What’s New

Overview

The SAS OLAP Server enables users to develop and deploy scalable Online Analytical Processing (OLAP) applications. In addition, automated data loading and cube building is available through the use of a new administration interface called the SAS OLAP Cube Studio, which was developed using Java technology.

OLAP queries are performed using the Multidimensional Expressions (MDX) query language in client applications that are connected to the OLAP Server by using

- the SQL Pass-Through Facility for OLAP, which is designed to process MDX queries within the PROC SQL environment.
- open access technologies such as OLE DB for OLAP, ADO MD, and Java.

Note: This section describes the features of the SAS OLAP Server that are new or enhanced since SAS 8.2.

Details

- There are two new tools for data loading and cube building:
  - The OLAP procedure, in addition to cube building, includes options for handling ragged hierarchies, defining global calculated members and named sets, assigning properties to levels, and optimizing cube creation and query performance. It also supports multiple hierarchies and drill-through tables.
  - The SAS OLAP Cube Studio is an alternative Java interface to the OLAP procedure. This interface is also integrated with SAS ETL Studio.
- Server performance is recorded and analyzed by using the Application Response Measurement (ARM) system.
- The new multi-threaded data storage and server functionality provide faster cube performance. The data can be stored in a multidimensional form (MOLAP) or in a form that includes existing aggregations from presummarized data sources.
- The metadata structure is improved, and metadata is stored with the cube.
- Caching and logging can be enabled or disabled.
- Support for ad hoc calculations and time dimensions is improved.
- An SQL Pass-Through Facility for OLAP is available in SAS for use in querying cubes.
- Aggregations can be added to or deleted from existing cubes.

Note: Version 8 of the SAS OLAP Server can be used with SAS 9. For help, see “V8 SAS OLAP Server” in SAS System Help and Documentation.
MDX Overview

Multidimensional Expressions (MDX) is a powerful syntax that enables you to query multidimensional objects and provide commands that retrieve and manipulate multidimensional data from those objects. MDX is designed to ease the process of accessing data from multiple dimensions. It addresses the conceptual differences between two-dimensional and multidimensional querying. MDX provides functionality for creating and querying multidimensional structures called cubes with a full and complete language of its own.

MDX is similar to the Structured Query Language (SQL), and MDX provides Data Definition Language (DDL) syntax for managing data structures. However, its features can be more complex and robust than SQL’s features. The SAS 9.1 OLAP Server technology uses MDX to create OLAP cubes and data queries. MDX is part of the underlying foundation for the SAS 9.1 OLAP Server architecture, and it offers detailed and efficient searches of multidimensional data.

With MDX, specific portions of data from a cube can be extracted and then further manipulated for analysis. This allows for a thorough and flexible examination of SAS OLAP cube data. Users of MDX can take advantage of such features as calculated measures, numeric operations, and axis and slicer dimensions.

Basic MDX and Cube Concepts

To better understand the MDX language and the OLAP technology it supports, a basic understanding of the OLAP cube components is required.
Dimensions

Dimensions are the top or highest categories of a cube. They contain subcategories of data known as levels and measures. A dimension can have multiple hierarchies and can be used in multiple cubes. A cube can have up to 64 dimensions.

Hierarchies

A dimension might be categorized into different hierarchies. For example, a company might categorize its profit dimension along the verticals of geography, sales territory, or market.

Levels

Levels are categories of organization within a dimension. Levels are hierarchical, and each level that is descended in a dimension is a component of the previous level. For example, a time dimension could include the following levels: Year, Quarter, Month, Week, and Day.

Members and Measures

An additional component of a dimension and a level is a member. A member is a component of a level and is analogous to the value of a variable on an individual record in a data set. It is the smallest level of data in an OLAP cube. In addition to creating dimension members, a user can create calculated members and named sets that are based on underlying members or on other calculated members and named sets. These user-defined objects are based on evaluated query data from the cube.

Calculated members and named sets can be created in three different ways:

- **Query scope calculated member** is only available during the query that defines it. It is created by using the WITH MEMBER/SET keyword.

- **Session scope calculated member** is available for the user that defines the object for the duration of that session. It is created by using the CREATE SESSION MEMBER/SET keyword.

- **Global scope calculated member** is available for anyone to use and is stored with the cube. It is created by using the CREATE GLOBAL MEMBER/SET keyword. Named sets have the same three scopes.

Calculated members can be created in the Measures dimension and can include any combination of members. Calculated members can also be created in any other dimension and are known as nonmeasure-based calculated members. Examples of measures include sales counts, profit margins, and distribution costs.

Additional MDX Concepts and Expressions - Tuples and Sets

MDX extracts multidimensional views of data. A tuple is a slice of data from a cube. It is a selection of members (or cells) across dimensions in a cube. It can also be viewed as a cross-section or vector of member data in a cube. A tuple can be composed of
member(s) from one or more dimensions. However, a tuple cannot be composed of more than one member from the same dimension.

Sets are collections of tuples. The order of tuples in a set is important when querying cube data and is known as dimensionality. It is important to note that the order of the dimension members in every tuple must be the same. For example, if your first tuple is (time_dimension_member, geography_dimension_member), then every other tuple in that set must also have two members in it, the first from the time dimension and the second from the geography dimension.

Additional MDX Documentation

In addition to the MDX usage examples, functions and related topics that are found in this documentation, a supplementary text for the SAS OLAP Server is available. The SAS OLAP Server: Concepts and Excerpts from “MDX Solutions with Microsoft SQL Server Analysis Services” includes basic MDX information such as the MDX data model, MDX construction, comments in MDX, and a complete MDX function and operator reference. You can locate this text at support.sas.com/publishing.
Basic MDX Queries and Syntax

Basic MDX queries use the SELECT statement to identify a data set that contains a subset of multidimensional data. The basic MDX SELECT statement is composed of the following clauses:

- **WITH clause** (optional). This allows calculated members or named sets to be computed during the processing of the SELECT and WHERE clauses.
- **SELECT clause**. The SELECT clause defines the axes for the MDX query structure by identifying the dimension members to include on each axis. The number of axis dimensions of an MDX SELECT statement is also determined by the SELECT clause. The members from each dimension (to include on each axis of the MDX query) must be identified.
- **FROM clause**. The cube that is being queried is named in the FROM clause. It determines which multidimensional data source will be used when extracting data to populate the result set of the MDX SELECT statement. The FROM clause (in an MDX query) can list only a single cube. Queries are restricted to a single data source or cube.
WHERE clause (optional). The WHERE clause further restricts the result data. The axis that is formed by the WHERE clause is often referred to as the slicer. The WHERE clause determines which dimension or member is used as a slicer dimension. This restricts the extracting of data to a specific dimension or member. Any dimension that does not appear on an axis in the SELECT clause can be named on the slicer.

Note: MDX queries, and specifically the SELECT statement, can have up to 128 axis dimensions. The first five axes have aliases. Furthermore, an axis can be referred to by its ordinal position within an MDX query or by its alias. In total you can have a maximum of 64 different axes.

The SELECT clause of the statement supports using MDX functions to construct different members in a set on axes. The WITH clause of the statement supports using MDX functions to construct calculated members to be used in an axis or slicer. The following example shows the syntax for the SELECT statement:

```sql
[WITH
  [MEMBER <member-name> AS '<value-expression>' |
   SET <set-name> AS '<set-expression>' ] . . .]
SELECT [ <axis_specification>
[, <axis_specification> . . . ]
FROM [ <cube_specification>]
[WHERE [ <slicer_specification>]]
```

Basic MDX DDL Syntax

The SAS OLAP Server provides support for the MDX Data Definition Language (DDL). DDL enables users and administrators to manage the definitions of calculated members and named sets at either a session or a global level. Management of calculated members and named sets is provided by the CREATE and DROP DDL statements.

By using the CREATE DDL statement, a user can create definitions of calculated members or named sets for use within a client session or for use within a cube on a global scale. Here is the format for the CREATE DDL statement:

```sql
CREATE [GLOBAL | SESSION]
  [MEMBER . AS '' |
   SET AS '' ] . . .
```

If GLOBAL or SESSION is not specified, then the default scope is SESSION. When a calculated member or named set is defined within the SESSION scope, the definition is available only for the lifetime of the user’s client session. When a calculated member or named set is defined within the GLOBAL scope, the definition is permanently attached to the cube definition and is visible to all current and future client sessions.

By using the DROP DDL statement, a user can remove definitions of calculated members or a named set from use within a client session or from use within a cube on a global scale. Here is the format for the DROP DDL statement:

```sql
DROP [MEMBER . . . ] |
```

When using the DROP statement, only calculated members or named sets can be dropped at the same time. However, a user cannot drop both calculated members and named sets in a single DROP statement.

