Available Topics That Provide WBGO Time Series Data

To get a list of the available topics of WBGO data, enter the following URL in your web browser:

http://api.worldbank.org/topics?format=xml

Table 54.4 shows the topics that are available.

<table>
<thead>
<tr>
<th>Topic ID</th>
<th>Topic Name and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Agriculture and Rural Development&lt;br&gt;For the 70% of the world’s poor who live in rural areas, agriculture is the main source of income and employment. But depletion and degradation of land and water pose serious challenges to producing enough food and other agricultural products to sustain livelihoods here and meet the needs of urban populations. Data presented here include measures of agricultural inputs, outputs, and productivity compiled by the United Nations’ Food and Agriculture Organization.</td>
</tr>
<tr>
<td>2</td>
<td>Aid Effectiveness&lt;br&gt;Aid effectiveness is the impact that aid has in reducing poverty and inequality, increasing growth, building capacity, and accelerating achievement of the Millennium Development Goals set by the international community. Indicators here cover aid received as well as progress in reducing poverty and improving education, health, and other measures of human welfare.</td>
</tr>
<tr>
<td>3</td>
<td>Economy and Growth&lt;br&gt;Economic growth is central to economic development. When national income grows, real people benefit. While there is no known formula for stimulating economic growth, data can help policy makers better understand their countries’ economic situations and guide any work toward improvement. Data here cover measures of economic growth, such as gross domestic product (GDP) and gross national income (GNI). They also include indicators that represent factors known to be relevant to economic growth, such as capital stock, employment, investment, savings, consumption, government spending, imports, and exports.</td>
</tr>
<tr>
<td>4</td>
<td>Education&lt;br&gt;Education is one of the most powerful instruments for reducing poverty and inequality and lays a foundation for sustained economic growth. The World Bank compiles data on education inputs, participation, efficiency, and outcomes. Data on education are compiled by the United Nations Educational, Scientific, and Cultural Organization (UNESCO) Institute for Statistics from official responses to surveys and from reports provided by education authorities in each country.</td>
</tr>
<tr>
<td>5</td>
<td>Energy and Mining&lt;br&gt;The world economy needs ever-increasing amounts of energy to sustain economic growth, raise living standards, and reduce poverty. But today’s trends in energy use are not sustainable. As the world’s population grows and economies become more industrialized, nonrenewable energy sources will become scarcer and more costly. Data here on energy production, use, dependency, and efficiency are compiled by the World Bank from the International Energy Agency and the Carbon Dioxide Information Analysis Center.</td>
</tr>
</tbody>
</table>
Table 54.4  continued

<table>
<thead>
<tr>
<th>Topic ID</th>
<th>Topic Name and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>6</td>
<td><strong>Environment</strong></td>
</tr>
<tr>
<td></td>
<td>Natural and man-made environmental resources—fresh water, clean air, forests, grasslands, marine resources, and agro-ecosystems—provide sustenance and a foundation for social and economic development. The need to safeguard these resources crosses all borders. Today, the World Bank is one of the key promoters and financiers of environmental upgrading in the developing world. Data here cover forests, biodiversity, emissions, and pollution. Other indicators relevant to the environment are found under data pages for Agriculture and Rural Development, Energy and Mining, Infrastructure, and Urban Development.</td>
</tr>
<tr>
<td>7</td>
<td><strong>Financial Sector</strong></td>
</tr>
<tr>
<td></td>
<td>An economy’s financial markets are critical to its overall development. Banking systems and stock markets enhance growth, the main factor in poverty reduction. Strong financial systems provide reliable and accessible information that lowers transaction costs, which in turn bolsters resource allocation and economic growth. Indicators here include the size and liquidity of stock markets; the accessibility, stability, and efficiency of financial systems; and international migration and workers’ remittances, which affect growth and social welfare in both sending and receiving countries.</td>
</tr>
<tr>
<td>8</td>
<td><strong>Health</strong></td>
</tr>
<tr>
<td></td>
<td>Improving health is central to the Millennium Development Goals, and the public sector is the main provider of health care in developing countries. To reduce inequities, many countries have emphasized primary health care, including immunization, sanitation, access to safe drinking water, and safe motherhood initiatives. Data here cover health systems, disease prevention, reproductive health, nutrition, and population dynamics. Data are from the United Nations Population Division, World Health Organization, United Nations Children’s Fund, Joint United Nations Programme on HIV/AIDS, and other sources.</td>
</tr>
<tr>
<td>9</td>
<td><strong>Infrastructure</strong></td>
</tr>
<tr>
<td></td>
<td>Infrastructure helps determine the success of manufacturing and agricultural activities. Investments in water, sanitation, energy, housing, and transport also improve lives and help reduce poverty. And new information and communication technologies promote growth, improve delivery of health and other services, expand the reach of education and support social and cultural advances. Data here are compiled from such sources as the International Road Federation, Containerisation International, the International Civil Aviation Organization, the International Energy Association, and the International Telecommunications Union.</td>
</tr>
<tr>
<td>10</td>
<td><strong>Social Protection and Labor</strong></td>
</tr>
<tr>
<td></td>
<td>The supply of labor available in an economy includes people who are employed, those who are unemployed but seeking work, and first-time job seekers. Not everyone who works is included: unpaid workers, family workers, and students are often omitted, while some countries do not count members of the armed forces. Data on labor and employment are compiled by the International Labour Organization (ILO) from labor force surveys, censuses, establishment censuses and surveys, and administrative records such as employment exchange registers and unemployment insurance schemes.</td>
</tr>
</tbody>
</table>
Table 54.4  continued

<table>
<thead>
<tr>
<th>Topic ID</th>
<th>Topic Name and Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>11</td>
<td>Poverty</td>
</tr>
<tr>
<td></td>
<td>For countries with an active poverty monitoring program, the World Bank—in collaboration with national institutions, other development agencies, and civil society—regularly conducts analytical work to assess the extent and causes of poverty and inequality, examine the impact of growth and public policy, and review household survey data and measurement methods. Data here include poverty and inequality measures generated from analytical reports, from national poverty monitoring programs, and from the World Bank’s Development Research Group, which has been producing internationally comparable and global poverty estimates and lines since 1990.</td>
</tr>
<tr>
<td>12</td>
<td>Private Sector</td>
</tr>
<tr>
<td></td>
<td>Private markets drive economic growth, tapping initiative and investment to create productive jobs and raise incomes. Trade is also a driver of economic growth as it integrates developing countries into the world economy and generates benefits for their people. Data on the private sector and trade are from the World Bank Group’s Private Participation in Infrastructure Project Database, Enterprise Surveys, and Doing Business Indicators, as well as from the International Monetary Fund’s Balance of Payments database and International Financial Statistics, the UN Commission on Trade and Development, the World Trade Organization, and other sources.</td>
</tr>
<tr>
<td>13</td>
<td>Public Sector</td>
</tr>
<tr>
<td></td>
<td>Effective governments improve people’s standard of living by ensuring access to essential services—health, education, water and sanitation, electricity, transport—and the opportunity to live and work in peace and security. Data here include World Bank staff assessments of country performance in economic management, structural policies, policies for social inclusion and equity, and public sector management and institutions for the poorest countries. Also included are indicators on revenues and expenses from the International Monetary Fund’s Government Finance Statistics, and on tax policies from various sources.</td>
</tr>
<tr>
<td>14</td>
<td>Science and Technology</td>
</tr>
<tr>
<td></td>
<td>Technological innovation, often fueled by governments, drives industrial growth and helps raise living standards. Data here aim to shed light on countries’ technology base: research and development, scientific and technical journal articles, high-technology exports, royalty and license fees, and patents and trademarks. Sources include the UNESCO Institute for Statistics, the US National Science Board, the UN Statistics Division, the International Monetary Fund, and the World Intellectual Property Organization.</td>
</tr>
<tr>
<td>15</td>
<td>Social Development</td>
</tr>
<tr>
<td></td>
<td>Data here cover child labor, gender issues, refugees, and asylum seekers. Children in many countries work long hours, often combining studying with work for pay. The data on their paid work are from household surveys conducted by the International Labour Organization (ILO), the United Nations Children’s Fund (UNICEF), the World Bank, and national statistical offices. Gender disparities are measured using a compilation of data on key topics such as education, health, labor force participation, and political participation. Data on refugees are from the United Nations High Commissioner for Refugees complemented by statistics on Palestinian refugees under the mandate of the United Nations Relief and Works Agency.</td>
</tr>
<tr>
<td>Topic ID</td>
<td>Topic Name and Description</td>
</tr>
<tr>
<td>---------</td>
<td>-----------------------------</td>
</tr>
<tr>
<td>16</td>
<td><strong>Urban Development</strong></td>
</tr>
<tr>
<td></td>
<td>Cities can be tremendously efficient. It is easier to provide water and sanitation to people living closer together, while access to health, education, and other social and cultural services is also much more readily available. However, as cities grow, the cost of meeting basic needs increases, as does the strain on the environment and natural resources. Data on urbanization, traffic and congestion, and air pollution are from the United Nations Population Division, World Health Organization, International Road Federation, World Resources Institute, and other sources.</td>
</tr>
<tr>
<td>17</td>
<td><strong>Gender</strong></td>
</tr>
<tr>
<td></td>
<td>Gender equality is a core development objective in its own right. It is also smart development policy and sound business practice. It is integral to economic growth, business growth, and good development outcomes. Gender equality can boost productivity, enhance prospects for the next generation, build resilience, and make institutions more representative and effective. In December 2015, the World Bank Group Board discussed its new Gender Equality Strategy 2016–2023, which aims to address persistent gaps and proposed a sharpened focus on more and better gender data. The World Bank Group is continually scaling up commitments and expanding partnerships to fill significant gaps in gender data. The database hosts the latest sex-disaggregated data and gender statistics covering demography, education, health, access to economic opportunities, public life and decision-making, and agency.</td>
</tr>
<tr>
<td>18</td>
<td><strong>Millennium Development Goals</strong></td>
</tr>
<tr>
<td></td>
<td>Achieve the following by 2015: To eradicate extreme poverty and hunger; to achieve universal primary education; to promote gender equality and empower women; to reduce child mortality; to improve maternal health; to combat HIV/AIDS, malaria, and other diseases; to ensure environmental sustainability; to develop a global partnership for development.</td>
</tr>
<tr>
<td>19</td>
<td><strong>Climate Change</strong></td>
</tr>
<tr>
<td></td>
<td>Climate change is expected to hit developing countries the hardest. Its effects—higher temperatures, changes in precipitation patterns, rising sea levels, and more frequent weather-related disasters—pose risks for agriculture, food, and water supplies. At stake are recent gains in the fight against poverty, hunger, and disease, and the lives and livelihoods of billions of people in developing countries. Addressing climate change requires unprecedented global cooperation across borders. The World Bank Group is helping support developing countries and contributing to a global solution, while tailoring its approach to the differing needs of developing country partners. Data here cover climate systems, exposure to climate impacts, resilience, greenhouse gas emissions, and energy use. Other indicators relevant to climate change are found under other data pages, particularly Environment, Agriculture and Rural Development, Energy and Mining, Health, Infrastructure, Poverty, and Urban Development.</td>
</tr>

</thead>
<tbody>
<tr>
<td>20</td>
<td><strong>External Debt</strong></td>
</tr>
<tr>
<td></td>
<td>Debt statistics provide a detailed picture of debt stocks and flows of developing countries. Data presented as part of the Quarterly External Debt Statistics take a closer look at the external debt of high-income countries and emerging markets to enable a more complete understanding of global financial flows. The Quarterly Public Sector debt database provides further data on public sector valuation methods; tiers of debt for central, state, and local debt instruments; and clearly defined government, as well as extra-budgetary agencies and funds. Data are gathered from national statistical organizations and central banks as well as by various major multilateral institutions and World Bank staff.</td>
</tr>
<tr>
<td>21</td>
<td><strong>Trade</strong></td>
</tr>
<tr>
<td></td>
<td>Trade is a key means to fight poverty and achieve the Millennium Development Goals, specifically by improving developing country access to markets and by supporting a rules-based, predictable trading system. In cooperation with other international development partners, the World Bank launched the Transparency in Trade Initiative to provide free and easy access to data on country-specific trade policies.</td>

You can use the URL= option to retrieve the series indicators available for a specified source ID. For an example, see Example 54.5.

You can use the URL= option to retrieve the series indicators available for a specified topic ID. For an example, see Example 54.6.

You can also use the URL= option to retrieve the country codes available for a specified income level. For more about income levels, see the section “Available Countries for a Specified Income Level” (which follows).

### Available Countries for a Specified Income Level

Each of the WBGO income levels has a corresponding country list. To get a list of countries for a specific income level, such as low income level (LIC), use the following URL= option in your LIBNAME statement:

```plaintext
   title 'WBGO Data for Low-Income-Level Countries';
   LIBNAME myLib sasewbgo "<physical pathname>"
      URL="http://api.worldbank.org/countries?incomeLevel=LIC&format=xml";

   data LICinc;
      set myLib.XWBGOTPU ;
   run;

   proc contents data=LICinc; run;
   proc print data=LICinc; run;
```

### Available Time Series for a Specified Source ID

Each source in the WBGO data has many time series. To get the list of time series indicators for a specific source ID (for example, source_id=1), use the following URL= option in your LIBNAME statement:

```sas
LIBNAME myLib sasewbgo "<physical pathname>"
URL="http://api.worldbank.org/source/1/indicators?format=xml";
```

See Example 54.5 for the sample code.

### Available Time Series for a Specified Topic ID

Each topic in the WBGO data has many time series. To get the list of time series indicators for a specific topic ID (for example, topic_id=5), use the following URL= option in your LIBNAME statement:

```sas
LIBNAME myLib sasewbgo "<physical pathname>"
```

See Example 54.6 for the sample code.
SAS Output Data Set

You can use the SAS DATA step to write the selected WBGO data to a SAS data set. This enables you to use SAS software to easily analyze the data.

The contents of the SAS data set include the date of each observation and the indicator of each series that is read from the WBGO data source.

The SASEWBGO interface engine maintains the sort order, so the time series are sorted in the resulting SAS data set by the order specified in the SORT= option, by date (time ID), and by variable (time series indicator).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEWBGO libref to create a custom view of your data.

SAS OUTXML File

The SAS XML (XML format) data that are retrieved from the WBGO website are placed in a file named by the OUTXML= option. The SAS XML data file is placed in the current working directory, but the SAS data set that is created by reading the XML data into SAS is placed in the location that is specified by the physical-name in the LIBNAME libref SASEWBGO statement, which is described in the section “The LIBNAME libref SASEWBGO Statement” on page 3720.

SAS XML Map File

The XML map that (by default) is automatically created is assigned the full pathname given by the XMLMAP= option in your LIBNAME libref SASEWBGO statement. The map file is either reused (not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE (the default). The SASEWBGO engine invokes the XMLV2 engine to create the map and to read the data into SAS.

XWBGOTPU SAS Data Set

You can use the URL= option to query for useful information such as income-level categories, sources, and topics and store the information in a temporary utility data set named XWBGOTPU. After you have this information, you can use it to select the data that you want to include in a subsequent SASEWBGO libref statement. For more information about the three possible types of XWBGOTPU contents, see the URL= option.

Available Time Series Data Reference: SASEWBGO Interface Engine

Table 54.6 shows the 2010 WDI time series indicators available for the IDLIST= option. Each indicator is unique. When you specify multiple indicators, separate them with commas.

Examples: SASEWBGO Interface Engine

Example 54.1: Reading Gross Domestic Product Data

This example shows how to access three of China’s GDP time series.

```sas
title 'WBGO Data: Gross Domestic Product (3 Series) for China';
LIBNAME myLib sasewbgo "<physical pathname>
    OUTXML=g2start
    AUTOMAP=replace
    MAPREF=MyMap
    XMLMAP="<fully qualified name of map file with .map file extension>"
    COUNTRYLIST='chn'
    IDLIST='NY.GDP.PCAP.CD,NY.GDP.PCAP.KN,NY.GDP.PCAP.PP.KD'
    RANGE='2010:2016'
;  
data gdp2chn;
    set myLib.g2start ;
run;

proc contents data=gdp2chn; run;
proc print data=gdp2chn(drop=total_count); run;
```

</tbody>
</table>
The SASEWBGO interface engine supports the XML format. The XML data that the WBGO website returns are placed in a file specified by the OUTXML= option. The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option.

To specify the list of time series that you want to retrieve, use the IDLIST= option. This option accepts a string enclosed in single quotation marks that denotes a list of time series indicators that you select for the resulting SAS data set. The series IDs (indicators) are separated by commas, so valid time series IDs cannot contain embedded commas or quotes. The gdp2chn data set contains three time series variables (NY.GDP.PCAP.CD, NY.GDP.PCAP.KN, and NY.GDP.PCAP.PP.KD), as specified in the IDLIST= option, and the observation range is controlled by the RANGE='2010:2016' option. The gdp2chn data set contains observations that range from the year 2010 to the year 2016, as specified by the RANGE= option. The frequency of the data is annual (default).

NOTE: The string ‘%20’ is a special character for URL encoding of blanks. If the time series ID that you name in the IDLIST= option contains a blank, you must use ‘%20’ wherever the blank appears in the time series name. If the time series ID contains an underscore, then you must use an underscore in the time series indicator. The blank and the underscore are not equivalent in the WBGO databases, so make sure that you use ‘%20’ (URL encoded space) to designate blank characters.

### Example 54.2: Retrieving Data for All Countries

This example shows how to get the GDP data for all countries by using the COUNTRYLIST='all' option. Because the amount of data retrieved shows only the first 50 observations (default for the PER_PAGE= option), and the total number of observations is large, use the PAGE= option to request a particular page of the data, such as PAGE=22.

```sas
title 'Retrieve GDP Data for All Countries';
libname wbgo sasewbgo "<physical pathname>"
    OUTXML=gdp5all
    AUTOMAP=replace
    MAPREF=MyMap
    XMLMAP="<fully qualified filename to map file with .map file extension>"
    COUNTRYLIST='all'
    IDLIST='NY.GDP.PCAP.CD,NY.GDP.PCAP.KN,NY.GDP.PCAP.PP.KD'
    RANGE='2010:2016'
    PAGE=22
    ;

data mygdp5all;
    set wbgo.gdp5all;
run;

proc contents data=mygdp5all; run;
proc print data=mygdp5all(drop=total_count); run;
```

Output 54.2.1 shows the data for the Kyrgyz Republic, the Republic of Korea, the Lao PDR, Lebanon, Latvia, and Kosovo. The SASEWBGO engine gives the information about the total number of pages (data_pages), the requested page number (data_page), the number of observations per page (data_per_page), and the total number of observations (data_total) in the SAS listing.

Example 54.3: Setting the Number of Observations Retrieved in One Page of Data

This example shows how to change the number of observations retrieved in one page of data by using the PER_PAGE= option.

```sas
title 'Using the PER_PAGE= Option';
libname wbgo sasewbgo "<physical pathname>"
  OUTXML=gdp2all
  AUTOMAP=replace
  MAPREF=MyMap
  XMLMAP="<fully qualified name of map file with .map file extension>"
  COUNTRYLIST='all'
  IDLIST='NY.GDP.PCAP.CD,NY.GDP.PCAP.KN,NY.GDP.PCAP.PP.KD'
  RANGE='2010:2016'
  PER_PAGE=75
  PAGE=2
  ;

data mygdp2all;
  set wbgo.gdp2all;
run;

proc contents data=mygdp2all; run;
proc print data=mygdp2all(drop=total_count); run;
```

### Output 54.3.1

**Using the PER_PAGE= Option**

Output 54.3.1 shows the data for page 2 (when PER_PAGE=75) for the countries with the following country IDs: EU, F1, T7, V3, XD, XE, XF, XG, XH, XI, ZJ, and ZT. Most of these country codes are aggregated subsets, based on debt, income level, or location.

Example 54.4: Sorting Time Series in Descending Order Using the Sort= Option

This example shows how to retrieve data that are sorted in descending order (within each country’s BY group).

```sas
title 'Using the SORT= Option';
libname wbgo sasewbgo "<physical pathname>"
    OUTXML=gdpdes
    AUTOMAP=replace
    MAPREF=MyMap
    XMLMAP="<fully qualified filename to map file with .map file extension>"
    COUNTRYLIST='chn;bra'
    IDLIST='NY.GDP.PCAP.CD,NY.GDP.PCAP.KN,NY.GDP.PCAP.PP.KD'
    RANGE='2010:2016'
    PER_PAGE=25
    SORT=desc
;

data mygdpdesc;
    set wbgo.gdpdesc;
run;

proc contents data=mygdpdesc; run;
proc print data=mygdpdesc(drop=total_count); run;
```

</table>
```

Output 54.4.1 shows the results of using the SORT= option to sort each country’s observations in descending order (most recent observation first). There are only 25 observations because the PER_PAGE=25 option is specified, and the default page is the first page of observations. The SASEWBGO engine defaults to SORT=ASC (ascending dates) within each BY group (country).
Example 54.5: Retrieving a List of Indicators for a Specified Source Using the URL= Option

This example demonstrates how to use the URL= option to retrieve a list of available time series indicators from a specified source.

```sas
title 'Retrieve a List of Indicators for a Specified Source Using the URL= Option';
libname wbgo sasewbgo "<physical pathname>"
  url="http://api.worldbank.org/source/1/indicators?format=xml"
;

data mylsource;
  set wbgo.XWBGOTPU;
run;

proc contents data=mylsource; run;
proc print data=mylsource; run;
```

</tbody>
</table>

Output 54.5.1 shows the list of indicators for the specified source. Each indicator can be listed in more than one topic, so an indicator might be listed multiple times in the results.

Example 54.6: Retrieving a List of Indicators for a Specified Topic Using the URL= Option

This example demonstrates how to use the URL= option to retrieve a list of available time series indicators for a specified topic.

```sas
title 'Retrieve a List of Indicators for a Specified Topic ID Using the URL= Option';
libname wbgo sasewbgo "<physical pathname>";
page=2;

data my5top2;
  set wbgo.XWBGOTPU;
run;

proc contents data=my5top2; run;
proc print data=my5top2; run;
```
Example 54.6: Retrieving a List of Indicators for a Specified Topic Using the URL= Option

Output 54.6.1 shows page 2 of the results. You can retrieve page 1 by removing the PAGE=2 option from the LIBNAME statement. Even though an indicator is selected based on the specified topic ID, all corresponding topics for that selected indicator are listed in the results.

</tbody>
</table>
Output 54.9.1 shows the results for all countries (ALL) listed in the COUNTRYLIST= option. Three time series are specified in the IDLIST= option. For the entire specified range, for years 2010–2016, the time series have a total of 1,848 observation values.

The X macro shows how to obtain the total observation count by first requesting only 50 observations (PER_PAGE=50, PAGE=1) in the first SASEWBGO LIBNAME statement. The SAS data set that the SASEWBGO engine creates is named GdpMall by the OUTXML= option in the first SASEWBGO LIBNAME statement. The PROC SQL SELECT statement stores the total number of observations from the SAS variable TOTAL_COUNT in the SAS macro variable named ALLNOBS. This allows the second SASEWBGO LIBNAME statement to use the total observation count in the PER_PAGE= option so that all 1,848 observations are downloaded in one page. The SAS data set gdpTall contains all 1,848 observations. For brevity, only the last 48 observations are shown in Output 54.9.1.

Overview: SASEXCCM Interface Engine

The SASEXCCM interface engine enables SAS users to access the CRSP/Compustat Merged (CCM) Database, which is created from data delivered via Compustat’s Xpressfeed product, the CRSP US Stock (STK) Database, and the CRSP US Stock and Indices (IND) Database. The SASEXCCM engine provides a seamless interface for CRSP, Compustat, and SAS data processing.

The SASEXCCM engine uses the LIBNAME statement to specify which database to open and what parts of the database to access.

To specify the database, you supply the combination of a physical path to indicate the location of the data files (CCM, STK, or IND data) and a set identifier (SETID) to identify the database that you want to access from those available at the physical path. The SASEXCCM engine supports data-item-handling access methods for the SETIDs in Table 55.1.

The SASECRSP engine no longer supports COMPUSTAT access. Instead, use the SASEXCCM engine, SETID 250, to read your CRSP/Compustat Merged data.

Getting Started: SASEXCCM Interface Engine

To specify what parts of the database to access, you supply two things: the appropriate keys for companies or securities that you want to access, and the list of data items that you want to retrieve.

When accessing CCM data, you select the companies that you want to access by specifying the GVKEY for each company. A GVKEY is Compustat’s unique identifier and primary key. CRSP uses KYGVKEY to refer to GVKEY in the CCM database. Use the GVKEY= option to specify which GVKEY to include. If no GVKEYs are specified, data for all companies are retrieved. You can use the KEEP= KYGVKEY CONM option to obtain a list of all companies (including their name and GVKEY) in the CCM database, as shown in Example 55.5.

For example, the following statements access the CCM database to retrieve annual sales data for IBM (GVKEY=6066) and Microsoft (GVKEY=12141):
LIBNAME myLib sasexccm 'physical-name'
  SETID=250
  GVKEY=6066 /* IBM */
  GVKEY=12141 /* MSFT */
  ITEMLIST='SALE';
  data yrlysale;
    set myLib.annitem;
  run;

When accessing CRSP US Stock (STK) data, you select the securities you want to access by specifying their PERMNOs. A PERMNO is CRSP’s unique permanent issue identification number and the primary key for its stock databases. You specify a PERMNO by using the PERMNO= option. If no PERMNOs are specified, data for all securities in the database are retrieved. You can use this feature to obtain a list of all PERMNOs in the STK database.

For example, the following statements access the STK database to retrieve monthly shares data for IBM (PERMNO=12490) and Microsoft (PERMNO=10107):

LIBNAME myLib sasexccm 'physical-name'
  SETID=20
  PERMNO=12490 /* IBM */
  PERMNO=10107 /* MSFT */
  ITEMLIST="MSHROUT.*;MSHRFLG.*";
  data mshares_all;
    set myLib.mshares;
  run;

When accessing CRSP US Stock and Indices (IND) data, you select the security and indices data from the CRSP Daily or Monthly Stock and Indices database by specifying their INDNOs. An INDNO is the primary key for CRSP Indices Databases. You specify an INDNO by using the INDNO= option. If no INDNOs are specified, data for all securities in the database are retrieved. You can use this feature to obtain a list of all INDNOs in the IND database.

For example, the following statements access the IND database to retrieve monthly Consumer Price Index data (INDNO=1000709):

LIBNAME myLib sasexccm 'physical-name'
  SETID=420
  INDNO=1000709 /* Consumer Price Index */
  ITEMLIST="MREBAL.*;MRBBEGDT.*;MRBENDDT.*;MRUSDCNT.*;MMINID.*;MMAXID.*;MMINSTAT.*";
  data mindts_all;
    set myLib.mindhdr;
    set myLib.mrebal;
  run;

To specify the list of data items that you want to retrieve, use the ITEMLIST= option. This option accepts a string that denotes a list of requested data items and the reporting format (for example, data format, population source, consolidation level, and so on) in standard CRSP notation by using CRSP’s unique mnemonic text name *itm_name* and the mnemonic tag *keyset*. For more information about CRSP notation, see the ITEMLIST= option in the section “The LIBNAME libref SASEXCCM Statement” on page 3784.
After the SAS library reference (libref) is assigned by the LIBNAME statement, the database is opened. The selected data are organized into groups such as ANNITEM for annual time series data or LINK for event-based CRSP/Compustat link data. You can also use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set.

The SASEXCCM engine supports Linux X64 (LAX), Solaris X64 (SAX), Solaris SPARC (S64), and Windows. Windows no longer requires you to install the CRSPAccess API, because it is now distributed automatically by your SAS/ETS installation. Your Windows setup does not require any special environment variables.

Syntax: SASEXCCM Interface Engine

The SASEXCCM interface engine uses standard engine syntax. Options that the SASEXCCM engine uses are summarized in Table 55.2. The SETID= and ITEMLIST= options are required.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETID=</td>
<td>Specifies which CRSP database at the physical path to open. For the complete list of supported SETIDs, see Table 55.1.</td>
</tr>
<tr>
<td>GVKEY=</td>
<td>Specifies a Compustat GVKEY for accessing CCM data. To select more than one GVKEY, use this option multiple times. See Example 55.1 and Example 55.2.</td>
</tr>
<tr>
<td>GVIIDKEY=</td>
<td>Specifies a composite GVKEY.IID for accessing security related items by both GVKEY and IID.</td>
</tr>
<tr>
<td>PERMNO=</td>
<td>Specifies a CRSP PERMNO for accessing STK data. To select more than one PERMNO, use this option multiple times.</td>
</tr>
<tr>
<td>INDNO=</td>
<td>Specifies a CRSP INDNO for accessing IND data. To select more than one INDNO, use this option multiple times.</td>
</tr>
<tr>
<td>ITEMLIST=</td>
<td>Specifies the selected data items to be accessed. This option accepts a string in standard CRSP notation.</td>
</tr>
</tbody>
</table>

The LIBNAME libref SASEXCCM Statement

```
LIBNAME libref SASEXCCM 'physical-name' SETID=crsp_setidnumber options;
```

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of CRSP data files where the CRSP database that you want to open is located. The required physical-name argument must end in a slash for UNIX environments and a backslash for Windows environments. The required SETID=crsp_setidnumber argument specifies the CRSP database that you want to read from. Choose one SETID from these values: 10, 20, 250, 400, 420, 440, and 460. For example, the following statement accesses the CCM database and retrieves the annual sales data for IBM (GVKEY=6066):
LIBNAME myLib SASEXCCM 'physical-name' SETID=250 GVKEY=6066 ITEMLIST='SALE';

You can specify the following options:

**GVKEY=crsp_gvkey**
selects the companies or issues whose data you want to retrieve. Specify the GVKEY (Compustat’s permanent SPC identifier) for the `crsp_gvkey`. There is no limit to the number of GVKEY= options that you can specify. If no GVKEY= options are specified, all GVKEYs in the database are selected.

For example, the following statement accesses the CCM database to retrieve annual sales data for IBM (GVKEY=6066) and Microsoft (GVKEY=12141):

```
LIBNAME myLib sasexccm 'physical-name'
SETID=250
GVKEY=6066 /* IBM */
GVKEY=12141 /* MSFT */
ITEMLIST='SALE';
```

**GVIIDKEY='crsp_gviidkey'**
selects the companies and issues whose data you want to retrieve. Specify both the GVKEY and the IID (Compustat’s permanent issue identifier) by concatenating the two with a ‘.’ and enclosing them in double quotation marks. There is no limit to the number of GVIIDKEY= options that you can specify. The following members use GVIIDKEY access: IDXCST_HIS, MTHSEC, SECHIST, SECURITY, SEC_MDIVFN, SEC_MSPFTN, SEC_MTHSPT, SEC_SPIND, SEC_TS_ITM, and SPIDX_CST.

For example, the following statements access the CCM database to retrieve the security member that gives security header information for Microsoft issue ID=01, IBM issue ID=01, and some other companies’ issues shown in the GVIIDKEY= options:

```
LIBNAME crsp sasexccm 'physical-name'
SETID=250
GVIIDKEY="12141.01" /* MSFT issue id 01 */
GVIIDKEY="6066.01" /* IBM issue id 01 */
GVIIDKEY="6008.01" /* INTC issue id 01 */
GVIIDKEY="12142.01" /* ORCL issue id 01 */
GVIIDKEY="62634.01" /* YHOO issue id 01 */
GVIIDKEY="5047.01" /* GE issue id 01 */
GVIIDKEY="7866.01" /* NYT issue id 01 */
GVIIDKEY="7866.02" /* NYTAB issue id 02 */
ITEMLIST="DLDTEI;DLRSNI;DSCI;EPF;EXCHG;IID;IID_SEQ_NUM;ISIN;SBEGDT;SENDDT;SCUSIP;
!SEDOL;SSECSTAT;TIC;TPCI";
data headersecurity;
  set crsp.security;
run;
```

**PERMNO=crsp_permno**
selects the companies or issues whose data you want to retrieve. Specify a CRSP company issue’s PERMNO for the `crsp_permno`. There is no limit to the number of PERMNO= options that you can specify. If no PERMNO= options are specified, all PERMNOs in the database are selected.

For example, the following statements access the STK database to retrieve monthly shares data for IBM (PERMNO=12490) and Microsoft (PERMNO=10107):
LIBNAME myLib saseccm 'physical-name'
SETID=20
PERMNO=12490 /* IBM */
PERMNO=10107 /* MSFT */
ITEMLIST="MSHROUT.**;MSHRFLG.**";
data mshares_all;
  set myLib.mshares;
run;

INDNO=crsp_indno
selects the time series or the group data from the index whose data you want to retrieve. Specify a CRSP Index’s INDNO for the crsp_indno. There is no limit to the number of INDNO= options that you can specify. If no INDNO= options are specified, all INDNOs in the database are selected.

For example, the following statements access the IND database to retrieve monthly consumer price index data (INDNO=1000709):

LIBNAME myLib saseccm 'physical-name'
SETID=420
INDNO=1000709 /* Consumer Price Index */
ITEMLIST=
  "MREBAL.**;MRBBEGDT.**;MRBENDDT.**;MRUSDCNT.**;MMINID.**;MMAXID.**;MMINSTAT.**";
data mindts_all;
  set myLib.mindhdr;
  set myLib.mrebal;
run;

ITEMLIST="crsp_itemlist"
specifies the items and groups of interest for selection based on keysets, which define the reporting format that you want. Specify a string in CRSP standard notation for crsp_itemlist. For an overview of items, groups, and reporting formats, see the section “Data Reference: Introduction” on page 3789. Reference sections that are based on CRSP documentation follow the overview. For more information, see the CRSPAccess User Guide for the CRSP/Compustat Merged Database, the CRSP US Stock and Indices Database, and the CRSP US Treasury Database.

The CRSP standard notation has the form

[global_section:]list_section

The list_section consists of a semicolon-delimited string of list elements in the form

list_element[;list_element]

Each list_element can be an item or group name. You can also specify a particular keyset for the item or group by appending a period and its keyset number. For example, “sale.2” selects the sales item for keyset 2, which contains the industrial format, consolidated information, and standardized summary data from the latest annual filing.
The optional *global_section* holds flags that modify all elements in the list section. The following flags are recognized:

- **f** adds applicable and populated footnote items for every item selected. For example, “f:sale;at;ceq” selects sales, total assets, and common equity items with default keysets and available footnotes for the selected items.

- **d** adds applicable and populated data code items for every item selected. For example, “d:sale;at;ceq” selects sales, total assets, and common equity items with default keysets and available data codes for the selected items.

- **k.list** applies the list of keysets to all items in the list that do not have a specified keyset. The list can be either `*` to select all available keysets or `#-#,#\...` to select keysets by their number. For example, “k.1:sale;at;ceq” selects the default keyset, keyset 1, for all items.

The following LIBNAME statement shows how to access the CCM database to retrieve the annual sales data and quarterly total assets data for IBM (GVKEY=6066) and Microsoft (GVKEY=12141):

```
LIBNAME myLib sasexccm 'physical-name'
   SETID=250
   GVKEY=6066 /* IBM */
   GVKEY=12141 /* MSFT */
   ITEMLIST='f:sale;actq';
```

After the libref is assigned, you can access any of the available groups (members) within the opened database:

- **STK daily** For more information about groups in the Daily Stock Database, SETID 10, see the section “Daily STK Data Groups” on page 3794.
- **STK mthly** For more information about groups in the Monthly Stock Database, SETID 20, see the section “Monthly STK Data Groups” on page 3795.
- **CCM** For more information about groups in the CRSP/Compustat Merged Databases, SETID 250, see the section “CCM Data Groups” on page 3792.
- **IND mthly grp** For more information about groups in the Monthly Indices Group Data Database, SETID 400, see the section “Monthly IND Group Data Group Names” on page 3796.
- **IND mthly ts** For more information about groups in the Monthly Indices Time Series Database, SETID 420, see the section “Monthly IND Time Series Data Group Names” on page 3797.
- **IND daily grp** For more information about groups in the Daily Indices Group Data Database, SETID 440, see the section “Daily IND Group Data Group Names” on page 3796.
- **IND daily ts** For more information about groups in the Daily Indices Time Series Database, SETID 460, see the section “Daily IND Time Series Data Group Names” on page 3798.
Details: SASEXCCM Interface Engine

SAS Output Data Set

You can use the SAS DATA step to write the selected CRSP or Compustat data to a SAS data set. This enables you to easily analyze the data by using SAS software. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the DATE of each observation, the series name of each series read from the CRSPAccess database, event variables, and the label or description of each series, event, or array.

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEXCCM libref to create a custom view of your data.

Missing Values

In general, CRSP missing values are represented as ‘.’ in the SAS data set. When accessing the CCM database, the SASEXCCM engine interprets missing values according to the conditions and codes defined by Compustat and represents them as SAS missing codes, as shown in Table 55.3.

<table>
<thead>
<tr>
<th>Missing Value</th>
<th>Missing Code</th>
<th>Condition</th>
</tr>
</thead>
<tbody>
<tr>
<td>0.0001</td>
<td>.</td>
<td>No data for data item</td>
</tr>
<tr>
<td>0.0002</td>
<td>.S</td>
<td>Data are available only on a semi-annual basis</td>
</tr>
<tr>
<td>0.0003</td>
<td>.A</td>
<td>Data are available only on an annual basis</td>
</tr>
<tr>
<td>0.0004</td>
<td>.C</td>
<td>Combined into other item</td>
</tr>
<tr>
<td>0.0007</td>
<td>.N</td>
<td>Data are not meaningful</td>
</tr>
<tr>
<td>0.0008</td>
<td>.I</td>
<td>Reported as insignificant</td>
</tr>
</tbody>
</table>

Missing value codes conform with Compustat’s Strategic Insight and binary conventions for missing values. For more information about how CRSP handles Compustat missing codes, see the section “Notes on Missing Values” in the second chapter of the CRSP/Compustat Merged Database Guide.
Data Reference: Introduction

Data reference details are presented for items, keysets, and groups available from four CRSPAccess databases in this order: CCM database, STK databases, and IND databases. In addition to summary tables, sample SAS statements show how to generate a customized list of item names available from each group for a particular database.

CCM Data Items

The CRSP/Compustat Merged (CCM) database is organized by company and security according to Compustat’s Permanent SPC Identifier (GVKEY) and Compustat’s Permanent Issue Identifier (IID). An identifying relationship exists between IID and GVKEY. The two identifiers must be accessed as a pair to properly identify a Compustat security. One GVKEY can have multiple IIDs. The SASEXCCM interface engine provides the GVIDKEY= option to provide access to Compustat securities through the composite key designated by “GVKEY.IID”.

CCM data are broken down into items, and items can be further qualified by a set of secondary keys. CRSP calls these known collections of keys and values a keyset, and it assigns a numeric code and mnemonic tag to each unique collection. Each keyset represents different output series. Items are also organized into groups for selection and presentation. A group can include other groups, or a group can include items. Items can belong to more than one group. Sometimes groups are also called members.

For example, the Compustat data item SALE has secondary keys for industry format, data format, population source, and consolidation level. A different value of company sales can be available for any combination of these keys, such as a combination that represents the originally reported sales or the final restated sales from a later filing. The SALE data item is a part of the ANNITEM (Annual Time Series Items, including footnotes and data codes) group.

The CCM database contains data items provided by Compustat in addition to structures and supplementary data items provided by CRSP. All data items include a mnemonic and a field name. This section provides a summary of Compustat data items whose mnemonic differs in the CCM database, and a summary of the supplementary data items provided by CRSP. For more information about the Compustat data items, refer to your Compustat data documentation or see www.compustatresources.com/support/index.html. For more information about the supplementary CRSP data items, see your CCM Database Guide.

Supplemental CRSP data items are organized into groups. For a list of the supplemental data groups, see the section “CCM Data Groups” on page 3792.

### CCM Keysets

Compustat items can be qualified by a set of secondary keys. This collection of secondary keys and values creates a keyset that assigns a numeric code and mnemonic tag to each unique collection. Each keyset represents different output series. For example, one keyset might represent originally reported sales, and another might represent the final restated sales from a later filing. Full details about keysets can be found in the CRSP/Compustat Merged Database Guide. For your convenience, Table 55.5 summarizes the keysets.

*Table 55.5  Summary of CCM Keysets*
CCM Data Groups

CCM items are organized into groups for ease of selection and presentation. Each group is given a group name. These names are unique and do not overlap with item names. A group can be made up of either items or other groups. Items can belong to more than one group. Table 55.6 provides a summary of some groups. For more information about CCM data groups, see your CCM Database Guide.

Daily STK Data Items

You can generate a customized list of item names available in the daily stock database (SETID=10) by running the following sample statements for each group name in Table 55.8:

```plaintext
libname dstock sasexccm
   "/thirdparty/crspdata/DIZ201006/"
setid=10 permno=12490
itemlist="group_name.*";

proc contents data=dstock.group_name; run;
```

The following statements generate an item list of all the item names available in the group named STKHDR_ID:

```plaintext
libname crsp sasexccm
   "/thirdparty/crspdata/DIZ201006/"
setid=10 permno=12490
itemlist="STKHDR_ID.*";

proc contents data=crsp.stkhdr_id; run;
```

The item names in group STKHDR_ID are listed in Table 55.7.

IND Group Data Item Names

You can generate a customized list of available indices group data item names by running the following sample statements for each daily or monthly group name from Table 55.10 or Table 55.11 and substituting the corresponding SETID, data path, and actual daily (or monthly) group name for the group_name:

```plaintext
libname crsp sasexccm
   "/thirdparty/crspdata/DIZ201006/"
setid=440
indno=1000040
itemlist="group_name.*";
proc contents data=crsp.group_name; run;
```
Monthly IND Group Data Group Names

The monthly group indices data consist of the groups listed in Table 55.10.

**Table 55.10** US IND Monthly Group Data Group Names

<table>
<thead>
<tr>
<th>Group Name</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>MINDHDRG</td>
<td>Monthly index group header</td>
</tr>
<tr>
<td>MINDSUMMG</td>
<td>Monthly index group summary</td>

</tbody>
</table>

Examples: SASEXCCM Interface Engine

Example 55.1: Retrieving SALE Data for One GVKEY

This simple example shows how to retrieve SALE data for one particular GVKEY=6066 (IBM). Because the ITEMLIST= option does not specify a keyset, the default (standard) keyset, KEYSET_TAG=STD, is selected. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

```sas
title 'Retrieve SALE data for IBM';
libname _all_ clear;

libname crsp sasexccm "/thirdparty/crspdata/CMZ201201/"
   setid=250
gvkey=6066
   itemlist="sale";

data recentsales;
   set crsp.annitem;
   where datadate >= '1jan2000'd;

proc print data=recentsales;
run;
```
Example 55.2: Retrieving SALE Data for Multiple Companies

This example shows how to retrieve several data items for several GVKEYs. Note how the item `offtitl` is not an annual item and is stored in its own member. The default (standard) keyset is used for all items. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

title 'Retrieve Sales, Revenue, Liabilities, and Officer data for IBM and MSFT';
libname _all_ clear;

libname crsp sasexccm "/thirdparty/crspdata/CMZ201201/"
    setid=250
    gvkey=6066
    gvkey=12141
    itemlist="sale;revt;lct;offtitl";

data recentannitems;
    set crsp.annitem;
    where datadate >= '1jan2000'd;

proc print data=recentannitems;
proc print data=crsp.offtitl;
run;
Output 55.2.1 Data Items for IBM and Microsoft

Retrieve Sales, Revenue, Liabilities, and Officer data for IBM and MSFT

Example 55.3: Retrieving Data from Different Keysets

This example shows how to retrieve several data items from different keysets. You request data about research and development (R&D) expenses (XRD) and net income (NI) over all available keysets by using the `itm_name.*` syntax in the ITEMLIST= option. Note that data are not available for all items in all keysets. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

```
title 'Retrieve R&D Expenses and Net Income for IBM';
libname _all_ clear;

libname crsp sasexccm "/thirdparty/crspdata/CMZ201201/"
   setid=250
gvkey=6066
   itemlist="xrd.*;ni.*";

data recent;
   set crsp.annitem;
   where datadate >= '1jan2001'd;
proc print data=recent;
run;
```

**Output 55.3.1**  R&D Expenses and Net Income for GVKEY=6066

Example 55.4: Retrieving Items by Using Global Options

This example shows how to retrieve data on total assets (ATQ) and after tax gain or loss (GLAQ) by using the global option for turning on footnote items, which uses the following syntax:

\[
\text{ITEMLIST}="f:itm\_name1;itm\_name2;\ldots;itm\_nameN"
\]

The default (standard) keyset is used for all items. For brevity, a subset of the data that contains the most recent figures is specified by the WHERE statement.

```
title 'Retrieve data for IBM with Footnotes';
libname _all_ clear;

libname crsp sasexccm "/thirdparty/crspdata/CMZ201201/"
  setid=250
  gvkey=6066
  itemlist="f:atq;glaq";

data recent;
  set crsp.qtritem;
  where datadate >= '1jan2004'd;

proc print data=recent;
run;
```

Example 55.5: Retrieving All GVKEYs and Company Names

This example shows how to retrieve the GVKEY and name for every company in the CCM database.

```sas
title 'Retrieve All GVKEYs and Company Names';
libname _all_ clear;

libname crsp sasexccm "thirdparty/crspdata/CMZ201201/"
   setid=250
   itemlist=company;

proc contents data=crsp.company;
   proc print data=crsp.company(keep=kygvkey conm obs=20);
run;
```

For brevity, only the first 20 observations are shown, and only KYGVKEY and CONM are kept in Output 55.5.1.

### Example 55.6: Retrieving Stock Time Series by PERMNO

This example shows how to retrieve the MPRC, MASK, and MBID time series by using PERMNO key access in the STK database. For brevity, the WHERE= option in the DATA step selects a range of MCALDT for 25 observations.

```plaintext

Example 55.10: Retrieving Daily Group Time Series by the INDNO= Option

This example shows how to retrieve daily group time series by using the INDNO keys in the IND database that were found in Example 55.9.

```
    title 'Retrieve Daily Group Time Series by INDNO';
    libname _all_ clear;
    libname crsp sasexccm
      '/thirdparty/crspdata/DIZ201006/'
      setid=440
      indno=1000012 indno=1000032
      itemlist="AINDG.*;ARETG.*;USDCNTG.*;USDVALG.*";
    data dgindts_all ( where=( caldt >= '29jun2010'd) );
      set crsp.dlygind_ts;
    run;
    proc print data=dgindts_all; run;
```

Overview: SASEXFSD Interface Engine

The SASEXFSD interface engine enables SAS users to access both FactSet data and FactSet-sourced data that are provided by the FactSet OnDemand service (formerly known as FASTFetch). This service provides access to many FactSet Data Sources and to many other databases. This chapter focuses on accessing the FactSet Fundamentals database, but additional databases and data types are available for use with the SASEXFSD interface engine. For a more comprehensive list of available data, enter the following URL in your web browser:

http://www.factset.com/data/data

For detailed descriptions of other databases that you can access, refer to the FactSet workstation Online Assistant.

The SASEXFSD engine uses the LIBNAME statement to specify which factlet (provided by FactSet) to use to open a database and what parts of the database to access. Factlets are functions that encapsulate business logic and data collection procedures. The technology is capable of cross referencing and dealing with time series for a large amount of data.

To specify the factlet, name one of the supported factlets that are listed in Table 56.1. Table 56.5 shows where to find a summary of each factlet’s options.

