql
libname mydblib sqlsvr user=testuser password=testpass;
```

In the following example, the libref MYDBLIB connects to a Microsoft SQL Server database using the NOPROMPT= option.

```sql
libname mydblib sqlsvr
    noprompt="uid=testuser;
pwd=testpass;
dsn=sqlservr;"
    stringdates=yes;
```

```sql
proc print data=mydblib.customers;
    where state='CA';
run;
```
Pass-Through Facility Specifics for Microsoft SQL Server

See the section about the Pass-Through Facility in SAS/ACCESS for Relational Databases: Reference for general information about this feature.

The Pass-Through Facility specifics for Microsoft SQL Server under UNIX hosts are as follows:

- The dbms-name is SQLSVR.
- The CONNECT statement is required.
- PROC SQL supports multiple connections to Microsoft SQL Server. If you use multiple simultaneous connections, you must use the alias argument to identify the different connections. If you do not specify an alias, the default alias is used. The functionality of multiple connections to the same Microsoft SQL Server data source might be limited by the particular data source's driver.
- The CONNECT statement database-connection-arguments are identical to its LIBNAME statement connection options.

<table>
<thead>
<tr>
<th>Option</th>
<th>Default Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>DBPROMPT=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>DBSASTYPE=</td>
<td>see “Data Types for Microsoft SQL Server” on page 11</td>
</tr>
<tr>
<td>DBSLICE=</td>
<td>none</td>
</tr>
<tr>
<td>DBSLICEPARM=</td>
<td>THREADED_APPS, 2 or 3</td>
</tr>
<tr>
<td>DBTYPE=</td>
<td>see “Data Types for Microsoft SQL Server” on page 11</td>
</tr>
<tr>
<td>ERRLIMIT=</td>
<td>1</td>
</tr>
<tr>
<td>IGNORE_READ_ONLY_COLUMNS=</td>
<td>NO</td>
</tr>
<tr>
<td>INSERT_SQL=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>INSERTBUFF=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>KEYSIZE=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>NULLCHAR=</td>
<td>SAS</td>
</tr>
<tr>
<td>NULLCHARVAL=</td>
<td>a blank character</td>
</tr>
<tr>
<td>PRESERVE_COL_NAMES=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>QUALIFIER=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>QUERY_TIMEOUT=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>READBUFF=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>READ_ISOLATION_LEVEL=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>READ_LOCK_TYPE=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>SASDATEFMT=</td>
<td>none</td>
</tr>
<tr>
<td>SCHEMA=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>UPDATE_ISOLATION_LEVEL=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>UPDATE_LOCK_TYPE=</td>
<td>LIBNAME option setting</td>
</tr>
<tr>
<td>UPDATE_SQL=</td>
<td>LIBNAME option setting</td>
</tr>
</tbody>
</table>
The following LIBNAME options are available with the CONNECT statement:

- **AUTOCOMMIT=**
- **CURSOR_TYPE=**
- **KEYSET_SIZE=**
- **QUERY_TIMEOUT=**
- **READBUFF=**
- **READ_ISOLATION_LEVEL=**
- **TRACE=**
- **TRACEFILE=**
- **USE_ODBC_CL=**

The **DBMS-SQL-query** argument can be a DBMS-specific SQL EXECUTE statement that executes a DBMS stored procedure. However, if the stored procedure contains more than one query, only the first query is processed.

---

### CONNECT Statement Examples

The following examples connect to a data source that is configured under the data source name **User’s Data** using the alias **USER1**. The first example uses the connection method that is guaranteed to be present at the lowest level of conformance. Note that DATASRC= names can contain quotation marks and spaces.

```sql
proc sql;
  connect to sqlsvr as user1
  (datasrc="User’s Data" user=testuser password=testpass);
```

The following example uses the connection method that represents a more advanced level of Microsoft SQL Server ODBC conformance. It uses the input dialog box that is provided by the driver. The DSN= and UID= arguments are within the connection string and are not parsed by the Pass-Through Facility. Instead, they are passed to the ODBC driver manager.

```sql
proc sql;
  connect to SQLSVR as user1
  (required = "dsn=User’s Data; uid=testuser");
```

The following example enables you to select any data source that is configured on your machine. The example uses the connection method that represents a more advanced level of Microsoft SQL Server ODBC conformance, Level 1. When a successful connection is made, the connection string is returned in the SQLXMSG and SYSDBMS MSG macro variables and can be stored if this method is used to configure a connection for later use.

