VAR variable < initial-values > . . . ;
WEIGHT variable ;
WHEN (expression )programming-statement ;

The following sections describe the statements available in PROC TMODEL but not in PROC MODEL.

CROSSSECTION Statement
CROSSSECTION variables ;
The CROSSSECTION statement specifies the variables that identify observations in the input data set that form time series. This statement is useful when the input data set contains more than one time series and when a dynamic model is being estimated using the FIT statement or simulated using the SOLVE statement. When you use the CROSSSECTION statement, observations within each cross section must be grouped together, and the observations in each cross section must be sorted.

FIT Statement
FIT < equations > < PARMS=(parameter < values> . . . ) > < START=(parameter values . . . ) > < DROP=(parameter . . . ) > < INITIAL=(variable < = parameter | constant > . . . ) > < / options > ;

PROC TMODEL includes additional options in the FIT statement to provide more control of the estimation process than PROC MODEL provides. For a complete description of the syntax of the FIT statement, see the section “FIT Statement” on page 1518 in Chapter 25, “The MODEL Procedure.” The syntax for specifying the new options follows:

FIT < . . . > < / QUADHESS=LINEAR | ANALYTIC | FDA < OPTIMIZER=type < (ORMP-optimizer-options) >> > ;

Options to Control the Estimation Process
QUADHESS=LINEAR | ANALYTIC | FDA
specifies which method to use to compute the Hessian matrix during the optimization process. For FIML and t distribution estimations, the HESSIAN= option (in PROC MODEL) is used to specify how the Hessian matrix is computed, and the QUADHESS= option has no effect.
FIT Statement ➤ 2835

**ANALYTIC** specifies that the Hessian matrix be evaluated using its exact analytical representation during the optimization process. This option might improve convergence properties for certain nonlinear models. It is not available for feasible GLS estimations or random-effects estimations.

**FDA** specifies that a finite difference approximation to the Hessian matrix be used during the optimization process. This option is available only when the OPTIMIZER=ORMP option is specified.

**LINEAR** specifies that the crossproduct of the Jacobian matrix be used as an approximation to the Hessian matrix during the optimization process.

By default, QUADHESS=LINEAR.

**Options to Control the Optimization Process**

**OPTIMIZER** specifies which optimizer to use to perform the numerical minimization. You can specify only one of the **types**. By default, OPTIMIZER=ORMP.

- **ZOPT** specifies that the optimizer used in PROC MODEL be used in the minimization.
- **ORMP** specifies that the nonlinear programming solver available in SAS/OR software be used in the minimization.

You can specify the following **ORMP-optimizer-options**:

- **ALGORITHM** specifies the optimization technique to be used to solve the problem. By default, ALGORITHM=INTERIORPOINT.
- **FEASTOL** defines the feasible tolerance. The default is $\epsilon=1E^{-6}$.
- **MAXITER** specifies that the NLP solver take at most $n$ major iterations to determine an optimum. The default is 5,000 iterations.
- **MAXTIME** specifies an upper limit of $t$ units of time for the optimization process. If you do not specify this option, the NLP solver does not stop based on the amount of time elapsed.
- **MSBNDRANGE** defines the range from which each variable can take values during the sampling process. The default value is 200.
- **MSDISTTOL** defines the tolerance by which two optimal points are considered distinct. Optimal points are considered distinct if the Euclidean distance between them is at least $\epsilon$. The default is $1.0E^{-6}$. 
**MSMAXSTARTS=n**

defines the maximum number of starting points to be used for local optimization. The default value is 100.

**MSMAXTIME=t**

defines the maximum allowable time \( t \) (in seconds) for the NLP solver to locate the best local optimum in multistart mode. If you do not specify this option, the multistart algorithm does not stop based on the amount of time elapsed.

**MULTISTART**

enables multistart mode. In this mode, the local solver solves the problem from multiple starting points, possibly finding a better local minimum as a result. By default, this option is disabled.

**OBJLIMIT=m**

specifies a limit on the magnitude of the objective value. The algorithm terminates when the objective value becomes less than \(-m\). The default is \( m=1E+20 \). The minimum acceptable value of \( m \) is \( 1E+8 \). If the specified value of \( m \) is less than \( 1E+8 \), the value is reset to the default value, \( 1E+20 \).

**OPTTOL=\( \epsilon \)**

defines the measure by which you can decide whether the current iterate is an acceptable approximation of a local minimum. The value of this option is a positive real number. The ORMP optimizer determines that the current iterate is a local minimum when the norm of the scaled vector of the optimality conditions is less than \( \epsilon \) and the true constraint violation is less than the value of the FEASTOL= option. The default is \( 1E-6 \).

**SEED=n**

specifies a positive integer to be used as the seed for generating random number sequences in multistart mode. The default value is 0. To ensure reproducible results, specify a nonzero value.

**TIMETYPE=CPU | REAL**

specifies the units of time that the MAXTIME= option uses. If you do not specify this option, the multistart algorithm does not stop based on the amount of time elapsed.

For more information about the optimizers available in PROC TMODEL, see the section “Nonlinear Optimization” on page 2842. For more information about the ORMP nonlinear solver, see Chapter 10, “The Nonlinear Programming Solver” (SAS/OR User’s Guide: Mathematical Programming).

---

**PERFORMANCE Statement**

```
PERFORMANCE <NTHREADS=n> <BYPRIORITY=priority> <REPPRIORITY=priority> <MSPRIORITY | GRIDPRIORITY=priority> <PARTPRIORITY=priority>;
```

The PERFORMANCE statement controls how an estimation or simulation task in PROC TMODEL uses multiple execution threads. You can specify two types of information in a PERFORMANCE statement: the
number of threads and the priority of calculations to which the threads are assigned. Calculations with a higher priority are allocated a greater number of threads, and calculations with a lower priority are allocated fewer threads. When a calculation is assigned a priority of zero, it is executed in one thread. When priority options are not specified, PROC TMODEL assigns default priority values based on properties of the model program and data.

Each PERFORMANCE statement is associated with the FIT or SOLVE statement that precedes it. When there is no preceding FIT or SOLVE statement, the PERFORMANCE statement is associated with the FIT or SOLVE statement that follows it.

The following options apply to both estimation and simulation tasks:

**BYPRIORITy=priority**

specifies the priority for allocating the computation threads to process BY groups concurrently in the input data set. The value of priority must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

**CPUCOUNT=n**

**NTHREADS=n**

specifies the approximate number of concurrent computation threads to use. By default, the global CPUCOUNT= option is used to specify the number of threads. The actual number of threads that are used might vary from the value that you specify in the CPUCOUNT= or NTHREADS= option based on the properties of the model program, the properties of the input data set, and the priority options specified in the PERFORMANCE statement.

**Options to Configure Estimation Threads**

**MSPRIORITY=priority**

**GRIDPRIORITY=priority**

specifies the priority for allocating computation threads for the concurrent execution of the optimizer during the estimation process. Concurrent execution of the optimizer is possible when the OPTIMIZER=ORMP(MULTISTART) option or the START= option is specified in the FIT statement. The value of priority must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

**PARTPRIORITY=priority**

specifies the priority for allocating computation threads for concurrent execution across partitions of the input data set. The value of priority must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

**Option to Configure Simulation Threads**

**REPPRIORITY=priority**

specifies the priority for allocating computation threads for the concurrent execution of repetitions of the input data set when you are performing Monte Carlo simulations. The value of priority must be between 0 and 1, where 0 specifies the lowest priority and 1 specifies the highest priority.

For more information about multithreading in PROC TMODEL, see the section “Multithreaded Calculations” on page 2844.
**RANDOM Statement**

```
RANDOM random-effects ~ distribution < options > ;
```

The RANDOM statement specifies which parameters in the model program are random effects and defines their distribution. The statement consists of a list of the random effects, a tilde (\~), and then the distribution of the random effects. The RANDOM statement must also be accompanied by a CROSSECTION statement, which specifies the subject variables. Only one RANDOM statement can be associated with each FIT statement.

The only distribution available for the random effects is normal\((m, \nu)\), with mean \(m\) and variance \(\nu\). This syntax is illustrated as follows for one effect:

```
random u ~ normal(0, s2u);
```

For multiple effects, you should specify bracketed vectors for \(m\) and \(\nu\), the latter consisting of the lower triangular elements of the random-effects variance matrix listed in row order. This is illustrated for two random effects as follows:

```
random b1 b2 ~ normal([0,0], [g11,g21,g22]);
```

Similarly, the syntax for three random effects is illustrated as follows:

```
random b1 b2 b3 ~ normal([0,0,0], [g11,g21,g22,g31,g32,g33]);
```

The variables that you specify in the CROSSECTION statement determine the unique realizations of the random effects. The observations for each value of the CROSSECTION variables must be grouped together in the input data set. PROC TMODEL processes the input data set sequentially and considers an observation to be from a new cross section whenever the values of the CROSSECTION variables change from the previous observation.

You can specify the following **options** in the RANDOM statement:

**EBEOSPT**

specifies that the empirical Bayes estimates of the random effects that are computed for each value of the CROSSECTION variables during the optimization process be computed by performing a nonlinear optimization. When you specify this option, the optimizer that you specify in the OPTIMIZER= option in the FIT statement is used to compute the empirical Bayes estimates. By default, a Newton search algorithm computes the empirical Bayes estimates.

**NOPSD**

specifies that the covariance matrix of random effects not be constrained to be positive semidefinite. This option might improve convergence properties for certain parameterizations of the random-effects covariance matrix.

**NUMQUADPTS=\(n\)**

specifies the number of quadrature points to use in the adaptive Gaussian quadrature approximation of the likelihood function. Each random effect is evaluated at \(n\) points during the approximation of the likelihood function, so if there are \(r\) random effects, the likelihood function is evaluated at \(n^r\) points. By default, NUMQUADPTS=1.
**PSD**

specifies that the covariance matrix of random effects be constrained to be positive semidefinite. PSD is the default.

---

**Details: TMODEL Procedure**

**Panel Data**

Panel data, also known as longitudinal data, consist of observations made over time for multiple subjects or cross sections. Data that are recorded in this form are often used to analyze dynamic models, which use past information to model the relationships among variables. In PROC TMODEL, you can analyze dynamic models that use panel data by identifying the cross-sectional variables in a CROSSSECTION statement. The following example illustrates how to use the CROSSSECTION statement to estimate an autoregressive model that has one parameter shared among five time series:

```sas
data d;
  length cs 8;
  array csname(5) $ _temporary_ ( 'first' 'second' 'third' 'fourth' 'fifth' );
  call streaminit (1);
  do pp = 1 to dim(csname);
    lagx = 0;
    do t = 1 to 10;
      x = 0.8*lagx + rand('normal');
      lagx = x;
      cs = csname[pp];
      output;
    end;
  end;
run;

proc tmodel data=d;
  endo x;
  crosssection cs;
  parms p;
  
  x = p*lag(x);
  fit;
quit;
```

In this example, PROC TMODEL skips the first observation in each time series because the first lag of $x$ is not available. Figure 40.2 shows that only 45 of the 50 observations contribute to the estimation, because the first observation in each series is skipped.
Figure 40.2 Observation Counts in a Dynamic Model Estimation

The TMODEL Procedure

<table>
<thead>
<tr>
<th>Number of Observations</th>
<th>Statistics for System</th>
</tr>
</thead>
<tbody>
<tr>
<td>Used 45</td>
<td>Objective 0.9694</td>
</tr>
<tr>
<td>Missing 0</td>
<td>Objective*N 43.623</td>
</tr>
</tbody>
</table>

Panel data are also treated differently from ordinary observational data for the purpose of multithreading. When no cross-sectional variables are specified, the observations in the DATA= data set are partitioned in a round-robin fashion among computational threads. Figure 40.3 shows how observations are partitioned among threads in the presence and absence of a cross-sectional variable specification.

Figure 40.3 Data Partitioning Strategies in a Multithreaded Environment

In the case where no cross sectional-variables are specified and a dynamic model with lag terms is being analyzed, all the observations are processed sequentially in a single thread.

Another use for panel data is in random-effects models, which model the variation among subjects in the data. In these models, the grouping of observations into subjects is achieved by specifying cross-sectional variables in the same manner as in the other panel data applications in PROC TMODEL.

Random-Effects Models

The general nonlinear model that is estimated by PROC MODEL and PROC TMODEL can be extended to accommodate observations on $M$ subjects as follows,

$$q(y_{it}, x_{it}, \phi, u_{it}) = \epsilon_{it}, \quad i = 1, \ldots, M \quad t = 1, \ldots, M_i$$
where $q \in R^g$ is a real-vector-valued function of $y_{it} \in R^g$, $x_{it} \in R^l$, $\phi \in R^p$, and $u_i \in R^r$, where $g$ is the number of equations, $l$ is the number of exogenous variables (lagged endogenous variables are considered exogenous here), $p$ is the number of fixed parameters, $r$ is the number of random effects, $M$ is the number of subjects, and $M_i$ is the number of observations on the $i$th subject. The random effects, $u_i$, that are associated with the $i$th subject are distributed as follows,

$$u_i \sim N(\mu, D)$$

$$\mu = \mu(\xi)$$

$$D = D(\xi)$$

where $\mu$ is an $r \times 1$ vector of means of the random effects, $D$ is an $r \times r$ covariance matrix of the random effects, and $\xi$ is a vector of parameters of the random-effects distribution.

The vector of unknown parameters for the random-effects models is $\theta = [\phi, \xi]$. PROC TMODEL performs a maximum likelihood estimation of $\theta$ and the covariance of $\theta$ by using the following marginal distribution of $y$ based on the joint distribution of $y$ and the random effects, $u_i$,

$$p(\theta) = \prod_{i=1}^{M} \int p(y_i | x_i, \phi, u_i) \, p(u_i | \xi) \, du_i$$

where $p(y_i | x_i, \phi, u_i)$ is the conditional distribution of $y$ for the $i$th subject and $p(u_i | \xi)$ is the conditional distribution of the random effects.

**Random-Effects Estimation**

Estimating the maximum likelihood values of $\theta$ requires computation of an integral over the random effects. PROC TMODEL approximates this integral by using the adaptive Gaussian quadrature method described in Pinheiro and Bates (1995).

PROC TMODEL minimizes the following negative log-likelihood function to estimate the parameters in random-effects models,

$$-\log p(\theta) \approx \sum_{i=1}^{M} \left( \frac{1}{2} \log |G_i| - \log \sum_{q=1}^{Q} e^{\text{obj}_{i,q}} \right) + \frac{M}{2} (\log |D| + r \log 2\pi)$$

where

$$\text{obj}_{i,q} = -\frac{1}{2} \sum_{j=1}^{M_i} q_j'(v_q)H^{-1}q_j(v_q) + z_q'z_q + \sum_{k=1}^{r} \log w_k - \frac{1}{2} v_q'D^{-1}v_q$$

$$H = \text{diag}(h_1, \ldots, h_g)$$

$$v_q = \hat{u}_i + \sqrt{2}G_i^{-1/2}z_q$$

$$G_i = -\nabla_{u_i} \text{obj}_i + D^{-1}$$

where $Q$ is the number of quadrature points used to approximate the integral, $M_i$ is the number of observations on the $i$th subject, $\text{obj}_i$ is the $i$th-subject-specific objective function evaluated at the empirical Bayes estimate of the random effects, $\text{obj}_{i,q}$ is the objective function evaluated at the $q$th quadrature point, $q_j$ is the vector of equation residuals, $h_i$ is the variance specified for the $i$th equation, $z_q$ is the $q$th quadrature point, $w_k$ is the weight for the $k$th element of the quadrature point vector, $v_q$ is the random-effects vector evaluated at the
Chapter 40: The TMODEL Procedure (Experimental)

$q$th quadrature point, $\mathbf{\hat{u}_i}$ is the empirical Bayes estimate of the random effects for the $i$th subject, $\mathbf{G}_i$ is the random-effects scale matrix for the $i$th subject, and $\nabla^2_{\mathbf{\hat{u}_i}} \text{obj}_i$ is the Hessian of the empirical Bayes estimate of the random effects for the $i$th subject. The gradient of the negative log-likelihood function is computed analytically, and the Hessian is computed numerically.

This approach is also used by PROC NLMIXED. For more information about the implementation of the adaptive Gaussian quadrature method, see Chapter 84, “The NLMIXED Procedure” (SAS/STAT User’s Guide).

The estimation of random-effects models in PROC TMODEL differs from that in PROC NLMIXED in the following ways:

- PROC TMODEL supports only the adaptive Gaussian quadrature method to compute the integral over random effects.
- PROC TMODEL does not compute the number of quadrature points adaptively.
- PROC TMODEL does not support models that contain variance parameters.
- PROC TMODEL constrains the covariance matrix of the random effects to be positive definite by imposing the nonlinear constraint $|\mathbf{D}| > 0$ in the optimization.
- PROC TMODEL does not support hierarchical random effects.
- PROC TMODEL supports models that have more than one endogenous variable.

Nonlinear Optimization

PROC TMODEL provides two numerical optimization systems, ZOPT and ORMP, to minimize the objective function associated with each of the available estimation methods. The ZOPT system is the same optimization system that PROC MODEL uses, and the nonlinear programming solver, ORMP, is the same optimization system that PROC OPTMODEL uses. The following sections summarize how both optimization systems address issues particular to the problem of estimating model parameters in PROC TMODEL.

Nonlinear Objective Function

The nonlinear dependence of model programs on parameters complicates the optimization process because it can cause the objective function to become a less predictable function of the parameters. The ZOPT optimizer provides the Gauss and Marquardt minimization methods to manage this nonlinear dependency during the numerical search for a minimum. The Gauss method implements a line search during the search process, and the Marquardt method improves the conditioning of the search for an optimum. The ORMP optimizer uses similar techniques to address nonlinearity and ill-conditioning of the minimization problem. In the ORMP optimizer, these techniques are implemented in a hybrid trust region and line-search algorithm.

Constraints on Parameters

Another difficulty occurs during the optimization process when constraints are placed on the parameters. In PROC TMODEL, linear and nonlinear constraints can be introduced through the use of the BOUNDS, RESTRICT, and TEST statements. The ZOPT optimizer handles constraints in the minimization by using an
active set algorithm to keep track of and enforce constraints. The ORMP optimizer provides two algorithms to handle constraints, an active set algorithm and an interior point algorithm. The active set algorithm manages constraints during the optimization, which is similar to the approach used by the ZOPT optimizer. The interior point algorithm imposes constraints by using barrier functions.

**Multiple Local Minima**

Occasionally, characteristics of the data or model program can cause there to be more than one local minimum in the minimization problem. In such cases the optimization process must choose the best minimum from among multiple local minima. In PROC TMODEL, you can specify a grid of initial parameter estimates by using the START= option in the FIT statement, and PROC TMODEL solves the minimization problem by using each point in the grid as an initial estimate. The grid point optimization that converges to the smallest minimum is then selected as the global minimum. Either the ZOPT system or the ORMP system can be used in the grid search approach to solving the global minimization problem.

The ORMP system also supports a multistart algorithm for finding the global minimum. The multistart algorithm chooses the best global minimum from among many local minima, as in the grid search approach; however, the multistart algorithm does not require you to specify the initial grid point estimates.

**Choosing an Optimizer**

For most problems, there is no need to choose between the ZOPT and ORMP optimizers, because they both converge quickly to the same optimum. However, in cases where the optimizers yield different results, the following general guidelines can help you choose which optimizer to use for a particular problem.

Some considerations for choosing the ZOPT optimizer follow:

- compatibility with PROC MODEL estimation results, because the ZOPT system is also used in PROC MODEL
- faster solutions for smaller problems and for problems that are subject to neither extreme nonlinearities nor ill-conditioning

Some considerations for choosing the ORMP optimizer follow:

- more robust convergence properties for larger problems
- faster and more reliable convergence when there are many constraints on the parameters
- improved estimates in the presence of multiple local minima, or when there is insufficient information to choose initial grid point estimates

**Hessian Evaluation**

PROC MODEL uses a linear approximation to the Hessian for all estimation methods by default. In most cases, this linear approximation to the Hessian matrix is sufficient to ensure convergence of the optimization. However, for some combinations of models, data, estimation methods, and optimization methods, the estimates that PROC MODEL produces are sensitive to the linear approximation error in the Hessian. To
correct for this shortcoming, PROC TMODEL computes an exact analytical representation of the Hessian for many of the estimation methods by default. The exact Hessian that PROC TMODEL uses also improves convergence properties of the ORMP optimizer for some problems. Table 40.2 summarizes estimation methods and exact analytical representations of the Hessian that are available in PROC TMODEL.

</table>

The variables in this table are defined as follows:

- $n$: the number of nonmissing observations
- $g$: the number of equations
- $k$: the number of instrumental variables
- $p$: the number of parameters
- $r$: the $ng \times 1$ vector of residuals for the $g$ equations stacked together
- $S$: a $g \times g$ matrix that estimates $\Sigma$, the covariances of the errors across equations (referred to as the $S$ matrix)
- $I$: an $n \times n$ identity matrix
- $X$: an $ng \times p$ matrix of partial derivatives of the residuals with respect to the parameters
- $Q$: an $ng \times p \times p$ vector of matrices of second-order partial derivatives of the residuals with respect to the parameters
- $W$: an $n \times n$ matrix, $Z(Z'Z)^{-1}Z'$
- $Z$: an $n \times k$ matrix of instruments

The exact analytic Hessians are not currently available for the FIML or GMM estimation methods or for models with random effects.

### Multithreaded Calculations

PROC TMODEL uses concurrent computation threads to reduce the time it takes to perform estimation and simulation tasks. Because the characteristics of the input data, model program, and task can vary, PROC TMODEL uses different strategies for breaking its calculations into pieces that can be executed concurrently. For example, when you are estimating a simple model by using a data set with many observations, the
most efficient multithreading strategy is to partition the observations and to evaluate the objective function concurrently across the partitions. However, for a highly nonlinear estimation problem with many parameters and fewer observations, the best strategy might be to execute the minimization problem concurrently for multiple regions of the parameter space and then choose the region that yields the optimal estimates.

PROC TMODEL automatically determines which threading strategy to use for each estimation or simulation modeling task by default. Alternatively, you can specify the threading strategy manually by specifying priority options in the PERFORMANCE statement. For each modeling task, the threading strategy is determined by the number of threads allocated to each job in the task. A job is an aspect or dimension of the task that can be executed concurrently with another job. The total number of threads that are used to complete each modeling task is determined as follows,

$$n^* = \prod_{i \in J} \text{ceil}(n \frac{p_i}{p_{\text{tot}}})$$  \quad \text{for} \quad p_{\text{tot}} = \sum_{k \in J} p_k$$

where $n^*$ is the actual number of threads used, $n$ is the number of threads specified, $p_i = \max(\text{priority}_i, 10^{-8})$, priority$_i \in [0, 1]$ is the priority specified for the $i$th job, and $J$ is the set of all jobs in the modeling task. The allocation of threads to jobs in modeling tasks creates the same number or more threads than the number specified in the PERFORMANCE statement and CPUCOUNT= system option.

**Multithreading Estimation Calculations**

The following jobs in estimation tasks can be executed currently:

- BY-group processing
- grid search for optimal parameters specified using the START= option in the FIT statement, or multistart global optimization specified by the MULTISTART suboption of the OPTIMIZER= option in the FIT statement
- evaluation of the objective function across partitions of the DATA= data set

For model programs that use lagging functions, the observations in the DATA= data set must be processed sequentially to compute the objective function. In these cases, multithreading across partitions of the data is not possible unless you specify a CROSSSECTION statement or a RANDOM statement. The priority of each estimation job can be specified in the PERFORMANCE statement. When no priorities are specified, PROC TMODEL assigns jobs priorities based on the number of BY groups in the input data set, the number of observations in the input data set, the presence of a START= or MULTISTART option in the FIT statement, and the lag length of the model program.

**Multithreading Simulation Calculations**

The following jobs in simulation tasks can be executed concurrently:

- BY-group processing
- processing repetitions in Monte Carlo simulations that are specified using the RANDOM= option in the SOLVE statement

The priority of each simulation job can be specified in the PERFORMANCE statement. When no priorities are specified, PROC TMODEL assigns jobs priorities based on the number of BY groups in the input data set, the presence of a RANDOM= option, and the lag length of the model program.
Examples: TMODEL Procedure

Example 40.1: Thread Allocation Using the Performance Statement

This example illustrates how you can use the PERFORMANCE statement to improve the performance of parameter estimation for a data set that contains multiple BY groups. For clarity, a small data set and a simple model are used. In practice, the benefits of configuring the thread allocation strategy are realized only for larger data sets and more computationally demanding models.

In the following PROC TMODEL step, a linear model is estimated for 20 BY groups, each of which contains 1,001 observations:

```sas
data d;
  call streaminit(1);
  do iby = 1 to 2;
    do jby = 1 to 10;
      do x = -500 to 500;
        y = 2*x + 1 + rand('normal');
        output;
      end;
    end;
  end;
run;

proc tmodel data=d;
  performance nthreads=4 bypriority=1 partpriority=1 / threadconfig timings;
  y = a*x + b;
  by iby jby;
  fit y;
quit;
```

In this example, PROC TMODEL performs the estimations in two concurrent threads, where each thread performs the estimation for 10 BY groups. Also, within the estimation of each BY group, the 1,001 observations are processed concurrently in two partitions, one with 501 observations and the other with 500 observations. Figure 40.1.1 shows how PROC TMODEL divides this estimation problem into threads and the time it takes to complete all 20 estimations.

**Output 40.1.1** Multithreading Performance for Two BY-Group Threads

<table>
<thead>
<tr>
<th>The TMODEL Procedure</th>
</tr>
</thead>
<tbody>
<tr>
<td>Multithreading Configuration</td>
</tr>
<tr>
<td>Calculation Type</td>
</tr>
<tr>
<td></td>
</tr>
<tr>
<td></td>
</tr>
</tbody>
</table>
Another way to perform these estimation tasks is to divide the 20 BY groups into four concurrent threads, where the estimation of each BY group is performed on a single partition that contains all 1,001 observations. You can do this by setting the PARTPRIORITY= option to 0 in the following PERFORMANCE statement:

```
proc tmodel data=d;
   performance nthreads=4 bypriority=1 partpriority=0 / threadconfig timings;
   y = a*x + b;
   by iby jby;
   fit y;
quit;
```

Figure 40.1.2 shows that maximizing the number of BY-group threads improves the performance of this model and data set.

**Example 40.2: Random-Effects Parameter Estimation**

This example models the circumference of five orange trees over 1,600 days by using a logistic curve to represent the growth of each tree over time in conjunction with a random-effects parameter that accounts for variation among the trees. The tree data for this example come from Draper and Smith (1981) and are displayed in Output 40.2.1.
Lindstrom and Bates (1990) and Pinheiro and Bates (1995) propose the following logistic nonlinear mixed model for these data:

\[
y_{ij} = \frac{b_1 + u_{i1}}{1 + \exp\left[-(d_{ij} - b_2)/b_3\right]} + e_{ij}
\]

Here, \(y_{ij}\) represents the \(j\)th circumference measurement on the \(i\)th tree \((i = 1, \ldots, 5; j = 1, \ldots, 7)\); \(d_{ij}\) is the corresponding day; \(b_1, b_2,\) and \(b_3\) are the fixed-effects parameters; \(u_{i1}\) are the random-effect parameters assumed to be iid \(N(0, \sigma_u^2)\); and \(e_{ij}\) are the residual errors assumed to be iid \(N(0, \sigma_e^2)\) and independent of the \(u_{i1}\). The random-effect parameters \(u_{i1}\) enter the model linearly.

The following PROC TMODEL step estimates the fixed-effects and random-effect parameters in this model:

```sas
proc tmodel data=tree;
  parms b1 200
         b2 800
         b3 800
         s2u;
  num = b1 + u1;
  ex  = exp(-(day-b2)/b3);
```
The four SAS programming statements in this PROC TMODEL step specify the logistic model for tree growth. The variable \( u_1 \) identifies the random effect in this model.

The CROSSECTION statement defines a variable that indicates when new realizations of the random effect are encountered in the DATA= data set; in this case the variable \( \text{tree} \) is used.

The RANDOM statement defines the single random effect to be \( u_1 \) and specifies that it follow a normal distribution with mean 0 and variance \( s^2_u \). For models that have a nonlinear dependence on the random-effects variables, you can use the NUMQUADPTS= option to specify the number of Gaussian quadrature points to use in the approximation of the likelihood function. In this example, the model has a linear dependence on \( u_1 \), so the default (NUMQUADPTS=1) is used.

For this example, as with many nonlinear random-effects models, the parameter optimization is sensitive to the selection of initial estimates. Therefore, in the PARMS statement, the values for the fixed-effects parameters are initialized with values based on a cursory examination of Output 40.2.1 to assure convergence. The parameter \( b_1 \) represents an asymptotic limit for the circumference of an average tree. The parameters \( b_2 \) and \( b_3 \) are characteristic of the growth period for the orange trees.

Figure 40.2.2 shows the estimates for the fixed-effects and random-effect parameters together with their standard errors and approximate \( t \)-values.

**Output 40.2.2** Fixed-Effects and Random-Effect Parameters for the Orange Tree Model

| Parameter | Estimate | Approx Std Err | Approx t Value | Approx Pr > |t| |
|-----------|----------|----------------|----------------|-------------|---------|
| \( b_1 \)  | 192.0409  | 13.6456        | 14.07          | <.0001      |
| \( b_2 \)  | 727.8899  | 4.4899         | 162.12         | <.0001      |
| \( b_3 \)  | 347.9685  | 3.4501         | 100.86         | <.0001      |
| \( s^2_u \) | 1016.531  | 535.2          | 1.90           | 0.0669      |

Chapter 41
The TSCSREG Procedure

Overview: The TSCSREG Procedure

The TSCSREG (time series cross section regression) procedure analyzes a class of linear econometric models that commonly arise when time series and cross-sectional data are combined. The TSCSREG procedure deals with panel data sets that consist of time series observations on each of several cross-sectional units.

The TSCSREG procedure is very similar to the PANEL procedure; for a full description, syntax details, models, and estimation methods, see Chapter 26, “The PANEL Procedure.” The TSCSREG procedure is no longer being updated, and it shares the code base with the PANEL procedure.

The original TSCSREG procedure was developed by Douglas J. Drummond and A. Ronald Gallant, and contributed to the Version 5 SUGI Supplemental Library in 1979. The original code was changed substantially over the years. Additional new methods as well as other new features are currently included in the PANEL PROCEDURE. SAS Institute would like to thank Dr. Drummond and Dr. Gallant for their contribution of the original version of the TSCSREG procedure.
Getting Started: The TSCSREG Procedure

Specifying the Input Data

The input data set used by the TSCSREG procedure must be sorted by cross section and by time within each cross section. Therefore, the first step in using PROC TSCSREG is to make sure that the input data set is sorted. Normally, the input data set contains a variable that identifies the cross section for each observation and a variable that identifies the time period for each observation.

To illustrate, suppose that you have a data set A that contains data over time for each of several states. You want to regress the variable Y on regressors X1 and X2. Cross sections are identified by the variable STATE, and time periods are identified by the variable DATE. The following statements sort the data set A appropriately:

```plaintext
proc sort data=a;
    by state date;
run;
```

The next step is to invoke the TSCSREG procedure and specify the cross section and time series variables in an ID statement. List the variables in the ID statement exactly as they are listed in the BY statement.

```plaintext
proc tscsreg data=a;
    id state date;
```

Alternatively, you can omit the ID statement and use the CS= and TS= options in the PROC TSCSREG statement to specify the number of cross sections in the data set and the number of time series observations in each cross section.

Unbalanced Data

In the case of fixed-effects and random-effects models, the TSCSREG procedure is capable of processing data with different numbers of time series observations across different cross sections. You must specify the ID statement to estimate models that use unbalanced data. The missing time series observations are recognized by the absence of time series ID variable values in some of the cross sections in the input data set. Moreover, if an observation with a particular time series ID value and cross-sectional ID value is present in the input data set, but one or more of the model variables are missing, that time series point is treated as missing for that cross section.
Specifying the Regression Model

Next, specify the linear regression model with a MODEL statement, as shown in the following statements:

```sas
proc tscsreg data=a;
   id state date;
   model y = x1 x2;
run;
```

The MODEL statement in PROC TSCSREG is specified like the MODEL statement in other SAS regression procedures: the dependent variable is listed first, followed by an equal sign, followed by the list of regressor variables.

The reason for using PROC TSCSREG instead of other SAS regression procedures is that you can incorporate a model for the structure of the random errors. It is important to consider what kind of error structure model is appropriate for your data and to specify the corresponding option in the MODEL statement.

The error structure options supported by the TSCSREG procedure are FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA. For more information about these methods and the error structures they assume, see the section “Details: The TSCSREG Procedure” on page 2861.

By default, the two-way random-effects error model structure is used while Fuller-Battese and Wansbeek-Kapteyn methods are used for the estimation of variance components in balanced data and unbalanced data, respectively. Thus, the preceding example is the same as specifying the RANTWO option, as shown in the following statements:

```sas
proc tscsreg data=a;
   id state date;
   model y = x1 x2 / rantwo;
run;
```

You can specify more than one error structure option in the MODEL statement; the analysis is repeated using each method specified. You can use any number of MODEL statements to estimate different regression models or estimate the same model by using different options.

In order to aid in model specification within this class of models, the procedure provides two specification test statistics. The first is an $F$ statistic that tests the null hypothesis that the fixed-effects parameters are all zero. The second is a Hausman $m$-statistic that provides information about the appropriateness of the random-effects specification. It is based on the idea that, under the null hypothesis of no correlation between the effects variables and the regressors, OLS and GLS are consistent, but OLS is inefficient. Hence, a test can be based on the result that the covariance of an efficient estimator with its difference from an inefficient estimator is zero. Rejection of the null hypothesis might suggest that the fixed-effects model is more appropriate.

The procedure also provides the Buse R-square measure, which is the most appropriate goodness-of-fit measure for models estimated by using GLS. This number is interpreted as a measure of the proportion of the transformed sum of squares of the dependent variable that is attributable to the influence of the independent variables. In the case of OLS estimation, the Buse R-square measure is equivalent to the usual R-square measure.
**Estimation Techniques**

If the effects are fixed, the models are essentially regression models with dummy variables that correspond to the specified effects. For fixed-effects models, ordinary least squares (OLS) estimation is equivalent to best linear unbiased estimation.

The output from PROC TSCSREG is identical to what one would obtain from creating dummy variables to represent the cross-sectional and time (fixed) effects. The output is presented in this manner to facilitate comparisons to the least squares dummy variables estimator (LSDV). As such, the inclusion of an intercept term implies that one dummy variable must be dropped. The actual estimation of the fixed-effects models is not LSDV. LSDV is much too cumbersome to implement. Instead, PROC TSCSREG operates in a two-step fashion. In the first step, the following occurs:

- **One-way fixed-effects model**: In the one-way fixed-effects model, the data are transformed by removing the cross-sectional means from the dependent and independent variables. The following is true:
  \[
  \tilde{y}_{it} = y_{it} - \bar{y}_i,
  \]
  \[
  \tilde{x}_{it} = x_{it} - \bar{x}_i.
  \]

- **Two-way fixed-effects model**: In the two-way fixed-effects model, the data are transformed by removing the cross-sectional and time means and adding back the overall means,
  \[
  \tilde{y}_{it} = y_{it} - \bar{y}_i - \bar{y}_t + \bar{y},
  \]
  \[
  \tilde{x}_{it} = x_{it} - \bar{x}_i - \bar{x}_t + \bar{x}.
  \]

where \(y_{it}\) and \(x_{it}\) are the dependent variable (a scalar) and the explanatory variables (a vector whose columns are the explanatory variables, not including a constant), respectively; \(\bar{y}_i\), and \(\bar{x}_i\) are cross section means; \(\bar{y}_t\) and \(\bar{x}_t\) are time means; and \(\bar{y}\) and \(\bar{x}\) are the overall means.