Table 56.1  Supported FactSet OnDemand Factlets

The Prefix column in Table 56.2 contains the parameters that you are most likely to refer to when requesting data, but each factlet has its own set of optional parameters and default settings. Often the items that you select use a prefix (see the Prefix column) to designate the database where the item resides. Because the availability of data libraries and their contents are constantly changing, Table 56.2 is included for instructional purposes only.

Table 56.2  Sample Databases Available through FactSet

<table>
<thead>
<tr>
<th>Prefix</th>
<th>Database</th>
</tr>
</thead>
<tbody>
<tr>
<td>ff</td>
<td>FactSet Fundamentals</td>

<td>FactSet Global</td>
</tr>
<tr>
<td>p</td>
<td>FactSet Prices—Security Price Data</td>
</tr>
</tbody>
</table>
Table 56.2 shows only a subset of the available FactSet databases. For a more comprehensive list that also includes third-party databases available through FactSet, refer to the FactSet Online Assistant, page ID 2014.

To specify the data library, specify both a physical path to indicate the location of the data files (XML data returned from FactSet OnDemand) and the LIBNAME statement options to specify which factlet to use to request data items and the desired key IDs (identifiers, such as tickers or country codes) for your selection. The orientation of the data that are returned is ETI, entity-time-item, and is kept with sorted keys (entities or BY groups); each observation is indexed by time interval, and each time series data item is organized in columns by item name (time series variable name). The SASEXFSD engine supports the parameters that are required for each supported factlet.

Use the SASEXFSD engine to access all available data library items. To get started, look at the FactSet Fundamentals data items in Table 56.3.

For a complete list of data items for every category, refer to the FactSet Online Assistant, page ID 16331. FactSet workstation user name and serial number credentials are necessary to launch the FactSet Online Assistant from the FactSet workstation. A FactSet representative can provide these credentials.

Because the availability of data libraries and their contents are constantly changing, Table 56.3 is included for instructional purposes only. At the time of this writing, the available data list and items for the FactSet Fundamentals database are as shown in Table 56.3.

For a comprehensive list of FactSet Fundamentals data items, refer to the FactSet Online Assistant, page ID 15099. If the page is not found, enter “FactSet Fundamentals” in the search box near the top of the page.
Getting Started: SASEXFSD Interface Engine

To specify the parts of the database that you want to access, you supply two things: the list of IDs for the companies or securities that you want to access, and the list of data items that you want to retrieve.

When accessing company or security data, use the ExtractFormulaHistory factlet. Use the IDS= option to specify the list of IDs that identify the companies that you want to access by specifying the entity ID (such as the ticker symbol) for each company.

For example, the following statements access the FactSet Fundamentals database for monthly sales data (ff_sales) and the Prices database for pricing data (p_price) for IBM (ID='ibm') and for FactSet Research Systems (ID='fds'). To include both IDs in the same request, specify IDS='ibm,fds'; to include both data items in the same request, specify ITEMS='p_price,ff_sales', as follows:

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

LIBNAME myLib sasexfsd "%sysget(FACTSET)"
   DEBUG=on
   FACTLET=ExtractFormulaHistory
   FORMAT=sml
   OUTXML=gstart1
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="%sysget(FACTSET)gstart1.map"
   IDS='ibm,fds'
   ITEMS='p_price,ff_sales'
   DATES='20110130:20110631:m'
   ORIENTATION=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data company_pvol;
   set myLib.gstart1;
run;

proc contents data=company_pvol; run;
proc print data=company_pvol; run;
```
The SASEXFSD engine supports only the SAS XML (SML) format and the ETI orientation. The XML data that are returned from the FactSet OnDemand service are placed in a file specified by the OUTXML= option. The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option. In the preceding example, the SASEXFSD engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename:

FILENAME MyMap "/sasusr/playpens/saskff/factset/gstart1.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file; this is described in the section “SAS OUTXML File” on page 3844. This data file is placed in the folder designated by “physical-name”, which is described in the section “The LIBNAME libref SASEXFSD Statement” on page 3828. You can refer to your data by using the myLib libref in your SASEXFSD LIBNAME statement. In the preceding program, this statement appears inside the DATA step in the SET statement, which names the input data set myLib.gstart1 and causes the reading of the GSTART1.xml file to be input and stored in the SAS data set Company_pvol.

The Company_pvol data set contains two time series variables (data items), p_price and ff_sales, as specified in the ITEMS= option, and the observation range is controlled by the DATES= option. The prefixes, ff_ and p_, are the database designators for the FactSet Fundamentals and Prices databases, respectively, as shown in Table 56.2. The Company_pvol data set contains observations that range from January 30, 2011, to June 31, 2011, as specified in the DATES= option. The frequency of the data is monthly, as specified by the “m” at the end of the DATES= option. Figure 56.1 shows the results.
To specify the list of data items that you want to retrieve, use the ITEMS= option. This option accepts a string, enclosed in single quotation marks, that denotes a list of data items that you are selecting for the resulting SAS data set. The data item names are separated by commas, so valid item names cannot contain embedded commas or quotation marks. The prefix in each data item name designates the data source as defined in the Prefix column of Table 56.2.

After the libref is assigned by the LIBNAME statement, the database is opened. The selected data are organized into group entities (BY groups) that are sorted by date. In Figure 56.1, the tickers are the BY groups, and within each ticker, the observations are sorted by the time ID variable DATE.

You can also use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set.

The SASEXFSD engine is supported on 64-bit Windows and Linux X64 (LAX) platforms.

**Syntax: SASEXFSD Interface Engine**

The SASEXFSD interface engine uses standard engine syntax. Table 56.4 summarizes the options that the SASEXFSD engine supports. In addition, there are two required options: USERNAME='fact_username' and PASS='fact_password'.
<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>CAL=</td>
<td>Specifies the calendar that replicates the PSETCAL function</td>
</tr>
<tr>
<td>CONNECT=</td>
<td>Specifies whether or not you need the connect method for a secure connection via a proxy server. You must specify the PROXY= option when you use the CONNECT=ON option. See the PROXY= option.</td>
</tr>
<tr>
<td>CONV=</td>
<td>Specifies the conversion technique for aggregating periods, when a data series of a higher frequency is converted to a lower frequency; for example, converting a quarterly series to an annual series (such as SUM, AVERAGE, or AVERAGEPN)</td>
</tr>
<tr>
<td>CURRENCY=</td>
<td>Specifies a currency in which the data are returned, using a three-character ISO code, such as USD for US dollars or EUR for euros</td>
</tr>
<tr>
<td>DATE=</td>
<td>Specifies one date in 'YYYYMMDD' format (default is 0B, for today’s date)</td>
</tr>
<tr>
<td>DATES=</td>
<td>Specifies a list with the start date, end date, and frequency, separated by colons (:)</td>
</tr>
<tr>
<td>DBSOURCE=</td>
<td>Specifies a standardized database source name, such as EWIN_ECON, GL_ECON, OECD_MEI, FDS_ECON, FDS_COM, or the default, a null string, which uses the standardized economic data (EWIN_ECON_RGDPR_Y)</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not to include diagnostic message logging in the SAS log window</td>
</tr>
<tr>
<td>DIST=</td>
<td>Specifies the distribution technique for spreading over periods when a data series of a lower frequency is distributed to a higher frequency; for example, distributing an annual series to a quarterly series (such as STEP, EVEN, or NONE)</td>
</tr>
<tr>
<td>END=</td>
<td>Specifies the end date for the selected data range (in 'YYYYMMDD' format)</td>
</tr>
<tr>
<td>FACTLET=</td>
<td>Specifies which factlet you want to use. For the complete list, see Table 56.5.</td>
</tr>
<tr>
<td>FORMAT=</td>
<td>Specifies a FactSet format. Only SAS XML format (SML format) is supported.</td>
</tr>
<tr>
<td>FQLFLAG=</td>
<td>Sets dates to use FQL instead of screening; FQLFLAG=N (default) or Y</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies the reporting frequency of the selected data, such as M for monthly and D for daily. For the complete list of frequencies, see Table 56.20.</td>
</tr>
<tr>
<td>FUNCTION=</td>
<td>Adds the FQL function property to change data value; for example, FUNCTION=ZSCORE</td>
</tr>
<tr>
<td>IDS=</td>
<td>Specifies a list of FactSet keys or entity identifiers for accessing FactSet OnDemand data. To select more than one ID, list the unique entity identifiers separated by commas.</td>
</tr>
<tr>
<td>ISON=</td>
<td>Specifies whether the company (security), such as SP500 or MSCl_WORLD, is on the specified database or index. For a list of additional ISON= option examples, refer to the FactSet Online Assistant, page ID 2014.</td>
</tr>
<tr>
<td>ISONPARAMS=</td>
<td>Specifies the parameters used by the ISON code</td>
</tr>
<tr>
<td>ITEM=</td>
<td>Specifies one FactSet data item name (time series name)</td>
</tr>
<tr>
<td>ITEMS=</td>
<td>Specifies a list of FactSet data items for accessing FactSet data sources. To select more than one item, list the data item names, separated by commas.</td>
</tr>
<tr>
<td>NAME=</td>
<td>Specifies whether to see the names of each security along with the CUSIP</td>
</tr>
<tr>
<td>NFB=</td>
<td>Specifies the “no-feel-back” option in FQL codes. If you do not use the NFB= option, the returned data series contains NAs where the data are not available (default is NFB=1).</td>
</tr>
<tr>
<td>OFDB=</td>
<td>Specifies the OFDB filename</td>
</tr>
<tr>
<td>ORIENTATION=</td>
<td>Specifies the layout of the selected data items for access. Only the ETI (entity-time-item) orientation is supported.</td>
</tr>
<tr>
<td>PERIOD=</td>
<td>Specifies the time interval between the data points (observations) in a time series. The valid period parameters are ANN, QTR, SEMI, MON, YTD, YTD_SEMI, LTM, LTM_SEMI, and SEMI-ANN. The default is ANN.</td>
</tr>
</tbody>
</table>
Table 56.4  continued

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>PROXY=</td>
<td>Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, use the CONNECT=ON option in addition to the PROXY= option. See the CONNECT= option.</td>
</tr>
<tr>
<td>SCREEN=</td>
<td>Specifies the screen file that contains a single user-defined screen for viewing CUSIPs</td>
</tr>
<tr>
<td>START=</td>
<td>Specifies the start date for the selected data range (in 'YYYYMMDD' format)</td>
</tr>
<tr>
<td>UNIVERSE=</td>
<td>Specifies the one account or benchmark. Use this instead of the IDS= option.</td>
</tr>
<tr>
<td>UNIVERSEGROUP=</td>
<td>Default value is EQUITY; for DEBT securities, use UNIVERSEGROUP=DEBT</td>
</tr>
</tbody>
</table>

The LIBNAME libref SASEXFSD Statement

```
LIBNAME libref SASEXFSD 'physical-name' FACTLET= fact_factletname options;
```

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of FactSet data files where the downloaded FactSet XML data are stored. Because the required 'physical name' argument specifies the location of the folder where your FactSet XML data reside, it should end in a backslash if you are in a Windows environment and a forward slash if you are in a UNIX environment.

FACTLET= fact_factletname specifies the FactSet factlet that you want to use to download your data. Choose one factlet from these possible values: ExtractEconData, ExtractFormulaHistory, ExtractDataSnapshot, ExtractBenchmarkDetail, ExtractOFDBItem, ExtractOFDBUniverse, and ExtractScreenUniverse. (See Table 56.1.)

For example, the following statements access the FactSet database for daily dividend yield data for IBM:

```
LIBNAME myLib SASEXFSD 'physical-name' FACTLET=ExtractFormulaHistory
   IDS='ibm'
   ITEMS='FG_DIV_YLD'
   FREQ=d
   USER='username'
   PASS='password';
```

After the libref is assigned, you can access the data items for the IDs (keys) from the requested factlet.

You can specify the following options in the LIBNAME libref SASEXFSD statement.

- **FACTLET= fact_factletname**
  
  Each factlet type has its own set of parameters (shown in Table 56.5 in the Factlet Options Table column), allowing flexibility and easy access to FactSet data. For more details about each factlet, refer first to the Factlet Description Section listed in Table 56.5. If you need more information, refer to the Online Assistant, page ID 16948. If the factlet is not listed on that page, then enter the factlet name in the search window of the Online Assistant to retrieve additional information about using the factlet.

</tr>
<tr>
<td>ExtractScreenUniverse</td>
<td>“The ExtractScreenUniverse Factlet” on page 3841</td>
<td>Table 56.18</td>
</tr>
</tbody>
</table>

**IDS=** `fact_ids`

specifies a list of FactSet IDs (entity identifiers or keys) for accessing FactSet OnDemand data. To select more than one ID, list the unique entity identifiers, separated by commas (as shown in the following statements). Examples of FactSet IDs include CUSIPs, tickers, SEDOLs, Quick Code, and CINS (CUSIP International Numbering System). For more information, see Example 56.6 and Example 56.7.

```sas
LIBNAME myLib sasexfsd 'physical-name'
   ids='IBM,MSFT'
   ITEMS='p_price,p_volume,ca_sales';
```

**UNIVERSE=** `fact_uni`

specifies the universe of securities that passes the specified screening criteria. Up to 500 securities can be returned when this option is specified together with the FACTLET=ExtractFormulaHistory option. This limit is due to the US_UNIV function that is used within the ExtractFormulaHistory factlet to fetch the universe. You can also specify this option together with the FACTLET=ExtractDataSnapshot option, but because the data that are returned as of one specified date, there is no limit on the number of securities that can be returned.

```sas
LIBNAME myLib sasexfsd 'physical-name'
   factlet=ExtractFormulaHistory
   universe="URANKX((FS_PARENT_EQUITY=CUSIP AND EC_MKT_CAP(0,'CUR=USD')>10
   AND P_PRICE(0,USD)>5 AND CONTAINS(P_EXCOUNTRY,'UNITED STATES'))=1,
   EC_MKT_CAP(0,'CUR=USD'))<=500S"
   items='p_price(0,-4,M)';
```

**ITEMS='fact_itemlist'**

specifies the items and groups of interest for selection based on IDs (keys). Use FactSet’s Formula Lookup for a complete list of data items, which is described in the FactSet Online Assistant.

Because the availability of data libraries and their contents are constantly changing, the following tables are included for instructional purposes only. Many other databases are available that are not shown in Table 56.6 to Table 56.9.

For more information, see the FactSet Online Assistant, page ID 1931. To see each data source’s list of available data items, use the search feature of the FactSet Online Assistant. You can open any page in the FactSet Online Assistant by entering the appropriate page ID number in the page ID window, which is located below the search window.

**DATES=’fact_startdate:fact_enddate:fact_freqcode’**

specifies the start date, end date, and frequency, separated by colons (:). For more information, see the section “Specifying Date Ranges and Frequency Codes” on page 3844. An alternative to using the DATES= option is to use the START=, END=, and FREQ= options.

**DEBUG=ON | OFF**

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be very useful for troubleshooting a problem.

**PERIOD=fact_period**

specifies the periodic frequencies of the actual data points (observations) in a time series. The valid period parameters are ANN, QTR, SEMI, MON, YTD, YTD_SEMI, LTM, LTM_SEMI, and SEMI-ANN. The default is ANN.

**OUTXML=fact_xmlfile**

specifies the name of both the XML file (downloaded from the FactSet OnDemand service) and the SAS data set created when the XML data are read into SAS. You can use the OUTXML= option to name your XML data file, which is placed in the current working directory. By default, OUTXML=FAST, which creates a file named FAST1.xml in the current working directory. The SAS data set created when the XML data are read into SAS is placed in the folder specified by the physical path in the LIBNAME libref SASEXFSD statement.
AUTOMAP=\texttt{fact\_automap}

specifies whether to overwrite the existing XML map file (AUTOMAP=REPLACE) or whether not to overwrite the existing XML map file (AUTOMAP=REUSE). You can set \texttt{fact\_automap} to REUSE so that a pre-existing XML map named by the XMLMAP= option is used. You can set \texttt{fact\_automap} to REPLACE so that the most current XML map generated by the SASEXFSD engine and named by the XMLMAP= option is used.

XMLMAP=\texttt{fact\_xmlmapfile}

specifies the fully qualified name of the file where the XML map is automatically stored.

MAPREF=\texttt{fact\_xmlmapref}

specifies the fileref to be used for the map assignment.

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file. This data is read into SAS and placed in a SAS data set in the folder designated by “physical-name”, and you can reference it by using the myLib libref in your SASEXFSD LIBNAME statement. This is shown in the section “Getting Started: SASEXFSD Interface Engine” on page 3824.

The following FILENAME statement is generated by the SASEXFSD interface engine by using the fileref, MyMap, from the MAPREF=MyMap option and from the fully designated filename in the XMLMAP= option:

\begin{verbatim}
FILENAME MyMap "/sasusr/playpens/saskff/factset/gstart1.map";
\end{verbatim}

FORMAT=\texttt{fact\_xmlformat}

specifies the SAS XML (SML) format, which is the only format that the SASEXFSD engine supports.

ORIENTATION=\texttt{fact\_xmlorient}

specifies the ETI orientation, which is the only orientation that the SASEXFSD engine supports. The ETI orientation means that the data are returned and stored in entity-time-item logical layout.

PROXY="\texttt{fact\_proxyserver}"

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused error or a connection-timed-out error occurs. For \texttt{fact\_proxyserver}, specify the server’s HTTP address followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY="http://inetgw.unx.sas.com:8118". See also the \texttt{CONNECT=} option.

CONNECT=ON | OFF

specifies whether or not to use the connect method along with the PROXY= option. \textbf{Note:} You must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option when you want to use the connect method. For more information about a secure connection, see the PROXY= option.

USERNAME='\texttt{fact\_username}'

specifies the FactSet user name that enables you to access the data provided by the FactSet OnDemand service.
The ExtractEconData Factlet

The ExtractEconData factlet provides access to a broad array of macroeconomic content, interest rates and yields, country indices, and various exchange rate measures from both the FactSet Economics and the Standardized Economic databases. The ExtractEconData factlet uses the options listed in Table 56.10 to extract Economic data items for a list of country IDs or for no country IDs over time.

The DBSOURCE= option specifies a standardized database source name, such as EWIN_ECON, GI_ECON, OECD_MEI, FDS_ECON, FDS_COM, or the default, a null string, which uses the Standardized Economic data (EWIN_ECON_RGDPR_Y). Use the IDS= option to specify one or more country IDs based on the database source. For the complete list of country IDs that work with the standardized codes for the FactSet Economics database, see Table 56.11.

Use the ITEM= option to specify an FQL item based on the database source. You can also use the ITEM= option with the downloading syntax for Economic Request Codes described in the FactSet Online Assistant, page ID 11794, and shown in Example 56.2. Example 56.2 uses the shorthand FQL syntax in the ITEM= option to retrieve the same time series data items.

The SASEXFSD engine supports retrieval of the following FQL_entities: ECON_EXPR_DATA, SPEC_ID_DATA, FDS_ECON_DATA, EIU_ECON_DATA, CNS_ECON_DATA, EURO_STAT_DATA, IBI_NIKKO_DATA, IMF_IFS_DATA, NTCS_ECON_DATA, OECD_OTLK_DATA, OECD_MEI_DATA, ONS_ECON_DATA, TCB_BCI_DATA, TCB_CCI_DATA, CEIC_ECON_DATA, and CEIC_CHINA_DATA.

A FactSet representative can provide you with permissions to access the databases that contain the time series data that you are interested in. For an example of using ECON_EXPR_DATA, see Example 56.3. For more information about using ECON_EXPR_DATA and SPEC_ID_DATA, see the section “Downloading Economic Function Codes to Excel” in the FactSet Online Assistant, page ID 12308. You can replace options such as START=, END=, FREQ=, CONV=, DIST=, NFB=, and FUNCTION= by using the corresponding placement of each option’s value in the FQL downloading syntax. In this example, ITEM="FDS_ECON_DATA('FRBIPSB50001', -121,-1,m,step,average)" gives the database source name (FDS_ECON), time series name (FRBIPSB50001), start and end dates, monthly frequency, distribution (step), and conversion (average); no-feel-back defaults to 1.

For the complete list of the data series codes available with the standardized FactSet Economics database, see the ExtractEconData appendix, linked in the FactSet Online Assistant, page ID 16948. The data are available at monthly, quarterly, and annual frequencies, as denoted by the _M, _Q, and _Y suffixes in the code.

Use the FREQ= option to specify the frequency of the data, and use the DATES= option to specify a date range for selecting time series data. For more information, see the section “Frequency” in the FactSet Online Assistant, page ID 11794.

You can use the CONV= option to specify CONV=SUM, AVERAGE, AVERAGENP, or none (the default is none).

You can use the DIST= option to specify DIST=STEP (step distribution), EVEN, or none (the default).
You can use the NFB= option to specify your no-feel-back setting (0, 1, or 2) to indicate full feel-back, no feel-back (the default), or feel-back until most recent data point, respectively (do not fill in data past the last available data point).

You can use the FUNCTION= option to apply an economic function to the data values of the time series (such as FUNCTION=ZSCORE). For a list of economic functions, see the FactSet Online Assistant, page ID 12308.

The ORIENTATION= option supports only ETI, which is the default.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDS=</td>
<td>Specifies a string array with a list of the country identifiers from the Standardized Economic database</td>
</tr>
<tr>
<td>ITEMS=</td>
<td>Specifies the economic series mnemonic (for example, US GDP database source [mnemonic] is FDS_ECON[BEANIPAA191RL1@US])</td>
</tr>
<tr>
<td>DATES=</td>
<td>Specifies a date string such as 'YYYYMMDD:YYYYMMDD:F' or relative dates '-1b:-4b:m'</td>
</tr>
<tr>
<td>START=</td>
<td>Specifies the numeric start date in 'YYYYMMDD' format</td>
</tr>
<tr>
<td>END=</td>
<td>Specifies the numeric end date in 'YYYYMMDD' format</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies the valid FQL frequencies, such as M, D, W, Q, and Y.</td>
</tr>
<tr>
<td></td>
<td>Note: For economic request codes, a frequency argument is</td>
</tr>
<tr>
<td></td>
<td>necessary to retrieve the data.</td>
</tr>
<tr>
<td>DBSOURCE=</td>
<td>Specifies a standardized database source name, such as EWIN_ECON, GL_ECON, OECD_MEI, FDS_ECON, FDS_COM, or the default, a null string, which uses the Standardized Economic data (EWIN_ECON_RGDPR_Y)</td>
</tr>
<tr>
<td>CONV=</td>
<td>Specifies the conversion technique for aggregating periods, when a data series of a higher frequency is converted to a lower frequency; for example, you can use this option to convert a quarterly series to an annual series (for example, SUM, AVERAGE, or AVERAGENP, which excludes NAs).</td>
</tr>
<tr>
<td>DIST=</td>
<td>Specifies the distribution technique for spreading over periods when a data series of a lower frequency is distributed to a higher frequency; for example, you can use it to distribute an annual series to a quarterly series (such as STEP, EVEN, or NONE).</td>
</tr>
<tr>
<td>NFB=</td>
<td>Specifies the optional “no-feel-back” argument in FQL codes. If you do not specify the NFB= option, the returned data series contains NAs where the data are not available (default is NFB=1). If you want the data to “feel back” over NAs to find the last actual data point and carry these data forward, specify either NFB=0 or NFB=2.</td>
</tr>
<tr>
<td>FUNCTION=</td>
<td>Adds FQL function property to change data value; for example, FUNCTION=ZSCORE</td>
</tr>
<tr>
<td>ORIENTATION=</td>
<td>Specifies an optional orientation (default is ETI, entity-time-item)</td>

</tbody>
</table>
The ExtractFormulaHistory Factlet

The ExtractFormulaHistory factlet is used for extracting one or more items for one security, for an index, or for a list of securities over time. ExtractFormulaHistory uses the FactSet Query Language (FQL). The ExtractFormulaHistory factlet uses the options listed in Table 56.12, such as the IDS= option, which specifies the IDs for one or more securities, or the ISON= and ISONPARAMS= options, which specify an FQL formula that extracts the universe along with any ISON parameters necessary for the ISON code. You can use the START=, END=, and FREQ= options or the DATES= option to specify a date range for selecting time series data. You can select data items by using the ITEMS= option, but only the name/value pairs syntax (not the standard FQL syntax) is supported. The ITEMS= option designates multiple shortcut items or item/statistic combinations. You can use any instance of the Formula Library for the ITEMS= option.

The PERIOD= option is used for FactSet Fundamentals database codes to specify the estimate period of the data that you want to select. The CAL= option enables you to set your calendar in the same way that the PSETCAL function in FQL works. You can specify the CAL= option to be LOCAL, FIVEDAY, FIVEDAYEOM, SEVENDAY, or an exchange code. The list of exchange codes is available in the FactSet Online Assistant, page ID 16610. The ORIENTATION= option is supported only for ETI (entity-time-item), so that your SAS output data set is organized by key entities such as CUSIP or ticker, by date so that observations are kept in time series order, and by item. ETI is the default setting for orientation.

Table 56.12  ExtractFormulaHistory Factlet Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDS=</td>
<td>Specifies one or more securities; for example, IDS=IBM,MSFT,FDS.</td>
</tr>
<tr>
<td>ISON=</td>
<td>Specifies the FQL value that extracts the universe; for example, ISON=SP500 is entered as ISON=SP500, and ISON_MSCI_WORLD(0,1) is written as ISON=MSCI_WORLD.</td>
</tr>
<tr>
<td>ISONPARAMS=</td>
<td>Specifies the ISON codes that use parameters; for example, ISON_MSCI_WORLD(0,1) is written as ISONPARAMS=0,1.</td>
</tr>
<tr>
<td>UNIVERSE=</td>
<td>Specifies the universe.</td>
</tr>
<tr>
<td>DATES=</td>
<td>Specifies a date string such as 'YYYYMMDD:YYYYMMDD:F' or relative dates -1b:-4b:m.</td>
</tr>
<tr>
<td>START=</td>
<td>Specifies a valid FQL date; START=0 is the default.</td>
</tr>
<tr>
<td>END=</td>
<td>Specifies a valid FQL date; END=0 is the default.</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies a valid FQL frequencies; for example, M, D, Y. See Table 56.20.</td>
</tr>
<tr>
<td>ITEMS=</td>
<td>Specifies one or more FQL items (only the name/value pair syntax is supported; for example, ff_sales, p_price).</td>
</tr>
<tr>
<td>PERIOD=</td>
<td>Specifies valid time intervals between the data points (observations) in a time series; for example, ANN, QTR, and SEMI-ANN; PERIOD=ANN is the default.</td>
</tr>
<tr>
<td>ORIENTATION=</td>
<td>Specifies an optional orientation (default is currently ETI).</td>
</tr>
<tr>
<td>CAL=</td>
<td>Specifies the calendar setting that replicates the PSETCAL function; for example, LOCAL, FIVEDAY, FIVEDAYEOM, and SEVENDAY, for exchange code CAL=AAM (for a list of exchange codes, see the FactSet Online Assistant, page ID 16610)</td>
</tr>
</tbody>
</table>
The ExtractDataSnapshot Factlet

The ExtractDataSnapshot factlet is used for efficiently extracting multiple items as of a single date, for a universe of both equity and fixed income securities. It uses the FactSet Screening Language to extract data for a large universe of securities as of a single date. The ExtractDataSnapshot factlet uses the options listed in Table 56.13, such as the IDS= option, which specifies the IDS for one or more securities, or you can specify fixed securities by using the UNIVERSEGROUP= option. If you want to access only current constituents, use the ISON= option to specify your ISON codes instead of using the IDS= option. If your ISON code uses parameters, then use the ISONPARAMS= option to specify the parameters for the code that you use in your ISON= option. Use DATE=YYYYMMDD to specify the day that your snapshot is for, or use the START=, END=, and FREQ= options for the FQL scalar data item date that you are interested in. Use the ITEMS= option to specify one or more screening items. The SASEXFSD engine does not support the standard screening syntax, so use the name/value pair syntax instead. For example, instead of using ITEMS=’FF_SALES(QTR,20110401)’, use ITEMS=’FF_SALES’ PERIOD=QTR REL_DATE=20110401 in your LIBNAME libref SASEXFSD statement. Specify the UNIVERSEGROUP= option to choose between the EQUITY group and the DEBT group. The CAL= option enables you to set your calendar in the same way that the PSETCAL function in FQL works. You can specify the CAL= option to be LOCAL, FIVEDAY, FIVEDAYEOM, SEVENDAY, or an exchange code. The list of exchange codes is available in the FactSet Online Assistant, page ID 16610. The ORIENTATION= option is supported only for ETI (entity-time-item), which is also the default.
### Table 56.13 ExtractDataSnapshot Factlet Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDS=</td>
<td>Specifies one or more securities; for example, IDS='IBM,MSFT'. Fixed securities are used in conjunction with UNIVERSEGROUP=DEBT (for example, IDS=88579EAE).</td>
</tr>
<tr>
<td>ISON=</td>
<td>Specifies a screening code that extracts the universe; for example, ISON_SP500 is entered as ISON=SP500, and ISON_MSCI_WORLD(0,1) is entered as ISON=MSCL_WORLD.</td>
</tr>
<tr>
<td>ISONPARAMS=</td>
<td>Specifies ISON codes that use parameters; for example, ISONPARAMS=0,1.</td>
</tr>
<tr>
<td>DATE=</td>
<td>Specifies one date in the format 'YYYYMMDD' (default is 0B, for today’s date)</td>
</tr>
<tr>
<td>START=</td>
<td>Specifies a valid start date; START=0 is the default.</td>
</tr>
<tr>
<td>END=</td>
<td>Specifies a valid end date; END=0 is the default.</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies a valid frequency; for example, M, D, Y. See Table 56.20.</td>
</tr>
<tr>
<td>ITEMS=</td>
<td>Specifies one or more screening items (only the name/value pair syntax is supported)</td>
</tr>
<tr>
<td>PERIOD=</td>
<td>Specifies a valid time interval between the data points (observations) in a time series; for example, ANN, QTR, SEMI-ANN; PERIOD=ANN is the default.</td>
</tr>
<tr>
<td>UNIVERSEGROUP=</td>
<td>Specifies the universe group. The default value is EQUITY; for DEBT securities, specify UNIVERSEGROUP=DEBT.</td>
</tr>
<tr>
<td>ORIENTATION=</td>
<td>Specifies an optional orientation (default is ETI)</td>
</tr>
<tr>
<td>CAL=</td>
<td>Specifies a calendar setting that replicates the PSETCAL function; for example, LOCAL, FIVEDAY, FIVEDAYEOM, and SEVENDAY, for exchange code CAL=AAM (for a list of exchange codes, refer to the FactSet Online Assistant, page ID 16610)</td>
</tr>
</tbody>
</table>

### The ExtractBenchmarkDetail Factlet

The ExtractBenchmarkDetail factlet is used for retrieving a more comprehensive overview of the index constituent data for a benchmark, without requiring the additional codes and calculations that are needed with the ExtractFormulaHistory factlet. ExtractBenchmarkDetail uses default output in which the identifiers are sorted in descending order by weight in the index, and each row shows the index ID, company ID, date, ticker, and weight. Any additional items are displayed at the end of each row.

The ExtractBenchmarkDetail factlet uses the options that are listed in Table 56.15, such as the IDS= option, which specifies the IDs for one or more benchmarks (indexes). Use DATES='YYYYMMDD:YYYYMMDD:freq' to specify the range of dates in 'start:end:freq' format.

You can designate dates in absolute or relative form, as shown in Table 56.14. Absolute dates specify a day in 'MM/DD/YYYY' format (such as 7/11/1999), a month end in 'MM/YYYY' format (such as 6/1999), a fiscal quarter end in 'YY/FQ' or 'YYY/FQ' format (such as 1999/1F, 2000/3F, or 2001/2F), a calendar quarter end in 'YY/CO' or 'YYYY/CO' format (such as 1999/1C, 00/3C, or 2001/1C), or a fiscal year end in 'YY' or 'YYYY' format (such as 2000, 01, or 1999).
Table 56.14  ExtractBenchmarkDetail Factlet Relative Date Arguments

<table>
<thead>
<tr>
<th>Relative Date Argument</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>D</td>
<td>0D is the most recent trading day; –1D is one trading day prior.</td>
</tr>
<tr>
<td>AW</td>
<td>0AW is the most recent trading day; –1AW is the one actual week (7 days) prior to the most recent trading day.</td>
</tr>
<tr>
<td>W</td>
<td>0W is the last day of the most recent trading week (usually Friday); –1W is the last trading day of the prior week.</td>
</tr>
<tr>
<td>AM</td>
<td>0AM is the most recent trading day; –1AM is the same day, one actual month prior.</td>
</tr>
<tr>
<td>M</td>
<td>0M is the last trading day of the most recent month; –1M is the last trading day of the prior month.</td>
</tr>
<tr>
<td>AQ</td>
<td>0AQ is the most recent trading day; –1AQ is the same day 3 months prior.</td>
</tr>
<tr>
<td>Q</td>
<td>0Q is the last trading day of the company’s most recent fiscal quarter; –1Q is the last day of the prior fiscal quarter.</td>
</tr>
<tr>
<td>CQ</td>
<td>0CQ is the last trading day of the most recent calendar quarter (March, June, September, or December); –1CQ is the last trading day of the prior calendar quarter.</td>
</tr>
<tr>
<td>AY</td>
<td>0AY is the most recent trading day; –1AY is one actual year (365 days) prior.</td>
</tr>
<tr>
<td>Y</td>
<td>0Y is the last trading day of the company’s most recent fiscal year; –1Y is the last trading day of the prior fiscal year.</td>
</tr>
<tr>
<td>CY</td>
<td>0CY is the last trading day of the most recent calendar year (the last trading day in December); –1CY is the last trading day of the prior calendar year.</td>
</tr>
</tbody>
</table>

Use the ITEMS= option to specify one or more screening items, such as p_price or ca_sales. The CUTOFF= option specifies the number of holdings to show. The default is to show all instances. The optional MATCHDATE= option is used to limit the output to not repeat the dates that “feel back” to a holiday. The default behavior (no MATCHDATE= option) repeats the dates that “feel back” to a holiday. The MATCHDATE= option is always used with a frequency argument set to B, which indicates business days. Use MATCHDATE=ON for better response time and to limit the large amount of data being returned. The UNIVERSEGROUPE= option is necessary only when you specify UNIVERSEGROUPE=DEBT. By default, UNIVERSEGROUPE=EQUITY.
Table 56.15 ExtractBenchmarkDetail Factlet Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>IDS=</td>
<td>Specifies one or more benchmarks; for example, IDS=SP50, R.3000</td>
</tr>
<tr>
<td>DATES=</td>
<td>Specifies one or more dates entered in 'start:end:freq' format, '20101215:20100115:d'</td>
</tr>
<tr>
<td>ITEMS=</td>
<td>Specifies one or more screening items (such as ITEMS='p_price, ca_sales'). FQL items are named with a preceding underscore.</td>
</tr>
<tr>
<td>CUTOFF=</td>
<td>Specifies an optional number of holdings to show; default (no cutoff) displays all instances.</td>
</tr>
<tr>
<td>MATCHDATE=</td>
<td>Specifies an optional argument that turns off the default behavior, in which dates are repeated when “feeling back” to a holiday. It is always used with a frequency argument set to B (indicating business days).</td>
</tr>
<tr>
<td>UNIVERSEGROUP=</td>
<td>Specifies the universe group. The default value is EQUITY. For fixed income indices, specify UNIVERSEGROUP=DEBT.</td>
</tr>
</tbody>
</table>

The ExtractOFDBItem Factlet

The ExtractOFDBItem factlet provides access to a list of securities and multiple data items for a range of dates uploaded into a single Open FactSet Database (OFDB). An OFDB is a high-performance multidimensional database system that securely stores proprietary numeric and textual data in FactSet. The ExtractOFDBItem factlet uses the options listed in Table 56.16, such as the OFDB= option, which specifies the OFDB file. Use either the IDS= option, which specifies the IDs for one or more securities, or the ISON= and ISONPARAMS= options, which specify an FQL formula (ISON code) that extracts the universe along with any ISON parameters necessary for the ISON code. Use the ITEMS= option to specify one or more items in the OFDB file. Use the DATES= option to specify a date range in 'YYYYMMDD:YYYYMMDD:freq' format, or use FQL dates when FQLFLAG=Y (yes). By default, FQLFLAG=N (no). The DATESONLY= option specifies whether only the dates in the OFDB file are reported. By default, DATESONLY=N. The ORIENTATION= option supports only ETI, which is the default.
The ExtractOFDBUniverse Factlet

The ExtractOFDBUniverse factlet is used for extracting a list of CUSIPs that belong to a single OFDB file or ISON code. Use the OFDB= option to specify a OFDB file, and use the DATE= option to specify the date for showing the list of CUSIPs.

Table 56.16  ExtractOFDBUniverse Factlet Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OFDB=</td>
<td>Specifies the OFDB file</td>
</tr>
<tr>
<td>IDS=</td>
<td>Specifies one or more securities; for example, IDS=IBM, GM</td>
</tr>
<tr>
<td>ISON=</td>
<td>Specifies the FQL value that extracts the universe; for example, ISON_SP500 is entered as ISON=SP500, and ISON_MSCI_WORLD(0,1) is written as ISON=MSCI_WORLD.</td>
</tr>
<tr>
<td>ISONPARAMS=</td>
<td>Specifies the parameters for the ISON codes that use parameters; for example, ISON_MSCI_WORLD(0,1) is written as ISONPARAMS=0,1.</td>
</tr>
<tr>
<td>ITEMS=</td>
<td>Specifies one or more data items from the OFDB file</td>
</tr>
<tr>
<td>DATES=</td>
<td>Specifies dates in the format 'YYYYMMDD:YYYYMMDD:F' or relative dates in relative format, such as -1b:-4b:m</td>
</tr>
<tr>
<td>DATE=</td>
<td>Specifies one date in the format 'YYYYMMDD' (default is 0B, for today’s date)</td>
</tr>
<tr>
<td>DATESONLY=</td>
<td>Specifies that dates are reported from the OFDB file only when the option is set to Y (default is N)</td>
</tr>
<tr>
<td>FQLFLAG=</td>
<td>Sets dates to use FQL instead of screening; FQLFLAG=N (default) or Y</td>
</tr>
<tr>
<td>ORIENTATION=</td>
<td>Specifies an optional orientation (default is currently ETI)</td>
</tr>
</tbody>
</table>

The ExtractScreenUniverse Factlet

The ExtractScreenUniverse factlet is used for extracting a list of CUSIPs stored in a single FactSet screen. On the FactSet workstation, a user can screen for equity and fixed income securities based on specified criteria and store a list of companies by using FactSet Universal Screening for equity or debt securities. The ExtractScreenUniverse factlet uses the options that are listed in Table 56.18 to extract a list of CUSIPs that belong to a single user-defined screen. Use the SCREEN= option to specify a screen file, and use the NAME= option to specify whether or not to make the names of the corresponding securities visible. Specify NAME=Y (yes) to view the security names for each CUSIP in the screen. NAME=N (no) is the default, for which security names are not shown with the CUSIP list. Because screen filenames can contain blanks and special characters, enclose the screen filename with single quotation marks:

Details: SASEXFSD Interface Engine

FactSet Data and FactSet Sourced Data

The SASEXFSD interface engine enables SAS users to access both FactSet data and FactSet sourced data that are provided by the FactSet OnDemand service. FactSet OnDemand offerings can provide access to many databases. Because the list of available data is constantly changing, Table 56.19 is included for instructional purposes only. Many other data offerings are available that are not shown in Table 56.19.

SAS Output Data Set

You can use the SAS DATA step to write the selected FactSet data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA step, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the BY groups, the date of each observation, and the series name of each series that is read from the FactSet data source.

The SASEXFSD interface engine sorts the IDs into keys or BY groups, so that the time series are sorted in the resulting SAS data set by key (entity identifier such as a ticker), by date (time ID), and by variable (time series item name).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEXFSD libref to create a custom view of your data.
SAS OUTXML File

The SAS XML (SML format) data that are returned from the FactSet OnDemand service are placed in a file named by the OUTXML= option. The SAS XML data are placed in the current working directory. The SAS data set created when the XML data are read into SAS is placed in the location specified by the physical-name in the LIBNAME libref SASEXFSD statement, which is described in the section “The LIBNAME libref SASEXFSD Statement” on page 3828.

SAS XML Map File

The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option in your LIBNAME libref SASEXFSD statement. The XML map file is either reused (not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE. The SASEXFSD interface engine invokes the XMLV2 engine to create the map and to read the data into SAS.

Specifying Date Ranges and Frequency Codes

When you specify a range of dates for selecting your time series observations, you can specify the range in either absolute or relative dates. The absolute start and end dates are given in 'YYYYMMDD' format and separated by a colon (:). The frequency is given along with the date range and can be any one of the codes shown in Table 56.20. The code frequency indicates the frequency with which you want to display data. Relative dates are relative to the most recently updated period (0). A minus sign (as in –1) represents the period prior to the most recently updated period. The zero date is determined by the natural frequency of the time series data, so a 0 for monthly data represents the most recent month end. Annual data use –1 to represent the fiscal year prior to the most recently updated fiscal year.
### Table 56.20  FactSet Frequency Codes

<table>
<thead>
<tr>
<th>Freq. Code</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AD</td>
<td>Displays data on an actual daily basis (that is, all days, not just trading days)</td>
</tr>
<tr>
<td>D</td>
<td>Displays data on a daily basis</td>
</tr>
<tr>
<td>AW</td>
<td>Displays data weekly, based on the day of the week of the start date</td>
</tr>
<tr>
<td>W</td>
<td>Displays data weekly, based on the last day of the completed trading week (usually Friday)</td>
</tr>
<tr>
<td>WTD</td>
<td>For a range item (such as price change), displays the week-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data weekly, based on the last day of the completed trading week (usually Friday).</td>
</tr>
<tr>
<td>AM</td>
<td>Displays data monthly, based on the start date (for example, if the start date is June 16, data are displayed for June 16, May 16, April 16, and so on)</td>
</tr>
<tr>
<td>M</td>
<td>Displays data monthly, based on the last trading day of the month</td>
</tr>
<tr>
<td>MTD</td>
<td>For a range item (such as price change), displays the month-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data monthly, based on the last trading day of the month.</td>
</tr>
<tr>
<td>QTD</td>
<td>For a range item (such as price change), displays the calendar quarter-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data quarterly, based on the last trading day of the quarter.</td>
</tr>
<tr>
<td>CQTD</td>
<td>For a range item (such as price change), displays the calendar quarter-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data quarterly, based on the last trading day of the calendar quarter.</td>
</tr>
<tr>
<td>FQTD</td>
<td>For a range item (such as price change), displays the fiscal quarter-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data quarterly, based on the last trading day of the fiscal quarter.</td>
</tr>
<tr>
<td>AQ</td>
<td>Displays data in three-month periods, based on the start date (for example, if the start date is April 7, data are displayed for April 7, January 7, October 7, July 7, and so on)</td>
</tr>
<tr>
<td>Q</td>
<td>Displays data quarterly, based on the last trading day of the company’s fiscal quarter</td>
</tr>
<tr>
<td>CQ</td>
<td>Displays data quarterly, based on the last trading day of the calendar quarter (March, June, September, or December)</td>
</tr>
<tr>
<td>FSA</td>
<td>Displays data semiannually, based on the last trading day of the fiscal semiannual period</td>
</tr>
<tr>
<td>CSA</td>
<td>Displays data semiannually, based on the last trading day of the calendar semiannual period</td>
</tr>
<tr>
<td>ASA</td>
<td>Displays data in six-month periods, based on the start date (for example, if the start date is June, data are displayed for June, January, June (prior), January (prior), and so on)</td>
</tr>
<tr>
<td>YTD</td>
<td>For a range item (such as price change), displays the calendar year-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data annually, based on the last trading day of the year.</td>
</tr>
<tr>
<td>CYTD</td>
<td>For a range item (such as price change), displays the calendar year-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data annually, based on the last trading day of the calendar year.</td>
</tr>
<tr>
<td>FYTD</td>
<td>For a range item (such as price change), displays the fiscal year-to-date value. For other items, displays the latest daily value. For the remainder of the time series, displays data annually, based on the last trading day of the fiscal year.</td>
</tr>
<tr>
<td>AY</td>
<td>Displays data annually, based on the start date (for example, if the start date is October 31, 1995, data are displayed for October 31, 1995, October 31, 1994, October 31, 1993, and so on)</td>
</tr>
<tr>
<td>Y</td>
<td>Displays data annually, based on the last trading day of the company’s fiscal year</td>
</tr>
<tr>
<td>CY</td>
<td>Displays data annually, based on the last trading day of the calendar year</td>

Example 56.1: Retrieving Standardized Economic Items for Multiple Countries

This example shows how to use the ExtractEconData factlet to retrieve the standardized government debt values, reflecting debt in billions of dollars at year end for the United States and Greece and using the country identifiers CC_US and CC_GR and the standardized FactSet economic code FDS_ECON_GDP_USD_Y.

```sas
options validvarname=any
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Standardized Economic Items for Multiple Countries (US,GR)';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
    debug=on
    factlet=ExtractEconData
    ids='CC_US,CC_GR'
    items='FDS_ECON_GDP_USD_Y'
    dates=''-6:-1:y'
    period=QTR
    format=sml
    outXml=fsdex06
    automap=replace
    mapref=MyMap
    xmlmap="%sysget(FACTSET)fsdex06.map"
    orientation=eti
    user='XXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXX';

data econStnd; set xfsd.fsdex06; run;
proc print data=econStnd; run;
```

**Output 56.1.1** Standardized Economic Items for Multiple Countries (US,GR)

Example 56.2: Retrieving Economic Items by Using the FQL Syntax for Function Z Score

This example shows how to use the ExtractEconData factlet to retrieve the Z score for the GRLM0347861 monthly time series for Greece over the last three years by using the FQL economic download syntax. It is not necessary to use the IDS= option, because all necessary information is contained in the ITEMS= option. The PRINT procedure uses the LABEL option to allow the time series name to be in the column heading in the output. Without the LABEL option, the column heading would be 'ECON_EXPR_DATA'.

```sas
option validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve the Z Score Using ECON_EXPR_DATA for the US CFTNCLOI%ALLNQ100CMEF Series';
libname _all_ clear;

libname xsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractEconData
   items="ECON_EXPR_DATA('ZSCORE(FDS_ECON[GRLM0347861],
                          -5AY,step,average)',0,0/0/-3,m)"
   format=sml
   outXml=fsdecon8z
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdecon8z.map"
   orientation=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data FQLeconFunc; set xsd.fsdecon8z; run;
proc print data=FQLeconFunc(firstobs=1 obs=34) label; run;
```
Example 56.2: Retrieving Economic Items by Using the FQL Syntax for Function Z Score

Output 56.2.1  Z Score Using ECON_EXPR_DATA for the GRLM0347861 Monthly Series for Greece

Retrieve the Z Score Using ECON_EXPR_DATA for the US CFTNCLOI%ALLNQ100CMEF Series

Example 56.3: Using ECON_EXPR_DATA with the FQL Syntax for Function Returns

This example shows how to use the ExtractEconData factlet to retrieve the Returns for the GDPEURNS quarterly time series for Greece over the last 10 years by using the FQL economic download syntax. It is not necessary to use the IDS= option, because the FQL downloading syntax allows '@@GR' to be appended to the series name in the ITEMS= option. The PRINT procedure uses the LABEL option to allow the time series name to be in the column heading in the output. Without the LABEL option, the column heading would be 'ECON_EXPR_DATA'.