```sql
proc sql;
  connect to SQLSVR (required);
```

The following example prompts you to specify the information that is required to make a connection to the DBMS. You are prompted to supply the data source name, user ID, and password in the dialog boxes that are displayed.

```sql
proc sql;
  connect to SQLSVR (prompt);
```

---

### Connection To Component Examples

The following example sends Microsoft SQL Server 6.5 (configured under the data source name "SQL Server") an SQL query for processing. The results from the query
serve as a virtual table for the PROC SQL FROM clause. In this example, MYDB is the connection alias.

```
proc sql;
connect to SQLSVR as mydb
   (datasrc="SQL Server" user=testuser password=testpass);
select * from connection to mydb
   (select CUSTOMER, NAME, COUNTRY
    from CUSTOMERS
    where COUNTRY <> 'USA');
quilt;
```

The following example returns a list of the columns in the CUSTOMERS table.

```
proc sql;
connect to SQLSVR as mydb
   (datasrc = "SQL Server" user=testuser password=testpass);
select * from connection to mydb
   (ODBC::SQLColumns (, , "CUSTOMERS"));
quilt;
```

---

**DBLOAD Procedure Specifics for Microsoft SQL Server**

See the section about the DBLOAD procedure in *SAS/ACCESS for Relational Databases: Reference* for general information about this feature.

The Microsoft SQL Server under UNIX hosts interface supports all of the DBLOAD procedure statements (except ACCDESC=) in batch mode. The Microsoft SQL Server interface specifics for the DBLOAD procedure are as follows:

- The DBLOAD step DBMS= value is **SQLSVR**.
- PROC DBLOAD uses the following database description statements:

  - **DSN=** `<database-name>`;
    
    specifies the name of the database in which you want to store the new Microsoft SQL Server table. The `database-name` is limited to eight characters.
    
    The database that you specify must already exist. If the database name contains any of the following special characters (_,$,@,#), you must enclose the database name in quotation marks. However, the Microsoft SQL Server standard recommends against using special characters in database names.

  - **USER=** `<username>`;
    
    enables you to connect to a Microsoft SQL Server database with a user ID that is different from the default ID.
    
    USER= is optional in the interface to Microsoft SQL Server. If you specify USER=, you must also specify PASSWORD=. If USER= is omitted, your default user ID is used.

  - **PASSWORD=** `<password>`;
    
    specifies the Microsoft SQL Server password that is associated with your user ID.
    
    PASSWORD= is optional in the interface to Microsoft SQL Server because users have default user IDs. If you specify USER=, you must specify PASSWORD=.

*Note:* If you do not wish to enter your SQL Server password in clear text on this statement, see PROC PWENCODE for a method to encode it.
Examples

The following example creates a new Microsoft SQL Server table, TESTUSER.EXCHANGE, from the DLIB.RATEOFEX data file. You must be granted the appropriate privileges in order to create new Microsoft SQL Server tables or views.

```sas
proc dbload dbms=SQLSVR data=dlib.rateofex;
  dsn=sample;
  user='testuser';
  password='testpass';
  table=exchange;
  rename fgnindol=fgnindollars
    4=dollarsinfgn;
  nulls updated=n fgnindollars=n
    dollarsinfgn=n country=n;
  load;
run;
```

The following example only sends a Microsoft SQL Server SQL GRANT statement to the SAMPLE database and does not create a new table. Therefore, the TABLE= and LOAD statements are omitted.