Note: The name of the calculated member or named set must contain the cube name.
### SAS Functions

SAS functions are functions that anyone can reference in MDX expressions. SAS functions are slightly limited in the arguments that they accept and return. Here is an MDX query that uses a SAS function called “MDY”:

```sql
WITH MEMBER measures.mdy AS 'SAS!MDY(2,9,2003)'
SELECT {cars.MEMBERS} ON 0 FROM MDDBCARS
WHERE (measures.mdy)
```

The resulting cells look like this:

- NOTE: 0.3[0]: f=15742 (u=15742.00)
- NOTE: 0.3[1]: f=15742 (u=15742.00)
- NOTE: 0.3[2]: f=15742 (u=15742.00)
- NOTE: 0.3[3]: f=15742 (u=15742.00)
- NOTE: 0.3[4]: f=15742 (u=15742.00)
- NOTE: 0.3[5]: f=15742 (u=15742.00)
- NOTE: 0.3[6]: f=15742 (u=15742.00)
- NOTE: 0.3[7]: f=15742 (u=15742.00)
- NOTE: 0.3[8]: f=15742 (u=15742.00)
- NOTE: 0.3[9]: f=15742 (u=15742.00)
- NOTE: 0.3[10]: f=15742 (u=15742.00)
- NOTE: 0.3[11]: f=15742 (u=15742.00)
- NOTE: 0.3[12]: f=15742 (u=15742.00)
- NOTE: 0.3[13]: f=15742 (u=15742.00)
- NOTE: 0.3[14]: f=15742 (u=15742.00)
- NOTE: 0.3[15]: f=15742 (u=15742.00)

In order to gain access to a SAS function library and before you can use a SAS function in a query, you must define or open the library for the current session. To do this, apply the USE statement at the beginning of your MDX query:

```sql
USE LIBRARY "SAS"
```

### Available SAS Functions Exposed for Use in MDX Expressions

#### Table 2.1 SAS Functions Exposed for Use in MDX Expressions

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
<th>Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATE</td>
<td>returns the current date in SAS date format</td>
<td>(none)</td>
</tr>
<tr>
<td>DATEJUL</td>
<td>converts a julian date to a SAS date value</td>
<td>&lt;julian-date&gt;</td>
</tr>
<tr>
<td>DATEPART</td>
<td>returns a SAS date value that corresponds to the date portion of a SAS datetime value</td>
<td>&lt;SAS datetime&gt;</td>
</tr>
<tr>
<td>DATETIMEx</td>
<td>returns the current data and time in SAS datetime format</td>
<td>(none)</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Argument</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>----------</td>
</tr>
<tr>
<td>DAY</td>
<td>returns an integer that represents the day of the month from a SAS date value</td>
<td>«SAS date»</td>
</tr>
<tr>
<td>DHMS</td>
<td>returns a SAS datetime value from a numeric expression that represents the date, hour, minute, and second</td>
<td>«SAS date», «hour», «minute», «second»</td>
</tr>
<tr>
<td>HMS</td>
<td>returns a SAS time value from a numeric expression that represents the hour, minute, and second</td>
<td>«hour», «minute», «second»</td>
</tr>
<tr>
<td>HOUR</td>
<td>returns a numeric value that represents the hour from a SAS time or datetime value</td>
<td>«SAS time»</td>
</tr>
<tr>
<td>IN</td>
<td>returns TRUE if the first expression is contained in the list of expressions that start from the second parameter to the end of the parameters provided; otherwise, FALSE</td>
<td>«expression», «expression1», . . «expressionN»</td>
</tr>
<tr>
<td>JULDATE</td>
<td>converts a SAS date value to a numeric value that represents a Julian date</td>
<td>«SAS date»</td>
</tr>
<tr>
<td>JULDATE7</td>
<td>converts a SAS date value to a numeric value that represents a Julian date with the year represented in 4 digits</td>
<td>«SAS date»</td>
</tr>
<tr>
<td>LEFT</td>
<td>returns the argument with leading blanks moved to the end of the value; the argument’s length does not change</td>
<td>«argument»</td>
</tr>
<tr>
<td>MDY</td>
<td>returns a SAS date value from numeric expressions that represent the month, day, and year</td>
<td>«month», «day», «year»</td>
</tr>
<tr>
<td>MINUTE</td>
<td>returns a numeric value that represents the minute from a SAS time or datetime value</td>
<td>«SAS time»</td>
</tr>
<tr>
<td>MONTH</td>
<td>returns a numeric value that represents the month from a SAS time</td>
<td>«SAS date»</td>
</tr>
<tr>
<td>QTR</td>
<td>returns a value of 1, 2, 3, or 4 from a SAS date value to indicate the quarter of the year during which the SAS date value falls</td>
<td>«SAS date»</td>
</tr>
<tr>
<td>RIGHT</td>
<td>returns the argument with trailing blanks moved to the beginning of the value; the argument’s length does not change</td>
<td>«argument»</td>
</tr>
<tr>
<td>ROUND</td>
<td>rounds the first argument to the nearest multiple of the second argument, or to the nearest integer when the second argument is omitted</td>
<td>(argument &lt;;rounding-unit&gt;)</td>

<tr>
<td>SECOND</td>
<td>returns a numeric value that represents the second from a SAS time or datetime value</td>
<td>«SAS time»</td>
</tr>
<tr>
<td>Function</td>
<td>Description</td>
<td>Argument</td>
</tr>
<tr>
<td>----------</td>
<td>-------------</td>
<td>----------</td>
</tr>
<tr>
<td>SUBSTR</td>
<td>returns a portion of the string expression argument, starting at the index position and returning up to &quot;n&quot; characters. If &quot;n&quot; is not specified, then the rest of the string is returned</td>
<td>&lt;argument&gt;, &lt;position&gt; &lt;, &lt;n&gt;</td>
</tr>
<tr>
<td>TIME</td>
<td>returns the current time in SAS time format</td>
<td>(none)</td>
</tr>
<tr>
<td>TIMEPART</td>
<td>returns a SAS time value that corresponds to the time portion of a SAS datetime value</td>
<td>&lt;SAS datetime&gt;</td>
</tr>
<tr>
<td>TODAY</td>
<td>returns the current date in SAS date format</td>
<td>(none)</td>
</tr>
<tr>
<td>TRIM</td>
<td>returns the argument with the trailing blanks removed; if the argument contains all blanks, then the result is a string with a single blank</td>
<td>&lt;argument&gt;</td>
</tr>
<tr>
<td>TRIMN</td>
<td>returns the argument with the trailing blanks removed; if the argument contains all blanks, then the result is a null string</td>
<td>&lt;argument&gt;</td>
</tr>
<tr>
<td>TRUNC</td>
<td>truncates a numeric value to a specified length</td>
<td>(number,length)</td>
</tr>
<tr>
<td>UPCASE</td>
<td>returns the argument with all lowercase characters converted to uppercase characters</td>
<td>&lt;argument&gt;</td>
</tr>
<tr>
<td>WEEKDAY</td>
<td>returns an integer that represents the day of the week, where 1 = Sunday, 2 = Monday, . . ., 7 = Saturday, from a SAS date value</td>
<td>&lt;SAS date&gt;</td>
</tr>
<tr>
<td>YEAR</td>
<td>returns a numeric value that represents the month from a SAS time</td>
<td>&lt;SAS date&gt;</td>
</tr>
<tr>
<td>YYQ</td>
<td>returns a SAS date value that corresponds to the first day of the specified quarter</td>
<td>&lt;year&gt;, «quarter»</td>
</tr>
</tbody>
</table>

**Function Arguments and Return Types**

Currently only floating-point (double) arguments, character string arguments, and return values are supported. There is no limit to the number of arguments. The promotion of arguments from MDX types to SAS data types is automatically performed when there is a difference between the two types.

**Numeric Precision**

To store numbers of large magnitude and to perform computations that require many digits of precision to the right of the decimal point, SAS OLAP Server stores all numeric values as floating-point representation. Floating-point representation is an
implementation of scientific notation, in which numbers are represented as numbers between 0 and 1 times a power of 10.

In most situations, the way SAS OLAP Server stores numeric values does not affect you as a user. However, floating-point representation can account for anomalies that you might notice in MDX numeric expressions. This section identifies the types of problems that can occur and how you can anticipate and avoid them.

**Magnitude versus Precision**

Floating-point representation allows for numbers of very large magnitude (such as $2^{30}$) and high degrees of precision (many digits to the right of the decimal place). However, operating systems differ on how much precision and how much magnitude to allow.

Whether magnitude or precision is more important depends on the characteristics of your data. For example, if you are working with engineering data, very large numbers might be needed and magnitude will probably be more important. However, if you are working with financial data where every digit is important, but the number of digits is not great, then precision is more important. Most often, applications that are created with SAS OLAP Server need a moderate amount of both magnitude and precision, which is handled well by floating-point representation.

**Computational Considerations of Fractions**

Regardless of how much precision is available, there is still the problem that some numbers cannot be represented exactly. For example, the fraction $1/3$ cannot be rendered exactly in floating-point representation. Likewise, $.1$ cannot be rendered exactly in a base 2 or base 16 representation, so it also cannot be accurately rendered in floating-point representation. This lack of precision is aggravated by arithmetic operations. Consider the following example:

$$((10 * .1) = 1)$$

This expression might not always return TRUE due to differences in numeric precision. However, the following expression uses the ROUND function to compensate for numeric precision and therefore will always return TRUE:

$$(\text{round}((10 * .1), .001) = 1)$$

Usually, if you are doing comparisons with fractional values, it is good practice to use the ROUND function.

**Using the TRUNC Function**

The TRUNC function truncates a number to a requested length and then expands the number back to full precision. The truncation and subsequent expansion duplicate the effect of storing numbers in less than full precision. So in the following example, the first expression would return FALSE and the second would return TRUE:

$$((1/3) = .333)$$

$$(\text{TRUNC}((1/3), 3) = .333)$$

When you compare the result of a numeric expression to be equal to a specific value, such as 0, it is important that you use the TRUNC and ROUND functions to ensure that the comparison evaluates as intended.
Differences with Microsoft Analysis Services 2000

Microsoft Analysis Services 2000 (AS2K) labels external functions as user-defined functions (UDFs). Because AS2K runs only on Windows, it supports calling COM libraries (usually written in Visual Basic). Because MDX evaluation can occur on either the client or the server, Microsoft provides a means to install and use libraries on either location (due to a dual-mode OLE DB for OLAP provider, MSOLAP).

If you use a client-side function, then all the execution is on the client. SAS OLAP Server is a thin-client system that is designed for high volume and scalability, with all evaluation done on the server. Therefore, external function libraries such as SAS functions can only be installed on the server. Additionally, with the proper license, you can run a server on your own computer and install any libraries that you need.