```sas
option validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Returns Using ECON_EXPR_DATA for the GDPEURNS@GR Series';
libname _all_ clear;

libname xsf xsasexsf "%sysget(FACTSET)"
    debug=on
    factlet=ExtractEconData
    items="ECON_EXPR_DATA('RETURNS(EURO_STAT[GDPEURNS@GR],-1AQ,4)',0,0/0/-10,q)"
    format=sml
    outXml=fsdecon20
    automap=replace
    xmlmap="%sysget(FACTSET)fsdecon20.map"
    orientation=eti
    user='XXXXXXXXXXXXXXXX'
    pass='XXXXXXXXXXXXXXXX';

data EUROFunc; set xsf.fsdecon20; run;
proc print data=EuroFunc label; run;
```

Example 56.5: Using Multiple Database Sources with the FQL Syntax

This example shows how to use the ExtractEconData factlet and two database sources, FDS_ECON_DATA and EURO_STAT_DATA, to retrieve two time series for the last 11 months by using the FQL economic download syntax. The database source name is prepended to the time series name to retain the integrity of the name of the database source (dbsource). Only the same frequency and same range of observations for multiple series can be requested concurrently.

```sas
option validvarname=any
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Monthly Data from Two Database Sources: FDS_ECON_DATA and EURO_STAT';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
    debug=on
    factlet=ExtractEconData
    items="FDS_ECON_DATA('FRBIPSB50001',-11,-1,M,STEP,AVERAGE,1),
          EURO_STAT_DATA('CONSCONFBAL@EUZ',-11,-1,M)
        format=sml
        outXml=fsdecon17
        automap=replace
        xmlmap="%sysget(FACTSET)fsdecon17.map"
        orientation=eti
        user='XXXXXXXXXXXXXXXX'
        pass='XXXXXXXXXXXXXXXX';

data TwoSources; set xfsd.fsdecon17; run;
proc print data=TwoSources; run;

Example 56.6: Retrieving Price Data for One Company

This simple example shows how to use the ExtractFormulaHistory factlet to retrieve price data for one company (in this case IBM).

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Price Data for IBM';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractFormulaHistory
   ids='ibm'
   items='p_price'
   dates='20110130:20111231:m'
   format=sml
   outXml=fsdex01
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdex01.map"
   orientation=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data recentprice; set xfsd.fsdex01; run;
proc print data=recentprice; run;
```

Output 56.6.1 Price Data for IBM

```

Example 56.7: Retrieving Price and Sales Data for Multiple Companies

This example shows how to use the ExtractFormulaHistory factlet to retrieve several data items for several companies. The data items are price and sales, and the companies are IBM and FactSet (FDS).

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Price and Sales Data for IBM and FactSet (FDS)';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractFormulaHistory
   ids='ibm,fds'
   items='p_price,ff_sales'
   dates='20110130:20110631:m'
   format=sml
   outXml=fsdex02
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdex02.map"
   orientation=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data priceSale; set xfsd.fsdex02; run;
proc print data=priceSale; run;
```

### Output 56.7.1  Multiple Data Items for IBM and FactSet

Example 56.8: Retrieving Book Value Data for One Company by Using Relative Dates

This example shows how to use the ExtractFormulaHistory factlet to retrieve book value data for one company (in this case Exxon Mobil, or XOM) by using relative dates. The book value represents the proportional common equity divided by outstanding shares at the end of the company’s fiscal year. The relative date specifies the date as \( n \) periods ago based on the frequency (specified or implied); for example, \( \text{DATES}=0:-8:y \) returns data for the nine years prior to the most recently updated year.

```sas
options validvarname=any
  sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Book Value Data for Exxon Mobil (XOM) for the Last 9 Years';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
  debug=on
  factlet=ExtractFormulaHistory
  ids='xom'
  items='ff_bps'
  dates='0:-8:y'
  format=sml
  outXml=fsdex03
  automap=replace
  mapref=MyMap
  xmlmap="%sysget(FACTSET)fsdex03.map"
  orientation=eti
  user='XXXXXXXXXXXXXXXX'
  pass='XXXXXXXXXXXXXXXX';

data bookRelative; set xfsd.fsdex03; run;
proc print data=bookRelative; run;
```

**Output 56.8.1** Book Value Data for Exxon Mobil for the Last 9 Years

<table>
<thead>
<tr>
<th>Obs</th>
<th>FQL_Entity</th>
<th>date</th>
<th>ff_bps</th>
</tr>
</thead>
<tbody>

</tr>
<tr>
<td>2</td>
<td>msft</td>
<td>04-01-2011</td>
<td>25.480</td>
<td>16428</td>
</tr>
</tbody>
</table>
Example 56.10: Retrieving Data by Using the ISON= and ISONPARAMS= Options

This example shows how to use the ExtractDataSnapshot factlet to retrieve price-to-earnings (PE) data for the quarterly estimate period by using the ISON= and ISONPARAMS= options. For brevity, only a subset of the output (the first 10 CUSIPs) is displayed.

```sas
options validvarname=any
   sslcafile="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem"

title 'Retrieve Price-to-Earnings Data by Using ISON/ISONPARAMS';
libname _all_ clear;
libname xfsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractDataSnapshot
   ison='sp500'
   isonparams='0,1'
   items='ff_pe'
   dates='20110401'
   period=QTR
   format=sml
   outXml=fsdex10
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdex10.map"
   orientation=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data snapIson; set xfsd.fsdex10; run;
proc print data=snapIson(firstobs=1 obs=10); run;
```

Output 56.10.1  Retrieving Price-to-Earnings Data by Using the ISON= and ISONPARAMS= Options

<table>
<thead>
<tr>
<th>Obs</th>
<th>FQL_Entity</th>
<th>date</th>
<th>ff_pe</th>
</tr>
</thead>
<tbody>
<tr>

</tr>
<tr>
<td>7</td>
<td>00130H10</td>
<td>04-01-2011</td>
<td>.</td>
</tr>
<tr>
<td>8</td>
<td>31190010</td>
<td>04-01-2011</td>
<td>33.0765</td>
</tr>
<tr>
<td>9</td>
<td>20911510</td>
<td>04-01-2011</td>
<td>13.5979</td>
</tr>
<tr>
<td>10</td>
<td>53983010</td>
<td>04-01-2011</td>
<td>10.0212</td>
</tr>
</tbody>
</table>
Example 56.11: Retrieving Benchmark Data by Using the CUTOFF= Option

This example shows how to use the ExtractBenchmarkDetail factlet to retrieve the holdings for the Standard & Poor’s (S&P) 500 (ID='sp50') and display the P_PRICE data that correspond to each holding. For brevity, only a subset of the output (the first 10 holdings) is displayed.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Benchmark Data for Top Ten Holdings, CUTOFF=10';
libname _all_ clear;

libname fsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractBenchmarkDetail
   ids='sp50'
   items='p_price,proper_name'
   dates='20130320'
   cutoff=10
   format=sml
   outXml=fsdex12
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdex12.map"
   orientation=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data bench;
   set fsd.fsdex12;
run;
proc print
   data=bench;
run;
```

The CUTOFF= option limits the output to the number of holdings that are specified. This example uses CUTOFF=10 to print the top 10 holdings. If you omit the CUTOFF= option, all 500 holdings are reported.
### Output 56.11.1  continued

Example 56.12: Retrieving Benchmark Data by Using the MATCHDATE= Option

This example shows how to use the ExtractBenchmarkDetail factlet to retrieve data from the Prices database for the Russell 1000 constituents (R.1000).

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Benchmark Data for R.1000 with MATCHDATE=ON';
libname _all_ clear;

libname fsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractBenchmarkDetail
   ids='r.1000'
   items='p_price'
   dates='20120118:20120113:b'
   matchDate=on
   format=sml
   outXml=fsdex13
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdex13.map"
   orientation=eti
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data benchmatch;
   set fsd.fsdex13;
run;
proc print
   data=benchmatch(firstobs=1 obs=50);
run;
```

If the frequency argument were not set to B (indicating business days) and the MATCHDATE= option were not turned on, the output would contain repetitive dates because of feel-back, resulting in unnecessarily lengthy output.
Output 56.12.1  Retrieving Benchmark Data for the Russell 1000 Index by Using the MATCHDATE=ON Option

Example 56.14: Retrieving a List of Securities from an OFDB File

This example shows how to use the ExtractOFDBUniverse factlet to retrieve a list of securities that belong to a single OFDB file named SASTESTING for February 27, 2012. For brevity, only a subset of the output (the first 15 securities) is displayed.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve List of Securities Belonging to a Single OFDB File';
libname _all_ clear;

libname xfsd sasexfsd "%sysget(FACTSET)"
   debug=on
   factlet=ExtractOFDBUniverse
   ofdb='SASTESTING.OFDB'
   dates='20120227'
   format=sml
   outXml=fsdex08
   automap=replace
   mapref=MyMap
   xmlmap="%sysget(FACTSET)fsdex08.map"
   user='XXXXXXXXXXXXXXXX'
   pass='XXXXXXXXXXXXXXXX';

data ofdbUniv; set xfsd.fsdex08; run;
proc print data=ofdbUniv(firstobs=1 obs=15); run;
```

Output 56.14.1 List of Securities from a Single OFDB File

Part IV

Time Series Forecasting System
Introduction

The Time Series Forecasting system forecasts future values of time series variables by extrapolating trends and patterns in the past values of the series or by extrapolating the effect of other variables on the series. The system provides convenient point-and-click windows to control the time series analysis and forecasting tools of SAS/ETS software.

You can use the system in a fully automatic mode, or you can use the system’s diagnostic features and time series modeling tools interactively to develop forecasting models customized to best predict your time series. The system provides both graphical and statistical features to help you choose the best forecasting method for each series.

The following is a brief summary of the features of the Time Series Forecasting system. You can use the system in the following ways:

- use a wide variety of forecasting methods, including several kinds of exponential smoothing models, Winters method, and ARIMA (Box-Jenkins) models. You can also produce forecasts by combining the forecasts from several models.
- use predictor variables in forecasting models. Forecasting models can include time trend curves, regressors, intervention effects (dummy variables), adjustments you specify, and dynamic regression (transfer function) models.
- view plots of the data, predicted versus actual values, prediction errors, and forecasts with confidence limits, as well as autocorrelations and results of white noise and stationarity tests. Any of these plots can be zoomed and can represent raw or transformed series.
- use hold-out samples to select the best forecasting method
- compare goodness-of-fit measures for any two forecasting models side by side or list all models sorted by a particular fit statistic
• view the predictions and errors for each model in a spreadsheet or compare the fit of any two models in a spreadsheet

• examine the fitted parameters of each forecasting model and their statistical significance

• control the automatic model selection process: the set of forecasting models considered, the goodness-of-fit measure used to select the best model, and the time period used to fit and evaluate models

• customize the system by adding forecasting models for the automatic model selection process and for point-and-click manual selection

• save your work in a project catalog

• print an audit trail of the forecasting process

• show source statements for PROC ARIMA code

• save and print system output including spreadsheets and graphs

---

**Using the Time Series Forecasting System**

Chapters starting from Chapter 58, “Getting Started with Time Series Forecasting,” through Chapter 62, “Using Predictor Variables,” contain a series of example sessions that show the major features of the system. Chapters from Chapter 63, “Command Reference,” through Chapter 65, “Forecasting Process Details,” serve as reference and provide more details about how the system operates. The reference chapters contain a complete list of system features.

To get started using the Time Series Forecasting system, it is a good idea to work through a few of the example sessions. Start with Chapter 58, “Getting Started with Time Series Forecasting,” and use the system to reproduce the steps shown in the examples. Continue with the other chapters when you feel comfortable using the system.

The example sessions make use of time series data sets contained in the SASHELP library: air, citimon, citiqr, citiyr, citiwk, citiday, gnp, retail, usecon, and workers. You can use these data sets to work through the example sessions or to experiment further with the system.

Once you are familiar with how the system operates, start working with your own data to build your own forecasting models. When you have questions, consult the reference chapters mentioned above for more information about particular features.

The Time Series Forecasting system forecasts time series, that is, variables that consist of ordered observations taken at regular intervals over time. Since the Time Series Forecasting system is a part of the SAS software system, time series values must be stored as variables in a SAS data set or data view, with the observations representing the time periods. The data can also be stored in an external spreadsheet or data base if you license SAS/ACCESS software.

The Time Series Forecasting System chapters refer to series and variables. Since time series are stored as variables in SAS data sets or data views, these terms are used interchangeably. However, the term series is preferred when attention is focused on the sequence of data values, and the term variable is preferred when attention is focused on the data set.
The Time Series Forecasting system is part of SAS/ETS software. To use it, you must have a license for SAS/ETS. To use the graphical display features of the system, you must also license SAS/GRAPH software.

This chapter outlines the forecasting process and introduces the major windows of the system through three example sessions.

The first example, beginning with the section “The Time Series Forecasting Window” on page 3878, shows how to use the system for fully automated forecasting of a set of time series. This example also introduces the system’s features for viewing data and forecasts through tables and interactive graphs. It also shows how to save and restore forecasting work in SAS catalogs.

The second example, beginning with the section “Develop Models Window” on page 3910, introduces the features for developing the best forecasting models for individual time series. The chapter concludes with an example showing how to create dating variables for your data in the form expected by the system.

After working through the examples in this chapter, you should be able to do the following:

- select a data set of time series to work with and specify its periodicity and time ID variable
- use the automatic forecasting model selection feature to create forecasting models for the variables in a data set
- produce and save forecasts of variables in a data set
- examine your data and forecasts as tables of values and through interactive graphs
- save and restore your forecasting models by using project files in a SAS catalog and edit project information
- use some of the model development features to fit and select forecasting models for individual time series variables

This chapter introduces these topics and helps you get started using the system. Later chapters present these topics in greater detail and document more advanced features and options.

---

**The Time Series Forecasting Window**

There are several ways to get to the Time Series Forecasting System. If you prefer to use commands, invoke the system by entering `forecast` on the command line. You can optionally specify additional information on the command line; for more information, see Chapter 63, “Command Reference.”

If you are using the SAS windowing environment with pull-down menus, select the Solutions menu from the menu bar, select the Analysis item, and then select `Time Series Forecasting System`, as shown in Figure 58.1.
You can invoke the Forecasting System from the SAS Explorer window by opening an existing forecasting project. By default these projects are stored in the FMSPROJ catalog in the SASUSER library. Select SASUSER in the Explorer to display its contents. Then select FMSPROJ. This catalog is created the first time you use the Forecasting System. If you have saved projects, they appear in the Explorer with the forecasting graph icon, as shown in Figure 58.2. Double-click one of the projects, or select it with the right mouse button and then select Open from the pop-up menu, as shown in the figure. This opens the Forecasting System and opens the selected project.
To invoke the Forecasting System in the SAS desktop environment, select the Solutions menu from the menu bar, select Desktop, and then open the Analysis folder. You can run the Time Series Forecasting System or the Time Series Viewer directly, or you can drag and drop. Figure 58.3 illustrates dragging a data set (known as a table in the Desktop environment) and dropping it on the Forecasting icon. In this example, the tables reside in a user-defined folder called Time Series Data.
If you are using SAS/ASSIST software, click the Planning button and then select Forecasting from the pop-up menu.

Any of these methods takes you to the Time Series Forecasting window, as shown in Figure 58.4.
At the top of the window is a data selection area for specifying a project file and the input data set containing historical data (the known past values) for the time series variables that you want to forecast. This area also contains buttons for opening viewers to explore your input data either graphically, one series at a time, or as a table, one data set at a time.

The Project and Description fields are used to specify a project file for saving and restoring forecasting models created by the system. Using project files is discussed later, and these fields are ignored for now.

The lower part of the window contains six buttons:

Develop Models
opens the Develop Models window, which you use to develop and fit forecasting models interactively for individual time series.

Fit Models Automatically
opens the Automatic Model Fitting window, which you use to search automatically for the best forecasting model for multiple series in the input data set.

Produce Forecasts
opens the Produce Forecasts window, which you use to compute forecasts for all the variables in the input data set for which forecasting models have been fit.
Manage Projects opens the Manage Forecasting Project window, which lists the time series for which you have fit forecasting models. You can drill down on a series to see the models that have been fit. You can delete series or models from the project, re-evaluate or refit models, and explore models and forecasts graphically or in tabular form.

Exit exits the Forecasting System.

Help displays information about the Forecasting System.

---

Outline of the Forecasting Process

The examples shown in the following sections illustrate the basic process you use with the Forecasting System.

Specify the Input Data Set

Suppose you have a number of time series, variables recorded over time, for which you want to forecast future values. The past values of these time series are stored as variables in a SAS data set or data view. The observations of this data set correspond to regular time periods, such as days, weeks, or months. The first step in the forecasting process is to tell the system to use this data set by setting the Data Set field.

If your time series are not in a SAS data set, you must provide a way for the SAS System to access the data. You can use SAS features to read your data into a SAS data set; see SAS Language Reference: Concepts. You can use a SAS/ACCESS product to establish a view of data in a database management system; refer to SAS/ACCESS documentation. You can use PROC SQL to create a SAS data view. You can use PROC DATASOURCE to read data from files supplied by supported data vendors; for more information, see Chapter 12, “The DATASOURCE Procedure.”

Provide a Valid Time ID Variable

To use the Forecasting System, your data set must be dated: the data set must contain a time ID variable that gives the date of each observation. The time ID variable must represent the observation dates with SAS date values or with SAS datetime values (for hourly data or other frequencies less than a day), or you can use a simple time index.

When SAS date values are used, the ID variable contains dates within the time periods corresponding to the observations. For example, for monthly data, the values for the time ID variable can be the date of the first day of the month corresponding to each observation, or the time ID variable can contain the date of the last day in the month. (Any date within the period serves as the time ID for the observation.)

If your data set already contains a valid time ID variable with SAS date or datetime values, the next step is to specify this time ID variable in the Time ID field. If the time ID variable is named DATE, the system fills in the Time ID field automatically.
If your data set does not contain a time ID, you must add a valid time ID variable before beginning the forecasting process. The Forecasting System provides features that make this easy to do. For more information, see Chapter 59, “Creating Time ID Variables.”

**Select and Fit a Forecasting Model for Each Series**

If you are using the automated model selection feature, the system performs this step for you and chooses a forecasting model for each series automatically. All you need to do is click the Fit Models Automatically button and then select the variables to fit models for.

If you want more control over forecasting model selection, you can click the Develop Models button, select the series you want to forecast, and use the Develop Models window to specify a forecasting model. As part of this process, you can use the Time Series Viewer and Model Viewer graphical tools. Once you have selected a model for the first series, you can select a different series to work with and repeat the model development process until you have created forecasting models for all the series you want to forecast.

The system provides many features to help you choose the best forecasting model for each series. The features of the Develop Models window and graphical viewer tools are introduced in later sections.

**Produce the Forecasts**

Once a forecasting model has been fit for each series, click the Produce Forecasts button and use the Produce Forecasts window to compute forecast values and store them in a SAS data set.

**Save Your Work**

If you want only a single forecast, your task is now complete. But you might want to produce updated forecasts later, as more data becomes available. In this case, you want to save the forecasting models you have created, so that you do not need to repeat the model selection and fitting process.

To save your work, fill in the Project field with the name of a SAS catalog member in which the system will store the model information when you exit the system. Later, you will select the same catalog member name when you first enter the Forecasting System, and the model information will be reloaded.

Note that any number of people can work with the same project file. If you are working on a forecasting project as part of a team, you should take care to avoid conflicting updates to the project file by different team members.

**Summary**

This is the basic outline of how the Forecasting System works. The system offers many other features and options that you might need to use (for example, the time range of the data used to fit models and how far into the future to forecast). These options will become apparent as you work with the Forecasting System.

As an introductory example, the following sections use the Automatic Model Fitting and Produce Forecasts windows to perform automated forecasting of the series in an example data set.
The Input Data Set

As the first step, you must specify the input data set.

The Data Set field in the Time Series Forecasting window gives the name of the input data set containing the time series to forecast. Initially, this field is blank. You can specify the input data set by typing the data set name in this field. Alternatively, you can click the Browse button at the right of the Data Set field to select the data set from a list, as shown in the following section.

The Data Set Selection Window

Click the Browse button to the right of the Data Set field. This opens the Data Set Selection window, as shown in Figure 58.5.

![Figure 58.5 Data Set Selection Window](image)

The Libraries list shows the SAS librefs that are currently allocated in your SAS session. Initially, the SASUSER library is selected, and the SAS Data Sets list shows the data sets available in your SASUSER library.
In the Libraries list, select the row that starts with SASHELP. The Data Set Selection window now lists the data sets in the SASHELP library, as shown in Figure 58.6.

**Figure 58.6 SASHELP Library**

Use the vertical scroll bar on the SAS Data Sets list to scroll down the list until the data set CITIQTR appears. Then select the CITIQTR row. This selects the data set SASHELP.CITIQTR as the input data set. Figure 58.7 shows the Data Set Selection window after selection of CITIQTR from the SAS Data Sets list.
Note that the Time ID field is now set to DATE and the Interval field is set to QTR. These fields are explained in the following section.

Now click the OK button to complete selection of the CITIQTR data set. This closes the Data Set Selection window and returns you to the Time Series Forecasting window, as shown in Figure 58.8.
Time Series Data Sets, ID Variables, and Time Intervals

Before you continue with the example, it is worthwhile to consider how the system determined the values for the Time ID and Interval fields in the Data Set Selection window.

The Forecasting System requires that the input data set contain time series observations, with one observation for each time period. The observations must be sorted in increasing time order, and there must be no gaps in the sequence of observations. The time period of each observation must be identified by an ID variable, which is shown in the Time ID field.
If the data set contains a variable named DATE, TIME, or DATETIME, the system assumes that this variable is the SAS date or datetime valued ID variable, and the Time ID field is filled in automatically. The time ID variable for the SASHELP:CI1IQTR data set is named DATE, and therefore the system sets the Time ID field to DATE.

If the time ID variable for a data set is not named DATE, TIME, or DATETIME, you must specify the time ID variable name. You can specify the time ID variable either by typing the ID variable name in the Time ID field or by clicking the Select button.

If your data set does not contain a time ID variable with SAS date values, you can add a time ID variable using one of the windows described in Chapter 59, “Creating Time ID Variables.”

Once the time ID variable is known, the Forecasting System examines the ID values to determine the time interval between observations. The data set SASHELP:CI1IQTR contains quarterly observations. Therefore, the system determined that the data have a quarterly interval, and set the Interval field to QTR.

If the system cannot determine the data frequency from the values of the time ID variable, you must specify the time interval between observations. You can specify the time interval by using the Interval combo box. In addition to the interval names provided in the pop-up list, you can type in more complex interval names to specify an interval that is a multiple of other intervals or that has date values in the middle of the interval (such as monthly data with time ID values falling on the 10th day of the month).

For more information about time intervals, SAS date values, and ID variables for time series data sets, see Chapter 3, “Working with Time Series Data,” and Chapter 4, “Date Intervals, Formats, and Functions.”

---

**Automatic Model Fitting Window**

Before you can produce forecasts, you must fit forecasting models to the time series. Click the Fit Models Automatically button. This opens the Automatic Model Fitting window, as shown in Figure 58.9.
The first part of the Automatic Model Fitting window confirms the project filename and the input data set name.

The Series to Process field shows the number and lists the names of the variables in the input data set to which the Automatic Model Fitting process will be applied. By default, all numeric variables (except the time ID variable) are processed. However, you can specify that models be generated for only a select subset of these variables.

Click the Select button to the right of the Series to Process field. This opens the Series to Process window, as shown in Figure 58.10.
Use the mouse and the CTRL key to select the personal consumption expenditures series (GC), the personal consumption expenditures for durable goods series (GCD), and the disposable personal income series (GYD), as shown in Figure 58.11. (Remember to hold down the CTRL key as you make the selections; otherwise, selecting a second series will deselect the first.)
Now click the OK button. This returns you to the Automatic Model Fitting window. The Series to Process field now shows the selected variables.

The Selection Criterion field shows the goodness-of-fit measure that the Forecasting System will use to select the best fitting model for each series. By default, the selection criterion is the root mean squared error. To illustrate how you can control the selection criterion, this example uses the mean absolute percent error to select the best fitting models.

Click the Select button to the right of the Selection Criterion field. This opens a list of statistics of fit, as shown in Figure 58.12.
Select Mean Absolute Percent Error and then click the OK button. The Automatic Model Fitting window now appears as shown in Figure 58.13.
Now that all the options are set appropriately, click the Run button.

The Forecasting System now displays a notice, shown in Figure 58.14, confirming that models will be fit for three series using the automatic forecasting model search feature. This prompt is displayed because it is possible to fit models for a large number of series at once, which might take a lot of time. So the system gives you a chance to cancel if you accidentally ask to fit models for more series than you intended. Click the OK button.
The system now fits several forecasting models to each of the three series you selected. While the models are being fit, the Forecasting System displays notices indicating what it is doing so that you can observe its progress, as shown in Figure 58.15.
For each series, the system saves the model that produces the smallest mean absolute percent error. You can have the system save all the models fit by selecting Automatic Fit from the Options menu.

After the Automatic Model Fitting process has completed, the results are displayed in the Automatic Model Fitting Results window, as shown in Figure 58.16.
This resizable window shows the list of series names and descriptive labels for the forecasting models chosen for them, as well as the values of the model selection criterion and other statistics of fit. Click the Close button.

This returns you to the Automatic Model Fitting window. You can now fit models for other series in this data set or change to a different data set and fit models for series in the new data set.

Click the Close button to return to the Time Series Forecasting window.

**Produce Forecasts Window**

Now that you have forecasting models for these three series, you are ready to produce forecasts. Click the Produce Forecasts button. This opens the Produce Forecasts window, as shown in Figure 58.17.
The Produce Forecasts window shows the input data set information and indicates the variables in the input data set for which forecasting models exist. Forecasts will be produced for these series. If you want to produce forecasts for only some of these series, use the Select button at the right of the Series field to select the series to forecast. The Data Set field in the Forecast Output box contains the name of the SAS data set in which the system will store the forecasts. The default output data set is WORK.FORECAST.

You can set the forecast horizon by using the controls on the line labeled Horizon. The default horizon is 12 periods. You can change it by specifying the number of periods, number of years, or the date of the last forecast period. Position the cursor in the date field and change the forecast ending date to 1 January 1996 by typing jan1996 and pressing the ENTER key.

The window now appears as shown in Figure 58.18.
Now click the Run button to produce the forecasts. The system indicates that the forecasts have been stored in the output data set. Select OK to dismiss the notice.

The Forecast Data Set

The Forecasting System can save the forecasts to a SAS data set in three different formats. Depending on your needs, you might find one of these output formats more convenient. The output data set format is controlled by the Format combo box. You can select the following output formats. The simple format is the default.

**Simple**

The data set contains time ID variables and the forecast variables, and it contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.

**Interleaved**

The data set contains time ID variables, the variable TYPE, and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the TYPE variable.
The data set contains the variable SERIES, time ID variables, and the variables ACTUAL, PREDICT, ERROR, UPPER, LOWER, and STD. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

### Simple Format Forecast Data Set

To see the simple format forecast data set that the system created, click the Output button. This opens a VIEWTABLE window to display the data set, as shown in Figure 58.19.

**Figure 58.19** Forecast Data Set—Simple Format

Figure 58.19 shows the default simple format. This form of the forecast data set contains time ID variables and the variables that you forecast. The forecast variables contain actual values or predicted values, depending on whether the date of the observation is within the range of data supplied in the input data set.

Select File and Close to close the VIEWTABLE window.
Interleaved Format Forecast Data Set

From the Produce Forecasts window, use the list to select the Interleaved format, as shown in Figure 58.20.

Figure 58.20  Forecast Data Set Options

Now click the Run button again. The system presents a warning notice reminding you that the data set WORK.FORECAST already exists and asking if you want to replace it. Select Replace.

The forecasts are stored in the data set WORK.FORECAST again, this time in the Interleaved format. Dismiss the notice that the forecast was stored.

Now click the Output button again. This opens a VIEWTABLE window to display the data set, as shown in Figure 58.21.
Figure 58.21 Forecast Data Set—Interleaved Format

In the interleaved format, there are several output observations for each input observation, identified by the TYPE variable. The values of the forecast variables for observations with different TYPE values are as follows:

**ACTUAL**
actual values copied from the input data set

**ERROR**
the difference between the actual and predicted values

**LOWER**
the lower confidence limits

**PREDICT**
the predicted values from the forecasting model. These are within-sample, one-step-ahead predictions for observations within the historical period, or multistep predictions for observations within the forecast period.

**STD**
the estimated standard deviations of the prediction errors

**UPPER**
the upper confidence limits

Select **File** and **Close** to close the VIEWTABLE window.
Concatenated Format Forecast Data Set

Use the list to select the Concatenated format. Create the forecast data set again, and then click the Output button.

The VIEWTABLE window showing the concatenated format of the forecast data set appears, as shown in Figure 58.22.

Figure 58.22 Forecast Data Set—Concatenated Format

This completes the example of how to use the Produce Forecasts window. Select File and Close to close the VIEWTABLE window. Click the Close button to return to the Time Series Forecasting window.

Forecasting Projects

The system collects all the forecasting models you create, together with the options you set, into a package called a forecasting project. You can save this information in a SAS catalog entry and restore your work in later forecasting sessions. You can store any number of forecasting projects under different catalog entry names.
To see how this works, click the Manage Projects button. This opens the Manage Forecasting Project window, as shown in Figure 58.23.

**Figure 58.23** Manage Forecasting Project Window

The table in this window lists the series for which forecasting models have been fit, and it shows for each series the forecasting model used to produce the forecasts. This window provides several features that allow you to manage the information in your forecasting project.

You can select a row of the table to drill down to the list of models fit to the series. Select the GYD row of the table, either by double-clicking with the mouse or by clicking once to highlight the table row and then selecting List Models from the toolbar or from the Tools menu. This opens the Model List window for this series, as shown in Figure 58.24.
Because the Automatic Model Fitting process kept only the best fitting model, only one model appears in the model list. You can fit and retain any number of models for each series, and all the models fit and kept will appear in the series’ model list.

Select Close from the toolbar or from the File menu to return to the Manage Forecasting Project window.

**Saving and Restoring Project Information**

To illustrate how you can save your work between sessions, in this section you will exit and then re-enter the Forecasting System.

From the Manage Forecasting Project window, select File and Save as. This opens the Forecasting Project to Save window. In the Project Name field, type the name WORK.TEST.TESTPROJ. In the Description field, type “Test of forecasting project file.” The window should now appear as shown in Figure 58.25.
Figure 58.25 Project to Save Name and Description

Click the OK button. This returns you to the Project Management window and displays a message indicating that the project was saved.

Select Close from the toolbar or from the File menu to return to the Time Series Forecasting window. Now click the Exit button. The system asks if you are sure you want to exit the system; select Yes. The forecasting application now terminates.

Open the forecasting application again. A new project name is displayed by default.

Now restore the forecasting project you saved previously. Click the Browse button to the right of the Project field. This opens the Forecasting Project File Selection window, as shown in Figure 58.26.
Select the WORK library from the Libraries list. The Catalogs list now shows all the SAS catalogs in the WORK library.

Select the TEST catalog. The Projects list now shows the list of forecasting projects in the catalog TEST. So far, you have created only one project file, TESTPROJ; so TESTPROJ is the only entry in the Projects list, as shown in Figure 58.27.
Select TESTPROJ from the Projects list and then click the OK button. This returns you to the Time Series Forecasting window.

The system loads the project information you saved in TESTPROJ and displays a message indicating this. The Project field is now set to WORK.TEST.TESTPROJ, and the description is the description you previously gave to TESTPROJ, as shown in Figure 58.28.
If you now click the Manage Projects button, you will see the list of series and forecasting models you created in the previous forecasting session.

**Sharing Projects**

If you plan to work with others on a forecasting project, you might need to consider how project information can be shared. The series, models, and results of your project are stored in a forecasting project (FMSPROJ) catalog entry in the location you specify, as illustrated in the previous section. You need only read access to the catalog to work with it, but you must have write access to save the project. Multiple users cannot open a project for update at the same time, but they can do so at different times if they all have write access to the catalog where it is stored.

Project options settings such as the *model selection criterion* and *number of models to keep* are stored in an SLIST catalog entry in the SASUSER or TSFSUSER library. Write access to this catalog is required. If you have only read access to the SASUSER library, you can use the -RSASUSER option when starting SAS. You will be prompted for a location for the TSFSUSER library, if it is not already assigned. If you want to use TSFSUSER routinely, assign it before you start the Time Series Forecasting System. Select New from the SAS Explorer file menu. In the New Library window, type TSFSUSER for the name. Click the Browse
button and select the directory or folder you want to use. Turn on the *enable at startup* option so this library will be assigned automatically in subsequent sessions.

The SASUSER library is typically used for private settings saved by individual users. This is the default location for project options. If a work group shares a single options catalog (SASUSER or TSFSUSER points to the same location for all users), then only one user can use the system at a time.

---

**Develop Models Window**

In the first forecasting example, you used the Automatic Model Fitting window to fit and select the forecasting model for each series automatically. In addition to this automatic forecasting process, you can also work with time series one at a time to fit forecasting models and apply your own judgment to choose the best forecasting model for each series.

Using the Automatic Model Fitting feature, the system acts like a “black box.” This section goes inside the black box to look at the kinds of forecasting methods that the system provides and introduces some of the tools the system offers to help you find the best forecasting model.

---

**Introduction**

From the Time Series Forecasting window, click the Browse button to the right of the Data Set field to open the Data Set Selection window. Select the USECON data set from the SASHELP library. This data set contains monthly data on the U.S. economy.

Click OK to close the selection window. Now click the Develop Models button. This opens the Series Selection window, as shown in Figure 58.29. You can enlarge this window for easier viewing of lists of data sets and series.
Select the series CHEMICAL: Sales of Chemicals and Allied Products, and then click the OK button.

This opens the Develop Models window, as shown in Figure 58.30.
The Data Set, Interval, and Series fields in the upper part of the Develop Models window indicate the series with which you are currently working. You can change the settings of these fields by clicking the Browse button.

The Data Range, Fit Range, and Evaluation Range fields show the time period over which data are available for the current series, and what parts of that time period are used to fit forecasting models to the series and to evaluate how well the models fit the data. You can change the settings of these fields by clicking the Set Ranges button.

The bottom part of the Develop Models window consists of a table of forecasting models fit to the series. Initially, the list is empty, as indicated by the message “No models.” You can fit any number of forecasting models to each series and designate which one you want to use to produce forecasts.

Graphical tools are available for exploring time series and fitted models. The two icons below the Browse button access the Time Series Viewer and the Model Viewer.

Select the left icon. This opens the Time Series Viewer window, as shown in Figure 58.31.
The Time Series Viewer displays a plot of the CHEMICAL series. The Time Series Viewer offers many useful features, which are explored in later sections.

The Time Series Viewer appears in a separate resizable window. You can switch back and forth between the Time Series Viewer window and other windows. For now, return to the Develop Models window. You can close the Time Series Viewer window or leave it open. (To close the Time Series Viewer window, select Close from the toolbar or from the File menu.)

**Fitting Models**

To open a menu of model fitting choices, select Edit from the menu bar and then select Fit Model, or select Fit Models from List in the toolbar, or simply select a blank line in the table as shown in Figure 58.32.
Chapter 58: Getting Started with Time Series Forecasting

Figure 58.32 Menu of Model Fitting Choices

The Forecasting System provides several ways to specify forecasting models. The eight choices given by the menu shown in Figure 58.32 are as follows:

- **Fit Models Automatically**
  performs for the current series the same automatic model selection process that the Automatic Model Fitting window applies to a set of series.

- **Fit Models from List**
  presents a list of commonly used forecasting models for convenient point-and-click selection.
Fit Smoothing Model

displays the Smoothing Model Specification window, which enables you to specify several kinds of exponential smoothing and Winters method forecasting models.

Fit ARIMA Model

displays the ARIMA Model Specification window, which enables you to specify many kinds of autoregressive integrated moving average (ARIMA) models, including seasonal ARIMA models and ARIMA models with regressors, transfer functions, and other predictors.

Fit Factored ARIMA Model

displays the Factored ARIMA Model Specification window, which enables you to specify more general ARIMA models, including subset models and models with unusual and/or multiple seasonal cycles. It also supports regressors, transfer functions, and other predictors.

Fit Custom Model

displays the Custom Model Specification window, which enables you to construct a forecasting model by specifying separate options for transforming the data, modeling the trend, modeling seasonality, modeling autocorrelation of the errors, and modeling the effect of regressors and other independent predictors.

Combine Forecasts

displays the Forecast Combination Model Specification window, which enables you to specify models that produce forecasts by combining, or averaging, the forecasts from other models. (This option is not available unless you have fit at least two models.)

Use External Forecasts

displays the External Forecast Model Specification window, which enables you to use judgmental or externally produced forecasts that have been saved in a separate series in the data set.

All of the forecasting models used by the system are ultimately specified through one of the four windows: Smoothing Method Specification, ARIMA Model Specification, Factored ARIMA Model Specification, or Custom Model Specification. You can specify the same models with either the ARIMA Model Specification window or the Custom Model Specification window, but the Custom Model Specification window can provide a more natural way to specify models for those who are less familiar with the Box-Jenkins style of time series model specification.

The Automatic Model feature, the Models to Fit window, and the Forecast Combination Model Specification window all deal with lists of forecasting models previously defined through the Smoothing Model, ARIMA Model, or Custom Model specification windows. These windows are discussed in detail in later sections.

To get started using the Develop Models window, select the Fit Models from List item from the menu shown in Figure 58.32. This opens the Models to Fit window, as shown in Figure 58.33.
You can select several models to fit at once by holding down the CTRL key as you make the selections. Select Linear Trend and Double (Brown) Exponential Smoothing, as shown in Figure 58.34, and then click the OK button.
The system fits the two models you selected. After the models are fit, the labels of the two models and their goodness-of-fit statistic are added to the model table, as shown in Figure 58.35.
Model List and Statistics of Fit

In the model list, the Model Title column shows the descriptive labels for the two fitted models, in this case Linear Trend and Double Exponential Smoothing.

The column labeled Root Mean Square Error (or labeled Mean Absolute Percent Error if you continued from the example in the previous section) shows the goodness-of-fit criterion used to decide which model fits better. By default, the criterion used is the root mean square error, but you can choose a different measure of fit. The linear trend model has a root mean square error of 1203, while the double exponential smoothing model fits better, with a RMSE of only 869.

The left column labeled Forecast Model consists of check boxes that indicate which one of the models in the list has been selected as the model to use to produce the forecasts for the series. When new models are fit and added to the model list, the system sets the Forecast Model flags to designate the one model with the best fit—as measured by the selected goodness-of-fit statistic—as the forecast model. (In the case of ties, the first model with the best fit is selected.)
Because the Double Exponential Smoothing model has the smaller RMSE of the two models in the list, its Forecast Model check box is set. If you would rather produce forecasts by using the Linear Trend model, choose it by selecting the corresponding check box in the Forecast Model column.

To use a different goodness-of-fit criterion, click the button with the current criterion name on it (Root Mean Square Error or Mean Absolute Percent Error). This opens the Model Selection Criterion window, as shown in Figure 58.36.

**Figure 58.36** Model Selection Criterion Window

The system provides many measures of fit that you can use as the model selection criterion. To avoid confusion, only the most popular of the available fit statistics are shown in this window by default. To display the complete list, you can select the Show all option. You can control the subset of statistics listed in this window through the Statistics of Fit item in the Options menu on the Develop Models window.

Initially, Root Mean Square Error is selected. Select R-Square and then click the OK button. This changes the fit statistic displayed in the model list, as shown in Figure 58.37.
Now that you have fit some models to the series, you can use the Model Viewer button to take a closer look at the predictions of these models.

## Model Viewer

In the Develop Models window, select the row in the table containing the Linear Trend model so that this model is highlighted. The model list should now appear as shown in Figure 58.38.
Figure 58.38 Selecting a Model to View

Note that the Linear Trend model is now highlighted, but the Forecast Model column still shows the Double Exponential Smoothing model as the model chosen to produce the final forecasts for the series. Selecting a model in the list means that this is the model that menu items such as View Model, Delete, Edit, and Refit will act upon. Choosing a model by selecting its check box in the Forecast Model column means that this model will be used by the Produce Forecasts process to generate forecasts.

Now open the Model Viewer by selecting the right-hand icon under the Browse button, or by selecting Model Predictions in the toolbar or from the View menu. The Model Viewer displays the Linear Trend model, as shown in Figure 58.39.
This graph shows the linear trend line representing the model predicted values together with a plot of the actual data values, which fluctuate about the trend line.

**Prediction Error Plots**

Select the second icon from the top in the vertical toolbar in the Model Viewer window. This switches the Viewer to display a plot of the model prediction errors (actual data values minus the predicted values), as shown in Figure 58.40.
If the model being viewed includes a transformation, prediction errors are defined as the difference between the transformed series actual values and model predictions. You can choose to graph instead the difference between the untransformed series values and untransformed model predictions, which are called model residuals. You can also graph normalized prediction errors or normalized model residuals. Use the Residual Plot Options submenu under the Options menu.

**Autocorrelation Plots**

Select the third icon from the top in the vertical toolbar. This switches the Viewer to display a plot of autocorrelations of the model prediction errors at different lags, as shown in Figure 58.41. Autocorrelations, partial autocorrelations, and inverse autocorrelations are displayed, with lines overlaid at plus and minus two standard errors. You can switch the graphs so that the bars represent significance probabilities by selecting the Correlation Probabilities item on the toolbar or from the View menu. For more information about the meaning and use of autocorrelation plots, see Chapter 7, “The ARIMA Procedure.”
Figure 58.41 Model Viewer: Autocorrelations Plot

White Noise and Stationarity Plots

Select the fourth icon from the top in the vertical toolbar. This switches the Viewer to display a plot of white noise and stationarity tests on the model prediction errors, as shown in Figure 58.42.
The white noise test bar chart shows significance probabilities of the Ljung-Box chi square statistic. Each bar shows the probability computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the prediction errors represent white noise. In this example, they are all significant beyond the 0.001 probability level, so that you reject the null hypothesis. In other words, the high level of significance at all lags makes it clear that the linear trend model is inadequate for this series.

The second bar chart shows significance probabilities of the augmented Dickey-Fuller test for unit roots. For example, the bar at lag three indicates a probability of 0.0014, so that you reject the null hypothesis that the series is nonstationary. The third bar chart is similar to the second except that it represents the seasonal lags. Since this series has a yearly seasonal cycle, the bars represent yearly intervals.

You can select any of the bars to display an interpretation. Select the fourth bar of the middle chart. This displays the Recommendation for Current View, as shown in Figure 58.43. This window gives an interpretation of the test represented by the bar that was selected; it is significant, therefore a stationary series is likely. It also gives a recommendation: You do not need to perform a simple difference to make the series stationary.
Figure 58.43  Model Viewer: Recommendation for Current View

Parameter Estimates Table

Select the fifth icon from the top in the vertical toolbar to the right of the graph. This switches the Viewer to display a table of parameter estimates for the fitted model, as shown in Figure 58.44.
For the linear trend model, the parameters are the intercept and slope coefficients. The table shows the values of the fitted coefficients together with standard errors and $t$ tests for the statistical significance of the estimates. The model residual variance is also shown.

**Statistics of Fit Table**

Select the sixth icon from the top in the vertical toolbar to the right of the table. This switches the Viewer to display a table of statistics of fit computed from the model prediction errors, as shown in Figure 58.45. The list of statistics displayed is controlled by selecting *Statistics of Fit* from the Options menu.
Changing to a Different Model

Select the first icon in the vertical toolbar to the right of the table to return the display to the predicted and actual values plots (Figure 58.39).

Now return to the Develop Models window, but do not close the Model Viewer window. You can use the Next Viewer icon in the toolbar or your system’s window manager controls to switch windows. You can resize the windows to make them both visible.

Select the Double Exponential Smoothing model so that this line of the model list is highlighted. The Model Viewer window is now updated to display a plot of the predicted values for the Double Exponential Smoothing model, as shown in Figure 58.46. The Model Viewer is automatically updated to display the currently selected model, unless you specify Unlink (the third icon in the window’s horizontal toolbar).
Forecasts and Confidence Limits Plots

Select the seventh icon from the top in the vertical toolbar to the right of the graph. This switches the Viewer to display a plot of forecast values and confidence limits, together with actual values and one-step-ahead within-sample predictions, as shown in Figure 58.47.
**Figure 58.47** Model Viewer: Forecasts and Confidence Limits

**Data Table**

Select the last icon at the bottom of the vertical toolbar to the right of the graph. This switches the Viewer to display the forecast data set as a table, as shown in Figure 58.48.
To view the full data set, use the vertical and horizontal scroll bars on the data table or enlarge the window.

Closing the Model Viewer

Other features of the Model Viewer and Develop Models window are discussed later in this book. For now, close the Model Viewer window and return to the Time Series Forecasting window.

To close the Model Viewer window, select Close from the window’s horizontal toolbar or from the File menu.

</thead>
<tbody>
<tr>
<td>Using Observation Numbers as the Time ID</td>
<td>3937</td>
</tr>
<tr>
<td>Creating a Time ID from Other Dating Variables</td>
<td>3941</td>
</tr>
</tbody>
</table>

The Forecasting System requires that the input data set contain a time ID variable. If the data you want to forecast are not in this form, you can use features of the Forecasting System to help you add time ID variables to your data set. This chapter shows examples of how to use these features.

Creating a Time ID Value from a Starting Date and Frequency

As a first example of adding a time ID variable, use the SAS data set created by the following statements. (Or use your own data set if you prefer.)

```sas
data no_id;
  input y @@;
  datalines;
    10 15 20 25 30 35 40 45
    50 55 60 65 70 75 80 85
run;
```

Submit these SAS statements to create the data set NO_ID. This data set contains the single variable Y. Assume that Y is a quarterly series and starts in the first quarter of 1991.

In the Time Series Forecasting window, use the Browse button to the right of the Data set field to bring up the Data Set Selection window. Select the WORK library, and then select the NO_ID data set.

You must create a time ID variable for the data set. Click the Create button to the right of the Time ID field. This opens a menu of choices for creating the time ID variable, as shown in Figure 59.1.
Chapter 59: Creating Time ID Variables

Figure 59.1 Time ID Creation Pop-up Menu

Select the first choice, Create from starting date and frequency. This opens the Time ID Creation from Starting Date window shown in Figure 59.2.
Enter the starting date, 1991:1, in the Starting Date field.

Select the Interval list arrow and select QTR. The Interval value QTR means that the time interval between successive observations is a quarter of a year; that is, the data frequency is quarterly.

Now select the OK button. The system prompts you for the name of the new data set. If you want to create a new copy of the input data set with the DATE variable added, enter a name for the new data set. If you want to replace the NO_ID data set with the new copy containing DATE, just select the OK button without changing the name.

For this example, change the New name field to WITH_ID and select the OK button. The data set WITH_ID is created containing the series Y from NO_ID and the added ID variable DATE. The system returns to the Data Set Selection window, which now appears as shown in Figure 59.3.
Figure 59.3 Data Set Selection Window after Creating Time ID

Select the **Table** button to see the new data set WITH_ID. This opens a VIEWTABLE window for the data set WITH_ID, as shown in Figure 59.4. Select **File** and **Close** to close the VIEWTABLE window.
Using Observation Numbers as the Time ID

Normally, the time ID variable contains date values. If you do not want to have dates associated with your forecasts, you can also use observation numbers as time ID variables. However, you still must have an ID variable. This can be illustrated by adding an observation index time ID variable to the data set NO_ID.

In the Data Set Selection window, select the data set NO_ID again. Select the Create button to the right of the Time ID field. Select the fourth choice, Create from observation numbers. This opens the Time ID Variable Creation window shown in Figure 59.5.
Select the **OK** button. This opens the New Data Set Name window. Enter “OBS_ID” in the **New data set name** field. Enter “T” in the **New ID variable name** field.