```sas
proc dbload dbms=SQLSVR;
  user='testuser';
  password='testpass';
  dsn=sample;
  sql grant select on testuser.exchange
    to dbitest;
run;
```

Passing SAS Functions to Microsoft SQL Server

The interface to Microsoft SQL Server passes the following SAS functions to the data source for processing (if the DBMS server supports the function). See the section about optimizing SQL usage in SAS/ACCESS for Relational Databases: Reference for information.

- ABS
- ARCOS
- ARSIN
- ATAN
- AVGCEIL
- COS
- EXP
- FLOOR
- LOG
- LOG10
- LOWCASE
- MIN
MAX
SIGN
SIN
SQRT
TAN
UPCASE
SUM
COUNT

Locking in the Microsoft SQL Server Interface

The following LIBNAME and data set options enable you to control how the interface to Microsoft SQL Server under UNIX hosts handles locking. See the section about the LIBNAME statement in SAS/ACCESS for Relational Databases: Reference for additional information about these options.

READ_LOCK_TYPE= ROW | TABLE | NOLOCK
UPDATE_LOCK_TYPE= ROW | TABLE | NOLOCK
READ_ISOLATION_LEVEL= S | RR | RC | RU | V
The Microsoft SQL Server ODBC driver manager supports the S, RR, RC, RU, and V isolation levels that are defined in the following table:

<table>
<thead>
<tr>
<th>Isolation Level</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>S (serializable)</td>
<td>Does not allow dirty reads, nonrepeatable reads, or phantom reads.</td>
</tr>
<tr>
<td>RR (repeatable read)</td>
<td>Does not allow dirty reads or nonrepeatable reads; does allow phantom reads.</td>
</tr>
<tr>
<td>RC (read committed)</td>
<td>Does not allow dirty reads or nonrepeatable reads; does allow phantom reads.</td>
</tr>
<tr>
<td>RU (read uncommitted)</td>
<td>Allows dirty reads, nonrepeatable reads and phantom reads.</td>
</tr>
<tr>
<td>V (versioning)</td>
<td>Does not allow dirty reads, nonrepeatable reads, or phantom reads. These transactions are serializable but higher concurrency is possible than with the serializable isolation level. Typically, a nonlocking protocol is used.</td>
</tr>
</tbody>
</table>

The terms in the table are defined as follows:

- Dirty read — A transaction that exhibits this phenomenon has very minimal isolation from concurrent transactions. In fact, the transaction can see changes that are made by those concurrent transactions even before they commit.

  For example, if transaction T1 performs an update on a row, transaction T2 then retrieves that row, and transaction T1 then terminates with rollback. Transaction T2 has then seen a row that no longer exists.
Nonrepeatable read — If a transaction exhibits this phenomenon, it is possible that it might read a row once and, if it attempts to read that row again later in the course of the same transaction, the row might have been changed or even deleted by another concurrent transaction. Therefore, the read is not necessarily repeatable.

For example, if transaction T1 retrieves a row, transaction T2 updates that row, and transaction T1 then retrieves the same row again. Transaction T1 has now retrieved the same row twice but has seen two different values for it.

Phantom reads — When a transaction exhibits this phenomenon, a set of rows that it reads once might be a different set of rows if the transaction attempts to read them again.

For example, if transaction T1 retrieves the set of all rows that satisfy some condition. If transaction T2 then inserts a new row that satisfies that same condition, and if transaction T1 now repeats its retrieval request, it sees a row that did not previously exist, a “phantom.”

UPDATE_ISOLATION_LEVEL= S | RR | RC | V

The Microsoft SQL Server ODBC driver manager supports the S, RR, RC, and V isolation levels that are defined in the preceding table.

### Naming Conventions for Microsoft SQL Server

The PRESERVE_COL_NAMES= and PRESERVE_TAB_NAMES= options determine how the interface to Microsoft SQL Server under UNIX hosts handles case sensitivity, spaces, and special characters. The default value for both of these options is YES for Microsoft Access, Microsoft Excel, and Microsoft SQL Server; NO for all others.

See the section about the LIBNAME statement in SAS/ACCESS for Relational Databases: Reference for additional information about these options.

The Microsoft SQL Server interface supports table and column names up to 32 characters long. If the DBMS table names or column names are longer than 32 characters, they are truncated to 32 characters. If truncating a name results in identical names, then SAS generates unique names by replacing the last character with a number.

### Data Types for Microsoft SQL Server

Every column in a table has a name and a data type. The data type tells the DBMS how much physical storage to set aside for the column and the form in which the data is stored.

The following table shows all of the data types and default SAS formats that are supported by the interface to Microsoft SQL Server under UNIX hosts.

<table>
<thead>
<tr>
<th>Microsoft SQL Server Data Type</th>
<th>Default SAS Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>SQL_CHAR</td>
<td>$n</td>
</tr>
<tr>
<td>SQL_VARCHAR</td>
<td>$n</td>
</tr>
<tr>
<td>SQL_LONGVARCHAR</td>
<td>$n</td>
</tr>
</tbody>
</table>
### Microsoft SQL Server Null Values

Microsoft SQL Server has a special value called NULL. A Microsoft SQL Server NULL value means an absence of information and is analogous to a SAS missing value.
When SAS/ACCESS reads a Microsoft SQL Server NULL value, it interprets it as a SAS missing value. Microsoft SQL Server columns can be defined as NOT NULL so that they require data (they cannot contain NULL values). When a column is defined as NOT NULL, the DBMS will not add a row to the table unless the row has a value for that column. When creating a DBMS table with SAS/ACCESS, you can use the the DBNULL= data set option to indicate whether NULL is a valid value for specified columns. For more information about how SAS handles NULL values, see in *SAS/ACCESS for Relational Databases: Reference*.