SAS MDX Reserved Keywords

A reserved keyword should not be used to reference a dimension, hierarchy, level, or member name unless the reference is enclosed in square brackets [ ]. Otherwise, the keyword might be interpreted incorrectly.

```
{ DRILLDOWNMEMBER NONEMPTYCROSSJOIN
  ) DRILLDOWNMEMBERBOTTOM NOT

External Functions

External functions are functions that can be written on a server that clients can later reference in MDX expressions. External functions can be written by most MDX users. External function names are case sensitive, and unlike internal functions, they are more limited in the arguments they can take. Here is an example of an MDX query that uses an external function called `addOne()`, which takes one parameter, a double argument, and adds one (1) to it. It then returns another double argument:

```mdx
WITH MEMBER measures.x AS 'addOne(measures.sales_sum)'
SELECT {cars.MEMBERS} ON 0 FROM Mddbcars
WHERE (measures.x)
```

The resulting cells look like this:

```
0.0[0]: 229001
0.0[1]: 27001
0.0[2]: 40001
0.0[3]: 86001
0.0[4]: 76001
0.0[5]: 17001
0.0[6]: 10001
0.0[7]: 20001
0.0[8]: 20001
0.0[9]: 10001
0.0[10]: 44001
0.0[11]: 17001
0.0[12]: 15001
0.0[13]: 4001
0.0[14]: 14001
0.0[15]: 58001
```

Here is the query and the resulting cells without the external `addOne()` function:

```mdx
SELECT {cars.MEMBERS} ON 0
FROM Mddbcars
WHERE (measures.sales_sum)
```

```
Array(0)=229000 Array(1)=27000
Array(2)=17000 Array(3)=10000
Array(4)=40000 Array(5)=20000
Array(6)=20000 Array(7)=86000
Array(8)=10000 Array(9)=44000
Array(10)=17000 Array(11)=15000
Array(12)=76000 Array(13)=4000
Array(14)=14000 Array(15)=58000
```
Defining External Functions in Java

SAS runs on many different types of computers. As a result, you can write external functions in the Java language. Here is a simple Java class that implements the `addOne()` function from earlier:

```java
public class Hello {
    public double addOne(double d) {
        return d + 1.0;
    }
}
```

To prepare this class for execution you must obtain and compile a copy of the Java Development Kit (JDK), which is available on the World Wide Web. Here is an example:

```
C:> javac Hello.java
```

After compiling the JDK, you install the resulting Hello.class file in a location where the server can find it. Currently this means you must list the directory that contains the .class file in the CLASSPATH environment variable before you start the server.

Gaining Access to an External Function Library or Class

Before you can use a function in a query, you must define or open the library for the current session. To do this, you execute the USE statement in MDX:

```
USE LIBRARY "Hello"
```

You do not add the .class extension, because it is automatically provided. When the session ends, the library is released. You can use a DROP statement to release the library before the session ends:

```
DROP LIBRARY "Hello"
```

State Information

The class is instantiated when the USE statement is first encountered in a session, and then it is released when the session ends or the DROP statement is executed. As a result, the state can be kept in a normal class and static variables can be maintained. Here is an example:

```java
public class Hello {
    static int count = 0;
    int instance;
    int iteration = 0;
    public Hello() {
        instance = count++;
        System.out.println("Hello constructor "+ instance);
    }
    public double addOne(double d)
```
{  
    System.out.println("addOne, world! " + instance + " " +
    iteration++);
    return d+1.0;
}
public void finalize()
{
    System.out.println("Hello finalize");
}

Note: System.out is used in the above example for illustration and cannot be used in a real function except for debugging.

Here is an example of the debugging output that is generated:

Hello constructor 0
addOne, world! 0 0
addOne, world! 0 2
Hello constructor 1
addOne, world! 0 3
addOne, world! 1 0
addOne, world! 1 1

Each time a new session (a user or client connection) uses this class, the Java constructor is called and a new `Hello` object is created. The count is incremented so that `instance` has a unique value. Example items that you might want to save in a real application include file handles, shopping cart lists, and database connection handles.

Although cleanup is automatic, you can have an optional `finalize` method for special circumstances. Normal Java garbage collection of the class occurs some time after the class is no longer needed. The `finalize` method should then be called. However, in accordance with Java standards, it is possible that the `finalize` method will never be called (for example, if the server is shut down early, or the class never needs to be removed by the garbage collector).

---

### Function Arguments and Return Types

Only floating-point (double) arguments and return values are supported by SAS 9.1 OLAP Server. Java function overloading is also supported and there is no limit to the number of arguments that are supported.

SAS OLAP Server looks at the parameters that are passed to an external function and creates a Java signature from that. It then looks up the function and signature in the class. In the `addOne()` example that was mentioned earlier, there is one parameter. Also, because it is a double argument, it looks for the signature “D(D)”.

---

### Performance

Certain OLAP hosts use an in-process Java virtual machine (JVM), while other OLAP hosts use an out-of-process JVM. An out-of-process JVM is much less efficient because each method call has to be packaged (marshaled) and transmitted to the JVM process. It is then unpackaged (unmarshaled) and run, and a return packet is sent.
back. Currently HP-UX, OpenVMS, and OS/390 use out-of-process JVMs. In later releases, hosts should be able to use in-process JVMs. OS/390 will use a shared address space so it can be optimized.

Although synthetic benchmarks show that calling Java is considerably slower than calling built-in functions, real-world performance tests show that the performance impact of calling Java methods was negligible (at least with in-process Java implementations). If you encounter a problem, reducing the number of function calls per output cell, the number of cells queried, and the number of parameters to the function can all boost performance.

---

### Deployment

To make a Java class available, copy the .class file to a directory that is listed in the CLASSPATH environment variable when the server is started. The CLASSPATH can contain any number of directories that are separated by semicolons (;). The current release of SAS OLAP Server does not contain a method to make the server reload a .class file after it has been loaded. Therefore, if you update the .class file after using it one time, the server will continue to use the old version. Currently you need either to restart the server or give the new class a different name.

It is possible that later releases of SAS OLAP Server will not use CLASSPATH. A benefit of using Java for external functions is that the .class files are portable. As a result, you can use JavaC to compile your class one time, and deploy it on different machines without recompiling.

---

### Security

Because the Java classes are loaded from the server’s local file system, they have full access to the server’s system (under the ID that started the server). Any public methods (on any classes) in the CLASSPATH can be invoked by any client. As a result, use caution when you decide which classes and directories to make visible.

---

### Differences with Microsoft Analysis Server (AS2K)

See “Differences with Microsoft Analysis Services 2000” on page 11.

---

### Supported Versions of Java

SAS OLAP Server 9.1 supports the same version of Java that SAS 9.1 does. For example, under Windows, SAS OLAP Server 9.1 and SAS 9.1 require Java Version 1.4.1.
Simple Examples

The data that is used in these simple examples is from a company that sells various makes and models of cars. The company needs to report sales figures for different months.

Here is a simple two-dimensional query:

```sql
select
  { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] } on columns,
  { [DATE].[All DATE].[March], [DATE].[All DATE].[April] } on rows
from mddbcars
```

Using this example code, you can flip the rows and columns:

```
select
  { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] } on rows,
  { [DATE].[All DATE].[March], [DATE].[All DATE].[April] } on columns
from mddbcars
```

Select a different measure (SALES_N) to be the default:

```
"select
  { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] } on columns,
  { [DATE].[All DATE].[March], [DATE].[All DATE].[April] } on rows
from mddbcars
where ([Measures].[SALES_N])
```

Demonstrate ":" to get a range of members:

```
select
  { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] } on columns,
  { [DATE].[All DATE].[January] : [DATE].[All DATE].[April] } on rows
from mddbcars
```

Demonstrate the .MEMBERS function:

```
select
  { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] } on columns,
  { [DATE].members } on rows
from mddbcars
```

Demonstrate the .CHILDREN function:

```
select
  { [CARS].[All CARS].[Ford].children } on columns,
  { [DATE].members } on rows
from mddbcars
```

Select more than one dimension in a tuple:

```
select
  { ( [CARS].[All CARS].[Chevy], [Measures].[SALES_SUM] ),
    ( [CARS].[All CARS].[Chevy], [Measures].[SALES_N] ),
    ( [CARS].[All CARS].[Ford], [Measures].[SALES_SUM] ),
    ( [CARS].[All CARS].[Ford], [Measures].[SALES_N] )
  } on columns,
  { [DATE].members } on rows
from mddbcars
```

The crossjoin function makes tuple combinations for you:

```
select
crossjoin { { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] },
            { [Measures].[SALES_SUM], [Measures].[SALES_N] } }
on columns,
  { [DATE].members } on rows
from mddbcars
```

The “non empty” keyword discards the row with no sales:

```
select
crossjoin { { [CARS].[All CARS].[Chevy], [CARS].[All CARS].[Ford] },
            { [Measures].[SALES_SUM], [Measures].[SALES_N] } }
on columns,
```
Query-Calculated Member Examples

The data that is used in these examples is from a company that sells various makes and models of cars. The company needs to report on sales figures for different months.

**Example 1**

This query creates a calculation for the average price of a car. The average price of a car is calculated by dividing the sales_sum by the count (sales_n). The query returns the sales_sum, sales_n, and the average price for March and April.

```mdx
with
select
  { [Measures].[SALES_SUM], [Measures].[SALES_N], [Measures].[Avg Price] } on columns,
  { [DATE].[All DATE].[March], [DATE].[All DATE].[April] } on rows
from mddbcars
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Date</th>
<th>Sales_sum</th>
<th>Sales_n</th>
<th>Avg Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>March</td>
<td>$59,000.00</td>
<td>4</td>
<td>14750</td>
</tr>
<tr>
<td>April</td>
<td>$34,000.00</td>
<td>3</td>
<td>11333.33</td>
</tr>
</tbody>
</table>

**Example 2**

This query has the same calculation that was created in example 1. This time the calculation is put in the slicer instead of an axis. In this query, the types of cars that were sold are on the column and the months that the cars were sold are on the rows. The value in the cells is the average price of the car for that month.

```mdx
with
select
  { [CARS].[CAR].members } on columns,
  { [DATE].members } on rows
from mddbcars
where ([Measures].[Avg Price])
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Date</th>
<th>Chevy</th>
<th>Chrysler</th>
<th>Ford</th>
<th>Toyota</th>
</tr>
</thead>
<tbody>
<tr>
<td>All date</td>
<td>13500</td>
<td>20000</td>
<td>12285.71</td>
<td>8444.45</td>
</tr>
<tr>
<td>January</td>
<td>20000</td>
<td>10000</td>
<td>8000</td>
<td></td>
</tr>
</tbody>
</table>
Example 3

This query adds the values of the Chevy, Chrysler, and Ford cars and combines them into one calculation called US cars. The query shows the sales_sum for the U.S. cars and the Toyota for January through May.