The second step consists of running OLS on the properly demeaned series, provided that the data are balanced. The unbalanced case is slightly more difficult, because the structure of the missing data must be retained. For this case, PROC TSCSREG uses a slight specialization on Wansbeek and Kapteyn.

The other alternative is to assume that the effects are random. In the one-way case, \(E(v_i) = 0\), \(E(v_i^2) = \sigma_v^2\), and \(E(v_i v_j) = 0\) for \(i \neq j\), and \(v_i\) is uncorrelated with \(\epsilon_{it}\) for all \(i\) and \(t\). In the two-way case, in addition to all of the preceding, \(E(e_t) = 0\), \(E(e_t^2) = \sigma_e^2\), and \(E(e_t e_s) = 0\) for \(t \neq s\), and the \(e_t\) are uncorrelated with the \(v_i\) and the \(\epsilon_{it}\) for all \(i\) and \(t\). Thus, the model is a variance components model, with the variance components \(\sigma_v^2\), \(\sigma_e^2\), and \(\sigma_e^2\), to be estimated. A crucial implication of such a specification is that the effects are independent of the regressors. For random-effects models, the estimation method is an estimated generalized least squares (EGLS) procedure that involves estimating the variance components in the first stage and using the estimated variance covariance matrix thus obtained to apply generalized least squares (GLS) to the data.
Introductory Example

This example uses the cost function data from Greene (1990) to estimate the variance components model. The variable OUTPUT is the log of output in millions of kilowatt-hours, and the variable COST is the log of cost in millions of dollars. For more information, see Greene (1990).

```plaintext
title1;
data greene;
  input firm year output cost @@;
  df1 = firm = 1;
  df2 = firm = 2;
  df3 = firm = 3;
  df4 = firm = 4;
  df5 = firm = 5;
  d60 = year = 1960;
  d65 = year = 1965;
  d70 = year = 1970;
datalines;
1 1955 5.36598 1.14867 1 1960 6.03787 1.45185
... more lines ...
```

Usually you cannot explicitly specify all the explanatory variables that affect the dependent variable. The omitted or unobservable variables are summarized in the error disturbances. The TSCSREG procedure used with the RANTWO option specifies the two-way random-effects error model where the variance components are estimated by the Fuller-Battese method, because the data are balanced and the parameters are efficiently estimated by using the GLS method. The variance components model used by the Fuller-Battese method is

$$y_{it} = \sum_{k=1}^{K} X_{itk} \beta_k + v_i + \epsilon_t + \epsilon_{it} \quad i = 1, \ldots, N, \quad t = 1, \ldots, T$$

The following statements fit this model:

```plaintext
proc sort data=greene;
  by firm year;
run;

proc tscsreg data=greene;
  model cost = output / rantwo;
  id firm year;
run;
```

The TSCSREG procedure output is shown in Figure 41.1. A model description is printed first; it reports the estimation method used and the number of cross sections and time periods. The variance components estimates are printed next. Finally, the table of regression parameter estimates shows the estimates, standard errors, and $t$ tests.

### Syntax: The TSCSREG Procedure

The following statements are used with the TSCSREG procedure:

```
PROC TSCSREG options ;
    BY variables ;
    ID cross-section-id-variable time-series-id-variable ;
    MODEL dependent = regressor-variables / options ;
    TEST equation1 < , equation2 . . . > ;
```
Functional Summary

The statements and options used with the TSCSREG procedure are summarized in Table 41.1.

**PROC TSCSREG Statement**

```
PROC TSCSREG options ;
```

The following options can be specified in the PROC TSCSREG statement:

- **DATA=SAS-data-set**
  names the input data set. The input data set must be sorted by cross section and by time period within cross section. If you omit the DATA= option, the most recently created SAS data set is used.

- **TS=number**
  specifies the number of observations in the time series for each cross section. The TS= option value must be greater than 1. The TS= option is required unless an ID statement is used. Note that the number of observations for each time series must be the same for each cross section and must cover the same time period.

- **CS=number**
  specifies the number of cross sections. The CS= option value must be greater than 1. The CS= option is required unless an ID statement is used.

- **OUTEST=SAS-data-set**
  writes the parameter estimates. When the OUTEST= option is not specified, the OUTEST= data set is not created.

- **OUTCOV**
  writes the covariance matrix of the parameter estimates to the OUTEST= data set.

- **OUTCORR**
  writes the correlation matrix of the parameter estimates to the OUTEST= data set.

In addition, any of the following MODEL statement options can be specified in the PROC TSCSREG statement: CORRB, COVB, FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, DASILVA, NOINT, NOPRINT, M=, PHI, RHO, and SINGULAR=. When specified in the PROC TSCSREG statement, these options are equivalent to specifying the options for every MODEL statement.

**BY Statement**

```
BY variables ;
```

A BY statement can be used with PROC TSCSREG to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the input data set must be sorted by the BY variables as well as by cross section and time period within the BY groups.

When both an ID statement and a BY statement are specified, the input data set must be sorted first with respect to BY variables and then with respect to the cross section and time series ID variables. For example:
When both a BY statement and an ID statement are used, the data set might have a different number of cross sections or a different number of time periods in each BY group. If no ID statement is used, the CS=N and TS=T options must be specified and each BY group must contain $N \times T$ observations.

**ID Statement**

```plaintext
ID cross-section-id-variable time-series-id-variable ;
```

The ID statement is used to specify variables in the input data set that identify the cross section and time period for each observation.

When an ID statement is used, the TSCSREG procedure verifies that the input data set is sorted by the cross section ID variable and by the time series ID variable within each cross section. The TSCSREG procedure also verifies that the time series ID values are the same for all cross sections.

To make sure the input data set is correctly sorted, use PROC SORT with a BY statement with the variables listed exactly as they are listed in the ID statement to sort the input data set. For example:

```plaintext
proc sort data=a;
   by csid tsid;
run;

proc tscsreg data=a;
   by csid tsid;
   id csid tsid;
   ... etc. ...;
run;
```

If the ID statement is not used, the TS= and CS= options must be specified in the PROC TSCSREG statement. Note that the input data must be sorted by time within cross section, regardless of whether the cross section structure is given by an ID statement or by the options TS= and CS=.

If an ID statement is specified, the time series length $T$ is set to the minimum number of observations for any cross section, and only the first $T$ observations in each cross section are used. If both the ID statement and the TS= and CS= options are specified, the TS= and CS= options are ignored.

**MODEL Statement**

```plaintext
MODEL response = regressors / options ;
```

The MODEL statement specifies the regression model and the error structure assumed for the regression residuals. The response variable on the left side of the equal sign is regressed on the independent variables...
listed after the equal sign. Any number of MODEL statements can be used. For each model statement, only one response variable can be specified on the left side of the equal sign.

The error structure is specified by the FIXONE, FIXTWO, RANONE, RANTWO, FULLER, PARKS, and DASILVA options. More than one of these options can be used, in which case the analysis is repeated for each error structure model specified.

Models can be given labels up to 32 characters in length. Model labels are used in the printed output to identify the results for different models. If no label is specified, the response variable name is used as the label for the model. The model label is specified as follows:

\[
\text{label: MODEL response = regressors / options ;}
\]

The following options can be specified in the MODEL statement after a slash (/):

**CORRB**
prints the matrix of estimated correlations between the parameter estimates.

**COVB**
prints the matrix of estimated covariances between the parameter estimates.

**FIXONE**
specifies that a one-way fixed-effects model be estimated with the one-way model that corresponds to group effects only.

**FIXTWO**
specifies that a two-way fixed-effects model be estimated.

**RANONE**
specifies that a one-way random-effects model be estimated.

**RANTWO**
specifies that a two-way random-effects model be estimated.

**FULLER**
specifies that the model be estimated by using the Fuller-Battese method, which assumes a variance components model for the error structure.

**PARKS**
specifies that the model be estimated by using the Parks method, which assumes a first-order autoregressive model for the error structure.

**DASILVA**
specifies that the model be estimated by using the Da Silva method, which assumes a mixed variance-component moving-average model for the error structure.

**M=**number
specifies the order of the moving-average process in the Da Silva method. The M= value must be less than \( T - 1 \). The default is \( M=1 \).
PHI
prints the $\Phi$ matrix of estimated covariances of the observations for the Parks method. The PHI option is relevant only when the PARKS option is used.

RHO
prints the estimated autocorrelation coefficients for the Parks method.

NOINT
NOMEAN
suppresses the intercept parameter from the model.

NOPRINT
suppresses the normal printed output.

SINGULAR=number
specifies a singularity criterion for the inversion of the matrix. The default depends on the precision of the computer system.

**TEST Statement**

```
TEST equation < , equation . . . > < / options > ;
```

The TEST statement performs $F$ tests of linear hypotheses about the regression parameters in the preceding MODEL statement. Each equation specifies a linear hypothesis to be tested. All hypotheses in one TEST statement are tested jointly. Variable names in the equations must correspond to regressors in the preceding MODEL statement, and each name represents the coefficient of the corresponding regressor. The keyword INTERCEPT refers to the coefficient of the intercept.

The following statements illustrate the use of the TEST statement:

```
proc tscsreg;
   model y = x1 x2 x3;
   test x1 = 0, x2 * .5 + 2 * x3 = 0;
   test_int: test intercept=0, x3 = 0;
```

Note that a test of the following form is not permitted:

```
test_bad: test x2 / 2 + 2 * x3 = 0;
```

Do not use the division sign in the TEST statement.

**Details: The TSCSREG Procedure**

Models, estimators, and methods are covered in detail in Chapter 26, “The PANEL Procedure.”
The TSCSREG Procedure

ODS Table Names

PROC TSCSREG assigns a name to each table it creates. You can use these names to reference the table when you use the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 41.2.

Overview: UCM Procedure

The UCM procedure analyzes and forecasts equally spaced univariate time series data by using an unobserved components model (UCM). The UCMs are also called structural models in the time series literature. A UCM decomposes the response series into components such as trend, seasonals, cycles, and the regression effects due to predictor series. The components in the model are supposed to capture the salient features of the series that are useful in explaining and predicting its behavior. Harvey (1989) and Pelagatti (2015) are good references for time series modeling that use the UCMs. Harvey calls the components in a UCM the “stylized facts” about the series under consideration. Traditionally, the ARIMA models and, to some limited extent, the exponential smoothing models have been the main tools in the analysis of this type of time series data. It is fair to say that the UCMs capture the versatility of the ARIMA models while possessing the interpretability of the smoothing models. A thorough discussion of the correspondence between the ARIMA models and the UCMs, and the relative merits of UCM and ARIMA modeling, is given in Harvey (1989). The UCMs are also very similar to another set of models, called the dynamic models, that are popular in the Bayesian time series literature (West and Harrison 1999). In SAS/ETS, you can use PROC SSM for multivariate (and more general univariate) UCMs (see Chapter 34, “The SSM Procedure”), PROC ARIMA for ARIMA modeling (see Chapter 7, “The ARIMA Procedure”), PROC ESM for exponential smoothing modeling (see Chapter 14, “The ESM Procedure”), and the Time Series Forecasting System for a point-and-click interface to ARIMA and exponential smoothing modeling.

You can use the UCM procedure to fit a wide range of UCMs that can incorporate complex trend, seasonal, and cyclical patterns and can include multiple predictors. It provides a variety of diagnostic tools to assess the fitted model and to suggest the possible extensions or modifications. The components in the UCM provide a succinct description of the underlying mechanism governing the series. You can print, save, or plot the estimates of these component series. Along with the standard forecast and residual plots, the study of these component plots is an essential part of time series analysis using the UCMs. Once a suitable UCM is found for the series under consideration, it can be used for a variety of purposes. For example, it can be used for the following:
• forecasting the values of the response series and the component series in the model
• obtaining a model-based seasonal decomposition of the series
• obtaining a “denoised” version and interpolating the missing values of the response series in the historical period
• obtaining the full sample or “smoothed” estimates of the component series in the model

Getting Started: UCM Procedure

The analysis of time series using the UCMs involves recognizing the salient features present in the series and modeling them suitably. The UCM procedure provides a variety of models for estimating and forecasting the commonly observed features in time series. These models are discussed in detail later in the section “An Introduction to Unobserved Component Models” on page 2902. First the procedure is illustrated using an example.

A Seasonal Series with Linear Trend

The airline passenger series, given as Series G in Box and Jenkins (1976), is often used in time series literature as an example of a nonstationary seasonal time series. This series is a monthly series consisting of the number of airline passengers who traveled during the years 1949 to 1960. Its main features are a steady rise in the number of passengers from year to year and the seasonal variation in the numbers during any given year. It also exhibits an increase in variability around the trend. A log transformation is used to stabilize this variability. The following DATA step prepares the log-transformed passenger series analyzed in this example:

```sas
data seriesG;
  set sashelp.air;
  logair = log( air );
run;
```

The following statements produce a time series plot of the series by using the TIMESERIES procedure (see Chapter 39, “The TIMESERIES Procedure”). The trend and seasonal features of the series are apparent in the plot in Figure 42.1.

```sas
proc timeseries data=seriesG plot=series;
  id date interval=month;
  var logair;
run;
```
In this example this series is modeled using an unobserved component model called the basic structural model (BSM). The BSM models a time series as a sum of three stochastic components: a trend component $\mu_t$, a seasonal component $\gamma_t$, and random error $\epsilon_t$. Formally, a BSM for a response series $y_t$ can be described as

$$y_t = \mu_t + \gamma_t + \epsilon_t$$

Each of the stochastic components in the model is modeled separately. The random error $\epsilon_t$, also called the irregular component, is modeled simply as a sequence of independent, identically distributed (iid) zero-mean Gaussian random variables. The trend and the seasonal components can be modeled in a few different ways. The model for trend used here is called a locally linear time trend. This trend model can be written as follows:

$$\begin{align*}
\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, & \eta_t &\sim \text{iid } N(0, \sigma_\eta^2) \\
\beta_t &= \beta_{t-1} + \xi_t, & \xi_t &\sim \text{iid } N(0, \sigma_\xi^2)
\end{align*}$$
These equations specify a trend where the level $\mu_t$ as well as the slope $\beta_t$ is allowed to vary over time. This variation in slope and level is governed by the variances of the disturbance terms $\eta_t$ and $\xi_t$ in their respective equations. Some interesting special cases of this model arise when you manipulate these disturbance variances. For example, if the variance of $\xi_t$ is zero, the slope will be constant (equal to $\beta_0$); if the variance of $\eta_t$ is also zero, $\mu_t$ will be a deterministic trend given by the line $\mu_0 + \beta_0 t$. The seasonal model used in this example is called a trigonometric seasonal. The stochastic equations governing a trigonometric seasonal are explained later (see the section “Modeling Seasons” on page 2904). However, it is interesting to note here that this seasonal model reduces to the familiar regression with deterministic seasonal dummies if the variance of the disturbance terms in its equations is equal to zero. The following statements specify a BSM with these three components:

```plaintext
proc ucm data=seriesG;
    id date interval=month;
    model logair;
        irregular;
        level;
        slope;
        season length=12 type=trig print=smooth;
        estimate;
        forecast lead=24 print=decomp;
run;
```

The PROC UCM statement signifies the start of the UCM procedure, and the input data set, seriesG, containing the dependent series is specified there. The optional ID statement is used to specify a date, datetime, or time identification variable, date in this example, to label the observations. The INTERVAL=MONTH option in the ID statement indicates that the measurements were collected on a monthly basis. The model specification begins with the MODEL statement, where the response series is specified (logair in this case). After this the components in the model are specified using separate statements that enable you to control their individual properties. The irregular component $\epsilon_t$ is specified using the IRREGULAR statement and the trend component $\mu_t$ is specified using the LEVEL and SLOPE statements. The seasonal component $\gamma_t$ is specified using the SEASON statement. The specifics of the seasonal characteristics such as the season length, its stochastic evolution properties, etc., are specified using the options in the SEASON statement. The seasonal component used in this example has a season length of 12, corresponding to the monthly seasonality, and is of the trigonometric type. Different types of seasonals are explained later (see the section “Modeling Seasons” on page 2904).

The parameters of this model are the variances of the disturbance terms in the evolution equations of $\mu_t$, $\beta_t$, and $\gamma_t$ and the variance of the irregular component $\epsilon_t$. These parameters are estimated by maximizing the likelihood of the data. The ESTIMATE statement options can be used to specify the span of data used in parameter estimation and to display and save the results of the estimation step and the model diagnostics. You can use the estimated model to obtain the forecasts of the series as well as the components. The options in the individual component statements can be used to display the component forecasts—for example, PRINT=SMOOTH option in the SEASON statement requests the displaying of smoothed forecasts of the seasonal component $\gamma_t$. The series forecasts and forecasts of the sum of components can be requested using the FORECAST statement. The option PRINT=DECOMP in the FORECAST statement requests the printing of the smoothed trend $\mu_t$ and the trend plus seasonal component ($\mu_t + \gamma_t$).

The parameter estimates for this model are displayed in Figure 42.2.
The estimates suggest that except for the slope component, the disturbance variances of all the components are significant—that is, all these components are stochastic. The slope component, however, appears to be deterministic because its error variance is quite insignificant. It might then be useful to check if the slope component can be dropped from the model—that is, if $\beta_0 = 0$. This can be checked by examining the significance analysis table of the components given in Figure 42.3.

**Figure 42.3** Component Significance Analysis for the Logair Series

</tr>
</tbody>
</table>

This table provides the significance of the components in the model at the end of the estimation span. If a component is deterministic, this analysis is equivalent to checking whether the corresponding regression effect is significant. However, if a component is stochastic, then this analysis pertains only to the portion of the series near the end of the estimation span. In this example the slope appears quite significant and should be retained in the model, possibly as a deterministic component. Note that, on the basis of this table, the irregular component’s contribution appears insignificant toward the end of the estimation span; however, since it is a stochastic component, it cannot be dropped from the model on the basis of this analysis alone. The slope component can be made deterministic by holding the value of its error variance fixed at zero. This is done by modifying the SLOPE statement as follows:

```
slope variance=0 noest;
```
After a tentative model is fit, its adequacy can be checked by examining different goodness-of-fit measures and other diagnostic tests and plots that are based on the model residuals. Once the model appears satisfactory, it can be used for forecasting. An interesting feature of the UCM procedure is that, apart from the series forecasts, you can request the forecasts of the individual components in the model. The plots of component forecasts can be useful in understanding their contributions to the series. The following statements illustrate some of these features:

```sas
proc ucm data=seriesG;
  id date interval = month;
  model logair;
  irregular;
  level plot=smooth;
  slope variance=0 noest;
  season length=12 type=trig
    plot=smooth;
  estimate;
  forecast lead=24 plot=decomp;
run;
```

The table given in Figure 42.4 shows the goodness-of-fit statistics that are computed by using the one-step-ahead prediction errors (see the section “Statistics of Fit” on page 2940). These measures indicate a good agreement between the model and the data. Additional diagnostic measures are also printed by default but are not shown here.

![Figure 42.4 Fit Statistics for the Logair Series](image)

The first plot, shown in Figure 42.5, is produced by the PLOT=SMOOTH option in the LEVEL statement, it shows the smoothed level of the series.
The second plot (Figure 42.6), produced by the PLOT=SMOOTH option in the SEASON statement, shows the smoothed seasonal component by itself.
The plot of the sum of the trend and seasonal component, produced by the PLOT=DECOMP option in the FORECAST statement, is shown in Figure 42.7. You can see that, at least visually, the model seems to fit the data well. In all these decomposition plots the component estimates are extrapolated for two years in the future based on the LEAD=24 option specified in the FORECAST statement.
Figure 42.7 Smoothed Trend plus Seasonal in the Logair Series
Syntax: UCM Procedure

The UCM procedure uses the following statements:

```
PROC UCM <options>;
   AUTOREG <options>;
   BLOCKSEASON options;
   BY variables;
   CYCLE <options>;
   DEPLAG options;
   ESTIMATE <options>;
   FORECAST <options>;
   ID variable options;
   IRREGULAR <options>;
   LEVEL <options>;
   MODEL dependent variable = regressors;
   NLOPTIONS options;
   PERFORMANCE options;
   OUTLIER options;
   RANDOMREG regressors / options;
   SEASON options;
   SLOPE <options>;
   SPLINEREG regressor <options>;
   SPLINESEASON options;
```

The PROC UCM and MODEL statements are required. In addition, the model must contain at least one component with nonzero disturbance variance.

Functional Summary

The statements and options controlling the UCM procedure are summarized in Table 42.1. Most commonly needed scenarios are listed; see the individual statements for additional details. You can use the PRINT= and PLOT= options in the individual component statements for printing and plotting the corresponding component forecasts.

PROC UCM Statement

PROC UCM <options> ;

The PROC UCM statement is required. The following options can be used in the PROC UCM statement:

DATA=SAS-data-set
specifies the name of the SAS data set containing the time series. If the DATA= option is not specified in the PROC UCM statement, the most recently created SAS data set is used.

NOPRINT
turns off all the printing for the procedure. The subsequent print options in the procedure are ignored.

PLOTS<(global-plot-options)> = plot-request <(options)>
controls the plots produced with ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Here are some examples:

plots=none
plots=all
plots=residuals(acf loess)
plots(noclm)=(smooth(decomp) residual(panel loess))

proc ucm;
  model y = x;
  irregular;
  level;
  run;

proc ucm plots=all;
  model y = x;
  irregular;
  level;
  run;

The first PROC UCM step does not specify the PLOTS= option, so the default plot that displays the series forecasts in the forecast region is produced. The PLOTS=ALL option in the second PROC UCM step produces all the plots that are appropriate for the specified model.

In addition to the PLOTS= option in the PROC UCM statement, you can request plots by using the PLOT= option in other statements of the UCM procedure. This way of requesting plots provides finer control over the plot production. If you do not specify any specific plot request, then PROC UCM produces the plot of series forecasts in the forecast horizon by default.
Global Plot Options
The `global-plot-options` apply to all relevant plots generated by the UCM procedure. The following `global-plot-option` is supported:

**NOCLM**
suppresses the confidence limits in all the component and forecast plots.

Specific Plot Options
The following list describes the specific plots and their options:

**ALL**
produces all plots appropriate for the particular analysis.

**NONE**
suppresses all plots.

**FILTER (<filter-plot-options>)**
produces time series plots of the filtered component estimates. The following `filter-plot-options` are available:

**ALL**
produces all the filtered component estimate plots appropriate for the particular analysis.

**LEVEL**
produces a time series plot of the filtered level component estimate, provided the model contains the level component.

**SLOPE**
produces a time series plot of the filtered slope component estimate, provided the model contains the slope component.

**CYCLE**
produces time series plots of the filtered cycle component estimates for all cycle components in the model, if there are any.

**SEASON**
produces time series plots of the filtered season component estimates for all seasonal components in the model, if there are any.

**DECOMP**
produces time series plots of the filtered estimates of the series decomposition.

**RESIDUAL (<residual-plot-options>)**
produces the residuals plots. The following `residual-plot-options` are available:

**ALL**
produces all the residual diagnostics plots appropriate for the particular analysis.

**ACF**
produces the autocorrelation plot of residuals.
CUSUM
produces the plot of cumulative residuals against time.

CUSUMSQ
produces the plot of cumulative squared residuals against time.

HISTOGRAM
produces the histogram of residuals.

LOESS
produces a scatter plot of residuals against time, which has an overlaid loess-fit.

PACF
produces the partial-autocorrelation plot of residuals.

PANEL
produces a summary panel of the residual diagnostics consisting of the following:
- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

QQ
produces a normal quantile plot of residuals.

RESIDUAL
produces a needle plot of residuals against time.

WN
produces the plot of Ljung-Box white-noise test p-values at different lags (in log scale).

SMOOTH (<smooth-plot-options>)
produces time series plots of the smoothed component estimates. The following smooth-plot-options are available:

ALL
produces all the smoothed component estimate plots appropriate for the particular analysis.

LEVEL
produces time series plot of the smoothed level component estimate, provided the model contains the level component.

SLOPE
produces time series plot of the smoothed slope component estimate, provided the model contains the slope component.
CYCLE
produces time series plots of the smoothed cycle component estimates for all cycle components in the model, if there are any.

SEASON
produces time series plots of the smoothed season component estimates for all season components in the model, if there are any.

DECOMP
produces time series plots of the smoothed estimates of the series decomposition.

PRINTALL
turns on all the printing options for the procedure. The subsequent NOPRINT options in the procedure are ignored.

AUTOREG Statement

AUTOREG < options > ;
The AUTOREG statement specifies an autoregressive component in the model. An autoregressive component is a special case of cycle that corresponds to the frequency of zero or $\pi$. It is modeled separately for easier interpretation. A stochastic equation for an autoregressive component $r_t$ can be written as follows:

$$r_t = \rho r_{t-1} + \nu_t, \quad \nu_t \sim \text{iid } N(0, \sigma^2)$$

The damping factor $\rho$ can take any value in the interval $(-1, 1)$, including $-1$ but excluding 1. If $\rho = 1$, the autoregressive component cannot be distinguished from the random walk level component. If $\rho = -1$, the autoregressive component corresponds to a seasonal component with a season length of 2, or a nonstationary cycle with period 2. If $|\rho| < 1$, then the autoregressive component is stationary. The following example illustrates the AUTOREG statement. This statement includes an autoregressive component in the model. The damping factor $\rho$ and the disturbance variance $\sigma^2$ are estimated from the data.

autoreg;

NOEST=RHO
NOEST=VARIANCE
NOEST=(RHO VARIANCE)
fixes the values of $\rho$ and $\sigma^2$ to those specified in the RHO= and VARIANCE= options.

PLOT=FILTER
PLOT=SMOOTH
PLOT=(<FILTER> <SMOOTH>)
requests plotting of the filtered or smoothed estimate of the autoreg component.
PRINT\text{=}FILTER
\quad PRINT\text{=}SMOOTH
\quad PRINT\text{=}(<\text{FILTER}>\ <\text{SMOOTH}>)
requests printing of the filtered or smoothed estimate of the autoreg component.

RHO=value
specifies an initial value for the damping factor $\rho$ during the parameter estimation process. The value of $\rho$ must be in the interval $(-1, 1)$, including $-1$ but excluding $1$.

VARIANCE=value
specifies an initial value for the disturbance variance $\sigma^2$ during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

**BLOCKSEASON Statement**

```
BLOCKSEASON NBLOCKS=integer BLOCKSIZE=integer <options> ;
```

The BLOCKSEASON or BLOCKSEASONAL statement is used to specify a seasonal component $\gamma_t$ that has a special block structure. The seasonal $\gamma_t$ is called a block seasonal of block size $m$ and number of blocks $k$ if its season length, $s$, can be factored as $s = m \times k$ and its seasonal effects have a block form—that is, the first $m$ seasonal effects are all equal to some number $\tau_1$, the next $m$ effects are all equal to some number $\tau_2$, and so on.

This type of seasonal structure can be appropriate in some cases; for example, consider a series that is recorded on an hourly basis. Further assume that, in this particular case, the hour-of-the-day effect and the day-of-the-week effect are additive. In this situation the hour-of-the-week seasonality, having a season length of 168, can be modeled as a sum of two components. The hour-of-the-day effect is modeled using a simple seasonal of season length 24, while the day-of-the-week is modeled as a block seasonal component that has the days of the week as blocks. This day-of-the-week block seasonal component has seven blocks, each of size 24.

A block seasonal specification requires, at the minimum, the block size $m$ and the number of blocks in the seasonal $k$. These are specified using the BLOCKSIZE= and NBLOCKS= option, respectively. In addition, you might need to specify the position of the first observation of the series by using the OFFSET= option if it is not at the beginning of one of the blocks. In the example just considered, this corresponds to a situation where the first series measurement is not at the start of the day. Suppose that the first measurement of the series corresponds to the hour between 6:00 and 7:00 a.m., which is the seventh hour within that day or at the seventh position within that block. This is specified as OFFSET=7.

The other options in this statement are very similar to the options in the SEASON statement; for example, a block seasonal can also be of one of the two types, DUMMY and TRIG. There can be more than one block seasonal component in the model, each specified using a separate BLOCKSEASON statement. No two block seasonals in the model can have the same NBLOCKS= and BLOCKSIZE= specifications. The following example illustrates the use of the BLOCKSEASON statement to specify the additive, hour-of-the-week seasonal model:

```
season length=24 type=trig;
blockseason nblocks=7 blocksize=24;
```
BLOCKSIZE=integer
specifies the block size, m. This is a required option in this statement. The block size can be any integer larger than or equal to two. Typical examples of block sizes are 24, corresponding to the hours of the day when a day is being used as a block in hourly data, or 60, corresponding to the minutes in an hour when an hour is being used as a block in data recorded by minutes, etc.

NBLOCKS=integer
specifies the number of blocks, k. This is a required option in this statement. The number of blocks can be any integer greater than or equal to two.

NOEST
fixes the value of the disturbance variance parameter to the value specified in the VARIANCE= option.

OFFSET=integer
specifies the position of the first measurement within the block, if the first measurement is not at the start of a block. The OFFSET= value must be between one and the block size. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the block size.

PLOT=FILTER
PLOT=SMOOTH
PLOT=F_ANNUAL
PLOT=S_ANNUAL
PLOT=( <plot-request> ... <plot-request> )
requests plots of the season component. When you specify only one plot-request, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component \( \gamma_t \). You can use the F_ANNUAL and S_ANNUAL options to get the plots of “annual” variation in the filtered and smoothed estimates of \( \gamma_t \). The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years. The first period in each block is plotted over the years.

PRINT=FILTER
PRINT=SMOOTH
PRINT=( <FILTER> <SMOOTH> )
requests the printing of the filtered or smoothed estimate of the block seasonal component \( \gamma_t \).

TYPE=DUMMY | TRIG
specifies the type of the block seasonal component. The default type is DUMMY.

VARIANCE=value
specifies an initial value for the disturbance variance, \( \sigma_w^2 \), in the \( \gamma_t \) equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.
BY Statement

BY variables;

A BY statement can be used in the UCM procedure to process a data set in groups of observations defined by the BY variables. The model specified using the MODEL and other component statements is applied to all the groups defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. The variables are one or more variables in the input data set.

CYCLE Statement

CYCLE <options>;

The CYCLE statement is used to specify a cycle component, \( \psi_t \), in the model. The stochastic equation governing a cycle component of period \( p \) and damping factor \( \rho \) is

\[
\begin{bmatrix}
\psi_t \\
\psi_t^*
\end{bmatrix} = \rho \begin{bmatrix}
\cos \lambda & \sin \lambda \\
-\sin \lambda & \cos \lambda
\end{bmatrix} \begin{bmatrix}
\psi_{t-1} \\
\psi_{t-1}^*
\end{bmatrix} + \begin{bmatrix}
v_t \\
v_t^*
\end{bmatrix}
\]

where \( v_t \) and \( v_t^* \) are independent, zero-mean, Gaussian disturbances with variance \( \sigma_v^2 \) and \( \lambda = 2 \pi / p \) is the angular frequency of the cycle. Any \( p \) strictly greater than two is an admissible value for the period, and the damping factor \( \rho \) can be any value in the interval (0, 1), including one but excluding zero. The cycles with frequency zero and \( \pi \), which correspond to the periods equal to infinity and two, respectively, can be specified using the AUTOREG statement. The values of \( \rho \) less than one give rise to a stationary cycle, while \( \rho = 1 \) gives rise to a nonstationary cycle. As a default, values of \( \rho, p, \) and \( \sigma_v^2 \) are estimated from the data. However, if necessary, you can fix the values of some or all of these parameters.

There can be multiple cycles in a model, each specified using a separate CYCLE statement. The examples that follow illustrate the use of the CYCLE statement.

The following statements request including two cycles in the model. The parameters of each of these cycles are estimated from the data.

```
cycle;
cycle;
```

The following statement requests inclusion of a nonstationary cycle in the model. The cycle period \( p \) and the disturbance variance \( \sigma_v^2 \) are estimated from the data.

```
cycle rho=1 noest=rho;
```

In the following statement, a nonstationary cycle with a fixed period of 12 is specified. Moreover, a starting value is supplied for \( \sigma_v^2 \).

```
cycle period=12 rho=1 variance=4 noest=(rho period);
```
NOEST=PERIOD
NOEST=RHO
NOEST=VARIANCE
NOEST=(<RHO><PERIOD><VARIANCE>)

fixes the values of the component parameters to those specified in the RHO=, PERIOD=, and VARIANCE= options. This option enables you to fix any combination of parameter values.

ORDER=integer (Experimental)
enables you to specify a higher-order cycle. A higher-order cycle (a cycle whose order is greater than 1) is a generalization of the stochastic cycle described at the beginning of this section, which can be thought of as a first-order cycle. Higher-order cycles are well explained in Trimbur (2005) and Pelagatti (2015, sect. 3.3.3). A cycle whose order is greater than 2 is rarely needed, and specifying cycles of large orders (for example, an order greater than 4) can lead to computational instability. See Example 42.9 for an example of the use of higher-order cycles.

PERIOD=value
specifies an initial value for the cycle period during the parameter estimation process. Period value must be strictly greater than 2.

PLOT=FILTER
PLOT=SMOOTH
PLOT=(<FILTER><SMOOTH>)
requests plotting of the filtered or smoothed estimate of the cycle component.

PRINT=FILTER
PRINT=SMOOTH
PRINT=(<FILTER><SMOOTH>)
requests the printing of a filtered or smoothed estimate of the cycle component $\psi_1$.

RHO=value
specifies an initial value for the damping factor in this component during the parameter estimation process. Any value in the interval (0, 1), including one but excluding zero, is an acceptable initial value for the damping factor.

VARIANCE=value
specifies an initial value for the disturbance variance parameter, $\sigma_n^2$, to be used during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.
DEPLEG Statement

DEPLEG LAGS=order < PHI=value ... > < NOEST >

The DEPLEG statement is used to specify the lags of the dependent variable to be included as predictors in the model. The following examples illustrate the use of the DEPLEG statement.

If the dependent series is denoted by \( y_t \), the following statement specifies the inclusion of \( \phi_1 y_{t-1} + \phi_2 y_{t-2} \) in the model. The parameters \( \phi_1 \) and \( \phi_2 \) are estimated from the data.

\[
\text{DEPLEG lags}=2;
\]

The following statement requests including \( \phi_1 y_{t-1} + \phi_2 y_{t-4} - \phi_1 \phi_2 y_{t-5} \) in the model. The values of \( \phi_1 \) and \( \phi_2 \) are fixed at 0.8 and -1.2.

\[
\text{DEPLEG lags}=(1)(4) \text{ phi}=0.8 \ -1.2 \text{ noest};
\]

The dependent lag parameters are not constrained to lie in any particular region. In particular, this implies that a UCM that contains only an irregular component and dependent lags, resulting in a traditional autoregressive model, is not constrained to be a stationary model. In the DEPLEG statement, if an initial value is supplied for any one of the parameters, the initial values must also be supplied for all other parameters.

LAGS=order

LAGS=(lag, ..., lag) ...(lag, ..., lag)

is a required option in this statement. LAGS=(l_1, l_2, ..., l_k) defines a model with specified lags of the dependent variable included as predictors. LAGS=order is equivalent to LAGS=(1, 2, ..., order).