*Note:* To control how SAS missing character values are handled by Microsoft SQL Server, use the NULLCHAR= and NULLCHARVAL= data set options.

This glossary defines SAS software terms that are used in this document as well as terms that relate specifically to SAS/ACCESS software.

**access descriptor**
- a SAS/ACCESS file that describes data that is managed by a data management system. After creating an access descriptor, you can use it as the basis for creating one or more view descriptors. See also view and view descriptor.

**browsing data**
- the process of viewing the contents of a file. Depending on how the file is accessed, you can view SAS data either one observation (row) at a time or as a group in a tabular format. You cannot update data that you are browsing.

**bulk load**
- to load large amounts of data into a database object, using methods that are specific to a particular DBMS. Bulk loading enables you to rapidly and efficiently add multiple rows of data to a table as a single unit.

**client**
- (1) a computer or application that requests services, data, or other resources from a server. (2) in the X Window System, an application program that interacts with the X server and can perform tasks such as terminal emulation or window management. For example, SAS is a client because it requests windows to be created, results to be displayed, and so on.

**column**
- in relational databases, a vertical component of a table. Each column has a unique name, contains data of a specific type, and has certain attributes. A column is analogous to a variable in SAS terminology.

**column function**
- an operation that is performed for each value in the column that is named as an argument of the function. For example, AVG(SALARY) is a column function.

**commit**
- the process that ends a transaction and makes permanent any changes to the database that the user made during the transaction. When the commit process occurs, locks on the database are released so that other applications can access the changed data. The SQL COMMIT statement initiates the commit process.
DATA step view
a type of SAS data set that consists of a stored DATA step program. Like other SAS data views, a DATA step view contains a definition of data that is stored elsewhere; the view does not contain the physical data. The view's input data can come from one or more sources, including external files and other SAS data sets. Because a DATA step view only reads (opens for input) other files, you cannot update the view's underlying data.

data type
a unit of character or numeric information in a SAS data set. A data value represents one variable in an observation.

data value
in SAS, a unit of character or numeric information in a SAS data set. A data value represents one variable in an observation.

database
an organized collection of related data. A database usually contains named files, named objects, or other named entities such as tables, views, and indexes

database management system (DBMS)
an organized collection of related data. A database usually contains named files, named objects, or other named entities such as tables, views, and indexes

editing data
the process of viewing the contents of a file with the intent and the ability to change those contents. Depending on how the file is accessed, you can view the data either one observation at a time or in a tabular format.

engine
a component of SAS software that reads from or writes to a file. Each engine enables SAS to access files that are in a particular format. There are several types of engines.

file
a collection of related records that are treated as a unit. SAS files are processed and controlled by SAS and are stored in SAS data libraries.

format
a collection of related records that are treated as a unit. SAS files are processed and controlled by SAS and are stored in SAS data libraries. In SAS/ACCESS software, the default formats vary according to the interface product.

index
(1) in SAS software, a component of a SAS data set that enables SAS to access observations in the SAS data set quickly and efficiently. The purpose of SAS indexes is to optimize WHERE-clause processing and to facilitate BY-group processing. (2) in other software vendors' databases, a named object that directs the DBMS to the storage location of a particular data value for a particular column. Some DBMSs have additional specifications. These indexes are also used to optimize the processing of WHERE clauses and joins. Depending on the SAS interface to a database product and how selection criteria are specified, SAS may or may not be able to use the indexes of the DBMS to speed data retrieval.
      Depending on how selection criteria are specified, SAS might use DBMS indices to speed data retrieval.

informat
a pattern or set of instructions that SAS uses to determine how data values in an input file should be interpreted. SAS provides a set of standard informats and also enables you to define your own informats.
**interface view engine**
a SAS engine that is used by SAS/ACCESS software to retrieve data from files that have been formatted by another vendor’s software. Each SAS/ACCESS interface has its own interface view engine, which reads the interface product data and returns the data in a form that SAS can understand (that is, in a SAS data set). SAS automatically uses an interface view engine; the engine name is stored in SAS/ACCESS descriptor files so that you do not need to specify the engine name in a LIBNAME statement.

**libref**
a name that is temporarily associated with a SAS data library. The complete name of a SAS file consists of two words, separated by a period. The libref, which is the first word, indicates the library. The second word is the name of the specific SAS file. For example, in VLIB.NEWBDAY, the libref VLIB tells SAS which library contains the file NEWBDAY. You assign a libref with a LIBNAME statement or with an operating system command.

**member**
a SAS file in a SAS data library.