```sql
with
    member [CARS].[All CARS].[US] as ' 
        Sum( [CARS].[All CARS].[Chevy], 
            [CARS].[All CARS].[Chrysler], 
            [CARS].[All CARS].[Ford] 
        ) ' 

select 
    { [CARS].[All CARS].US, [CARS].[All CARS].Toyota } on columns,
    { [DATE].members } on rows
from mddbcars 
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Date</th>
<th>U.S.</th>
<th>Toyota</th>
</tr>
</thead>
<tbody>
<tr>
<td>All Date</td>
<td>$153,000.00</td>
<td>$76,000.00</td>
</tr>
<tr>
<td>January</td>
<td>$30,000.00</td>
<td>$24,000.00</td>
</tr>
<tr>
<td>February</td>
<td>$20,000.00</td>
<td>$44,000.00</td>
</tr>
<tr>
<td>March</td>
<td>$59,000.00</td>
<td></td>
</tr>
<tr>
<td>April</td>
<td>$34,000.00</td>
<td></td>
</tr>
<tr>
<td>May</td>
<td>$10,000.00</td>
<td>$8,000.00</td>
</tr>
</tbody>
</table>

Session-Level Calculated Member Examples

The data that is used in these examples is from a company that sells electronics and outdoor and sporting goods equipment.

Example 1

This example creates the session-level calculated member called avg_price in the sales cube on the Measures dimension. This calculated measure shows the average price:
create session
  member [sales].[measures].[avg_price] as
  
  
  
  
  Nothing is returned when you create a session-level calculated member.

---

**Example 2**

This example uses the session-level calculated member called “avg_price.” It shows the quantity, total, and average price of goods sold from 1998 through 2000.

```sql
select
  {[Measures].[Qty], [Measures].[Total], [measures].[avg_price]} on columns,
  {[time].[All time].children} on rows
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Year</th>
<th>Qty</th>
<th>Total</th>
<th>Average Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>1998</td>
<td>440,852</td>
<td>10,782,352.94</td>
<td>24.4579880322648</td>
</tr>
<tr>
<td>1999</td>
<td>539,433</td>
<td>14,080,419.58</td>
<td>26.102584454418</td>
</tr>
<tr>
<td>2000</td>
<td>32,267</td>
<td>859,108.83</td>
<td>26.6249986053863</td>
</tr>
</tbody>
</table>

---

**Example 3**

This example uses the session-level calculated member called “avg_price.” It shows the quantity, total, and average price of goods sold in different customer regions.

```sql
select
  {[Measures].[Qty], [Measures].[Total], [measures].[avg_price]} on columns,
  {[Customer].[All Customer].children} on rows
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Region</th>
<th>Qty</th>
<th>Total</th>
<th>Average Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Central</td>
<td>157,659</td>
<td>3,942,290.26</td>
<td>25.0051710336866</td>
</tr>
<tr>
<td>Mid-Atlantic</td>
<td>79,555</td>
<td>2,011,008.77</td>
<td>25.2782197222048</td>
</tr>
<tr>
<td>Midwest</td>
<td>259,759</td>
<td>6,614,999.09</td>
<td>25.4659091311562</td>
</tr>
<tr>
<td>Mountains</td>
<td>32,768</td>
<td>838,064.62</td>
<td>25.5757025146485</td>
</tr>
<tr>
<td>Northeast</td>
<td>143,934</td>
<td>3,658,452.99</td>
<td>25.4175732627454</td>
</tr>
<tr>
<td>South-Central</td>
<td>64,943</td>
<td>1,662,479.79</td>
<td>25.5990605607995</td>
</tr>
</tbody>
</table>
**Example 4**

This example uses the session-level calculated member called “avg_price.” It shows the quantity, total, and average price of goods sold in the different product groups.

```sql
select
    {[Measures].[Qty], [Measures].[Total], [measures].[avg_price]} on columns,
    {[Product].[All Product].children} on rows
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Product</th>
<th>Qty</th>
<th>Total</th>
<th>Average Price</th>
</tr>
</thead>
<tbody>
<tr>
<td>Doing</td>
<td>191,321</td>
<td>4,850,302.26</td>
<td>25.3516459771797</td>
</tr>
<tr>
<td>Electronics</td>
<td>330,977</td>
<td>8,426,846.64</td>
<td>25.4605203382712</td>
</tr>
<tr>
<td>Health &amp; Fitness</td>
<td>185,909</td>
<td>4,717,790.80</td>
<td>25.3768822380842</td>
</tr>
<tr>
<td>Outdoor &amp; Sporting</td>
<td>304,345</td>
<td>7,726,941.65</td>
<td>25.3887583170415</td>
</tr>
</tbody>
</table>

**Example 5**

This example removes (drops) the session-level calculated member called “avg_price” in the Sales cube in the Measures dimension.

```sql
drop member [sales].[measures].[avg_price]
```

Nothing is returned when you drop a session-level calculated member.

**Drill-Down Examples**

The data that is used in these examples is from a company that sells electronics and outdoor and sporting goods equipment.

**Example 1**

This example drills down on the electronics and outdoor and sporting members down from the family level.

```sql
select
    {[Measures].[Qty]} on 0,
```
Example 2

This example drills down on the electronics and outdoor and sporting members down to the family level, but it shows only the top two members at each level based on the value of Qty.

```
select
    { [Measures].[Qty] } on 0,
    drilldownleveltop
    ( 
        { [Product].[All Product].[Electronics],
        [Product].[All Product].[Outdoor & Sporting] },
        [Product].[family],
    on 1
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Item</th>
<th>Qty</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electronics</td>
<td>330,977</td>
</tr>
<tr>
<td>Auto Electronics</td>
<td>13,862</td>
</tr>
<tr>
<td>Computers, Peripherals</td>
<td>78,263</td>
</tr>
<tr>
<td>Digital Photography</td>
<td>9,008</td>
</tr>
<tr>
<td>Home Audio</td>
<td>38,925</td>
</tr>
<tr>
<td>Personal Electronics</td>
<td>31,979</td>
</tr>
<tr>
<td>Phones</td>
<td>59,964</td>
</tr>
<tr>
<td>Portable Audio</td>
<td>27,645</td>
</tr>
<tr>
<td>TV, DVD, Video</td>
<td>47,725</td>
</tr>
<tr>
<td>Video Games</td>
<td>23,606</td>
</tr>
<tr>
<td>Outdoor &amp; Sporting</td>
<td>304,345</td>
</tr>
<tr>
<td>Bikes, Scooters</td>
<td>45,297</td>
</tr>
<tr>
<td>Camping, Hiking</td>
<td>63,362</td>
</tr>
<tr>
<td>Exercise, Fitness</td>
<td>50,700</td>
</tr>
<tr>
<td>Golf</td>
<td>41,467</td>
</tr>
<tr>
<td>Outdoor Gear</td>
<td>52,305</td>
</tr>
<tr>
<td>Sports Equipment</td>
<td>51,214</td>
</tr>
</tbody>
</table>
Example 3

This example drills down on the electronics and outdoor and sporting members down to the family level, but it shows only the bottom two members at each level based on the value of Qty.

```sql
select
    {[Measures].[Qty]} on 0,
    drilldownlevelbottom
    (  
        {[Product].[All Product].[Electronics],  
           [Product].[All Product].[Outdoor & Sporting]  
        ),
        2,
        [Product].[family],
        [Measures].[Qty]  
    ) on 1
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Item</th>
<th>Qty</th>
</tr>
</thead>
<tbody>
<tr>
<td>Electronics</td>
<td>330,977</td>
</tr>
<tr>
<td>Digital Photography</td>
<td>9,008</td>
</tr>
<tr>
<td>Auto Electronics</td>
<td>13,862</td>
</tr>
<tr>
<td>Outdoor &amp; Sporting</td>
<td>304,345</td>
</tr>
<tr>
<td>Golf</td>
<td>41,467</td>
</tr>
<tr>
<td>Bikes, Scooters</td>
<td>45,297</td>
</tr>
</tbody>
</table>
Example 4

This example drills up the members of the set that are below the category level. It returns only those members that are at the category level or higher.

```plaintext
select
    {[Measures].[Qty]} on 0,
    drilluplevel
    {
        {[Product].[All Product].[Electronics].[Computers, Peripherals],
        [Product].[All Product].[Electronics].[TV, DVD, Video],
        [Product].[All Product].[Electronics].[Video Games].[GamePlace],
        [Product].[All Product].[Electronics].[Video Games].[Play Guy Color].[caller],
        [Product].[All Product].[Outdoor & Sporting],
        [Product].[All Product].[Outdoor & Sporting].[Bikes, Scooters].[Kids' Bikes],
        [Product].[All Product].[Outdoor & Sporting].[Golf].[Clubs].[designed],
        [Product].[All Product].[Outdoor & Sporting].[Sports Equipment],
        [Product].[All Product].[Outdoor & Sporting].[Sports Equipment].[Baseball]}
    } on 1
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>Item</th>
<th>Qty</th>
</tr>
</thead>
<tbody>
<tr>
<td>Computers, Peripherals</td>
<td>78,263</td>
</tr>
<tr>
<td>TV, DVD, Video</td>
<td>47,725</td>
</tr>
<tr>
<td>Outdoor &amp; Sporting</td>
<td>304,345</td>
</tr>
<tr>
<td>Sports Equipment</td>
<td>51,214</td>
</tr>
</tbody>
</table>

Session-Named Set Examples

The data that is used in these examples is from a company that sells electronics and outdoor and sporting goods equipment.