A concatenation of parenthesized lists specifies a factored model. For example, LAGS=(1)(12) specifies that the lag values, 1, 12, and 13, corresponding to the following polynomial in the backward shift operator, be included in the model:

\[
(1 - \phi_{1, 1} B)(1 - \phi_{2, 1} B^{12})
\]

Note that, in this case, the coefficient of the thirteenth lag is constrained to be the product of the coefficients of the first and twelfth lags.

NOEST

fixes the values of the parameters to those specified in PHI= option.

PHI=value ...

lists starting values for the coefficients of the lagged dependent variable. The order of the values listed corresponds with the order of the lags specified in the LAGS= option.

ESTIMATE Statement

ESTIMATE < options >;

The ESTIMATE statement is an optional statement used to control the overall model-fitting environment. Using this statement, you can control the span of observations used to fit the model by using the SKIPFIRST= and BACK= options. This can be useful in model diagnostics. You can request a variety of goodness-of-fit
statistics and other model diagnostic information including different residual diagnostic plots. Note that the 
ESTIMATE statement is not used to control the nonlinear optimization process itself. That is done using 
the NLOPTIONS statement, where you can control the number of iterations, choose between the different 
optimization techniques, and so on. You can save the estimated parameters and other related information 
in a data set by using the OUTEST= option. You can request the optimization of the profile likelihood, 
the likelihood obtained by concentrating out a disturbance variance, for parameter estimation by using the 
PROFILE option. The following example illustrates the use of this statement:

```
estimate skipfirst=12 back=24;
```

This statement requests that the initial 12 measurements and the last 24 measurements be excluded during the 
model-fitting process. The actual observation span used to fit the model is decided as follows: Suppose that 
\(n_0\) and \(n_1\) are the observation numbers of the first and the last nonmissing values of the response variable, 
respectively. As a result of SKIPFIRST=12 and BACK=24, the measurements between observation numbers 
\(n_0 + 12\) and \(n_1 - 24\) form the estimation span. Of course, the model fitting might not take place if there 
are insufficient data in the resulting span. The model fitting does not take place if there are regressors in the 
model that have missing values in the estimation span.

**BACK=integer**

**SKIPLAST=integer**

indicates that some ending part of the data needs to be ignored during the parameter estimation. This 
can be useful when you want to study the forecasting performance of a model on the observed data. 
BACK=10 results in skipping the last 10 measurements of the response series during the parameter 
estimation. The default is BACK=0.

**EXTRADIFFUSE=k**

enables continuation of the diffuse filtering iterations for \(k\) additional iterations beyond the first instance 
where the initialization of the diffuse state would have otherwise taken place. If the specified \(k\) is larger 
than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-
ahead residuals are produced only after the diffuse state is initialized. Delaying the initialization leads 
to a reduction in the number of one-step-ahead residuals available for computing the residual diagnostic 
measures. This option is useful when you want to ignore the first few one-step-ahead residuals that 
often have large variance.

**NOPROFILE**

requests that the usual likelihood be optimized for parameter estimation. For more information, see the 
section “Parameter Estimation by Profile Likelihood Optimization” on page 2918.

**OUTEST=SAS-data-set**

specifies an output data set for the estimated parameters.

In the ESTIMATE statement, the PLOT= option is used to obtain different residual diagnostic plots. 
The different possibilities are as follows:
PLOT=ACF
PLOT=MODEL
PLOT=LOESS
PLOT=HISTOGRAM
PLOT=PACF
PLOT=PANEL
PLOT=QQ
PLOT=RESIDUAL
PLOT=WN
PLOT=(<plot-request> ... <plot-request>)

requests different residual diagnostic plots. The different options are as follows:

**ACF**
produces the residual-autocorrelation plot.

**CUSUM**
produces the plot of cumulative residuals against time.

**CUSUMSQ**
produces the plot of cumulative squared residuals against time.

**MODEL**
produces the plot of one-step-ahead forecasts in the estimation span.

**HISTOGRAM**
produces the histogram of residuals.

**LOESS**
produces a scatter plot of residuals against time, which has an overlaid loess-fit.

**PACF**
produces the residual-partial-autocorrelation plot.

**PANEL**
produces a summary panel of the residual diagnostics consisting of the following:

- histogram of residuals
- normal quantile plot of residuals
- the residual-autocorrelation-plot
- the residual-partial-autocorrelation-plot

**QQ**
produces a normal quantile plot of residuals.

**RESIDUAL**
produces a needle plot of residuals against time.
WN
produces a plot of p-values, in log-scale, at different lags for the Ljung-Box portmanteau white noise test statistics.

PRINT=NONE
suppresses all the printed output related to the model fitting, such as the parameter estimates, the goodness-of-fit statistics, and so on.

PROFILE
requests that the profile likelihood, obtained by concentrating out one of the disturbance variances from the likelihood, be optimized for parameter estimation. By default, the profile likelihood is not optimized if any of the disturbance variance parameters is held fixed to a nonzero value. For more information see the section “Parameter Estimation by Profile Likelihood Optimization” on page 2918.

SKIPFIRST=integer
indicates that some early part of the data needs to be ignored during the parameter estimation. This can be useful if there is a reason to believe that the model being estimated is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the parameter estimation. The default is SKIPFIRST=0.

FORECAST Statement

FORECAST < options> ;

The FORECAST statement is an optional statement that is used to specify the overall forecasting environment for the specified model. It can be used to specify the span of observations, the historical period, to use to compute the forecasts of the future observations. This is done using the SKIPFIRST= and BACK= options. The number of periods to forecast beyond the historical period, and the significance level of the forecast confidence interval, is specified using the LEAD= and ALPHA= options. You can request one-step-ahead series and component forecasts by using the PRINT= option. You can save the series forecasts, and the model-based decomposition of the series, in a data set by using the OUTFOR= option. You can use the BOOTSTRAP option to request the computation of bootstrap prediction standard errors and the associated confidence intervals. The following example illustrates the use of this statement:

    forecast skipfirst=12 back=24 lead=30;

This statement requests that the initial 12 and the last 24 response values be excluded during the forecast computations. The forecast horizon, specified using the LEAD= option, is 30 periods; that is, multistep forecasting begins at the end of the historical period and continues for 30 periods. The actual observation span used to compute the multistep forecasting is decided as follows: Suppose that \( n_0 \) and \( n_1 \) are the observation numbers of the first and the last nonmissing values of the response variable, respectively. As a result of SKIPFIRST=12 and BACK=24, the historical period, or the forecast span, begins at \( n_0 + 12 \) and ends at \( n_1 - 24 \). Multistep forecasts are produced for the next 30 periods—that is, for the observation numbers \( n_1 - 23 \) to \( n_1 + 6 \). Of course, the forecast computations can fail if the model has regressor variables that have missing values in the forecast span. If the regressors contain missing values in the forecast horizon—that is, between the observations \( n_1 - 23 \) and \( n_1 + 6 \)—the forecast horizon is reduced accordingly.
**ALPHA=value**
specifies the significance level of the forecast confidence intervals; for example, ALPHA=0.05, which is the default, results in a 95% confidence interval.

**BACK=integer**
**SKIPLAST=integer**
specifies the holdout sample for the evaluation of the forecasting performance of the model. For example, BACK=10 results in treating the last 10 observed values of the response series as unobserved. A post-sample-prediction-analysis table is produced for comparing the predicted values with the actual values in the holdout period. The default is BACK=0.

**BOOTSTRAP(NREP=integer < SEED=integer >)  (Experimental)**
enables the computation of bootstrap prediction standard errors based on the specified number of replications (NREP). The value of NREP must be at least 2. Optionally, you can specify the random number seed that is associated with the first replication by using the SEED= option. The seeds for the subsequent replications are assigned sequentially. The default seed value that is associated with the first replication is 123. The BOOTSTRAP option has no effect if the number of parameters to be estimated is zero (that is, all the model parameters are known). Note that this option is computationally expensive. The computational cost of NREP replications is comparable to the cost of estimating parameters NREP times.

**EXTRADIFFUSE=k**
enables continuation of the diffuse filtering iterations for k additional iterations beyond the first instance where the initialization of the diffuse state would have otherwise taken place. If the specified k is larger than the sample size, the diffuse iterations continue until the end of the sample. Note that one-step-ahead forecasts are produced only after the diffuse state is initialized. Delaying the initialization leads to reduction in the number of one-step-ahead forecasts. This option is useful when you want to ignore the first few one-step-ahead forecasts that often have large variance.

**LEAD=integer**
specifies the number of periods to forecast beyond the historical period defined by the SKIPFIRST= and BACK= options; for example, LEAD=10 results in the forecasting of 10 future values of the response series. The default is LEAD=12.

**OUTFOR=SAS-data-set**
specifies an output data set for the forecasts. The output data set contains the ID variable (if specified), the response and predictor series, the one-step-ahead and out-of-sample response series forecasts, the forecast confidence intervals, the smoothed values of the response series, and the smoothed forecasts produced as a result of the model-based decomposition of the series.

**PLOT=DECOMP**
**PLOT=DECOMPVAR**
**PLOT=FDECOMP**
**PLOT=FDECOMPVAR**
**PLOT=FORECASTS**
**PLOT=TREND**
**PLOT=( <plot-request> . . . <plot-request> )**
requests forecast and model decomposition plots. The FORECASTS option provides the plot of the series forecasts, the TREND and DECOMP options provide the plots of the smoothed trend and other decompositions, the DECOMPVAR option can be used to plot the variance of these components, and the FDECOMP and FDECOMPVAR options provide the same plots for the filtered decomposition estimates and their variances.
ID Statement

**PRINT**

- **PRINT=DECOMP**
- **PRINT=FDECOMP**
- **PRINT=FORECASTS**
- **PRINT=NONE**
- **PRINT=( < print-request > ... < print-request > )**

controls the printing of the series forecasts and the printing of smoothed model decomposition estimates. By default, the series forecasts are printed only for the forecast horizon specified by the LEAD= option; that is, the one-step-ahead predicted values are not printed. You can request forecasts for the entire forecast span by specifying the PRINT=FORECASTS option. Using PRINT=DECOMP, you can get smoothed estimates of the following effects: trend, trend plus regression, trend plus regression plus cycle, and sum of all components except the irregular. If some of these effects are absent in the model, then they are ignored. Similarly, you can get filtered estimates of these effects by using PRINT=FDECOMP. You can use PRINT=NONE to suppress the printing of all the forecast output.

**SKIPFIRST=integer**

indicates that some early part of the data needs to be ignored during the forecasting calculations. This can be useful if there is a reason to believe that the model being used for forecasting is not appropriate for this portion of the data. SKIPFIRST=10 results in skipping the first 10 measurements of the response series during the forecast calculations. The default is SKIPFIRST=0.

---

**ID Statement**

```
ID variable INTERVAL=value < ALIGN=value> ;
```

The ID statement names a numeric variable that identifies observations in the input and output data sets. The ID variable’s values are assumed to be SAS date, time, or datetime values. In addition, the ID statement specifies the frequency associated with the time series. The ID statement options also specify how the observations are aligned to form the time series. If the ID statement is specified, the INTERVAL= option must also be specified. If the ID statement is not specified, the observation number, with respect to the BY group, is used as the time ID. The values of the ID variable are extrapolated for the forecast observations based on the values of the INTERVAL= option.

**ALIGN=value**

controls the alignment of SAS dates used to identify output observations. The ALIGN= option has the following possible values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable with the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

**INTERVAL=value**

specifies the time interval between observations. This option is required in the ID statement. INTERVAL=value is used in conjunction with the ID variable to check that the input data are in order and have no gaps. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data. For a complete discussion of the intervals supported, see Chapter 4, “Date Intervals, Formats, and Functions.”
Chapter 42: The UCM Procedure

IRREGULAR Statement

IRREGULAR <options> ;

The IRREGULAR statement includes an irregular component in the model. There can be at most one IRREGULAR statement in the model specification. The irregular component corresponds to the overall random error \( \epsilon_t \) in the model. By default the irregular component is modeled as white noise—that is, as a sequence of independent, identically distributed, zero-mean, Gaussian random variables. However, you can also model it as an autoregressive moving average (ARMA) process. The options for specifying an ARMA model for the irregular component are given in a separate subsection: “ARMA Specification” on page 2890.

The options in this statement enable you to specify the model for the irregular component and to output its estimates. Two examples of the IRREGULAR statement are given next. In the first example the statement is in its simplest form, resulting in the inclusion of an irregular component that is white noise with unknown variance:

irregular;

The following statement provides a starting value for the white noise variance \( \sigma^2 \) to be used in the nonlinear parameter estimation process. It also requests the printing of smoothed estimates of \( \epsilon_t \). The smoothed irregulars are useful in model diagnostics.

irregular variance=4 print=smooth;

NOEST

fixes the value of \( \sigma^2 \) to the value specified in the VARIANCE= option. Also see the NOEST= option in the subsection “ARMA Specification” on page 2890.

PLOT=FILTER

PLOT=SMOOTH

PLOT=( <FILTER> <SMOOTH> )

requests plotting of the filtered or smoothed estimate of the irregular component.

PRINT=FILTER

PRINT=SMOOTH

PRINT=( <FILTER> <SMOOTH> )

requests printing of the filtered or smoothed estimate of the irregular component.

VARIANCE= value

specifies an initial value for \( \sigma^2 \) during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

ARMA Specification

This section details the options for specifying an ARMA model for the irregular component. The specification of ARMA models requires some notation, which is explained first.

Let \( B \) denote the backshift operator—that is, for any sequence \( \epsilon_t \), \( B\epsilon_t = \epsilon_{t-1} \). The higher powers of \( B \) represent larger shifts (for example, \( B^3\epsilon_t = \epsilon_{t-3} \)). A random sequence \( \epsilon_t \) follows a zero-mean ARMA\((p,q)\times(P,Q)_s\) model with nonseasonal autoregressive order \( p \), seasonal autoregressive order \( P \), nonseasonal moving average order \( q \), and seasonal moving average order \( Q \), if it satisfies the following difference
equation specified in terms of the polynomials in the backshift operator where $a_t$ is a white noise sequence and $s$ is the season length:

$$\phi(B)\phi(B^s)\epsilon_t = \theta(B)\Theta(B^s)a_t$$

The polynomials $\phi$, $\Phi$, $\theta$, and $\Theta$ are of orders $p$, $P$, $q$, and $Q$, respectively, which can be any nonnegative integers. The season length $s$ must be a positive integer. For example, $\epsilon_t$ satisfies an ARMA(1,1) model (that is, $p = 1$, $q = 1$, $P = 0$, and $Q = 0$) if

$$\epsilon_t = \phi_1\epsilon_{t-1} + a_t - \theta_1a_{t-1}$$

for some coefficients $\phi_1$ and $\theta_1$ and a white noise sequence $a_t$. Similarly, $\epsilon_t$ satisfies an ARMA(1,1)$\times$(1,1)$_{12}$ model if

$$\epsilon_t = \phi_1\epsilon_{t-1} + \Phi_1\epsilon_{t-12} - \phi_1\Phi_1\epsilon_{t-13} + a_t - \theta_1a_{t-1} - \Theta_1a_{t-12} + \theta_1\Theta_1a_{t-13}$$

for some coefficients $\phi_1$, $\Phi_1$, $\theta_1$, and $\Theta_1$ and a white noise sequence $a_t$. The ARMA process is stationary and invertible if the defining polynomials $\phi$, $\Phi$, $\theta$, and $\Theta$ have all their roots outside the unit circle—that is, their absolute values are strictly larger than 1.0. It is assumed that the ARMA model specified for the irregular component is stationary and invertible—that is, the coefficients of the polynomials $\phi$, $\Phi$, $\theta$, and $\Theta$ are constrained so that the stationarity and invertibility conditions are satisfied. The unknown coefficients of these polynomials become part of the model parameter vector that is estimated using the data.

The notation for a closely related class of models, autoregressive integrated moving average (ARIMA) models, is also given here. A random sequence $y_t$ is said to follow an ARIMA($p,d,q$)$\times$($P,D,Q$)$_s$ model if, for some nonnegative integers $d$ and $D$, the differenced series $\epsilon_t = (1 - B)^d(1 - B^s)^D y_t$ follows an ARMA($p,q$)$\times$($P,Q$)$_s$ model. The integers $d$ and $D$ are called nonseasonal and seasonal differencing orders, respectively. You can specify ARIMA models by using the DEPLAG statement for specifying the differencing orders and by using the IRREGULAR statement for the ARMA specification. For an example of ARIMA(0,1,1)$\times$(0,1,1)$_{12}$ model specification, see Example 42.8. Brockwell and Davis (1991) can be consulted for additional information about ARIMA models.

You can use options of the IRREGULAR statement to specify the desired ARMA model and to request printed and graphical output. A few examples of the IRREGULAR statement are given next.

The following statement specifies an irregular component that is modeled as an ARMA(1,1) process. It also requests plotting its smoothed estimate.

```
irregular p=1 q=1 plot=smooth;
```

The following statement specifies an ARMA(1,1)$\times$(1,1)$_{12}$ model. It also fixes the coefficient of the first-order seasonal moving average polynomial to 0.1. The other coefficients and the white noise variance are estimated using the data.

```
irregular p=1 sp=1 q=1 sq=1 s=12 sma=0.1 noest=(sma);
```

lists the starting values of the coefficients of the nonseasonal autoregressive polynomial

$$\phi(B) = 1 - \phi_1 B - \cdots - \phi_p B^p$$

where the order $p$ is specified in the $P=$ option. The coefficients $\phi_i$ must define a stationary autoregressive polynomial.
Chapter 42: The UCM Procedure

MA=\(\theta_1 \theta_2 \ldots \theta_q\)
lists the starting values of the coefficients of the nonseasonal moving average polynomial
\[
\theta(B) = 1 - \theta_1 B - \cdots - \theta_q B^q
\]
where the order \(q\) is specified in the Q= option. The coefficients \(\theta_i\) must define an invertible moving average polynomial.

NOEST=(<VARIANCE> <AR> <SAR> <MA> <SMA>)
fixes the values of the ARMA parameters and the value of the white noise variance to those specified in the AR=, SAR=, MA=, SMA=, or VARIANCE= options.

P=integer
specifies the order of the nonseasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

Q=integer
specifies the order of the nonseasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1, 2, or 3.

S=integer
specifies the season length used during the specification of the seasonal autoregressive or seasonal moving average polynomial. The season length can be any positive integer; for example, S=4 might be an appropriate value for a quarterly series. The default value is S=1.

SAR=\(\hat{\Phi}_1 \hat{\Phi}_2 \ldots \hat{\Phi}_P\)
lists the starting values of the coefficients of the seasonal autoregressive polynomial
\[
\Phi(B^s) = 1 - \hat{\Phi}_1 B^s - \cdots - \hat{\Phi}_P B^{sP}
\]
where the order \(P\) is specified in the SP= option and the season length \(s\) is specified in the S= option. The coefficients \(\hat{\Phi}_i\) must define a stationary autoregressive polynomial.

SMA=\(\hat{\Theta}_1 \hat{\Theta}_2 \ldots \hat{\Theta}_Q\)
lists the starting values of the coefficients of the seasonal moving average polynomial
\[
\Theta(B^s) = 1 - \hat{\Theta}_1 B^s - \cdots - \hat{\Theta}_Q B^{sQ}
\]
where the order \(Q\) is specified in the SQ= option and the season length \(s\) is specified in the S= option. The coefficients \(\hat{\Theta}_i\) must define an invertible moving average polynomial.

SP=integer
specifies the order of the seasonal autoregressive polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.

SQ=integer
specifies the order of the seasonal moving average polynomial. The order can be any nonnegative integer; the default value is 0. In practice the order is a small integer such as 1 or 2.
LEVEL Statement

LEVEL <options> ;

The LEVEL statement is used to include a level component in the model. The level component, either by itself or together with a slope component (see the SLOPE statement), forms the trend component, $\mu_t$, of the model. If the slope component is absent, the resulting trend is a random walk (RW) specified by the following equations:

$$\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma^2)$$

If the slope component is present, signified by the presence of a SLOPE statement, a locally linear trend (LLT) is obtained. The equations of LLT are as follows:

$$\mu_t = \mu_{t-1} + \beta_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma^2)$$
$$\beta_t = \beta_{t-1} + \xi_t, \quad \xi_t \sim \text{iid } N(0, \sigma^2)$$

In either case, the options in the LEVEL statement are used to specify the value of $\sigma^2$ and to request forecasts of $\mu_t$. The SLOPE statement is used for similar purposes in the case of slope $\beta_t$. The following examples illustrate the use of the LEVEL statement. Assuming that a SLOPE statement is not added subsequently, a simple random walk trend is specified by the following statement:

```
level;
```

The following statements specify a locally linear trend with value of $\sigma^2$ fixed at 4. It also requests printing of filtered values of $\mu_t$. The value of $\sigma^2$, the disturbance variance in the slope equation, is estimated from the data.

```
level variance=4 noest print=filter;
slope;
```

**CHECKBREAK**

turns on the checking of breaks in the level component.

**NOEST**

fixes the value of $\sigma^2$ to the value specified in the VARIANCE= option.

**PLOT=FILTER**
**PLOT=SMOOTH**
**PLOT=(<FILTER> <SMOOTH>)**

requests plotting of the filtered or smoothed estimate of the level component.

**PRINT=FILTER**
**PRINT=SMOOTH**
**PRINT=(<FILTER> <SMOOTH>)**

requests printing of the filtered or smoothed estimate of the level component.
VARIANCE=value
specifies an initial value for \( \sigma^2_n \), the disturbance variance in the \( \mu_t \) equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

**MODEL Statement**

```
MODEL dependent <= regressors;
```

The MODEL statement specifies the response variable and, optionally, the predictor or regressor variables for the UCM model. This is a required statement in the UCM procedure. The predictors specified in the MODEL statement are assumed to have a linear and time-invariant relationship with the response. The predictors that have time-varying regression coefficients are specified separately in the RANDOMREG statement. Similarly, the predictors that have a nonlinear effect on the response variable are specified separately in the SPLINEREG statement. Only one MODEL statement can be specified.

**NLOPTIONS Statement**

```
NLOPTIONS < options >;
```

PROC UCM uses the nonlinear optimization (NLO) subsystem to perform the nonlinear optimization of the likelihood function during the estimation of model parameters. You can use the NLOPTIONS statement to control different aspects of this optimization process. For most problems the default settings of the optimization process are adequate. However, in some cases it might be useful to change the optimization technique or to change the maximum number of iterations. This can be done by using the TECH= and MAXITER= options in the NLOPTIONS statement as follows:

```
nloptions tech=dbldog maxiter=200;
```

This sets the maximum number of iterations to 200 and changes the optimization technique to DBLDOG rather than the default technique, TRUREG, used in PROC UCM. A discussion of the full range of options that can be used with the NLOPTIONS statement is given in Chapter 6, “Nonlinear Optimization Methods.” In PROC UCM all these options are available except the options related to the printing of the optimization history. In this version of PROC UCM all the printed output from the NLO subsystem is suppressed.

**OUTLIER Statement**

```
OUTLIER < options >;
```

The OUTLIER statement enables you to control the reporting of the additive outliers (AO) and level shifts (LS) in the response series. The AOs are searched by default. You can turn on the search for LSs by using the CHECKBREAK option in the LEVEL statement.

```
ALPHA=significance-level
```

specifies the significance level for reporting the outliers. The default is 0.05.
PERFORMANCE Statement

PERFORMANCE options;

The PERFORMANCE statement defines performance parameters for distributed and multithreaded computing and passes variables that describe the distributed computing environment. In the UCM procedure, this statement is applicable only if you specify the BOOTSTRAP option in the FORECAST statement. In addition, the number of nodes that you specify in the NODES= option in the PERFORMANCE statement must be strictly smaller than the number of bootstrap replications that you specify in the BOOTSTRAP option. The following statements illustrate how you can use this statement to perform bootstrap computations that use 10 nodes on a grid named hpa.sas.com:

```sas
proc ucm data=seriesG;
  id date interval=month;
  model logair;
  irregular;
  level;
  forecast lead=24 bootstrap(nrep=50 seed=1234);
  performance nodes=10 host="hpa.sas.com";
run;
```

For more information about the PERFORMANCE statement, see the section “PERFORMANCE Statement” (Chapter 2, SAS/ETS User’s Guide: High-Performance Procedures).

RANDOMREG Statement

RANDOMREG regressors </options> ;

The RANDOMREG statement is used to specify regressors with time-varying regression coefficients. Each regression coefficient—for example, $\beta_t$—is assumed to evolve as a random walk:

$$\beta_t = \beta_{t-1} + \eta_t, \quad \eta_t \sim iid \ N(0, \sigma^2)$$

Of course, if the random walk disturbance variance $\sigma^2$ is zero, then the regression coefficient is not time varying, and it reduces to the standard regression setting. There can be multiple RANDOMREG statements,
and each statement can contain one or more regressors. The regressors in a given RANDOMREG statement form a group that is assumed to share the same disturbance variance parameter. The random walks associated with different regressors are assumed to be independent. For an example of using this statement see Example 42.4. For additional information about the way parameter estimates are reported for this type of regressors, see the section “Reporting Parameter Estimates for Random Regressors” on page 2915.

**NOEST**

fixes the value of $\sigma^2$ to the value specified in the VARIANCE= option.

**PLOT=FILTER**

**PLOT=SMOOTH**

**PLOT=(<FILTER><SMOOTH>)**

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

**PRINT=FILTER**

**PRINT=SMOOTH**

**PRINT=(<FILTER><SMOOTH>)**

requests printing of the filtered or smoothed estimate of the time-varying regression coefficient.

**VARIANCE=value**

specifies an initial value for $\sigma^2$ during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

---

**SEASON Statement**

**SEASON LENGTH=integer < options>;**

The SEASON or SEASONAL statement is used to specify a seasonal component, $\gamma_t$, in the model. A seasonal component can be one of the two types, DUMMY or TRIG. A DUMMY seasonal with season length $s$ satisfies the following stochastic equation:

$$\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t,$$

$$\omega_t \sim iid N(0, \sigma^2)$$

The equations for a TRIG (short for trigonometric) seasonal component are as follows

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if $s$ is even and $(s-1)/2$ if it is odd. The sinusoids, also called harmonics, $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$\begin{bmatrix} \gamma_{j,t} \\ \gamma_{j,t}^* \end{bmatrix} = \begin{bmatrix} \cos \lambda_j & \sin \lambda_j \\ -\sin \lambda_j & \cos \lambda_j \end{bmatrix} \begin{bmatrix} \gamma_{j,t-1} \\ \gamma_{j,t-1}^* \end{bmatrix} + \begin{bmatrix} \omega_{j,t} \\ \omega_{j,t}^* \end{bmatrix}$$
where the disturbances $\omega_{j,t}$ and $\omega^*_{j,t}$ are assumed to be independent and, for fixed $j$, $\omega_{j,t}$ and $\omega^*_{j,t} \sim N(0, \sigma^2_\omega)$. If $s$ is even, then the equation for $\gamma^*_{s/2,t}$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

In the TRIG seasonal case, the option KEEPH= or DROPH= can be used to obtain *subset trigonometric* seasonals that contain only a subset of the full set of harmonics $\gamma_{j,t}$, $j = 1, 2,\ldots,[s/2]$. This is particularly useful when the season length $s$ is large and the seasonal pattern is relatively smooth.

Note that whether the seasonal type is DUMMY or TRIG, there is only one parameter, the disturbance variance $\sigma^2_\omega$, in the seasonal model.

There can be more than one seasonal component in the model, necessarily with different season lengths if the seasons are full. You can have multiple *subset* season components with the same season length, if you need to use separate disturbance variances for different sets of harmonics. Each seasonal component is specified using a separate SEASON statement. A model with multiple seasonal components can easily become quite complex and might need a large amount of data and computing resources for its estimation and forecasting. The examples that follow illustrate the use of SEASON statement.

The following statement specifies a DUMMY type (default) seasonal component with a season length of four, corresponding to the quarterly seasonality. The disturbance variance $\sigma^2_\omega$ is estimated from the data.

```plaintext
season length=4;
```

The following statement specifies a trigonometric seasonal with monthly seasonality. It also provides a starting value for $\sigma^2_\omega$.

```plaintext
season length=12 type=trig variance=4;
```

**DROPHARMONICS | DROPH=**number-list | n TO m BY p  

enables you to drop some harmonics $\gamma_{j,t}$ from the full set of harmonics used to obtain a trigonometric seasonal. The drop list can include any integer between 1 and $[s/2]$, $s$ being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length 12 that consists of only the first four harmonics $\gamma_{j,t}$, $j = 1, 2, 3, 4$:

```plaintext
season length=12 type=trig DROPH=5 6;
```

The last two high-frequency harmonics are dropped. The DROPH= option cannot be used with the KEEPH= option.

**KEEPHARMONICS | KEEPH=**number-list | n TO m BY p  

enables you to keep only the harmonics $\gamma_{j,t}$ listed in the option to obtain a trigonometric seasonal. The keep list can include any integer between 1 and $[s/2]$, $s$ being the season length. For example, the following specification results in a specification of a trigonometric seasonal with a season length of 12 that consists of all six harmonics $\gamma_{j,t}$, $j = 1,\ldots,6$:

```plaintext
season length=12 type=trig KEEPH=1 to 3;
season length=12 type=trig KEEPH=4 to 6;
```

However, these six harmonics are grouped into two groups, each having its own disturbance variance parameter. The DROPH= option cannot be used with the KEEPH= option.
LENGTH=integer
specifies the season length, s. This is a required option in this statement. The season length can be any integer greater than or equal to 2. Typical examples of season lengths are 12, corresponding to the monthly seasonality, or 4, corresponding to the quarterly seasonality.

NOEST
fixes the value of the disturbance variance parameter to the value specified in the VARIANCE= option.

PLOT=FILTER
PLOT=SMOOTH
PLOT=F_ANNUAL
PLOT=S_ANNUAL
PLOT=(<plot-request> ... <plot-request>)
requests plots of the season component. When you specify only one plot-request, you can omit the parentheses around it. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component \( \gamma_t \). You can use the F_ANNUAL and S_ANNUAL options to get the plots of “annual” variation in the filtered and smoothed estimates of \( \gamma_t \). The annual plots are useful to see the change in the contribution of a particular month over the span of years. Here “month” and “year” are generic terms that change appropriately with the interval type being used to label the observations and the season length. For example, for monthly data with a season length of 12, the usual meaning applies, while for daily data with a season length of 7, the days of the week serve as months and the weeks serve as years.

PRINT=HARMONICS
requests printing of the summary of harmonics present in the seasonal component. This option is valid only for the trigonometric seasonal component.

PRINT=FILTER
PRINT=SMOOTH
PRINT=(<print-request> ... <print-request>)
requests printing of the filtered or smoothed estimate of the seasonal component \( \gamma_t \).

TYPE=DUMMY | TRIG
specifies the type of the seasonal component. The default type is DUMMY.

VARIANCE=value
specifies an initial value for the disturbance variance, \( \sigma^2 \), in the \( \gamma_t \) equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

---

**SLOPE Statement**

SLOPE <options> ;

The SLOPE statement is used to include a slope component in the model. The slope component cannot be used without the level component (see the LEVEL statement). The level and slope specifications jointly
define the trend component of the model. A SLOPE statement without the accompanying LEVEL statement is ignored. The equations of the trend, defined jointly by the level \( \mu_t \) and slope \( \beta_t \), are as follows:

\[
\begin{align*}
\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad \eta_t \sim iid \ N(0, \sigma_\eta^2) \\
\beta_t &= \beta_{t-1} + \xi_t, \quad \xi_t \sim iid \ N(0, \sigma_\xi^2)
\end{align*}
\]

The SLOPE statement is used to specify the value of the disturbance variance, \( \sigma_\xi^2 \), in the slope equation, and to request forecasts of \( \beta_t \). The following examples illustrate this statement:

```plaintext
level;  
slope;  
```

The preceding statements fit a model with a locally linear trend. The disturbance variances \( \sigma_\eta^2 \) and \( \sigma_\xi^2 \) are estimated from the data. You can request a locally linear trend with fixed slope by using the following statements:

```plaintext
level;  
slope variance=0 noest;  
```

**NOEST**

fixes the value of the disturbance variance, \( \sigma_\xi^2 \), to the value specified in the VARIANCE= option.

**PLOT=FILTER**

**PLOT=SMOOTH**

**PLOT=( <FILTER> <SMOOTH> )**

requests plotting of the filtered or smoothed estimate of the slope component.

**PRINT=FILTER**

**PRINT=SMOOTH**

**PRINT=( <FILTER> <SMOOTH> )**

requests printing of the filtered or smoothed estimate of the slope component \( \beta_t \).

**VARIANCE=value**

specifies an initial value for the disturbance variance, \( \sigma_\xi^2 \), in the \( \beta_t \) equation at the start of the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

---

**SPLINEREG Statement**

**SPLINEREG regressor <options> ;**

The SPLINEREG statement is used to specify a regressor that has a nonlinear relationship with the dependent series that can be approximated by a given B-spline. If the specified spline has degree \( d \) and is based on \( n \) internal knots, then it is known that it can be written as a linear combination of \( (n + d + 1) \) regressors that are derived from the original regressor. The span of these \( (n + d + 1) \) derived regressors includes constant; therefore, to avoid multicollinearity with the level component, one of these regressors is dropped. Specifying the SPLINEREG statement is equivalent to specifying a RANDOMREG statement with these derived regressors. There can be multiple SPLINEREG statements. You must specify at least one interior knot, either using the NKNOTS= option or the KNOTS= option. For more information about splines, see Chapter 120, “The TRANSREG Procedure” (SAS/STAT User’s Guide). For an example of using this
statement, see Example 42.6. For additional information about the way parameter estimates are reported for this type of regressors, see the section “Reporting Parameter Estimates for Random Regressors” on page 2915.

**DEGREE=** `integer`

specifies the degree of the spline. It can be any integer larger than or equal to zero. The default value is 3. The polynomial degree should be a small integer, usually 0, 1, 2, or 3. Larger values are rarely useful. If you have any doubt as to what degree to specify, use the default.

**KNOTS=** `number-list | n TO m BY p`

specifies the interior knots or break points. The values in the knot list must be nondecreasing and must lie between the minimum and the maximum of the spline regressor values in the input data set. The first time you specify a value in the knot list, it indicates a discontinuity in the `n`th (from `DEGREE=n`) derivative of the transformation function at the value of the knot. The second mention of a value indicates a discontinuity in the `(n-1)`th derivative of the transformation function at the value of the knot. Knots can be repeated any number of times for decreasing smoothness at the break points, but the values in the knot list can never decrease.

You cannot use the **KNOTS=** option with the **NKNOTS=** option. You should keep the number of knots small.

**NKNOTS=** `m`

creates `m` knots, the first at the `100/(m + 1)` percentile, the second at the `200/(m + 1)` percentile, and so on. Knots are always placed at data values; there is no interpolation. For example, if `NKNOTS=3`, knots are placed at the 25th percentile, the median, and the 75th percentile. The value specified for the **NKNOTS=** option must be `≥ 1`. You cannot use the **NKNOTS=** option with the **KNOTS=** option.

**NOTE:** Specifying knots by using the **NKNOTS=** option can result in different sets of knots in the estimation and forecast stages if the distributions of regressor values in the estimation and forecast spans differ. The estimation span is based on the **BACK=** and **SKIPFIRST=** options in the **ESTIMATE** statement, and the forecast span is based on the **BACK=** and **SKIPFIRST=** options in the **FORECAST** statement.

**NOEST**

fixes the value of the regression coefficient random walk disturbance variance to the value specified in the **VARIANCE=** option.