**member name**
a name that is given to a SAS file in a SAS data library.

**member type**
a SAS name that identifies the type of information that is stored in a SAS file. Member types include ACCESS, DATA, CATALOG, PROGRAM, and VIEW.

**missing value**
in SAS, a term that describes the contents of a variable that contains no data for a particular row or observation. By default, SAS prints or displays a missing numeric value as a single period, and it prints or displays a missing character value as a blank space.

**observation**
a row in a SAS data set. All of the data values in an observation are associated with a single entity such as a customer or a state. Each observation contains one data value for each variable. In a database product table, an observation is analogous to a row. Unlike rows in a database product table or file, observations in a SAS data file have an inherent order.

**Pass-Through Facility**
a group of SQL procedure statements that send and receive data directly between a relational database management system and SAS. The Pass-Through Facility includes the CONNECT, DISCONNECT, and EXECUTE statements, and the CONNECTION TO component. SAS/ACCESS software is required in order to use the Pass-Through Facility.

**PROC SQL view**
a SAS data set (of type VIEW) that is created by the SQL procedure. A PROC SQL view contains no data. Instead, it stores information that enables it to read data values from other files, which can include SAS data files, SAS/ACCESS views, DATA step views, or other PROC SQL views. A PROC SQL view’s output can be either a subset or a superset of one or more files.

**query**
a set of instructions that requests particular information from one or more data sources.
referential integrity
a set of rules that a DBMS uses to ensure that whenever a data value in one table is changed, the appropriate change is also made to any related values in other tables or in the same table. Referential integrity is also used to ensure that related data is not deleted or changed accidentally.

relational database management system
a database management system that organizes and accesses data according to relationships between data items. Oracle and DB2 are examples of relational database management systems.

rollback
in most databases, the process that restores the database to its state when changes were last committed, voiding any recent changes. The SQL ROLLBACK statement initiates the rollback processes. See also commit.

row
in relational database management systems, the horizontal component of a table. A row is analogous to a SAS observation.

SAS data file
a type of SAS data set that contains data values as well as descriptor information that is associated with the data. The descriptor information includes information such as the data types and lengths of the variables, as well as the name of the engine that was used to create the data. A PROC SQL table is a SAS data file. SAS data files are of member type DATA.

SAS data library
a collection of one or more SAS files that are recognized by SAS and that are referenced and stored as a unit. Each file is a member of the library.

SAS data set
a file whose contents are in one of the native SAS file formats. There are two types of SAS data sets: SAS data files and SAS data views. SAS data files contain data values in addition to descriptor information that is associated with the data. SAS data views contain only the descriptor information plus other information that is required for retrieving data values from other SAS data sets or from files whose contents are in other software vendors’ file formats.

SAS data view
a file whose contents are in one of the native SAS file formats. There are two types of SAS data sets: SAS data files and SAS data views. SAS data files contain data values in addition to descriptor information that is associated with the data. SAS data views contain only the descriptor information plus other information that is required for retrieving data values from other SAS data sets or from files whose contents are in other software vendors’ file formats.

SAS/ACCESS views
See view descriptor and SAS data view.

server
in a network, a computer that is reserved for servicing other computers in the network. Servers can provide several different types of services, such as file services and communication services. Servers can also enable users to access shared resources such as disks, data, and modems.

Structured Query Language (SQL)
the standardized, high-level query language that is used in relational database management systems to create and manipulate database management system objects. SAS implements SQL through the SQL procedure.
table
a two-dimensional representation of data, in which the data values are arranged in rows and columns.

trigger
a type of user-defined stored procedure that is executed whenever a user issues a data-modification command such as INSERT, DELETE, or UPDATE for a specified table or column. Triggers can be used to implement referential integrity or to maintain business constraints.

variable
a column in a SAS data set. A variable is a set of data values that describe a given characteristic across all observations.

view
a definition of a virtual data set. The definition is named and stored for later use. A view contains no data; it merely describes or defines data that is stored elsewhere. SAS data views can be created by the ACCESS and SQL procedures.

view descriptor
a file created by SAS/ACCESS software that defines part or all of the database management system (DBMS) data or PC file data that is described by an access descriptor. The access descriptor describes the data in a single DBMS table, DBMS view, or PC file.

wildcard
a file created by SAS/ACCESS software that defines part or all of the database management system (DBMS) data or PC file data that is described by an access descriptor. The access descriptor describes the data in a single DBMS table, DBMS view, or PC file.