Example 1

This example creates the session-named set called “prod in SE” in the sales cube. This named set shows the crossing of the product family with the customer members in the Southeast.

```plaintext
create session
    set sales.[prod in SE] as 'crossjoin
    {
```
Example 2

This example creates the session-named set called “prod in NE” in the sales cube. This named set shows the crossing of the product family with the customer members in the Northeast.

```sql
create session
    set sales.[prod in NE] as '
          crossjoin
          {
             [CUSTOMER].[All CUSTOMER].[Northeast].children,
             [Product].[Family].members
          }
    '
```

Nothing is returned when you create a session-named set.

Example 3

This example uses the session-named set called “prod in SE.” It shows the quantity and total sales for products that customers in the Southeast purchased.

```sql
select
    {[Measures].[Qty], [Measures].[Total]} on columns,
    [prod in SE] on rows
from sales
```

Here is the resulting output:

<table>
<thead>
<tr>
<th>State</th>

Example 5

This example uses both of the session-named sets called “prod in NE.” It shows the quantity and total sales for products that customers in the Northeast and the Southeast purchased.

select
  {[Measures].[Qty], [Measures].[Total]} on columns,
  {[prod in NE], [prod in SE]} on rows
from sales

Here is the resulting output:

<table>
<thead>
<tr>
<th>State</th>
<th>Product</th>

</table>
Example 6

This example removes (drops) the session-named set called “prod in SE” in the sales cube.

```
drop set sales.[prod in SE]
```

Nothing is returned when you drop a session-named set.

Example 7

This example removes (drops) the session-named set called “prod in NE” in the sales cube.

```
drop set [sales].[prod in NE]
```

Nothing is returned when you drop a session-named set.
Dimension Functions

The MDX functions that are listed here indicate their return type.

Dimension Functions returns a dimension that contains a specified member, level, or hierarchy.

- `<Member>.Dimension`
- `<Level>.Dimension`
- `<Hierarchy>.Dimension`

Dimensions Functions returns a dimension that is specified by a numeric or string expression.

- `Dimensions(<Numeric Expression>)`
- `Dimensions(<String Expression>)`
Hierarchy Functions

The MDX functions that are listed here indicate their return type.

Hierarchy returns a hierarchy that contains a specified member or level.

\(<\text{Member}>\).\text{Hierarchy}

\(<\text{Level}>\).\text{Hierarchy}

Level Functions

The MDX functions that are listed here indicate their return type.

Level returns the level of a member.

\(<\text{Member}>\).\text{Level}

Levels returns levels that are specified by a numeric or string expression.

\(<\text{Dimension}>\).\text{Levels}(\langle\text{NumericExpression}\rangle)

Levels(\langle\text{StringExpression}\rangle)

Logical Functions

The MDX functions that are listed here indicate their return type.

IsEmpty if the evaluated expression is an empty cell value, then TRUE is returned. Otherwise, FALSE is returned.

\(\text{IsEmpty}(\langle\text{Value Expression}\rangle)\)

IS if two compared objects are equivalent, then TRUE is returned. Otherwise, FALSE is returned.

\(<\text{Object 1}>\text{IS Null}\)

\(<\text{Object 1}>\text{IS } <\text{Object 2}>\)

IsAncestor if a specified member is an ancestor of another specified member, then TRUE is returned. Otherwise, FALSE is returned.

\(\text{IsAncestor}(\langle\text{Member1}\rangle, <\text{Member2}\rangle)\)

IsLeaf if a specified member is a leaf member, then TRUE is returned. Otherwise, FALSE is returned.

\(\text{IsLeaf}(\langle\text{Member}\rangle)\)
IsSibling  
if a specified member is a sibling of another specified member, then TRUE is returned. Otherwise, FALSE is returned.

IsSibling(<Member1>,<Member2>)

---

**Member Functions**

The MDX functions that are listed here indicate their return type.

**Ancestor**
returns the ancestor of a member at a specified level or distance.

Ancestor(<Member>,<Level>)

Ancestor(<Member>,<Numeric Expression>)

**ClosingPeriod**
returns the last sibling among the descendants of a member to a specified level.

ClosingPeriod([<Level>[,<Member>]])

**Cousin**
returns the child member with the same relative position under its parent member as the specified child member.

Cousin (<Member1>,<Member2>)

**CurrentMember**
returns the current member of a dimension or hierarchy during an iteration over a set of members of that dimension or hierarchy.

<Dimension>.CurrentMember

<Hierarchy>.CurrentMember

**DataMember**
returns a system-generated data member that is associated with a non-leaf member of a dimension.

<Member>.DataMember

**DefaultMember**
returns the default member of a dimension or hierarchy.

<Dimension>.DefaultMember

<Hierarchy>.DefaultMember

**FirstChild**
returns the first child of a specified member.

<Member>.FirstChild

**FirstSibling**
returns the first child of the parent of a specified member.

<Member>.FirstSibling
Item returns a member from a specified tuple. Alternatively, it returns a tuple from a set.

<Tuple>.Item(<Index>)

Note: If a tuple is returned, then it is a tuple function, not a member function.

Lag returns a member that is located at a specified number of positions before a designated member at the same level as that member.

<Member>.Lag(<Numeric Expression>)

LastChild returns the last child of a specified member.

<Member>.LastChild

LastSibling returns the last child of the parent of a specified member.

<Member>.LastSibling

Lead returns a member that is located at a specified number of positions before a designated member at the same level as that member.

<Member>.Lead(<Numeric Expression>)

NextMember returns the next member of the level that contains the specified member.

<Member>.NextMember

OpeningPeriod returns the first sibling among the descendants of a specified member at the specified level.

OpeningPeriod([<Level>[,<Member>]])

ParallelPeriod returns a member at the level of the specified member that is in the same relative position under its ancestor at the specified level.

ParallelPeriod([<Level>[,<Numeric Expression>[,<Member>]]])

Parent returns the parent of a member.

<Member>.Parent

PrevMember returns the previous member at the level of the specified member.

<Member>.PrevMember

StrToMember returns a member from a string expression in Multidimensional Expressions (MDX) format.

StrToMember(<String Expression>)

---

**Numeric Functions**

The MDX functions that are listed here indicate their return type.
Aggregate returns a calculated value by using the appropriate aggregate function, which is based on the aggregation type of the member.

Agggregate(<Set[,<Numeric Expression>]])

Avg returns the average value of a numeric expression that is evaluated over a set.

Avg(<Set[,<Numeric Expression>]])

CoalesceEmpty returns a coalesced value. This value is derived when an empty cell value is coalesced to a number or string.

CoalesceEmpty(<Numeric Expression>[,<Numeric Expression>])

Correlation returns the correlation of two series that are evaluated over a set.

Correlation(<Set>,<Numeric Expression>[,<Numeric Expression>])

Count depending on the collection, returns the number of items in a collection.

<Dimension>|<Hierarchy>.Levels.Count

<Tuple>.count

<Set>.Count

Count(<Set[,ExcludeEmpty | IncludeEmpty])

Covariance returns the population covariance of two series that are evaluated over a set by using the biased population formula.

Covariance(<Set>,<Numeric Expression>[,<Numeric Expression>])

CovarianceN returns the sample covariance of two series that are evaluated over a set by using the unbiased population formula.

CovarianceN(<Set>,<Numeric Expression>[,<Numeric Expression>])

DistinctCount returns the number of distinct, non-empty tuples in a set.

DistinctCount(<Set>)

IIf returns one of two numeric or string values that are determined by a logical test.

IIf(<Logical Expression>, <Numeric Expression1>,<Numeric Expression2>)

Note: If a string is returned, then it is a string function, not a numeric function.

LinRegIntercept calculates the linear regression of a set and returns the value of b in the regression line y = ax + b.

LinRegIntercept(<Set>,<Numeric Expression>[,<Numeric Expression>])

LinRegPoint calculates the linear regression of a set and returns the value of y in the regression line y = ax + b.

LinRegPoint(<NumericExpression>,<Set>,<NumericExpression> [,<Numeric Expression>])
LinRegR2 calculates the linear regression of a set and returns $R^2$ (the coefficient of determination).

\[(\text{Set}, \text{Numeric Expression}[, \text{Numeric Expression}])\]

LinRegSlope calculates the linear regression of a set and returns the value of $a$ in the regression line $y = ax + b$.

\[\text{LinRegSlope(} <\text{Set}>, <\text{NumericExpression}>[, <\text{NumericExpression}>]\text{)}\]

LinRegVariance calculates the linear regression of a set and returns the variance associated with the regression line $y = ax + b$.

\[(\text{Set}, \text{Numeric Expression}[, \text{Numeric Expression}])\]

Max returns the maximum value of a numeric expression that is evaluated over a set.

\[\text{Max(} <\text{Set}>[, <\text{Numeric Expression}>]\text{)}\]

Median returns the median value of a numeric expression that is evaluated over a set.

\[\text{Median(} <\text{Set}>[, <\text{Numeric Expression}>]\text{)}\]

Min returns the minimum value of a numeric expression that is evaluated over a set.

\[\text{Min(} <\text{Set}>[, <\text{Numeric Expression}>]\text{)}\]

Ordinal returns the zero-based ordinal value that is associated with a level.

\[<\text{Level}\\text{.Ordinal}\]

Range returns the range, which is the difference between the maximum and minimum value of a numeric expression that is evaluated over a set.

\[\text{Range (} <\text{Set}>[, <\text{Numeric Expression}>]\text{)}\]

Rank returns the one-based rank of a specified tuple in a specified set.

\[\text{Rank(} <\text{Tuple}>, <\text{Set}>[, <\text{Calc Expression}>]\text{)}\]

RollupChildren returns a value that is generated by rolling up the values of the children of a specified member by using the specified unary operator.

\[\text{RollupChildren(}<\text{Member}, <\text{String Expression}>\text{)}\]

Stdev using the unbiased population formula, returns the sample standard deviation of a numeric expression that is evaluated over a set.

\[\text{Stdev(} <\text{set}>[, <\text{Numeric Expression}>]\text{)}\]

StdevP using the biased population formula, returns the population standard deviation of a numeric expression that is evaluated over a set.

\[\text{StdevP(} <\text{set}>[, <\text{Numeric Expression}>]\text{)}\]

StrToValue returns a value from a string expression.

\[\text{StrToValue(}<\text{StringExpression}>\text{)}\]
Sum returns the sum of a numeric expression that is evaluated over a set.

\[ \text{Sum}(\text{<Set>}[\text{, <Numeric Expression> }]) \]

Value returns the value of a measure.

\[ <\text{Member}>.\text{Value} \]

Var using the unbiased population formula, returns the sample variance of a numeric expression that is evaluated over a set.

\[ \text{Var}(\text{<Set>}[\text{, <Numeric Expression> }]) \]

VarP using the biased population formula, returns the population variance of a numeric expression that is evaluated over a set.

\[ \text{VarP}(\text{<Set>}[\text{, <Numeric Expression> }]) \]

Set Functions

The MDX functions that are listed here indicate their return type.