**PLOT=** **FILTER**

**PLOT=** **SMOOTH**

**PLOT=( <FILTER> <SMOOTH> )**

requests plotting of filtered or smoothed estimate of the time-varying regression coefficient.

**PRINT=** **FILTER**

**PRINT=** **SMOOTH**

**PRINT=( <FILTER> <SMOOTH> )**

requests printing of filtered or smoothed estimate of the time-varying regression coefficient.
**VARIANCE=**value
specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

---

**SPLINESEASON Statement**

```
SPLINESEASON LENGTH=integer KNOTS=integer1 integer2 ... <options> ;
```

The SPLINESEASON statement is used to specify a seasonal pattern that is to be approximated by a given B-spline. If the specified spline has degree \( d \) and is based on \( n \) internal knots, then it can be written as a linear combination of \( (n + d) \) regressors that are derived from the seasonal dummy regressors. The SPLINESEASON specification is equivalent to specifying a RANDOMREG specification with these derived regressors. Such approximation is useful only if the season length is relatively large, at least larger than \( (n + d) \). For additional information about splines, see Chapter 120, “The TRANSREG Procedure” (SAS/STAT User’s Guide). For an example of using this statement, see Example 42.3.

**DEGREE=**integer
specifies the degree of the spline. It can be any integer greater than or equal to zero. The default value is 3.

**KNOTS=**integer1 integer2 ...
lists the internal knots. This list of values must be a nondecreasing sequence of integers within the range of 2 to \( (s - 1) \), where \( s \) is the season length specified in the LENGTH= option. This is a required option in this statement.

**LENGTH=**integer
specifies the season length, \( s \). This is a required option in this statement. The length can be any integer greater than or equal to three.

**NOEST**
fixes the value of the regression coefficient random walk disturbance variance to the value specified in the VARIANCE= option.

**OFFSET=**integer
specifies the position of the first measurement within the season, if the first measurement is not at the start of the season. The OFFSET= value must be between one and the season length. The default value is one. The first measurement refers to the start of the estimation span and the forecast span. If these spans differ, their starting measurements must be separated by an integer multiple of the season length.

**PLOT=**FILTER
**PLOT=**SMOOTH
**PLOT=( <FILTER> <SMOOTH> )
requests plots of the season component. When you specify only one plot request, you can omit the parentheses around the plot request. You can use the FILTER and SMOOTH options to plot the filtered and smoothed estimates of the season component.
PRINT=FILTER
PRINT=SMOOTH
PRINT=(<FILTER><SMOOTH>)
requests the printing of the filtered or smoothed estimate of the spline season component.

RKNOTS=(knot, . . . , knot) . . . (knot, . . . , knot)
specifies a grouping of knots such that the knots within the same group have identical seasonal values. The knots specified in this option must already be present in the list specified by the KNOTS= option. The knot groups must be non-overlapping and without any repeated knots.

VARIANCE=value
specifies an initial value for the regression coefficient random walk disturbance variance during the parameter estimation process. Any nonnegative value, including zero, is an acceptable starting value.

Details: UCM Procedure

An Introduction to Unobserved Component Models

A UCM decomposes the response series into components such as trend, seasons, cycles, and the regression effects due to predictor series. The following model shows a possible scenario:

$$y_t = \mu_t + \gamma_t + \psi_t + \sum_{j=1}^{m} \beta_j x_{jt} + \epsilon_t$$

$$\epsilon_t \sim \text{iid } N(0, \sigma_{\epsilon}^2)$$

The terms $\mu_t$, $\gamma_t$, and $\psi_t$ represent the trend, seasonal, and cyclical components, respectively. In fact the model can contain multiple seasons and cycles, and the seasons can be of different types. For simplicity of discussion the preceding model contains only one of each of these components. The regression term, $\sum_{j=1}^{m} \beta_j x_{jt}$, includes contribution of regression variables with fixed regression coefficients. A model can also contain regression variables that have time-varying regression coefficients or that have a nonlinear relationship with the dependent series (see “Incorporating Predictors of Different Kinds” on page 2914). The disturbance term $\epsilon_t$, also called the irregular component, is usually assumed to be Gaussian white noise. In some cases it is useful to model the irregular component as a stationary ARMA process. For additional information, see the section “Modeling the Irregular Component” on page 2906.

By controlling the presence or absence of various terms and by choosing the proper flavor of the included terms, the UCMs can generate a rich variety of time series patterns. A UCM can be applied to variables after transforming them by transforms such as $\log$ and $\text{difference}$.

The components $\mu_t$, $\gamma_t$, and $\psi_t$ model structurally different aspects of the time series. For example, the trend $\mu_t$ models the natural tendency of the series in the absence of any other perturbing effects such as seasonality, cyclical components, and the effects of exogenous variables, while the seasonal component $\gamma_t$ models the correction to the level due to the seasonal effects. These components are assumed to be statistically independent of each other and independent of the irregular component. All of the component
models can be thought of as stochastic generalizations of the relevant deterministic patterns in time. This way the deterministic cases emerge as special cases of the stochastic models. The different models available for these unobserved components are discussed next.

**Modeling the Trend**

As mentioned earlier, the trend in a series can be loosely defined as the natural tendency of the series in the absence of any other perturbing effects. The UCM procedure offers two ways to model the trend component \( \mu_t \). The first model, called the random walk (RW) model, implies that the trend remains roughly constant throughout the life of the series without any persistent upward or downward drift. In the second model the trend is modeled as a locally linear time trend (LLT). The RW model can be described as

\[
\mu_t = \mu_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma^2_{\eta})
\]

Note that if \( \sigma^2_{\eta} = 0 \), then the model becomes \( \mu_t = \text{constant} \). In the LLT model the trend is locally linear, consisting of both the level and slope. The LLT model is

\[
\begin{align*}
\mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t, \quad \eta_t \sim \text{iid } N(0, \sigma^2_{\eta}) \\
\beta_t &= \beta_{t-1} + \xi_t, \quad \xi_t \sim \text{iid } N(0, \sigma^2_{\xi})
\end{align*}
\]

The disturbances \( \eta_t \) and \( \xi_t \) are assumed to be independent. There are some interesting special cases of this model obtained by setting one or both of the disturbance variances \( \sigma^2_{\eta} \) and \( \sigma^2_{\xi} \) equal to zero. If \( \sigma^2_{\eta} \) is set equal to zero, then you get a linear trend model with fixed slope. If \( \sigma^2_{\xi} \) is set to zero, then the resulting model usually has a smoother trend. If both the variances are set to zero, then the resulting model is the deterministic linear time trend: \( \mu_t = \mu_0 + \beta_0 t \).

You can incorporate these trend patterns in your model by using the LEVEL and SLOPE statements.

**Modeling a Cycle**

A deterministic cycle \( \psi_t \) with frequency \( \lambda, 0 < \lambda < \pi \), can be written as

\[
\psi_t = \alpha \cos(\lambda t) + \beta \sin(\lambda t)
\]

If the argument \( t \) is measured on a continuous scale, then \( \psi_t \) is a periodic function with period \( 2\pi/\lambda \), amplitude \( \gamma = (\alpha^2 + \beta^2)^{1/2} \), and phase \( \phi = \tan^{-1}(\beta/\alpha) \). Equivalently, the cycle can be written in terms of the amplitude and phase as

\[
\psi_t = \gamma \cos(\lambda t - \phi)
\]

Note that when \( \psi_t \) is measured only at the integer values, it is not exactly periodic, unless \( \lambda = (2\pi j)/k \) for some integers \( j \) and \( k \). The cycles in their pure form are not used very often in practice. However, they are very useful as building blocks for more complex periodic patterns. It is well known that the periodic pattern of any complexity can be written as a sum of pure cycles of different frequencies and amplitudes. In time series situations it is useful to generalize this simple cyclical pattern to a stochastic cycle that has a fixed expected period but time-varying amplitude and phase. The stochastic cycle considered here is motivated by the following recursive formula for computing \( \psi_t \),

\[
\begin{bmatrix}
\psi_t \\
\psi_t^*
\end{bmatrix} =
\begin{bmatrix}
\cos \lambda & \sin \lambda \\
-\sin \lambda & \cos \lambda
\end{bmatrix}
\begin{bmatrix}
\psi_{t-1} \\
\psi_{t-1}^*
\end{bmatrix}
\]
starting with $\psi_0 = \alpha$ and $\psi_0^* = \beta$. Note that $\psi_t$ and $\psi_t^*$ satisfy the relation

$$\psi_t^2 + \psi_t^{*2} = \alpha^2 + \beta^2 \quad \text{for all } t$$

A stochastic generalization of the cycle $\psi_t$ can be obtained by adding random noise to this recursion and by introducing a damping factor, $\rho$, for additional modeling flexibility. This model can be described as follows,

$$
\begin{bmatrix}
\psi_t \\
\psi_t^*
\end{bmatrix} = \rho 
\begin{bmatrix}
\cos \lambda & \sin \lambda \\
-\sin \lambda & \cos \lambda
\end{bmatrix} 
\begin{bmatrix}
\psi_{t-1} \\
\psi_{t-1}^*
\end{bmatrix}
+ 
\begin{bmatrix}
v_t \\
v_t^*
\end{bmatrix}
$$

where $0 \leq \rho \leq 1$, and the disturbances $v_t$ and $v_t^*$ are independent $N(0, \sigma_v^2)$ variables. The resulting stochastic cycle has a fixed expected period but time-varying amplitude and phase. The stationarity properties of the random sequence $\psi_t$ depend on the damping factor $\rho$. If $\rho < 1$, $\psi_t$ has a stationary distribution with mean zero and variance $\sigma_v^2/(1 - \rho^2)$. If $\rho = 1$, $\psi_t$ is nonstationary.

You can incorporate a cycle in a UCM by specifying a CYCLE statement. You can include multiple cycles in the model by using separate CYCLE statements for each included cycle.

As mentioned before, the cycles are very useful as building blocks for constructing more complex periodic patterns. Periodic patterns of almost any complexity can be created by superimposing cycles of different periods and amplitudes. In particular, the seasonal patterns, general periodic patterns with integer periods, can be constructed as sums of cycles. This important topic of modeling the seasonal components is considered next.

**Modeling Seasons**

Seasonal fluctuations are a common source of variation in time series data. These fluctuations arise because of the regular changes in seasons or some other periodic events. The seasonal effects are regarded as corrections to the general trend of the series due to the seasonal variations, and these effects sum to zero when summed over the full season cycle. Therefore the seasonal component $\gamma_t$ is modeled as a stochastic periodic pattern of an integer period $s$ such that the sum $\sum_{i=0}^{s-1} \gamma_{t-i}$ is always zero in the mean. The period $s$ is called the season length. Two different models for the seasonal component are considered here. The first model is called the dummy variable form of the seasonal component. It is described by the equation

$$
\sum_{i=0}^{s-1} \gamma_{t-i} = \omega_t, \quad \omega_t \sim iid \ N(0, \sigma_\omega^2)
$$

The other model is called the trigonometric form of the seasonal component. In this case $\gamma_t$ is modeled as a sum of cycles of different frequencies. This model is given by

$$\gamma_t = \sum_{j=1}^{[s/2]} \gamma_{j,t}$$

where $[s/2]$ equals $s/2$ if $s$ is even and $(s - 1)/2$ if it is odd. The cycles $\gamma_{j,t}$ have frequencies $\lambda_j = 2\pi j/s$ and are specified by the matrix equation

$$
\begin{bmatrix}
\gamma_{j,t} \\
\gamma_{j,t}^*
\end{bmatrix} = 
\begin{bmatrix}
\cos \lambda_j & \sin \lambda_j \\
-\sin \lambda_j & \cos \lambda_j
\end{bmatrix} 
\begin{bmatrix}
\gamma_{j,t-1} \\
\gamma_{j,t-1}^*
\end{bmatrix}
+ 
\begin{bmatrix}
\omega_{j,t} \\
\omega_{j,t}^*
\end{bmatrix}
$$
where the disturbances $\omega_{j,t}$ and $\omega^*_{j,t}$ are assumed to be independent and, for fixed $j$, $\omega_{j,t}$ and $\omega^*_{j,t} \sim N(0, \sigma^2_\omega)$. If $s$ is even, then the equation for $\gamma^*_{s/2,t}$ is not needed and $\gamma_{s/2,t}$ is given by

$$\gamma_{s/2,t} = -\gamma_{s/2,t-1} + \omega_{s/2,t}$$

The cycles $\gamma_{j,t}$ are called harmonics. If the seasonal component is deterministic, the decomposition of the seasonal effects into these harmonics is identical to its Fourier decomposition. In this case the sum of squares of the seasonal factors equals the sum of squares of the amplitudes of these harmonics. In many practical situations, the contribution of the high-frequency harmonics is negligible and can be ignored, giving rise to a simpler description of the seasonal. In the case of stochastic seasonals, the situation might not be so transparent; however, similar considerations still apply. Note that if the disturbance variance $\sigma^2_\omega = 0$, then both the dummy and the trigonometric forms of seasonal components reduce to constant seasonal effects. That is, the seasonal component reduces to a deterministic function that is completely determined by its first $s - 1$ values.

In the UCM procedure you can specify a seasonal component in a variety of ways, the `SEASON` statement being the simplest of these. The dummy and the trigonometric seasonal components discussed so far can be considered as saturated seasonal components that put no restrictions on the $s - 1$ seasonal values. In some cases a more parsimonious representation of the seasonal might be more appropriate. This is particularly useful for seasonal components with large season lengths. In the UCM procedure you can obtain parsimonious representations of the seasonal components by one of the following ways:

- Use a subset trigonometric seasonal component obtained by deleting a few of the $[s/2]$ harmonics used in its sum. For example, a slightly smoother seasonal component of length 12, corresponding to the monthly seasonality, can be obtained by deleting the highest-frequency harmonic of period 2. That is, such a seasonal component will be a sum of five stochastic cycles that have periods 12, 6, 4, 3, and 2.4. You can specify such subset seasonal components by using the `KEEPH=` or `DROPH=` option in the `SEASON` statement.

- Approximate the seasonal pattern by a suitable spline approximation. You can do this by using the `SPLINESEASON` statement.

- A block-seasonal pattern is a seasonal pattern where the pattern is divided into a few blocks of equal length such that the season values within a block are the same—for example, a monthly seasonal pattern that has only four different values, one for each quarter. In some situations a long seasonal pattern can be approximated by the sum of block season and a simple season, the length of the simple season being equal to the block length of the block season. You can obtain such approximation by using a combination of `BLOCKSEASON` and `SEASON` statements.

- Consider a seasonal component of a large season length as a sum of two or more seasonal components that are each of much smaller season lengths. This can be done by specifying more than one `SEASON` statements.

Note that the preceding techniques of obtaining parsimonious seasonal components can also enable you to specify seasonal components that are more general than the simple saturated seasonal components. For example, you can specify a saturated trigonometric seasonal component that has some of its harmonics evolving according to one disturbance variance parameter while the others evolve with another disturbance variance parameter.
Chapter 42: The UCM Procedure

Modeling an Autoregression

An autoregression of order one can be thought of as a special case of a cycle when the frequency $\lambda$ is either 0 or $\pi$. Modeling this special case separately helps interpretation and parameter estimation. The autoregression component $r_t$ is modeled as

$$r_t = \rho r_{t-1} + v_t, \quad v_t \sim \text{iid } N(0, \sigma_v^2)$$

where $-1 \leq \rho < 1$. An autoregression can also provide an alternative to the IRREGULAR component when the model errors show some autocorrelation. You can incorporate an autoregression in your model by using the AUTOREG statement.

Modeling Regression Effects

A predictor variable can affect the response variable in a variety of ways. The UCM procedure enables you to model several different types of predictor-response relationships:

- The predictor-response relationship is **linear**, and the regression coefficient does not change with time. This is the simplest kind of relationship and such predictors are specified in the MODEL statement.

- The predictor-response relationship is **linear**, but the regression coefficient does change with time. Such predictors are specified in the RANDOMREG statement. Here the regression coefficient is assumed to evolve as a random walk.

- The predictor-response relationship is **nonlinear** and the relationship can change with time. This type of relationship can be approximated by an appropriate time-varying spline. Such predictors are specified in the SPLINEREG statement.

A response variable can depend on its own past values—that is, lagged dependent values. Such a relationship can be specified in the DEPLAG statement.

Modeling the Irregular Component

The components—such as trend, seasonal and regression effects, and nonstationary cycles—are used to capture the structural dynamics of a response series. In contrast, the stationary cycles and the autoregression are used to capture the transient aspects of the response series that are important for its short-range prediction but have little impact on its long-term forecasts. The irregular component represents the residual variation remaining in the response series that is modeled using an appropriate selection of structural and transient effects. In most cases, the irregular component can be assumed to be simply Gaussian white noise. In some other cases, however, the residual variation can be more complicated. In such situations, it might be necessary to model the irregular component as a stationary ARMA process. Moreover, you can use the ARMA irregular component together with the dependent lag specification (see the DEPLAG statement) to specify an ARIMA($p,d,q$)×$(P,D,Q)_s$ model for the response series. For an explanation of the ARIMA notation, see the IRREGULAR statement. For an example of modeling a series by using an ARIMA(0,1,1)×(0,1,1)$_{12}$ model, see Example 42.8.
The Model Parameters

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression, and the regression coefficients in the regression terms. These parameters are estimated by maximizing the likelihood. It is possible to restrict the values of the model parameters to user-specified values.

Model Specification

A UCM is specified by describing the components in the model. For example, consider the model

\[ y_t = \mu_t + \gamma_t + \epsilon_t \]

consisting of the irregular, level, slope, and seasonal components. This model is called the basic structural model (BSM) by Harvey (1989). The syntax for a BSM with monthly seasonality of trigonometric type is as follows:

```
model y;
irregular;
level;
slope;
season length=12 type=trig;
```

Similarly, the following syntax specifies a BSM with a response variable \( y \), a regressor \( x \), and dummy-type monthly seasonality:

```
model y = x;
irregular;
level;
slope variance=0 noest;
season length=12 type=dummy;
```

Moreover, the disturbance variance of the slope component is restricted to zero, giving rise to a local linear trend with fixed slope.

A model can contain multiple cycle and seasonal components. In such cases the model syntax contains a separate statement for each of these multiple cycle or seasonal components; for example, the syntax for a model containing irregular and level components along with two cycle components could be as follows:

```
model y = x;
irregular;
level;
cycle;
cycle;
```
The UCMs as State Space Models

The UCMs considered in PROC UCM can be thought of as special cases of more general models, called (linear) Gaussian state space models (GSSM). A GSSM can be described as follows:

\[ y_t = Z_t \alpha_t \]
\[ \alpha_{t+1} = T_t \alpha_t + \zeta_t + 1, \quad \zeta_t \sim \mathcal{N}(0, Q_t) \]
\[ \alpha_1 \sim \mathcal{N}(0, P) \]

The first equation, called the observation equation, relates the response series \( y_t \) to a state vector \( \alpha_t \) that is usually unobserved. The second equation, called the state equation, describes the evolution of the state vector in time. The system matrices \( Z_t \) and \( T_t \) are of appropriate dimensions and are known, except possibly for some unknown elements that become part of the parameter vector of the model. The noise series \( \zeta_t \) consists of independent, zero-mean, Gaussian vectors with covariance matrices \( Q_t \). For most of the UCMs considered here, the system matrices \( Z_t \) and \( T_t \), and the noise covariances \( Q_t \), are time invariant—that is, they do not depend on time. In a few cases, however, some or all of them can depend on time. The initial state vector \( \alpha_1 \) is assumed to be independent of the noise series, and its covariance matrix \( P \) can be partially diffuse. A random vector has a partially diffuse covariance matrix if it can be partitioned such that one part of the vector has a properly defined probability distribution, while the covariance matrix of the other part is infinite—that is, you have no prior information about this part of the vector. The covariance of the initial state \( \alpha_1 \) is assumed to have the form

\[ P = P_\ast + \kappa P_\infty \]

where \( P_\ast \) and \( P_\infty \) are nonnegative definite, symmetric matrices and \( \kappa \) is a constant that is assumed to be close to \( \infty \). In the case of UCMs considered here, \( P_\infty \) is always a diagonal matrix that consists of zeros and ones, and, if a particular diagonal element of \( P_\infty \) is one, then the corresponding row and column in \( P_\ast \) are zero.

The state space formulation of a UCM has many computational advantages. In this formulation there are convenient algorithms for estimating and forecasting the unobserved states \( \{\alpha_t\} \) by using the observed series \( \{y_t\} \). These algorithms also yield the in-sample and out-of-sample forecasts and the likelihood of \( \{y_t\} \). The state space representation of a UCM does not need to be unique. In the representation used here, the unobserved components in the UCM often appear as elements of the state vector. This makes the elements of the state interpretable and, more important, the sample estimates and forecasts of these unobserved components are easily obtained. For additional information about the computational aspects of the state space modeling, see Durbin and Koopman (2001). Next, some notation is developed to describe the essential quantities computed during the analysis of the state space models.

Let \( \{y_t, t = 1, \ldots, n\} \) be the observed sample from a series that satisfies a state space model. Next, for \( 1 \leq t \leq n \), let the one-step-ahead forecasts of the series, the states, and their variances be defined as follows, using the usual notation to denote the conditional expectation and conditional variance:

\[ \hat{\alpha}_t = \text{E}(\alpha_t | y_1, y_2, \ldots, y_{t-1}) \]
\[ \Gamma_t = \text{Var}(\alpha_t | y_1, y_2, \ldots, y_{t-1}) \]
\[ \hat{y}_t = \text{E}(y_t | y_1, y_2, \ldots, y_{t-1}) \]
\[ F_t = \text{Var}(y_t | y_1, y_2, \ldots, y_{t-1}) \]
These are also called the filtered estimates of the series and the states. Similarly, for \( t \geq 1 \), let the following denote the full-sample estimates of the series and the state values at time \( t \):

\[
\tilde{\alpha}_t = E(\alpha_t | y_1, y_2, \ldots, y_n) \\
\Delta_t = \text{Var}(\alpha_t | y_1, y_2, \ldots, y_n) \\
\tilde{y}_t = E(y_t | y_1, y_2, \ldots, y_n) \\
G_t = \text{Var}(y_t | y_1, y_2, \ldots, y_n)
\]

If the time \( t \) is in the historical period—that is, if \( 1 \leq t \leq n \)—then the full-sample estimates are called the smoothed estimates, and if \( t \) lies in the future then they are called out-of-sample forecasts. Note that if \( 1 \leq t \leq n \), then \( \tilde{y}_t = y_t \) and \( G_t = 0 \), unless \( y_t \) is missing.

All the filtered and smoothed estimates (\( \tilde{\alpha}_t, \tilde{\alpha}_t, \ldots, G_t \), and so on) are computed by using the Kalman filtering and smoothing (KFS) algorithm, which is an iterative process. If the initial state is diffuse, as is often the case for the UCMs, its treatment requires modification of the traditional KFS, which is called the diffuse KFS (DKFS). The details of DKFS implemented in the UCM procedure can be found in De Jong and Chu-Chun-Lin (2003). Additional information on the state space models can be found in Durbin and Koopman (2001). The likelihood formulas described in this section are taken from the latter reference.

In the case of diffuse initial condition, the effect of the improper prior distribution of \( \alpha_1 \) manifests itself in the first few filtering iterations. During these initial filtering iterations the distribution of the filtered quantities remains diffuse; that is, during these iterations the one-step-ahead series and state forecast variances \( F_t \) and \( \Gamma_t \) have the following form:

\[
F_t = F^* + \kappa F_{\infty} \\
\Gamma_t = \Gamma^* + \kappa \Gamma_{\infty}
\]

The actual number of iterations—for example, \( I \)—affected by this improper prior depends on the nature of the vectors \( Z_t \), the number of nonzero diagonal elements of \( P_{\infty} \), and the pattern of missing values in the dependent series. After \( I \) iterations, \( \Gamma_{\infty} \) and \( F_{\infty} \) become zero and the one-step-ahead series and state forecasts have proper distributions. These first \( I \) iterations constitute the initialization phase of the DKFS algorithm. The post-initialization phase of the DKFS and the traditional KFS is the same. In the state space modeling literature the pre-initialization and post-initialization phases are sometimes called pre-collapse and post-collapse phases of the diffuse Kalman filtering. In certain missing value patterns it is possible for \( I \) to exceed the sample size; that is, the sample information can be insufficient to create a proper prior for the filtering process. In these cases, parameter estimation and forecasting is done on the basis of this improper prior, and some or all of the series and component forecasts can have infinite variances (or zero precision). The forecasts that have infinite variance are set to missing. The same situation can occur if the specified model contains components that are essentially multicollinear. In these situations no residual analysis is possible; in particular, no residuals-based goodness-of-fit statistics are produced.

The log likelihood of the sample (\( L_{\infty} \)), which takes account of this diffuse initialization step, is computed by using the one-step-ahead series forecasts as follows,

\[
L_{\infty}(y_1, \ldots, y_n) = -\frac{(n - d)}{2} \log 2\pi - \frac{1}{2} \sum_{t=1}^{I} w_t - \frac{1}{2} \sum_{t=I+1}^{n} \left( \log F_t + \frac{v_t^2}{F_t} \right)
\]
where $d$ is the number of diffuse elements in the initial state $\alpha_1$, $\nu_t = y_t - Z_t \hat{\alpha}_t$ are the one-step-ahead residuals, and

$$
\begin{align*}
    w_t &= \log F_{\infty} & \text{if } F_{\infty} > 0 \\
    &= \log F_{st} + \frac{\nu_t^2}{F_{st}} & \text{if } F_{\infty} = 0
\end{align*}
$$

If $y_t$ is missing at some time $t$, then the corresponding summand in the log likelihood expression is deleted, and the constant term is adjusted suitably. Moreover, if the initialization step does not complete—that is, if $I$ exceeds the sample size—then the value of $d$ is reduced to the number of diffuse states that are successfully initialized.

The portion of the log likelihood that corresponds to the post-initialization period is called the nondiffuse log likelihood ($L_0$). The nondiffuse log likelihood is given by

$$
L_0(y_1, \ldots, y_n) = -\frac{1}{2} \sum_{t=I+1}^{n} \left( \log F_t + \frac{\nu_t^2}{F_t} \right)
$$

In the case of UCMs considered in PROC UCM, it often happens that the diffuse part of the likelihood, $\sum_{t=1}^I w_t$, does not depend on the model parameters, and in these cases the maximization of nondiffuse and diffuse likelihoods is equivalent. However, in some cases, such as when the model consists of dependent lags, the diffuse part does depend on the model parameters. In these cases the maximization of the diffuse and nondiffuse likelihood can produce different parameter estimates.

In some situations it is convenient to reparameterize the nondiffuse initial state covariance $P_*$ as $\sigma^2 P_*$ and the state noise covariance $Q_t$ as $\sigma^2 Q_t$ for some common scalar parameter $\sigma^2$. In this case the preceding log-likelihood expression, up to a constant, can be written as

$$
L_\infty(y_1, \ldots, y_n) = -\frac{1}{2} \sum_{t=1}^{I} w_t - \frac{1}{2} \sum_{t=I+1}^{n} \log F_t - \frac{1}{2\sigma^2} \sum_{t=I+1}^{n} \frac{\nu_t^2}{F_t} - \frac{(n-d)}{2} \log \sigma^2
$$

Solving analytically for the optimum, the maximum likelihood estimate of $\sigma^2$ can be shown to be

$$
\hat{\sigma}^2 = \frac{1}{(n-d)} \sum_{t=I+1}^{n} \frac{\nu_t^2}{F_t}
$$

When this expression of $\sigma^2$ is substituted back into the likelihood formula, an expression called the profile likelihood ($L_{\text{profile}}$) of the data is obtained:

$$
-2L_{\text{profile}}(y_1, \ldots, y_n) = \sum_{t=1}^{I} w_t + \sum_{t=I+1}^{n} \log F_t + (n-d) \log\left( \sum_{t=I+1}^{n} \frac{\nu_t^2}{F_t} \right)
$$

In some situations the parameter estimation is done by optimizing the profile likelihood (see the section “Parameter Estimation by Profile Likelihood Optimization” on page 2918 and the PROFILE option in the ESTIMATE statement).

In the remainder of this section the state space formulation of UCMs is further explained by using some particular UCMs as examples. The examples show that the state space formulation of the UCMs depends
The UCMs as State Space Models

on the components in the model in a simple fashion; for example, the system matrix $T$ is usually a block diagonal matrix with blocks that correspond to the components in the model. The only exception to this pattern is the UCMs that consist of the lags of dependent variable. This case is considered at the end of the section.

In what follows, $\text{Diag} \left[ \xi_1, \xi_2, \ldots \right]$ denotes a diagonal matrix with diagonal entries $\left[ \xi_1, \xi_2, \ldots \right]$, and the transpose of a matrix $T$ is denoted as $T^\top$.

**Locally Linear Trend Model**

Recall that the dynamics of the locally linear trend model are

$$
\begin{align*}
    y_t &= \mu_t + \epsilon_t \\
    \mu_t &= \mu_{t-1} + \beta_{t-1} + \eta_t \\
    \beta_t &= \beta_{t-1} + \xi_t
\end{align*}
$$

Here $y_t$ is the response series and $\epsilon_t, \eta_t, \text{and } \xi_t$ are independent, zero-mean Gaussian disturbance sequences with variances $\sigma^2_{\epsilon}, \sigma^2_{\eta}, \text{and } \sigma^2_{\xi}$, respectively. This model can be formulated as a state space model where the state vector $\alpha_t = [ \epsilon_t \ \mu_t \ \beta_t ]$ and the state noise $\zeta_t = [ \epsilon_t \ \eta_t \ \xi_t ]$. Note that the elements of the state vector are precisely the unobserved components in the model. The system matrices $T$ and $Z$ and the noise covariance $Q$ corresponding to this choice of state and state noise vectors can be seen to be time invariant and are given by

$$
Z = \begin{bmatrix} 1 & 1 & 0 \end{bmatrix}, \quad T = \begin{bmatrix} 0 & 0 & 0 \\ 0 & 1 & 1 \\ 0 & 0 & 1 \end{bmatrix} \quad \text{and } Q = \text{Diag} \left[ \sigma^2_{\epsilon}, \sigma^2_{\eta}, \sigma^2_{\xi} \right]
$$

The distribution of the initial state vector $\alpha_1$ is diffuse, with $P_\bullet = \text{Diag} \left[ \sigma^2_{\epsilon}, 0, 0 \right]$ and $P_\infty = \text{Diag} \left[ 0, 1, 1 \right]$. The parameter vector $\theta$ consists of all the disturbance variances—that is, $\theta = (\sigma^2_{\epsilon}, \sigma^2_{\eta}, \sigma^2_{\xi})$.

**Basic Structural Model**

The basic structural model (BSM) is obtained by adding a seasonal component, $\gamma_t$, to the local level model. In order to economize on the space, the state space formulation of a BSM with a relatively short season length, season length = 4 (quarterly seasonality), is considered here. The pattern for longer season lengths such as 12 (monthly) and 52 (weekly) is easy to see.

Let us first consider the dummy form of seasonality. In this case the state and state noise vectors are $\alpha_t = [ \epsilon_t \ \mu_t \ \beta_t \ \gamma_{1,t} \ \gamma_{2,t} \ \gamma_{3,t} ]$ and $\zeta_t = [ \epsilon_t \ \eta_t \ \xi_t \ \omega_t \ 0 \ 0 ]$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{1,t}, \gamma_{2,t}$, are lagged versions of the seasonal component $\gamma_t$. $\gamma_{1,t}$ corresponds to lag zero—that is, the same as $\gamma_t$, $\gamma_{2,t}$ to lag 1 and $\gamma_{3,t}$ to lag 2. The system matrices are

$$
Z = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 0 \end{bmatrix}, \quad T = \\
\begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 1 & 1 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & -1 & -1 & -1 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 1 & 0 
\end{bmatrix}
$$
and $Q = \text{Diag} \left[ \sigma_e^2, \sigma_n^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0 \right]$. The distribution of the initial state vector $\alpha_1$ is diffuse, with $P_\star = \text{Diag} \left[ \sigma_e^2, 0, 0, 0, 0, 0 \right]$ and $P_\infty = \text{Diag} \left[ 0, 1, 1, 1, 1 \right]$.

In the case of the trigonometric type of seasonality, $\alpha_t = \left[ \epsilon_t \ \mu_t \ \beta_t \ \gamma_{1,t}^* \ \gamma_{2,t}^* \right]'$ and $\zeta_t = \left[ \epsilon_t \ \eta_t \ \xi_t \ \omega_{1,t}^* \ \omega_{2,t}^* \right]'$. The disturbance sequences, $\omega_{j,t}, 1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance $\sigma_\omega^2$. The system matrices are

$$Z = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 1 \end{bmatrix}, \quad T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\ 0 & 0 & 0 & 0 & 0 & \cos \lambda_2 \\ 0 & 0 & 0 & 0 & 0 & 0 \end{bmatrix}$$

and $Q = \text{Diag} \left[ \sigma_e^2, \sigma_n^2, \sigma_\xi^2, \sigma_\omega^2, \sigma_\omega^2, \sigma_\omega^2 \right]$. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector $\alpha_1$ is diffuse, with $P_\star = \text{Diag} \left[ \sigma_e^2, 0, 0, 0, 0, 0 \right]$ and $P_\infty = \text{Diag} \left[ 0, 1, 1, 1, 1 \right]$. The parameter vector in both the cases is $\theta = (\sigma_e^2, \sigma_n^2, \sigma_\xi^2, \sigma_\omega^2)$.

**Seasons with Blocked Seasonal Values**

*Block seasonals* are special seasonal components that impose a special block structure on the seasonal effects. Let us consider a BSM with monthly seasonality that has a quarterly block structure—that is, months within the same quarter are assumed to have identical effects except for some random perturbation. Such a seasonal component is a block seasonal with block size $m$ equal to 3 and the number of blocks $k$ equal to 4. The state space structure for such a model with dummy-type seasonality is as follows: The state and state noise vectors are $\alpha_t = \left[ \epsilon_t \ \mu_t \ \beta_t \ \gamma_{1,t} \ \gamma_{2,t} \ \gamma_{3,t} \right]'$ and $\zeta_t = \left[ \epsilon_t \ \eta_t \ \xi_t \ \omega_t \ 0 \ 0 \right]'$, respectively. The first three elements of the state vector are the irregular, level, and slope components, respectively. The remaining elements, $\gamma_{i,t}$, are lagged versions of the seasonal component $\gamma_t$. $\gamma_{1,t}$ corresponds to lag zero—that is, the same as $\gamma_t$, $\gamma_{2,t}$ to lag $m$ and $\gamma_{3,t}$ to lag $2m$. All the system matrices are time invariant, except the matrix $T$. They can be seen to be $Z = \begin{bmatrix} 1 & 1 & 0 & 1 & 0 & 0 \end{bmatrix}$, $Q = \text{Diag} \left[ \sigma_e^2, \sigma_n^2, \sigma_\xi^2, \sigma_\omega^2, 0, 0 \right]$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & -1 & -1 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \end{bmatrix}$$

when $t$ is a multiple of the block size $m$, and

$$T_t = \begin{bmatrix} 0 & 0 & 0 & 0 & 0 & 0 \\ 0 & 1 & 1 & 0 & 0 & 0 \\ 0 & 0 & 1 & 0 & 0 & 0 \\ 0 & 0 & 0 & 1 & 0 & 0 \\ 0 & 0 & 0 & 0 & 1 & 0 \\ 0 & 0 & 0 & 0 & 0 & 1 \end{bmatrix}$$
The UCMs as State Space Models

otherwise. Note that when $t$ is not a multiple of $m$, the portion of the $T_t$ matrix corresponding to the seasonal is identity. The distribution of the initial state vector $\alpha_1$ is diffuse, with $P_* = \text{Diag}[\sigma^2_\xi, 0, 0, 0, 0, 0]$ and $P_{\infty} = \text{Diag}[0, 1, 1, 1, 1, 1]$.