Now select the **OK** button. The new data set OBS_ID is created, and the system returns to the Data Set Selection window, which now appears as shown in Figure 59.6.
The **Interval** field for OBS_ID has the value ‘1’. This means that the values of the time ID variable T increment by one between successive observations.

Select the **Table** button to look at the OBS_ID data set, as shown in Figure 59.7.
Select **File** and **Close** to close the VIEWTABLE window. Select the **OK** button from the Data Set Selection window to return to the Time Series Forecasting window.
Creating a Time ID from Other Dating Variables

Your data set might contain ID variables that date the observations in a different way than the SAS date valued ID variable expected by the forecasting system. For example, for monthly data, the data set might contain the ID variables YEAR and MONTH, which together date the observations.

In these cases, you can use the Forecasting System’s Create Time ID features to compute a time ID variable with SAS date values from the existing dating variables. As an example of this, use the SAS data set read in by the following SAS statements:

```sas
data id_parts;
  input yr qtr y;
datalines;
  91 1 10
  91 2 15
  91 3 20
  91 4 25
  92 1 30
  92 2 35
  92 3 40
  92 4 45
  93 1 50
  93 2 55
  93 3 60
  93 4 65
  94 1 70
  94 2 75
  94 3 80
  94 4 85
run;
```

Submit these SAS statements to create the data set ID_PARTS. This data set contains the three variables YR, QTR, and Y. YR and QTR are ID variables that together date the observations, but each variable provides only part of the date information. Because the forecasting system requires a single dating variable containing SAS date values, you need to combine YR and QTR to create a single variable DATE.

Type “ID_PARTS” in the Data Set field and press the ENTER key. (You could also use the Browse button to open the Data Set Selection window, as in the previous example, and complete this example from there.)

Select the Create button at the right of the Time ID field. This opens the menu of Create Time ID choices, as shown in Figure 59.8.
Select the second choice, Create from existing variables. This opens the window shown in Figure 59.9.
In the Variables list, select YR. In the Date Part list, select YEAR as shown in Figure 59.10.
Now click the right-pointing arrow button. The variable YR and the part code YEAR are added to the Existing Time IDs list.

Next select QTR from the Variables list, select QTR from the Date Part list, and click the arrow button. This adds the variable QTR and the part code QTR to the Existing Time IDs list, as shown in Figure 59.11.
Now select the OK button. This opens the New Data Set Name window. Change the New data set name field to NEWDATE, and then select the OK button.

The data set NEWDATE is created, and the system returns to the Time Series Forecasting window with NEWDATE as the selected Data Set. The Time ID field is set to DATE, and the Interval field is set to QTR.

This chapter explores the tools available through the Develop Models window for investigating the properties of time series and for specifying and fitting models. The first section shows you how to diagnose time series properties in order to determine the class of models appropriate for forecasting series with such properties. Later sections show you how to specify and fit different kinds of forecasting models.

Series Diagnostics

The series diagnostics tool helps you determine the kinds of forecasting models that are appropriate for the data series so that you can limit the search for the best forecasting model. The series diagnostics address these three questions: Is a log transformation needed to stabilize the variance? Is a time trend present in the data? Is there a seasonal pattern to the data?

The automatic model fitting process, which you used in the previous chapter through the Automatic Model Fitting window, performs series diagnostics and selects trial models from a list according to the results. You can also look at the diagnostic information and make your own decisions as to the kinds of models appropriate for the series. The following example illustrates the series diagnostics features.

Select “Develop Models” from the Time Series Forecasting window. Select the library SASHELP, the data set CITIMON, and the series RCARD. This series represents domestic retail sales of passenger cars. To look at this series, select “View Series” from the Develop Models window. This opens the Time Series Viewer window, as shown in Figure 60.1.
Select “Diagnose Series” from the Tools menu. You can do this from the Develop Models window or from the Time Series Viewer window. Figure 60.2 shows this from the Develop Models window.
This opens the Series Diagnostics window, as shown in Figure 60.3.
Each of the three series characteristics—need for log transformation, presence of a trend, and seasonality—has a set of options for Yes, No, and Maybe. Yes indicates that the series has the characteristic and that forecasting models fit to the series should be able to model and predict this behavior. No indicates that you do not need to consider forecasting models designed to predict series with this characteristic. Maybe indicates that models with and without the characteristic should be considered. Initially, all these values are set to Maybe.

To have the system diagnose the series characteristics, click the Automatic Series Diagnostics button. This runs the diagnostic routines described in Chapter 65, “Forecasting Process Details,” and sets the options according to the results. In this example, Trend and Seasonality are changed from Maybe to Yes, while Log Transform remains set to Maybe.

These diagnostic criteria affect the models displayed when you use the Models to Fit window or the Automatic Model Selection model-fitting options described in the following section. You can set the criteria manually, according to your judgment, by selecting any of the options, whether you have used the Automatic Series Diagnostics button or not. For this exercise, leave them as set by the automatic diagnostics. Click the OK button to close the Series Diagnostics window.
Models to Fit Window

As you saw in the previous chapter, you can select models from a list. Invoke the Models to Fit window by clicking the middle of the table and selecting “Fit Models from List” from the menu. This can also be selected from the toolbar or the Fit Model submenu of the Edit menu. The Models to Fit window comes up, as shown in Figure 60.4.

Since you have performed series diagnostics, the models shown are the subset that fits the diagnostic criteria. Suppose you want to consider models other than those in this subset because you are undecided about including a trend in the model. Select the Show all models option. Now the entire model selection list is shown. Scroll through the list until you find Log Seasonal Exponential Smoothing, as shown in Figure 60.5.
This is a nontrended model, which seems a good candidate. Select this model, and then click the OK button. The model is fit to the series and then appears in the table with the value of the selected fit criterion, as shown in Figure 60.6.
You can edit the model list that appears in the Models to Fit window by selecting “Options” and “Model Selection List” from the menu bar or by selecting the Edit Model List toolbar icon. You can then delete models you are not interested in from the default list and add models using any of the model specification methods described in this chapter. When you save your project, the edited model selection list is saved in the project file. In this way, you can use the Select from List item and the Automatic Model Selection item to select models from a customized search set.
Automatic Model Selection

Automatic model selection is equivalent to choosing Select from List, as you did in the preceding section, fitting all the models in the subset list and then deleting all except the best fitting of the models. If series diagnostics have not yet been done, they are performed automatically to determine the model subset to fit. If you set the series diagnostics for log, trend, or seasonal criteria manually using the radio buttons, these choices are honored by the automatic fitting process.

Using automatic selection, the system does not pause to warn you of model fitting errors, such as failure of the estimates to converge (you can track these using the audit trail feature).

By default, only the best fitting model is kept. However, you can control the number of automatically fit models retained in the Develop Models list, and the following example shows how to do this.

From the menu bar, select “Options” and “Automatic Fit.” This opens the Automatic Model Selection Options window. Click the Models to Keep list arrow, and select “All models,” as shown in Figure 60.7. Now click OK.

Figure 60.7 Selecting Number of Automatic Fit Models to Keep
Next, select “Fit Models Automatically” by clicking the middle of the table or using the toolbar or Edit menu. The Automatic Model Selection window appears, showing the diagnostic criteria in effect and the number of models to be fit, as shown in Figure 60.8.

**Figure 60.8 Automatic Model Selection Window**

![Automatic Model Selection Window](image)

Click the OK button. After the models have been fit, all of them appear in the table, in addition to the model which you fit earlier, as shown in Figure 60.9.
To fit exponential smoothing and Winters models not already provided in the Models to Fit window, select “Fit Smoothing Model” from the pop-up menu or toolbar or select “Smoothing Model” from the Fit Model submenu of the Edit menu. This opens the Smoothing Model Specification window, as shown in Figure 60.10.
The Smoothing Model Specification window consists of several parts. At the top is the series name and a field for the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The Smoothing Methods box lists the different methods available. Below the Smoothing Methods box is the Transformation field, which is used to apply the smoothing method to transformed series values.

The Smoothing Weights box specifies how the smoothing weights are determined. By default, the smoothing weights are automatically set to optimize the fit of the model to the data. For more information about how the smoothing weights are fit, see Chapter 65, “Forecasting Process Details.”

Under smoothing methods, select “Winters Method – Additive.” Notice the smoothing weights box to the right. The third item, Damping, is grayed out, while the other items, Level, Trend, and Season, show the word Optimize. This tells you that these three smoothing weights are applicable to the smoothing method that you selected and that the system is currently set to optimize these weights for you.

Next, specify a transformation using the Transformation list. A menu of transformation choices pops up, as shown in Figure 60.11.
You can specify a logarithmic, logistic, square root, or Box-Cox transformation. For this example, select “Square Root” from the list. The Transformation field is now set to Square Root.

This means that the system will first take the square roots of the series values, apply the additive version of the Winters method to the square root series, and then produce the predictions for the original series by squaring the Winters method predictions (and multiplying by a variance factor if the Mean Prediction option is set in the Forecast Options window). For more information about predictions from transformed models, see Chapter 65, “Forecasting Process Details.”

The Smoothing Model Specification window should now appear as shown in Figure 60.12. Click the OK button to fit the model. The model is added to the table of fitted models in the Develop Models window.
To fit ARIMA or Box-Jenkins models not already provided in the Models to Fit window, select the ARIMA model item from the pop-up menu, toolbar, or Edit menu. This opens the ARIMA Model Specification window, as shown in Figure 60.13.
This ARIMA Model Specification window is structured according to the Box and Jenkins approach to time series modeling. You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you may find one more convenient than the other.

At the top of the ARIMA Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

Using the ARIMA Model Specification window, you can specify autoregressive (p), differencing (d), and moving average (q) orders for both simple and seasonal factors. You can specify transformations with the Transformation list. You can also specify whether an intercept is included in the ARIMA model.

In addition to specifying seasonal and nonseasonal ARIMA processes, you can also specify predictor variables and other terms as inputs to the model. ARIMA models with inputs are sometimes called ARIMAX models or Box-Tiao models. Another term for this kind of model is dynamic regression.

In the lower part of the ARIMA Model Specification window is the list of predictors to the model (initially empty). You can specify predictors by using the Add button. This opens a menu of different kinds of independent effects, as shown in Figure 60.14.
The kinds of predictor effects allowed include time trends, regressors, adjustments, dynamic regression (transfer functions), intervention effects, and seasonal dummy variables. How to use different kinds of predictors is explained in Chapter 62, “Using Predictor Variables.”

As an example, in the ARIMA Options box, set the order of differencing $d$ to 1 and the moving average order $q$ to 2. You can either type in these values or click the arrows and select the values from pop-up lists.

These selections specify an ARIMA(0,1,2) or IMA(1,2) model. (For more information about the notation used for ARIMA models, see Chapter 7, “The ARIMA Procedure.”) Notice that the model label at the top is now IMA(1,2) NOINT, meaning that the data are differenced once and a second-order moving-average term is included with no intercept.

In the Seasonal ARIMA Options box, set the seasonal moving-average order $Q$ to 1. This adds a first-order moving-average term at the seasonal (12 month) lag. Finally, select “Log” in the Transformation combo box.

The model label is now Log ARIMA(0,1,2)(0,0,1)s NOINT, and the window appears as shown in Figure 60.15.
Click the OK button to fit the model. The model is fit and added to the Develop Models table.
Factored ARIMA Model Specification Window

To fit a factored ARIMA model, select the Factored ARIMA model item from the pop-up menu, toolbar, or Edit menu. This brings up the Factored ARIMA Model Specification window, shown in Figure 60.16.

**Figure 60.16** Factored ARIMA Model Specification Window

The Factored ARIMA Model Specification window is similar to the ARIMA Model Specification window and has the same features, but it uses a more general specification of the autoregressive (p), differencing (d), and moving-average (q) terms. To specify these terms, click the corresponding Set button, as shown in Figure 60.16. For example, to specify autoregressive terms, click the first Set button. This opens the AR Polynomial Specification Window, shown in Figure 60.17.
To add AR polynomial terms, click the New button. This opens the Polynomial Specification Window, shown in Figure 60.18. Specify the first lag you want to include by using the Lag spin box, then click the Add button. Repeat this process, adding each lag you want to include in the current list. All lags must be specified. For example, if you add only lag 3, the model contains only lag 3, not 1 through 3.

As an example, add lags 1 and 3, then click the OK button. The AR Polynomial Specification Window now shows (1,3) in the list of polynomials. Now select “New” again. Add lags 6 and 12 and click “OK”. Now the AR Polynomial Specification Window shows (1,3) and (6,12) as shown in Figure 60.17. Select “OK” to close this window. The Factored ARIMA Model Specification Window now shows the factored model \( p=(1,3)(6,12) \). Use the same technique to specify the \( q \) terms, or moving-average part of the model. There is no limit to the number of lags or the number of factors you can include in the model.
To specify differencing lags, click the middle Set button to open the Differencing Specification window. Specify lags using the spin box and add them to the list with the Add button. When you click "OK" to close the window, the differencing lags appear after $d$ in the Factored ARIMA Specification Window, within a single pair of parentheses.

You can use the Factored ARIMA Model Specification Window to specify any model that you can specify with the ARIMA Model and Custom Model windows, but the notation is more similar to that of the ARIMA procedure (see Chapter 7, "The ARIMA Procedure"). Consider as an example the classic Airline model fit to the International Airline Travel series, SASHELP.AIR. This is a factored model with one moving-average term at lag one and one moving-average term at the seasonal lag, with first-order differencing at the simple and seasonal lags. Using the ARIMA Model Specification Window, you specify the value 1 for the $q$ and $d$ terms and also for the $Q$ and $D$ terms, which represent the seasonal lags. For monthly data, the seasonal lags represent lag 12, since a yearly seasonal cycle is assumed.
By contrast, the Factored ARIMA Model Specification Window makes no assumptions about seasonal cycles. The Airline model is written as IMA \( d=(1,12) \) \( q=(1) (12) \) NOINT. To specify the differencing terms, add the values 1 and 12 in the Differencing Specification Window and click OK. Then select “New” in the MA Polynomial Specification Window, add the value 1, and select OK. To add the factored term, select “New” again, add the value 12, and click OK. Remember to select “No” in the Intercept radio box, since it is not selected by default. Click OK to close the Factored ARIMA Model Specification Window and fit the model.

You can show that the results are the same as they are when you specify the model by using the ARIMA Model Specification Window and when you select Airline Model from the default model list. If you are familiar with the ARIMA Procedure (Chapter 7, “The ARIMA Procedure”), you might want to turn on the Show Source Statements option before fitting the model, then examine the procedure source statements in the log window after fitting the model.

The strength of the Factored ARIMA Specification approach lies in its ability to construct unusual ARIMA models, such as the following:

- **Subset models**
  These are models of order \( n \), where fewer than \( n \) lags are specified. For example, an AR order 3 model might include lags 1 and 3 but not lag 2.

- **Unusual seasonal cycles**
  For example, a monthly series might cycle two or four times per year instead of just once.

- **Multiple cycles**
  For example, a daily sales series might peak on a certain day each week and also once a year at the Christmas season. Given sufficient data, you can fit a three-factor model, such as IMA \( d=(1) \) \( q=(1) (7) (365) \).

Models with high order lags take longer to fit and often fail to converge. To save time, select the Conditional Least Squares or Unconditional Least Squares estimation method (see Figure 60.16). Once you have narrowed down the list of candidate models, change to the Maximum Likelihood estimation method.

---

**Custom Model Specification Window**

To fit a custom time series model not already provided in the Models to Fit window, select the Custom Model item from the pop-up menu, toolbar, or Edit menu. This opens the Custom Model Specification window, as shown in Figure 60.19.
You can specify the same time series models with the Custom Model Specification window and the ARIMA Model Specification window, but the windows are structured differently, and you might find one more convenient than the other.

At the top of the Custom Model Specification window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Custom Model Specification window consists of four fields: Transformation, Trend Model, Seasonal Model, and Error Model. These fields allow you to specify the model in four parts. Each part specifies how a different aspect of the pattern of the time series is modeled and predicted.

The Predictors list at the bottom of the Custom Model Specification window allows you to include different kinds of predictor variables in the forecasting model. The Predictors feature for the Custom Model Specification window is like the Predictors feature for the ARIMA Model Specification window, except that time trend predictors are provided through the Trend Model field and seasonal dummy variable predictors are provided through the Seasonal Model field.

To illustrate how to use the Custom Model Specification window, the following example specifies the same model you fit by using the ARIMA Model Specification window.
First, specify the data transformation to use. Select “Log” using the Transformation combo box.

Second, specify how to model the trend in the series. Select **First Difference** in the **Trend Model** combo box, as shown in **Figure 60.20**.

![Figure 60.20 Trend Model Options](image)

Next, specify how to model the seasonal pattern in the series. Select “Seasonal ARIMA” in the Seasonal Model combo box, as shown in **Figure 60.21**.
This opens the Seasonal ARIMA Model Options window, as shown in Figure 60.22.
Specify a first-order seasonal moving-average term by typing 1 or by selecting “1” from the Moving Average: Q= combo box pop-up menu, and then click the OK button.

Finally, specify how to model the autocorrelation pattern in the model prediction errors. Click the Set button to the right of the Error Model field. This opens the Error Model Options window, as shown in Figure 60.23. This window allows you to specify an ARMA error process. Set the Moving Average order q to 2, and then click the OK button.
The Custom Model Specification window should now appear as shown in Figure 60.24. The model label at the top of the Custom Model Specification window should now read \( \log \ ARIMA(0,1,2)(0,0,1)s \) NOINT, just as it did when you used the ARIMA Model Specification window.
Now that you have seen how the Custom Model Specification window works, click “Cancel” to exit the window without fitting the model. This should return you to the Develop Models window.
Editing the Model Selection List

Now that you know how to specify new models that are not included in the system default model selection list, you can edit the model selection list to add models that you expect to use in the future or to delete models that you do not expect to use. When you save the forecasting project to a SAS catalog, the edited model selection list is saved with the project file, and the list is restored when you load the project.

There are two reasons why you would add a model to the model selection list. First, by adding the model to the list, you can fit the model to different time series by selecting it through the Fit Models from List action. You do not need to specify the model again every time you use it.

Second, once the model is added to the model selection list, it is available to the automatic model selection process. The model is then considered automatically whenever you use the automatic model selection feature for any series.

To edit the model selection list, select “Model Selection List” from the Options menu as shown in Figure 60.25, or select the Edit Model List toolbar icon.

![Figure 60.25 Model Selection List Option](image-url)
This selection brings up the Model Selection List editor window, as shown in Figure 60.26. This window consists of the model selection list and an “Auto Fit” column, which controls for each model whether the model is included in the list of models used by the automatic model selection process.

Figure 60.26  Model Selection List Window

To add a model to the list, select “Add Model” from the Edit menu and then select “Smoothing Model,” “ARIMA Model,” “Factored ARIMA Model,” or “Custom Model” from the submenu. Alternatively, click the corresponding icon on the toolbar.

As an example, select “Smoothing Model.” This brings up the Smoothing Model Specification window. Note that the series name is “-Null-.” This means that you are not specifying a model to be fit to a particular series, but are specifying a model to be added to the selection list for later reference.

Specify a smoothing model. For example, select “Simple Smoothing” and then select the Square Root transformation. The window appears as shown in Figure 60.27.
Click the OK button to add the model to the end of the model selection list and return you to the Model Selection List window, as shown in Figure 60.28. You can now select the Fit Models from List model-fitting option to use the edited selection list.
If you want to delete one or more models from the list, select the model labels to highlight them in the list. Click a second time to clear a selected model. Then select “Delete” from the Edit pull-down menu, or the corresponding toolbar icon. As an example, delete the Square Root Simple Exponential Smoothing model that you just added.

The Model Selection List editor window gives you a lot of flexibility for managing multiple model lists, as explained in the section “Model Selection List Editor Window” on page 4100. For example, you can create your own model lists from scratch or modify or combine previously saved model lists and those provided with the software, and you can save them and designate one as the default for future projects.

Now select “Close” from the File menu (or the Close icon) to close the Model Selection List editor window.

Forecast Combination Model Specification Window

Once you have fit several forecasting models to a series, you face the question of which model to use to produce the final forecasts. One possible answer is to combine or average the forecasts from several models. Combining the predictions from several different forecasting methods is a popular approach to forecasting.

The way that you produce forecast combinations with the Time Series Forecasting System is to use the Forecast Combination Model Specification window to specify a new forecasting model that performs the averaging of forecasts from the models you want to combine. This new model is added to the list of fitted models just like other models. You can then use the Model Viewer window features and Model Fit Comparison window features to examine the fit of the combined model.

To specify a forecast combination model, select “Combine Forecasts” from the pop-up menu or toolbar, or select “Edit” and “Fit Model” from the menu bar. This brings up the Forecast Combination Model Specification window, as shown in Figure 60.29.
At the top of the Forecast Combination window is the name and label of the series and the label of the model you are specifying. The model label is filled in with an automatically generated label as you specify options. You can type over the automatic label with your own label for the model. To restore the automatic label, enter a blank label.

The middle part of the Forecast Combination window consists of the list of models that you have fit to the series. This table shows the label and goodness-of-fit measure for each model and the combining weight assigned to the model.

The Weight column controls how much weight is given to each model in the combined forecasts. A missing weight means that the model is not used. Initially, all the models have missing weight values.

You can enter the weight values you want to use in the Weight column. Alternatively, you can select models from the Model Description column, and weight values for the models you select are set automatically. To remove a model from the combination, select it again. This resets its weight value to missing.

At the bottom of the Forecast Combination window are two buttons: Normalize Weights and Fit Regression Weights. The Normalize Weights button adjusts the nonmissing weight values so that they sum to one. The Fit Regression Weights button uses linear regression to compute the weight values that produce the combination of model predictions with the best fit to the series.
If no models are selected, the Fit Regression Weights button fits weights for all the models in the list. You can compute regression weights for only some of the models by first selecting the models you want to combine and then selecting Fit Regression Weights. In this case, only the nonmissing Weight values are replaced with regression weights.

As an example of how to combine forecasting models, select all the models in the list. After you have finished selecting the models, all the models in the list should now have equal weight values, which implies a simple average of the forecasts.

Now click the Fit Regression Weights button. The system performs a linear regression of the series on the predictions from the models with nonmissing weight values and replaces the weight values with the estimated regression coefficients. These are the combining weights that produce the smallest mean square prediction error within the sample.

The Forecast Combination window should now appear as shown in Figure 60.30. (Note that some of the regression weight values are negative.)

Click the OK button to fit the combined model. Now the Develop Models window shows this model to be the best fitting according to the root mean square error, as shown in Figure 60.31.
Incorporating Forecasts from Other Sources

You might have forecasts from other sources that you want to include in the forecasting process. Examples of other forecasts you might want to use are “best guess” forecasts based on personal judgments, forecasts produced by government agencies or commercial forecasting services, planning scenarios, and reference or “base line” projections. Because such forecasts are produced externally to the Time Series Forecasting System, they are referred to as external forecasts.

You can include external forecasts in combination models to produce compromise forecasts that split the difference between the external forecast and forecasting models that you fit. You can use external forecasts to compare them to the forecasts from models that are fit by the system.

Notice that the combined model has a smaller root mean square error than any one of the models included in the combination. The confidence limits for forecast combinations are produced by taking a weighted average of the mean square prediction errors for the component forecasts, ignoring the covariance between the prediction errors.
To include external forecasts in the Time Series Forecasting process, you must first supply the external forecast as a variable in the input data set. You then specify a special kind of forecasting “model” whose predictions are identical to the external forecast recorded in the data set.

As an example, suppose you have 12 months of sales data and five months of sales forecasts based on a consensus opinion of the sales staff. The following statements create a SAS data set containing made-up numbers for this situation.

```sas
data widgets;
    input date monyy5. sales staff;
    format date monyy5.;
    label sales = "Widget Sales"
                   staff = "Sales Staff Consensus Forecast";
    datalines;
    jun94  142.1  .
    jul94  139.6  .
    aug94  145.0  .
    sep94  150.2  .
    oct94  151.1  .
    nov94  154.3  .
    dec94  158.7  .
    jan95  155.9  .
    feb95  159.2  .
    mar95  160.8  .
    apr95  162.0  .
    may95  163.3  .
    jun95  .  166.
    jul95  .  168.
    aug95  .  170.
    sep95  .  171.
    oct95  .  177.
    run;
```

Submit the preceding statements in the SAS Program Editor window. From the Time Series Forecasting window, select “Develop Models.” In the Series Selection window, select the data set WORK.WIDGETS and the variable SALES. The Develop Models window should now appear as shown in Figure 60.32.
Now select “Edit,” “Fit Model,” and “External Forecasts” from the menu bar of the Develop Models window, as shown in Figure 60.33, or the Use External Forecasts toolbar icon.
This selection opens the External Forecast Model Specification window. Select the STAFF variable as shown in Figure 60.34.
Select the OK button. The external forecast model is now “fit” and added to the Develop Models list, as shown in Figure 60.35.
You can now use this model for comparison with the predictions from other forecasting models that you fit, or you can include it in a forecast combination model.

Note that no fitting is actually performed for an external forecast model. The predictions of the external forecast model are simply the values of the external forecast series read from the input data set. The goodness-of-fit statistics for such models will depend on the values that the external forecast series contains for observations within the period of fit. In this case, no STAFF values are given for past periods, and therefore the fit statistics for the model are missing.

The Time Series Forecasting System provides a variety of tools for identifying potential forecasting models and for choosing the best fitting model. It allows you to decide how much control you want to have over the process, from a hands-on approach to one that is completely automated. This chapter begins with an exploration of the tools available through the Series Viewer and Model Viewer. It presents an example of identifying models graphically and exercising your knowledge of model properties. The remainder of the chapter shows you how to compare models by using a variety of statistics and by controlling the fit and evaluation time ranges. It concludes by showing you how to refit existing models and how to compare models using hold-out samples.

Time Series Viewer Features

The Time Series Viewer is a graphical tool for viewing and analyzing time series. It can be used separately from the Time Series Forecasting System by using the TSVIEW command or by selecting Time Series Viewer from the Analysis pull-down menu under Solutions.

In this chapter you will use the Time Series Viewer to examine plots of your series before fitting models. Begin this example by invoking the Forecasting system and clicking the View Series Graphically button, as shown in Figure 61.1, or the View Series toolbar icon.
From the Series Selection window, select SASHELP as the library, WORKERS as the data set, and MA-SONRY as the time series, and then click the Graph button. The Time Series Viewer displays a plot of the series, as shown in Figure 61.2.
Select the Zoom In icon, the first one on the window’s horizontal toolbar. Notice that the mouse pointer changes shape and that “Note: Click on a corner of the region, then drag to the other corner” appears on the message line. Outline an area, as shown in Figure 61.3, by clicking the mouse at the upper-left corner, holding the button down, dragging to the lower-right corner, and releasing the button.
Figure 61.3 Selecting an Area for Zoom

The zoomed plot should appear as shown in Figure 61.4.
You can repeat the process to zoom in still further. To return to the previous view, select the Zoom Out icon, the second icon on the window’s horizontal toolbar.

The third icon on the horizontal toolbar is used to link or unlink the viewer window. By default, the viewer is linked, meaning that it is automatically updated to reflect selection of a different time series. To see this, return to the Series Selection window by clicking on it or using the Window menu or Next Viewer toolbar icon. Select the Electric series in the Time Series Variables list box. Notice that the Time Series Viewer window is updated to show a plot of the ELECTRIC series. Select the Link/Unlink icon if you prefer to unlink the viewer so that it is not automatically updated in this way. Successive selections toggle between the linked and unlinked state. A note on the message line informs you of the state of the Time Series Viewer window.

When a Time Series Viewer window is linked, selecting View Series again makes the linked Viewer window active. When no Time Series Viewer window is linked, selecting View Series opens an additional Time Series Viewer window. You can bring up as many Time Series Viewer windows as you want.

Having seen the plot in Figure 61.2, you might suspect that the series is nonstationary and seasonal. You can gain further insight into this by examining the sample autocorrelation function (ACF), partial autocorrelation function (PACF), and inverse autocorrelation function (IACF) plots. To switch the display to the autocorrelation plots, select the second icon from the top on the vertical toolbar at the right side of the Time Series Viewer. The plot appears as shown in Figure 61.5.
Each bar represents the value of the correlation coefficient at the given lag. The overlaid lines represent confidence limits computed at plus and minus two standard errors. You can switch the graphs to show significance probabilities by selecting Correlation Probabilities under the Options pull-down menu, or by selecting the Toggle ACF Probabilities toolbar icon.

The slow decline of the ACF suggests that first differencing might be warranted. To see the effect of first differencing, select the simple difference icon, the fifth icon from the left on the window’s horizontal toolbar. The plot now appears as shown in Figure 61.6.
Since the ACF still displays slow decline at seasonal lags, seasonal differencing is appropriate (in addition to the first differencing already applied). Select the Seasonal Difference icon, the sixth icon from the left on the horizontal toolbar. The plot now appears as shown in Figure 61.7.
Leave the Time Series Viewer open for the remainder of this exercise. Drag it out of the way or push it to the background so that you can return to the Time Series Forecasting window. Select Develop Models, then click an empty part of the table to bring up the pop-up menu, and select Fit ARIMA Model. Define the ARIMA(0,1,0)(0,1,0)s model by selecting 1 for Differencing under ARIMA Options, 1 for Differencing under Seasonal ARIMA Options, and No for Intercept, as shown in Figure 61.8.
When you click the OK button, the model is fit and you are returned to the Develop Models window. Click on an empty part of the table and choose Fit Models from List from the pop-up menu. Select Airline Model from the window. (Airline Model is a common name for the ARIMA(0,1,1)(0,1,1)s model, which is often used for seasonal data with a linear trend.) Click the OK button. Once the model has been fit, the table shows the two models and their root mean square errors. Notice that the Airline Model provides only a slight improvement over the differencing model, ARIMA(0,1,0)(0,1,0)s. Select the first row to highlight the differencing model, as shown in Figure 61.9.
Now click the View Selected Model Graphically button, below the Browse button at the right side of the Develop Models window. The Model Viewer window appears, showing the actual data and model predictions for the MASONRY series. (Note that predicted values are missing for the first 13 observations due to simple and seasonal differencing.)

To examine the ACF plot for the model prediction errors, select the third icon from the top on the vertical toolbar. For this model, the prediction error ACF is the same as the ACF of the original data with first differencing and seasonal differencing applied. This differencing is apparent if you bring the Time Series Viewer back into view for comparison.

Return to the Develop Models Window by clicking on it or using the window pull-down menu or the Next Viewer toolbar icon. Select the second row of the table in the Develop Models window to highlight the Airline Model. The Model Viewer is automatically updated to show the prediction error ACF of the newly selected model, as shown in Figure 61.10.
Another helpful tool available within the Model Viewer is the parameter estimates table. Select the fifth icon from the top of the vertical toolbar. The table gives the parameter estimates for the two moving-average terms in the Airline Model, as well as the model residual variance, as shown in Figure 61.11.
### Figure 61.11 Parameter Estimates for the Airline Model

You can adjust the column widths in the table by dragging the vertical borders of the column titles with the mouse. Notice that neither of the parameter estimates is significantly different from zero at the 0.05 level of significance, since $\text{Prob>|t|}$ is greater than 0.05. This suggests that the Airline Model should be discarded in favor of the more parsimonious differencing model, which has no parameters to estimate.

### The Model Selection Criterion

Return to the Develop Models window (Figure 61.9) and notice the Root Mean Square Error button at the right side of the table banner. This is the model selection criterion—the statistic used by the system to select the best fitting model. So far in this example you have fit two models and have left the default criterion, root mean square error (RMSE), in effect. Because the Airline Model has the smaller value of this criterion and because smaller values of the RMSE indicate better fit, the system has chosen this model as the forecasting model, indicated by the check box in the **Forecast Model** column.

The statistics available as model selection criteria are a subset of the statistics available for informational purposes. To access the entire set, select **Options** from the menu bar, and then select **Statistics of Fit**. The **Statistics of Fit Selection** window appears, as shown in Figure 61.12.
By default, five of the more well known statistics are selected. You can select and deselect statistics by clicking the check boxes in the left column. For this exercise, select All, and notice that all the check boxes become checked. Click the OK button to close the window. Now if you choose Statistics of Fit in the Model Viewer window, all of the statistics will be shown for the selected model.

To change the model selection criterion, click the Root Mean Square Error button or select Options from the menu bar and then select Model Selection Criterion. Notice that most of the statistics of fit are shown, but those which are not relevant to model selection, such as number of observations, are not shown. Select Schwarz Bayesian Information Criterion and click OK. Since this statistic puts a high penalty on models with larger numbers of parameters, the ARIMA(0,1,0)(0,1,0)s model comes out with the better fit.

Notice that changing the selection criterion does not automatically select the model that is best according to that criterion. You can always choose the model you want to use for forecasts by selecting its check box in the Forecast Model column.

Now bring up the Model Selection Criterion window again and select Akaike Information Criterion. This statistic puts a lesser penalty on number of parameters, and the Airline Model comes out as the better fitting model.
Sorting and Selecting Models

Select Sort Models on the Tools menu or from the toolbar. This sorts the current list of fitted models by the current selection criterion. Although some selection criteria assign larger values to better fitting models (for example, R-square) while others assign smaller values to better fitting models, Sort Models always orders models with the best fitting model—in this case, the Airline Model—at the top of the list.

When you select a model in the table, its name and criterion value become highlighted, and actions that apply to that model become available. If your system supports a right mouse button, you can click it to invoke a pop-up menu, as shown in Figure 61.13.

![Figure 61.13 Right Mouse Button Pop-up Menu](image)

Whether or not you have a right mouse button, the same choices are available under Edit and View from the menu bar. If the model viewer has been invoked, it is automatically updated to show the selected model, unless you have unlinked the viewer by using the Link/Unlink toolbar button.

Select the highlighted model in the table again. Notice that it is no longer highlighted. When no models are highlighted, the right mouse button pop-up menu changes, and items on the menu bar that apply to a selected model become unavailable. For example, you can choose Edit from the menu bar, but you can’t choose the Edit Model or Delete Model selections unless you have highlighted a model in the table.

When you select the check box in the Forecast Model column of the table, the model in that row becomes
the forecasting model. This is the model that will be used the next time forecasts are generated by choosing View Forecasts or by using the Produce Forecasts window. Note that this forecasting model flag is automatically set when you use Fit Automatic Model or when you fit an individual model that fits better, using the current selection criterion, than the current forecasting model.

---

### Comparing Models

Select Tools and Compare Models from the menu bar. This displays the Model Fit Comparison table, as shown in Figure 61.14.

**Figure 61.14 Model Comparison Window**

The two models you have fit are shown as Model 1 and Model 2. When there are more than two models, you can bring any two of them into the table by selecting the up and down arrows. In this way, it is easy to do pairwise comparisons on any number of models, looking at as many statistics of fit as you like. Since you previously chose to display all statistics of fit, all of them are shown in the comparison table. Use the vertical scroll bar to move through the list.

After you have examined the model comparison table, click the Close button to return to the Develop Models window.
Controlling the Period of Evaluation and Fit

Notice the three time ranges shown on the Develop Models window (Figure 61.9). The data range shows the beginning and ending dates of the MASONRY time series. The period of fit shows the beginning and ending dates of data used to fit the models. The period of evaluation shows the beginning and ending dates of data used to compute statistics of fit. By default, the fit and evaluate ranges are the same as the data range. To change these ranges, click the Set Ranges button, or select Options and Time Ranges from the menu bar. This brings up the Time Ranges Specification window, as shown in Figure 61.15.

For this example, suppose the early data in the series is unreliable, and you want to use the range June 1978 to the latest available for both model fitting and model evaluation. You can either type JUN1978 in the From column for Period of Fit and Period of Evaluation, or you can advance these dates by clicking the right pointing arrows. The outer arrow advances the date by a large amount (in this case, by a year), and the inner arrow advances it by a single period (in this case, by a month). Once you have changed the Period of Fit and the Period of Evaluation to JUN1978 in the From column, click the OK button to return to the Develop Models window. Notice that these time ranges are updated at the top of the window, but the models already fit have not been affected. Your changes to the time ranges affect subsequently fit models.
Refitting and Reevaluating Models

If you fit the ARIMA(0,1,0)(0,1,0)s and Airline models again in the same way as before, they will be added to the model list, with the same names but with different values of the model selection criterion. Parameter estimates will be different, due to the new fit range, and statistics of fit will be different, due to the new evaluation range.

For this exercise, instead of specifying the models again, refit the existing models by selecting Edit from the menu bar and then selecting Refit Models and All Models. After the models have been refit, you should see the same two models listed in the table but with slightly different values for the selection criterion. The ARIMA (0,1,0)(0,1,0)s and Airline models have now been fit to the MASONRY series by using data from June 1978 to July 1982, since this is the period of fit you specified. The statistics of fit have been computed for the period of evaluation, which was the same as the period of fit. If you had specified a period of evaluation different from the period of fit, the statistics would have been computed accordingly.

In practice, another common reason for refitting models is the availability of new data. For example, when data for a new month become available for a monthly series, you might add them to the input data set, then invoke the forecasting system, open the project containing models fit previously, and refit the models prior to generating new forecasts. Unless you specify the period of fit and period of evaluation in the Time Ranges Specification window, they default to the full data range of the series found in the input data set at the time of refitting.

If you prefer to apply previously fit models to revised data without refitting, use Reevaluate Models instead of Refit Models. This recomputes the statistics of fit by using the current evaluation range, but does not re-estimate the model parameters.

Using Hold-out Samples

One important application of model fitting where the period of fit is different from the period of evaluation is the use of hold-out samples. With this technique of model evaluation, the period of fit ends at a time point before the end of the data series, and the remainder of the data are held out as a nonoverlapping period of evaluation. With respect to the period of fit, the hold-out sample is a period in the future, used to compare the forecasting accuracy of models fit to past data.

For this exercise, use a hold-out sample of 12 months. Bring up the Time Ranges Specification window again by clicking the Set Ranges button. Set Hold-out Sample to 12 using the combo box, as shown in Figure 61.16. You can also type in a value. To specify a hold-out sample period in different units, you can use the Periods combo box. In this case, it allows you to select years as the unit, instead of periods.
Notice that setting the hold-out sample to 12 automatically sets the fit range to JUN1978–JUL1981 and the evaluation range to AUG1981–JUL1982. If you had set the period of fit and period of evaluation to these ranges, the hold-out sample would have been automatically set to 12 periods.

Click the **OK** button to return to the **Develop Models** window. Now refit the models again. Select **Tools** and **Compare Models** to compare the models now that they have been fit to the period June 1978 through July 1981 and evaluated for the hold-out sample period August 1981 through July 1982. Note that the fit statistics for the hold-out sample are based on one-step-ahead forecasts. (See the section “Statistics of Fit” in Chapter 65, “Forecasting Process Details.”)

As shown in Figure 61.17, the ARIMA (0,1,0)(0,1,0)s model now seems to provide a better fit to the data than does the Airline model. It should be noted that the results can be quite different if you choose a different size hold-out sample.

Forecasting models predict the future values of a series by using two sources of information: the past values of the series and the values of other time series variables. Other variables used to predict a series are called predictor variables.

Predictor variables that are used to predict the dependent series can be variables in the input data set, such as regressors and adjustment variables, or they can be special variables computed by the system as functions of time, such as trend curves, intervention variables, and seasonal dummies.

You can specify seven different types of predictors in forecasting models by using the ARIMA Model or Custom Model Specification windows. You cannot specify predictor variables with the Smoothing Model Specification window.

Figure 62.1 shows the menu of options for adding predictors to an ARIMA model that is opened by clicking the Add button. The Add menu for the Custom Model Specification menu is similar.
These types of predictors are as follows:

**Linear Trend**
adds a variable that indexes time as a predictor series. A straight line time trend is fit to the series by regression when you specify a linear trend.

**Trend Curve**
provides a menu of various functions of time that you can add to the model to fit nonlinear time trends. The Linear Trend option is a special case of the Trend Curve option for which the trend curve is a straight line.

**Regressors**
allows you to predict the series by regressing it on other variables in the data set.

**Adjustments**
allows you to specify other variables in the data set that supply adjustments to the forecast.

**Dynamic Regressor**
allows you to select a predictor variable from the input data set and specify a complex model for the way that the predictor variable affects the dependent series.

**Interventions**
allows you to model the effect of special events that “intervene” to change the pattern of the dependent series. Examples of intervention effects are strikes, tax increases, and special sales promotions.

**Seasonal Dummies**
adds seasonal indicator or “dummy” variables as regressors to model seasonal effects.
You can add any number of predictors to a forecasting model, and you can combine predictor variables with other model options.

The following sections explain these seven kinds of predictors in greater detail and provide examples of their use. The examples illustrate these different kinds of predictors by using series in the SASHELP.USECON data set.

Click the Develop Models button in the main window. Select the data set SASHELP.USECON, and select the series PETROL. Then click the View Series Graphically button in the Develop Models window. The plot of the example series PETROL appears as shown in Figure 62.2.

Figure 62.2  Sales of Petroleum and Coal

Linear Trend

From the Develop Models window, select Fit ARIMA Model. In the ARIMA Model Specification window, click Add and then select Linear Trend from the menu (shown in Figure 62.1).

A linear trend is added to the Predictors list, as shown in Figure 62.3.
The description for the linear trend item shown in the Predictors list has the following meaning. The first part of the description, Trend Curve, describes the type of predictor. The second part, _LINEAR_, gives the variable name of the predictor series. In this case, the variable is a time index that the system computes. This variable is included in the output forecast data set. The final part, Linear Trend, describes the predictor.

Notice that the model you have specified consists only of the time index regressor _LINEAR_ and an intercept. Although this window is normally used to specify ARIMA models, in this case no ARIMA model options are specified, and the model is a simple regression on time.

Click the **Ok** button. The Linear Trend model is fit and added to the model list in the Develop Models window.

Now open the Model Viewer by using the **View Model Graphically** icon or the **Model Predictions** item under the **View** pull-down menu or toolbar. This displays a plot of the model predictions and actual series values, as shown in **Figure 62.4**. The predicted values lie along the least squares trend line.
Time Trend Curves

From the Develop Models window, select Fit ARIMA Model. In the ARIMA Model Specification window, click Add and then select Trend Curve from the menu (shown in Figure 62.1). A menu of different kinds of trend curves is displayed, as shown in Figure 62.5.
These trend curves work in a similar way as the Linear Trend option (which is a special case of a trend curve and one of the choices on the menu), but with the Trend Curve menu you have a choice of various nonlinear time trends.

Select Quadratic Trend. This adds a quadratic time trend to the Predictors list, as shown in Figure 62.6.
Now click the OK button. The quadratic trend model is fit and added to the list of models in the Develop Models window. The Model Viewer displays a plot of the quadratic trend model, as shown in Figure 62.7.
Chapter 62: Using Predictor Variables

Figure 62.7 Quadratic Trend Model

This curve does not fit the PETROL series very well, but the View Model plot illustrates how time trend models work. You might want to experiment with different trend models to see what the different trend curves look like.

Some of the trend curves require transforming the dependent series. When you specify one of these curves, a notice is displayed reminding you that a transformation is needed, and the Transformation field is automatically filled in. Therefore, you cannot control the Transformation specification when some kinds of trend curves are specified.

For more information about the different trend curves, see the section “Time Trend Curves” on page 4009 in Chapter 65, “Forecasting Process Details.”
Regressors

From the Develop Models window, select Fit ARIMA Model. In the ARIMA Model Specification window, click Add and then select Regressors from the menu (shown in Figure 62.1). This displays the Regressors Selection window, as shown in Figure 62.8. This window allows you to select any number of other series in the input data set as regressors to predict the dependent series.

For this example, select CHEMICAL, Sales: Chemicals and Allied Products, and VEHICLES, Sales: Motor Vehicles and Parts. (Note: You do not need to use the CTRL key when selecting more than one regressor.) Then click the OK button. The two variables you selected are added to the Predictors list as regressor type predictors, as shown in Figure 62.9.
You must have forecasts of the future values of the regressor variables in order to use them as predictors. To do this, you can specify a forecasting model for each regressor, have the system automatically select forecasting models for the regressors, or supply predicted future values for the regressors in the input data set.

Even if you have supplied future values for a regressor variable, the system requires a forecasting model for the regressor. Future values that you supply in the input data set take precedence over predicted values from the regressor’s forecasting model when the system computes the forecasts for the dependent series.

Click the **OK** button. The system starts to fit the regression model but then stops and displays a warning that the regressors that you selected do not have forecasting models, as shown in Figure 62.10.
If you want the system to create forecasting models automatically for the regressor variables by using the automatic model selection process, click the **OK** button. If not, you can click the **Cancel** button to abort fitting the regression model.

For this example, click the **OK** button. The system now performs the automatic model selection process for **CHEMICAL** and **VEHICLES**. The selected forecasting models for **CHEMICAL** and **VEHICLES** are added to the model lists for those series. If you switch the current time series in the Develop Models window to **CHEMICAL** or **VEHICLES**, you will see the model that the system selected for that series.

Once forecasting models have been fit for all regressors, the system proceeds to fit the regression model for **PETROL**. The fitted regression model is added to the model list displayed in the Develop Models window.

---

**Adjustments**

An *adjustment* predictor is a variable in the input data set that is used to adjust the forecast values produced by the forecasting model. Unlike a regressor, an adjustment variable does not have a regression coefficient. No model fitting is performed for adjustments. Nonmissing values of the adjustment series are simply added to the model prediction for the corresponding period. Missing adjustment values are ignored. If you supply
adjustment values for observations within the period of fit, the adjustment values are subtracted from the actual values, and the model is fit to these adjusted values.

To add adjustments, click Add and then select Adjustments from the pop-up menu (shown in Figure 62.1). This displays the Adjustments Selection window. The Adjustments Selection window functions the same as the Regressor Selection window (which is shown in Figure 62.8). You can select any number of adjustment variables as predictors.

Unlike regressors, adjustments do not require forecasting models for the adjustment variables. If a variable that is used as an adjustment does have a forecasting model fit to it, the adjustment variable’s forecasting model is ignored when the variable is used as an adjustment.

You can use forecast adjustments to account for expected future events that have no precedent in the past and so cannot be modeled by regression. For example, suppose you are trying to forecast the sales of a product, and you know that a special promotional campaign for the product is planned during part of the period you want to forecast. If such sales promotion programs have been frequent in the past, then you can record the past and expected future level of promotional efforts in a variable in the data set and use that variable as a regressor in the forecasting model.

However, if this is the first sales promotion of its kind for this product, you have no way to estimate the effect of the promotion from past data. In this case, the best you can do is to make an educated guess at the effect the promotion will have and add that guess to what your forecasting model would predict in the absence of the special sales campaign.

Adjustments are also useful for making judgmental alterations to forecasts. For example, suppose you have produced forecast sales data for the next 12 months. Your supervisor believes that the forecasts are too optimistic near the end and asks you to prepare a forecast graph in which the numbers that you have forecast are reduced by 1000 in the last three months. You can accomplish this task by editing the input data set so that it contains observations for the actual data range of sales plus 12 additional observations for the forecast period, and a new variable called, for example, ADJUSTMENT. The variable ADJUSTMENT contains the value 1000 for the last three observations and is missing for all other observations. You fit the same model previously selected for forecasting by using the ARIMA Model Specification or Custom Model Specification window, but with an adjustment added that uses the variable ADJUSTMENT. Now when you graph the forecasts by using the Model Viewer, the last three periods of the forecast are reduced by 1000. The confidence limits are unchanged, which helps draw attention to the fact that the adjustments to the forecast deviate from what would be expected statistically.