AddCalculated Members returns a set that includes calculated members that meet the criteria of a given set definition (by default, calculated members are not returned by set functions).

\[ \text{AddCalculatedMembers}(\text{<Set>}) \]

AllMembers returns a set that contains all members of the specified dimension, hierarchy, or level, including calculated members.

\[ <\text{Dimension}>.\text{AllMembers} \]

\[ <\text{Hierarchy}>.\text{AllMembers} \]

\[ <\text{Level}>.\text{AllMembers} \]

Ancestors returns the set of ancestors of a member to a specified level or distance. This includes or excludes ancestors at other levels. Here is the syntax for the Ancestors function:

\[ \text{Ancestors}(\text{<Member>},[\text{<Level>}[\text{, <Anc_flags> }]]) \]

\[ \text{Ancestors}(\text{<Member>},\text{<Distance>}[\text{, <Anc_flags> }]) \]

Level returns the set of ancestors of a member that are specified by \text{<Member>} to the level that is specified by \text{<Level>}. Optionally, the set is modified by a flag that is specified in \text{<Anc_flags>}

\[ \text{Ancestors}(\text{<Member>},[\text{<Level>}[\text{, <Anc_flags> }]]) \]

If no \text{<Level>} or \text{<Anc_flags>} arguments are specified, then the function behaves as in the following syntax:

\[ \text{Ancestors}(\text{<Member>}, \text{<Member>}.\text{Level}, \text{SELF BEFORE AFTER}) \]
Distance
returns the set of ancestors of a member. The set of ancestors are specified by `<Member>` and are `<Distance>` steps away in the hierarchy. Optionally, the set is modified by a flag that is specified in `<Anc_flags>`. Specifying a `<Distance>` of 0 returns a set consisting only of the member that is specified in `<Member>`.

Ancestors(<Member>, <Distance>[,<Anc_flags>])

<table>
<thead>
<tr>
<th>Options</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFTER</td>
<td>returns ancestor members from all levels between <code>&lt;Level&gt;</code> and <code>&lt;Member&gt;</code>, including <code>&lt;Member&gt;</code> itself, but not member(s) found at <code>&lt;Level&gt;</code></td>
</tr>
<tr>
<td>BEFORE</td>
<td>returns ancestor members from all levels above <code>&lt;Level&gt;</code></td>
</tr>
<tr>
<td>BEFORE_AND_AFTER</td>
<td>returns ancestor members from all levels above the level of <code>&lt;Member&gt;</code> except members from <code>&lt;Level&gt;</code></td>
</tr>
<tr>
<td>ROOT</td>
<td>returns the root-level member. This flag is the opposite of the LEAVES flag for the Descendants function</td>
</tr>
<tr>
<td>SELF (default)</td>
<td>returns ancestor members from <code>&lt;Level&gt;</code> only. Includes <code>&lt;Member&gt;</code>, if and only if <code>&lt;Level&gt;</code> that is specified is the level of <code>&lt;Member&gt;</code></td>
</tr>
<tr>
<td>SELF_AND_AFTER</td>
<td>returns ancestor members from <code>&lt;Level&gt;</code> and all levels below <code>&lt;Level&gt;</code>, down to and including <code>&lt;Member&gt;</code></td>
</tr>
<tr>
<td>SELF_AND_BEFORE</td>
<td>returns ancestor members from <code>&lt;Level&gt;</code> and all levels between and above <code>&lt;Member&gt;</code></td>
</tr>
<tr>
<td>SELF_BEFORE_AFTER</td>
<td>returns ancestor members from all levels above the level of <code>&lt;Member&gt;</code>, including <code>&lt;Member&gt;</code> and member(s) at <code>&lt;Level&gt;</code></td>
</tr>
</tbody>
</table>

Note. By default, only members at the specified level or distance are included. This function corresponds to an `<Anc_flags>` value of SELF. By changing the value of `<Anc_flags>`, you can include or exclude ancestors at the specified level or distance, the ancestors before or the ancestors after the specified level or distance (until the root node), as well as all requests of the root ancestor(s) regardless of the specified level or distance.

Assuming that the levels in the Location dimension are named in a hierarchical order, an example of levels would be All, Countries, States, Counties, and Cities.
### Table A1.2  Ancestor Expressions and Returns

<table>
<thead>
<tr>
<th>Expressions</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>Ancestors (USA)</td>
<td>All members</td>
</tr>
<tr>
<td>Ancestors (Wake, Counties)</td>
<td>USA</td>
</tr>
<tr>
<td>Ancestors (Wake, Counties, SELF)</td>
<td>USA</td>
</tr>
<tr>
<td>Ancestors (Wake, States, BEFORE)</td>
<td>USA, All</td>
</tr>
<tr>
<td>Ancestors (Wake, Counties, AFTER)</td>
<td>Wake (includes member itself), North Carolina</td>
</tr>
<tr>
<td>Ancestors (Raleigh, States, BEFORE_AND_AFTER)</td>
<td>Raleigh, Wake, USA, All members</td>
</tr>
<tr>
<td>Ancestors (Raleigh, States, SELF_BEFORE_AFTER)</td>
<td>Raleigh, Wake, NC, USA, All members</td>
</tr>
<tr>
<td>Ancestors (NC, Counties, Root)</td>
<td>All members</td>
</tr>
<tr>
<td>Ancestors (Wake, 1)</td>
<td>North Carolina</td>
</tr>
<tr>
<td>Ancestors (Wake, 2, SELF_BEFORE_AFTER)</td>
<td>Wake, NC, USA, All members</td>
</tr>
</tbody>
</table>

**Ascendants**

returns all ancestors of the specified member up through the root level, including the member itself.

\[\text{Ascendants (<Member>)}\]

**Axis**

returns a set that is defined in an axis. Axis (0) pertains to row members while Axis (1) pertains to column members.

\[\text{Axis (<Numeric Expression>)}\]

**Example:**

```
Axis (0)
Axis (1)
```

**Note:** The Axis function is not allowed in session- or global-named sets or calculations.

**BottomCount**

returns a specified number of items from the bottom of a set.

\[\text{BottomCount(<Set>,<Count>,<Numeric Expression>,<True|False>)}\]

**Note:** The True|False flag is for including duplicates. If it is set to TRUE, then any member that has the same value as the last member will also be returned. If it is set to FALSE, then it will work as it always did. The default value for the flag is FALSE.

**Note:** Constant numeric expressions should not be entered for this function.

**BottomPercent**

sorts a set and returns the specified number of bottommost elements whose cumulative total is at least a specified percentage.

\[\text{(<Set>,<Percentage>,<Numeric Expression>)}\]

**Note:** Constant numeric expressions should not be entered for this function.
BottomSum sorts a set by using a numeric expression and returns the specified number of bottommost elements whose sum is at least a specified value.

\[ (<\text{Set}>, <\text{Value}>, [<\text{Numeric Expression}>]) \]

Note: Constant numeric expressions should not be entered for this function.

Children returns the children of a member.

\[ <\text{Member}>::Children \]

Crossjoin returns the cross-product of two sets.

\[ \text{Crossjoin}(<\text{Set1}>, <\text{Set2}>) \]

MAX SET SIZE — limits the size of sets that the OLAP server creates. A value of 0 indicates there is no limit. The default is 1,000,000 components, where components are defined as the number of tuples in the set times the number of dimensions in each tuple. This enables the administrator to control the system resources that are used by individual queries.

Descendants returns the set of descendants of a member to a specified level or distance. Optionally, this includes or excludes descendants at other levels. By default, only members at the specified level or distance are included.

\[ \text{Descendants}(<\text{Member}>, [<\text{Level}>, [<\text{Desc_flags}>]]) \]

\[ \text{Descendants}(<\text{Member}>, <\text{Distance}>, [<\text{Desc_flags}>]) \]