Similarly, in the case of the trigonometric form of seasonality, $\alpha_t = \left[ \epsilon_t, \mu_t, \beta_t, \gamma_{1,t}, \gamma_{1,t}^*, \gamma_{2,t} \right]^\top$ and $\zeta_t = \left[ \epsilon_t, \eta_t, \xi_t, \omega_{1,t}, \omega_{1,t}^*, \omega_{2,t} \right]^\top$. The disturbance sequences, $\omega_{j,t}, 1 \leq j \leq 2$, and $\omega_{1,t}^*$, are independent, zero-mean, Gaussian sequences with variance $\sigma^2_{\omega}$. $Z = [1 \ 1 \ 0 \ 1 \ 0 \ 1]$, $Q = \text{Diag}[\sigma^2_\xi, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega, \sigma^2_\omega, \sigma^2_\omega]$, and

$$T_t = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \cos \lambda_1 \\
0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\
0 & 0 & 0 & 0 & 0 & \cos \lambda_2
\end{bmatrix}$$

when $t$ is a multiple of the block size $m$, and

$$T_t = \begin{bmatrix}
0 & 0 & 0 & 0 & 0 & 0 \\
0 & 0 & 1 & 0 & 0 & 0 \\
0 & 0 & 0 & 1 & 0 & 0 \\
0 & 0 & 0 & 0 & 0 & \cos \lambda_1 \\
0 & 0 & 0 & -\sin \lambda_1 & \cos \lambda_1 & 0 \\
0 & 0 & 0 & 0 & 0 & \cos \lambda_2
\end{bmatrix}$$

otherwise. As before, when $t$ is not a multiple of $m$, the portion of the $T_t$ matrix corresponding to the seasonal is identity. Here $\lambda_j = (2\pi j)/4$. The distribution of the initial state vector $\alpha_1$ is diffuse, with $P_* = \text{Diag}[\sigma^2_\xi, 0, 0, 0, 0, 0]$ and $P_{\infty} = \text{Diag}[0, 1, 1, 1, 1, 1]$. The parameter vector in both the cases is $\theta = (\sigma^2_\xi, \sigma^2_\eta, \sigma^2_\xi, \sigma^2_\omega)$.

Cycles and Autoregression

The preceding examples have illustrated how to build a state space model corresponding to a UCM that includes components such as irregular, trend, and seasonal. There you can see that the state vector and the system matrices have a simple block structure with blocks corresponding to the components in the model. Therefore, here only a simple model consisting of a single cycle and an irregular component is considered. The state space form for more complex UCMs consisting of multiple cycles and other components can be easily deduced from this example.

Recall that a stochastic cycle $\psi_t$ with frequency $\lambda$, $0 < \lambda < \pi$, and damping coefficient $\rho$ can be modeled as

$$\begin{bmatrix}
\psi_t \\
\psi_t^*
\end{bmatrix} = \rho \begin{bmatrix}
\cos \lambda & \sin \lambda \\
-\sin \lambda & \cos \lambda
\end{bmatrix} \begin{bmatrix}
\psi_{t-1} \\
\psi_{t-1}^*
\end{bmatrix} + \begin{bmatrix}
v_t \\
v_t^*
\end{bmatrix}$$

where $v_t$ and $v_t^*$ are independent, zero-mean, Gaussian disturbances with variance $\sigma^2_v$. In what follows, a state space form for a model consisting of such a stochastic cycle and an irregular component is given.

The state vector $\alpha_t = \left[ \epsilon_t, \psi_t, \psi_t^* \right]^\top$, and the state noise vector $\zeta_t = \left[ \epsilon_t, v_t, v_t^* \right]^\top$. The system matrices are

$$Z = [1 \ 1 \ 0] \quad T = \begin{bmatrix}
0 & 0 & 0 \\
0 & \rho \cos \lambda & \rho \sin \lambda \\
0 & -\rho \sin \lambda & \rho \cos \lambda
\end{bmatrix} \quad Q = \text{Diag}[\sigma^2_\epsilon, \sigma^2_\psi, \sigma^2_v]$$
The distribution of the initial state vector $\alpha_1$ is proper, with $P_* = \text{Diag} \left[ \sigma_{\varepsilon}^2, \sigma_{\psi}^2, \sigma_{\xi}^2 \right]$, where $\sigma_{\psi}^2 = \sigma_{\psi}^2 (1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_{\varepsilon}^2, \rho, \lambda, \sigma_{\xi}^2)$.

An autoregression $r_t$ can be considered as a special case of cycle with frequency $\lambda$ equal to 0 or $\pi$. In this case the equation for $\psi_t^*$ is not needed. Therefore, for a UCM consisting of an autoregressive component and an irregular component, the state space model simplifies to the following form.

The state vector $\alpha_t = [ \epsilon_t \ r_t ]'$, and the state noise vector $\xi_t = [ \epsilon_t \ \nu_t ]'$. The system matrices are

$$Z = \begin{bmatrix} 1 & 1 \end{bmatrix}, \quad T = \begin{bmatrix} 0 & 0 \\ 0 & \rho \end{bmatrix} \quad \text{and} \quad Q = \text{Diag} \left[ \sigma_{\epsilon}^2, \sigma_{\nu}^2 \right]$$

The distribution of the initial state vector $\alpha_1$ is proper, with $P_* = \text{Diag} \left[ \sigma_{\epsilon}^2, \sigma_{\nu}^2 \right]$, where $\sigma_{\nu}^2 = \sigma_{\nu}^2 (1 - \rho^2)^{-1}$. The parameter vector $\theta = (\sigma_{\epsilon}^2, \rho, \sigma_{\nu}^2)$.

**Incorporating Predictors of Different Kinds**

In the UCM procedure, predictors can be incorporated in a UCM in a variety of ways: simple time-invariant linear predictors are specified in the MODEL statement, predictors with time-varying coefficients can be specified in the RANDOMREG statement, and predictors that have a nonlinear relationship with the response variable can be specified in the SPLINEREG statement. As with earlier examples, how to obtain a state space form of a UCM consisting of such variety of predictors is illustrated using a simple special case. Consider a random walk trend model with predictors $x, u_1, u_2,$ and $v$. Assume that $x$ is a simple regressor specified in the MODEL statement, $u_1$ and $u_2$ are random regressors with time-varying regression coefficients that are specified in the same RANDOMREG statement, and $v$ is a nonlinear regressor specified on a SPLINEREG statement. Further assume that the spline associated with $v$ has degree one and is based on two internal knots. As explained in the section “SPLINEREG Statement” on page 2899, using $v$ is equivalent to using $(n \text{ knots} + \text{degree}) = (2 + 1) = 3$ derived (random) regressors: for example, $s_1, s_2, s_3$. In all there are $(1 + 2 + 3) = 6$ regressors, the first one being a simple regressor and the others being time-varying coefficient regressors. The time-varying regressors are in two groups, the first consisting of $u_1$ and $u_2$ and the other consisting of $s_1, s_2$, and $s_3$. The dynamics of this model are as follows:

$$y_t = \mu_t + \beta x_t + \kappa_{1t} u_{1t} + \kappa_{2t} u_{2t} + \sum_{i=1}^{3} \gamma_{lt} s_{lt} + \epsilon_t$$

$$\mu_t = \mu_{t-1} + \eta_t$$

$$\kappa_{1t} = \kappa_{1(t-1)} + \xi_{1t}$$

$$\kappa_{2t} = \kappa_{2(t-1)} + \xi_{2t}$$

$$\gamma_{1t} = \gamma_{1(t-1)} + \zeta_{1t}$$

$$\gamma_{2t} = \gamma_{2(t-1)} + \zeta_{2t}$$

$$\gamma_{3t} = \gamma_{3(t-1)} + \zeta_{3t}$$

All the disturbances $\epsilon_t, \eta_t, \xi_{1t}, \xi_{2t}, \xi_{1t}, \xi_{2t},$ and $\xi_{3t}$ are independent, zero-mean, Gaussian variables, where $\xi_{1t}, \xi_{2t}$ share a common variance parameter $\sigma_{\xi}^2$ and $\xi_{1t}, \xi_{2t}, \xi_{3t}$ share a common variance $\sigma_{\xi}^2$. These dynamics can be captured in the state space form by taking state $\alpha_t = [ \epsilon_t \ \mu_t \ \beta \ \kappa_{1t} \ \kappa_{2t} \ \gamma_{1t} \ \gamma_{2t} \ \gamma_{3t} ]'$, state
The UCMs as State Space Models

The disturbance \[ \zeta_t = [ \epsilon_t \ \eta_t \ 0 \ \xi_{1t} \ \xi_{2t} \ \xi_{1t} \ \xi_{2t} \ \xi_{3t} ]' \], and the system matrices

\[
Z_t = \begin{bmatrix} 1 & 1 & x_t & u_{1t} & u_{2t} & s_{1t} & s_{2t} & s_{3t} \end{bmatrix}
\]

\[ T = \text{Diag}[0, 1, 1, 1, 1, 1, 1, 1] \]

\[ Q = \text{Diag} \left[ \sigma^2_{\epsilon}, \sigma^2_{\eta}, 0, \sigma^2_{\xi_1}, \sigma^2_{\xi_2}, \sigma^2_{\xi_3} \right] \]

Note that the regression coefficients are elements of the state vector and that the system vector \( Z_t \) is not time invariant. The distribution of the initial state vector \( \alpha_1 \) is diffuse, with \( P_* = \text{Diag} \left[ \sigma^2_{\epsilon}, 0, 0, 0, 0, 0, 0, 0 \right] \) and \( P_\infty = \text{Diag} \left[ 0, 1, 1, 1, 1, 1, 1, 1 \right] \). The parameters of this model are the disturbance variances, \( \sigma^2_{\epsilon}, \sigma^2_{\eta}, \sigma^2_{\xi_1}, \sigma^2_{\xi_2}, \sigma^2_{\xi_3} \), which get estimated by maximizing the likelihood. The regression coefficients, time-invariant \( \beta \) and time-varying \( \kappa_{1t}, \kappa_{2t}, \gamma_{1t}, \gamma_{2t}, \gamma_{3t}, \) get implicitly estimated during the state estimation (smoothing).

**Reporting Parameter Estimates for Random Regressors**

If the random walk disturbance variance associated with a random regressor is held fixed at zero, then its coefficient is no longer time-varying. In the UCM procedure the random regressor parameter estimates are reported differently if the random walk disturbance variance associated with a random regressor is held fixed at zero. The following points explain how the parameter estimates are reported in the parameter estimates table and in the OUTEST= data set:

- If the random walk disturbance variance associated with a random regressor is not held fixed, then its estimate is reported in the parameter estimates table and in the OUTEST= data set.
- If more that one random regressor is specified in a RANDOMREG statement, then the first regressor in the list is used as a representative of the list while reporting the corresponding common variance parameter estimate.
- If the random walk disturbance variance is held fixed at zero, then the parameter estimates table and the OUTEST= data set contain the corresponding regression parameter estimate rather than the variance parameter estimate.
- Similar considerations apply in the case of the derived random regressors associated with a spline-regressor.

**Forecasting with Predictor Variables**

If regression effects are included in the model (via a MODEL statement or RANDOMREG and SPLINEREG statements) and the FORECAST statement is used to compute multistep forecasts, then future values of the predictor variables must be included in the DATA= data set for the forecast horizon that is defined by the BACK= and LEAD= options. For more information about how the forecast horizon is defined, see the FORECAST statement.

**ARMA Irregular Component**

The state space form for the irregular component that follows an ARMA\((p,q)\times(P,Q)\)s model is described in this section. The notation for ARMA models is explained in the IRREGULAR statement. A number of alternate state space forms are possible in this case; the one given here is based on Jones (1980). With slight abuse of notation, let \( p = p + sP \) denote the effective autoregressive order and \( q = q + sQ \) denote the effective moving average order of the model. Similarly, let \( \phi \) be the effective autoregressive polynomial...
and $\theta$ be the effective moving average polynomial in the backshift operator with coefficients $\phi_1, \ldots, \phi_p$ and $\theta_1, \ldots, \theta_q$, obtained by multiplying the respective nonseasonal and seasonal factors. Then, a random sequence $\epsilon_t$ that follows an ARMA($p,q$) model with a white noise sequence $a_t$ has a state space form with state vector of size $m = \max(p,q+1)$. The system matrices, which are time invariant, are as follows: $Z = [1 \ 0 \ \ldots \ 0]$. The state transition matrix $T$, in a blocked form, is given by

$$T = \begin{bmatrix} 0 & I_{m-1} \\
\phi_m & \ldots & \phi_1 \end{bmatrix}$$

where $\phi_i = 0$ if $i > p$ and $I_{m-1}$ is an $(m-1)$ dimensional identity matrix. The covariance of the state disturbance matrix $Q = \sigma^2 \psi \psi'$ where $\sigma^2$ is the variance of the white noise sequence $a_t$ and the vector $\psi = [\psi_0 \ \ldots \ \psi_{m-1}]$ contains the first $m$ values of the impulse response function—that is, the first $m$ coefficients in the expansion of the ratio $\theta/\phi$. Since $\epsilon_t$ is a stationary sequence, the initial state is nondiffuse and $P_\infty = 0$. The description of $P_*$, the covariance matrix of the initial state, is a little involved; the details are given in Jones (1980).

### Models with Dependent Lags

The state space form of a UCM consisting of the lags of the dependent variable is quite different from the state space forms considered so far. Let us consider an example to illustrate this situation. Consider a model that has random walk trend, two simple time-invariant regressors, and that also includes a few—for example, $k$—lags of the dependent variable. That is,

$$y_t = \sum_{i=1}^{k} \phi_i y_{t-i} + \mu_t + \beta_1 x_{1t} + \beta_2 x_{2t} + \epsilon_t$$

$$\mu_t = \mu_{t-1} + \eta_t$$

The state space form of this augmented model can be described in terms of the state space form of a model that has random walk trend with two simple time-invariant regressors. A superscript dagger (†) has been added to distinguish the augmented model state space entities from the corresponding entities of the state space form of the random walk with predictors model. With this notation, the state vector of the augmented model $\alpha_t^† = \left[ \alpha_t' \ y_t \ y_{t-1} \ \ldots \ y_{t-k+1} \right]'$ and the new state noise vector $\xi_t^† = \left[ \xi_t' \ u_t \ 0 \ \ldots \ 0 \right]'$, where $u_t$ is the matrix product $Z_t \xi_t$. Note that the length of the new state vector is $k + \text{length}(\alpha_t) = k + 4$. The new system matrices, in block form, are

$$Z_t^† = \begin{bmatrix} 0 & 0 & 0 & 0 & 1 & \ldots & 0 \end{bmatrix}, \quad T_t^† = \begin{bmatrix} T_t & 0 & \ldots & 0 \\
Z_{t+1} & T_t & \phi_1 & \ldots & \phi_k \\
0 & I_{k-1,k-1} & 0 \end{bmatrix}$$

where $I_{k-1,k-1}$ is the $k-1$ dimensional identity matrix and

$$Q_t^† = \begin{bmatrix} Q_t & Q_t Z_t' \\
Z_t Q_t & Z_t Q_t Z_t' \\
0 & 0 & 0 \end{bmatrix}$$

Note that the $T$ and $Q$ matrices of the random walk with predictors model are time invariant, and in the expressions above their time indices are kept because they illustrate the pattern for more general models. The initial state vector is diffuse, with

$$P_*^† = \begin{bmatrix} P_* & 0 \ 0 & 0 \end{bmatrix}, \quad P_\infty^† = \begin{bmatrix} P_\infty & 0 \\
0 & I_{k,k} \end{bmatrix}$$
The parameters of this model are the disturbance variances $\sigma^2_\epsilon$ and $\sigma^2_\eta$, the lag coefficients $\phi_1, \phi_2, \ldots, \phi_k$, and the regression coefficients $\beta_1$ and $\beta_2$. As before, the regression coefficients get estimated during the state smoothing, and the other parameters are estimated by maximizing the likelihood.

**Outlier Detection**

In time series analysis it is often useful to detect changes over time in the characteristics of the response series. In the UCM procedure you can search for two types of changes, additive outliers (AO) and level shifts (LS). An additive outlier is an unusual value in the series, the cause of which might be a data recording error or a temporary shock to the series generation process. A level shift represents a permanent shift, either up or down, in the level of the series. You can control different aspects of the outlier search, such as the significance level of the reported outliers, by choosing different options in the OUTLIER statement. The search for AOs is done by default, whereas the CHECKBREAK option in the LEVEL statement must be used to turn on the search for LSs.

The outlier detection process implemented in the UCM procedure is based on De Jong and Penzer (1998). In this approach the fitted model is taken to be the null model, and the series values and level shifts that are not adequately accounted for by the null model are flagged as outliers. The unusualness of a response series value at a particular time point $t_0$, with respect to the fitted model, can be judged by estimating its value based on the rest of the data (that is, the series obtained by deleting the series value at $t_0$) and comparing the estimated value to the observed value. If the difference between the estimated and observed values is statistically significant, then such value can be regarded as an AO. Note that this difference between the estimated and observed values is also the regression coefficient of a dummy regressor that takes the value 1.0 at $t_0$ and is 0.0 elsewhere, assuming such a regressor is added to the null model. In this way the series value at $t_0$ is regarded as AO if the regression coefficient of this dummy regressor is significant. Similarly, you can say that a level shift has occurred at a time point $t_0$ if the regression coefficient of a regressor, which is 0.0 before $t_0$ and 1.0 at $t_0$ and thereafter, is statistically significant. De Jong and Penzer (1998) provide an efficient way to compute such AO and LS regression coefficients and their standard errors at all time points in the series. The outlier summary table, which is produced by default, simply lists the most statistically significant candidates among these.

**Missing Values**

Embedded missing values in the dependent variable usually cause no problems in UCM modeling. However, no missing values are allowed in the predictor variables. Certain patterns of missing values in the dependent variable can lead to failure of the initialization step of the diffuse Kalman filtering for some models. For example, if in a monthly series all values are missing for a certain month—such as May—then a BSM with monthly seasonality leads to such a situation. However, in this case the initialization step can complete successfully for a nonseasonal model such as local linear model.

**Parameter Estimation**

The parameter vector in a UCM consists of the variances of the disturbance terms of the unobserved components, the damping coefficients and frequencies in the cycles, the damping coefficient in the autoregression,
the lag coefficients of the dependent lags, and the regression coefficients in the regression terms. The regression coefficients are always part of the state vector and are estimated by state smoothing. The remaining parameters are estimated by maximizing either the full diffuse likelihood or the nondiffuse likelihood. The decision to use the full diffuse likelihood or the nondiffuse likelihood depends on the presence or absence of the dependent lag coefficients in the parameter vector. If the parameter vector does not contain any dependent lag coefficients, then the full diffuse likelihood is used. If, on the other hand, the parameter vector does contain some dependent lag coefficients, then the parameters are estimated by maximizing the nondiffuse likelihood. The optimization of the full diffuse likelihood is often unstable when the parameter vector contains dependent lag coefficients. In this sense, when the parameter vector contains dependent lag coefficients, the parameter estimates are not true maximum likelihood estimates.

The optimization of the likelihood, either full or nondiffuse, is carried out using one of several nonlinear optimization algorithms. The user can control many aspects of the optimization process by using the NLOPTIONS statement and by providing the starting values of the parameters while specifying the corresponding components. However, in most cases the default settings work quite well. The optimization process is not guaranteed to converge to a maximum likelihood estimate. In most cases the difficulties in parameter estimation are associated with the specification of a model that is not appropriate for the series being modeled.

**Parameter Estimation by Profile Likelihood Optimization**

If a disturbance variance, such as the disturbance variance of the irregular component, is a part of the UCM and is a free parameter, then it can be profiled out of the likelihood. This means solving analytically for its optimum and plugging this expression back into the likelihood formula, giving rise to the so-called profile likelihood. The expression of the profile likelihood and the MLE of the profiled variance are given earlier in the section “The UCMs as State Space Models” on page 2908, where the computation of the likelihood of the state space model is also discussed.

In some situations the optimization of the profile likelihood can be more efficient because the number of parameters to optimize is reduced by one; however, for a variety of reasons such gains might not always be observed. Moreover, in theory the estimates obtained by optimizing the profile likelihood and the usual likelihood should be the same, but in practice this might not hold because of numerical rounding and other conditions.

In the UCM procedure, by default the usual likelihood is optimized if any of the disturbance variance parameters is held fixed to a nonzero value by using the NOEST option in the corresponding component statement. In other cases the decision whether to optimize the profile likelihood or the usual likelihood is based on several factors that are difficult to document. You can choose which likelihood to optimize during parameter estimation by specifying the PROFILE option for the profile likelihood optimization or the NOPROFILE option for the usual likelihood optimization. In the presence of the PROFILE option, the disturbance variance to profile is checked in a specific order, so that if the irregular component disturbance variance is free then it is always chosen. The situation in other cases is more complicated.

**Profiling in the Presence of Fixed Variance Parameters**

Note that when the parameter estimation is done by optimizing the profile likelihood, the interpretation of the variance parameters that are held fixed to nonzero values changes. In the presence of the PROFILE option, the disturbance variances that are held at a fixed value by using the NOEST option in their respective component statements are interpreted as being restricted to be that fixed multiple of the profiled variance rather than being fixed at that nominal value. That is, implicitly, the parameter estimation is done under the restriction of holding the disturbance variance ratio fixed at a given value rather than the disturbance
variance itself. For an example of this type of restriction to obtain a UC model that is equivalent to the famous Hodrick-Prescott filter, see Example 42.5.

**t Values**

The t values reported in the table of parameter estimates are approximations whose accuracy depends on the validity of the model, the nature of the model, and the length of the observed series. The distributional properties of the maximum likelihood estimates of general unobserved components models have not been explored fully; therefore the probability values that correspond to a t distribution should be interpreted carefully, as they can be misleading. This is particularly true if the parameters in question are close to the boundary of the parameter space. The two sources by Harvey (1989, 2001) are good references for information about this topic. For some parameters, such as the cycle period, the reported t values are uninformative because comparison of the estimated parameter with zero is never needed. In such cases the t values and the corresponding probability values should be ignored.

---

**Bootstrap Prediction Intervals (Experimental)**

By default, the UCM procedure computes the standard errors of the series and component forecasts (both the filtered and smoothed estimates) by assuming that the estimated parameters are in fact the true parameters. Rodriguez and Ruiz (2010) describe a bootstrap-based procedure to compute the standard errors of the series and component forecasts that takes into account the uncertainty of parameter estimation. As an experimental feature in this release, you can request the computation of standard errors based on this bootstrap-based procedure by specifying the `BOOTSTRAP` option in the FORECAST statement. Subsequently, the confidence intervals for the series and component forecasts are based on these bootstrap standard errors. The algorithm that PROC UCM uses closely follows the first procedure described in Section 3 of Rodriguez and Ruiz (2010). Note that this bootstrap algorithm is computationally expensive. The computational burden increases with the number of bootstrap replications and is comparable to the computational burden of fitting the specified model as many times as the number of replications. Fortunately, these replications can be executed in parallel, and the UCM procedure can use multiple cores and multiple grid nodes (if they are available) to complete these calculations faster. For a single machine with multiple cores, the procedure automatically detects and uses all the cores. If a grid environment with multiple machines is available (with the appropriate SAS license), you must use the `PERFORMANCE` statement to supply the necessary information to the UCM procedure.

---

**Computational Issues**

**Convergence Problems**

As explained in the section “Parameter Estimation” on page 2917, the model parameters are estimated by nonlinear optimization of the likelihood. This process is not guaranteed to succeed. For some data sets, the optimization algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data. It is also possible for the algorithm to converge to a point that is not the global optimum of the likelihood.

If you experience convergence problems, the following points might be helpful:
Data that are extremely large or extremely small can adversely affect results because of the internal tolerances used during the filtering steps of the likelihood calculation. Rescaling the data can improve stability.

Examine your model for redundancies in the included components and regressors. If some of the included components or regressors are nearly collinear to each other, then the optimization process can become unstable.

Experimenting with different options offered by the NLOPTIONS statement can help.

Lack of convergence can indicate model misspecification or a violation of the normality assumption.

Computer Resource Requirements

The computing resources required for the UCM procedure depend on several factors. The memory requirement for the procedure is largely dependent on the number of observations to be processed and the size of the state vector underlying the specified model. If \( n \) denotes the sample size and \( m \) denotes the size of the state vector, the memory requirement for the smoothing stage of the Kalman filter is of the order of \( 6 \times 8 \times n \times m^2 \) bytes, ignoring the lower-order terms. If the smoothed component estimates are not needed then the memory requirement is of the order of \( 6 \times 8 \times (m^2 + n) \) bytes. Besides \( m \) and \( n \), the computing time for the parameter estimation depends on the type of components included in the model. For example, the parameter estimation is usually faster if the model parameter vector consists only of disturbance variances, because in this case there is an efficient way to compute the likelihood gradient.

Displayed Output

The default printed output produced by the UCM procedure is described in the following list:

- brief information about the input data set, including the data set name and label, and the name of the ID variable specified in the ID statement
- summary statistics for the data in the estimation and forecast spans, including the names of the variables in the model, their categorization as dependent or predictor, the index of the beginning and ending observations in the spans, the total number of observations and the number of missing observations, the smallest and largest measurements, and the mean and standard deviation
- information about the model parameters at the start of the model-fitting stage, including the fixed parameters in the model and the initial estimates of the free parameters in the model
- convergence status of the likelihood optimization process if any parameter estimation is done
- estimates of the free parameters at the end of the model fitting-stage, including the parameter estimates, their approximate standard errors, \( t \) statistics, and the approximate \( p \)-value
- the likelihood-based goodness-of-fit statistics, including the full likelihood, the portion of the likelihood corresponding to the diffuse initialization, the sum of squares of residuals normalized by their standard errors, and the information criteria: AIC, AICC, HQIC, BIC, and CAIC
• the fit statistics that are based on the raw residuals (observed minus predicted), including the mean squared error (MSE), the root mean squared error (RMSE), the mean absolute percentage error (MAPE), the maximum percentage error (MAXPE), the R-square, the adjusted R-square, the random walk R-square, and Amemiya’s R-square

• the significance analysis of the components included in the model that is based on the estimation span

• brief information about the components included in the model

• additive outliers in the series, if any are detected

• the multistep series forecasts

• post-sample-prediction analysis table that compares the multistep forecasts with the observed series values, if the BACK= option is used in the FORECAST statement

Statistical Graphics

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

This section provides information about the basic ODS statistical graphics produced by the UCM procedure.

You can obtain most plots relevant to the specified model by using the global PLOTS= option in the PROC UCM statement. The plot of series forecasts in the forecast horizon is produced by default. You can further control the production of individual plots by using the PLOT= options in the different statements.

The main types of plots available are as follows:

• Time series plots of the component estimates, either filtered or smoothed, can be requested by using the PLOT= option in the respective component statements. For example, the use of PLOT=SMOOTH option in a CYCLE statement produces a plot of smoothed estimate of that cycle.

• Residual plots for model diagnostics can be obtained by using the PLOT= option in the ESTIMATE statement.

• Plots of series forecasts and model decompositions can be obtained by using the PLOT= option in the FORECAST statement.

The following example is a simple illustration of the available plot options.
Analysis of Sunspot Data: Illustration of ODS Graphics

In this example a well-known series, Wolfer’s sunspot data (Anderson 1971), is considered. The data consist of yearly sunspot numbers recorded from 1749 to 1924. These sunspot numbers are known to have a cyclical pattern with a period of about eleven years. The following DATA step creates the input data set:

```plaintext
data sunspot;
  input year  wolfer @@;
  year = mdy(1,1, year);
  format year year4.;
datalines;

```

The following statements specify a UCM that includes a cycle component and a random walk trend component:

```plaintext
proc ucm data=sunspot;
  id year interval=year;
  model wolfer;
  irregular;
  level;
  cycle plot=(filter smooth);
  estimate back=24 plot=(loess panel cusum wn);
  forecast back=24 lead=24 plot=(forecasts decomp);
run;
```

The following subsections explain the graphics produced by the preceding statements.

**Component Plots**

The plots in Figure 42.8 and Figure 42.9, produced by specifying PLOT=(FILTER SMOOTH) in the CYCLE statement, show the filtered and smoothed estimates, respectively, of the cycle component in the model. Note that the smoothed estimate appears smoother than the filtered estimate. This is always true because the filtered estimate of a component at time $t$ is based on the observations prior to time $t$—that is, it uses measurements from the first observation up to the $(t - 1)$th observation. On the other hand, the corresponding smoothed estimate uses all the available observations—that is, all the measurements from the first observation to the last. This makes the smoothed estimate of the component more precise than the filtered estimate for the time points within historical period. In the forecast horizon, both filtered and smoothed estimates are identical, being based on the same set of observations.
Figure 42.8  Sunspots Series: Filtered Cycle

Filtered Cycle for wolfes

Period = 10.45
Residual Diagnostics

If the fitted model is appropriate for the given data, then the corresponding one-step-ahead residuals should be approximately white—that is, uncorrelated—and approximately normal. Moreover, the residuals should not display any discernible pattern. You can detect departures from these conditions graphically. Different residual diagnostic plots can be requested by using the PLOT= option in the ESTIMATE statement.

The normality can be checked by examining the histogram and the normal quantile plot of residuals. The whiteness can be checked by examining the ACF and PACF plots that show the sample autocorrelation and sample partial-autocorrelation at different lags. The diagnostic panel shown in Figure 42.10, produced by specifying PLOT=PANEL, contains these four plots.
The residual histogram and Q-Q plot show no serious violation of normality. The histogram appears reasonably symmetric and follows the overlaid normal density curve reasonably closely. Similarly, in the Q-Q plot the residuals follow the reference line fairly closely. The ACF and PACF plots also do not exhibit any violation of the whiteness assumption; the correlations at all nonzero lags seem to be insignificant.

The residual whiteness can also be formally tested by using the Ljung-Box portmanteau test. The plot in Figure 42.11, produced by specifying PLOT=WN, shows the p-values of the Ljung-Box test statistics at different lags. In these plots the p-values for the first few lags, equal to the number of estimated parameters in the model, are not shown because they are always missing. This portion of the plot is shaded blue to indicate this fact. In the case of this model, five parameters are estimated so the p-values for the first five lags are not shown. The p-values are displayed on a log scale in such a way that higher bars imply more extreme test statistics. In this plot some early p-values appear extreme. However, these p-values are based on large sample theory, which suggests that these statistics should be examined for lags larger than the square root of sample size. In this example it means that the p-values for the first $\sqrt{154} \approx 12$ lags can be ignored. With this consideration, the plot shows no violation of whiteness since the p-values after the 12th lag do not appear extreme.
The plot in Figure 42.12, produced by specifying PLOT=LOESS, shows the residuals plotted against time with an overlaid loess curve. This plot is useful for checking whether any discernible pattern remains in the residuals. Here again, no significant pattern appears to be present.
Figure 42.12 Sunspots Series: Residual Loess Plot

The plot in Figure 42.13, produced by specifying PLOT=CUSUM, shows the cumulative residuals plotted against time. This plot is useful for checking structural breaks. Here, there appears to be no evidence of structural break since the cumulative residuals remain within the confidence band throughout the sample period. Similarly, you can request a plot of the squared cumulative residuals by specifying PLOT=CUSUMSQ.
Brockwell and Davis (1991) can be consulted for additional information on diagnosing residuals. For more information about CUSUM and CUSUMSQ plots, you can consult Harvey (1989).
**Forecast and Series Decomposition Plots**
You can use the PLOT= option in the FORECAST statement to obtain the series forecast plot and the series decomposition plots. The series decomposition plots show the result of successively adding different components in the model starting with the trend component. The IRREGULAR component is left out of this process. The following two plots, produced by specifying PLOT=DECOMP, show the results of successive component addition for this example. The first plot, shown in Figure 42.14, shows the smoothed trend component and the second plot, shown in Figure 42.15, shows the sum of smoothed trend and cycle.

**Figure 42.14** Sunspots Series: Smoothed Trend
Finally, Figure 42.16 shows the forecast plot.
**Figure 42.16** Sunspots Series: Series Forecasts

### ODS Table Names

The UCM procedure assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in **Table 42.2**.

</tr>
</tbody>
</table>

**NOTE:** The tables are related to a single series within a BY group. In the case of models that contain multiple cycles, seasonal components, or block seasonal components, the corresponding component estimate tables are sequentially numbered. For example, if a model contains two cycles and a seasonal component and the PRINT=SMOOTH option is used for each of them, the ODS tables containing the smoothed estimates will be named SmoothedCycle1, SmoothedCycle2, and SmoothedSeason. Note that the seasonal table is not numbered because there is only one seasonal component. There are some exceptions to this numbering rule: the tables, FilteredRandomReg, SmoothedRandomReg, FilteredSplineReg, and SmoothedSplineReg, are always numbered starting with zero.

**ODS Graph Names**

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.
You can reference every graph produced through ODS Graphics with a name. The names of the graphs that PROC UCM generates are listed in Table 42.3, along with the required statements and options.

OUTFOR= Data Set

You can use the OUTFOR= option in the FORECAST statement to store the series and component forecasts produced by the procedure. This data set contains the following columns:

- the BY variables
- the ID variable. If an ID variable is not specified, then a numerical variable, _ID_, is created that contains the observation numbers from the input data set.
- the dependent series and the predictor series
- FORECAST, a numerical variable containing the one-step-ahead predicted values and the multistep forecasts
- RESIDUAL, a numerical variable containing the difference between the actual and forecast values
- STD, a numerical variable containing the standard error of prediction
- LCL and UCL, numerical variables containing the lower and upper forecast confidence limits
- S_SERIES and VS_SERIES, numerical variables containing the smoothed values of the dependent series and their variances
- S_IRREG and VS_IRREG, numerical variables containing the smoothed values of the irregular component and their variances. These variables are present only if the model has an irregular component.
- F_LEVEL, VF_LEVEL, S_LEVEL, and VS_LEVEL, numerical variables containing the filtered and smoothed values of the level component and the respective variances. These variables are present only if the model has a level component.
- F_SLOPE, VF_SLOPE, S_SLOPE, and VS_SLOPE, numerical variables containing the filtered and smoothed values of the slope component and the respective variances. These variables are present only if the model has a slope component.
- F_AUTOREG, VF_AUTOREG, S_AUTOREG, and VS_AUTOREG, numerical variables containing the filtered and smoothed values of the autoreg component and the respective variances. These variables are present only if the model has an autoreg component.
- F_CYCLE, VF_CYCLE, S_CYCLE, and VS_CYCLE, numerical variables containing the filtered and smoothed values of the cycle component and the respective variances. If there are multiple cycles in the model, these variables are sequentially numbered as F_CYCLE1, F_CYCLE2, and so on. These variables are present only if the model has at least one cycle component.
- F_SEASON, VF_SEASON, S_SEASON, and VS_SEASON, numerical variables containing the filtered and smoothed values of the season component and the respective variances. If there are multiple seasons in the model, these variables are sequentially numbered as F_SEASON1, F_SEASON2, and so on. These variables are present only if the model has at least one season component.
- F_BLKSEAS, VF_BLKSEAS, S_BLKSEAS, and VS_BLKSEAS, numerical variables containing the filtered and smoothed values of the blockseason component and the respective variances. If there are multiple block seasons in the model, these variables are sequentially numbered as F_BLKSEAS1, F_BLKSEAS2, and so on.
F_SPLSEAS, VF_SPLSEAS, S_SPLSEAS, and VS_SPLSEAS, numerical variables containing the filtered and smoothed values of the splinesseason component and the respective variances. If there are multiple spline seasons in the model, these variables are sequentially numbered as F_SPLSEAS1, F_SPLSEAS2, and so on. These variables are present only if the model has at least one splinesseason component.