---

**Dynamic Regressor**

Selecting Dynamic Regressor from the Add Predictors menu (shown in Figure 62.1) allows you to specify a complex time series model of the way that a predictor variable influences the series that you are forecasting.

When you specify a predictor variable as a simple regressor, only the current period value of the predictor affects the forecast for the period. By specifying the predictor with the Dynamic Regression option, you can use past values of the predictor series, and you can model effects that take place gradually.

Dynamic regression models are an advanced feature that you are unlikely to find useful unless you have studied the theory of statistical time series analysis. You might want to skip this section if you are not trained in time series modeling.
The term *dynamic regression* was introduced by Pankratz (1991) and refers to what Box and Jenkins (1976) named *transfer function models*. In dynamic regression, you have a time series model, similar to an ARIMA model, that predicts how changes in the predictor series affect the dependent series over time.

The dynamic regression model relates the predictor variable to the expected value of the dependent series in the same way that an ARIMA model relates the fluctuations of the dependent series about its conditional mean to the random error term (which is also called the innovation series). For more information about dynamic regression or transfer function, see Pankratz (1991); Box and Jenkins (1976). See also Chapter 7, “The ARIMA Procedure.”

From the Develop Models window, select *Fit ARIMA Model*. In the ARIMA Model Specification window, click *Add* and then select *Linear Trend* from the menu (shown in Figure 62.1).

Now click *Add* and select *Dynamic Regressor*. This displays the *Dynamic Regressors Selection* window, as shown in Figure 62.11.

**Figure 62.11** Dynamic Regressors Selection Window
You can select only one predictor series when specifying a dynamic regression model. For this example, select VEHICLES, Sales: Motor Vehicles and Parts. Then click the OK button.

This displays the **Dynamic Regression Specification** window, as shown in **Figure 62.12**.

**Figure 62.12** Dynamic Regression Specification Window

This window consists of four parts. The **Input Transformations** fields enable you to transform or lag the predictor variable. For example, you might use the lagged logarithm of the variable as the predictor series.

The **Order of Differencing** fields enable you to specify simple and seasonal differencing of the predictor series. For example, you might use changes in the predictor variable instead of the variable itself as the predictor series.

The **Numerator Factors** and **Denominator Factors** fields enable you to specify the orders of simple and seasonal numerator and denominator factors of the transfer function.
Simple regression is a special case of dynamic regression in which the dynamic regression model consists of only a single regression coefficient for the current value of the predictor series. If you click the OK button without specifying any options in the Dynamic Regression Specification window, a simple regressor will be added to the model.

For this example, use the Simple Order combo box for Denominator Factors and set its value to 1. The window now appears as shown in Figure 62.13.

**Figure 62.13** Distributed Lag Regression Specified

This model is equivalent to regression on an exponentially weighted infinite distributed lag of VEHICLES (in the same way an MA(1) model is equivalent to single exponential smoothing).

Click the OK button to add the dynamic regressor to the model predictors list.

In the ARIMA Model Specification window, the Predictors list should now contain two items, a linear trend and a dynamic regressor for VEHICLES, as shown in Figure 62.14.
This model is a multiple regression of PETROL on a time trend variable and an infinite distributed lag of VEHICLES. Click the OK button to fit the model.

As with simple regressors, if VEHICLES does not already have a forecasting model, an automatic model selection process is performed to find a forecasting model for VEHICLES before the dynamic regression model for PETROL is fit.
Interventions

An intervention is a special indicator variable, computed automatically by the system, that identifies time periods affected by unusual events that influence or intervene in the normal path of the time series you are forecasting. When you add an intervention predictor, the indicator variable of the intervention is used as a regressor, and the impact of the intervention event is estimated by regression analysis.

To add an intervention to the Predictors list, you must use the Intervention Specification window to specify the time or times that the intervening event took place and to specify the type of intervention. You can add interventions either through the Interventions item of the Add action or by selecting Tools from the menu bar and then selecting Define Interventions.

Intervention specifications are associated with the series. You can specify any number of interventions for each series, and once you define interventions you can select them for inclusion in forecasting models. If you select the Include Interventions option in the Options menu, any interventions that you have previously specified for a series are automatically added as predictors to forecasting models for the series.

From the Develop Models window, invoke the series viewer by selecting the View Series Graphically icon or Series under the View menu. This displays the Time Series Viewer, as was shown in Figure 62.2.

Note that the trend in the PETROL series shows several clear changes in direction. The upward trend in the first part of the series reverses in 1981. There is a sharp drop in the series towards the end of 1985, after which the trend is again upwardly sloped. Finally, in 1991 the series takes a sharp upward excursion but quickly returns to the trend line.

You might have no idea what events caused these changes in the trend of the series, but you can use these patterns to illustrate the use of intervention predictors. To do this, you fit a linear trend model to the series, but modify that trend line by adding intervention effects to model the changes in trend you observe in the series plot.

The Intervention Specification Window

From the Develop Models window, select Fit ARIMA model. In the ARIMA Model Specification window, click Add and then select Linear Trend from the menu (shown in Figure 62.1).

Select Add again and then select Interventions. If you have any interventions already defined for the series, this selection displays the Interventions for Series window. However, since you have not previously defined any interventions, this list is empty. Therefore, the system assumes that you want to add an intervention and displays the Intervention Specification window instead, as shown in Figure 62.15.
Chapter 62: Using Predictor Variables

Figure 62.15 Interventions Specification Window

The top of the Intervention Specification window shows the current series and the label for the new intervention (initially blank). At the right side of the window is a scrollable table showing the values of the series. This table helps you locate the dates of the events you want to model.

At the left of the window is an area titled Intervention Specification that contains the options for defining the intervention predictor. The Date field specifies the time that the intervention occurs. You can type a date value in the Date field, or you can set the Date value by selecting a row from the table of series values at the right side of the window.

The area titled Type of Intervention controls the kind of indicator variable constructed to model the intervention effect. You can specify the following kinds of interventions:

Point is used to indicate an event that occurs in a single time period. An example of a point event is a strike that shuts down production for part of a time period. The value of the intervention’s indicator variable is zero except for the date specified.

Step is used to indicate a continuing event that changes the level of the series. An example of a step event is a change in the law, such as a tax rate increase. The value of the intervention’s indicator variable is zero before the date specified and 1 thereafter.
Specifying a Trend Change Intervention

Ramp is used to indicate a continuing event that changes the trend of the series. The value of the intervention’s indicator variable is zero before the date specified, and it increases linearly with time thereafter.

The areas titled Effect Time Window and Effect Decay Pattern specify how to model the effect that the intervention has on the dependent series. These options are not used for simple interventions, they will be discussed later in this chapter.

Specifying a Trend Change Intervention

In the Time Series Viewer window position the mouse over the highest point in 1981 and select the point. This displays the data value, 19425, and date, February 1981, of that point in the upper-right corner of the Time Series Viewer, as shown in Figure 62.16.

Figure 62.16 Identifying the Turning Point

Now that you know the date that the trend reversal occurred, enter that date in the Date field of the Intervention Specification window. Select Ramp as the type of intervention. The window should now appear as shown in Figure 62.17.
Click the OK button. This adds the intervention to the list of interventions for the PETROL series, and returns you to the Interventions for Series window, as shown in Figure 62.18.
This window allows you to select interventions for inclusion in the forecasting model. Since you need to define other interventions, click the Add button. This returns you to the Intervention Specification window (shown in Figure 62.15).
Specifying a Level Change Intervention

Now add an intervention to account for the drop in the series in late 1985. You can locate the date of this event by selecting points in the Time Series Viewer plot or by scrolling through the data values table in the Interventions Specification window. Use the latter method so that you can see how this works.

Scrolling through the table, you see that the drop was from 15262 in December 1985, to 13937 in January 1986, to 12002 in February, to 10834 in March. Since the drop took place over several periods, you could use another ramp type intervention. However, this example represents the drop as a sudden event by using a step intervention and uses February 1986 as the approximate time of the drop.

Select the table row for February 1986 to set the Date field. Select Step as the intervention type. The window should now appear as shown in Figure 62.19.

Click the OK button to add this intervention to the list for the series.

Since the trend reverses again after the drop, add a ramp intervention for the same date as the step intervention. Click Add from the Interventions for Series window. Enter FEB86 in the Date field, select Ramp, and then click the OK button.
Modeling Complex Intervention Effects

You have now defined three interventions to model the changes in trend and level. The excursion near the end of the series remains to be dealt with.

Click Add in the Interventions for Series window. Scroll through the data values and select the date on which the excursion began, August 1990. Leave the intervention type as Point.

The pattern of the series from August 1990 through January 1991 is more complex than a simple shift in level or trend. For this pattern, you need a complex intervention model for an event that causes a sharp rise followed by a rapid return to the previous trend line. To specify this model, use the Effect Time Window and Effect Decay Rate options.

The Effect Time Window option controls the number of lags of the intervention’s indicator variable used to model the effect of the intervention on the dependent series. For a simple intervention, the number of lags is zero, which means that the effect of the intervention is modeled by fitting a single regression coefficient to the intervention’s indicator variable.

When you set the number of lags greater than zero, regression coefficients are fit to lags of the indicator variable. This allows you to model interventions whose effects take place gradually, or to model rebound effects. For example, severe weather might reduce production during one period but cause an increase in production in the following period as producers struggle to catch up. You could model this by using a point intervention with an effect time window of 1 lag. This would fit two coefficients for the intervention, one for the immediate effect and one for the delayed effect.

The Effect Decay Pattern option controls how the effect of the intervention dissipates over time. None specifies that there is no gradual decay: for point interventions, the effect ends immediately; for step and ramp interventions, the effect continues indefinitely. Exp specifies that the effect declines at an exponential rate. Wave specifies that the effect declines like an exponentially damped sine wave (or as the sum of two exponentials, depending on the fit to the data).

If you are familiar with time series analysis, these options might be clearer if you note that together the Effect Time Window and Effect Decay Pattern options define the numerator and denominator orders of a transfer function or dynamic regression model for the indicator variable of the intervention. For more information, see the section “Dynamic Regressor” on page 4016.

For this example, select 2 lags as the value of the Event Time Window option, and select Exp as the Effect Decay Pattern option. The window should now appear as shown in Figure 62.20.
Click the **OK** button to add the intervention to the list.

**Fitting the Intervention Model**

The Interventions for Series window now contains definitions for four intervention predictors. Select all four interventions, as shown in Figure 62.21.
Click the OK button. This returns you to the ARIMA Model Specification window, which now lists items in the Predictors list, as shown in Figure 62.22.
Click the OK button to fit this model. After the model is fit, bring up the Model Viewer. You will see a plot of
the model predictions, as shown in Figure 62.23.
You can use the Zoom In feature to take a closer look at how the complex intervention effect fits the excursion in the series starting in August 1990.
Limitations of Intervention Predictors

Note that the model you have just fit is intended only to illustrate the specification of interventions. It is not intended as an example of good forecasting practice.

The use of continuing (step and ramp type) interventions as predictors has some limitations that you should consider. If you model a change in trend with a simple ramp intervention, then the trend in the data before the date of the intervention has no influence on the forecasts. Likewise, when you use a step intervention, the average level of the series before the intervention has no influence on the forecasts.

Only the final trend and level at the end of the series are extrapolated into the forecast period. If a linear trend is the only pattern of interest, then instead of specifying step or ramp interventions, it would be simpler to adjust the period of fit so that the model ignores the data before the final trend or level change.

Step and ramp interventions are valuable when there are other patterns in the data—such as seasonality, autocorrelated errors, and error variance—that are stable across the changes in level or trend. Step and ramp interventions enable you to fit seasonal and error autocorrelation patterns to the whole series while fitting the trend only to the latter part of the series.

Point interventions are a useful tool for dealing with outliers in the data. A point intervention will fit the series value at the specified date exactly, and it has the effect of removing that point from the analysis. When you specify an effect time window, a point intervention will exactly fit as many additional points as the number of lags specified.

Seasonal Dummies

A Seasonal Dummies predictor is a special feature that adds to the model seasonal indicator or “dummy” variables to serve as regressors for seasonal effects.

From the Develop Models window, select Fit ARIMA Model. In the ARIMA Model Specification window, click Add and then select Seasonal Dummies from the menu (shown in Figure 62.1).

A Seasonal Dummies input is added to the Predictors list, as shown in Figure 62.24.
Click the OK button. A model consisting of an intercept and 11 seasonal dummy variables is fit and added to the model list in the Develop Models window. This is effectively a mean model with a separate mean for each month.

Now return to the Model Viewer, which displays a plot of the model predictions and actual series values, as shown in Figure 62.25. This is obviously a poor model for this series, but it serves to illustrate how seasonal dummy variables work.
Now select the parameter estimates icon, the fifth from the top on the vertical toolbar. This displays the Parameter Estimates table, as shown in Figure 62.26.
Since the data for this example are monthly, the Seasonal Dummies option added 11 seasonal dummy variables. These include a dummy regressor variable that is 1.0 for January and 0 for other months, a regressor that is 1.0 only for February, and so forth through November.

Because the model includes an intercept, no dummy variable is added for December. The December effect is measured by the intercept, while the effect of other seasons is measured by the difference between the intercept and the estimated regression coefficient for the season’s dummy variable.

The same principle applies for other data frequencies: the “Seasonal Dummy 1” parameter always refers to the first period in the seasonal cycle; and, when an intercept is present in the model, there is no seasonal dummy parameter for the last period in the seasonal cycle.

TSVIEW Command and Macro

The TSVIEW command invokes the Time Series Viewer. This is a component of the Time Series Forecasting System that can also be used as a standalone graphical viewer for any time series data set or view. For more information, see the section “Time Series Viewer Window” in Chapter 64, “Window Reference.”

The TSVIEW command must be specified from the command line or an SCL program. If you need to submit from the program editor, use the %TSVIEW macro instead. You can use the macro within a DATA step program, but you must submit it within the SAS windowing environment.

If the TSVIEW command or %TSVIEW macro is issued without arguments, the Series Selection window appears to enable you to select an input data set and series. This is equivalent to selecting “Time Series Viewer” from the Analysis submenu of the Solutions menu. By specifying the DATA= and VAR= arguments, you can bring up the Time Series Viewer window directly. The ID= and INTERVAL= arguments are useful when the system cannot determine them automatically from the data.

Syntax

The TSVIEW command has the following form:

\[
\text{TSVIEW} \ [\text{options}] ; \\
\]

The %TSVIEW macro has the following form:

\[
\%\text{TSVIEW} \ [(\text{option, \ldots, option})] ; \\
\]

The following options can be specified for the command and the macro:
DATA=data-set-name
    specifies the name of the SAS data set containing the input data.

VAR=time-series-variable-name
    specifies the series variable name. It must be a numeric variable contained in the data set.

ID=time-id-variable-name
    specifies the time ID variable name for the data set. If the ID= option is not specified, the system attempts to locate the variables named DATE, DATETIME, and TIME in the data set specified by the DATA= option.

INTERVAL=interval-name
    specifies the time ID interval between observations in the data set.

Examples

TSVIEW Command

    tsview data=sashelp.air var=air
    tsview data=dept.prod var=units id=period interval=qtr

%TSVIEW Macro

    %tsview( data=sashelp.air, var=air);
    %tsview( data=dept.prod, var=units, id=period, interval=qtr);

FORECAST Command and Macro

The FORECAST command invokes the Time Series Forecasting System. The command must be specified from the command line or an SCL program. If you need to submit from the program editor, use the %FORECAST macro instead. You can use the macro within a data step program, but you must submit it within the SAS windowing environment.

If the FORECAST command or %FORECAST macro is issued without arguments, the Time Series Forecasting window appears. This is equivalent to selecting “Time Series Forecasting System” from the Analysis submenu of the Solutions menu.

Using the arguments, it is possible to do the following:

- Bring up the system with information already filled into some of the fields.
- Bring up the system starting at a different window than the default Time Series Forecasting window.
- Run the system in unattended mode so that a task such as creating a forecast data set is accomplished without any user interaction. By submitting such commands repeatedly from a SAS/AF or SAS/EIS application, it is possible to do “batch” processing for many data sets or BY-group processing for many subsets of a data set. You can create a project in unattended mode and later open it for inspection.
interactively. You can also create a project interactively in order to set options, fit a model, or edit the list of models, and then use this project later in unattended mode.

The Forecast Command Builder, a point-and-click SAS/AF application, makes it easy to specify, run, save, and rerun forecasting jobs by using the FORECAST command. To use it, enter the following on the command line (not the program editor):

   \%FCB

or

   AF C=SASHELP.FORCAST.FORCCMD.FRAME.

---

**Syntax**

The FORECAST command has the following form:

```
FORECAST [options] ;
```

The %FORECAST macro has the following form:

```
%FORECAST [(option, . . . , option)] ;
```

The following options can be specified for the command and the macro.

- **PROJECT=** `project-name`  
  specifies the name of the SAS catalog entry in which forecasting models and other results are stored and from which previously stored results are loaded into the forecasting system.

- **DATA=** `data-set-name`  
  specifies the name of the SAS data set containing the input data.

- **VAR=** `time-series-variable-name`  
  specifies the series variable name. It must be a numeric variable contained in the data set.

- **ID=** `time-id-variable-name`  
  specifies the time ID variable name for the data set. If the ID= option is not specified, the system attempts to locate the variables named DATE, DATETIME, and TIME in the data set specified by the DATA= option. However, it is recommended that you specify the time ID variable whenever you are using the ENTRY= argument.

- **INTERVAL=** `interval-name`  
  specifies the time ID interval between observations in the data set. Commonly used intervals are year, semiyear, qtr, month, semimonth, week, weekday, day, hour, minute, and second. For information about more complex interval specifications, see Chapter 4, “Date Intervals, Formats, and Functions.” If the INTERVAL= option is not specified, the system attempts to determine the interval based on the time ID variable. However, it is recommended that you specify the interval whenever you are using the ENTRY= argument.
STAT=statistic
specifies the name of the goodness-of-fit statistic to be used as the model selection criterion. The default is RMSE. You can specify the following statistics:

- **SSE** specifies the sum of square error.
- **MSE** specifies the mean square error.
- **RMSE** specifies the root mean square error.
- **MAE** specifies the mean absolute error.
- **MAPE** specifies the mean absolute percent error.
- **AIC** specifies Akaike’s information criterion.
- **SBC** specifies the Schwarz Bayesian information criterion.
- **RSQUARE** specifies the R-square.
- **AJDRSQ** specifies the adjusted R-square.
- **RWRSQ** specifies the random walk R-square.
- **ARSQ** specifies Amemiya’s adjusted R-square.
- **APC** specifies Amemiya’s prediction criterion.

CLIMIT=integer
specifies the level of the confidence limits to be computed for the forecast. This integer represents a percentage; for example, 925 indicates 92.5% confidence limits. The default is 95—that is, 95% confidence limits.

HORIZON=integer
specifies the number of periods into the future for which forecasts are computed. The default is 12 periods. The maximum is 9999.

ENTRY=name
specifies the name of an entry point into the system. You can specify the following names:

- **MAIN** starts the system at the Time Series Forecasting window (default).
- **DEVMOD** starts the system at the Develop Models window.
- **VIEWMOD** starts the system at the Model Viewer window. Specify a project that contains a forecasting model by using the PROJECT= option. If a project containing a model is not specified, the message “No forecasting model to view” appears.
- **VIEWSER** starts the system at the Time Series Viewer window.
- **AUTOFIT** runs the system in unattended mode, fitting a forecasting model automatically and saving it in a project. If PROJECT= is not specified, the default project name SASUSER.FMSPROJ.PROJ is used.
- **FORECAST** runs the system in unattended mode to generate a forecast data set. The name of this data set is specified by the OUT= parameter. If OUT= is not specified, a window appears to prompt for the name and label of the output data set. If PROJECT= is not specified, the default project name SASUSER.FMSPROJ.PROJ is used. If the project does not exist or does not contain a forecasting model for the specified
series, automatic model fitting is performed and the forecast is computed by using the automatically selected model. If the project exists and contains a forecasting model for the specified series, the forecast is computed by using this model. If the series covers a different time range than it did when the project was created, use the REFIT or REEVAL keyword to reset the time ranges.

**OUT=**argument
specifies one or two-level name of a SAS data set in which forecasts are saved. Use in conjunction with ENTRY=FORECAST. If omitted, the system prompts for the name of the forecast data set.

**KEEP=**argument
specifies the number of models to keep in the project when automatic model fitting is performed. This corresponds to Models to Keep in the Automatic Model Selection Options window. A value greater than 9 indicates that all models are kept. The default is 1.

**DIAG=YES | NO**
specifies which models to search with regard to series diagnostics. DIAG=YES causes the automatic model selection process to search only over those models that are consistent with the series diagnostics. DIAG=NO causes the automatic model selection process to search over all models in the selection list, without regard for the series diagnostics. This corresponds to Models to Fit in the Automatic Model Selection Options window. The default is YES.

**REFIT=**keyword
(for macro usage) refits a previously saved forecasting model by using the current fit range; that is, it reestimates the model parameters. Refitting also causes the model to be reevaluated (statistics of fit recomputed), and it causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). This keyword has no effect if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REFIT keyword if you have added new data to the input series and you want to refit the forecasting model and update the forecast by using the new time ranges. Be sure to use the same project, data set, and series names that you used previously.

**REEVAL=**keyword
(for macro usage) reevaluates a previously saved forecasting model by using the current evaluation range; that is, it recomputes the statistics of fit. Reevaluating also causes the time ranges to be reset if the data range has changed (for example, if new observations have been added to the series). It does not refit the model parameters. This keyword has no effect if you also specify REFIT, or if you do not use the PROJECT= argument to reference an existing project containing a forecasting model. Use the REEVAL keyword if you have added new data to the input series and want to update your forecast by using a previously fit forecasting model and the same project, data set, and series names that you used previously.
Examples

**FORECAST Command**

The following command opens the Time Series Forecasting window with the data set name and series name filled in. The time ID variable is also filled in since the data set contains the variable DATE. The interval is filled in because the system recognizes that the observations are monthly.

```
forecast data=sashelp.air var=air
```

The following command opens the Time Series Forecasting window with the project, data set name, series, time ID, and interval fields filled in, assuming that the project SAMPROJ was previously saved either interactively or by using unattended mode as depicted below. Previously fit models appear when the Develop Models or Manage Projects window is opened.

```
forecast project=samproj
```

The following command runs the system in unattended mode, fitting a model automatically, storing it in the project SAMPROJ in the default catalog SASUSER.FMSPROJ, and placing the forecasts in the data set WORK.SAMPOUT:

```
forecast data=sashelp.workers var=electric id=date interval=month
          project=samproj entry=forecast out=sampout
```

The following command assumes that a new month’s data have been added to the data set from the previous example and that an updated forecast is needed that uses the previously fit model. Time ranges are automatically updated to include the new data since the REEVAL keyword is included. Substitute REFIT for REEVAL if you want the system to reestimate the model parameters.

```
forecast data=sashelp.workers var=electric id=date interval=month
          project=samproj entry=forecast out=sampout reeval
```

The following command opens the model viewer with the project created in the previous example and with 99% confidence limits in the forecast graph:

```
forecast data=sashelp.workers var=electric id=date interval=month
          project=samproj entry=viewmod climit=99
```

The final example illustrates using unattended mode with an existing project that has been defined interactively. In this example, the goal is to add a model to the model selection list, to specify that all models in that list be fit, and that all models which are fit successfully be retained.

First open the Time Series Forecasting window and specify a new project name, WORKPROJ. Then select Develop Models, choosing SASHELP.WORKERS as the data set and MASONRY as the series. Now select “Model Selection List” from the Options menu. In the Model Selection List window, click Actions, then Add, and then ARIMA Model. Define the model ARIMA(0,1,0)(0,1,0)s NOINT by setting the differencing value to 1 under both ARIMA Options and Seasonal ARIMA Options. Click OK to save the model and OK to close the Model Selection List window. Now select “Automatic Fit” from the Options menu. In the Automatic Model Selection Options window, select “All autofit models in selection list” in the Models to fit radio box, select “All models” from the Models to keep combo box, and then click OK to close the window. Select “Save Project” from the File menu, and then close the Develop Models window and the Time Series Forecasting window. You now have a project with a new model added to the selection list, options set for automatic model fitting, and one series selected but no models fit.
Now enter the following command:

```
forecast data=sashelp.workers var=electric id=date interval=month
  project=workproj entry=forecast out=workforc
```

The system runs in unattended mode to update the project and create the forecast data set WORKFORC. Check the messages in the Log window to find out if the run was successful and which model was selected for forecasting. To see the forecast data set, issue the command `viewtable WORKFORC`. To see the contents of the project, open the Time Series Forecasting window, open the project WORKPROJ, and select “Manage Projects.” You will see that the variable ELECTRIC was added to the project and has a forecasting model. Select this row in the table and then select `List Models` from the Tools menu. You will see that all of the models in the selection list which fit successfully are there, including the new model you added to the selection list.

%FORECAST Macro

This example demonstrates the use of the `%FORECAST` macro to start the Time Series Forecasting System from a SAS program submitted from the Editor window. The SQL procedure is used to create a view of a subset of a products data set. Then the `%FORECAST` macro is used to produce forecasts.

```
proc sql;
   create view selprod as
      select * from products
      where type eq 'A'
      order by date;
run;

%forecast(data=selprod, var=amount, id=date, interval=day,
   entry=forecast, out=typea, project=proda, refit=);
```

Overview

This chapter provides a reference to the various windows of the Time Series Forecasting System. The windows are presented in alphabetical order by name. Each section describes the purpose of the window, how to open it, its controls, fields, and menus. For windows that have their own menus, there is a description of each menu item under the heading “Menu Bar.” These windows also have a toolbar with icons that duplicate the more commonly used menu items. Each icon has a screen tip: a brief description that appears when you hover the mouse pointer over the icon. If you don’t see the screen tips, open the SAS Preferences window, under the Options submenu of the Tools menu. Select the View tab and make sure the “Screen tips” check box is checked.

Adjustments Selection Window

Use the Adjustments Selection window to select input variables for use as adjustments to the forecasts and add them to the Predictors list. Invoke this window from the pop-up menu that appears when you click the Add button in the ARIMA Model Specification window or Custom Model Specification window. For more information, see the “Adjustments” section in Chapter 62, “Using Predictor Variables.”
AR/MA Polynomial Specification Window

Controls and Fields

Dependent
is the name and variable label of the current series.

Adjustments
is a table that lists the names and labels in the input data set available for selection as adjustments. The variables you select are highlighted. Selecting a highlighted row again deselects that variable.

OK
closes the Adjustments Selection window and adds the selected variables as adjustments in the model.

Cancel
closes the window without adding any adjustments.

Reset
resets all selections to their initial values upon entry to the window.

AR/MA Polynomial Specification Window

Use these windows to specify the autoregressive and moving-average terms in a factored ARIMA model. Access the AR Polynomial Specification window from the Set button next to the Autoregressive term in the Factored ARIMA Model Specification window. Access the MA Polynomial Specification window from the Set button next to the Moving Average term.
Chapter 64: Window Reference

Controls and Fields

List of Polynomials

lists the polynomials that have been specified. Each polynomial is represented by a comma-delimited list of lag values enclosed in parentheses.

New
opens the Polynomial Specification window to add a new polynomial to the model.

Edit
opens the Polynomial Specification window to edit a polynomial that has been selected. If no polynomial is selected, this button is unavailable.

Remove
removes a selected polynomial from the list. If none are selected, this button is unavailable.

Remove All
clears the list of polynomials.

Move Up
moves a selected polynomial up one position in the list. If no polynomial is selected, or the first one is selected, this button is unavailable.

Move Down
moves a selected polynomial down one position in the list. If no polynomial is selected, or the last one is selected, this button is unavailable.

OK
closes the window and returns the specified list of polynomials to the Factored ARIMA Model Specification window.
ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit on the menu bar, or from the pop-up menu when you click an empty area of the model table.

### ARIMA Model Specification

<table>
<thead>
<tr>
<th>Series:</th>
<th>HSTOTAL: Housing Starts, Total Private</th>
</tr>
</thead>
<tbody>
<tr>
<td>Model:</td>
<td></td>
</tr>
</tbody>
</table>

**ARIMA Options**

- **Autoregressive**: \( p = 0 \)  
- **Differencing**: \( d = 0 \)  
- **Moving Average**: \( q = 0 \)  

**Seasonal ARIMA Options**

- **Autoregressive**: \( P = 0 \)  
- **Differencing**: \( D = 0 \)  
- **Moving Average**: \( Q = 0 \)  

**Transformation**: None

**Predictors**

| OK | Cancel | Reset | Clear | Add... | Delete | Edit... | Help |

### Controls and Fields

**Series**

is the name and variable label of the current series.

**Model**

is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

**ARIMA Options**

specify the orders of the ARIMA model. You can either type in a value or click the arrow to select from a list.

- **Autoregressive**
  
  defines the order of the autoregressive part of the model.
Differencing
defines the order of simple differencing—for example, first difference or second difference.

Moving Average
defines the order of the moving-average part of the model.

Seasonal ARIMA Options
specifies the orders of the seasonal part of the ARIMA model. You can either type in a value or click the arrow to select from a list.

Autoregressive
defines the order of the seasonal autoregressive part of the model.

Differencing
defines the order of seasonal differencing—for example, first difference or second difference at the seasonal lags.

Moving Average
defines the order of the seasonal moving-average part of the model.

Transformation
defines the series transformation for the model. When a transformation is specified, the ARIMA model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the ARIMA model predictions. The available transformations are Log, Logistic, Square Root, Box-Cox, and None.

Intercept specifies whether a mean or intercept parameter is included in the ARIMA model. By default, the Intercept option is set to No when the model includes differencing and Yes when there is no differencing.

Predictors lists the predictor effects included as inputs in the model.

OK closes the ARIMA Model Specification window and fits the model.

Cancel closes the ARIMA Model Specification window without fitting the model. Any options you specified are lost.

Reset resets all options to their initial values upon entry to the ARIMA Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear resets all options to their default values.

Add opens a menu of types of predictors to add to the Predictors list.

Delete deletes the selected (highlighted) entry from the Predictors list.

Edit edits the selected (highlighted) entry in the Predictors list.
Mouse Button Actions

You can select or deselect entries in the Predictors list by clicking them. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you right-click an entry in the Predictors list, the system displays the following menu of actions that encompass the features of the Add, Delete, and Edit buttons.

Add Linear Trend
adds a Linear Trend item to the Predictors list.

Add Trend Curve
opens a menu of different time trend curves and adds the curve you select to the Predictors list. Certain trend curve specifications also set the Transformation field.

Add Regressors
opens the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

Add Adjustments
opens the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

Add Dynamic Regressor
opens the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

Add Interventions
opens the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

Add Seasonal Dummies
adds a Seasonal Dummies predictor item to the Predictors list.

Edit Predictor
edits the selected (highlighted) entry in the Predictors list.

Delete Predictors
deletes the selected (highlighted) entry from the Predictors list.

ARIMA Process Specification Window

Use the ARIMA Process Specification window to define ARIMA processes for simulation. Invoke this window from the Add Series button in the Time Series Simulation window.
Chapter 64: Window Reference

Controls and Fields

Series Name
is the variable name for the series to be simulated.

Series Label
is the variable label for the series to be simulated.

Series Mean
is the mean of the simulated series.

Transformation
defines the series transformation.

Simple Differencing
is the order of simple differencing for the series.

Seasonal Differencing
is the order of seasonal differencing for the series.

AR Parameters
is a table of autoregressive terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the AR part of the process you want to simulate. For a non-factored AR model, make the Factor values the same for all terms. For a factored AR model, use different Factor values to group the terms into the factors.

MA Parameters
is a table of moving-average terms for the simulated ARIMA process. Enter a value for Factor, Lag, and Value for each term of the MA part of the process you want to simulate. For a non-factored MA model, make the Factor values the same for all terms. For a factored MA model, use different Factor values to group the terms into the factors.
OK

- closes the ARIMA Process Specification window and adds the specified process to the Series to Generate list in the Time Series Simulation window.

Cancel

- closes the window without adding to the Series to Generate list. Any options you specified are lost.

Reset

- resets all the fields to their initial values upon entry to the window.

Clear

- resets all the fields to their default values.

---

Automatic Model Fitting Window

Use the Automatic Model Fitting window to perform automatic model selection on all series or selected series in an input data set. Invoke this window by using the Fit Models Automatically button in the Time Series Forecasting window. Note that you can also perform automatic model fitting, one series at a time, from the Develop Models window.

**Controls and Fields**

**Project**

- is the name of the SAS catalog entry in which the results of the model search process are stored.
Input Data Set
is the name of the current input data set. You can type in a one-level or two-level data set name here.

Browse button
opens the Data Set Selection window for selecting an input data set.

Time ID
is the name of the ID variable for the input data set. You can type in the variable name here or use the
Select or Create button.

time ID Select button
opens the Time ID Variable Specification window.

time ID Create button
opens a menu of choices of methods for creating a time ID variable for the input data set. Use this
feature if the input data set does not already contain a valid time ID variable.

Interval
is the time interval between observations (data frequency) in the current input data set. You can type in
an interval name or select one by using the combo box pop-up menu.

Series to Process
indicates the number and names of time series variables for which forecasting model selection will be
applied.

Series to Process Select button
opens the Series to Process window to let you select the series for which you want to fit models.

Selection Criterion
shows the goodness-of-fit statistic that will be used to determine the best fitting model for each series.

Selection Criterion Select button
opens the Model Selection Criterion window to enable you to select the goodness-of-fit statistic that
will be used to determine the best fitting model for each series.

Run button
begins the automatic model fitting process.

Models Fit button
opens the Automatic Model Fitting Results window to display the models fit during the current
invocation of the Automatic Model Fitting window. The results appear automatically when model
fitting is complete, but this button enables you to redisplay the results window.

Close button
closes the Automatic Model Fitting window.

Menu Bar

File

Import Data
is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or database to a SAS data set for use in the Time Series Forecasting System.
Export Data
is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

Print Setup
opens the Print Setup window, which allows you to access your operating system print setup.

Close
closes the Automatic Model Fitting window.

View

Input Data Set
opens a Viewtable window to browse the current input data set.

Models Fit
opens Automatic Model Fitting Results window to show the forecasting models fit during the current invocation of the Automatic Model Fitting window. This has the same function as the Models Fit button.

Tools

Fit Models
performs the automatic model selection process for the selected series. This has the same function as the Run button.

Options

Default Time Ranges
opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series.

Model Selection List
opens the Model Selection List editor window. Use this action to control the forecasting models considered by the automatic model selection process and displayed in the Models to Fit window.

Model Selection Criterion
opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This has the same function as the Selection Criterion Select button.

Statistics of Fit
opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection from the Model Selection Criterion menu.

Forecast Options
opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.
Forecast Data Set
See the section “Produce Forecasts Window” on page 4111.

Alignment of Dates

Beginning
aligns dates that the system generates to identify forecast observations in output data sets to
the beginning of the time intervals.

Middle
aligns dates that the system generates to identify forecast observations in output data sets to
the midpoints of the time intervals.

End
aligns dates that the system generates to identify forecast observations in output data sets to
the end of the time intervals.

Automatic Fit
opens the Automatic Model Selection Options window, which enables you to control the number
of models retained by the automatic model selection process and whether the models considered
for automatic selection are subset according to the series diagnostics.

Tool Bar Type

Image Only
displays the toolbar items as icons without text.

Label Only
displays the toolbar items as text without icon images.

Both
displays the toolbar items with both text and icon images.

Include Interventions
controls whether intervention effects defined for the current series are automatically added as
predictors to the models considered by the automatic selection process. A check mark or filled
check box next to this item indicates that the option is turned on.

Print Audit Trail
prints to the SAS log information about the models fit by the system. A check mark or filled
check box next to this item indicates that the audit option is turned on.

Show Source Statements
controls whether SAS statements submitted by the forecasting system are printed in the SAS log.
When the Show Source Statements option is selected, the system sets the SAS system option
SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option.
Note that only some of the functions performed by the forecasting system are accomplished by
submitting SAS statements. A check mark or filled check box next to this item indicates that the
option is turned on.
Automatic Model Fitting Results Window

This resizable window displays the models fit by the most recent invocation of the Automatic Model Fitting window. It appears automatically after Automatic Model Fitting runs, and can be opened repeatedly from that window by using the Models Fit button or by selecting Models Fit from the View menu. Once you exit the Automatic Model Fitting window, the Automatic Model Fitting Results window cannot be opened again until you fit additional models by using Automatic Model Fitting.

Table Contents

The results table displays the series name in the first column and the model label in the second column. If you have chosen to retain more than one model by using the Automatic Model Selection Options window, more than one row appears in the table for each series; that is, there is a row for each model fit. If you have already fit models to the same series before invoking the Automatic Model Fitting window, those models do not appear here, since the Automatic Model Fitting Results window is intended to show the results of the current operation of Automatic Model Fitting. To see all models that have been fit, use the Manage Projects window.

The third column of the table shows the values of the current model selection criterion statistic. Additional columns show the values of other fit statistics. The set of statistics shown are selectable by using the Statistics of Fit Selection window.

The table can be sorted by any column other than Series Name by clicking on the column heading.
Controls and Fields

Graph
opens the Model Viewer window on the model currently selected in the table.

Stats
opens the Statistics of Fit Selection window. This controls the set of goodness-of-fit statistics displayed in the table and in other parts of the Time Series Forecasting System.

Compare
opens the Model Fit Comparison window for the series currently selected in the table. This button is unavailable if the currently selected row in the table represents a series for which fewer than two models have been fit.

Save
opens an output data set dialog box, enabling you to specify a SAS data set to which the contents of the table are saved. Note that this operation saves what you see in the table. If you want to save the models themselves for use in a future session, use the Manage Projects window.

Print
prints the contents of the table.

Close
closes the window and returns to the Automatic Model Fitting window.

Menu Bar

File

Save
opens an output data set dialog box, enabling you to specify a SAS data set to which the contents of the table are saved. This has the same function as the Save button.

Print
prints the contents of the table. This has the same function as the Print button.

Import Data
is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data
is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

Print Setup
opens the Print Setup window, which allows you to access your operating system print setup.

Close
closes the window and returns to the Automatic Model Fitting window.
View

Model Predictions
opens the Model Viewer to display a predicted and actual plot for the currently highlighted model.

Prediction Errors
opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations
opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests
opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates
opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit
opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph
opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table
opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Tools

Compare Models
opens the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This item is unavailable until you select a series in the table for which the automatic model fitting run selected two or more models.

Options

Statistics of Fit
opens the Statistics of Fit Selection window. This is the same as the Stats button.

Column Labels
selects long or short column labels for the table. Long column labels are used by default.

ID Columns
freezes or unfreezes the series and model columns. By default they are frozen so that they remain visible when you scroll the table horizontally to view other columns.
Automatic Model Selection Options Window

Use the Automatic Model Selection Options window to control the automatic selection process. This window is available from the Automatic Fit item of the Options menu in the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.

**Controls and Fields**

**Models to fit**

*Subset by series diagnostics*
when selected, causes the automatic model selection process to search only over those models consistent with the series diagnostics.

*All autofit models in selection list*
when selected, causes the automatic model selection process to search over all models in the search list, without regard for the series diagnostics.

**Models to keep**

specifies how many of the models tried by the automatic model selection process are retained and added to the model list for the series. You can specify the best fitting model only, the best $n$ models, where $n$ can be 1 through 9, or all models tried.

**OK**
closes the window and saves the automatic model selection options you specified.

**Cancel**
closes the window without changing the automatic model selection options.
Custom Model Specification Window

Use the Custom Model Specification window to specify and fit an ARIMA model with or without predictor effects as inputs. Access it from the Develop Models window, where it is invoked from the Fit Model item under the Edit menu, or from the pop-up menu when you click an empty area of the model table.

Controls and Fields

Series
is the name and variable label of the current series.

Model
is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Transformation
defines the series transformation for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the resulting forecasts. The following transformations are available:

Log
specifies a logarithmic transformation.

Logistic
specifies a logistic transformation.
Square Root
specifies a square root transformation.

Box-Cox
specifies a Box-Cox transform and opens a window to specify the Box-Cox $\lambda$ parameter.

None
specifies no series transformation.

Trend Model
controls the model options to model and forecast the series trend. Select from the following:

Linear Trend
adds a Linear Trend item to the Predictors list.

Trend Curve
brings up a menu of different time trend curves and adds the curve you select to the Predictors list.

First Difference
specifies differencing the series.

Second Difference
specifies second-order differencing of the series.

None
specifies no model for the series trend.

Seasonal Model
controls the model options to model and forecast the series seasonality. Select from the following:

Seasonal ARIMA
opens the Seasonal ARIMA Model Options window to enable you to specify an ARIMA model for the seasonal pattern in the series.

Seasonal Difference
specifies differencing the series at the seasonal lag.

Seasonal Dummy Regressors
adds a Seasonal Dummies predictor item to the Predictors list.

None
specifies no seasonal model.

Error Model
displays the current settings of the autoregressive and moving-average terms, if any, for modeling the prediction error autocorrelation pattern in the series.

Set button
opens the Error Model Options window to enable you to set the autoregressive and moving-average terms for modeling the prediction error autocorrelation pattern in the series.

Intercept
specifies whether a mean or intercept parameter is included in the model. By default, the Intercept option is set to No when the model includes differencing and set to Yes when there is no differencing.

Predictors
is a list of the predictor effects included as inputs in the model.
OK
closes the Custom Model Specification window and fits the model.

Cancel
closes the Custom Model Specification window without fitting the model. Any options you specified are lost.

Reset
resets all options to their initial values upon entry to the Custom Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear
resets all options to their default values.

Add
opens a menu of types of predictors to add to the Predictors list. Select from the following:

Linear Trend
adds a Linear Trend item to the Predictors list.

Trend Curve
opens a menu of different time trend curves and adds the curve you select to the Predictors list.

Regressors
opens the Regressors Selection window to enable you to select other series in the input data set as regressors to predict the dependent series and add them to the Predictors list.

Adjustments
opens the Adjustments Selection window to enable you to select other series in the input data set for use as adjustments to the forecasts and add them to the Predictors list.

Dynamic Regressor
opens the Dynamic Regressor Selection window to enable you to select a series in the input data set as a predictor of the dependent series and also specify a transfer function model for the effect of the predictor series.

Interventions
opens the Interventions for Series window to enable you to define and select intervention effects and add them to the Predictors list.

Seasonal Dummies
adds a Seasonal Dummies predictor item to the Predictors list. This is unavailable if the series interval is not one which has a seasonal cycle.

Delete
deletes the selected (highlighted) entry from the Predictors list.

Edit
edits the selected (highlighted) entry in the Predictors list.
Mouse Button Actions

You can select or deselect entries in the Predictors list by clicking them. The selected (highlighted) predictor effect is acted on by the Delete and Edit buttons. Double-clicking on a predictor in the list invokes an appropriate edit action for that predictor.

If you right-click an entry in the Predictors list and press the right mouse button, the system displays a menu of actions that encompass the features of the Add, Delete, and Edit buttons.

Data Set Selection Window

Use this resizable window to select a data set to process by specifying a library and a SAS data set or view. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set.

Access this window by using the Browse button to the right of the Data Set field in the Time Series Forecasting, Automatic Model Fitting, and Produce Forecasts windows. It functions in the same way as the Series Selection window, except that it does not allow you to select or view a time series variable.

Controls and Fields

Library
is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname. See also Libraries under Selection Lists.
Data Set

is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted.

Time ID

is the name of the ID variable for the selected input data set. To specify the ID variable, you can type the ID variable name in this field or select the control arrows to the right of the field.

Time ID Select button

opens the Time ID Variable Specification window.

Time ID Create button

opens a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

Interval

is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically identified by the system, you can type in the interval name or select it from a list by clicking the combo box arrow. For more information about intervals, see Chapter 4, “Date Intervals, Formats, and Functions,” in this book.

OK

closes the Data Set Selection window and makes the selected data set the current input data set.

Cancel

closes the window without applying any selections made.

Table

opens a Viewtable window for browsing the selected data set.

Reset

resets the fields to their initial values upon entry to the window.

Refresh

updates all fields and lists in the window. If you assign a new libname without exiting the Data Set Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname.

Selection Lists

Libraries

displays a list of currently assigned libnames. You can select a libname by clicking it with the left mouse button, which is equivalent to typing its name in the Library field.

If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File menu, then select “Library” and “OK.” This opens the New Library window. You also assign a libname by submitting a libname statement from the Editor window. Click the Refresh button to make the new libname available in the libraries list.

SAS Data Sets

displays a list of the SAS data sets (data files or data views) contained in the selected library. You can select one of these by clicking with the left mouse button, which is equivalent to typing its name in the Data set field. You can double-click a data set name to select it and exit the window.
Chapter 64: Window Reference

Default Time Ranges Window

Use the Default Time Ranges window to control how the period of fit and evaluation and the forecasting horizon are determined for each series when you do not explicitly set these ranges for a particular series. Invoke this window from the Options menu of the Develop Models, Automatic Model Fitting, ProducForecasts, and Manage Forecasting Project windows. The settings you make in this window affect subsequently selected series; they do not alter the time ranges of series you have already selected.

Controls and Fields

Forecast Horizon

specifies the forecast horizon as either a number of periods or years from the last nonmissing data value or as a fixed date. You can type a number or date value in this field. Date value must be entered in a form recognized by a SAS date informat. (For information about SAS date informats, see SAS Language Reference: Concepts.)

Forecast Horizon Units

indicates whether the value in the forecast horizon field represents periods or years or a date. Click the arrow and select one from the pop-up list.

Hold-out Sample Size

specifies that a number of observations, number of years, or percent of the data at the end of the data range be used for the period of evaluation with the remainder of data used as the period of fit.

Hold-out Sample Size Units

indicates whether the hold-out sample size represents periods or years or percent of data range.

Period of Fit

specifies how much of the data range for a series is to be used as the period of fit for models fit to the series. ALL indicates that all the available data is used. You can specify a number of periods, number of years, or a fixed date, depending on the value of the units field to the right. When you specify a date, the start of the period of fit is the specified date or the first nonmissing series value, whichever is more recent. Date value must be entered in a form recognized by a SAS date informat. (For information about SAS date informats, see SAS Language Reference: Concepts.) When you specify the number of
periods or years, the start of the period of fit is computed as the date that number of periods or years from the end of the data.

**Period of Fit Units**
indicates whether the period-of-fit value represents periods or years or a date.

**OK**
closes the window and stores the specified changes.

**Cancel**
closes the window without saving changes. Any options you specified are lost.

**Defaults**
resets all options to their default values.

**Reset**
resets the options to their initial values upon entry to the window.

---

**Develop Models Window**

This resizable window provides access to all of the Forecasting System’s interactive model fitting and graphical tools. Use it to fit forecasting models to an individual time series and choose the best model to use to produce the final forecasts of the series. Invoke this window by using the Develop Models button in the Time Series Forecasting window.

---

![Develop Models Window](image)
Controls and Fields

Data Set
is the name of the current input data set.

Interval
is the time interval (data frequency) for the input data set.

Series
is the variable name and label of the current time series.

Browse button
opens the Series Selection window to enable you to change the current input data set or series.

Data Range
is the date of the first and last nonmissing data values available for the current series in the input data set.

Fit Range
is the current period of fit setting. This is the range of data that will be used to fit models to the series.

Evaluation Range
is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series.

Set Ranges button
opens the Time Ranges Specification window to enable you to change the fit range or evaluation range.

Note: A new fit range is applied when new models are fit or when existing models are refit. A new evaluation range is applied when new models are fit or when existing models are refit or reevaluated. Changing the ranges does not automatically refit or reevaluate any models in the table: Use the Refit Models or Reevaluate Models items under the Edit menu.