**Table A1.3 Descendants Flag Options**

<table>
<thead>
<tr>
<th>Options</th>
<th>Returns</th>
</tr>
</thead>
<tbody>
<tr>
<td>AFTER</td>
<td>returns descendant members from all levels that are subordinate to (&lt;\text{Level})&gt;</td>
</tr>
<tr>
<td>BEFORE</td>
<td>returns descendant members from all levels between (&lt;\text{Member})&gt; and (&lt;\text{Level})&gt; , not including members from (&lt;\text{Level})&gt;</td>
</tr>
<tr>
<td>BEFORE_AND_AFTER</td>
<td>returns descendant members from all levels that are subordinate to the level of (&lt;\text{Member}&gt;) except members from (&lt;\text{Level})&gt;</td>
</tr>
<tr>
<td>LEAVES</td>
<td>returns leaf descendant members between (&lt;\text{Member}&gt;) and (&lt;\text{Level}&gt;) or (&lt;\text{Distance}&gt;) . This flag is the opposite of the ROOT flag for the Ancestors function</td>
</tr>
<tr>
<td>SELF (default)</td>
<td>returns descendant members from (&lt;\text{Level}&gt;) only. Includes (&lt;\text{Member}&gt;) , only if (&lt;\text{Level}&gt;) is specified at the level of (&lt;\text{Member}&gt;)</td>
</tr>
<tr>
<td>SELF_AND_AFTER</td>
<td>returns descendant members from (&lt;\text{Level}&gt;) and all levels subordinate to (&lt;\text{Level}&gt;)</td>
</tr>
<tr>
<td>Options</td>
<td>Returns</td>
</tr>
<tr>
<td>-----------------------</td>
<td>--------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>SELF_AND_BEFORE</td>
<td>returns descendant members from &lt;Level&gt; and all levels between &lt;Member&gt; and &lt;Level&gt;</td>
</tr>
<tr>
<td>SELF_BEFORE_AFTER</td>
<td>returns descendant members from all levels that are subordinate to the level of &lt;Member&gt;</td>
</tr>
<tr>
<td>Distinct</td>
<td>returns a set by removing duplicate tuples from a specified set. Duplicates are eliminated from the tail.</td>
</tr>
<tr>
<td>Drilldown Level</td>
<td>drills down to the members of a set one level below the lowest level that is represented in the set, or to one level below an optionally specified level of a member that is represented in the set.</td>
</tr>
<tr>
<td>Drilldown LevelBottom</td>
<td>drills down the members of a set to one level below the lowest level that is represented in the set, or to one level below an optionally specified level of a member that is represented in the set. However, instead of including all children for each member at the specified &lt;level&gt;, only the bottom &lt;count&gt; of children is returned, based on &lt;Numeric Expression&gt;.</td>
</tr>
<tr>
<td>Drilldown LevelTop</td>
<td>drills down the members of a set to one level below the lowest level that is represented in the set, or to one level below an optionally specified level of a member that is represented in the set. However, instead of including all children for each member at the specified &lt;level&gt;, only the top &lt;count&gt; of children is returned, based on &lt;Numeric Expression&gt;.</td>
</tr>
<tr>
<td>Drilldown Member</td>
<td>drills down to the members in a specified set that are present in a second specified set.</td>
</tr>
<tr>
<td>Drilldown MemberBottom</td>
<td>drills down to the members in a specified set that are present in a second specified set, therefore limiting the result set to a specified number of members.</td>
</tr>
<tr>
<td>Drilldown MemberTop</td>
<td>drills to the members in a specified set that are present in a second specified set, therefore limiting the result set to a specified number of members.</td>
</tr>
</tbody>
</table>
DrilldownMemberTop(<Set1>,<Set2>, <Count>[,[<Numeric Expression>] [,Recursive]])

Note: Constant numeric expressions should not be entered for this function.

DrillupLevel removes all members in the set that are below the specified level. If the level is not given, then it determines the lowest level in the set and removes all members at that level.

DrillupLevel(<Set>[,[<Level>]])

DrillupMember drills to the members in a specified set that are present in a second specified set.

DrillupMember(<Set1>,<Set2>)

Except locates the difference between two sets and optionally retains duplicates.

Except(<Set1>,<Set2>[,[All]])

Extract returns a set of tuples from extracted dimension elements.

Extract(<Set>,<Dimension>[,[<Dimension>...]])

Filter returns the set that results from filtering a specified set that is based on a search condition.

Filter(<Set>,<Search Condition>)

Generate applies a set to each member of another set and is joined to the resulting sets.

Generate(<Set1>,<Set2>[,[All]])

Head returns the first specified number of elements in a set.

Head(<Set>[,[<Numeric Expression>]])

Hierarchize orders the members of a set in a hierarchy.

Hierarchize(<Set>)

Intersect returns the intersection of two input sets and optionally retains duplicates.

Intersect(<Set1>,<Set2>[,[All]])

LastPeriods returns a set of members prior to and including a specified member.

LastPeriods(<Index>[,[<Member>]])

Members returns the set of members in a dimension, level, or hierarchy.

<Dimension>.Members
<Level>.Members

<Hierarchy>.Members

Mtd returns the set of members that consist of the descendants of the Month level ancestor of the specified member, including the specified member itself. This function is analogous to the PeriodsToDate() function with the level defined as Month.

\text{Mtd}([\text{<Member>2}])

NameToSet returns a set that contains a single member. The set is based on a string expression that contains a member name.

\text{NameToSet}(<\text{Member Name}>)

NonEmptyCrossjoin returns the cross-product of one or more sets as a set. This excludes empty tuples and tuples without associated fact table data.

\text{NonEmptyCrossjoin}(<\text{Set1}>,<\text{Set2}>,<\text{Set3}>,...,<\text{Crossjoin Set Count}>)

MAX SET SIZE — limits the size of sets that the OLAP server creates. A value of 0 indicates there is no limit. The default is 1,000,000 components, where components are defined as the number of tuples in the set times the number of dimensions in each tuple. This enables the administrator to control the system resources that are used by individual queries.

Order arranges members of a specified set and optionally preserves or breaks the hierarchy.

\text{Order}(<\text{Set}>,<\text{Numeric Expression}>\{ASC|DESC|BASC|BDESC\})

\text{Order}(<\text{Set}>,<\text{String Expression}>\{ASC|DESC|BASC|BDESC\})

Note: Constant numeric expressions should not be entered for this function.

PeriodsToDate returns the set of members that consist of the descendants of the ancestor of the specified member at the specified level, including the specified member itself.

\text{PeriodsToDate}([\text{<Level>},<\text{Member}>])

Qtd returns the set of members that consist of the descendants of the Quarter level ancestor of the specified member, including the specified member itself. This function is analogous to the PeriodsToDate() function with the level defined as Quarter.

\text{Qtd}([\text{<Member>2}])

Siblings returns the siblings of a specified member, including the member itself.

\text{<Member>}.Siblings

StripCalculatedMembers returns a set that is generated by removing calculated members from a specified set.

\text{StripCalculatedMembers}(<\text{Set}>)
StrToSet returns a set that is constructed from a specified string expression in Multidimensional Expressions (MDX) format.

\[
\text{StrToSet} \ (<\text{String Expression}>)
\]

Subset returns a subset of tuples from a specified set.

\[
\text{Subset}(<\text{Set}>,<\text{Start}>,<\text{Count}>)
\]

Tail returns a subset from the end of a set.

\[
\text{Tail}(<\text{Set}>,<\text{Count}>)
\]

ToggleDrillState Toggles the drill state of members.

\[
\text{ToggleDrillState}(<\text{Set}1>,<\text{Set}2>,<\text{RECURSIVE}>)
\]

Note: In a graphical user interface, drilling up and down is often accomplished by double-clicking a label to expand or contract the information. Drilling down on a member causes the member's children to be returned; drilling up causes them to disappear from the results.

TopCount returns a specified number of items from the topmost members of a specified set.

\[
\text{TopCount}(<\text{Set}>,<\text{Count}>,<\text{Numeric Expression}>,<\text{True|False}>)
\]

Note: The True|False flag is for including duplicates. If it is set to TRUE, then any member that has the same value as the last member will also be returned. If it is set to FALSE, then it will work as it always did. The default value for the flag is FALSE.

Note: Constant numeric expressions should not be entered for this function.

TopPercent sorts a set and returns the topmost elements, whose cumulative total is at least a specified percentage.

\[
\text{TopPercent}(<\text{Set}>,<\text{Percentage}>,<\text{Numeric Expression}>)
\]

Note: Constant numeric expressions should not be entered for this function.

TopSum sorts a set and returns the topmost elements whose cumulative total is at least a specified value.

\[
\text{TopSum}(<\text{Set}>,<\text{Value}>,<\text{Numeric Expression}>)
\]

Note: Constant numeric expressions should not be entered for this function.

Union returns a set that is generated by the union of two sets. Optionally, duplicate members are retained.

\[
\text{Union}(<\text{Set}1>,<\text{Set}2>,<\text{All}>)
\]

VisualTotals returns a set that is generated by dynamically totaling child members in a specified set. A pattern for the name of the parent member in the result set is used.

\[
\text{VisualTotals} (<\text{Set}>,<\text{Pattern}>)
\]

Wtd returns the set of members that consist of the descendants of the Week level ancestor of the specified member, including the specified
Ytd returns the set of members that consist of the descendants of the Year level ancestor of the specified member, including the specified member itself. This function is analogous to the PeriodsToDate() function with the level defined as Year.

Ytd([<Member>])

---

String Functions

The MDX functions that are listed here indicate their return type.

- **CoalesceEmpty** coalesces an empty cell value to a number or string and returns the coalesced value.
  
  CoalesceEmpty(<String Expression>[,<String Expression>]...)

- **Generate** returns a concatenated string that is created by evaluating a string expression over a set. Alternatively, it returns a concatenated string that is created by evaluating a string expression over a set.
  
  Generate(<Set>,<String Expression>[,Delimiter])

- **IIf** returns one of two numeric or string values that are determined by a logical test.
  
  IIf(<Logical Expression>,<String Expression1>,<String Expression2>)

  Note: If a numeric value is returned, then it is a numeric function, not a string function. 

- **MemberToStr** returns a string in Multidimensional Expressions (MDX) format from a member.
  
  MemberToStr(<Member>)

- **Name** returns the name of a level, dimension, member, or hierarchy.
  
  <Level>.Name

  <Dimension>.Name

  <Member>.Name

  <Hierarchy>.Name

- **Properties** returns a string that contains a member property value.
  
  <Member>.Properties(Caption)

  <Member>.Properties(Name)
<Member>.Properties(UniqueName)

<Member>.Properties(<String Expression>)

Put returns a string that contains the formatted output based on a SAS format.

Put(<Numeric Expression>,<String Expression>)

Put(<String Expression>,<String Expression>)

SetToStr constructs a string in Multidimensional Expressions (MDX) format from a set.

SetToStr(<Set>)

TupleToStr returns a string in Multidimensional Expressions (MDX) format from a specified tuple.

TupleToStr(<Tuple>)

UniqueName returns the unique name of a specified level, dimension, member, or hierarchy.

<Level>.UniqueName

<Dimension>.UniqueName

<Member>.UniqueName

<Hierarchy>.UniqueName

UserName returns the domain name and user name of the current connection.

UserName

<member>.member_caption returns the caption of the member. It is in non-standard MDX format.

<dimension>.caption returns the caption of the member. It is in non-standard MDX format.

<hierarchy>.caption returns the caption of the member. It is in non-standard MDX format.