Filtered and smoothed estimates, and their variances, of the time-varying regression coefficients of the variables specified in the RANDOMREG and SPLINEREG statements. A variable is not included if its coefficient is time-invariant, that is, if the associated disturbance variance is zero.

S_TREG and VS_TREG, numerical variables containing the smoothed values of level plus regression component and their variances. These variables are present only if the model has at least one predictor variable or has dependent lags.

S_TREGCYC and VS_TREGCYC, numerical variables containing the smoothed values of level plus regression plus cycle component and their variances. These variables are present only if the model has at least one cycle or an autoreg component.

S_NOIRREG and VS_NOIRREG, numerical variables containing the smoothed values of the sum of all components except the irregular component and their variances. These variables are present only if the model has at least one seasonal or block seasonal component.

**OUTEST= Data Set**

You can use the OUTEST= option in the ESTIMATE statement to store the model parameters and the related estimation details. This data set contains the following columns:

- the BY variables
- COMPONENT, a character variable containing the name of the component corresponding to the parameter being described
- PARAMETER, a character variable containing the parameter name
- TYPE, a character variable indicating whether the parameter value was fixed by the user or estimated
- _STATUS_, a character variable indicating whether the parameter estimation process converged or failed or there was an error of some other kind
- ESTIMATE, a numerical variable containing the parameter estimate
- STD, a numerical variable containing the standard error of the parameter estimate. This has a missing value if the parameter value is fixed.
- TVALUE, a numerical variable containing the $t$-statistic. This has a missing value if the parameter value is fixed.
- PVALUE, a numerical variable containing the $p$-value. This has a missing value if the parameter value is fixed.
Statistics of Fit

This section explains the goodness-of-fit statistics reported to measure how well the specified model fits the data.

First the various statistics of fit that are computed using the prediction errors, \( y_t - \hat{y}_t \), are considered. In these formulas, \( n \) is the number of nonmissing prediction errors and \( k \) is the number of fitted parameters in the model. Moreover, the sum of squared errors, \( \text{SSE} = \sum (y_t - \hat{y}_t)^2 \), and the total sum of squares for the series corrected for the mean, \( \text{SST} = \sum (y_t - \bar{y})^2 \), where \( \bar{y} \) is the series mean, and the sums are over all the nonmissing prediction errors.

**Mean Squared Error**
The mean squared prediction error, \( \text{MSE} = \frac{1}{n} \text{SSE} \)

**Root Mean Squared Error**
The root mean square error, \( \text{RMSE} = \sqrt{\text{MSE}} \)

**Mean Absolute Percent Error**
The mean absolute percent prediction error, \( \text{MAPE} = \frac{100}{n} \sum_{t=1}^{n} |(y_t - \hat{y}_t)/y_t| \).
The summation ignores observations where \( y_t = 0 \).

**R-Square**
The R-square statistic, \( R^2 = 1 - \frac{\text{SSE}}{\text{SST}} \).
If the model fits the series badly, the model error sum of squares, \( \text{SSE} \), might be larger than \( \text{SST} \) and the R-square statistic will be negative.

**Adjusted R-Square**
The adjusted R-square statistic, \( 1 - \left( \frac{n-1}{n-k} \right) (1 - R^2) \)

**Amemiya’s Adjusted R-Square**
Amemiya’s adjusted R-square, \( 1 - \left( \frac{n+k}{n-k} \right) (1 - R^2) \)

**Random Walk R-Square**
The random walk R-square statistic (Harvey’s R-square statistic that uses the random walk model for comparison), \( 1 - \left( \frac{n-1}{n} \right) \text{RWSSE} \), where \( \text{RWSSE} = \sum_{t=2}^{n} (y_t - y_{t-1} - \mu)^2 \), and \( \mu = \frac{1}{n-1} \sum_{t=2}^{n} (y_t - y_{t-1}) \)

**Maximum Percent Error**
The largest percent prediction error, \( 100 \max((y_t - \hat{y}_t)/y_t) \). In this computation the observations where \( y_t = 0 \) are ignored.

The likelihood-based fit statistics are reported separately (see the section “The UCMs as State Space Models” on page 2908). They include the full log likelihood (\( L_{\infty} \)), the diffuse part of the log likelihood, the normalized residual sum of squares, and several information criteria: AIC, AICC, HQIC, BIC, and CAIC. Let \( q \) denote the number of estimated parameters, \( n \) be the number of nonmissing measurements in the estimation span, and \( d \) be the number of diffuse elements in the initial state vector that are successfully initialized during the Kalman filtering process. Moreover, let \( n* = (n - d) \). The reported information criteria, all in smaller-is-better form, are described in Table 42.4:

Examples: UCM Procedure

Example 42.1: The Airline Series Revisited

The series in this example, the monthly airline passenger series, has already been discussed earlier; see the section “A Seasonal Series with Linear Trend” on page 2865. Recall that the series consists of monthly numbers of international airline travelers (from January 1949 to December 1960). Here additional output features of the UCM procedure are illustrated, such as how to use the ESTIMATE and FORECAST statements to limit the span of the data used in parameter estimation and forecasting. The following statements fit a BSM to the logarithm of the airline passenger numbers. The disturbance variance for the slope component is held fixed at value 0; that is, the trend is locally linear with constant slope. In order to evaluate the performance of the fitted model on observed data, some of the observed data are withheld during parameter estimation and forecasting. The observations in the last two years, years 1959 and 1960, are not used in parameter estimation, while the observations in the last year, year 1960, are not used in the forecasting computations. This is done using the BACK= option in the ESTIMATE and FORECAST statements. In addition, a panel of residual diagnostic plots is obtained using the PLOT=PANEL option in the ESTIMATE statement.

data seriesG;
  set sashelp.air;
  logair = log(air);
run;

proc ucm data = seriesG;
  id date interval = month;
  model logair;
  irregular;
  level;
  slope var = 0 noest;
  season length = 12 type=trig;
  estimate back=24 plot=panel;
  forecast back=12 lead=24 print=forecasts;
run;
The following tables display the summary of data used in estimation and forecasting (Output 42.1.1 and Output 42.1.2). These tables provide simple summary statistics for the estimation and forecast spans; they include useful information such as the beginning and ending dates of the span, the number of nonmissing values, and so on.

Two types of goodness-of-fit statistics are reported after a model is fit to the series (see Output 42.1.6 and Output 42.1.7). The first type is the likelihood-based goodness-of-fit statistics, which include the full likelihood of the data, the diffuse portion of the likelihood (see the section “Details: UCM Procedure” on page 2902), and the information criteria. The second type of statistics is based on the raw residuals, residual = observed – predicted. If the model is nonstationary, then one-step-ahead predictions are not available for some initial observations, and the number of values used in computing these fit statistics will be different from those used in computing the likelihood-based test statistics.

Number of non-missing residuals used for computing the fit statistics = 107
The diagnostic plots based on the one-step-ahead residuals are shown in Output 42.1.8. The residual histogram and the Q-Q plot show no reasons to question the approximate normality of the residual distribution. The remaining plots check for the whiteness of the residuals. The sample correlation plots, the autocorrelation function (ACF) and the partial autocorrelation function (PACF), also do not show any significant violations of the whiteness of the residuals. Therefore, on the whole, the model seems to fit the data well.

**Output 42.1.8** Residual Diagnostics for the Airline Series Using a BSM
The forecasts are given in Output 42.1.9. In order to save the space, the upper and lower confidence limit columns are dropped from the output, and only the rows corresponding to the year 1960 are shown. Recall that the actual measurements in the years 1959 and 1960 were withheld during the parameter estimation, and the ones in 1960 were not used in the forecast computations.

The figure Output 42.1.10 shows the forecast plot. The forecasts in the year 1960 show that the model predictions were quite good.
Example 42.2: Variable Star Data

The series in this example is studied in detail in Bloomfield (2000). This series consists of brightness measurements (magnitude) of a variable star taken at midnight for 600 consecutive days. The data can be downloaded from a time series archive maintained by the University of York, England (http://www.york.ac.uk/depts/maths/data/ts/welcome.htm (series number 26)). The following DATA step statements read the data in a SAS data set:

```sas
data star;
  input magnitude @@;
  day = _n_;
datalines;
25 28 31 32 33 32 31 28 25 22 18
14 10 7 4 2 0 0 0 2 4 8 11
15 19 23 26 29 32 33 34 33 32 30 27
24 20 17 13 10 7 5 3 3 3 4 5
7 10 13 16 19 22 24 26 27 28 29 28
27 25 24 21 19 17 15 13 12 11 11 10
10 11 12 12 13 14 15 16 17 18 19 19
...
```

... more lines ...
The following statements use the TIMESERIES procedure to get a timeseries plot of the series (see Output 42.2.1):

```plaintext
proc timeseries data=star plot=series;
  var magnitude;
run;
```

**Output 42.2.1** Plot of Star Brightness on Successive Days

The plot clearly shows the cyclic nature of the series. Bloomfield shows that the series is very well explained by a model that includes two deterministic cycles that have periods 29.0003 and 24.0001 days, a constant term, and a simple error term. He also mentions the difficulty involved in estimating the periods from the data (Bloomfield 2000, Chapter 3). In his case the cycle periods are estimated by least squares, and the sum of squares surface has multiple local optima and ridges. The following statements show how to use the UCM procedure to fit this two-cycle model to the series. The constant term in the model is specified by holding the variance parameter of the level component to zero.
The UCM Procedure

**proc ucm data=star;**
**model magnitude;**
**irregular;**
**level var=0 noest;**
**cycle;**
**cycle;**
**estimate;**
run;**

The final parameter estimates and the goodness-of-fit statistics are shown in **Output 42.2.2** and **Output 42.2.3**, respectively. The model fit appears to be good.

**Output 42.2.2** Two-Cycle Model: Parameter Estimates

| Component | Parameter            | Estimate | Std Error | t Value | Approx Pr > |t| |
|-----------|----------------------|----------|-----------|---------|-------------|---|
| Irregular | Error Variance       | 0.09257  | 0.0053845 | 17.19   | <.0001      |   |

</tbody>
</table>

Note that the estimated periods are the same as in Bloomfield’s model, the damping factors are nearly equal to 1.0, and the disturbance variances are very close to zero, implying persistent deterministic cycles. In fact, this model is identical to Bloomfield’s model.
Example 42.3: Modeling Long Seasonal Patterns

This example illustrates some of the techniques you can use to model long seasonal patterns in a series. If the seasonal pattern is of moderate length and the underlying dynamics are simple, then it is easily modeled by using the basic settings of the SEASON statement and these additional techniques are not needed. However, if the seasonal pattern has a long season length and/or has a complex stochastic dynamics, then the techniques discussed here can be useful. You can obtain parsimonious models for a long seasonal pattern by using an appropriate subset of trigonometric harmonics, or by using a suitable spline function, or by using a block-season pattern in combination with a seasonal component of much smaller length. You can also vary the disturbance variances of the subcomponents that combine to form the seasonal component.

The time series used in this example consists of number of calls received per shift at a call center. Each shift is six hours long, and the first shift of the day begins at midnight, resulting in four shifts per day. The observations are available from December 15, 1999, to April 30, 2000. This series is seasonal with season length 28, which is moderate, and in fact there is no particular need to use pattern approximation techniques in this case. However, it is adequate for demonstration purposes. The plan of this example is as follows. First an initial model with a full seasonal component is created. This model is used as a baseline for comparing alternate models created by the techniques that are being illustrated. In practice any candidate model is first checked for adequacy by using various diagnostic procedures. In this illustration the main focus is on the different ways a long seasonal pattern can be modeled and no model diagnostics are done for the models being entertained. The alternate models are compared by using the sum of absolute prediction errors in the holdout region.

The following DATA step statements create the input data set used in this example:

```plaintext
data callCenter;
  input calls @@;
  label calls= "Number of Calls Received in a 6 Hour Shift";
  start = '15dec99:00:00'dt;
  datetime = INTNX( 'dthour6', start, _n_-1 );
  format datetime datetime10.;
datalines;
  18 122 244 128 19 113 230 119 17 112
  219 93 14 73 139 53 11 32 74 56
  15 137 289 153 20 125 227 106 16 101
  201 92 14 94 187 69 11 59 94 21

... more lines ...
```

Initial exploration of the series clearly indicates that the series does not show any significant trend, and time of day and day of the week have a significant influence on the number of calls received. These considerations suggest a simple random walk trend model along with a seasonal component of season length 28, the total number of shifts in a week. The following statements specify this model. Note the PRINT=HARMONICS option in the SEASON statement, which produces a table that lists the full set of harmonics contributing to the seasonal along with the significance of their contribution. This table will be useful later in choosing a subset trigonometric model. The BACK=28 and LEAD=28 specifications in the FORECAST statement create a holdout region of 28 observations. The sum of absolute prediction errors (SAE) in this holdout region is used to compare the different models.
The forecasting performance of this model in the holdout region is shown in Output 42.3.1. The SAE is 516.22, which appears in the last row of the holdout analysis table.

Now that a baseline model is created, the exploration for alternate models can begin. The review of the harmonic table in Output 42.3.2 shows that all but the last three harmonics are significant, and deleting any of them to form a subset trigonometric seasonal component will lead to a poorer model. The last three harmonics, 12th, 13th, and 14th, with periods of 2.333, 2.15 and 2.0, respectively, do appear to be possible choices for deletion. Note that the disturbance variance of the seasonal component is not very insignificant (see Output 42.3.3); therefore the seasonal component is stochastic and the preceding logic, which is based on the final state estimate, provides only a rough guideline.

**Output 42.3.3** Parameter Estimates: Initial Model

| Component | Parameter | Estimate | Approx Std Error | t Value | Approx Pr > |t| |
|-----------|-----------|----------|------------------|---------|-------------|---|
| Irregular | Error Variance | 92.14591 | 13.10986 | 7.03 | <.0001 |
| Level     | Error Variance | 44.83595 | 10.65465 | 4.21 | <.0001 |
| Season    | Error Variance | 0.01250 | 0.0065153 | 1.92 | 0.0551 |

The following statements fit a subset trigonometric model formed by dropping the last three harmonics by specifying the DROPH= option in the SEASON statement:

```plaintext
proc ucm data=callCenter;
   id datetime interval=dthour6;
   model calls;
   irregular;
   level;
   season length=28 type=trig droph=12 13 14;
   estimate back=28;
   forecast back=28 lead=28;
run;
```
The last row of the holdout region prediction analysis table for the preceding model is shown in Output 42.3.4. It shows that the subset trigonometric model has better prediction performance in the holdout region than the full trigonometric model; its SAE is 471.53, compared to an SAE of 516.22 for the full model.

**Output 42.3.4** SAE for the Subset Trigonometric Model

<table>
<thead>
<tr>
<th>Obs</th>
<th>datetime</th>
<th>Actual</th>
<th>Forecast</th>
<th>Error</th>
<th>SAE</th>
</tr>
</thead>
<tbody>
<tr>
<td>552</td>

<td>40.836</td>
<td>20.164</td>
<td>471.534</td>
</tr>
</tbody>
</table>

The following statements illustrate a spline approximation to this seasonal component. In the spline specification the knot placement is quite important, and usually some experimentation is needed. In the following model the knots are placed at the beginning and the middle of each day. Note that the knots at the beginning and end of the season, 1 and 28 in this case, should not be listed in the knot list because knots are always placed there anyway.

```sas
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
    irregular;
      level;
      splineseason length=28
        knots=3 5 7 9 11 13 15 17 19 21 23 25 27
        degree=3;
        estimate back=28;
        forecast back=28 lead=28;
  run;
```

The spline season model takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in Output 42.3.5, which shows that the spline season model performs even better than the previous two models in the holdout region; its SAE is 313.79, compared to an SAE of 471.53 for the previous model.

**Output 42.3.5** SAE for the Spline Season Model

<table>
<thead>
<tr>

<td>37.650</td>
<td>313.792</td>
</tr>
</tbody>
</table>

The following statements illustrate yet another way to approximate a long seasonal component. Here a combination of BLOCKSEASON and SEASON statements results in a seasonal component that is a sum of two seasonal patterns: one seasonal pattern is simply a regular season with season length 4 that captures the within-day seasonal pattern, and the other seasonal pattern is a block seasonal pattern that remains constant during the day but varies from day to day within a week. Note the use of the NLOPTIONS statement to change the optimization technique during the parameter estimation to DBLDOG, which in this case performs better than the default technique, TRUREG.
Example 42.4: Modeling Time-Varying Regression Effects

In April 1979, the Albuquerque Police Department began a special enforcement program aimed at reducing the number of DWI (driving while intoxicated) accidents. The program was administered by a squad of police officers, who used breath alcohol testing (BAT) devices and a van that houses a BAT device (Batmobile). These data were collected by the Division of Governmental Research of the University of New Mexico, under a contract with the National Highway Traffic Safety Administration of the U.S. Department of Transportation, to evaluate the Batmobile program. The first 29 observations are for a control period, and the next 23 observations are for the experimental (Batmobile) period. The data, available at http://lib.stat.cmu.edu/DASL/Datafiles/batdat.html, consist of two variables: ACC, which represents injuries and fatalities from Wednesday to Saturday nighttime accidents, and FUEL, which represents fuel consumption (millions of gallons) in Albuquerque. The variables are measured quarterly starting from the first quarter of 1972 up to the last quarter of 1984, covering the span of 13 years. The following DATA step statements create the input data set:

```plaintext
proc ucm data=callCenter;
  id datetime interval=dthour6;
  model calls;
  irregular;
  level;
  season length=4 type=trig;
  blockseason nblocks=7 blocksize=4 type=trig;
  estimate back=28;
  forecast back=28 lead=28;
  nloptions tech=dbldog;
run;
```

This model also takes about half the time to fit that the baseline model takes. The last row of the holdout region prediction analysis table for this model is shown in Output 42.3.6, which shows that the block season model does slightly better than the baseline model but not as well as the other two models; its SAE is 508.52, compared to an SAE of 516.22 for the baseline model.

Output 42.3.6 SAE for the Block Season Model

<table>
<thead>
<tr>
<th>Obs</th>
<th>datetime</th>

<td>21.661</td>
<td>508.522</td>
</tr>
</tbody>
</table>

This example showed a few different ways to model a long seasonal pattern. It showed that parsimonious models for long seasonal patterns can be useful, and in some cases even more effective than the full model. Moreover, for very long seasonal patterns the high memory requirements and long computing times might make full models impractical.

;

There are a number of ways to study these data and the question of the effectiveness of the BAT program. One possibility is to study the before-after difference in the injuries and fatalities per million gallons of fuel consumed, by regressing ACC on FUEL and the dummy variable BATPROGRAM, which is zero before the program began and one while the program is in place. However, it is possible that the effect of the Batmobiles might well be cumulative, because as awareness of the program becomes dispersed, its effectiveness as a deterrent to driving while intoxicated increases. This suggests that the regression coefficient of the BATPROGRAM variable might be time-varying. The following program fits a model that incorporates these considerations. A seasonal component is included in the model since it is easy to see that the data show strong quarterly seasonality.

proc ucm data=bat;
  model acc = fuel;
  id date interval=qtr;
  irregular;
  level var=0 noest;
  randomreg batProgram / plot=smooth;
  season length=4 var=0 noest plot=smooth;
  estimate plot=(panel residual);
  forecast plot=(panel residual) lead=0;
run;
The model seems to fit the data adequately. No data are withheld for model validation because the series is relatively short. The plot of the time-varying coefficient of BATPROGRAM is shown in Output 42.4.1. As expected, it shows that the effectiveness of the program increases as awareness of the program becomes dispersed. The effectiveness eventually seems to level off. The residual diagnostic plots are shown in Output 42.4.2 and Output 42.4.3, the forecast plot is in Output 42.4.4, the goodness-of-fit statistics are in Output 42.4.5, and the parameter estimates are in Output 42.4.6.

### Example 42.5: Trend Removal Using the Hodrick-Prescott Filter

The Hodrick-Prescott filter (Hodrick and Prescott 1997) is a popular tool in macroeconomics for fitting a smooth trend to time series. It is well known that the trend computation according to this filter is equivalent to fitting the local linear trend plus irregular model with the level disturbance variance restricted to zero and the slope disturbance variance restricted to be a suitable multiple of the irregular component variance. The multiple used depends on the frequency of the series; for example, for quarterly series the commonly recommended multiple is $1/1600 = 0.000625$. For other intervals there is no consensus, but a frequently suggested value for monthly series is $1/14400$ and the value for an annual series can range from $1/400 = 0.0025$ to $1/7 = 0.15$. The data set considered in this example consists of quarterly GNP values for the United States from 1960 to 1991. In the UCM procedure statements that follow, the presence of the PROFILE option in the ESTIMATE statement implies that the restriction that the disturbance variance of the slope component be fixed at 0.000625 is interpreted differently: it implies that the disturbance variance of the slope component be restricted to be 0.000625 times the estimated irregular component variance, as needed for the Hodrick-Prescott filter. The plot of the fitted trend is shown in Output 42.5.1, and the plot of the smoothed irregular component, which corresponds to the detrended series, is given in Output 42.5.2. The detrended series can be further analyzed for business cycles.

```sas
proc ucm data=sashelp.gnp;
   id date interval=qtr;
   model gnp;
   irregular plot=smooth;
   level var=0 noest plot=smooth;
   slope var=0.000625 noest;
   estimate PROFILE;
   forecast plot=(decomp);
run;
```
Output 42.5.1 Smoothed Trend for the GNP Series as per the Hodrick-Prescott Filter
Example 42.6: Using Splines to Incorporate Nonlinear Effects

The data in this example are created to mirror the electricity demand and temperature data recorded at a utility company in the midwest region of the United States. The data set (not shown), utility, has three variables: load, temp, and date. The load column contains the daily electricity demand, the temp column has the average daily temperature readings, and the date column records the observation date.

The following statements produce a plot, shown in Output 42.6.1, of electricity load versus temperature. Clearly the relationship is smooth but nonlinear: the load generally increases when the temperatures are away from the comfortable sixties.

```plaintext
proc sgplot data=utility;
   loess x=temp y=load / smooth=0.4;
run;
```
The time series plot of the load (not shown) also shows that, apart from a day-of-the-week seasonal effect, there are no additional easily identifiable patterns in the series. The series has no apparent upward or downward trend. The following statements fit a UCM to the series that takes into account these observations. The particular choice of the model is a result of a little modeling exercise that compared a small number of competing models. The chosen model is adequate but by no means the best possible. The temperature effect is modeled by a deterministic three-degree spline with knots at 30, 40, 50, 60, and 75. The knot locations and the degree were chosen by visual inspection of the plot (Output 42.6.1). An autoreg component is used in place of the simple irregular component, which improved the residual analysis. The last 60 days of data are withheld for out-of-sample forecast evaluation (note the BACK= option in both the ESTIMATE and FORECAST statements). The OUTLIER statement is used to increase the number of outliers reported to 10. Since no CHECKBREAK option is used in the LEVEL statement, only the additive outliers are searched. In this example the use of the EXTRADIFFUSE= option in the ESTIMATE and FORECAST statements is useful for discarding some early one-step-ahead forecasts and residuals with large variance.

```sas
proc ucm data=utility;
   id date interval=day;
   model load;
       autoreg;
   level plot=smooth;
```
Example 42.6: Using Splines to Incorporate Nonlinear Effects

smlinereg temp knots=30 40 50 65 75 degree=3 variance=0 noest;
season length=7 var=0 noest;
estimate plot=panel back=60 extradiffuse=50;
outlier maxnum=10;
forecast back=60 lead=60 extradiffuse=50;
run;

The parameter estimates are given in Output 42.6.2, and the residual goodness-of-fit statistics are shown in Output 42.6.3. The residual diagnostic plots are shown in Output 42.6.4. The ACF and PACF plots appear satisfactory, but the normality plots, particularly the Q-Q plot, show possible violations. It appears that, at least in part, this nonnormal behavior of the residuals might be attributable to the outliers in the series. The outlier summary table, Output 42.6.5, shows the most likely outlying observations. Notice that most of these outliers are holidays, like July 4th, when the electricity load is lower than usual for that day of the week.

Output 42.6.2 Electricity Load: Parameter Estimates

The UCM Procedure

| Component | Parameter            | Estimate | Approx Std Error | t Value | Approx Pr > |t|

The plot of the load forecasts for the withheld data is shown in **Output 42.6.6**.
Example 42.7: Detection of Level Shift

The series in this example consists of the yearly water level readings of the Nile River recorded at Aswan, Egypt (Cobb 1978; De Jong and Penzer 1998). The readings are from the years 1871 to 1970. The series does not show any apparent trend or any other distinctive patterns; however, there is a shift in the water level starting at the year 1899. This shift could be attributed to the start of construction of a dam near Aswan in that year. A time series plot of this series is given in Output 42.7.1. The following DATA step statements create the input data set:

```plaintext
data nile;
  input waterlevel @@;
  year = intnx('year', '1jan1871'd, _n_-1);
  format year year4.;
datalines;
1120 1160 963 1210 1160 1160 813 1230 1370 1140
995 935 1110 994 1020 960 1180 799 958 1140
1100 1210 1150 1250 1260 1220 1030 1100 774 840
874 694 940 833 701 916 692 1020 1050 969
831 726 456 824 702 1120 1100 832 764 821
```

Output 42.6.6  Electricity Load: Forecast Evaluation of the Withheld Data
In this situation it is known that a shift in the water level occurred within the span of the series, and its effect can be easily taken into account by including an appropriate indicator variable as a regressor. However, in many situation such prior information is not available, and it is useful to detect such a shift in a data analytic fashion. You can check for breaks in the level by using the CHECKBREAK option in the LEVEL statement. The following statements fit a simple locally constant level plus error model to the series:

```
proc timeseries data=nile plot=series;
  id year interval=year;
  var waterlevel;
run;
```

**Output 42.7.1** Nile Water Level
Example 42.7: Detection of Level Shift

```
proc ucm data=nile;
  id year interval=year;
  model waterlevel;
  irregular;
  level plot=smooth checkbreak;
  estimate;
  forecast plot=decomp;
run;
```

The plot in Output 42.7.2 shows a noticeable drop in the smoothed water level around 1899.

**Output 42.7.2** Smoothed Trend without the Shift of 1899

![Smoothed Level Component for waterlevel](image)

The “Outlier Summary” table in Output 42.7.3 shows the most likely types of breaks and their locations within the series span. The shift of 1899 is easily detected.

**Output 42.7.3** Detection of Structural Breaks in the Nile River Level

```
Obs  year  Break Type  Estimate Standard Error Chi-Square DF  Pr > ChiSq
29  1899  Level    -315.73791  97.639753  10.46  1  0.0012
```
The following statements specify a UCM that models the level of the river as a locally constant series with a shift in the year 1899, represented by a dummy regressor (SHIFT1899):

```plaintext
data nile;
  set nile;
  shift1899 = ( year >= '1jan1899'd );
run;

proc ucm data=nile;
  id year interval=year;
  model waterlevel = shift1899;
  irregular;
  level;
  estimate;
  forecast plot=decomp;
run;
```

The plot in Output 42.7.4 shows the smoothed trend, including the correction due to the shift in the year 1899. Notice the simplicity in the shape of the smoothed curve after the incorporation of the shift information.

**Output 42.7.4** Smoothed Trend plus Shift of 1899
Example 42.8: ARIMA Modeling

This example shows how you can use the UCM procedure for ARIMA modeling. The parameter estimates and predictions for ARIMA models obtained by using PROC UCM will be close to those obtained by using PROC ARIMA (in the presence of the ML option in its ESTIMATE statement) if the model is stationary or if the model is nonstationary and there are no missing values in the data. For more information about the ARIMA procedure, see Chapter 7, “The ARIMA Procedure.” However, if there are missing values in the data and the model is nonstationary, then the UCM and ARIMA procedures can produce significantly different parameter estimates and predictions. An article by Kohn and Ansley (1986) suggests a statistically sound method of estimation, prediction, and interpolation for nonstationary ARIMA models with missing data. This method is based on an algorithm that is equivalent to the Kalman filtering and smoothing algorithm used in the UCM procedure. The results of an illustrative example in their article are reproduced here using the UCM procedure. In this example an ARIMA(0,1,1)×(0,1,1)_{12} model is applied to the logarithm of the air series in the sashelp.air data set. Four different missing value patterns are considered to highlight different aspects of the problem:

- **Data1.** The full data set of 144 observations.
- **Data2.** The set of 78 observations that omit January through November in each of the last 6 years.
- **Data3.** The data set with the 5 observations July 1949, June, July, and August 1957, and July 1960 missing.
- **Data4.** The data set with all July observations missing and June and August 1957 also missing.

The following DATA steps create these data sets:

```latex
\begin{verbatim}
data Data1;
   set sashelp.air;
   logair = log(air);
run;

data Data2;
   set data1;
   if year(date) >= 1955 and month(date) < 12 then logair = .;
run;

data Data3;
   set data1;
   if (year(date) = 1949 and month(date) = 7) then logair = .;
   if (year(date) = 1957 and (month(date) = 6 or month(date) = 7 or month(date) = 8))
      then logair = .;
   if (year(date) = 1960 and month(date) = 7) then logair = .;
run;

data Data4;
   set data1;
   if month(date) = 7 then logair = .;
   if year(date) = 1957 and (month(date) = 6 or month(date) = 8)
      then logair = .;
run;
\end{verbatim}
```
The following statements specify the ARIMA\((0, 1, 1) \times (0, 1, 1)_12\) model for the logair series in the first data set (Data1):

```
proc ucm data=Data1;
  id date interval=month;
  model logair;
  irregular q=1 sq=1 s=12;
  deplag lags=(1)(12) phi=1 noest;
  estimate outest=est1;
  forecast outfor=for1;
run;
```

Note that the moving average part of the model is specified by using the Q=, SQ=, and S= options in the IRREGULAR statement and the differencing operator, \((1 - B)(1 - B^{12})\), is specified by using the DEPLAG statement. The model does not contain an intercept term; therefore no LEVEL statement is needed. The parameter estimates are saved in a data set EST1 by using the OUTEST= option in the ESTIMATE statement and the forecasts and the component estimates are saved in a data set FOR1 by using the OUTFOR= option in the FORECAST statement. The same analysis is performed on the other three data sets, but is not shown here.

Output 42.8.1 resembles Table 1 in Kohn and Ansley (1986). This table is generated by merging the parameter estimates from the four analyses. Only the moving average parameter estimates and their standard errors are reported. The columns EST1 and STD1 correspond to the estimates for Data1. The parameter estimates and their standard errors for other three data sets are similarly named. Note that the parameter estimates closely match the parameter estimates in the article. However, their standard errors differ slightly. This difference could be the result of different ways of computing the Hessian at the optimum. The white noise error variance estimates are not reported here, but they agree quite closely with those in the article.

```
Output 42.8.1 Data Sets 1–4: Parameter Estimates and Standard Errors

```
Output 42.8.3 is based on Data2. It resembles Table 3 in Kohn and Ansley (1986). The columns S_SERIES and VS_SERIES in the OUTFOR= data set contain the interpolated values of logair and their variances. The estimate column in Output 42.8.3 reports interpolated values (which are the same as S_SERIES), and the std column reports their standard errors (which are computed as square root of VS_SERIES) for January–November 1957. The actual logair values for these months, which are missing in Data2, are also provided for comparison. The numbers are very close to those in the article.

Output 42.8.3 Data Set 2: Interpolated Values and Standard Errors

<td>6.045</td>
<td>6.023</td>
<td>0.030</td>
</tr>
<tr>
<td>AUG57</td>
<td>6.146</td>
<td>6.147</td>
<td>0.030</td>
</tr>
</tbody>
</table>

The similarity between the outputs in this example and the results shown in Kohn and Ansley (1986) demonstrate that PROC UCM can be effectively used for nonstationary ARIMA models with missing data.
Example 42.9: Extracting A Business Cycle (Experimental)

The data set (not shown) gdp in this example has two variables: date dates the observations, and lgdp contains the quarterly readings of the US real GDP (in log scale). Pelagatti (2015, Example 3.3, Example 8.2) uses this quarterly time series (lgdp) to illustrate how you can adjust the smoothness of the estimated cycle by changing the order of the cycle in a trend-cycle decomposition,

\[ \text{lgdp}_t = \mu_t + \psi_t + \epsilon_t \]

where \( \mu_t \) is an integrated random walk trend, \( \psi_t \) is a cycle component, and \( \epsilon_t \) is an irregular component.

The following statements fit the model \( \text{lgdp}_t = \mu_t + \psi_t + \epsilon_t \), where the cycle component has an order of 1 (default):

```plaintext
proc ucm data=gdp;
   where year(date) >= 1970;
   id date interval=quarter;
   model lgdp;
   irregular;
   level variance=0 noest plot=smooth;
   slope;
   cycle plot=smooth;
   estimate plot=panel;
   forecast plot=decomp outfor=for1;
run;
```

The following statements fit the same model, except that the cycle order is 2. Similarly, a model with a cycle order of 4 is also fit (not shown).

```plaintext
proc ucm data=gdp;
   where year(date) >= 1970;
   id date interval=quarter;
   model lgdp;
   irregular;
   level variance=0 noest plot=smooth;
   slope;
   cycle order=2 plot=smooth;
   estimate plot=panel;
   forecast plot=decomp outfor=for2;
run;
```

Output 42.9.1 summarizes the features of the estimated cycles of different orders. The estimated periods of the first-order and second-order cycles, 31.59 and 45.18, are reasonable. However, the period of the fourth-order cycle seems quite unreasonable. Fortunately, Pelagatti (2015, Example 8.2) mentions that cycles of order 3 or higher are rarely needed when you are working with real economic series. Although they are not the same, the parameter estimates that the UCM procedure produces are reasonably close to those reported in Pelagatti (2015, Example 8.2).
Output 42.9.1 Cycles of Orders 1, 2, and 4: Summary

<table>
<thead>
<tr>
<th>order</th>
<th>period</th>
<th>Frequency</th>
<th>Rho</th>
<th>ErrorVar</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>31.59294</td>
<td>0.19888</td>
<td>0.94371</td>
<td>0.00004873</td>
</tr>
<tr>
<td>2</td>
<td>45.18259</td>
<td>0.13906</td>
<td>0.76177</td>
<td>0.00000956</td>
</tr>
<tr>
<td>4</td>
<td>38878</td>
<td>0.00016161</td>
<td>0.52055</td>
<td>0.00000856</td>
</tr>
</tbody>
</table>

Output 42.9.2 shows the plot of the first-order cycle, Output 42.9.3 shows the plot of the second-order cycle, and Output 42.9.4 shows the plot of the fourth-order cycle. You can see that although the overall form of the estimated cycle remains the same, the smoothness of the plot of the estimated cycle increases with the order.