View Series Graphically icon
opens the Time Series Viewer window to display plots of the current series.

View Selected Model Graphically icon
opens the Model Viewer to display graphs and tables for the currently highlighted model.

Forecast Model
is the column of the model table that contains check boxes to select which model is used to produce the final forecasts for the current series.

Model Title
is the column of the model table that contains the descriptive labels of the forecasting models fit to the current series.

Root Mean Square Error (or other statistic name) button
is the button above the right side of the table. It displays the name of the current model selection criterion: a statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button opens the Model Selection Criterion window to let you to select a different statistic. When you select a statistic, the model table the Develop Models window is updated to show current values of that statistic.
Menu Bar

File

New Project
opens a dialog box that lets you create a new project, assign it a name and description, and make it the active project.

Open Project
opens a dialog box that lets you select and load a previously saved project.

Save Project
saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

Save Project as
saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

Clear Project
clears the system, deleting all the models for all series.

Save Forecast
writes forecasts from the currently highlighted model to an output data set.

Save Forecast As
prompts for an output data set name and saves the forecasts from the currently highlighted model.

Output Forecast Data Set
opens a dialog box for specifying the default data set used when you select “Save Forecast.”

Import Data
is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or database to a SAS data set for use in the Time Series Forecasting System.

Export Data
is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or data base.

Print Setup
opens the Print Setup window, which enables you to access your operating system print setup.

Close
closes the Develop Models window and returns to the main window.
Edit

Fit Model

Automatic Fit
invokes the automatic model selection process.

Select From List
opens the Models to Fit window.

Smoothing Model
opens the Smoothing Model Specification window.

ARIMA Model
opens the ARIMA Model Specification window.

Custom Model
opens the Custom Model Specification window.

Combine Forecasts
opens the Forecast Combination Model Specification window.

External Forecasts
opens the External Forecast Model Specification window.

Edit Model
enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

Delete Model
deletes the currently highlighted model from the model table.

Refit Models

All Models
refits all models in the table by using data within the current fit range.

Selected Model
refits the currently highlighted model by using data within the current fit range.

Reevaluate Models

All Models
recomputes statistics of fit for all models in the table by using data within the current evaluation range.

Selected Model
recomputes statistics of fit for the currently highlighted model by using data within the current evaluation range.

View

Project
opens the Manage Forecasting Project window.
Data Set
opens a Viewtable window to display the current input data set.

Series
opens the Time Series Viewer window to display plots of the current series. This has the same function as the View Series Graphically icon.

Model Predictions
opens the Model Viewer to display a predicted versus actual plot for the currently highlighted model. This has the same function as the View Selected Model Graphically icon.

Prediction Errors
opens the Model Viewer to display the prediction errors for the currently highlighted model.

Prediction Error Autocorrelations
opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests
opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates
opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit
opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph
opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table
opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Tools

Diagnose Series
opens the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

Define Interventions
opens the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

Sort Models
sorts the models in the table by the values of the currently displayed fit statistic.

Compare Models
opens the Model Fit Comparison window to display fit statistics for selected pairs of forecasting models. This is unavailable if there are fewer than two models in the table.
Generate Data
opens the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

Options

Time Ranges
opens the Time Ranges Specification window to enable you to change the fit and evaluation time ranges and the forecast horizon. This has the same function as the Set Ranges button.

Default Time Ranges
opens the Default Time Ranges window to enable you to control how the system sets the time ranges for series when you do not explicitly set time ranges with the Time Ranges Specification window. Settings made by using this window do not affect series you are already working with; they take effect when you select a new series.

Model Selection List
opens the Model Selection List editor window. Use this action to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Model Selection Criterion
opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model. This has the same function as the button above the table that displays the name of the current model selection criterion.

Statistics of Fit
opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

Forecast Options
opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Alignment of Dates

Beginning
aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle
aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End
aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.
Automatic Fit

opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Include Interventions

d-controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process and displayed by the Models to Fit window. When the Include Interventions option is selected, the series interventions are also automatically added to the predictors list when you specify a model in the ARIMA and Custom Models Specification windows. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail

prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements

c-controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Left Mouse Button Actions for the Model Table

When the mouse pointer is over the description of a model in the table, the left mouse button selects (highlights) or deselects that model. On some computer systems, you can double-click to open the Model Viewer window for the selected model.

When the mouse pointer is over an empty part of the model table, the left mouse button opens a menu of model fitting choices. These choices are the same as those on the Fit Model submenu of the Edit menu.

Right Mouse Button Actions for the Model Table

When a model in the table is selected, the right mouse opens a menu of actions that apply to the highlighted model. The actions available from this menu are as follows.

View Model

opens the Model Viewer for the selected model. This has the same function as the View Model Graphically icon.

View Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model. This has the same function as the Parameter Estimates item on the View menu.

View Statistics of Fit

opens the Model Viewer to display a table of goodness-of-fit statistics for the currently highlighted model. This has the same function as the Statistics of Fit item on the View menu.
Chapter 64: Window Reference

Edit Model
enables you to modify the specification of the currently highlighted model in the table and fit the modified model. This has the same function as the Edit Model item on the Edit menu.

Refit Model
refits the highlighted model by using data within the current fit range. This has the same function as the Selected Model item on the Refit Models submenu of the Edit menu.

Reevaluate Model
reevaluates the highlighted model by using data within the evaluation fit range. This has the same function as the Selected Model item on the Reevaluate Models submenu of the Edit menu.

Delete Model
deletes the currently highlighted model from the model table. This has the same function as the Delete Model item on the Edit menu.

View Forecasts
opens the Model Viewer to display the forecasts for the currently highlighted model. This has the same function as the Forecast Graph item on the View menu.

When the model list is empty or when no model is selected, the right mouse button opens the same menu of model fitting actions as the left mouse button.

Differencing Specification Window

Use the Differencing Specification window to specify the list of differencing lags \(d=(\text{lag}, \ldots, \text{lag})\) in a factored ARIMA model. To specify a first difference, add the value 1 (\(d=(1)\)). To specify a second difference (difference twice at lag 1), add the value 1 again (\(d=(1,1)\)). For first differencing at lags 1 and 12, use the values 1 and 12 (\(d=(1,12)\)).
Controls and Fields

Lag
specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows. Duplicates are allowed.

Add
adds the value in the Lag spin box to the list of differencing lags.

Remove
deletes a selected lag from the list of differencing lags.

OK
closes the window and returns the specified list to the Factored ARIMA Model Specification window.

Cancel
closes the window and discards any lags added to the list.

Dynamic Regression Specification Window

Use the Dynamic Regression Specification window to specify a dynamic regression or transfer function model for the effect of the predictor variable. It is invoked from the Dynamic Regressors Selection window.

Dynamic Regression Specification Specification Window

Series: HSTOTAL: Housing Starts, Total Private
Input Model: VEHICLES

Input Transformations:
Transformation: None
Lagging periods: 0

Order of Differencing:
Simple: 0
Seasonal: 0

Numerator Factors:
Simple Order: 0
Seasonal Order: 0

Denominator Factors:
Simple Order: 0
Seasonal Order: 0

OK  Cancel  Reset  Clear  Help

Controls and Fields

Series
is the name and variable label of the current series.

Input Model
is a descriptive label for the dynamic regression model. You can type a label in this field or allow the
system to provide the label. If you leave the label blank, a label is generated automatically based on
the options you specify. When no options are specified, the label is the name and variable label of the
predictor variable.

Input Transformation
displays the transformation specified for the predictor variable. When a transformation is specified, the
transfer function model is fit to the transformed input variable.

Lagging periods
is the pure delay in the effect of the predictor, \( l \).

Simple Order of Differencing
is the order of differencing, \( d \). Set this field to 1 to use the changes in the predictor variable.

Seasonal Order of Differencing
is the order of seasonal differencing, \( D \). Set this field to 1 to difference the predictor variable at the
seasonal lags—for example, to use the year-over-year or week-over-week changes in the predictor
variable.

Simple Order Numerator Factors
is the order of the numerator factor of the transfer function, \( p \).

Seasonal Order Numerator Factors
is the order of the seasonal numerator factor of the transfer function, \( P \).

Simple Order Denominator Factors
is the order of the denominator factor of the transfer function, \( q \).

Seasonal Order Denominator Factors
is the order of the seasonal denominator factor of the transfer function, \( Q \).

OK
closes the window and adds the dynamic regression model specified to the model predictors list.

Cancel
closes the window without adding the dynamic regression model. Any options you specified are lost.

Reset
resets all options to their initial values upon entry to the window. This might be useful when editing a
predictor specification; otherwise, Reset has the same function as Clear.

Clear
resets all options to their default values.

---

**Dynamic Regressors Selection Window**

Use the Dynamic Regressors Selection window to select an input variable as a dynamic regressor. Access
this window from the pop-up menu that appears when you click the Add button in the ARIMA Model
Specification window or Custom Model Specification window.
Controls and Fields

Dependent
is the name and variable label of the current series.

Dynamic Regressors
is a table listing the variables in the input data set. Select one variable in this list as the predictor series.

OK
opens the Dynamic Regression Specification window for you to specify the form of the dynamic regression for the selected predictor series, and then closes the Dynamic Regressors Selection window and adds the specified dynamic regression to the model predictors list.

Cancel
closes the window without adding the dynamic regression model. Any options you specified are lost.

Reset
resets all options to their initial values upon entry to the window.

Error Model Options Window

Use the Error Model Options window to specify the autoregressive and moving-average orders for the residual autocorrelation part of a model defined by using the Custom Model Specification window. Access it by using the Set button in that window.
Controls and Fields

ARIMA Options
Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a pop-up list.

Autoregressive
defines the order of the autoregressive part of the model.

Moving Average
defines the order of the moving-average term.

OK
closes the Error Model Options window and returns to the Custom Model Specification window.

Cancel
closes the Error Model Options window and returns to the Custom Model Specification window, discarding any changes made.

Reset
resets all options to their initial values upon entry to the window.

External Forecast Model Specification Window

Use the External Forecast Model Specification window to add to the current project forecasts produced externally to the Time Series Forecasting System. To add an external forecast, select a variable from the selection list and click the OK button. The name of the selected variable will be added to the list of models fit, and the values of this variable will be used as the forecast. For more information, see “Incorporating Forecasts from Other Sources” in the “Specifying Forecasting Models” chapter.
Factored ARIMA Model Specification Window

Use the ARIMA Model Specification window to specify an ARIMA model by using the notation:

\[ p = (\text{lag, ..., lag}) \ldots (\text{lag, ..., lag}) \]
\[ d = (\text{lag, ..., lag}) \]
\[ q = (\text{lag, ..., lag}) \ldots (\text{lag, ..., lag}) \]

where \( p \), \( d \), and \( q \) represent autoregressive, differencing, and moving-average terms, respectively.

Access it from the Develop Models menu, where it is invoked from the Fit Model item under Edit on the menu bar, or from the pop-up menu when you click an empty area of the model table.
Chapter 64: Window Reference

The Factored ARIMA Model Specification window is identical to the ARIMA Model Specification window, except that the p, d, and q terms are specified in a more general and less limited way. Only those controls and fields that differ from the ARIMA Model Specification window are described here.

Controls and Fields

Model

is a descriptive label for the model. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the p, d, and q terms that you specify. For example, if you specify \( p=(1,2,3), \ d=(1), \ q=(12) \) and no intercept, the model label is ARIMA \( p=(1,2,3) \ d=(1) \ q=(12) \) NOINT. For monthly data, this is equivalent to the model ARIMA \( (3,1,0)(0,0,1)s \) NOINT as specified in the ARIMA Model Specification window or the Custom Model Specification window.

ARIMA Options

specifies the ARIMA model in terms of the autoregressive lags (p), differencing lags (d), and moving-average lags (q).

Autoregressive

defines the autoregressive part of the model. Click the Set button to open the AR Polynomial Specification window, where you can add any set of autoregressive lags grouped into any number of factors.
Differencing
specifies differencing to be applied to the input data. Click the Set button to open the Differencing Specification window, where you can specify any set of differencing lags.

Moving Average
defines the moving-average part of the model. Click the Set button to open the MA Polynomial Specification window, where you can add any set of moving-average lags grouped into any number of factors.

Estimation Method
specifies the method used to estimate the model parameters. The Conditional Least Squares and Unconditional Least Squares methods generally require fewer computing resources and are more likely to succeed in fitting complex models. The Maximum Likelihood method requires more resources but provides a better fit in some cases. See also the section “Estimation Details” in Chapter 7, “The ARIMA Procedure.”

Forecast Combination Model Specification Window

Use the Forecast Combination Model Specification window to produce forecasts by averaging the forecasts of two or more forecasting models. The specified combination of models is added to the model list for the series. Access this window from the Develop Models window whenever two or more models have been fit to the current series. It is invoked by selecting Combine Forecasts from the Fit Model submenu of the Edit menu, or from the pop-up menu which appears when you click an empty part of the model table.
Controls and Fields

Series
is the name and variable label of the current series.

Model
is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Weight
is a column of the forecasting model table that contains the weight values for each model. The forecasts for the combined model are computed as a weighted average of the predictions from the models in the table that use these weights. Models with missing weight values are not included in the forecast combination. You can type weight values in these fields or you can use other features of the window to set the weights.

Model Description
is a column of the forecasting model table that contains the descriptive labels of the forecasting models fit to the current series that are available for combination.

Root Mean Square Error (or other statistic name) button
is the button above the right side of the table. It displays the name of the current model selection criterion: a statistic that measures how well each model in the table fits the values of the current series for observations within the evaluation range. Clicking this button opens the Model Selection Criterion window to enable you to select a different statistic.

Normalize Weights button
replaces each nonmissing value in the Weights column with the current value divided by the sum of the weights. The resulting weights are proportional to original weights and sum to 1.

Fit Regression Weights button
computes weight values for the models in the table by regressing the series on the predictions from the models. The values in the Weights column are replaced by the estimated coefficients produced by this linear regression. If some weight values are nonmissing and some are missing, only models with nonmissing weight values are included in the regression. If all weights are missing, all models are used.

OK
closes the Forecast Combination Model Specification window and fits the model.

Cancel
closes the Forecast Combination Model Specification window without fitting the model. Any options you specified are lost.

Reset
resets all options to their initial values upon entry to the Forecast Combination Model Specification window. This might be useful when editing an existing model specification; otherwise, Reset has the same function as Clear.

Clear
resets all options to their default values.
**Mouse Button Actions**

You can select or deselect models for inclusion in the combination model by positioning the mouse pointer over the model description and pressing the left mouse button. When you select a model in this way, the weights are automatically updated.

The newly selected model is given a weight equal to the average weight of the previously selected models, and all the nonmissing weights are normalized to sum to 1. When you use the mouse to remove a model from the combination, the weight of the deselected model is set to missing and the remaining nonmissing weights are normalized to sum to 1.

---

**Forecasting Project File Selection Window**

Use the Forecasting Project File Selection window to locate and load a previously stored forecasting project. Access it from the project Browse button in the Manage Forecasting Project window or the Time Series Forecasting window or from the Open Project item on the File menu of the Develop Models window.

---

**Selection Lists**

**Libraries**

is a list of currently assigned libraries. When you select a library from this list, the catalogs in that library are shown in the catalog selection list.

**Catalogs**

is a list of catalogs contained in the currently selected library. When you select a catalog from this list, any forecasting project entries stored in that catalog are shown in the projects selection list.

**Projects**

is a list of forecasting project entries contained in the currently selected catalog.
Chapter 64: Window Reference

Controls and Fields

OK

Closes the window and opens the selected project.

Cancel

Closes the window without selecting a project.

Delete

Deletes the selected project file.

Reset

Restores selections to those which were set before the window was opened.

Forecast Options Window

Use the Forecast Options window to set options to control how forecasts and confidence limits are computed. It is available from the Forecast Options item in the Options menu of the Develop Models window, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

Controls and Fields

Confidence Limits

Specifies the size of the confidence limits for the forecast values. For example, a value of 0.95 specifies 95% confidence intervals. You can type in a number or select from the pop-up list.

Predictions for transformed models

Controls how forecast values are computed for models that employ a series transformation. See the section Predictions for Transformed Models in Chapter 65, “Forecasting Process Details,” for more information. The values are as follows.

Mean

Specifies that forecast values be predictions of the conditional mean of the series.

Median

Specifies that forecast values be predictions of the conditional median of the series.
Intervention Specification Window

Use the Intervention Specification window to specify intervention effects to model the impact on the series of unusual events. Access it from the Intervention for Series window. For more information, see the section “Interventions” on page 4021.

Controls and Fields

Series

is the name and variable label of the current series.

Label

is a descriptive label for the intervention effect that you specify. You can type a label in this field or allow the system to provide the label. If you leave the label blank, a label is generated automatically based on the options you specify.

Date

is the date that the intervention occurs. You can type a date value in this field, or you can set the date by selecting a row of the data table on the right side of the window.
Type of Intervention

Point
specifies that the intervention variable is zero except for the specified date.

Step
specifies that the intervention variable is zero before the specified date and a constant 1.0 after the date.

Ramp
specifies that the intervention variable is an increasing linear function of time after the date of the intervention and zero before the intervention date.

Number of lags
specifies the numerator order for the transfer function model for the intervention effect. Select a value from the pop-up list.

Effect Decay Pattern
specifies the denominator order for the transfer function model for the intervention effect. The value “Exp” specifies a single lag denominator factor; the value “Wave” specifies a two-lag denominator factor.

OK
closes the window and adds the intervention effect specified to the series interventions list.

Cancel
closes the window without adding the intervention. Any options you specified are lost.

Reset
resets all options to their initial values upon entry to the window. This might be useful when editing an intervention specification; otherwise, Reset has the same function as Clear.

Clear
resets all options to their default values.

Interventions for Series Window

Use the Interventions for Series window to create and edit a list of intervention effects to model the impact on the series of unusual events and to select intervention effects as predictors for forecasting models. Access it from the Add button pop-up menu of the ARIMA Model Specification or Custom Model Specification window, or by selecting Define Interventions from the Tools in the Develop Models window. For more information, see the section “Interventions” on page 4021.
Controls and Fields

Series
is the name and variable label of the current series.

OK
closes the window. If you access this window from the ARIMA Model Specification window or the Custom Model Specification window, any interventions that are selected (highlighted) in the list are added to the model. If you access this window from the Tools menu, all interventions in the list are saved for the current series.

Cancel
closes the window without returning a selection or changing the interventions list. Any options you specified are lost.

Reset
resets the list as it was on entry to the window.

Clear
deletes all interventions from the list.

Add
opens the Intervention Specification window to specify a new intervention effect and add it to the list.

Delete
deletes the currently selected (highlighted) entries from the list.

Edit
opens the Intervention Specification window to edit the currently selected (highlighted) intervention.
Mouse Button Actions

To select or deselect interventions, position the mouse pointer over the intervention’s label in the Interventions list and press the left mouse button.

When you position the mouse pointer in the Interventions list and press the right mouse button, a menu containing the actions Add, Delete, and Edit appears. These actions are the same as clicking the Add, Delete, and Edit buttons.

Double-clicking on an intervention in the list invokes an Edit action for that intervention specification.

Manage Forecasting Project Window

Use this resizable window to work with collections of series, models, and options called projects. The window contains a project name, a description field, and a table of information about all the series for which you have fit forecasting models. Access it by using the Manage Projects button in the Time Series Forecasting window.

Controls and Fields

Project Name is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project
by typing a SAS catalog entry name in this field or by selecting the Browse button to the right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one-level name, it is assumed to be the name of a project in the “fmsproj” catalog in the “sasuser” library. For example, typing samproj is equivalent to typing sasuser.fmsproj.samproj.

project Browse button
opens the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored project files.

Description
is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field if you save the project.

Series List Table
The table of series for which forecasting models have been fit contains the following columns.

Series Name
is the name of the time series variable represented in the given row of the table.

Series Frequency
is the time interval (data frequency) for the time series.

Input Data Set Name
is the input data set that provided the data for the series.

Forecasting Model
is the descriptive label for the forecasting model selected for the series.

Statistic Name
is the statistic of fit for the forecasting model selected for the series.

Number of Models
is the total number of forecasting models fit to the series. If there is more than one model for a series, use the Model List window to see a list of models.

Series Label
is the variable label for the series.

Time ID Variable Name
is the time ID variable for the input data set for the series.

Series Data Range
is the time range of the nonmissing values of the series.

Model Fit Range
is the period of fit used for the series.

Model Evaluation Range
is the evaluation period used for the series.

Forecast Range
is the forecast period set for the series.
**Menu Bar**

**File**

- **New**
  opens a dialog box that lets you create a new project, assign it a name and description, and make it the active project.

- **Open**
  opens a dialog box that lets you select and load a previously saved project.

- **Close**
  closes the Manage Forecasting Project window and returns to the main window.

- **Save**
  saves the current state of the system (including all the models fit to a series) to the current project catalog entry.

- **Save As**
  saves the current state of the system with a prompt for the name of the catalog entry in which to store the information.

- **Save to Data Set**
  saves the current project file information in a SAS data set. The contents of the data set are the same as the information displayed in the series list table.

- **Delete**
  deletes the current project file.

- **Import Data**
  is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or database to a SAS data set for use in the Time Series Forecasting System.

- **Export Data**
  is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

- **Print**
  prints the current project file information.

- **Print Setup**
  opens the Print Setup window, which allows you to access your operating system print setup.

**Edit**

- **Delete Series**
  deletes all models for the selected (highlighted) row of the table and removes the series from the project.
Clear  
resets the system, deleting all series and models from the project.

Reset  
restores the Manage Forecasting Project window to its initial state.

View

Data Set  
opens a Viewtable window to display the input data set for the selected (highlighted) series.

Series  
opens the Time Series Viewer window to display plots of the selected (highlighted) series.

Model  
opens the Model Viewer window to show the current forecasting model for the selected series.

Forecast  
opens the Model Viewer to display plots of the forecasts produced by the forecasting model for the selected (highlighted) series.

Tools

Diagnose Series  
opens the Series Diagnostics window to perform the automatic series diagnostic process to determine the kinds of forecasting models appropriate for the selected (highlighted) series.

List Models  
opens the Model List window for the selected (highlighted) series, which displays a list of all the models that you fit for the series. This action is the same as double-clicking the mouse on the table row.

Generate Data  
opens the Time Series Simulation window. This window enables you to simulate ARIMA time series processes and is useful for educational exercises or testing the system.

Refit Models

All Series  
refits all the models for all the series in the project by using data within the current fit range.

Selected Series  
refits all the models for the currently highlighted series by using data within the current fit range.
Chapter 64: Window Reference

Reevaluate Models

All Series
reevaluates all the models for all the series in the project by using data within the current
evaluation fit range.

Selected Series
reevaluates all the models for the currently highlighted series by using data within the
current evaluation range.

Options

Time Ranges
opens the Time Ranges Specification window to enable you to change the fit and evaluation time
ranges and the forecast horizon.

Default Time Ranges
opens the Default Time Ranges window to enable you to control how the system sets the time
ranges for series when you do not explicitly set time ranges with the Time Ranges Specification
window. Settings made by using this window do not affect series you are already working with;
they take effect when you select a new series.

Model Selection List
opens the Model Selection List editor window. Use this to edit the set of forecasting models
considered by the automatic model selection process and displayed by the Models to Fit window.

Statistics of Fit
opens the Statistics of Fit Selection window, which controls which of the available statistics will
be displayed.

Forecast Options
opens the Forecast Options window, which enables you to control the widths of forecast confi-
dence limits and control the kind of predicted values computed for models that include series
transformations.

Column Labels
enables you to set long or short column labels. Long labels are used by default.

Include Interventions
controls whether intervention effects defined for the current series are automatically added as
predictors to the models considered by the automatic selection process and displayed by the
Model Selection List editor window. When the Include Interventions option is selected, the series
interventions are also automatically added to the predictors list when you specify a model in the
ARIMA and Custom Models Specification windows.

Print Audit Trail
prints to the SAS log information about the models fit by the system. A check mark or filled
check box next to this item indicates that the audit option is turned on.

Show Source Statements
controls whether SAS statements submitted by the forecasting system are printed in the SAS log.
When the Show Source Statements option is selected, the system sets the SAS system option
SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

**Left Mouse Button Actions**

If you select a series in the table by positioning the mouse pointer over the table row and clicking with the left mouse button once, that row of the table is highlighted. Menu bar actions such as Delete Series will apply to the highlighted row of the table.

If you select a series in the table by positioning the mouse pointer over the table row and double-clicking with the left mouse button, the system opens the Model List window for that series, which displays a list of all the models that you fit for the series. This has the same function as the List Models item under Tools on the menu bar.

**Right Mouse Button Actions**

Clicking the right mouse button invokes a pop-up menu of actions applicable to the highlighted series. The actions in this menu are as follows:

- **Delete Series**
  deletes the highlighted series and its models from the project. This has the same function as the Delete Series item on the Edit menu.

- **Refit All Models**
  refits all models attached to the highlighted series by using data within the current fit range. This has the same function as the Selected Series item under Refit Models on the Tools menu.

- **Reevaluate All Models**
  reevaluates all models attached to the highlighted series by using data within the current evaluation range. This has the same function as the Selected Series item under Reevaluate Models on the Tools menu.

- **List Models**
  invokes the Model List window. This has the same function as List Models on the Tools menu.

- **View Series**
  opens the Time Series Viewer window to display plots of the highlighted series. This has the same function as the Series item on the View menu.

- **View Forecasting Model**
  invokes the Model Viewer window to display the forecasting model for the highlighted series. This has the same function as the Model item on the View menu.

- **View Forecast**
  opens the Model Viewer window to display the forecasts for the highlighted series. This has the same function as the Forecast item on the View menu.

- **Refresh**
  updates information shown in the Manage Forecasting Project window.
Chapter 64: Window Reference

Model Fit Comparison Window

Use the Model Fit Comparison window to compare goodness-of-fit statistics for any two models fit to the current series. Access it from the Tools menu of the Develop Models window and the Automatic Model Fitting Results window whenever two or more models have been fit to the series.

Controls and Fields

Series
identifies the current time series variable.

Range
displays the starting and ending dates of the series data range.

Model 1
shows the model currently identified as Model 1.

Model 1 upward arrow button
enables you to change the model identified as Model 1 if it is not already the first model in the list of models associated with the series. Click this button to cycle upward through the list of models.
Model 1 downward arrow button
enables you to change the model identified as Model 1 if it is not already the last model in the list of
models. Click this button to cycle downward through the list of models.

Model 2
shows the model currently identified as Model 2.

Model 2 upward arrow button
enables you to change the model identified as Model 2 if it is not already the first model in the list of
models associated with the series. Click this button to cycle upward through the list of models.

Model 2 downward arrow button
enables you to change the model identified as Model 2 if it is not already the last model in the list of
models. Click this button to cycle downward through the list of models.

Close
closes the Model Fit Comparison window.

Save
opens a dialog box for specifying the name and label of a SAS data set to which the statistics will be
saved. The data set will contain all available statistics and their values for Model 1 and Model 2, as
well as a flag variable that is set to 1 for those statistics that were displayed.

Print
prints the contents of the table to the SAS Output window. If you find that the contents do not appear
immediately in the Output window, you need to set scrolling options. Select “Preferences” under the
Options submenu of the Tools menu. In the Preferences window, select the Advanced tab, then set
output scroll lines to a number greater than zero.

If you want to route the contents to a printer, go to the Output window and select “Print” from the File
menu.

Statistics
opens the Statistics of Fit Selection window for controlling which statistics are displayed.

Model List Window
This resizable window shows all of the models that have been fit to a particular series in a project. Access it
from the Manage Forecasting Project window by selecting a series in the series list table and choosing “List
Models” from the Tools menu or by double-clicking the series.
Chapter 64: Window Reference

Controls and Fields

Data Set
is the name of the current input data set.

Interval
is the time interval (data frequency) for the input data set.

Series
is the variable name and label of the current time series.

Data Range
is the date of the first and last nonmissing data values available for the current series in the input data set.

Fit Range
is the current period of fit setting. This is the range of data that will be used to fit models to the series. It might be different from the fit ranges shown in the table, which were in effect when the models were fit.

Evaluation Range
is the current period of evaluation setting. This is the range of data that will be used to calculate the goodness-of-fit statistics for models fit to the series. It might be different from the evaluation ranges shown in the table, which were in effect when the models were fit.

View Series Graphically icon
opens the Time Series Viewer window to display plots of the current series.
View Model Graphically

opens the Model Viewer to display graphs and tables for the currently highlighted model.

Model List Table

The table of models fit to the series contains columns that show the model label, the fit range and evaluation range used to fit the models, and all of the currently selected fit statistics. You can change the selection of fit statistics by using the Statistics of Fit Selection window.

Click on column headings to sort the table by a particular column. If a model is highlighted, clicking with the right mouse button invokes a pop-up menu that provides actions applicable to the highlighted model. It includes the following items.

View Model

opens the Model Viewer on the selected model. This has the same function as “Model Predictions” on the View menu.

View Parameter Estimates

opens the Model Viewer to display the parameter estimates table for the currently highlighted model. This has the same function as “Parameter Estimates” on the View menu.

View Statistics of Fit

opens the Model Viewer to display the statistics of fit table for the currently highlighted model. This has the same function as “Statistics of Fit” on the View menu.

Edit Model

opens the appropriate model specification window for changing the attributes of the highlighted model and fitting the modified model.

Refit Model

refits the highlighted model using the current fit range.

Reevaluate Model

reevaluates the highlighted model using the current evaluation range.

Delete Model

deletes the highlighted model from the project.

View Forecasts

opens the Model Viewer to show the forecasts for the highlighted model. This has the same function as “Forecast Graph” on the View menu.

Menu Bar

File

Save

opens a dialog box that lets you save the contents of the table to a specified SAS data set.

Import Data

is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.
Export Data
is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

Print
sends the contents of the table to a printer as defined through Print Setup.

Print Setup
opens the Print Setup window, which allows you to access your operating system print setup.

Close
closes the window and returns to the Manage Forecasting Projects window.

Edit

Edit Model
enables you to modify the specification of the currently highlighted model in the table and fit the modified model. The new model replaces the current model in the table.

Refit Model
refits the currently highlighted model using data within the current fit range.

Reevaluate Model
recomputes statistics of fit for the currently highlighted model using data within the current evaluation range.

Delete Model
deletes the currently highlighted model from the model table.

Reset
restores the contents of the Model List window to the state initially displayed.

View

Series
opens the Time Series Viewer window to display plots of the current series. This has the same function as the View Series Graphically icon.

Model Predictions
opens the Model Viewer to display a predicted and actual plot for the currently highlighted model. This has the same function as the View Model Graphically icon.

Prediction Errors
opens the Model Viewer to display the prediction errors for the currently highlighted model.
Prediction Error Autocorrelations
opens the Model Viewer to display the prediction error autocorrelations, partial autocorrelations, and inverse autocorrelations for the currently highlighted model.

Prediction Error Tests
opens the Model Viewer to display graphs of white noise and stationarity tests on the prediction errors of the currently highlighted model.

Parameter Estimates
opens the Model Viewer to display the parameter estimates table for the currently highlighted model.

Statistics of Fit
opens the Model Viewer window to display goodness-of-fit statistics for the currently highlighted model.

Forecast Graph
opens the Model Viewer to graph the forecasts for the currently highlighted model.

Forecast Table
opens the Model Viewer to display forecasts for the currently highlighted model in a table.

Options

Statistics of Fit
opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Model Viewer, Automatic Model Fitting Results, and Model Fit Comparison windows and available for selection in the Model Selection Criterion menu.

Column Labels
enables you to set long or short column labels. Long labels are used by default.

Model Selection Criterion Window

Use the Model Selection Criterion window to select the model selection criterion statistic used by the automatic selection process to determine the best fitting forecasting model. Model selection criterion statistics are a subset of those shown in the Statistics of Fit Selection window, since some statistics of fit, such as number of observations, are not useful for model selection.

This window is available from the Model Selection Criterion item of the Options menu of the Develop Models window, Automatic Model Fitting window, and Produce Forecasts window.
Controls and Fields

Show subset
when selected, lists only those model selection criterion statistics that are selected in the Statistics of Fit Selection window.

Show all
when selected, lists all available model selection criterion statistics.

OK
closes the window and sets the model selection criterion to the statistic you specified.

Cancel
closes the window without changing the model selection criterion.

Model Selection List Editor Window

Use the Model Selection List Editor window to edit the model selection list, including adding your own custom models, and to specify which models in the list are to be used in the automatic fitting process. Access it from the Options menu in the Develop Models, Automatic Model Fitting window, Produce Forecasts, and Manage Projects windows.

The window initially displays the current model list for your project. You can modify this set of models in several ways:

- Open one or more alternate model lists to replace or append to the current model list. These can be either model lists included with the software or model lists previously saved by you or other users.
• Turn the autofit option on or off for individual models. Those that are not flagged for autofit will be available by using the Models to Fit window but not by using automatic model fitting.

• Delete models from the list that are not needed for your project.

• Reorder the models in the list.

• Edit models in the list.

• Create a new empty list.

• Add new models to the list.

Having modified the current model list, you can save it for future use in several ways:

• Save it in a catalog so it can be opened later in the Model Selection List Editor.

• Save it as the user default to be used automatically when new projects are created.

• Select close to close the Model Selection List Editor and attach the modified model selection list to the current project.

• Select cancel to close the Model Selection List Editor without changing the current project’s model selection list.

Since model selection lists are not bound to specific data sources, care must be taken when including data-specific features such as interventions and regressors. When you add an ARIMA, Factored ARIMA, or Custom model to the list, you can add regressors by selecting from the variables in the current data set. If there is no current data set, you will be prompted to specify a data set so you can select regressors from the series it contains.

If you use a model list that has models with a particular regressor name on a data set that does not contain a series of that name, model fitting will fail. However, you can make global changes to the regressor names in the model list by using Set regressor names. For example, you might use the list of dynamic regression models found in the sashelp.forcast catalog. It uses the regressor name “price.” If your regressor series is named “x,” you can specify “price” as the current regressor name and “x” as the “change to” name. The change will be applied to all models in the list that contain the specified regressor name.

Interventions cannot be defined for models defined from the Model Selection List Editor. However, you can define interventions by using the Intervention Specification Window and apply them to your models by turning on the Include Interventions option.
Chapter 64: Window Reference

Auto Fit

The auto fit column of check boxes enables you to eliminate some of the models from being used in the automatic fitting process without having to delete them from the list. By default, all models are checked, meaning that they are all used for automatic fitting.

Model

This column displays the descriptions of all models in the model selection list. You can select one or more models by clicking them. Selected models are highlighted and become the object of the actions Edit, Move, and Delete.

Menu Bar

File

New

creates a new empty model selection list.

Open

opens a dialog box for selecting one or more existing model selection lists to open. If you select multiple lists, they are all opened at once as a concatenated list. This helps you build large specialized model lists quickly by mixing and matching various existing lists such as the various ARIMA model lists included in SASHELP.FORCAST. By default, the lists you open replace the current model list. Select the “append” radio button if you want to append them to the current model list.
Open System Default
opens the default model list supplied with the product.

Cancel
exits the window without applying any changes to the current project’s model selection list.

Close
closes the window and applies any changes made to the project’s model selection list.

Save
opens a dialog box for saving the edited model selection list in a catalog of your choice.

Save as User Default
saves your edited model list as a default list for new projects. The location of this saved list is shown on the message line. When you create new projects, the system searches for this model list and uses it if it is found. If it is not found, the system uses the original default model list supplied with the product.

Edit

Reset
restores the list to its initial state when the window was invoked.

Add Model
enables you to add new models to the selection list. You can use the Smoothing Model Specification window, the ARIMA Model Specification window, the Factored ARIMA Model Specification window, or the Custom Model Specification window.

Edit Selected
opens the appropriate model specification window for changing the attributes of the highlighted model and adding the modified model to the selection list. The original model is not deleted.

Move Selected
enables you to reorder the models in the list. Select one or more models, then select Move Selected from the menu or toolbar. A note appears on the message line: “Select the row after which the selected models are to be moved.” Then select any unhighlighted row in the table. The selected models will be moved after this row.

Delete
deletes any highlighted models from the list. This item is not available if no models are selected.

Set Regressor Names
opens a dialog box for changing all occurrences of a given regressor name in the models of the current model selection list to a name that you specify.

Select All
selects all models in the list.

Clear Selections
deselects all models in the list.

Select All for Autofit
checks the autofit check boxes of all models in the list.

Clear Autofit Selections
deselects the autofit check boxes of all models in the list.
Mouse Button Actions

Clicking any model description in the table selects (highlights) that model. Clicking the same model again deselects it. Multiple selections are allowed.

Clicking the auto fit check box in any row toggles the associated model’s eligibility for use in automatic model fitting.

Right-clicking the right mouse button opens a pop-up menu.

Model Viewer Window

This resizable window provides plots and tables of actual values, model predictions, forecasts, and related statistics. The various plots and tables available are referred to as views. The section “View Selection Icons” on page 4105 explains how to change the view.

You can access Model Viewer in a number of ways, including the View Model Graphically icon of the Develop Models and Model List windows, the Graph button of the Automatic Model Fitting Results window, and the Model item under the View menu in the Manage Forecasting Project window. In addition, you can go directly to a selected view in the Model Viewer window by selecting Model Predictions, Prediction Errors, Statistics of Fit, Prediction Error Autocorrelations, Prediction Error Tests, Parameter Estimates, Forecast Graph, or Forecast Table from the View menu or corresponding toolbar icon or pop-up menu item in the Develop Models, Model List, or Automatic Model Fitting Results windows.
The state of the Model Viewer window is controlled by the current model and the currently selected view. You can resize this window, and you can use other windows without closing the Model Viewer window. By default, the Model Viewer window is automatically updated to display the new model when you switch to working with another model (that is, when you highlight a different model). You can unlink the Model Viewer window from the current model selection by selecting the Link/Unlink icon from the window’s horizontal toolbar. See “Link/Unlink” in the section “Toolbar Icons” on page 4105.

For more information, see the section “Model Viewer” on page 3920.

**Toolbar Icons**

The Model Viewer window contains a horizontal row of icons called the Toolbar. Corresponding menu items appear under various menus. The function of each icon is explained in the following list.

**Zoom in**

In the Model Predictions, Prediction Errors, and Forecast Graph views, the Zoom In action changes the mouse pointer into cross hairs that you can use with the left mouse button to define a region of the graph to zoom in on. In the Prediction Error Autocorrelations and Prediction Error Tests views, Zoom In reduces the number of lags displayed.

**Zoom out**

reverses the previous Zoom In action.

**Link/Unlink viewer**

disconnects or connects the Model Viewer window to the model table (Develop Models window, Model List window, or Automatic Model Fitting Results window). When the viewer is linked, selecting another model in the model table causes the model viewer to be updated to show the selected model. When the Viewer is unlinked, selecting another model does not affect the viewer. This feature is useful for comparing two or more models graphically. You can display a model of interest in the Model Viewer, unlink it, then select another model and open another Model Viewer window for that model. Position the viewer windows side by side for convenient comparisons of models, or use the Next Viewer icon or F12 function key to switch between them.

**Save**

saves the contents of the Model Viewer window. By default, an HTML page is created. This enables you to display graphs and tables by using the Results Viewer or publish them on the web or your intranet. See also “Save Graph As” and “Save Data As” under “Menu Bar” below.

**Print**

prints the contents of the viewer window.

**Close**

closes the Model Viewer window and returns to the window from which it was invoked.

**View Selection Icons**

At the right hand side of the Model Viewer window is a vertical toolbar to select the view—that is, the kind of plot or table that the viewer displays. Corresponding menu items appear under View on the menu bar. The function of each icon is explained in the following list.
Model Predictions displays a plot of actual series values and model predictions over time. Click individual points in the graph to get a display of the type (actual or predicted), ID value, and data value in the upper right corner of the window.

Prediction Errors displays a plot of model prediction errors (residuals) over time. Click individual points in the graph to get a display of the prediction error value in the upper right corner of the window.

Prediction Error Autocorrelations displays horizontal bar charts of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the model prediction errors. Overlaid line plots represent confidence limits computed at plus and minus two standard errors. Click any of the bars to display its value.

Prediction Error Tests displays horizontal bar charts that represent results of white noise and stationarity tests on the model prediction errors. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click any of the bars to display an interpretation. The second bar chart shows tests of stationarity of the model prediction errors, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click on any of the bars to display an interpretation.

Parameter Estimates displays a table showing model parameter estimates along with standard errors and $t$ tests for the null hypothesis that the parameter is zero.

Statistics of Fit displays a table of statistics of fit for the selected model. The set of statistics shown can be changed by using the Statistics of Fit item under Options on the menu bar.

Forecast Graph displays a plot of actual and predicted values for the series data range, followed by a horizontal reference line and forecasted values with confidence limits. Click individual points in the graph to get a display of the type, date/time, and value of the data point in the upper right corner of the window.

Forecast Table displays a data table with columns containing the date/time, actual, predicted, error (residual), lower confidence limit, and upper confidence limit values, together with any predictor series.

**Menu Bar**

**File**

Save Graph saves the plot displayed in viewer window as a SAS/GRAH grseg catalog entry. When the current view is a table, this menu item is not available. See also “Save” in the section “Toolbar Icons” on page 4105. If a graphics catalog entry name has not already been specified, this action functions like “Save Graph As.”
Save Graph As
saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the graph embedded as a gif image.

Save Data
saves the data displayed in the viewer window in a SAS data set, where applicable.

Save Data As
saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the data displayed as a table.

Import Data
is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or data base to a SAS data set for use in the Time Series Forecasting System.

Export Data
is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

Print Graph
prints the contents of the viewer window if the current view is a graph. This has the same function as the Print toolbar icon. If the current view is a table, this menu item is not available.

Print Data
prints the data displayed in the viewer window, where applicable.

Print Setup
opens the Print Setup window, which allows you to access your operating system print setup.

Print Preview
opens a preview window to show how your plots will appear when printed.

Close
Closes the Model Viewer window and returns to the window from which it was invoked.

Edit

Edit Model
enables you to modify the specification of the current model and to fit the modified model, which is then displayed in the viewer.

Refit Model
refits the current model by using data within the current fit range. This action also causes the ranges to be reset if the data range has changed.

Reevaluate Model
reevaluates the current model by using data within the current evaluation range. This action also causes the ranges to be reset if the data range has changed.

View
See “View Selection Icons” on page 4105. It describes each of the items available under “View,” except “Zoom Way Out.”
Chapter 64: Window Reference

Zoom Way Out
zooms the plot out as far as it will go, undoing all prior zoom in operations.

Tools

Link Viewer
See “Link/Unlink” in the section “Toolbar Icons” on page 4105.

Options

Time Ranges
opens the Time Ranges Specification window to enable you to change the period of fit, period of evaluation, or forecast horizon to be applied to subsequently fit models.

Statistics of Fit
opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the statistics of fit table and available for selection in the Model Selection Criterion menu.

Forecast Options
opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Residual Plot Options
provides a choice of four methods of computing prediction errors for models which include a data transformation.

Prediction Errors
computes the difference between the transformed series actual values and model predictions.

Normalized Prediction Errors
computes prediction errors in normalized form.

Model Residuals
computes the difference between the untransformed series values and the untransformed model predictions.

Normalized Model Residuals
computes model residuals in normalized form.

Number of Lags
opens a window to enable you to specify the number of lags shown in the Prediction Error Autocorrelations and Prediction Error Tests views. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

Correlation Probabilities
controls whether the bar charts in the Prediction Error Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.
Include Interventions
controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail
prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.

Show Source Statements
controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When the Show Source Statements option is selected, the system sets the SAS system option SOURCE before submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some of the functions performed by the forecasting system are accomplished by submitting SAS statements. A check mark or filled check box next to this item indicates that the option is turned on.

Mouse Button Actions

You can examine the data values of individual points in the Model Predictions, Model Prediction Errors, and Forecast Graph views of the Model Viewer by clicking the point. The date/time and data values as well as the type (actual, predicted, and so forth) are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

Similarly, you can display values in the Prediction Error Autocorrelations view by clicking any of the bars. Clicking bars in the Prediction Error Tests view displays a Recommendation for Current View window which explains the test represented by the bar.

When you select the Zoom In action in the Predicted Values, Model Prediction Errors, and Forecasted Values views, you can use the mouse to define a region of the graph to zoom. Position the mouse pointer at one corner of the region, press the left mouse button, and move the mouse pointer to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

Models to Fit Window

Use the Models to Fit window to fit models by choosing them from the current model selection list. Access it by using “Fit Models from List” on the Fit Model submenu of the Edit menu in the Develop Models window, or the pop-up menu that appears when you click an empty area of the model table in the Develop Models window. If you want to alter the list of models that appears here, use the Model Selection List editor window.
To select a model to be fit, use the left mouse button. To select more than one model to fit, drag with the mouse, or select the first model, then press the shift key while selecting the last model. For noncontiguous selections, press the control key while selecting with the mouse. To begin fitting the models, double-click the last selection or select the OK button.

If series diagnostics have been performed, the radio box is available. If the Subset by series diagnostics radio button is selected, only those models in the selection list that fit the diagnostic criteria will be shown for selection. If you want to choose models that do not fit the diagnostic criteria, click the Show all models button.

**Controls and Fields**

- **Show all models**
  when selected, lists all available models, regardless of the setting of the series diagnostics options.

- **Subset by series diagnostics**
  when selected, lists only the available models that are consistent with the series diagnostics options.

- **OK**
  closes the Models to Fit window and fits the selected models.

- **Cancel**
  closes the window without fitting any models. Any selections you made are lost.

---

**Polynomial Specification Window**

Use the Polynomial Specification window to add a polynomial to an ARIMA model. The set of lags defined here become a polynomial factor, denoted by a list of lags in parentheses, when you click “OK.” If you accessed this window from the AR Polynomial Specification window, then it is added to the autoregressive
part of the model. If you accessed it from the MA Polynomial Specification window, it is added to the moving-average part of the model.

**Controls and Fields**

**Lag**
- Specifies a lag value to add to the list. Type in a positive integer or select one by clicking the spin box arrows.

**Add**
- Adds the value in the Lag spin box to the list of polynomial lags. Duplicate values are not allowed.

**Remove**
- Deletes a selected lag from the list of polynomial lags.

**Polynomial Lags**
- Is a list of unique integers that represent lags to be added to the model.

**OK**
- Closes the window and returns the specified polynomial to the AR or MA polynomial specification window.

**Cancel**
- Closes the window and discards any polynomial lags added to the list.

---

**Produce Forecasts Window**

Use the Produce Forecasts window to produce forecasts for the series in the current input data set for which you have fit forecasting models. Access it by using the Produce Forecasts button of the Time Series Forecasting window.
Input Data Set
is the name of the current input data set. To specify the input data set, you can type a one-level or
two-level SAS data set name in this field or click the Browse button to the right of the field.

Input data set Browse button
opens the Data Set Selection window to enable you to select the input data set.

Time ID
is the name of the time ID variable for the input data set. To specify this variable, you can type the ID
variable name in this field or use the Select button.

Time ID Select button
opens the Time ID Variable Specification window.

Create button
opens a menu of choices of methods for creating a time ID variable for the input data set. Use this
feature if the input data set does not already contain a valid time ID variable.

Interval
is the time interval between observations (data frequency) in the current input data set. If the interval is
not automatically filled in by the system, you can type in an interval name here, or select one from the
pop-up list.

Series
indicates the number and names of time series variables for which forecasts will be produced.

Series Select button
opens the Series to Process window to let you select the series for which you want to produce forecasts.