<level>.caption returns the caption of the member. It is in non-standard MDX format.

<Member>.caption returns the caption of the member. It is in non-standard MDX format.

---

**Tuple Functions**

The MDX functions that are listed here indicate their return type.
Current returns the current tuple from a set during an iteration.

\[ \text{<Set>.Current} \]

Item returns a member from a specified tuple. Alternatively, it returns a tuple from a set.

\[ \text{<Set>.Item(<Index>)} \]

Note: If a member is returned, then it is a member function, not a tuple function.

StrToTuple constructs a tuple from a specified string expression in Multidimensional Expressions (MDX) format.

\[ \text{StrToTuple(<String expression>)} \]

### Miscellaneous Functions and Operators

- **,** (comma operator) an operator to combine tuples to construct sets such as \{[time].[all time].[2001].[January],[time].[all time].[2001].[February],[time].[all time].[2001].[March]\}, or to combine members to construct tuples such as ([Time].[January 2001], [Geography].[U.S.A]).

- **:** (colon operator) an operator to specify ranges of tuples to contract sets such as \{{[Time].[all Time].[2001].[January] : [Time].[all Time].[2001].[March]}\}. It is the set constructor operator.

- **{** (braces) an alternative to crossjoin().

- **,** (asterisk operator) an alternative to nested crossjoins.

- **+** (plus operator for sets) an alternative to union().

- **+** (plus operator for strings) a concatenation of two strings.

- **/* */** (style comments)

- **//** (style comments)

- **-** (style comments)

- NON EMPTY

- **<Set> AS aliasname**
Supports TRUE
and FALSE

Call<UDF Name> executes a void returning user-defined function.

---

**Additional MDX Documentation**

In addition to the MDX usage examples, functions and related topics that are found in this documentation, a supplementary text for the SAS OLAP Server is available. The SAS OLAP Server: Concepts and Excerpts from “MDX Solutions with Microsoft SQL Server Analysis Services” includes basic MDX information such as the MDX data model, MDX construction, comments in MDX, and a complete MDX function and operator reference. You can locate this text at [support.sas.com/publishing](http://support.sas.com/publishing).

Glossary

aggregation
   a summary of detail data that is stored with or referred to by a cube. Aggregations support rapid and efficient answers to business questions.

ancestor
   within a dimension hierarchy, a member that resides at a higher level in relation to other members in the hierarchy. For example, if a Geography dimension includes the levels Country and City, then France would be an ancestor of Paris, and Japan would be an ancestor of Tokyo.

ARM (Application Response Measurement)
   an application programming interface that was developed by an industry partnership and which is used to monitor the availability and performance of software applications. ARM monitors the application tasks that are important to a particular business.

calculated member
   in a dimension, a member whose value is derived from the values of other members.

cell
   in a cube, the intersection that is defined by selecting one member from each dimension of that cube.

child
   within a dimension hierarchy, a descendant in level n-1 of a member that is at level n. For example, if a Geography dimension includes the levels Country and City, then Bangkok would be a child of Thailand, and Hamburg would be a child of Germany.

cube
   a logical set of data that is organized and structured in a hierarchical, multidimensional arrangement. A cube is a directory structure, not a single file. A cube can include measures, and it can have numerous dimensions and levels of data.

descendant
   in a dimension hierarchy, a member that resides at a lower level in relation to other members in the hierarchy. For example, if a Geography dimension includes the levels Country, State, and City, then California and Los Angeles would be descendants of USA.
**dimension**

A group of closely related hierarchies. Different hierarchies within a single dimension typically represent different measurements of a single concept. For example, a Time dimension might consist of two hierarchies: (1) Year, Month, Date, and (2) Year, Week, Day.

**drill down**

In a hierarchical tree view of a data repository, to start at a top-level directory and to click through one or more intermediate-level directories until you reach the directory or file that you are interested in.

**drill up**

In a hierarchical tree view of a data repository, to start at a file or lower-level directory and to click through one or more higher-level directories until you reach the directory that you are interested in.

**fact**

A single piece of factual information in a data table. For example, a fact can be an employee name, a customer's phone number, or a sales amount. It can also be a derived value such as the percentage by which total revenues increased or decreased from one year to the next.

**hierarchy**

An arrangement of members of a dimension into levels that are based on parent-child relationships. Members of a hierarchy are arranged from more general to more specific. For example, in a Time dimension, a hierarchy might consist of Year, Quarter, Month, and Day. In a Geography dimension, a hierarchy might consist of Country, State or Province, and City. More than one hierarchy can be defined for a dimension. Each hierarchy provides a navigational path that enables users to drill down to increasing levels of detail.

**leaf member**

The lowest-level member of a hierarchy. Leaf members do not have any child members.

**level**

An element of a dimension hierarchy. Levels describe the dimension from the highest (most summarized) level to the lowest (most detailed) level. For example, possible levels for a Geography dimension are Country, Region, State or Province, and City.

**MDDB (multidimensional database)**

A specialized data storage structure in which data is presummarized and cross-tabulated and then stored as individual cells in a matrix format, rather than in the row-and-column format of relational database tables. The source data can come either from a data warehouse or from other data sources. MDDBs can give users quick, unlimited views of multiple relationships in large quantities of summarized data.

**MDX (multidimensional expressions) language**

A standardized, high-level language that is used for querying multidimensional data sources. MDX is the multidimensional equivalent of SQL (Structured Query Language).

**measure**

A special dimension that usually represents numeric data values that are analyzed. Actual Sales, Predicted Sales, and Revenue are all examples of measures. For
example, you might drill down within the Clothing hierarchy of the Product dimension to see the value of the Actual Sales measure for the Shirts classification variable.

**member**

a name that represents a particular data item within a dimension. For example, September 1996 might be a member of the Time dimension. A member can be either unique or non-unique. For example, 1997 and 1998 represent unique members in the Year level of a Time dimension. January represents non-unique members in the Month level, because there can be more than one January in the Time dimension if the Time dimension contains data for more than one year.

**metadata repository**

a collection of related metadata objects, such as the metadata for a set of tables and columns that are maintained by an application. The Open Metadata Repository is an example.

**metadata server**

a server that provides metadata management services to one or more client applications. The Open Metadata Server is an example.

**MOLAP (multidimensional online analytical processing)**

a type of OLAP that stores aggregates in multidimensional database structures.

**navigate**

to purposefully move from one view of the data in a table (or in some other data structure, such as a cube) to another. Drilling down and drilling up are two examples of navigation.

**OLE**

(Object Linking and Embedding)

a method of interprocess communication supported by Windows that involves a client/server architecture. OLE enables an object that was created by one application to be embedded in or linked to another application.

**OLE DB**

an open specification that has been developed by Microsoft for accessing both relational and nonrelational data. OLE DB interfaces can provide much of the same functionality that is provided by database management systems. OLE DB evolved from the Open Database Connectivity (ODBC) application programming interface. See also OLE (Object Linking and Embedding).

**OLE DB for OLAP**

a Microsoft OLAP API that is used to link OLAP clients and servers by means of a multidimensional language, MDX.

**parent**

within a dimension hierarchy, the ancestor in level n of a member in level n-1. For example, if a Geography dimension includes the levels Country and City, then Thailand would be the parent of Bangkok, and Germany would be the parent of Hamburg. The parent value is usually a consolidation of all of its children's values.

**result set**

the set of rows or records that a server or other application returns in response to a query.

**roll up**

to summarize (or apply some other type of calculation or formula to) data values at one level of a dimension hierarchy in order to derive values for a parent level. For
example, sales figures for January can be rolled up to Quarter 1, and employee data for one department can be rolled up to the division level.

**SAS ARM interface**

an interface that can be used to monitor the performance of SAS applications. In the SAS ARM interface, the ARM API is implemented as an ARM agent. In addition, SAS supplies ARM macros, which generate calls to the ARM API function calls, and ARM system options, which enable you to manage the ARM environment and to log internal SAS processing transactions. See also ARM (Application Response Measurement).

**SAS OLAP server**
a server that provides access to multidimensional data. The data is queried using the multidimensional expression language (MDX).

**SAS OLAP Cube Studio**
a Java interface for defining and building OLAP cubes in SAS System 9 or later. Its main feature is the Cube Designer wizard, which guides you through the process of registering and creating cubes.

**slice**
a subset of data from a cube, where the data in the slice pertains to one or more members of one or more dimensions. For example, from a cube that contains data about customer feedback, one slice might pertain to feedback on one particular product (one member of the Product dimension). Another slice might pertain to feedback on that product from customers residing in particular geographic areas who submitted their feedback during a certain time period (one member of the Product dimension, multiple members of the Geography dimension, one or more members of the Time dimension).

**SQL (Structured Query Language)**
a standardized, high-level query language that is used in relational database management systems to create and manipulate database management system objects.

**thread**
a single path of execution of a process in a single CPU, or a basic unit of program execution in a thread-enabled operating environment. In a symmetric multiprocessing (SMP) environment, which uses multiple CPUs, multiple threads can be spawned and processed simultaneously. Regardless of whether there is one CPU or many, each thread is an independent flow of control that is scheduled by the operating system. See also threading, thread-enabled operating system, SMP.

**threading**
a high-performance method of data I/O or data processing in which the I/O or processing is divided into multiple threads that are executed in parallel. In the "boss-worker" model of threading, the same code for the I/O or calculation process is executed simultaneously in separate threads on multiple CPUs. In the "pipeline" model, a process is divided into steps, which are then executed simultaneously in separate threads on multiple CPUs. See also SMP, parallel processing, parallel I/O.

**Time dimension**
a dimension that divides time into levels such as Year, Quarter, Month, and Day.

**tuple**
a data object that contains two or more components. Unlike elements of a list, the components of a tuple can be of different data types. In OLAP, a tuple is a slice of
data from a cube. It is a selection of members (or cells) across dimensions in a cube. It can also be viewed as a cross-section of member data in a cube. For example, ⎯ is a tuple that contains data from the ⎯, ⎯, and ⎯ dimensions.