Output 42.9.2 Estimated Cycle: Order = 1

![Smoothed Cycle for igdp](image)
Output 42.9.3 Estimated Cycle: Order = 2
Output 42.9.4 Estimated Cycle: Order = 4

Output 42.9.5 shows the three cycle estimates in the same plot. It shows that the estimates don’t differ very much.
**Output 42.9.5** Estimated Cycles of Orders 1, 2, and 4

Overview: VARMAX Procedure

Given a multivariate time series, the VARMAX procedure estimates the model parameters and generates forecasts that are associated with vector autoregressive moving average processes with exogenous regressors (VARMAX) models. Often, economic or financial variables are not only contemporaneously correlated with each other, but also correlated with each other’s past values. You can use the VARMAX procedure to model these types of time relationships. In many economic and financial applications, the variables of interest (dependent, response, or endogenous variables) are influenced by variables external to the system under consideration (independent, input, predictor, regressor, or exogenous variables). The VARMAX procedure enables you to model the dynamic relationships both among the dependent variables and between the dependent and independent variables.

A VARMAX model is defined in terms of the orders of the autoregressive or moving average processes (or both). When you use the VARMAX procedure, these orders can be specified by options or they can be automatically determined according to the information criteria. The VARMAX procedure supports the following information criteria: Akaike’s information criterion (AIC), the corrected AIC (AICC), the Hannan-Quinn criterion (HQC), the final prediction error (FPE), and the Schwarz Bayesian criterion (SBC), which is
Overview: VARMAX Procedure

also known as the Bayesian information criterion (BIC). For the definitions and usages of the information criteria, see the section “The Minimum Information Criterion (MINIC) Method” on page 3091.

If you do not want to use automatic order selection, the VARMAX procedure provides the following autoregressive order identification aids: partial cross-correlations, partial autoregressive coefficients, partial canonical correlations, and Yule-Walker estimates.

For situations where the stationarity of the time series is in question, the VARMAX procedure provides the following tests to aid in determining the presence of unit roots and cointegration: Dickey-Fuller tests, the Stock-Watson common trends test for the possibility of cointegration among nonstationary vector processes of integrated order one, and Johansen cointegration tests for nonstationary vector processes of integrated order one and order two.

For stationary vector times series or nonstationary series that are made stationary by appropriate differencing or cointegration, the VARMAX procedure provides the vector autoregressive and moving average (VARMA) model and the vector error correction model (VECM). The vector error correction model can be in both autoregressive (AR) and autoregressive and moving average (ARMA) forms.

To cope with the problem of high dimensionality in the parameters of the VAR model and the VECM, the VARMAX procedure provides both the Bayesian vector autoregressive (BVAR) model and the Bayesian vector error correction model (BVECM). Bayesian models are used when prior information about the model parameters is available.

The VARMAX procedure also allows independent (exogenous) variables and their distributed lags to influence dependent (endogenous) variables in various models. These models are identified by an X suffix added to the original model name; for example, VARMAX, VECMX, BVARX, and BVECMX.

Correlations in the second moments of the vector time series might exist; this is called conditional heteroscedasticity. The VARMAX procedure supports three forms of multivariate generalized autoregressive conditional heteroscedasticity (GARCH) models to model the conditional heteroscedasticity: the Baba-Engle-Kroner-Kraft (BEKK) GARCH model, the constant conditional correlation (CCC) GARCH model, and the dynamic conditional correlation (DCC) GARCH model. For CCC and DCC GARCH models, five subforms of univariate GARCH models are supported: the GARCH model, the exponential GARCH (EGARCH) model, the quadratic GARCH (QGARCH) model, the threshold GARCH (TGARCH) model, and the power GARCH (PGARCH) model.

You can use the VARMAX-GARCH model or the VEC-ARMAX-GARCH model to simultaneously model both the first and second moments of the time series.

Finally, for stationary time series exhibiting long-range dependence (also known as long memory or persistence), that is series with a slowly decaying sample autocorrelation function, the VARMAX procedure supports the VARFIMA (vector autoregressive fractionally integrated moving average) and VARFIMAX models.

Forecasting is one of the main objectives of multivariate time series analysis. After successfully fitting the VARMAX, BVARX, VECMX, BVECMX, VARFIMAX and multivariate GARCH models, the VARMAX procedure computes predicted values and conditional heteroscedasticity based on the parameter estimates and the past values of the vector time series. Out-of-sample multistep-ahead forecasts are also supported.

The following model parameter estimation methods are supported:

- the least squares (LS) method, which can be applied to VARX models
Chapter 43: The VARMAX Procedure

- the maximum likelihood (ML) method, which can be applied to all types of models and is used by default for VARFIMAX models,
- the conditional maximum likelihood (CML) method, which can be applied to VARMAX models

When you use the ML or CML method, you can start your optimization with the default or with different initial parameter values.

The VARMAX procedure supports the estimation of the restricted model when you impose linear constraints on the parameters of interest. The VARMAX procedure also supports various hypothesis tests of long-run effects and adjustment coefficients by using the likelihood ratio test that is based on Johansen cointegration analysis. It also supports the likelihood ratio test of weak exogeneity for each variable. In fact, because the VARMAX procedure outputs log-likelihood values for all models, you can always use the likelihood ratio test to check any linear hypothesis on parameters that are estimated in the models by estimating the restricted and unrestricted models separately. The VARMAX procedure also supports another alternative test, the Wald test.

After fitting the model parameters, the VARMAX procedure uses the following tests to provide model checks and residual analysis: Durbin-Watson (DW) statistics, the $F$ test for autoregressive conditional heteroscedastic (ARCH) disturbance, the $F$ test for AR disturbance, the Jarque-Bera normality test, and the portmanteau test.

The VARMAX procedure supports several modeling features, including seasonal deterministic terms, linear and quadratic time trends, subset models, multiple regression with distributed lags, the dead-start model (which does not have present values of the exogenous variables), and so on.

The VARMAX procedure provides a Granger causality test to determine the Granger-causal relationships between two distinct groups of variables. It also provides the following: the infinite order AR representation, the impulse response function (also called infinite order MA representation), the decomposition of the predicted error covariances, roots of the characteristic functions for both the AR and MA parts to evaluate the proximity of the roots to the unit circle, and contemporaneous relationships among the components of the vector time series.

---

Getting Started: VARMAX Procedure

This section provides several examples of the types of models that the VARMAX procedure supports.

Vector Autoregressive Model

Let $y_t = (y_{1t}, \ldots, y_{kt})'$, $t = 1, 2, \ldots$, denote a $k$-dimensional time series vector of random variables of interest. The $p$th-order VAR process is written as

$$y_t = \delta + \Phi_1 y_{t-1} + \cdots + \Phi_p y_{t-p} + \epsilon_t$$

where $\epsilon_t = (\epsilon_{1t}, \ldots, \epsilon_{kt})'$ is a vector white noise process such that $E(\epsilon_t) = 0$, $E(\epsilon_t \epsilon_s') = \Sigma$, and $E(\epsilon_t \epsilon_s') = 0$ for $t \neq s$; $\delta = (\delta_1, \ldots, \delta_k)'$ is a constant vector; and $\Phi_i$ is a $k \times k$ matrix.
Analyzing and modeling the series jointly enables you to understand the dynamic relationships over time among the series and to improve the accuracy of forecasts for individual series by using the additional information available from the related series and their forecasts.

Consider the first-order stationary bivariate vector autoregressive model:

$$y_t = \begin{pmatrix} 1.2 & -0.5 \\ 0.6 & 0.3 \end{pmatrix} y_{t-1} + \epsilon_t, \quad \text{with} \quad \Sigma = \begin{pmatrix} 1.0 & 0.5 \\ 0.5 & 1.25 \end{pmatrix}$$

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```plaintext
proc iml;
    sig = {1.0 0.5, 0.5 1.25};
    phi = {1.2 -0.5, 0.6 0.3};
    /* simulate the vector time series */
    call varmasim(y,phi) sigma = sig n = 100 seed = 34657;
    cn = {'y1' 'y2'};
    create simull from y[colname=cn];
    append from y;
quit;
```

The following statements plot the simulated vector time series $y_t$, which is shown in Figure 43.1:

```plaintext
data simull;
    set simull;
    date = intnx( 'year', '01jan1900'd, _n_-1 );
    format date year4.;
run;

proc sgplot data=simull;
    series x=date y=y1 / lineattrs=(pattern=solid);
    series x=date y=y2 / lineattrs=(pattern=dash);
yaxis label="Series";
run;
```
The following statements fit a VAR(1) model to the simulated data:

```sas
/*--- Vector Autoregressive Model ---*/
proc varmax data=simul1;
    id date interval=year;
    model y1 y2 / p=1 noint lagmax=3
        print=(estimates diagnose);
    output out=for lead=5;
run;
```
First, you specify the input data set in the PROC VARMAX statement. Then, you use the MODEL statement to designate the dependent variables, $y_1$ and $y_2$. To estimate a zero-mean VAR model, you specify the order of the autoregressive model in the P= option and the NOINT option. The MODEL statement fits the model to the data and prints parameter estimates and their significance. The PRINT=ESTIMATES option prints the matrix form of parameter estimates, and the PRINT=DIAGNOSE option prints various diagnostic tests. The LAGMAX=3 option prints the output for the residual diagnostic checks.

To output the forecasts to a data set, you specify the OUT= option in the OUTPUT statement. If you want to forecast five steps ahead, you use the LEAD=5 option. The ID statement specifies the yearly interval between observations and provides the Time column in the forecast output.

The VARMAX procedure output is shown in Figure 43.2 through Figure 43.10. The VARMAX procedure first displays descriptive statistics, as shown in Figure 43.2. The Type column indicates that the variables are dependent variables. The N column indicates the number of nonmissing observations.

Figure 43.3 shows the model type and the estimation method that is used to fit the model to the simulated data. It also shows the AR coefficient matrix in terms of lag 1, the schematic representation, and the parameter estimates and their significance that can indicate how well the model fits the data.

The “AR” table shows the AR coefficient matrix. The “Schematic Representation” table schematically represents the parameter estimates and enables you to easily verify their significance in matrix form.

In the “Model Parameter Estimates” table, the first column shows the variable on the left side of the equation; the second column is the parameter name AR/$i,j$, which indicates the ($i,j$) element of the lag $l$ autoregressive coefficient; the next four columns provide the estimate, standard error, $t$ value, and $p$-value for the parameter; and the last column is the regressor that corresponds to the displayed parameter.
The fitted VAR(1) model with estimated standard errors in parentheses is given as

\[
y_t = \begin{pmatrix} 1.160 & -0.511 \\ 0.055 & 0.059 \\ 0.546 & 0.385 \\ 0.058 & 0.062 \end{pmatrix} y_{t-1} + \epsilon_t
\]

Clearly, all parameter estimates in the coefficient matrix \( \Phi_1 \) are significant.

The model can also be written as two univariate regression equations:

\[
y_{1t} = 1.160 y_{1,t-1} - 0.511 y_{2,t-1} + \epsilon_{1t}
\]
\[
y_{2t} = 0.546 y_{1,t-1} + 0.385 y_{2,t-1} + \epsilon_{2t}
\]

The table in Figure 43.4 shows the innovation covariance matrix estimates, the log likelihood, and the various information criteria results. The variable names in the table for the innovation covariance matrix estimates \( \Sigma \) are printed for convenience: \( y_1 \) means the innovation for \( y_1 \), and \( y_2 \) means the innovation...
for \( y_2 \). The log likelihood for a VAR model that is estimated through least squares method is defined as
\[-T \log (|\hat{\Sigma}_{ML}|) + k / 2\]
where \( T(= 100 - 1 = 99) \) is the sample size except the presample being skipped because of the AR lag order, \( k(= 2) \) is the number of dependent variables, and \( \hat{\Sigma}_{ML} \) is the maximum likelihood estimate (MLE) of innovation covariance matrix. The matrix \( \hat{\Sigma}_{ML} \) is computed from the reported least squares estimate of the innovation covariance matrix, \( \hat{\Sigma} \), by adjusting the degrees of freedom.
\[
\hat{\Sigma}_{ML} = \frac{T - r_b}{T} \hat{\Sigma},
\]
where \( r_b (= 2) \) is the number of parameters in each equation. You can use the information criteria to compare the fit of competing models to a set of data. The model that has a smaller value of the information criterion is preferred when it is compared to other models. For more information about how to calculate the information criteria, see the section “Multivariate Model Diagnostic Checks” on page 3110.

The VARMAX procedure provides diagnostic checks for the univariate form of the equations. The table in Figure 43.8 describes how well each univariate equation fits the data. From the two univariate regression equations shown in Figure 43.3, the values of \( R^2 \) in the second column of Figure 43.8 are 0.84 and 0.79. The standard deviations in the third column are the square roots of the diagonal elements of the covariance matrix from Figure 43.4. The \( F \) statistics in the fourth column test the null hypotheses \( \phi_{11} = \phi_{12} = 0 \) and \( \phi_{21} = \phi_{22} = 0 \), where \( \phi_{ij} \) is the \((i,j)\) element of the matrix \( \Phi_1 \). The last column shows the \( p \)-values of the \( F \) statistics. The results show that each univariate model is significant.

The check for white noise residuals in terms of the univariate equation is shown in Figure 43.9. This output contains information that indicates whether the residuals are correlated and heteroscedastic. In the first table, the second column contains the Durbin-Watson test statistics to test the null hypothesis that the residuals are
Bayesian Vector Autoregressive Model

The Bayesian vector autoregressive (BVAR) model avoids problems of collinearity and overparameterization that often occur with the use of VAR models. BVAR models avoid these problems by imposing priors on the AR parameters.

The following statements fit a BVAR(1) model to the simulated data:

```
Bayesian Vector Autoregressive Model

The Bayesian vector autoregressive (BVAR) model avoids problems of collinearity and overparameterization that often occur with the use of VAR models. BVAR models avoid these problems by imposing priors on the AR parameters.

The following statements fit a BVAR(1) model to the simulated data:
```
Chapter 43: The VARMAX Procedure

/*--- Bayesian Vector Autoregressive Process ---*/

proc varmax data=simul1;
   model y1 y2 / p=1 noint
       prior=(lambda=0.9 theta=0.1);
run;

The hyperparameters, LAMBDA=0.9 and THETA=0.1, in the PRIOR= option control the prior covariance. Part of the VARMAX procedure output is shown in Figure 43.11, whose parameter estimates are slightly different from those in Figure 43.3. By choosing the appropriate priors, you might be able to obtain more accurate forecasts by using a BVAR model instead of an unconstrained VAR model. For more information, see the section “Bayesian VAR and VARX Modeling” on page 3099.

**Vector Error Correction Model**

A vector error correction model (VECM) can lead to a better understanding of the nature of any nonstationarity among the different component series and can also improve longer-term forecasting compared to an unconstrained model.

The VECM(\(p\)) form with the cointegration rank, \(r(\leq k)\), is written as

\[
\Delta y_t = \delta + \Pi y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t
\]
where $\Delta$ is the differencing operator, such that $\Delta y_t = y_t - y_{t-1}$; $\Pi = \alpha \beta'$, where $\alpha$ and $\beta$ are $k \times r$ matrices; and $\Phi_i^*$ is a $k \times k$ matrix.

The VECM($p$) form has an equivalent VAR($p$) representation as described in the section “Vector Autoregressive Model” on page 2982.

$$y_t = \delta + (I_k + \Pi + \Phi_1^*)y_{t-1} + \sum_{i=2}^{p-1} (\Phi_i^* - \Phi_{i-1}^*)y_{t-i} - \Phi_{p-1}^*y_{t-p} + \epsilon_t$$

where $I_k$ is a $k \times k$ identity matrix.

An example of the second-order nonstationary vector autoregressive model is

$$y_t = \begin{pmatrix} -0.2 & 0.1 \\ 0.5 & 0.2 \end{pmatrix} y_{t-1} + \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} y_{t-2} + \epsilon_t$$

with

$$\Sigma = \begin{pmatrix} 100 & 0 \\ 0 & 100 \end{pmatrix} \text{ and } y_{-1} = y_0 = \begin{pmatrix} 0 \\ 0 \end{pmatrix}$$

This process can be given the following VECM(2) representation with the cointegration rank one:

$$\Delta y_t = \begin{pmatrix} -0.4 \\ 0.1 \end{pmatrix} (1,-2)y_{t-1} - \begin{pmatrix} 0.8 & 0.7 \\ -0.4 & 0.6 \end{pmatrix} \Delta y_{t-1} + \epsilon_t$$

The following PROC IML statements generate simulated data for this VECM(2) form and the PROC SGPLOT statements plot the data, as shown in Figure 43.12:

```plaintext
proc iml;
    sig = 100*i(2);
    phi = {-0.2 0.1, 0.5 0.2, 0.8 0.7, -0.4 0.6};
    call varmasim(y,phi) sigma=sig n=100 initial=0 seed=45876;
    cn = {'y1' 'y2'};
    create simul2 from y[colname=cn];
    append from y;
quit;

data simul2;
```
Cointegration Testing

The following statements use the Johansen cointegration rank test. The COINTTEST=(JOHANSEN) option performs the Johansen trace test and is equivalent to specifying the COINTTEST option with no additional suboptions or specifying the COINTTEST=(JOHANSEN=(TYPE=TRACE)) option.
/*--- Cointegration Test ---*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint df test coint test=(johansen);
run;

Figure 43.13 shows the output for Dickey-Fuller tests for the nonstationarity of each series and the Johansen
cointegration rank test between series.

<table>
<thead>

<td>-50.49</td>
<td>0.0003</td>
<td>-4.92</td>
<td>0.0006</td>
</tr>
</tbody>
</table>

In Dickey-Fuller tests, the second column specifies three types of models, which are zero mean, single mean,
or trend. The third column (Rho) and the fifth column (Tau) are the test statistics that are used to test the null
hypothesis that the series has a unit root. Other columns are their p-values. You can see that both series have
unit roots. For a description of Dickey-Fuller tests, see the section “PROBDF Function for Dickey-Fuller
Tests” on page 167 in Chapter 5, “SAS Macros and Functions.”

In the “Cointegration Rank Test Using Trace” table, the last two columns explain the drift in the model or
process. Because the NOINT option is specified, the model is

\[ \Delta y_t = \Pi y_{t-1} + \Phi^*_1 \Delta y_{t-1} + \epsilon_t \]

The column Drift in ECM indicates that there is no separate drift in the error correction model, and the
column Drift in Process indicates that the process has a constant drift before differencing.

H0 is the null hypothesis, and H1 is the alternative hypothesis. The first row tests the cointegration rank
\( r = 0 \) against \( r > 0 \), and the second row tests \( r = 1 \) against \( r > 1 \). The trace test statistics in the fourth
column are computed by \(-T \sum_{i=r+1}^k \log(1 - \lambda_i)\), where \( T \) is the available number of observations and \( \lambda_i \)
is the eigenvalue in the third column. The p-values for these statistics are output in the fifth column. If you
compare the p-value in each row to the significance level of interest (such as 5%), the null hypothesis that
there is no cointegrated process (H0: \( r = 0 \)) is rejected, whereas the null hypothesis that there is at most one
cointegrated process (H0: \( r = 1 \)) cannot be rejected.

The following statements fit a VECM(2) form to the simulated data:
/*---- Vector Error Correction Model ----*/

proc varmax data=simul2;
  model y1 y2 / p=2 noint lagmax=3
          print=(iarr estimates);
  cointeg rank=1 normalize=y1;
run;

The results in Figure 43.13 indicate that the time series are cointegrated with rank = 1. So you might want to specify the RANK=1 option in the COINTEG statement. For normalizing the value of the cointegrated vector, you specify the normalized variable by using the NORMALIZE= option in the COINTEG statement. The COINTEG statement produces the estimates of the long-run parameter, \( \beta \), and the adjustment coefficient, \( \alpha \). The PRINT=(IARR) option provides the VAR(2) representation.

The VARMAX procedure output is shown in Figure 43.14 through Figure 43.17. In Figure 43.14, “1” indicates the first column of the \( \alpha \) and \( \beta \) matrices. Because the cointegration rank is 1 in the bivariate system, \( \alpha \) and \( \beta \) are two-dimensional vectors. The estimated cointegrating vector is \( \hat{\beta} = (1, -1.96)' \). Therefore, the long-run relationship between \( y_{1t} \) and \( y_{2t} \) is \( y_{1t} = 1.96y_{2t} \). The first element of \( \hat{\beta} \) is 1 because \( y_1 \) is specified as the normalized variable. Asymptotically, \( \alpha \) follows a normal distribution, and the \( t \) values and \( p \)-values of its elements are shown in the “Alpha and Beta Parameter Estimates” table; however, because \( \beta \) follows a nonnormal distribution, the corresponding standard errors, \( t \) values, and \( p \)-values are missing. The Variable column shows the variables that correspond to the coefficients. For example, for the coefficient \( \alpha_{ij} \) (the \( i \)th element in the \( j \)th column of \( \alpha \)), \( \text{ALPHA}_i \_j \), the variable is the inner product of the transpose of the \( j \)th column of \( \beta \) (Beta\[j\]'\_\_DEP\_(t-1)) and the vector of lag 1 dependent variables \( y_{t-1} \_ \_DEP\_(t-1) \).

Figure 43.15 shows the parameter estimates in terms of lag 1 coefficients, $y_{t-1}$, and lag 1 first-differenced coefficients, $\Delta y_{t-1}$, and their significance. “Alpha * Beta” indicates the coefficients of $y_{t-1}$ and is obtained by multiplying the Alpha and Beta estimates in Figure 43.14. The parameter $AR1_{i-j}$ (which is shown in the “Model Parameter Estimates” table) corresponds to the elements in the “Alpha * Beta” matrix. The parameter $AR2_{i-j}$ corresponds to the elements in the differenced lagged AR coefficient matrix. The “D_” prefixed to a variable name in Figure 43.15 implies differencing.

The PRINT=(IARR) option in the previous SAS statements prints the reparameterized coefficient estimates. Because LAGMAX=3 in those statements, the coefficient matrix of lag 3 is zero.

The VECM(2) form in Figure 43.17 can be rewritten as the following second-order vector autoregressive model:

\[ y_t = \begin{pmatrix} -0.210 & 0.167 \\ 0.512 & 0.220 \end{pmatrix} y_{t-1} + \begin{pmatrix} 0.743 & 0.746 \\ -0.405 & 0.572 \end{pmatrix} y_{t-2} + \epsilon_t \]

**Bayesian Vector Error Correction Model**

Bayesian inference on a cointegrated system begins by using the priors of \( \beta \), which are obtained from the VECM(\( p \)) form. Bayesian vector error correction models can improve forecast accuracy for cointegrated processes.

To use a Bayesian vector error correction model, you specify both the PRIOR= option in the MODEL statement and the COINTEG statement. The following statements fit a BVECM(2) form to the simulated data:

```sas
/*--- Bayesian Vector Error Correction Model ---*/
proc varmax data=simul2;
   model y1 y2 / p=2 noint
       prior=( lambda=0.5 theta=0.2 )
       print=(estimates);
   cointeg rank=1 normalize=y1;
run;
```
The VARMAX procedure output in Figure 43.18 shows the model type fitted to the data, the estimates of the adjustment coefficient (\( \alpha \)), the parameter estimates in terms of lag 1 coefficients (\( y_{t-1} \)), and lag 1 first-differenced coefficients (\( \Delta y_{t-1} \)).

### Fractionally integrated models

Fractionally integrated models can be used to model stationary time series whose sample autocorrelation function decays slowly at large positive and negative lags. This behavior is often referred to as long-range dependence (LRD), long memory, or persistence; series that exhibit such behavior are called long-range dependent (LRD).

A typical parametric model for a \( k \)-dimensional series \( y_t = (y_{1t}, \ldots, y_{kt})' \), \( t = 1, \ldots, T \), whose individual components are LRD is the VARFIMA (vector autoregressive fractionally integrated moving average) model. It is obtained as a natural extension of the well-known class of ARFIMA models by fractionally integrating the individual components of a \( k \)-dimensional white noise series. For example, a bivariate VARFIMA(0, \( D \), 0) series with no intercept term is given by

\[
y_t = \begin{pmatrix} y_{1t} \\ y_{2t} \end{pmatrix} = \begin{pmatrix} (I - B)^{-d_1} & 0 \\ 0 & (I - B)^{-d_2} \end{pmatrix} \begin{pmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{pmatrix} = (I - B)^{-D} \epsilon_t
\]

where \( B \) is the backshift operator; \( I = B^0 \) is the identity operator; \( d_1, d_2 \in (-1/2, 1/2) \) are the LRD parameters of the component series \( \{y_{1t}\}_{t \in \mathbb{Z}} \) and \( \{y_{2t}\}_{t \in \mathbb{Z}} \), respectively; \( D = \text{diag}(d_1, d_2) \); and \( \{\epsilon_t\}_{t \in \mathbb{Z}} = \ldots \)
\{(\epsilon_{1t}, \epsilon_{2t})\}_{t \in \mathbb{Z}} is a bivariate white noise series indexed by the set of integers \(\mathbb{Z}\) with zero mean \(\mathbb{E}\epsilon_t = 0\) and covariance \(\mathbb{E}\epsilon_t \epsilon_t' = \Sigma\).

The multivariate VARFIMA model is defined analogously. The matrix \(\Sigma\) is in general nondiagonal, which enables the VARFIMA model to capture dependence between the individual series.

The following statements plot a simulated bivariate VARFIMA(0, \(D, 0\)) series with \(d_1 = 0.2, d_2 = 0.4\), and Gaussian errors with \(\Sigma_{11} = \Sigma_{22} = 3\) and \(\Sigma_{12} = 0.5\):

```plaintext
data VARFIMA0D0;
  time = _N_;  
  input y1 y2;
  datalines;
  1.6380971 1.877144
... more lines ...
  0.3482938 4.8601886
  1.5320803 2.8687495
;  
proc sgplot data = VARFIMA0D0;
  series x = time y=y1 / lineattrs=(pattern=solid);
  series x = time y=y2 / lineattrs=(pattern=dash);
  yaxis label="Series";
run;
```
Before fitting a VARFIMA model to a data set, you should plot the series’ sample autocorrelation function to confirm its slow decay. It is also instructive to plot the periodogram of the series. In the presence of long memory, the periodogram explodes at frequencies near 0.

The following statements produce the periodogram and the sample autocorrelation function for the specified data:

```sas
ods graphics on;
proc timeseries data= VARFIMA0D0 plots = (periodogram acf);
   var y1 y2;
   spectra freq / adjmean;
   corr / NLAG = 30;
run;
```
The magnitude of the LRD parameters $d_1$ and $d_2$ controls the memory of the two series. Series $y_2$ has a larger LRD parameter than series $y_1$ and hence is expected to exhibit longer memory. In the time domain, this effect is illustrated in Figure 43.20, where the autocorrelation function of series $y_2$ (right plot in Figure 43.20) decays more slowly than the autocorrelation function of series $y_1$ (left plot in Figure 43.20) with the increasing lag.

Figure 43.21 is the frequency domain analogue of Figure 43.20. In this case, the longer memory of series $y_2$ is reflected by its periodogram (right plot in Figure 43.21), which blows up higher than the periodogram of series $y_1$ (left plot in Figure 43.21) at frequencies near 0. Note the different scales used in the two plots.

The following statements fit the VARFIMA(0, D, 0) model with no intercept term to the data. The FI option in the MODEL statement specifies fractional integration.

```plaintext
proc varmax data = VARFIMA0D0;
   model y1 y2 / fi noint method = ML;
run;
```
Vector Autoregressive Model with Exogenous Variables

A VAR process can be affected by other observable variables that are determined outside the system of interest. Such variables are called exogenous (independent) variables. Exogenous variables can be stochastic or nonstochastic. The process can also be affected by the lags of exogenous variables. A model used to describe this process is called a VARX(\(p,s\)) model.

The VARX(\(p,s\)) model is written as

\[
y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]

where \(x_t = (x_{1t}, \ldots, x_{rt})'\) is an \(r\)-dimensional time series vector and \(\Theta_i^*\) is a \(k \times r\) matrix.

For example, a VARX(1,0) model is

\[
y_t = \delta + \Phi_1 y_{t-1} + \Theta_0^* x_t + \epsilon_t
\]

where \(y_t = (y_{1t}, y_{2t}, y_{3t})'\) and \(x_t = (x_{1t}, x_{2t})'\).

The following statements fit the VARX(1,0) model to the given data:
data grunfeld;
  input year y1 y2 y3 x1 x2 x3;
  label y1='Gross Investment GE'
    y2='Capital Stock Lagged GE'
    y3='Value of Outstanding Shares GE Lagged'
    x1='Gross Investment W'

0.164 \\
0.002
\end{pmatrix}
\begin{pmatrix}
y_{1,t-1} \\
y_{2,t-1} \\
y_{3,t-1}
\end{pmatrix}
+ \begin{pmatrix}
0.029 \\
-0.841 \\
0.938
\end{pmatrix}
\begin{pmatrix}
0.016 \\
0.152 \\
0.006
\end{pmatrix}
\begin{pmatrix}
\epsilon_{1t} \\
\epsilon_{2t} \\
\epsilon_{3t}
\end{pmatrix}
\]

Parameter Estimation and Testing on Restrictions

In the previous example, the VARX(1,0) model is written as

\[y_t = \delta + \Theta_1^* x_t + \Phi_1 y_{t-1} + \epsilon_t\]
Parameter Estimation and Testing on Restrictions

with

\[
\Theta_0^* = \begin{pmatrix}
\theta_{11}^* & \theta_{12}^* \\
\theta_{21}^* & \theta_{22}^* \\
\theta_{31}^* & \theta_{32}^*
\end{pmatrix}
\]

\[
\Phi_1 = \begin{pmatrix}
\phi_{11} & \phi_{12} & \phi_{13} \\
\phi_{21} & \phi_{22} & \phi_{23} \\
\phi_{31} & \phi_{32} & \phi_{33}
\end{pmatrix}
\]

In Figure 43.25 of the preceding section, you can see several insignificant parameters. For example, the coefficients XL0_1_2, AR1_1_2, and AR1_3_2 are insignificant.

The following statements restrict the coefficients of \( \theta_{12}^* = \phi_{12} = \phi_{32} = 0 \) for the VARX(1,0) model:

```plaintext
/*---- Models with Restrictions and Tests ----*/
proc varmax data=grunfeld;
  model y1-y3 = x1 x2 / p=1 print=(estimates);
  restrict XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;
```

The output in Figure 43.26 shows that three parameters \( \theta_{12}^*, \phi_{12}, \) and \( \phi_{32} \) are replaced by the restricted values, zeros, and their standard errors are also zeros to indicate that the parameters are fixed to these values.

**Figure 43.26** Parameter Estimation with Restrictions

The output in Figure 43.27 shows the estimates of the Lagrangian parameters and their significance. Based on the \( p \)-values associated with the Lagrangian parameters, you cannot reject the null hypotheses \( \theta_{12}^* = 0, \phi_{12} = 0, \) and \( \phi_{32} = 0 \) with the 0.05 significance level.
### Figure 43.27 RESTRICT Statement Results

| Parameter  | Estimate | Standard Error | t Value | Pr > |t| | Equation       |
|------------|----------|----------------|---------|-------|---|----------------|
| Restrict0  | 1.74969  | 21.44026       | 0.08    | 0.9389|   | XL0_1_2 = 0    |
| Restrict1  | 30.36254 | 70.74347       | 0.43    | 0.6899|   | AR1_1_2 = 0    |
| Restrict2  | 55.42191 | 164.03075      | 0.34    | 0.7524|   | AR1_3_2 = 0    |

The TEST statement in the following example tests $\phi_{31} = 0$ and $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ for the VARX(1,0) model:

```plaintext
proc varmax data=grunfeld;
   model y1-y3 = x1 x2 / p=1;
   test AR(1,3,1)=0;
   test XL(0,1,2)=0, AR(1,1,2)=0, AR(1,3,2)=0;
run;
```

The output in Figure 43.28 shows that the first column in the output is the index corresponding to each TEST statement. You can reject the hypothesis test $\phi_{31} = 0$ at the 0.05 significance level, but you cannot reject the joint hypothesis test $\theta_{12}^* = \phi_{12} = \phi_{32} = 0$ at the 0.05 significance level.

### Causality Testing

The following statements use the CAUSAL statement to compute the Granger causality test for a VAR(1) model. For the Granger causality tests, the autoregressive order should be defined by the P= option in the MODEL statement. The variable groups are defined in the CAUSAL statement as well. Regardless of whether the variables specified in the GROUP1= and GROUP2= options are designated as dependent or exogenous (independent) variables in the MODEL statement, the CAUSAL statement fits the VAR(p) model by considering the variables in the two groups as dependent variables.