Controls and Fields
**Forecast Output Data Set**

is the name of the output data set that will contain the forecasts. Type the name of the output data set in this field or click the Browse button.

**Forecast Output Browse button**

opens a dialog box to let you locate an existing data set to which to save the forecasts.

**Format**

enables you to select one of three formats for the forecast data set:

- **Simple**
  
specifies the simple format for the output data set. The data set contains the time ID variable and the forecast variables and contains one observation per time period. Observations for earlier time periods contain actual values copied from the input data set; later observations contain the forecasts.

- **Interleaved**
  
specifies the interleaved format for the output data set. The data set contains the time ID variable, the variable TYPE, and the forecast variables. There are several observations per time period, with the meaning of each observation identified by the TYPE variable.

- **Concatenated**
  
specifies the concatenated format for the output data set. The data set contains the variable SERIES, the time ID variable, and the variables ACTUAL, PREDICT, ERROR, LOWER, and UPPER. There is one observation per time period per forecast series. The variable SERIES contains the name of the forecast series, and the data set is sorted by SERIES and DATE.

**Horizon**

is the number of periods or years to forecast beyond the end of the input data range. To specify the forecast horizon, you can type a value in this field or select one from the pop-up list.

**Horizon periods**

selects the units to apply to the horizon. By default, the horizon value represents number of periods. For example, if the interval is month, the horizon represents the number of months to forecast. Depending on the interval, you can also select weeks or years, so that the horizon is measured in those units.

**Horizon date**

is the ending date of the forecast horizon. You can type in a date that uses a form recognized by a SAS date informat, or you can increment or decrement the date shown by using the left and right arrows. The outer arrows change the date by a larger amount than the inner arrows. The date field and the horizon field reset each other, so you can use either one to specify the forecasting horizon.

**Run button**

produces forecasts for the selected series and stores the forecasts in the specified output SAS data set.

**Output button**

opens a Viewtable window to display the output data set. This button becomes available once the forecasts have been written to the data set.

**Close button**

closes the Produce Forecasts window and returns to the Time Series Forecasting window.
Menu Bar

File

Import Data
is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or database to a SAS data set for use in the Time Series Forecasting System.

Export Data
is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

Print Setup
opens the Print Setup window, which allows you to access your operating system print setup.

Close
closes the Produce Forecasts window and returns to the Time Series Forecasting window.

View

Input Data Set
opens a Viewtable window to browse the current input data set.

Output Data Set
opens a Viewtable window to browse the output data set. This has the same function as the Output button.

Tools

Produce Forecasts
produces forecasts for the selected series and stores the forecasts in the specified output SAS data set. This has the same function as the Run button.

Options

Default Time Ranges
opens the Default Time Ranges window to enable you to control how the system sets the time ranges when new series are selected.

Model Selection List
opens the Model Selection List editor window. Use this to edit the set of forecasting models considered by the automatic model selection process and displayed by the Models to Fit window.

Model Selection Criterion
opens the Model Selection Criterion window, which presents a list of goodness-of-fit statistics and enables you to select the fit statistic that is displayed in the table and used by the automatic model selection process to determine the best fitting model.
Statistics of Fit
opens the Statistics of Fit Selection window, which presents a list of statistics that the system can display. Use this action to customize the list of statistics shown in the Statistics of Fit table and available for selection in the Model Selection Criterion window.

Forecast Options
opens the Forecast Options window, which enables you to control the widths of forecast confidence limits and control the kind of predicted values computed for models that include series transformations.

Forecast Data Set
enables you to select one of three formats for the forecast data set. See Format, which is described previously in this section.

Alignment of Dates

Beginning
aligns dates that the system generates to identify forecast observations in output data sets to the beginning of the time intervals.

Middle
aligns dates that the system generates to identify forecast observations in output data sets to the midpoints of the time intervals.

End
aligns dates that the system generates to identify forecast observations in output data sets to the end of the time intervals.

Automatic Fit
opens the Automatic Model Selection Options window, which enables you to control the number of models retained by the automatic model selection process and whether the models considered for automatic selection are subset according to the series diagnostics.

Set Toolbar Type

Image Only
displays the toolbar items as icons without text.

Label Only
displays the toolbar items as text without icon images.

Both
displays the toolbar items as both text and icon images.

Include Interventions
controls whether intervention effects defined for the current series are automatically added as predictors to the models considered by the automatic selection process. A check mark or filled check box next to this item indicates that the option is turned on.

Print Audit Trail
prints to the SAS log information about the models fit by the system. A check mark or filled check box next to this item indicates that the audit option is turned on.
Show Source Statements
controls whether SAS statements submitted by the forecasting system are printed in the SAS log. When
the Show Source Statements option is selected, the system sets the SAS system option SOURCE before
submitting SAS statements; otherwise, the system uses the NOSOURCE option. Note that only some
of the functions performed by the forecasting system are accomplished by submitting SAS statements.
A check mark or filled check box next to this item indicates that the option is turned on.

Regressors Selection Window
Use the Regressors Selection window to select one or more time series variables in the input data set to
include as regressors in the forecasting model to predict the dependent series. Access it from the pop-up
menu that appears when you click the Add button in the ARIMA Model Specification window or Custom
Model Specification window.

<table>
<thead>
<tr>
<th>Regressors Selection</th>

</tr>
<tr>
<td>NONDUR</td>
</tr>
<tr>
<td>PETROL</td>
</tr>
<tr>
<td>TOBACCO</td>
</tr>
<tr>
<td>VEHICLES</td>
</tr>
</tbody>
</table>

Controls and Fields

Dependent
is the name and variable label of the current series.

Regressors
is a table listing the names and labels of the variables in the input data set available for selection as
regressors. The variables that you select are highlighted. Selecting a highlighted row again deselects
that variable.

OK
  closes the Regressors Selection window and adds the selected variables as regressors in the model.

Cancel
  closes the window without adding any regressors. Any selections you made are lost.
Reset resets all options to their initial values upon entry to the window.

Save Data As

Use Save Data As from the Time Series Viewer Window or the Model Viewer Window to save data displayed in a table to a SAS data set or external file.

Use Save Forecast As from the Develop Models Window to save forecasts and related data including the series name, model, and interval. It supports append mode, enabling you to accumulate the forecasts of multiple series in a single data set.

To save your data in a SAS data set, provide a library name or assign one by using the Browse button, then provide a data set name or accept the default. Enter a descriptive label for the data set in the Label field. Click OK to save the data set. If you specify an existing data set, it will be overwritten, except in the case of Save Forecast As.

External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating HTML tables for web reporting. You can build a set of web pages quickly and use the ODS Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, and then select the Results tab in the Preferences dialog box.
If you have previously saved data of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro that contains ODS statements. The default macro simply runs the PRINT procedure. A custom macro can be used to add PRINT procedure and/or ODS statements to customize the type and organization of output files produced.

**Save Graph As**

Use Save Graph As from the Time Series Viewer Window or the Model Viewer Window to save any of the graphs in a catalog or external file.

To save your graph as a grseg catalog entry, enter a two level name for the catalog or select Browse to open an Open dialog box. Use it to select an existing library or assign a new one and then select a catalog to contain the graph. Click the Open button to open the catalog and close the dialog box. Then enter a graphics entry name (eight characters or less) and a label or accept the defaults and click the OK button to save the graph.

External file output takes advantage of the Output Delivery System (ODS) and is designed primarily for creating gif images and HTML for web reporting. You can build a set of web pages that contain graphs and use the Results window to view and organize them. To use this feature, check Save External File in the External File Output box. To set ODS options, click Results Preferences, and then select the Results tab in the Preferences dialog box.

![Save Forecast Graph as window](image)

In the Save Forecast Graph as window, you can specify the catalog name, graphics entry name, and label for saving the graph in a catalog entry. For external file output, you can save the graph as a GIF image or HTML file by checking the Save External File option. The Options button allows you to set ODS options.
If you have previously saved graphs of the current type, the system remembers your previous labels and titles. To reuse them, click the arrow button to the right of each of these window fields.

Use the Customize button if you need to specify the name of a custom macro that contains ODS statements. The default macro simply runs the GREPLAY procedure. Users familiar with ODS might want to add statements to the macro to customize the type and organization of output files produced.

Seasonal ARIMA Model Options Window

Use the Seasonal ARIMA Model Options window to specify the autoregressive, differencing, and moving-average orders for the seasonal part of a model defined by using the Custom Model Specification window. Access it by selecting “Seasonal ARIMA…” from the Seasonal Model combo box of that window.

Controls and Fields

ARIMA Options

Use these combo boxes to specify the orders of the ARIMA model. You can either type in a value or click the combo box arrow to select from a pop-up list.

Autoregressive

defines the order of the seasonal autoregressive part of the model.

Differencing

defines the order of seasonal differencing.

Moving Average

defines the order of the seasonal moving-average term.

OK

closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification window.
Cancel
closes the Seasonal ARIMA Model Options window and returns to the Custom Model Specification
window, discarding any changes made.

Reset
resets all options to their initial values upon entry to the window.

Series Diagnostics Window

Use the Series Diagnostics window to set options to limit the kinds of forecasting models considered for the
series according to series characteristics. Access it by selecting “Diagnose Series” from the Tools menu in
the Develop Models, Manage Project, and Time Series Viewer window menu bars. You can let the system
diagnose the series characteristics automatically or you can specify series characteristics according to your
judgment by using the radio buttons.

<table>
<thead>
<tr>
<th>Series Diagnostics</th>
</tr>
</thead>
<tbody>
<tr>
<td>Series:</td>
</tr>
<tr>
<td>Series Characteristics:</td>
</tr>
<tr>
<td>Log Transform:</td>
</tr>
<tr>
<td>Trend:</td>
</tr>
<tr>
<td>Seasonality:</td>
</tr>
</tbody>
</table>

For each of the options Log Transform, Trend, and Seasonality, the value “Yes” means that only models
appropriate for series with that characteristic should be considered. The value “No” means that only models
appropriate for series without that characteristic should be considered. The value “Maybe” means that models
should be considered without regard for that characteristic.
**Controls and Fields**

**Series**
- is the name and variable label of the current series.

**Series Characteristics**

- **Log Transform**
  - specifies whether forecasting models with or without a logarithmic series transformation are appropriate for the series.

- **Trend**
  - specifies whether forecasting models with or without a trend component are appropriate for the series.

- **Seasonality**
  - specifies whether forecasting models with or without a seasonal component are appropriate for the series.

**Automatic Series Diagnostics**
- performs the automatic series diagnostic process. The options Log Transform, Trend, and Seasonality are set according to the results of statistical tests.

**OK**
- closes the Series Diagnostics window.

**Cancel**
- closes the Series Diagnostics window without changing the series diagnostics options. Any options you specified are lost.

**Reset**
- resets all options to their initial values upon entry to the Series Diagnostics window.

**Clear**
- resets all options to their default values.

---

**Series Selection Window**

Use this resizable window to select a time series variable by specifying a library, a SAS data set or view, and a variable. These selections can be made by typing, by selecting from lists, or by a combination of the two. In addition, you can control the time ID variable and time interval, and you can browse the data set or view plots of the series from this window.
This window appears automatically when you click the View Series Graphically or Develop Models button in the Time Series Forecasting window and no series has been selected, and when you open the Time Series Viewer as a stand-alone tool. It is also invoked by using the Browse button in the Develop Models window.

The system requires that series names be unique for each frequency (interval) within the forecasting project. If you select a series from the current input data set that already exists in the project with the same interval but a different input data set name, the system warns you and gives you the option to cancel the selection, to refit all models associated with the series by using the data from the current input data set, to delete the models for the series, or to inherit the existing models.

### Controls and Fields

**Library**
- is a SAS libname assigned within the current SAS session. If you know the libname associated with the data set of interest, you can type it in this field and press Return. If it is a valid choice, it will appear in the libraries list and will be highlighted. The SAS Data Sets list will be populated with data sets associated with that libname.

**Data Set**
- is the name of a SAS data set (data file or data view) that resides under the selected libname. If you know the name, you can type it in and press Return. If it is a valid choice, it will appear in the SAS Data Sets list and will be highlighted, and the Time Series Variables list will be populated with the numeric variables in the data set.

**Variable**
- is the name of a numeric variable contained in the selected data set. You can type the variable name in this field or you can select the variable with the mouse from the Time Series Variables list.

**Time ID**
- is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or click the Select button.
Select button
opens the Time ID Variable Specification window to let you select an existing variable in the data set as the Time ID.

Create button
opens a menu of methods for creating a time ID variable for the input data set. Use this feature if the data set does not already contain a valid time ID variable.

Interval
is the time interval between observations (data frequency) in the selected data set. If the interval is not automatically filled in by the system, you can type in an interval name or select one from the pop-up list. For more information about intervals, see Chapter 4, “Date Intervals, Formats, and Functions,” in this book.

OK
is a button that is present when you have selected “Develop Models” from the Time Series Forecasting window. It closes the Series Selection window and makes the selected series the current series.

Close
If you have selected the View Series Graphically icon from the Time Series Forecasting window, this button returns you to that window. If you have selected a series, it remains selected as the current series.
If you are using the Time Series Viewer as a stand-alone application, this button closes the application.

Cancel
is a button that is present when you have selected “Develop Models” from the Time Series Forecasting window. It closes the Series Selection window without applying any selections made.

Reset
resets the fields to their initial values at entry to the window.

Table
opens a Viewtable window for browsing the selected data set. This can assist you in locating the variable containing data you are looking for.

Graph
opens the Time Series Viewer window to display the selected time series variable. You can switch to a different series in the Series Selection window without closing the Time Series Viewer window. Position the windows so they are both visible, or use the Next Viewer toolbar icon or F12 function key to switch between windows.

Refresh
updates all fields and lists in the window. If you assign a new libname without exiting the Series Selection window, use the refresh action to update the Libraries list so that it will include the newly assigned libname. Also use the Refresh action to update the variables list if the input data set is changed.

**Selection Lists**

Libraries
displays a list of currently assigned libnames. You can select a libname by clicking it, which is equivalent to typing its name in the Library field. If you cannot locate the library or directory you are interested in, go to the SAS Explorer window, select “New” from the File menu, then select “Library” and “OK.” This opens the New Library dialog box. You also assign a libname by submitting a libname statement from the Editor window. Click the Refresh button to make the new libname available in the libraries list.
SAS Data Sets

displays a list of the SAS data sets (data files or data views) located under the selected libname. You can select one of these by clicking it, which is equivalent to typing its name in the Data Set field.

Time Series Variables

displays a list of numeric variables contained within the selected data set. You can select one of these by clicking it, which is equivalent to typing its name in the Variable field. You can double-click a series to select it and exit the window.

---

Series to Process Window

Use the Series to Process window to select series for model fitting or forecasting. Access it by using the Select button in the Automatic Model Fitting and Produce Forecasts windows. Hold down the shift key or drag with the left mouse button for multiple selections. Use the control key for noncontiguous multiple selections. Once you make selections and click OK, the number of selected series and their names are listed in the Series to Process field of the calling window (with ellipses if not all the names will fit).

When invoked from Automatic Model Fitting, the Series to Process window shows all the numeric variables in the input data set except the time ID variable. These are the series which are currently available for model fitting.

When invoked from Produce Forecasts, the Series to Process window shows all the series in the input data set for which models have been fit. These are the series which are currently available for forecasting.

---

### Available Series

</tbody>
</table>
Controls and Fields

**OK**
closes the window and applies the series selection(s) which have been made. At least one series must be selected.

**Cancel**
closes the window, ignoring series selections which have been made, if any.

**Clear**
deselects all series in the selection list.

**All**
selects all series in the selection list.

---

Series Viewer Transformations Window

Use the Series Viewer Transformations window to view plots of transformations of the current series in the Time Series Viewer window. It provides a larger set of transformations than those available from the viewer window’s toolbar. It is invoked by using “Other Transformations” under the Tools menu of the Time Series Viewer window. The options that you specify in this window are applied to the series displayed in the Time Series Viewer window when you select “OK” or “Apply.”

Use the Apply button if you want to make repeated transformations to a series without having to close and reopen the Series Viewer Transformations window each time.
Controls and Fields

Series
is the variable name for the current time series.

Transformation
is the transformation applied to the time series displayed in the Time Series Viewer window. Select Log, Logistic, Square Root, Box-Cox, or none from the pop-up list.

Simple Differencing
is the order of differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 5 from the pop-up list.

Seasonal Differencing
is the order of seasonal differencing applied to the time series displayed in the Time Series Viewer window. Select a number from 0 to 3 from the pop-up list.

Percent Change
is a check box that if selected displays the series in terms of percent change from the previous period.

Additive Decomposition
is a check box that produces a display of a selected series component derived by using additive decomposition.

Multiplicative Decomposition
is a check box that produces a display of a selected series component derived using multiplicative decomposition.

Component
selects a series component to display when either additive or multiplicative decomposition is turned on. You can display the seasonally adjusted component, the trend-cycle component, the seasonal component, or the irregular component—that is, the residual that remains after removal of the other components. The heading in the viewer window shows which component is currently displayed.

OK
applies the transformation options you selected to the series displayed in the Time Series Viewer window and closes the Series Viewer Transformations window.

Cancel
closes the Series Viewer Transformations window without changing the series displayed by the Time Series Viewer window.

Apply
applies the transformation options you selected to the series displayed in the Time Series Viewer window without closing the Series Viewer Transformations window.

Reset
resets the transformation options to their initial values upon entry to the Series Viewer Transformations window.

Clear
resets the transformation options to their default values (no transformations).
Smoothing Model Specification Window

Use the Smoothing Model Specification window to specify and fit exponential smoothing and Winters method models. Access it from the Develop Models window by using the Fit Model submenu of the Edit menu or from the pop-up menu when you click an empty area of the model table.

Smoothing Model Specification

Series: HSTOTAL: Housing Starts, Total Private

Model: Winters Method -- Multiplicative

Smoothing Methods:
- Simple Smoothing
- Double (Brown) Smoothing
- Seasonal Smoothing
- Linear (Holt) Smoothing
- Damped-Trend Smoothing
- Winters Method - Additive
- Winters Method - Multiplicative

Smoothing Weights:
- Level: Optimize
- Trend: Optimize
- Damping: Optimize
- Season: Optimize
- Bounds: Zero-One/Additive

Controls and Fields

Series
is the name and variable label of the current series.

Model
is a descriptive label for the model that you specify. You can type a label in this field or allow the system to provide a label. If you leave the label blank, a label is generated automatically based on the options you specify.

Smoothing Methods

Simple Smoothing
specifies simple (single) exponential smoothing.

Double (Brown) Smoothing
specifies double exponential smoothing by using Brown’s one parameter model (single exponential smoothing applied twice).

Seasonal Smoothing
specifies seasonal exponential smoothing. (This is like Winters method with the trend term omitted.)

Linear (Holt) Smoothing
specifies exponential smoothing of both the series level and trend (Holt’s two parameter model).
Damped-Trend Smoothing
specifies exponential smoothing of both the series level and trend with a trend damping weight.

Winters Method - Additive
specifies Winters method with additive seasonal factors.

Winters Method - Multiplicative
specifies Winters method with multiplicative seasonal factors.

Smoothing Weights
displays the values used for the smoothing weights. By default, the Smoothing Weights fields are set to “optimize,” which means that the system will compute the weight values that best fit the data. You can also type smoothing weight values in these fields.

Level
is the smoothing weight used for the level of the series.

Trend
is the smoothing weight used for the trend of the series.

Damping
is the smoothing weight used by the damped-trend method to damp the forecasted trend towards zero as the forecast horizon increases.

Season
is the smoothing weight used for the seasonal factors in Winters method and seasonal exponential smoothing.

Transformation
displays the series transformation specified for the model. When a transformation is specified, the model is fit to the transformed series, and forecasts are produced by applying the inverse transformation to the model predictions. Select Log, Logistic, Square Root, Box-Cox, or None from the pop-up list.

Bounds
displays the constraints imposed on the fitted smoothing weights. Select one of the following from the pop-up list:

Zero-One/Additive
sets the smoothing weight optimization region to the intersection of the region bounded by the intervals from zero (0.001) to one (0.999) and the additive invertible region. This is the default.

Zero-One Boundaries
sets the smoothing weight optimization region to the region bounded by the intervals from zero (0.001) to one (0.999).

Additive Invertible
sets the smoothing weight optimization region to the additive invertible region.

Unrestricted
sets the smoothing weight optimization region to be unbounded.

Custom
opens the Smoothing Weights window to enable you to customize the constraints for smoothing weights optimization.
Smoothing Weight Optimization Window

Use the Smoothing Weight Optimization window to specify constraints for the automatic fitting of smoothing weights for exponential smoothing and Winters method models. Access it from the Smoothing Models Specification window when you select “Custom” in the “Bounds” combo box.

Controls and Fields

No restrictions
when selected, specifies unrestricted smoothing weights.

Bounded region
when selected, restricts the fitted smoothing weights to be within the bounds that you specify with the “Smoothing Weight Bounded Region” options.

Additive invertible region
when selected, restricts the fitted smoothing weights to be within the additive invertible region of the parameter space of the ARIMA model equivalent to the smoothing model. (For more information, see the section “Smoothing Models” on page 4156.)
Additive invertible and bounded region
when selected, restricts the fitted smoothing weights to be both within the additive invertible region and
within bounds that you specify.

Smoothing Weight Bounded Region
is a group of numeric entry fields that enable you to specify lower and upper limits on the fitted value
of each smoothing weight. The fields that appear in this part of the window depend on the kind of
smoothing model that you specified.

OK
closes the window and sets the options that you specified.

Cancel
closes the window without changing any options. Any values you specified are lost.

Reset
resets all options to their initial values upon entry to the window.

Clear
resets all options to their default values.

Statistics of Fit Selection Window

Use the Statistics of Fit Selection window to specify which of the available goodness-of-fit statistics are
reported for models you fit and are available for selection as the model selection criterion used by the
automatic selection process. This window is available under the Options menu in the Develop Models,
Automatic Model Fitting, Produce Forecasts, and Model List windows, and from the Statistics button in the
Model Fit Comparison window and Automatic Model Fitting results windows.
Controls and Fields

Select Statistics Table
list the available statistics. Select a row of the table to select or deselect the statistic shown in that row.

OK
closes the window and applies the selections made.

Cancel
closes the window without applying any selections.

Clear
deselects all statistics.

All
selects all statistics.

Time ID Creation – 1,2,3 Window

Use the Time ID Creation – 1,2,3 window to add a time ID variable to an input data set with observation numbers as the ID values. The interval for the series will be 1. Use this approach if the data frequency does not match any of the system's date or date-time intervals, or if other methods of assigning a time ID do not work. To access this window, select “Create from observation numbers” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 4, “Date Intervals, Formats, and Functions,” in this book.

Controls and Fields

Data set name
is the name of the input data set.

New ID variable name
is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK
closes the window and proceeds to the next step in the time ID creation process.
Cancel

closes the window without creating a Time ID variable. Any options you specified are lost.

Time ID Creation from Several Variables Window

Use the Time ID Creation from Several Variables window to add a SAS date valued time ID variable to an input data set when the input data set already contains several dating variables, such as day, month, and year. To access this window, select “Create from existing variables” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 59, “Creating Time ID Variables.”

Controls and Fields

Variables
is a list of variables in the input data set. Select existing ID variables from this list.

Date Part
is a list of date parts that you can specify for the selected ID variable. For each ID variable that you select from the Variables list, select the Date Part value that describes what the values of the ID variable represent.

arrow button
moves the selected existing ID variable and date part specification to the “Existing Time IDs” list. Once you have done this, you can select another ID variable from the Variables list.
New variable is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

New interval is the time interval between observations in the input data set implied by the date part ID variables you have selected.

OK closes the window and proceeds to the next step in the time ID creation process.

Cancel closes the window without creating a time ID. Any options you specified are lost.

Reset resets the options to their initial values upon entry to the window.

Time ID Creation from Starting Date Window

Use the Time ID Creation from Starting Date window to add a SAS date valued time ID variable to an input data set. This is a convenient way to add a time ID of any interval as long as you know the starting date of the series. To access this window, select “Create from starting date and frequency” from the Create pop-up list in any window where you can select a Time ID variable. For more information, see Chapter 59, “Creating Time ID Variables.”

Controls and Fields

Data set name

is the name of the input data set.
Chapter 64: Window Reference

Starting Date
is the starting date for the time series in the data set. Enter a date value in this field, using a form recognizable by a SAS date informat, for example, 1998:1, feb1997, or 03mar1998.

Interval
is the time interval between observations in the data set. Select an interval from the pop-up list.

New ID variable name
is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

OK
closes the window and proceeds to the next step in the time ID creation process.

Cancel
closes the window without changing the input data set. Any options you specified are lost.

Time ID Creation Using Informat Window

Use the Time ID Creation using Informat window to add a SAS date valued time ID variable to an input data set. Use this window if your data set contains a date variable that is stored as a character string. Using the appropriate SAS date informat, the date string is read in and used to create a date or date-time variable. To access this window, select “Create from existing variable/informat” from the Create pop-up list in any window where you can select a Time ID variable.

Existing Variable and Informat:

Variable Name: 
Select...
Informat: 
▼
First obs: 
Date Value: 

New ID variable name: DATE

NOTE: The system automatically recognizes the time ID variable if you specify the name DATE.

OK Cancel Reset Help
**Controls and Fields**

**Variable Name**

is the name of an existing ID variable in the input data set. Click the Select button to select a variable.

**Select button**

opens a list of variables in the input data set for you to select from.

**Informat**

is a SAS date or datetime informat for reading date or datetime value from the values of the specified existing ID variable. You can type in an informat or select one from the pop-up list.

**First Obs**

is the value of the variable you selected from the first observation in the data set, displayed here for convenience.

**Date Value**

is the SAS date or datetime value read from the first observation value that uses the informat that you specified.

**New ID variable name**

is the name of the time ID variable to be created. You can type any valid SAS variable name in this field.

**OK**

closes the window and proceeds to the next step in the time ID creation process.

**Cancel**

closes the window without changing the input data set. Any options you specified are lost.

**Reset**

resets the options to their initial values upon entry to the window.

---

**Time ID Variable Specification Window**

Use the Time ID Variable Specification window to specify a variable in the input data set that contains the SAS date or datetime value of each observation. You do not need to use this window if your time ID variable is named `date`, `time`, or `datetime`, since these are picked up automatically. Invoke the window from the Select button to the right of the Time ID field in the Data Set Selection, Automatic Model Fitting, Produce Forecasts, Series Selection, and Time Series Forecasting windows.
Chapter 64: Window Reference

Controls and Fields

Data Set
is the name of the current input data set.

Time ID
is the name of the currently selected Time ID variable, if any.

Interval
is the time interval between observations (data frequency) in the input data set.

Select a Time ID Variable
is a selection list of variables in the input set. Select one variable to assign it as the Time ID variable.

OK
Closes the window and retains the selection made, if it is a valid time ID.

Cancel
Closes the window and ignores any selection made.

Reset
Restores the time ID variable to the one assigned when the window was initially opened, if any.

Time Ranges Specification Window

Use the Time Ranges Specification window to control the period of fit and evaluation and the forecasting horizon. Invoke this window from the Options menu in the Develop Models, Manage Forecasting Project, and Model Viewer windows or the Set Ranges button in the Develop Models window.
**Time Ranges Specification**

**Data Set:** SASHELP.usecon

**Interval:** MONTH

**Series:** HSTOTAL: Housing Starts, Total Private

**Time Ranges:**

<table>
<thead>
<tr>
<th></th>
<th>From</th>
<th>To</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Data Range:</strong></td>
<td>JAN1975</td>
<td>DEC1991</td>
</tr>
<tr>
<td><strong>Period of Fit:</strong></td>
<td>← JAN1975</td>
<td>▶ ▶ DEC1991</td>
</tr>
<tr>
<td><strong>Period of Evaluation:</strong></td>

<tr>
<td><strong>Hold-out Sample:</strong></td>
<td>0 ▼ Periods ▼</td>
<td></td>
</tr>
</tbody>
</table>

**Controls and Fields**

**Data Set**
- is the name of the current input data set.

**Interval**
- is the time interval (data frequency) for the input data set.

**Series**
- is the variable name and label of the current time series.

**Data Range**
- gives the date of the first and last nonmissing data values available for the current series in the input data set.

**Period of Fit**
- gives the starting and ending dates of the period of fit. This is the time range used for estimating model parameters. By default, it is the same as the data range. You can type dates in these fields, or you can use the arrow buttons to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See SAS Language Reference: Concepts for information about SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.

**Period of Evaluation**
- gives the starting and ending dates of the period of evaluation. This is the time range used for evaluating models in terms of statistics of fit. By default, it is the same as the data range. You can type dates in these fields, or you can use the control arrows to the left and right of the date fields to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (See SAS Language Reference: Concepts for information about SAS date informats.) The inner arrows increment by periods, the outer arrows increment by larger amounts, depending on the data interval.
Forecast Horizon is the forecasting horizon expressed as a number of forecast periods or number of years (or number of weeks for daily data). You can type a number or select one from the pop-up list. The ending date for the forecast period is automatically updated when you change the number of forecasts periods.

Forecast Horizon - Units indicates whether the Forecast Horizon value represents periods or years (or weeks for daily data).

Forecast Horizon Date Value is the date of the last forecast observation. You can type a date in this field, or you can use the arrow buttons to the left and right of the date field to decrement or increment the date values shown. Date values must be entered in a form recognized by a SAS date informat. (For information about SAS date informats, see SAS Language Reference: Concepts.) The Forecast Horizon is automatically updated when you change the ending date for the forecast period.

Hold-out Sample specifies that a number of observations or years (or weeks) of data at the end of the data range be used for the period of evaluation with the remainder of data used as the period of fit. You can type a number in this field or select one from the pop-up list. When the hold-out sample value is changed, the Period of Fit and Period of Evaluation ranges are changed to reflect the hold-out sample specification.

Hold-out Sample - Units indicates whether the hold-out sample field represents periods or years (or weeks for daily data).

OK closes the window and stores the specified changes.

Cancel closes the window without saving changes. Any options you specified are lost.

Reset resets the options to their initial values upon entry to the window.

Clear resets all options to their default values.

---

**Time Series Forecasting Window**

The Time Series Forecasting window is the main application window that appears when you invoke the Time Series Forecasting System. It enables you to specify a project file and an input data set and provides access to the other windows described in this chapter.
Controls and Fields

**Project**

is the name of the SAS catalog entry in which forecasting models and other results will be stored and from which previously stored results are loaded into the forecasting system. You can specify the project by typing a SAS catalog entry name in this field or by clicking the Browse button to right of this field. If you specify the name of an existing catalog entry, the information in the project file is loaded. If you specify a one-level name, the catalog name is assumed to be fmsproj and the library is assumed to be sasuser. For example, samproj is equivalent to sasuser.fmsproj.samproj.

**Project Browse button**

opens the Forecasting Project File Selection window to enable you to select and load the project from a list of previously stored projects.

**Description**

is a descriptive label for the forecasting project. The description you type in this field will be stored with the catalog entry shown in the Project field.

**Data Set**

is the name of the current input data set. To specify the input data set, you can type the data set name in this field or use the Browse button to the right of the field.
Data set Browse button
opens the Data Set Selection window to enable you to select the input data set.

Time ID
is the name of the ID variable for the input data set. To specify the ID variable, you can type the ID variable name in this field or use the Select button. If the time ID variable is named date, time, or datetime, it is automatically picked up by the system.

Select button
opens the Time ID Variable Specification window.

Create button
opens a menu of choices of methods for creating a time ID variable for the input data set. Use this feature if the input data set does not already contain a valid time ID variable.

Interval
is the time interval between observations (data frequency) in the current input data set. If the interval is not automatically filled in, you can type an interval name or select one from the pop-up list. For more information about intervals, see the section “Time Series Data Sets, ID Variables, and Time Intervals” on page 3888.

View Series Graphically icon
opens the Time Series Viewer window to display plots of series in the current input data set.

View Data as a Table
opens a Viewtable window for browsing the selected input data set.

Develop Models
opens the Develop Models window to enable you to fit forecasting models to individual time series and choose the best models to use to produce the final forecasts of each series.

Fit Models Automatically
opens the Automatic Model Fitting window for applying the automatic model selection process to all series or to selected series in an input data set.

Produce Forecast
opens the Produce Forecasts window for producing forecasts for the series in the current input data set for which you have fit forecasting models.

Manage Projects
opens the Manage Forecasting Project window for viewing or editing information stored in projects.

Exit
closes the Time Series Forecasting system.

Help
accesses the help system.

---

**Time Series Simulation Window**

Use the Time Series Simulation window to create a data set of simulated series generated by ARIMA processes. Access this window from the Tools menu in the Develop Models and Manage Forecasting Project windows.
**Controls and Fields**

**Output Data Set**
- is the name of the data set to be created. Type in a one-level or two-level SAS data set name.

**Interval**
- is the time interval between observations (data frequency) in the simulated data set. Type in an interval name or select one from the pop-up list.

**Seed**
- is the seed for the random number generator used to produce the simulated time series.

**N Observations**
- is the number of time periods to simulate.

**Starting Date**
- is the starting date for the simulated observations. Type in a date in a form recognizable by a SAS data informat, for example, 1998:1, feb1997, or 03mar1998.

**Ending Date**
- is the ending date for the simulated observations. Type in a date in a form recognizable by a SAS data informat.

**Series to Generate**
- is the list of variable names and ARIMA processes to simulate.

**Add Series**
- opens the ARIMA Process Specification window to enable you to add entries to the Series to Generate list.

**Delete Series**
- deletes selected (highlighted) entries from the Series to Generate list.
OK
closes the Time Series Simulation window and performs the specified simulations and creates the
specified data set.

Cancel
closes the window without creating a simulated data set. Any options you specified are lost.

Time Series Viewer Window

Use the Time Series Viewer window to explore time series data using plots, transformations, statistical tests,
and tables. It is available as a stand-alone application and as part of the Time Series Forecasting System. To
use it as a stand-alone application, select it from the Analysis submenu of the Solutions menu, or use the
tsv command (see Chapter 63, “Command Reference,” in this book). To use it within the Time Series
Forecasting System, select the View Series Graphically icon in the Time Series Forecasting, Develop Models,
or Model List window, or select “Series” from the View menu of the Develop Models, Manage Project, or
Model List window.

The various plots and tables available are referred to as views. The section “View Selection Icons” on
page 4105 explains how to change the view.

The state of the Time Series Viewer window is controlled by the current series, the current series transfor-
mation specification, and the currently selected view. You can resize this window, and you can use other
windows without closing the Time Series Viewer window. You can explore a number of series conveniently
by keeping the Series Selection window open. Each time you make a selection, the viewer window is updated
to show the selected series. Keep both windows visible, or switch between them by using the Next Viewer
toolbar icon or the F12 function key.

You can open multiple Time Series Viewer windows. This enables you to “freeze” a plot so you can come
back to it later, or compare two plots side by side on your screen. To do this, unlink the viewer by using the
Link/Unlink icon on the window’s toolbar or the corresponding item in the Tools menu. While the viewer
window remains unlinked, it is not updated when other selections are made in the Series Selection window.
Instead, when you select a series and click the Graph button, a new Time Series Viewer window is invoked.
You can continue this process to open as many viewer windows as you want. The Next Viewer icon and
corresponding F12 function key are useful for navigating between windows when they are not simultaneously
visible on your screen.

A wide range of series transformations is available. Basic transformations are available from the window’s
horizontal toolbar, and others are available by selecting “Other Transformations” from the Tools menu.

**Horizontal Tool Bar**

The Time Series Viewer window contains a horizontal toolbar with the following icons:

**Zoom in**
changes the mouse pointer into cross hairs that you can use with the left mouse button to drag out a
region of the time series plot to zoom in on. In the Autocorrelations view and the White Noise and
Stationarity Tests view, Zoom In reduces the number of lags displayed.

**Zoom out**
reverses the previous Zoom In action and expands the time range of the plot to show more of the series.
In the Autocorrelations view and the White Noise and Stationarity Tests view, Zoom Out increases the
number of lags displayed.

**Link/Unlink viewer**
disconnects or connects the Time Series Viewer window to the window in which the series was selected.
When the Viewer is linked, it always shows the current series. If you select another series, linked
Viewers are updated. Unlinking a Viewer freezes its current state, and changing the current series has
no effect on the Viewer’s display. The View Series action creates a new Series Viewer window if there
is no linked Viewer. By using the unlink feature, you can open several Time Series Viewer windows
and display several different series simultaneously.

**Log Transform**
applies a log transform to the current view. This can be combined with other transformations; the
current transformations are shown in the title.

**Difference**
applies a simple difference to the current view. This can be combined with other transformations; the
current transformations are shown in the title.

**Seasonal Difference**
applies a seasonal difference to the current view. For example, if the data are monthly, the seasonal
cycle is one year. Each value has subtracted from it the value from one year previous. This can be
combined with other transformations; the current transformations are shown in the title.

**Close**
closes the Time Series Viewer window and returns to the window from which it was invoked.
**Vertical Toolbar View Selection Icons**

At the right-hand side of the Time Series Viewer window is a vertical toolbar used to select the kind of plot or table that the Viewer displays.

**Series**
- displays a plot of series values over time.

**Autocorrelations**
- displays plots of the sample autocorrelations, partial autocorrelation, and inverse autocorrelation functions for the series, with lines overlaid at plus and minus two standard errors.

**White Noise and Stationarity Tests**
- displays horizontal bar charts that represent results of white noise and stationarity tests. The first bar chart shows the significance probability of the Ljung-Box chi-square statistic computed on autocorrelations up to the given lag. Longer bars favor rejection of the null hypothesis that the series is white noise. Click any of the bars to display an interpretation.
- The second bar chart shows tests of stationarity, where longer bars favor the conclusion that the series is stationary. Each bar displays the significance probability of the augmented Dickey-Fuller unit root test to the given autoregressive lag. Long bars represent higher levels of significance against the null hypothesis that the series contains a unit root. For seasonal data, a third bar chart appears for seasonal root tests. Click any of the bars to display an interpretation.

**Data Table**
- displays a data table containing the values in the input data set.

**Menu Bar**

**File**

**Save Graph**
- saves the current plot as a SAS/GRAPH grseg catalog entry in a default or most recently specified catalog. This item is unavailable in the Data Table view.

**Save Graph as**
- saves the current graph as a SAS/GRAPH grseg catalog entry in a SAS catalog that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the graph embedded as a gif image. This item is unavailable in the Data Table view.

**Save Data**
- saves the data displayed in the viewer window to an output SAS data set. This item is unavailable in the Series view.

**Save Data as**
- saves the data in a SAS data set that you specify and/or as an Output Delivery System (ODS) object. By default, an HTML page is created, with the data displayed as a table.

**Import Data**
- is available if you license SAS/ACCESS software. It opens an Import Wizard, which you can use to import your data from an external spreadsheet or database to a SAS data set for use in the Time Series Forecasting System.
Export Data

is available if you license SAS/ACCESS software. It opens an Export Wizard, which you can use to export a SAS data set, such as a forecast data set created with the Time Series Forecasting System, to an external spreadsheet or database.

Print Graph

prints the plot displayed in the viewer window. This item is unavailable in the Data Table view.

Print Data

prints the data displayed in the viewer window. This item is unavailable in the Series view.

Print Setup

opens the Print Setup window, which allows you to access your operating system print setup.

Print Preview

opens a preview window to show how your plots will look when printed.

Close

closes the Time Series Viewer window and returns to the window from which it was invoked.

View

Series

displays a plot of series values over time. This has the same function as the Series icon on the vertical toolbar.

Autocorrelations

displays plots of the sample autocorrelation, partial autocorrelation, and inverse autocorrelation functions for the series. This has the same function as the Autocorrelations icon on the vertical toolbar.

White Noise and Stationarity Tests

displays horizontal bar charts representing results of white noise and stationarity tests. This has the same function as the White Noise and Stationarity Tests icon on the vertical toolbar.

Data Table

displays a data table containing the values in the input data set. This has the same function as the Data Table icon on the vertical toolbar.

Zoom In

zooms the display. This has the same function as the Zoom In icon on the window’s horizontal toolbar.

Zoom Out

undoes the last zoom in action. This has the same function as the Zoom Out icon on the window’s horizontal toolbar.

Zoom Way Out

reverses all previous Zoom In actions and expands the time range of the plot to show all of the series, or shows the maximum number of lags in the Autocorrelations View or the White Noise and Stationarity Tests view.

Tools

Log Transform

applies a log transformation. This has the same function as the Log Transform icon on the window’s horizontal toolbar.
Difference
applies simple differencing. This has the same function as the Difference icon on the window’s horizontal toolbar.

Seasonal Difference
applies seasonal differencing. This has the same function as the Seasonal Difference icon on the window’s horizontal toolbar.

Other Transformations
opens the Series Viewer Transformations window to enable you to apply a wide range of transformations.

Diagnose Series
opens the Series Diagnostics window to determine the kinds of forecasting models appropriate for the current series.

Define Interventions
opens the Interventions for Series window to enable you to edit or add intervention effects for use in modeling the current series.

Link Viewer
connects or disconnects the Time Series Viewer window to the window from which series are selected. This has the same function as the Link item on the window’s horizontal toolbar.

Options

Number of Lags
opens a window to let you specify the number of lags shown in the Autocorrelations view and the White Noise and Stationarity Tests view. You can also use the Zoom In and Zoom Out actions to control the number of lags displayed.

Correlation Probabilities
controls whether the bar charts in the Autocorrelations view represent significance probabilities or values of the correlation coefficient. A check mark or filled check box next to this item indicates that significance probabilities are displayed. In each case the bar graph horizontal axis label changes accordingly.

Mouse Button Actions

You can examine the data value and date of individual points in the Series view by clicking them. The date and value are displayed in a box that appears in the upper right corner of the Viewer window. Click the mouse elsewhere or select any action to dismiss the data box.

You can examine the values of the bars and confidence limits at different lags in the Autocorrelations view by clicking individual bars in the vertical bar charts.
You can display an interpretation of the tests in the White Noise and Stationarity Tests view by clicking the bars.

When you select the Zoom In action, you can use the mouse to define a region of the graph to take a closer look at. Position the mouse pointer at one corner of the region, press the left mouse button, and move the mouse pointer to the opposite corner of the region while holding the left mouse button down. When you release the mouse button, the plot is redrawn to show an expanded view of the data within the region you selected.

This chapter provides computational details about several aspects of the Time Series Forecasting System.

Forecasting Process Summary

This section summarizes the forecasting process.
**Parameter Estimation**

The parameter estimation process for ARIMA and smoothing models is described graphically in Figure 65.1.

*Figure 65.1 Model Fitting Flow Diagram*

---

The specification of smoothing and ARIMA models is described in Chapter 60, “Specifying Forecasting Models.” Computational details about these kinds of models are provided in the sections “Smoothing Models” on page 4156 and “ARIMA Models” on page 4167. The results of the parameter estimation process are displayed in the Parameter Estimates table of the Model Viewer windows along with the estimate of the model variance and the final smoothing state.

---

**Model Evaluation**

The model evaluation process is described graphically in Figure 65.2.
Figure 65.2 Model Evaluation Flow Diagram
Model evaluation is based on the one-step-ahead prediction errors for observations within the period of evaluation. The one-step-ahead predictions are generated from the model specification and parameter estimates. The predictions are inverse transformed (median or mean) and adjustments are removed. The prediction errors (the difference of the dependent series and the predictions) are used to compute the statistics of fit, which are described in the section “Series Diagnostic Tests” on page 4174. The results generated by the evaluation process are displayed in the Statistics of Fit table of the Model Viewer window.

**Forecasting**

The forecasting generation process is described graphically in Figure 65.3.
The forecasting process is similar to the model evaluation process described in the preceding section, except that \( k \)-step-ahead predictions are made from the end of the data through the specified forecast horizon, and prediction standard errors and confidence limits are calculated. The forecasts and confidence limits are displayed in the Forecast plot or table of the Model Viewer window.
Forecast Combination Models

This section discusses the computation of predicted values and confidence limits for forecast combination models. For information about how to specify forecast combination models and their combining weights, see Chapter 60, “Specifying Forecasting Models.”

Given the response time series \( \{ y_t : 1 \leq t \leq n \} \) with previously generated forecasts for the \( m \) component models, a combined forecast is created from the component forecasts as follows:

- Predictions: \( \hat{y}_t = \sum_{i=1}^{m} w_i \hat{y}_{i,t} \)
- Prediction errors: \( \hat{e}_t = y_t - \hat{y}_t \)

where \( \hat{y}_{i,t} \) are the forecasts of the component models and \( w_i \) are the combining weights.

The estimate of the root mean square prediction error and forecast confidence limits for the combined forecast are computed by assuming independence of the prediction errors of the component forecasts, as follows:

- Standard errors: \( \hat{\sigma}_t = \sqrt{\sum_{i=1}^{m} w_i^2 \hat{\sigma}^2_{i,t}} \)
- Confidence limits: \( \pm \hat{\sigma}_t Z_{\alpha/2} \)

where \( \hat{\sigma}_{i,t} \) are the estimated root mean square prediction errors for the component models, \( \alpha \) is the confidence limit width, \( 1 - \alpha \) is the confidence level, and \( Z_{\alpha/2} \) is the \( \frac{\alpha}{2} \) quantile of the standard normal distribution.

Since, in practice, there might be positive correlation between the prediction errors of the component forecasts, these confidence limits may be too narrow.

External or User-Supplied Forecasts

This section discusses the computation of predicted values and confidence limits for external forecast models.

Given a response time series \( y_t \) and external forecast series \( \hat{y}_t \), the prediction errors are computed as \( \hat{e}_t = y_t - \hat{y}_t \) for those \( t \) for which both \( y_t \) and \( \hat{y}_t \) are nonmissing. The mean squared error (MSE) is computed from the prediction errors.

The variance of the \( k \)-step-ahead prediction errors is set to \( k \) times the MSE. From these variances, the standard errors and confidence limits are computed in the usual way. If the supplied predictions contain so many missing values within the time range of the response series that the MSE estimate cannot be computed, the confidence limits, standard errors, and statistics of fit are set to missing.

Adjustments

Adjustment predictors are subtracted from the response time series prior to model parameter estimation, evaluation, and forecasting. After the predictions of the adjusted response time series are obtained from the forecasting model, the adjustments are added back to produce the forecasts.

If \( y_t \) is the response time series and \( X_{i,t}, 1 \leq i \leq m \) are \( m \) adjustment predictor series, then the adjusted response series \( w_t \) is

\[
w_t = y_t - \sum_{i=1}^{m} X_{i,t}
\]
Parameter estimation for the model is performed by using the adjusted response time series \( w_t \). The forecasts \( \hat{w}_t \) of \( w_t \) are adjusted to obtain the forecasts \( \hat{y}_t \) of \( y_t \).

\[
\hat{y}_t = \hat{w}_t + \sum_{i=1}^{m} X_{i,t}
\]

Missing values in an adjustment series are ignored in these computations.

### Series Transformations

For pure ARIMA models, transforming the response time series can aid in obtaining stationary noise series. For general ARIMA models with inputs, transforming the response time series or one or more of the input time series can provide a better model fit. Similarly, the fit of smoothing models can improve when the response series is transformed.

There are four transformations available, for strictly positive series only. Let \( y_t > 0 \) be the original time series, and let \( w_t \) be the transformed series. The transformations are defined as follows:

- **Log** is the logarithmic transformation,
  \[
w_t = \ln(y_t)
  \]

- **Logistic** is the logistic transformation,
  \[
w_t = \ln(c y_t/(1 - c y_t))
  \]
  where the scaling factor \( c \) is
  \[
c = (1 - 10^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))}
  \]
  and \( \text{ceil}(x) \) is the smallest integer greater than or equal to \( x \).

- **Square Root** is the square root transformation,
  \[
w_t = \sqrt{y_t}
  \]

- **Box-Cox** is the Box-Cox transformation,
  \[
w_t = \begin{cases} 
  \frac{y_t^{\lambda} - 1}{\lambda}, & \lambda \neq 0 \\
  \ln(y_t), & \lambda = 0
  \end{cases}
  \]

Parameter estimation is performed by using the transformed series. The transformed model predictions and confidence limits are then obtained from the transformed time series and these parameter estimates.

The transformed model predictions \( \hat{w}_t \) are used to obtain either the minimum mean absolute error (MMAE) or minimum mean squared error (MMSE) predictions \( \hat{y}_t \), depending on the setting of the forecast options. The model is then evaluated based on the residuals of the original time series and these predictions. The transformed model confidence limits are inverse-transformed to obtain the forecast confidence limits.
Predictions for Transformed Models

Since the transformations described in the previous section are monotonic, applying the inverse-transformation to the transformed model predictions results in the median of the conditional probability density function at each point in time. This is the minimum mean absolute error (MMAE) prediction.

If \( w_t = F(y_t) \) is the transform with inverse-transform \( y_t = F^{-1}(w_t) \), then

\[
\text{median}(\hat{y}_t) = F^{-1}(E[w_t]) = F^{-1}(\hat{w}_t)
\]

The minimum mean squared error (MMSE) predictions are the mean of the conditional probability density function at each point in time. Assuming that the prediction errors are normally distributed with variance \( \sigma_t^2 \), the MMSE predictions for each of the transformations are as follows:

- **Log** is the conditional expectation of inverse-logarithmic transformation,
  \[
  \hat{y}_t = E[e^{w_t}] = \exp(\hat{w}_t + \sigma_t^2/2)
  \]

- **Logistic** is the conditional expectation of inverse-logistic transformation,
  \[
  \hat{y}_t = E\left[\frac{1}{c(1 + \exp(-w_t))}\right]
  \]
  where the scaling factor \( c = (1 - e^{-6})10^{-\text{ceil}(\log_{10}(\max(y_t)))} \).

- **Square Root** is the conditional expectation of the inverse-square root transformation,
  \[
  \hat{y}_t = E[w_t^2] = \hat{w}_t^2 + \sigma_t^2
  \]

- **Box-Cox** is the conditional expectation of the inverse Box-Cox transformation,
  \[
  \hat{y}_t = \begin{cases} 
  E[(\lambda w_t + 1)^{1/\lambda}], & \lambda \neq 0 \\
  E[e^{w_t}] = \exp(\hat{w}_t + \frac{1}{2}\sigma_t^2), & \lambda = 0 
  \end{cases}
  \]

The expectations of the inverse logistic and Box-Cox (\( \lambda \neq 0 \)) transformations do not generally have explicit solutions and are computed by using numerical integration.

Smoothing Models

This section details the computations performed for the exponential smoothing and Winters method forecasting models.

Smoothing Model Calculations

The descriptions and properties of various smoothing methods can be found in Gardner (1985); Chatfield (1978); Bowerman and O’Connell (1979). The following section summarizes the smoothing model computations.
Given a time series \( \{ Y_t : 1 \leq t \leq n \} \), the underlying model assumed by the smoothing models has the following (additive seasonal) form,

\[
Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t
\]

where

- \( \mu_t \): represents the time-varying mean term.
- \( \beta_t \): represents the time-varying slope.
- \( s_p(t) \): represents the time-varying seasonal contribution for one of the \( p \) seasons.
- \( \epsilon_t \): are disturbances.

For smoothing models without trend terms, \( \beta_t = 0 \); and for smoothing models without seasonal terms, \( s_p(t) = 0 \). Each smoothing model is described in the following sections.

At each time \( t \), the smoothing models estimate the time-varying components described above with the smoothing state. After initialization, the smoothing state is updated for each observation using the smoothing equations. The smoothing state at the last nonmissing observation is used for predictions.

### Smoothing State and Smoothing Equations

Depending on the smoothing model, the smoothing state at time \( t \) consists of the following:

- \( L_t \): is a smoothed level that estimates \( \mu_t \).
- \( T_t \): is a smoothed trend that estimates \( \beta_t \).
- \( S_{t-j}, j = 0, \ldots, p-1 \): are seasonal factors that estimate \( s_p(t) \).

The smoothing process starts with an initial estimate of the smoothing state, which is subsequently updated for each observation by using the smoothing equations.

The smoothing equations determine how the smoothing state changes as time progresses. Knowledge of the smoothing state at time \( t-1 \) and that of the time series value at time \( t \) uniquely determine the smoothing state at time \( t \). The smoothing weights determine the contribution of the previous smoothing state to the current smoothing state. The smoothing equations for each smoothing model are listed in the following sections.

### Smoothing State Initialization

Given a time series \( \{ Y_t : 1 \leq t \leq n \} \), the smoothing process first computes the smoothing state for time \( t = 1 \). However, this computation requires an initial estimate of the smoothing state at time \( t = 0 \), even though no data exist at or before time \( t = 0 \).

An appropriate choice for the initial smoothing state is made by backcasting from time \( t = n \) to \( t = 1 \) to obtain a prediction at \( t = 0 \). The initialization for the backcast is obtained by regression with constant and linear terms and seasonal dummies (additive or multiplicative) as appropriate for the smoothing model. For models with linear or seasonal terms, the estimates obtained by the regression are used for initial smoothed trend and seasonal factors; however, the initial smoothed level for backcasting is always set to the last observation, \( Y_n \).
The smoothing state at time \( t = 0 \) obtained from the backcast is used to initialize the smoothing process from time \( t = 1 \) to \( t = n \) (Chatfield and Yar 1988).

For models with seasonal terms, the smoothing state is normalized so that the seasonal factors \( S_t-j \) for \( j = 0, \ldots, p - 1 \) sum to zero for models that assume additive seasonality and average to one for models (such as Winters method models) that assume multiplicative seasonality.

### Missing Values

When a missing value is encountered at time \( t \), the smoothed values are updated using the *error-correction form* of the smoothing equations with the one-step-ahead prediction error, \( e_t \), set to zero. The missing value is estimated using the one-step-ahead prediction at time \( t - 1 \)—that is, \( \hat{Y}_{t-1}(1) \) (Aldrin and Damsleth 1989). The error-correction forms of each of the smoothing models are listed in the following sections.

### Predictions and Prediction Errors

Predictions are made based on the last known smoothing state. Predictions made at time \( t \) for \( k \) steps ahead are denoted \( \hat{Y}_t(k) \) and the associated prediction errors are denoted \( e_t(k) = Y_{t+k} - \hat{Y}_t(k) \). The prediction equation for each smoothing model is listed in the following sections.

The *one-step-ahead predictions* refer to predictions made at time \( t - 1 \) for one time unit into the future—that is, \( \hat{Y}_{t-1}(1) \). The *one-step-ahead prediction errors* are more simply denoted \( e_t = e_{t-1}(1) = Y_t - \hat{Y}_{t-1}(1) \). The one-step-ahead prediction errors are also the model residuals, and the sum of squares of the one-step-ahead prediction errors is the objective function used in smoothing weight optimization.

The *variance of the prediction errors* are used to calculate the confidence limits (Sweet 1985; McKenzie 1986; Yar and Chatfield 1990; Chatfield and Yar 1991). The equations for the variance of the prediction errors for each smoothing model are listed in the following sections.

Note: \( \text{var}(e_t) \) is estimated by the mean square of the one-step-ahead prediction errors.

### Smoothing Weights

Depending on the smoothing model, the smoothing weights consist of the following:

- \( \alpha \) is a level smoothing weight.
- \( \gamma \) is a trend smoothing weight.
- \( \delta \) is a seasonal smoothing weight.
- \( \phi \) is a trend damping weight.

Larger smoothing weights (less damping) permit the more recent data to have a greater influence on the predictions. Smaller smoothing weights (more damping) give less weight to recent data.
Specifying the Smoothing Weights

Typically the smoothing weights are chosen to be from zero to one. (This is intuitive because the weights associated with the past smoothing state and the value of current observation would normally sum to one.) However, each smoothing model (except Winters method—multiplicative version) has an ARIMA equivalent. Weights chosen to be within the ARIMA additive-invertible region will guarantee stable predictions (Archibald 1990; Gardner 1985). The ARIMA equivalent and the additive-invertible region for each smoothing model are listed in the following sections.

Optimizing the Smoothing Weights

Smoothing weights are determined so as to minimize the sum of squared, one-step-ahead prediction errors. The optimization is initialized by choosing from a predetermined grid the initial smoothing weights that result in the smallest sum of squared, one-step-ahead prediction errors. The optimization process is highly dependent on this initialization. It is possible that the optimization process will fail due to the inability to obtain stable initial values for the smoothing weights (Greene 1993; Judge et al. 1980), and it is possible for the optimization to result in a local minima.

The optimization process can result in weights to be chosen outside both the zero-to-one range and the ARIMA additive-invertible region. By restricting weight optimization to additive-invertible region, you can obtain a local minimum with stable predictions. Likewise, weight optimization can be restricted to the zero-to-one range or other ranges. It is also possible to fix certain weights to a specific value and optimize the remaining weights.

Standard Errors

The standard errors associated with the smoothing weights are calculated from the Hessian matrix of the sum of squared, one-step-ahead prediction errors with respect to the smoothing weights used in the optimization process.

Weights Near Zero or One

Sometimes the optimization process results in weights near zero or one.

For simple or double (Brown) exponential smoothing, a level weight near zero implies that simple differencing of the time series might be appropriate.

For linear (Holt) exponential smoothing, a level weight near zero implies that the smoothed trend is constant and that an ARIMA model with deterministic trend might be a more appropriate model.

For damped-trend linear exponential smoothing, a damping weight near one implies that linear (Holt) exponential smoothing might be a more appropriate model.

For Winters method and seasonal exponential smoothing, a seasonal weight near one implies that a nonseasonal model might be more appropriate and a seasonal weight near zero implies that deterministic seasonal factors might be present.
Equations for the Smoothing Models

Simple Exponential Smoothing

The model equation for simple exponential smoothing is

\[ Y_t = \mu_t + \epsilon_t \]

The smoothing equation is

\[ L_t = \alpha Y_t + (1 - \alpha) L_{t-1} \]

The error-correction form of the smoothing equation is

\[ L_t = L_{t-1} + \alpha e_t \]

(Note: For missing values, \( e_t = 0 \).)

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = L_t \]

The ARIMA model equivalency to simple exponential smoothing is the ARIMA(0,1,1) model

\[ (1 - B) Y_t = (1 - \theta B) \epsilon_t \]
\[ \theta = 1 - \alpha \]

The moving-average form of the equation is

\[ Y_t = \epsilon_t + \sum_{j=1}^{\infty} \alpha \epsilon_{t-j} \]

For simple exponential smoothing, the additive-invertible region is

\[ \{0 < \alpha < 2\} \]

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ 1 + \sum_{j=1}^{k-1} \alpha^2 \right] = \text{var}(\epsilon_t)(1 + (k - 1)\alpha^2) \]
Double (Brown) Exponential Smoothing

The model equation for double exponential smoothing is

\[ Y_t = \mu_t + \beta_t t + \epsilon_t \]

The smoothing equations are

\[ \begin{align*}
L_t &= \alpha Y_t + (1 - \alpha) L_{t-1} \\
T_t &= \alpha (L_t - L_{t-1}) + (1 - \alpha) T_{t-1}
\end{align*} \]

This method can be equivalently described in terms of two successive applications of simple exponential smoothing,

\[ \begin{align*}
S_{t}^{[1]} &= \alpha Y_t + (1 - \alpha) S_{t-1}^{[1]} \\
S_{t}^{[2]} &= \alpha S_{t}^{[1]} + (1 - \alpha) S_{t-1}^{[2]}
\end{align*} \]

where \( S_{t}^{[1]} \) are the smoothed values of \( Y_t \), and \( S_{t}^{[2]} \) are the smoothed values of \( S_{t}^{[1]} \). The prediction equation then takes the following form:

\[ \hat{Y}_t(k) = (2 + ak/(1 - \alpha)) S_{t}^{[1]} - (1 + ak/(1 - \alpha)) S_{t}^{[2]} \]

The error-correction forms of the smoothing equations are

\[ \begin{align*}
L_t &= L_{t-1} + T_{t-1} + \alpha e_t \\
T_t &= T_{t-1} + \alpha^2 e_t
\end{align*} \]

(Note: For missing values, \( e_t = 0 \).)

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = L_t + ((k - 1) + 1/\alpha) T_t \]

The ARIMA model equivalency to double exponential smoothing is the ARIMA(0,2,2) model,

\[ \begin{align*}
(1 - B)^2 Y_t &= (1 - \theta B)^2 \epsilon_t \\
\theta &= 1 - \alpha
\end{align*} \]

The moving-average form of the equation is

\[ Y_t = \epsilon_t + \sum_{j=1}^{\infty} (2\alpha + (j - 1)\alpha^2) \epsilon_{t-j} \]

For double exponential smoothing, the additive-invertible region is

\[ \{0 < \alpha < 2\} \]

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ 1 + \sum_{j=1}^{k-1} (2\alpha + (j - 1)\alpha^2)^2 \right] \]
Linear (Holt) Exponential Smoothing

The model equation for linear exponential smoothing is

\[ Y_t = \mu_t + \beta_t t + \epsilon_t \]

The smoothing equations are

\[ L_t = \alpha Y_t + (1 - \alpha)(L_{t-1} + T_{t-1}) \]
\[ T_t = \gamma (L_t - L_{t-1}) + (1 - \gamma) T_{t-1} \]

The error-correction form of the smoothing equations is

\[ L_t = L_{t-1} + T_{t-1} + \alpha e_t \]
\[ T_t = T_{t-1} + \alpha \gamma e_t \]

(Note: For missing values, \( e_t = 0 \).)

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = L_t + kT_t \]

The ARIMA model equivalency to linear exponential smoothing is the ARIMA(0,2,2) model,

\[ (1 - B)^2 Y_t = (1 - \theta_1 B - \theta_2 B^2) \epsilon_t \]
\[ \theta_1 = 2 - \alpha - \alpha \gamma \]
\[ \theta_2 = \alpha - 1 \]

The moving-average form of the equation is

\[ Y_t = \epsilon_t + \sum_{j=1}^{\infty} (\alpha + j \alpha \gamma) \epsilon_{t-j} \]

For linear exponential smoothing, the additive-invertible region is

\[ \{0 < \alpha < 2\} \]
\[ \{0 < \gamma < 4/\alpha - 2\} \]

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ 1 + \sum_{j=1}^{k-1} (\alpha + j \alpha \gamma)^2 \right] \]
Damped-Trend Linear Exponential Smoothing

The model equation for damped-trend linear exponential smoothing is

\[ Y_t = \mu_t + \beta_t t + \epsilon_t \]

The smoothing equations are

\[ L_t = \alpha Y_t + (1 - \alpha)(L_{t-1} + \phi T_{t-1}) \]
\[ T_t = \gamma (L_t - L_{t-1}) + (1 - \gamma)\phi T_{t-1} \]

The error-correction form of the smoothing equations is

\[ L_t = L_{t-1} + \phi T_{t-1} + \alpha e_t, \quad T_t = \phi T_{t-1} + \alpha \gamma e_t \]

(Note: For missing values, \( e_t = 0 \).)

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = L_t + \sum_{i=1}^{k} \phi^j T_t \]

The ARIMA model equivalency to damped-trend linear exponential smoothing is the ARIMA(1,1,2) model,

\[ (1 - \phi B)(1 - B) Y_t = (1 - \theta_1 B - \theta_2 B^2)\epsilon_t \]
\[ \theta_1 = 1 + \phi - \alpha - \alpha \gamma \phi \]
\[ \theta_2 = (\alpha - 1)\phi \]

The moving-average form of the equation (assuming \(|\phi| < 1\)) is

\[ Y_t = \epsilon_t + \sum_{j=1}^{\infty} \left( \alpha + \alpha \gamma \phi (\phi^j - 1)/(\phi - 1) \right)\epsilon_{t-j} \]

For damped-trend linear exponential smoothing, the additive-invertible region is

\[ \{0 < \alpha < 2\} \]
\[ \{0 < \phi \gamma < 4/\alpha - 2\} \]

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ 1 + \sum_{j=1}^{k-1} (\alpha + \alpha \gamma \phi (\phi^j - 1)/(\phi - 1))^2 \right] \]
Seasonal Exponential Smoothing

The model equation for seasonal exponential smoothing is

\[ Y_t = \mu_t + s_p(t) + \epsilon_t \]

The smoothing equations are

\[ L_t = \alpha(Y_t - S_{t-p}) + (1 - \alpha)L_{t-1} \]
\[ S_t = \delta(Y_t - L_t) + (1 - \delta)S_{t-p} \]

The error-correction form of the smoothing equations is

\[ L_t = L_{t-1} + \alpha e_t \]
\[ S_t = S_{t-p} + \delta(1 - \alpha)e_t \]

(Note: For missing values, \( e_t = 0 \).)

The k-step prediction equation is

\[ \hat{Y}_t(k) = L_t + S_{t-p+k} \]

The ARIMA model equivalency to seasonal exponential smoothing is the ARIMA(0,1,p+1)(0,1,0)_p model,

\[ (1 - B)(1 - B^p)Y_t = (1 - \theta_1 B - \theta_2 B^p - \theta_3 B^{p+1})\epsilon_t \]
\[ \theta_1 = 1 - \alpha \]
\[ \theta_2 = 1 - \delta(1 - \alpha) \]
\[ \theta_3 = (1 - \alpha)(\delta - 1) \]

The moving-average form of the equation is

\[ Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j} \]
\[ \psi_j = \begin{cases} 
\alpha & \text{for } j \mod p \neq 0 \\
\alpha + \delta(1 - \alpha) & \text{for } j \mod p = 0 
\end{cases} \]

For seasonal exponential smoothing, the additive-invertible region is

\[ \{ \max(-p\alpha, 0) < \delta(1 - \alpha) < (2 - \alpha) \} \]

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ 1 + \sum_{j=1}^{k-1} \psi_j^2 \right] \]
Multiplicative Seasonal Smoothing

In order to use the multiplicative version of seasonal smoothing, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of seasonal smoothing is

\[ Y_t = \mu_t s_p(t) + \epsilon_t \]

The smoothing equations are

\[ \begin{align*}
L_t &= \alpha(Y_t / S_{t-p}) + (1 - \alpha)L_{t-1} \\
S_t &= \delta(Y_t / L_t) + (1 - \delta)S_{t-p}
\end{align*} \]

The error-correction form of the smoothing equations is

\[ \begin{align*}
L_t &= L_{t-1} + \alpha e_t / S_{t-p} \\
S_t &= S_{t-p} + \delta(1 - \alpha)e_t / L_t
\end{align*} \]

(Note: For missing values, \( e_t = 0 \).)

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = L_t S_{t-p+k} \]

The multiplicative version of seasonal smoothing does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of seasonal described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

\[ \text{var}(e_t(k)) = \text{var}(\epsilon_t) \left[ \sum_{i=0}^{\infty} \sum_{j=0}^{p-1} (\psi_{j+i}p S_{t+k}/S_{t+k-j})^2 \right] \]

where \( \psi_j \) are as described for the additive version of seasonal method, and \( \psi_j = 0 \) for \( j \geq k \).

Winters Method—Additive Version

The model equation for the additive version of the Winters method is

\[ Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t \]

The smoothing equations are

\[ \begin{align*}
L_t &= \alpha(Y_t - S_{t-p}) + (1 - \alpha)(L_{t-1} + T_{t-1}) \\
T_t &= \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1} \\
S_t &= \delta(Y_t - L_t) + (1 - \delta)S_{t-p}
\end{align*} \]

Winters Method—Additive Version

The model equation for the additive version of the Winters method is

\[ Y_t = \mu_t + \beta_t t + s_p(t) + \epsilon_t \]

The smoothing equations are

\[ \begin{align*}
L_t &= \alpha(Y_t - S_{t-p}) + (1 - \alpha)(L_{t-1} + T_{t-1}) \\
T_t &= \gamma(L_t - L_{t-1}) + (1 - \gamma)T_{t-1} \\
S_t &= \delta(Y_t - L_t) + (1 - \delta)S_{t-p}
\end{align*} \]
The error-correction form of the smoothing equations is

\[ L_t = L_{t-1} + T_{t-1} + \alpha e_t \]
\[ T_t = T_{t-1} + \alpha \gamma e_t \]
\[ S_t = S_{t-p} + \delta(1 - \alpha)e_t \]

(Note: For missing values, \( e_t = 0 \).)

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = L_t + kT_t + S_{t-p+k} \]

The ARIMA model equivalency to the additive version of the Winters method is the ARIMA(0,1,p+1)(0,1,0)\( _p \) model,

\[ (1 - B)(1 - B^p)Y_t = \left[ 1 - \sum_{i=1}^{p+1} \theta_i B^i \right] \epsilon_t \]

\[ \theta_j = \begin{cases} 
1 - \alpha - \alpha \gamma & j = 1 \\
-\alpha \gamma & 2 \leq j \leq p - 1 \\
1 - \alpha \gamma - \delta(1 - \alpha) & j = p \\
(1 - \alpha)(\delta - 1) & j = p + 1 
\end{cases} \]

The moving-average form of the equation is

\[ Y_t = \epsilon_t + \sum_{j=1}^{\infty} \psi_j \epsilon_{t-j} \]

\[ \psi_j = \begin{cases} 
\alpha + j\alpha \gamma & \text{for } j \mod p \neq 0 \\
\alpha + j\alpha \gamma + \delta(1 - \alpha), & \text{for } j \mod p = 0 
\end{cases} \]

For the additive version of the Winters method (Archibald 1990), the additive-invertible region is

\[ \{ \max(-p\alpha, 0) < \delta(1 - \alpha) < (2 - \alpha) \} \]
\[ \{ 0 < \alpha \gamma < 2 - \alpha - \delta(1 - \alpha)(1 - \cos(\hat{\vartheta})) \} \]

where \( \hat{\vartheta} \) is the smallest nonnegative solution to the equations listed in Archibald (1990).

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ 1 + \sum_{j=1}^{k-1} \psi_j^2 \right] \]
Winters Method—Multiplicative Version

In order to use the multiplicative version of the Winters method, the time series and all predictions must be strictly positive.

The model equation for the multiplicative version of the Winters method is

\[ Y_t = (\mu_t + \beta_t t) s_p(t) + \epsilon_t \]

The smoothing equations are

\[ L_t = \alpha (Y_t / S_{t-p}) + (1 - \alpha) (L_{t-1} + T_{t-1}) \]
\[ T_t = \gamma (L_t - L_{t-1}) + (1 - \gamma) T_{t-1} \]
\[ S_t = \delta (Y_t / L_t) + (1 - \delta) S_{t-p} \]

The error-correction form of the smoothing equations is

\[ L_t = L_{t-1} + T_{t-1} + \alpha \epsilon_t / S_{t-p} \]
\[ T_t = T_{t-1} + \alpha \gamma \epsilon_t / S_{t-p} \]
\[ S_t = S_{t-p} + \delta (1 - \alpha) \epsilon_t / L_t \]

**NOTE:** For missing values, \( \epsilon_t = 0 \).

The \( k \)-step prediction equation is

\[ \hat{Y}_t(k) = (L_t + k T_t) S_{t-p+k} \]

The multiplicative version of the Winters method does not have an ARIMA equivalent; however, when the seasonal variation is small, the ARIMA additive-invertible region of the additive version of the Winters method described in the preceding section can approximate the stability region of the multiplicative version.

The variance of the prediction errors is estimated as

\[ \text{var}(\epsilon_t(k)) = \text{var}(\epsilon_t) \left[ \sum_{i=0}^{\infty} \sum_{j=0}^{p-1} (\psi_{j+i+p} S_{t+k}/S_{t+k-j})^2 \right] \]

where \( \psi_j \) are as described for the additive version of the Winters method and \( \psi_j = 0 \) for \( j \geq k \).

---

**ARIMA Models**

Autoregressive integrated moving-average (ARIMA) models predict values of a dependent time series with a linear combination of its own past values, past errors (also called shocks or innovations), and current and past values of other time series (predictor time series).

The Time Series Forecasting System uses the ARIMA procedure of SAS/ETS software to fit and forecast ARIMA models. The maximum likelihood method is used for parameter estimation. For more information about ARIMA model estimation and forecasting, see Chapter 7, “The ARIMA Procedure.”

This section summarizes the notation used for ARIMA models.
Notation for ARIMA Models

A dependent time series that is modeled as a linear combination of its own past values and past values of an error series is known as a (pure) ARIMA model.

Nonseasonal ARIMA Model Notation

The order of an ARIMA model is usually denoted by the notation ARIMA$(p,d,q)$, where

\[
p \quad \text{is the order of the autoregressive part.}
\]

\[
d \quad \text{is the order of the differencing (rarely should } d > 2 \text{ be needed).}
\]

\[
q \quad \text{is the order of the moving-average process.}
\]

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA model is written as

\[
(1 - B)^d Y_t = \mu + \frac{\theta(B)}{\phi(B)} a_t
\]

where

\[
t \quad \text{indexes time.}
\]

\[
\mu \quad \text{is the mean term.}
\]

\[
B \quad \text{is the backshift operator; that is, } BX_t = X_{t-1}.
\]

\[
\phi(B) \quad \text{is the autoregressive operator, represented as a polynomial in the backshift operator: } \phi(B) = 1 - \phi_1 B - \cdots - \phi_p B^p.
\]

\[
\theta(B) \quad \text{is the moving-average operator, represented as a polynomial in the backshift operator: } \theta(B) = 1 - \theta_1 B - \cdots - \theta_q B^q.
\]

\[
a_t \quad \text{is the independent disturbance, also called the random error.}
\]

For example, the mathematical form of the ARIMA$(1,1,2)$ model is

\[
(1 - B)Y_t = \mu + \frac{(1 - \theta_1 B - \theta_2 B^2)}{(1 - \phi_1 B)} a_t
\]

Seasonal ARIMA Model Notation

Seasonal ARIMA models are expressed in factored form by the notation ARIMA$(p,d,q)(P,D,Q)_s$,

\[
P \quad \text{is the order of the seasonal autoregressive part.}
\]

\[
D \quad \text{is the order of the seasonal differencing (rarely should } D > 1 \text{ be needed).}
\]

\[
Q \quad \text{is the order of the seasonal moving-average process.}
\]

\[
s \quad \text{is the length of the seasonal cycle.}
\]

Given a dependent time series $\{Y_t : 1 \leq t \leq n\}$, mathematically the ARIMA seasonal model is written as

\[
(1 - B)^d (1 - B^s)^D Y_t = \mu + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)} a_t
\]

where
\( \phi_s(B^s) \) is the seasonal autoregressive operator, represented as a polynomial in the backshift operator: \( \phi_s(B^s) = 1 - \phi_{s,1}B^s - \cdots - \phi_{s,P}B^{sp} \).

\( \theta_s(B^s) \) is the seasonal moving-average operator, represented as a polynomial in the backshift operator: \( \theta_s(B^s) = 1 - \theta_{s,1}B^s - \cdots - \theta_{s,Q}B^{sq} \).

For example, the mathematical form of the ARIMA(1,0,1)(1,1,2)_{12} model is

\[
(1 - B^{12})Y_t = \mu + \frac{(1 - \theta_1 B)(1 - \theta_{s,1}B^{12} - \theta_{s,2}B^{24})}{(1 - \phi_1 B)(1 - \phi_{s,1}B^{12})}a_t
\]

**Abbreviated Notation for ARIMA Models**

If the differencing order, autoregressive order, or moving-average order is zero, the notation is further abbreviated as follows:

- I\((d)D_s\) integrated model or ARIMA\((0,d,0)(0,D,0)\)
- AR\((p)P_s\) autoregressive model or ARIMA\((p,0,0)(P,0,0)\)
- IAR\((p,d)(P,D)_s\) integrated autoregressive model or ARIMA\((p,d,0)(P,D,0)_s\)
- MA\((q)Q_s\) moving average model or ARIMA\((0,0,q)(0,0,Q)_s\)
- IMA\((d,q)(D,Q)_s\) integrated moving average model or ARIMA\((0,d,q)(0,D,Q)_s\)
- ARMA\((p,q)(P,Q)_s\) autoregressive moving-average model or ARIMA\((p,0,q)(P,0,Q)_s\)

**Notation for Transfer Functions**

A transfer function can be used to filter a predictor time series to form a dynamic regression model.

Let \( Y_t \) be the dependent series, let \( X_t \) be the predictor series, and let \( \Psi(B) \) be a linear filter or transfer function for the effect of \( X_t \) on \( Y_t \). The ARIMA model is then

\[
(1 - B)^d(1 - B^s)^D Y_t = \mu + \Psi(B)(1 - B)^d(1 - B^s)^D X_t + \frac{\theta(B)\theta_s(B^s)}{\phi(B)\phi_s(B^s)}a_t
\]

This model is called a dynamic regression of \( Y_t \) on \( X_t \).

**Nonseasonal Transfer Function Notation**

Given the \( i \)th predictor time series \( \{X_{i,t} : 1 \leq t \leq n\} \), the transfer function is written as

\[
\text{Dif}(d_i)\text{Lag}(k_i)\text{N}(q_i)/D(p_i)
\]

where

- \( d_i \) is the simple order of the differencing for the \( i \)th predictor time series, \( (1 - B)^{d_i}X_{i,t} \) (rarely should \( d_i > 2 \) be needed).
- \( k_i \) is the pure time delay (lag) for the effect of the \( i \)th predictor time series, \( X_{i,t}B^{k_i} = X_{i,t-k_i} \).
Chapter 65: Forecasting Process Details

\( p_i \) is the simple order of the denominator for the \( i \)th predictor time series.

\( q_i \) is the simple order of the numerator for the \( i \)th predictor time series.

The mathematical notation used to describe a transfer function is

\[
\Psi_i(B) = \frac{\omega_i(B)}{\delta_i(B)} (1 - B)^d_i B^k_i
\]

where

\( B \) is the backshift operator; that is, \( BX_t = X_{t-1} \).

\( \delta_i(B) \) is the denominator polynomial of the transfer function for the \( i \)th predictor time series: \( \delta_i(B) = 1 - \delta_{i,1} B - \cdots - \delta_{i,p_i} B^{p_i} \).

\( \omega_i(B) \) is the numerator polynomial of the transfer function for the \( i \)th predictor time series: \( \omega_i(B) = 1 - \omega_{i,1} B - \cdots - \omega_{i,q_i} B^{q_i} \).

The numerator factors for a transfer function for a predictor series are like the MA part of the ARMA model for the noise series. The denominator factors for a transfer function for a predictor series are like the AR part of the ARMA model for the noise series. Denominator factors introduce exponentially weighted, infinite distributed lags into the transfer function.

For example, the transfer function for the \( i \)th predictor time series with

\( k_i = 3 \) time lag is 3

\( d_i = 1 \) simple order of differencing is one

\( p_i = 1 \) simple order of the denominator is one

\( q_i = 2 \) simple order of the numerator is two

would be written as \([\text{Dif}(1)\text{Lag}(3)\text{N}(2)/\text{D}(1)]\). The mathematical notation for the transfer function in this example is

\[
\Psi_i(B) = \frac{(1 - \omega_{i,1} B - \omega_{i,2} B^2)}{(1 - \delta_{i,1} B)} (1 - B) B^3
\]

**Seasonal Transfer Function Notation**

The general transfer function notation for the \( i \)th predictor time series \( X_{i,t} \) with seasonal factors is \([\text{Dif}(d_i)(D_i)_s \text{Lag}(k_i)_s N(q_i)_s)/(P_i)_s \text{D}(p_i)(P_i)_s]\), where

\( D_i \) is the seasonal order of the differencing for the \( i \)th predictor time series (rarely should \( D_i > 1 \) be needed).

\( P_i \) is the seasonal order of the denominator for the \( i \)th predictor time series (rarely should \( P_i > 2 \) be needed).

\( Q_i \) is the seasonal order of the numerator for the \( i \)th predictor time series, (rarely should \( Q_i > 2 \) be needed).

\( s \) is the length of the seasonal cycle.
The mathematical notation used to describe a seasonal transfer function is

\[
\Psi_i(B) = \frac{\omega_i(B)\omega_{s,i}(B^s)}{\delta_i(B)\delta_{s,i}(B^s)}(1 - B)^d_i(1 - B^s)^D_i B^{k_i}
\]

where

\[
\delta_{s,i}(B^s) \quad \text{is the denominator seasonal polynomial of the transfer function for the } i\text{th predictor time series: } \delta_{s,i}(B) = 1 - \delta_{s,i,1}B - \cdots - \delta_{s,i,p_i}B^{sP_i}.
\]

\[
\omega_{s,i}(B^s) \quad \text{is the numerator seasonal polynomial of the transfer function for the } i\text{th predictor time series: } \omega_{s,i}(B) = 1 - \omega_{s,i,1}B - \cdots - \omega_{s,i,q_i}B^{sQ_i}.
\]

For example, the transfer function for the \(i\)th predictor time series \(X_{i,t}\) whose seasonal cycle \(s = 12\) with

- \(d_i = 2\) \quad \text{simple order of differencing is two}
- \(D_i = 1\) \quad \text{seasonal order of differencing is one}
- \(q_i = 2\) \quad \text{simple order of the numerator is two}
- \(Q_i = 1\) \quad \text{seasonal order of the numerator is one}

would be written as \([\text{Dif}(2)(1)s \ N(2)(1)s]\). The mathematical notation for the transfer function in this example is

\[
\Psi_i(B) = (1 - \omega_{i,1}B - \omega_{i,2}B^2)(1 - \omega_{s,i,1}B^{12})(1 - B^2)(1 - B^{12})
\]

Note: In this case, \([\text{Dif}(2)(1)s \ N(2)(1)s]\) = \([\text{Dif}(2)(1)s \text{Lag}(0)N(2)(1)s/D(0)(0)s]\).

---

**Predictor Series**

This section discusses time trend curves, seasonal dummies, interventions, and adjustments.

**Time Trend Curves**

When you specify a time trend curve as a predictor in a forecasting model, the system computes a predictor series that is a deterministic function of time. This variable is then included in the model as a regressor, and the trend curve is fit to the dependent series by linear regression, in addition to other predictor series.

Some kinds of nonlinear trend curves are fit by transforming the dependent series. For example, the exponential trend curve is actually a linear time trend fit to the logarithm of the series. For these trend curve specifications, the series transformation option is set automatically, and you cannot independently control both the time trend curve and transformation option.

The computed time trend variable is included in the output data set in a variable named in accordance with the trend curve type. Let \(t\) represent the observation count from the start of the period of fit for the model, and let \(X_t\) represent the value of the time trend variable at observation \(t\) within the period of fit. The names and definitions of these variables are as follows. (Note: These deterministic variables are reserved variable names.)
Linear trend variable name _LINEAR_, with \( X_t = t - c \).

Quadratic trend variable name _QUAD_, with \( X_t = (t - c)^2 \). Note that a quadratic trend implies a linear trend as a special case and results in two regressors: _QUAD_ and _LINEAR_.

Cubic trend variable name _CUBE_, with \( X_t = (t - c)^3 \). Note that a cubic trend implies a quadratic trend as a special case and results in three regressors: _CUBE_, _QUAD_, and _LINEAR_.

Logistic trend variable name _LOGIT_, with \( X_t = t \). The model is a linear time trend applied to the logistic transform of the dependent series. Thus, specifying a logistic trend is equivalent to specifying the logistic series transformation and a linear time trend. A logistic trend predictor can be used only in conjunction with the logistic transformation, which is set automatically when you specify logistic trend.

Logarithmic trend variable name _LOG_, with \( X_t = \ln(t) \).

Exponential trend variable name _EXP_, with \( X_t = t \). The model is a linear time trend applied to the logarithms of the dependent series. Thus, specifying an exponential trend is equivalent to specifying the log series transformation and a linear time trend. An exponential trend predictor can be used only in conjunction with the log transformation, which is set automatically when you specify exponential trend.

Hyperbolic trend variable name _HYP_, with \( X_t = 1/t \).

Power curve trend variable name _POW_, with \( X_t = \ln(t) \). The model is a logarithmic time trend applied to the logarithms of the dependent series. Thus, specifying a power curve is equivalent to specifying the log series transformation and a logarithmic time trend. A power curve predictor can be used only in conjunction with the log transformation, which is set automatically when you specify a power curve trend.

EXP(A+B/TIME) trend variable name _ERT_, with \( X_t = 1/t \). The model is a hyperbolic time trend applied to the logarithms of the dependent series. Thus, specifying this trend curve is equivalent to specifying the log series transformation and a hyperbolic time trend. This trend curve can be used only in conjunction with the log transformation, which is set automatically when you specify this trend.

Intervention Effects

Interventions are used for modeling events that occur at specific times. That is, they are known changes that affect the dependent series or outliers.

The \( i \)th intervention series is included in the output data set with variable name _INTV\(_i\)_., which is a reserved variable name.

Point Interventions

The point intervention is a one-time event. The \( i \)th intervention series \( X_{i,t} \) has a point intervention at time \( t_{int} \) when the series is nonzero only at time \( t_{int} \)—that is,

\[
X_{i,t} = \begin{cases} 
1, & t = t_{int} \\
0, & \text{otherwise} 
\end{cases}
\]
**Step Interventions**

Step interventions are continuing, and the input time series flags periods after the intervention. For a step intervention, before time $t_{int}$, the $i$th intervention series $X_{i,t}$ is zero and then steps to a constant level thereafter—that is,

$$X_{i,t} = \begin{cases} 
1, & t \geq t_{int} \\
0, & \text{otherwise}
\end{cases}$$

**Ramp Interventions**

A ramp intervention is a continuing intervention that increases linearly after the intervention time. For a ramp intervention, before time $t_{int}$, the $i$th intervention series $X_{i,t}$ is zero and increases linearly thereafter—that is, proportional to time.

$$X_{i,t} = \begin{cases} 
(t - t_{int}), & t \geq t_{int} \\
0, & \text{otherwise}
\end{cases}$$

**Intervention Effect**

Given the $i$th intervention series $X_{i,t}$, you can define how the intervention takes effect by filters (transfer functions) of the form

$$\Psi_i(B) = \frac{1 - \omega_{i,1} B - \ldots - \omega_{i,q_i} B^{q_i}}{1 - \delta_{i,1} B - \ldots - \delta_{i,p_i} B^{p_i}}$$

where $B$ is the backshift operator $B y_t = y_{t-1}$.

The denominator of the transfer function determines the decay pattern of the intervention effect, whereas the numerator terms determine the size of the intervention effect time window.

For example, the following intervention effects are associated with the respective transfer functions:

- Immediately: $\Psi_i(B) = 1$
- Gradually: $\Psi_i(B) = 1/(1 - \delta_{i,1} B)$
- 1 lag window: $\Psi_i(B) = 1 - \omega_{i,1} B$
- 3 lag window: $\Psi_i(B) = 1 - \omega_{i,1} B - \omega_{i,2} B^2 - \omega_{i,3} B^3$

**Intervention Notation**

The notation used to describe intervention effects has the form $\text{type}:t_{int} (q_i)/(p_i)$, where $\text{type}$ is point, step, or ramp; $t_{int}$ is the time of the intervention (for example, OCT87); $q_i$ is the transfer function numerator order; and $p_i$ is the transfer function denominator order. If $q_i = 0$, the part “$(q_i)$” is omitted; if $p_i = 0$, the part “$/p_i$” is omitted.

In the Intervention Specification window, the Number of Lags option specifies the transfer function numerator order $q_i$, and the Effect Decay Pattern option specifies the transfer function denominator order $p_i$. In the Effect Decay Pattern options, values and resulting $p_i$ are as follows: None, $p_i = 0$ Exp, $p_i = 1$ Wave, $p_i = 2$

For example, a step intervention with date 08MAR90 and effect pattern Exp is denoted “Step:08MAR90/(1)” and has a transfer function filter $\Psi_i(B) = 1/(1 - \delta_1 B)$. A ramp intervention immediately applied on 08MAR90 is denoted “Ramp:08MAR90” and has a transfer function filter $\Psi_i(B) = 1$. 
### Seasonal Dummy Inputs

For a seasonal cycle of length \( s \), the seasonal dummy regressors include

\[
\{X_{i,t} : 1 \leq i \leq (s - 1), 1 \leq t \leq n\}
\]

for models that include an intercept term and

\[
\{X_{i,t} : 1 \leq i \leq s, 1 \leq t \leq n\}
\]

for models that exclude an intercept term. Each element of a seasonal dummy regressor is either zero or one, based on the following rule:

\[
X_{i,t} = \begin{cases} 
1, & \text{when } i = t \mod s \\
0, & \text{otherwise}
\end{cases}
\]

Note that if the model includes an intercept term, the number of seasonal dummy regressors is one less than \( s \) to ensure that the linear system is full rank.

The seasonal dummy variables are included in the output data set with variable names prefixed with "SDUMMYi" and sequentially numbered. They are reserved variable names.

### Series Diagnostic Tests

This section describes the diagnostic tests that are used to determine the kinds of forecasting models appropriate for a series.

The series diagnostics are a set of heuristics that provide recommendations on whether or not the forecasting model should contain a log transform, trend terms, and seasonal terms. These recommendations are used by the automatic model selection process to restrict the model search to a subset of the model selection list. (You can disable this behavior by using the Automatic Model Selection Options window.)

The tests that are used by the series diagnostics do not always produce the correct classification of the series. They are intended to accelerate the process of searching for a good forecasting model for the series, but you should not rely on them if finding the very best model is important to you.

If you have information about the appropriate kinds of forecasting models (perhaps from studying the plots and autocorrelations shown in the Series Viewer window), you can set the series diagnostic flags in the Series Diagnostics window. Select the YES, NO, or MAYBE values for the Log Transform, Trend, and Seasonality options in the Series Diagnostics window as you think appropriate.

The series diagnostics tests are intended as a heuristic tool only, and no statistical validity is claimed for them. These tests might be modified and enhanced in future releases of the Time Series Forecasting System. The testing strategy is as follows:

1. **Log transform test.** The log test fits a high-order autoregressive model to the series and to the log of the series and compares goodness-of-fit measures for the prediction errors of the two models. If this test finds that log transforming the series is suitable, the Log Transform option is set to YES, and the subsequent diagnostic tests are performed on the log transformed series.
2. **Trend test.** The resultant series is tested for presence of a trend by using an augmented Dickey-Fuller test and a random walk with drift test. If either test finds that the series appears to have a trend, the Trend option is set to YES, and the subsequent diagnostic tests are performed on the differenced series.

3. **Seasonality test.** The resultant series is tested for seasonality. A seasonal dummy model with AR(1) errors is fit and the joint significance of the seasonal dummy estimates is tested. If the seasonal dummies are significant, the AIC statistic for this model is compared to the AIC for and AR(1) model without seasonal dummies. If the AIC for the seasonal model is lower than that of the nonseasonal model, the Seasonal option is set to YES.

---

**Statistics of Fit**

This section explains the goodness-of-fit statistics reported to measure how well different models fit the data. The statistics of fit for the various forecasting models can be viewed or stored in a data set by using the Model Viewer window.

Statistics of fit are computed by using the actual and forecasted values for observations in the period of evaluation. One-step forecasted values are used whenever possible, including the case when a hold-out sample contains no missing values. If a one-step forecast for an observation cannot be computed due to missing values for previous series observations, a multi-step forecast is computed, using the minimum number of steps as the previous nonmissing values in the data range permit.

The various statistics of fit reported are as follows. In these formulas, \( n \) is the number of nonmissing observations and \( k \) is the number of fitted parameters in the model.

- **Number of Nonmissing Observations**
  The number of nonmissing observations used to fit the model.

- **Number of Observations**
  The total number of observations used to fit the model, including both missing and nonmissing observations.

- **Number of Missing Actuals**
  The number of missing actual values.

- **Number of Missing Predicted Values**
  The number of missing predicted values.

- **Number of Model Parameters**
  The number of parameters fit to the data. For combined forecast, this is the number of forecast components.

- **Total Sum of Squares (Uncorrected)**
  The total sum of squares for the series, SST, uncorrected for the mean: \( \sum_{t=1}^{n} y_t^2 \).

- **Total Sum of Squares (Corrected)**
  The total sum of squares for the series, SST, corrected for the mean: \( \sum_{t=1}^{n} (y_t - \bar{y})^2 \), where \( \bar{y} \) is the series mean.
**Sum of Square Errors**
The sum of the squared prediction errors, SSE. $SSE = \sum_{t=1}^{n} (y_t - \hat{y}_t)^2$, where $\hat{y}_t$ is the one-step predicted value.

**Mean Squared Error**
The mean squared prediction error, MSE, calculated from the one-step-ahead forecasts. $MSE = \frac{1}{n} SSE$. This formula enables you to evaluate small hold-out samples.

**Root Mean Squared Error**
The root mean square error (RMSE), $\sqrt{MSE}$.

**Mean Absolute Percent Error**
The mean absolute percent prediction error (MAPE), $\frac{100}{n} \sum_{t=1}^{n} \left| \frac{y_t - \hat{y}_t}{y_t} \right|$. The summation ignores observations where $y_t = 0$.

**Mean Absolute Error**
The mean absolute prediction error, $\frac{1}{n} \sum_{t=1}^{n} |y_t - \hat{y}_t|$.

**R-Square**
The $R^2$ statistic, $R^2 = 1 - \frac{SSE}{SST}$. If the model fits the series badly, the model error sum of squares, SSE, can be larger than SST and the $R^2$ statistic will be negative.

**Adjusted R-Square**
The adjusted $R^2$ statistic, $1 - \left( \frac{n-1}{n-k} \right) (1 - R^2)$.

**Amemiya’s Adjusted R-Square**
Amemiya’s adjusted $R^2$, $1 - \left( \frac{n+k}{n-k} \right) (1 - R^2)$.

**Random Walk R-Square**
The random walk $R^2$ statistic (Harvey’s $R^2$ statistic by using the random walk model for comparison), $1 - \left( \frac{n-1}{n} \right) \frac{SSE}{RWSSE}$, where $RWSSE = \sum_{t=2}^{n} (y_t - y_{t-1} - \mu)^2$, and $\mu = \frac{1}{n-1} \sum_{t=2}^{n} (y_t - y_{t-1})$.

**Akaike’s Information Criterion**
Akaike’s information criterion (AIC), $n \ln(MSE) + 2k$.

**Schwarz Bayesian Information Criterion**
Schwarz Bayesian information criterion (SBC or BIC), $n \ln(MSE) + k \ln(n)$.

**Amemiya’s Prediction Criterion**
Amemiya’s prediction criterion, $\frac{1}{n} SST \left( \frac{n+k}{n-k} \right) (1 - R^2) = \left( \frac{n+k}{n-k} \right) \frac{1}{n} SSE$.

**Maximum Error**
The largest prediction error.

**Minimum Error**
The smallest prediction error.

**Maximum Percent Error**
The largest percent prediction error, $100 \max((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

**Minimum Percent Error**
The smallest percent prediction error, $100 \min((y_t - \hat{y}_t)/y_t)$. The summation ignores observations where $y_t = 0$.

**Mean Error**
The mean prediction error, $\frac{1}{n} \sum_{t=1}^{n} (y_t - \hat{y}_t)$.
Mean Percent Error
The mean percent prediction error, \( \frac{100}{n} \sum_{t=1}^{n} \frac{(y_t - \hat{y}_t)}{y_t} \). The summation ignores observations where \( y_t = 0 \).