```plaintext
/*---- Causality Testing ----*/
proc varmax data=grunfeld;
   model y1-y3 = x1 x2 / p=1 noprint;
   causal group1=(x1) group2=(y1-y3);
   causal group1=(y3) group2=(y1 y2);
run;
```
The output in Figure 43.29 is associated with the CAUSAL statement. The first CAUSAL statement fits the VAR(1) model by using the variables \( y_1, y_2, y_3, \) and \( x_1 \). The second CAUSAL statement fits the VAR(1) model by using the variables \( y_1, y_3, \) and \( y_2 \).

**Figure 43.29** CAUSAL Statement Results

<table>
<thead>
<tr>
<th>Test</th>
<th>DF</th>
<th>Chi-Square</th>
<th>Pr &gt; ChiSq</th>

</tbody>
</table>

Test 1: Group 1 Variables: \( x_1 \)
Group 2 Variables: \( y_1, y_2, y_3 \)

Test 2: Group 1 Variables: \( y_3 \)
Group 2 Variables: \( y_1, y_2 \)

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2.

The first column in the output is the index corresponding to each CAUSAL statement. The output shows that you cannot reject that \( x_1 \) is influenced by itself and not by \( (y_1, y_2, y_3) \) at the 0.05 significance level for Test 1. You can reject that \( y_3 \) is influenced by itself and not by \( (y_1, y_2) \) for Test 2. For more information, see the section “VAR and VARX Modeling” on page 3092.

**Multivariate GARCH Models**

Modeling and forecasting the volatility of time series has been the focus of many researchers and practitioners, especially in the fields of risk management, portfolio optimization, and asset pricing. One of the most powerful tools for volatility modeling is the autoregressive conditional heteroscedasticity (ARCH) model proposed by Engle (1982) and extended by Bollerslev (1986) to the generalized autoregressive conditional heteroscedasticity (GARCH) model. The VARMAX procedure supports three forms of multivariate GARCH models: BEKK, CCC, and DCC. This section shows some examples of how to specify, estimate, and compare various forms of multivariate GARCH models.

Data about two indices, the Dow Jones Industrial Average index and the Standard & Poor's 500 index, are obtained from Yahoo Finance and used in this section. The sample contains daily data from February 16, 2005, to February 13, 2015. The following statements input the daily prices and then generate the daily returns:

```plaintext
data indices;
  input date : MMDDYY10. DJIA SP500;
  logDJIA = log(DJIA); logSP500 = log(SP500);
  rdJIA = (logDJIA-lag(logDJIA))*100;
  rSP500 = (logSP500-lag(logSP500))*100;
datalines;
2/16/2005  10834.88  1210.34
2/17/2005  10754.26  1200.75
2/18/2005  10785.22  1201.59
```

The output in Figure 43.29 is associated with the CAUSAL statement. The first CAUSAL statement fits the VAR(1) model by using the variables \( y_1, y_2, y_3, \) and \( x_1 \). The second CAUSAL statement fits the VAR(1) model by using the variables \( y_1, y_3, \) and \( y_2 \).
To model the volatility of bivariate returns, rDJIA and rSP500, you can start with the BEKK GARCH(1,1) model. The following equations describe the bivariate BEKK GARCH(1,1) model:

\[
\begin{align*}
  r_t &= H_t^{1/2}\epsilon_t \\
  H_t &= C + A^1_{t-1}r_{t-1}' + G^1_{t}H_{t-1}G_1 \\
  &= \begin{bmatrix} c_{11} & c_{12} \\ c_{12} & c_{22} \end{bmatrix} + \begin{bmatrix} a_{11,1} & a_{12,1} \\ a_{21,1} & a_{22,1} \end{bmatrix}\begin{bmatrix} r_{1,t-1} \\ r_{2,t-1} \end{bmatrix} + \begin{bmatrix} g_{11,1} & g_{12,1} \\ g_{21,1} & g_{22,1} \end{bmatrix}\begin{bmatrix} h_{11,t-1} & h_{12,t-1} \\ h_{21,t-1} & h_{22,t-1} \end{bmatrix} \\
  &+ \begin{bmatrix} a_{11,1} & a_{12,1} \\ a_{21,1} & a_{22,1} \end{bmatrix}\begin{bmatrix} g_{11,1} & g_{12,1} \\ g_{21,1} & g_{22,1} \end{bmatrix}
\end{align*}
\]

In these equations, \( r_t \) is the vector of returns at time \( t \), \( H_t \) is the conditional covariance matrix of \( r_t \), \( H_t^{1/2} \) denotes the square root of \( H_t \) such that the square of matrix \( H_t^{1/2} \) is \( H_t \), \( \epsilon_t \) is the innovation at time \( t \) and follows an iid bivariate standard normal distribution, \( C \) is a \( 2 \times 2 \) symmetric parameter matrix, \( A_1 \) is a \( 2 \times 2 \) full parameter matrix for the first lag of the ARCH term, and \( G_1 \) is a \( 2 \times 2 \) full parameter matrix for the first lag of the GARCH term. Hence, there are 11 parameters in total for a bivariate BEKK GARCH(1,1) model; that is, a vector \( (c_{11}, c_{12}, c_{22}, a_{11,1}, a_{12,1}, a_{21,1}, a_{22,1}, g_{11,1}, g_{12,1}, g_{21,1}, g_{22,1})' \).

You can use the FORM=BEKK option in the GARCH statement to specify the BEKK GARCH form, or you can omit this option because BEKK is the default value for the FORM= option. The Q= option in the GARCH statement specifies the lags of the ARCH terms, and the P= option in the GARCH statement specifies the lags of the GARCH terms. The forecasts of conditional covariance matrices are output to a SAS data set when you specify the OUTHT= option in the GARCH statement. The parameter estimates and their covariance matrix are output to a SAS data set when you specify the OUTEST= option together with the OUTCOV option in the PROC VARMAX statement.

The following statement specifies the BEKK GARCH(1,1) model:

```sas
/**** BEKK ****/
proc varmax data=indices outest=oebekk outcov;
   model rDJIA rSP500 / noint;
   garch p=1 q=1 form=bekk outht=ohbekk;
run;
```

Figure 43.30 shows the log likelihood and the information criteria. They are used later in the model comparison.
Figure 43.30  BEKK GARCH Log Likelihood and Information Criteria

The VARMAX Procedure

<table>

</tbody>
</table>

Log-likelihood 1360.976

AICC -2699.85
HQC -2676.68
AIC -2699.95
SBC -2635.82
FPEC 0.080617

Figure 43.31 shows the parameters estimates for the BEKK GARCH(1,1) model. For the constant term $C$, $GCH_{i,j}$, $i, j = 1, 2$, correspond to parameters $c_{ij}$, respectively. Because $C$ is symmetric, $GCH_{2,1}$ is omitted. For the ARCH and GARCH terms, $ACH_{i,j,l}$, $l = 1, i, j = 1, 2$, correspond to $a_{ij,l}$, respectively, and $GCH_{i,j,l}$, $l = 1, i, j = 1, 2$, correspond to $g_{ij,l}$, respectively.

Figure 43.31  BEKK GARCH Parameter Estimates

<table>
<thead>
<tr>
<th>GARCH Model Parameter Estimates</th>
</tr>
</thead>
<tbody>
<tr>

<tr>
<td>ACH1_1_1</td>
</tr>
<tr>
<td>ACH1_1_2</td>
</tr>
<tr>
<td>ACH1_2_2</td>
</tr>
</tbody>
</table>

As shown in Figure 43.31, the standard errors of $GCHC1_1$ and $GCHC1_2$ are both zeros. It might be a sign that the numerical optimization for the BEKK GARCH model converges to a local minimum instead of the global minimum, which often happens for nonlinear optimization of complex models that have many parameters. A possible way to solve this problem is to try different initial values. To obtain reasonable initial values, the following statements fit a diagonal BEKK GARCH model (that is, a restricted BEKK GARCH model in which the ARCH and GARCH parameter matrices are diagonal):

```plaintext
/*--- Diagonal BEKK ---*/

proc varmax data=indices outest=oebekk outcov;
  model rDJIA rSP500 / noint;
  garch p=1 q=1 form=bekk;
  restrict ach(1,1,2), ach(1,2,1), gch(1,1,2), gch(1,2,1);
run;
```
The parameter estimates of the diagonal BEKK GARCH model are shown in Figure 43.32. As expected, the standard errors of the off-diagonal elements of the ARCH and GARCH parameter matrices (namely $ACH_{1,1,2}$, $ACH_{1,2,1}$, $GCH_{1,1,2}$, and $GCH_{1,2,1}$) are all zeros because they are restricted in the RESTRICT statement. All other parameters have valid standard errors.

**Figure 43.32** Diagonal BEKK GARCH Parameter Estimates

The VARMAX Procedure

| Parameter  | Estimate | Standard Error | t Value | Pr > |t| |
|------------|----------|----------------|---------|-------|
| $GCHC_{1,1}$ | 0.01407 | 0.00254 | 5.53 | 0.0001 |
| $GCHC_{1,2}$ | 0.01446 | 0.00262 | 5.51 | 0.0001 |
| $GCHC_{2,2}$ | 0.01598 | 0.00299 | 5.34 | 0.0001 |
| $ACH_{1,1,1}$ | 0.25702 | 0.01251 | 20.54 | 0.0001 |
| $ACH_{1,2,1}$ | 0.00000 | 0.00000 | | |
| $ACH_{1,1,2}$ | 0.00000 | 0.00000 | | |
| $ACH_{1,2,2}$ | 0.26061 | 0.01302 | 20.02 | 0.0001 |
| $GCH_{1,1,1}$ | -0.95794 | 0.00413 | -231.85 | 0.0001 |
| $GCH_{1,2,1}$ | 0.00000 | 0.00000 | | |
| $GCH_{1,1,2}$ | 0.00000 | 0.00000 | | |
| $GCH_{1,2,2}$ | -0.95694 | 0.00443 | -216.10 | 0.0001 |

Figure 43.33 shows the log likelihood and the information criteria. The log likelihood for the diagonal BEKK GARCH model is larger than that of the previous estimated BEKK GARCH model (which is shown in Figure 43.30). The larger value confirms that the previous BEKK GARCH model does not converge to the global minimum.

The following statements reestimate the BEKK GARCH model whose initial values are parameter estimates of the diagonal BEKK GARCH model (which are shown in Figure 43.32):

```plaintext
/*---- BEKK with Initial Values ----*/

proc varmax data=indices outest=oebekk outcov;
  model rDJIA rSP500 / noint;
  garch p=1 q=1 form=bekk;
  initial gchc(1,1)=0.01407, gchc(1,2)=0.01446, gchc(2,2)=0.01598,
```
The parameter estimates of the reestimated BEKK GARCH models are shown in Figure 43.34. The standard errors of all parameters are valid.

```
run;
```

Figure 43.34 Reestimated BEKK GARCH Parameter Estimates

| Parameter  | Estimate | Standard Error | t Value | Pr > |t| |
|------------|----------|----------------|---------|------|---|
| GCHC1_1    | 0.01999  | 0.00394        | 5.07    | 0.0001 |
| GCHC1_2    | 0.02043  | 0.00391        | 5.22    | 0.0001 |

| GCH1_1_2   | 0.03746  | 0.04018        | 0.93    | 0.3513 |
| GCH1_2_2   | -0.97038 | 0.03589        | -27.04  | 0.0001 |

Figure 43.35 shows the log likelihood and information criteria of the reestimated BEKK GARCH model. As expected, the log likelihood of the reestimated BEKK GARCH model is larger than that of the diagonal BEKK GARCH model. Moreover, the reestimated BEKK GARCH model has a smaller SBC, compared to the SBC of the diagonal BEKK GARCH model (which is shown in Figure 43.33). The smaller SBC means that the BEKK GARCH model should be chosen instead of the diagonal BEKK GARCH model.

```

```

The number of parameters for a BEKK GARCH model increases very quickly as the number of dependent variables increases. There are \((p + q)k^2 + k(k + 1)/2\) parameters for a \(k\)-variate BEKK GARCH(\(p, q\)) model. For example, a 16-variate BEKK GARCH(1,1) model has 648 parameters to be estimated.

Compared with BEKK GARCH models, CCC GARCH models are much more parsimonious. In a CCC GARCH model, each series follows a GARCH process and their composition through the constant conditional
Chapter 43: The VARMAX Procedure

A bivariate CCC GARCH(1,1) has the form

\[
\begin{align*}
    r_t &= H_t^\frac{1}{2} \epsilon_t \\
    H_t &= D_t S D_t \\
    D_t &= \begin{bmatrix}
        \sqrt{h_{11,t}} & 0 \\
        0 & \sqrt{h_{22,t}}
    \end{bmatrix} \\
    S &= \begin{bmatrix}
        1 & s_{12} \\
        s_{12} & 1
    \end{bmatrix} \\
    h_{11,t} &= c_{11} + a_{11,1} r_{1,t-1}^2 + g_{11,1} h_{11,t-1} \\
    h_{22,t} &= c_{22} + a_{22,1} r_{2,t-1}^2 + g_{22,1} h_{22,t-1}
\end{align*}
\]

where \( D_t \) is the diagonal matrix with conditional standard deviations and \( S \) is the time-invariant conditional correlation matrix. Hence, there are seven parameters to be estimated; that is, a vector \( (s_{12}, c_{11}, c_{22}, a_{11,1}, a_{22,1}, g_{11,1}, g_{22,1})^{\prime} \). A \( k \)-variate CCC GARCH(\( p, q \)) model has \((p + q + 1)k + k(k - 1)/2\) parameters. For example, a 16-variate CCC GARCH(1,1) model has 168 parameters to be estimated, about \(1/4\) of the number that a BEKK GARCH(1,1) model has.

The following statements estimate a CCC GARCH(1,1) model:

```plaintext
/*--- CCC ---*/
proc varmax data=indices outest=oeccc outcov;
    model rDJIA rSP500 / noint;
    garch p=1 q=1 form=ccc outht=ohccc;
run;
```

Figure 43.36 shows the parameter estimates for the CCC GARCH(1,1) model. For the constant conditional correlation matrix \( S \), \( CCC1_2 \) corresponds to the parameter \( s_{12} \).

**Figure 43.36** CCC GARCH Parameter Estimates

| Parameter | Estimate | Standard Error | t Value | Pr > |t| |
|-----------|----------|----------------|---------|------|---|
| CCC1_2    | 0.97294  | 0.00109        | 890.75  | 0.0001 | 0  |
| GCHC1_1   | 0.03713  | 0.00504        | 7.37    | 0.0001 |    |
| GCHC2_2   | 0.04004  | 0.00536        | 7.47    | 0.0001 |    |

| GCH1_2_2  | 0.88916  | 0.01099        | 80.92   | 0.0001 |    |
Figure 43.37 shows the log likelihood and the information criteria. Compared to the SBC for the BEKK GARCH model (shown in Figure 43.35), the SBC for the CCC GARCH model is much larger, which means the CCC GARCH model should not be preferred.

![Figure 43.37 CCC GARCH Log Likelihood and Information Criteria](image)

The CCC GARCH model is not preferred over the BEKK GARCH model in this case because the basic assumption in the CCC GARCH model—that the conditional correlation matrix is time-invariant—might not hold. A DCC GARCH model relaxes this assumption and models the time-varying conditional correlation matrix in an ARMA form. A bivariate DCC GARCH(1,1) has the form

\[
\begin{align*}
    r_t &= H_t^{1/2} \epsilon_t \\
    H_t &= D_t S_t D_t \\
    D_t &= \begin{bmatrix} \sqrt{h_{11,t}} & 0 \\ 0 & \sqrt{h_{22,t}} \end{bmatrix} \\
    h_{11,t} &= c_{11} + a_{11,1} r_{1,t-1}^2 + g_{11,1} h_{11,t-1} \\
    h_{22,t} &= c_{11} + a_{22,1} r_{2,t-1}^2 + g_{22,1} h_{22,t-1} \\
    S_t &= \begin{bmatrix} 1 & s_{12,t} \\ s_{12,t} & 1 \end{bmatrix} \\
    q_{12,t} &= \frac{s_{12,t}}{\sqrt{s_{12,t}^2 + q_{22,t}}} \\
    q_{12,t} &= (1 - \alpha - \beta) S_{12} + \alpha \frac{r_{1,t-1}}{\sqrt{h_{11,t-1}}} \frac{r_{2,t-1}}{\sqrt{h_{22,t-1}}} + \beta q_{12,t-1} \\
    q_{11,t} &= (1 - \alpha - \beta) \frac{r_{1,t-1}}{h_{11,t-1}} + \beta q_{11,t-1} \\
    q_{22,t} &= (1 - \alpha - \beta) \frac{r_{2,t-1}}{h_{22,t-1}} + \beta q_{22,t-1}
\end{align*}
\]

where \( S_t \) is the time-varying conditional correlation matrix at time \( t \). Compared to the CCC GARCH model, two more parameters, \( \alpha \) and \( \beta \), are added into the DCC GARCH model. There are nine parameters in total; that is, a vector \((\alpha, \beta, s_{12}, c_{11}, c_{22}, a_{11,1}, a_{22,1}, g_{11,1}, g_{22,1})^T\).
The following statements estimate a DCC GARCH model:

```sas
/*--- DCC ---*/
proc varmax data=indices outest=oedcc outcov;
    model rDJIA rSP500 / noint;
    garch p=1 q=1 form=dcc outht=ohdcc;
run;
```

Figure 43.38 shows the parameter estimates for the DCC GARCH(1,1) model. DCCA corresponds to the parameter $\alpha$, DCCB corresponds to the parameter $\beta$, and DCCS1_2 corresponds to the parameter $s_{12}$, the off-diagonal element in the unconditional correlation matrix. The standard errors of many parameter estimates are zeros, which might be a sign that the model does not converge to the global minimum.

**Figure 43.38** DCC GARCH Parameter Estimates

| Parameter | Estimate | Standard Error | t Value | Pr > |t| |
|-----------|---------|----------------|---------|------|---|
| DCCA      | 0.01540 | 0.00000        |         |      |   |
| DCCB      | 0.00000 | 0.00000        |         |      |   |
| DCCS1_2   | 0.98743 | 0.00040        | 999.00  | 0.0001 |   |
| GCHC1_1   | 1.28530 | 0.00000        |         |      |   |
| GCHC2_2   | 1.50117 | 0.00000        |         |      |   |
| ACH1_1_1  | 0.03378 | 0.00216        | 15.62   | 0.0001 |   |
| ACH1_2_2  | 0.02694 | 0.00084        | 32.07   | 0.0001 |   |
| GCH1_1_1  | 0.07596 | 0.00000        |         |      |   |
| GCH1_2_2  | 0.09939 | 0.00000        |         |      |   |

Figure 43.39 shows the log likelihood and the information criteria.

Because a CCC GARCH model can be regarded as a restricted DCC GARCH model in which $\alpha$ and $\beta$ in the conditional correlation equations are restricted to zeros, it is expected that the log likelihood of the “unrestricted” DCC GARCH model should always be larger than (or at least equal to) the log likelihood of the
corresponding CCC GARCH model, even though DCC might have a larger information criterion and not be chosen. Hence, it is unexpected that the log likelihood of the DCC GARCH model (shown in Figure 43.39) is smaller than that of the CCC GARCH model (shown in Figure 43.37). This unexpected phenomenon confirms that the numerical optimization for the DCC GARCH model converges to a local minimum instead of the global minimum. Different initial values should be tried. In addition to some reasonable values for parameters DCCA and DCCB, the INITIAL statement specifies the initial values for the DCC GARCH model parameters in the following statements; these values are based on the corresponding parameter estimates of the CCC GARCH model (shown in Figure 43.36):

```latex
/**** DCC with Initial Values ****/

proc varmax data=indices outest=oedcc outcov;
  model rDJIA rSP500 / noint;
  garch p=1 q=1 form=dcc outht=ohdcc;
  initial DCCA=0.01, DCCB=0.98, DCCS(1,2) = 0.97294,
          GCHC(1,1) = 0.03713, GCHC(2,2) = 0.04004,
          ACH(1,1,1) = 0.06862, ACH(1,2,2) = 0.06684,
          GCH(1,1,1) = 0.88472, GCH(1,2,2) = 0.88916;
run;
```

Figure 43.40 shows the parameter estimates for the reestimated DCC GARCH(1,1) model. All standard errors of parameter estimates are valid.

![Figure 43.40](image)

The VARMAX Procedure

| Parameter  | Estimate | Standard Error | t Value | Pr > |t| |
|------------|----------|----------------|---------|------|---|
| DCCA       | 0.03802  | 0.00634        | 6.00    | 0.0001 |
| DCCB       | 0.93782  | 0.01084        | 86.49   | 0.0001 |
| DCCS1_2    | 0.97401  | 0.00247        | 394.22  | 0.0001 |
| GCHC1_1    | 0.02193  | 0.00370        | 5.93    | 0.0001 |
| GCHC2_2    | 0.02395  | 0.00401        | 5.97    | 0.0001 |
| ACH1_1_1   | 0.07842  | 0.00787        | 9.97    | 0.0001 |
| ACH1_2_2   | 0.07758  | 0.00770        | 10.07   | 0.0001 |
| GCH1_1_1   | 0.89540  | 0.01046        | 85.58   | 0.0001 |
| GCH1_2_2   | 0.89738  | 0.01012        | 88.64   | 0.0001 |

As shown in Figure 43.41, the log likelihood of the DCC GARCH model increases dramatically. Compared to the SBC of the CCC GARCH model (shown in Figure 43.37), the SBC for the DCC GARCH model is much smaller, and the DCC GARCH model is chosen. However, compared to the SBC for the BEKK GARCH model (shown in Figure 43.35), the SBC for the DCC GARCH model is a little larger. The BEKK GARCH model should be chosen although it has two more parameters than the DCC GARCH model.
Compared to the BEKK GARCH model, in addition to parsimony, another advantage of the DCC (and also the CCC) GARCH model is that you can use subforms other than GARCH to model the conditional covariance of each series. For example, you can use the threshold GARCH (TGARCH) model for modeling the conditional covariances of rDJIA and rSP500. A bivariate DCC TGARCH(1,1) has the same form as the bivariate DCC GARCH(1,1) except that the conditional covariance equations are replaced by

\[
\begin{align*}
    h_{11,t} &= c_{11} + a_{11,1} r_{1,t-1}^2 + 1_{r_{1,t-1} < 0} b_{11,1} r_{1,t-1}^2 + g_{11,1} h_{11,t-1} \\
    h_{22,t} &= c_{22} + a_{22,1} r_{2,t-1}^2 + 1_{r_{2,t-1} < 0} b_{22,1} r_{2,t-1}^2 + g_{22,1} h_{22,t-1}
\end{align*}
\]

where the indicator function \(1_A\) is 1 if \(A\) is true and 0 otherwise. Compared to the DCC GARCH model, two more parameters, \(b_{11,1}\) and \(b_{22,1}\), are added to the DCC TGARCH model to catch the so-called leverage effect (that is, the positive and negative returns have different impacts on future volatility).

The following statements include the SUBFORM=TARCH option to fit a bivariate DCC TGARCH(1,1) model with the same initial values that are used for the previous DCC GARCH(1,1) model:

```plaintext
proc varmax data=indices outest=oedcct outcov;
    model rDJIARSP500 / noint;
    garch p=1 q=1 form=dcc outht=ohdcct subform=tgarch;
    initial DCCA=0.01, DCCB=0.98, DCCS(1,2) = 0.97294,
            GCHC(1,1) = 0.03713, GCHC(2,2) = 0.04004,
            ACH(1,1,1) = 0.06862, ACH(1,2,2) = 0.06684,
            GCH(1,1,1) = 0.88472, GCH(1,2,2) = 0.88916;
    output out=odcct lead=0;
run;
```

Figure 43.42 shows the parameter estimates for the DCC TGARCH(1,1) model. \(TACH1 \_1 \_1\) and \(TACH1 \_2 \_2\) correspond to the parameters \(b_{11,1}\) and \(b_{22,1}\), respectively. They are significant, which means that the leverage effect exists.
Figure 43.42  DCC TGARCH Parameter Estimates

The VARMAX Procedure

| Parameter | Estimate | Standard Error | t Value | Pr > |t| |
|-----------|----------|----------------|---------|-------|-----|
| DCCA      | 0.04302  | 0.00669        | 6.43    | 0.0001|
| DCCB      | 0.92807  | 0.01142        | 81.26   | 0.0001|
| DCCS1_2   | 0.97309  | 0.00248        | 392.01  | 0.0001|
| GCHC1_1   | 0.02068  | 0.00305        | 6.78    | 0.0001|
| GCHC2_2   | 0.02329  | 0.00346        | 6.73    | 0.0001|
| ACH1_1_1  | 0.00104  | 0.00684        | 0.15    | 0.8787|
| ACH1_2_2  | 0.00314  | 0.00698        | 0.45    | 0.6525|
| TACH1_1_1 | 0.11443  | 0.01207        | 9.48    | 0.0001|
| TACH1_2_2 | 0.10805  | 0.01166        | 9.27    | 0.0001|
| GCH1_1_1  | 0.91490  | 0.00956        | 95.68   | 0.0001|
| GCH1_2_2  | 0.91574  | 0.00964        | 95.03   | 0.0001|

Figure 43.43 shows the log likelihood and the information criteria. The SBC for the DCC TGARCH model is smaller than the SBC for the BEKK GARCH model (which is shown in Figure 43.35). The smaller SBC means that the DCC TGARCH model is the final winner.

Other subforms of GARCH models—the exponential GARCH (EGARCH) model, the quadratic GARCH (QGARCH) model, and the power GARCH (PGARCH) model—are also supported for the CCC and DCC GARCH models. Furthermore, the multivariate GARCH models can be used together with VARMAX or vector error correction models. For more information and examples, see the sections “Multivariate GARCH Modeling” on page 3135 and “Example 43.4: Analysis of Euro Foreign Exchange Reference Rates” on page 3197.

**PROC VARMAX Statement**

```latex
PROC VARMAX options;
```

The following options can be used in the PROC VARMAX statement:

- **DATA=SAS-data-set**
  - specifies the input SAS data set. If the DATA= option is not specified, the PROC VARMAX statement uses the most recently created SAS data set.

- **OUTEST=SAS-data-set**
  - writes the parameter estimates to the output data set.

- **COVOUT**
  - specifies that the covariance matrix for the parameter estimates is also output.

- **OUTCOV**
  - writes the covariance matrix for the parameter estimates to the OUTTEST= data set. This option is valid only if the OUTTEST= option is specified.

---

1Starting with SAS/ETS 14.1, it is recommended that you use the COINTEG statement instead.

---

</tbody>
</table>
OUTSTAT=SAS-data-set
writes residual diagnostic results to an output data set. If the COINTTEST=(JOHANSEN) option is specified, the results of this option are also written to the output data set.

The following statements are the examples of these options in the PROC VARMAX statement:

```sas
proc varmax data=one outest=est outcov outstat=stat;
  model y1-y3 / p=1;
run;
```

```sas
proc varmax data=one outest=est outstat=stat;
  model y1-y3 / p=1 cointtest=(johansen);
run;
```

PLOTS< (global-plot-option) > = plot-request-option <(options)>
PLOTS< (global-plot-option) > = ( plot-request-option <(options) > ... plot-request-option <(options) > )
controls the plots produced through ODS Graphics. When you specify only one plot, you can omit the parentheses around the plot request. Some examples follow:

```sas
plots=none
plots=all
plots(unpack)=residual(residual normal)
plots=(forecasts model)
```

```sas
proc varmax data=one plots=impulse(simple);
  model y1-y3 / p=1;
run;
```

```sas
proc varmax data=one plots=(model residual);
  model y1-y3 / p=1;
run;
```

```sas
proc varmax data=one plots=forecasts;
  model y1-y3 / p=1;
  output lead=12;
run;
```

The first VARMAX program produces the simple response impulse plots. The second VARMAX program produces the plots associated with the model and prediction errors. The plots associated with prediction errors are the ACF, PACF, IACF, distribution, white-noise, and Normal quantile plots and the prediction error plot. The third VARMAX program produces the FORECASTS and FORECASTSONLY plots.

The global-plot-option applies to the impulse and prediction error analysis plots generated by the VARMAX procedure. The following global-plot-option is available:
UNPACK displays each graph separately. (By default, some graphs can appear together in a single panel.)

The following plot-request-options are available:

ALL produces all plots appropriate for the particular analysis.

FORECASTS produces plots of the forecasts. The forecasts-only plot that shows the multistep forecasts in the forecast region is produced by default. The following forecasts-plot-options are available:

ALL produces the FORECASTSONLY and the FORECASTS plots. This is the default.

FORECASTS produces a plot that shows the one-step-ahead as well as the multistep forecasts.

FORECASTSONLY produces a plot that shows only the multistep forecasts.

IMPULSE produces the plots of impulse response function and the impulse response of the transfer function.

ALL produces all impulse plots. This is the default.

ACCUM produces the accumulated impulse plot.

ORTH produces the orthogonalized impulse plot.

SIMPLE produces the simple impulse plot.

MODEL produces plots of dependent variables listed in the MODEL statement and plots of the one-step-ahead predicted values for each dependent variables.

NONE suppresses all plots.

RESIDUAL produces plots associated with the prediction errors obtained after modeling the data. The following residual-plot-options are available:

ALL produces all plots associated with the analysis of the prediction errors. This is the default.

RESIDUAL produces prediction error plot.

DIAGNOSTICS produces a panel of plots useful in assessing the autocorrelations and white-noise of the prediction errors. The panel consists of the following:

- the autocorrelation plot of the prediction errors
- the partial autocorrelation plot of the prediction errors
- the inverse autocorrelation plot of the prediction errors
- the log scaled white noise plot of the prediction errors

NORMAL produces a panel of plots useful in assessing normality of the prediction errors. The panel consists of the following:

- distribution of the prediction errors with overlaid the normal curve
- normal quantile plot of the prediction errors
Other Options

In addition, any of the following MODEL statement options can be specified in the PROC VARMAX statement, which is equivalent to specifying the option for every MODEL statement: CENTER, DFTEST=, DIF=, DIFX=, DIFY=, LAGMAX=, METHOD=, MINIC=, NOCURRENTX, NOINT, NOPRINT, NSEASON=, P=, PRINT=, PRINTALL, PRINTFORM=, Q=, SCENTER, TREND=, VARDEF=, and XLAG= options.

The following is an example of the options in the PROC VARMAX statement:

```sas
proc varmax data=one lagmax=3 method=ml;
   model y1-y3 / p=1;
run;
```

BOUND Statement

**BOUND** restriction, . . . , restriction;

The BOUND statement sets up linear bounds for parameters when the maximum likelihood method is applied to the estimation of VARMAX, VECM, VARMAX-GARCH, and VEC-ARMAX-GARCH models. Only one BOUND statement is allowed. If you specify more than one restriction, separate them with commas.

The restrictions are specified in the same manner as the restrictions in the RESTRICT statement. For information about how to define restrictions by using matrix expressions, operators, and functions, see the section “RESTRICT Statement” on page 3050. Both equality and inequality constraints are allowed in the BOUND statement, although usually equality constraints are specified in the RESTRICT statement and inequality constraints are specified in the BOUND statement.

To use the BOUND statement, you need to know the form of the model. If you do not specify the GARCH statement, the COINTEG statement, or the ECM=, P=, Q=, or XLAG= option in the MODEL statement, then the BOUND statement is not applicable. If you specify the ECM=(NORMALIZE=), METHOD=LS, or PRIOR= option in the MODEL statement, or if you specify the EXOGENEITY, H=, J=, or NORMALIZE= option in the COINTEG statement, the BOUND statement is ignored. Nonlinear restrictions on parameters are not supported.

The following is an example of the BOUND statement for a bivariate (k=2) zero-mean VARMA(1,1) model, which is by default estimated by maximum likelihood method because the MA term is present:

```sas
proc varmax data=one;
   model y1 y2 / noint p=1 q=1;
   bound AR+MA>=0.001;
run;
```

This BOUND statement specifies that all AR parameters must be between −1 and 1 and that all MA parameters must be positive.

You can use the BOUND statement together with the RESTRICT statement, as in the following bivariate (k=2) zero-mean VARMA(1,1) model:

```sas
proc varmax data=one;
   model y1 y2 / noint p=1 q=1;
   bound -1<=AR<=1, 0<MA;
run;
```

The following is an example of the BOUND statement:
BY Statement

BY variables;

A BY statement can be used with PROC VARMAX to obtain separate analyses on observations in groups defined by the BY variables.

When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data using the SORT procedure with a similar BY statement.
- Specify the BY statement option NOTSORTED or DESCENDING in the BY statement for the VARMAX procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables using the DATASETS procedure.

For more information about the BY statement, see in SAS Language Reference: Concepts. For more information about the DATASETS procedure, see the discussion in the Base SAS Procedures Guide.

The following is an example of the BY statement:

```
proc varmax data=one;
  by region;
    model y1-y3 / p=1;
run;
```

CAUSAL Statement

CAUSAL GROUP1=(variables)GROUP2=(variables);

A CAUSAL statement prints the Granger causality test by fitting the VAR($p$) model by using all variables defined in GROUP1 and GROUP2. Any number of CAUSAL statements can be specified. The CAUSAL statement proceeds with the MODEL statement and uses the variables and the autoregressive order, $p$, specified in the MODEL statement. Variables in the GROUP1= and GROUP2= options should be defined in the MODEL statement. If the P=0 option is specified in the MODEL statement, the CAUSAL statement is not applicable.

The null hypothesis of the Granger causality test is that GROUP1 is influenced only by itself, and not by GROUP2. If the hypothesis test fails to reject the null, then the variables listed in GROUP1 might be considered as independent variables.

For more information, see the section “VAR and VARX Modeling” on page 3092.

The following is an example of the CAUSAL statement. You specify the CAUSAL statement with the GROUP1= and GROUP2= options.
proc varmax data=one;
    model y1-y3 = x1 / p=1;
    causal group1=(x1) group2=(y1-y3);
    causal group1=(y2) group2=(y1 y3);
run;

The first CAUSAL statement fits the VAR(1) model by using the variables y1, y2, y3, and x1 and tests the null hypothesis that x1 causes the other variables, y1, y2, and y3, but the other variables do not cause x1. The second CAUSAL statement fits the VAR(1) model by using the variables y1, y3, and y2 and tests the null hypothesis that y2 causes the other variables, y1 and y3, but the other variables do not cause y2.

### COINTEG Statement

**COINTEG**

**RANK=**number <options> ;

The COINTEG statement fits the vector error correction model to the data, tests the restrictions of the long-run parameters and the adjustment parameters, and tests for weak exogeneity in the long-run parameters. The P= option in the MODEL statement specifies the autoregressive order of the VECM. Only one COINTEG statement is allowed.

The cointegrated system uses maximum likelihood estimation. If there are no moving average (MA) terms specified by the Q= option in the MODEL statement, no GARCH terms specified in the GARCH statement, and no general restrictions specified in the BOUND and RESTRICT statements, then PROC VARMAX applies the maximum likelihood analysis proposed by Johansen and Juselius (1990); Johansen (1995a, b). Otherwise, the likelihood is maximized using an optimizer whose options can be specified in the NLOPTIONS statement.

The following statements fit a VECM(2):

```
proc varmax data=one;
    model y1-y3 / p=2;
    cointeg rank=1;
run;
```

To test restrictions on \( \alpha \) and \( \beta \), you specify the J= option and the H= option, respectively. You specify the EXOGENEITY option in the COINTEG statement for tests of weak exogeneity in the long-run parameters.

The following example of the COINTEG statement specifies tests of restrictions on \( \alpha \) and \( \beta \), along with tests of weak exogeneity:

```
proc varmax data=one;
    model y1-y3 / p=2;
    cointeg rank=1 h=(1 0, -1 0, 0 1) j=(1 0, 0 0, 0 1) exogeneity;
run;
```

You must specify the following option:

**RANK=**number

specifies the cointegration rank of the cointegrated system. The rank of cointegration should be greater than 0 and less than the number of dependent (endogenous) variables. If number is different from
the value of the RANK= option specified in the ECM= option in the MODEL statement, the `number` specified here is used for the rank.

You can also specify the following `options` in the COINTEG statement:

**ECTREND**

specifies the restriction on the drift in the VECM. This option is used in the following cases:

- There is no separate drift in the VECM, but a constant enters only through the error correction term. For example, for VECM($p$),

  \[
  \Delta y_t = \alpha (\beta', \beta_0) (y_{t-1}' - 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t
  \]

  An example of the ECTREND option follows:

  ```
  model y1 y2 / p=2;
  cointeg rank=1 ectrend;
  ```

- There is a separate drift and no separate linear trend in the VECM, but a linear trend enters only through the error correction term. For example, for VECM($p$),

  \[
  \Delta y_t = \alpha (\beta', \beta_1) (y_{t-1}' - 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \epsilon_t
  \]

  An example of the ECTREND option with the TREND= option follows:

  ```
  model y1 y2 / p=2 trend=linear;
  cointeg rank=1 ectrend;
  ```

If you specify both this option and the NSEASON option in the MODEL statement, then the NSEASON option is ignored. If you specify the NOINT option in the MODEL statement, then this option is ignored.

**EXOGENITY**

formulates the likelihood ratio tests for testing weak exogeneity in the long-run parameters. The null hypothesis is that one variable is weakly exogenous for the others.

\[
H = (matrix)
\]

specifies the restrictions $H$ on the $k \times r$ or $(k + 1) \times r$ cointegrated coefficient matrix $\tilde{\beta}$ such that $\tilde{\beta} = H \phi$, where $H$ is known and $\phi$ is unknown. If you do not specify the ECTREND option, then the cointegrated coefficient matrix $\tilde{\beta}$ is the cointegrating matrix $\beta$ and the $H$ matrix has dimension $k \times m$. If you specify the ECTREND option, then the cointegrated coefficient matrix $\tilde{\beta}$ is the cointegrating matrix $\beta$ stacked with the coefficient row vector $\beta_0$ or $\beta_1$ for the constant or linear trend in the error correction term, and the $H$ matrix has dimension $(k + 1) \times m$. Here $k$ is the number of dependent variables and $m$ is $r \leq m < k$, where $r$ is defined in the RANK=$r$ option.

For example, consider a VECM(2) with rank equal to 1 on four dependent variables. Then, $\beta = (\beta_{11}, \beta_{21}, \beta_{31}, \beta_{41})'$. To test the null hypothesis $\beta_{11} + \beta_{21} = 0$ (that is, $H_\perp \beta = 0$, where $H_\perp = (1 - 1 0 0)'$), you can use the following statements to specify the restriction matrix $H$:
Chapter 43: The VARMAX Procedure

model y1-y4 / p=2;
cointeg rank=1 h=(1 0 0, -1 0 0, 0 1 0, 0 0 1);

Here the dimension of matrix \( H \) is \( 4 \times 3 \) because \( k = 4 \) and \( m = 3 \), and each row of the matrix \( H \) is separated by commas. Note that \( H' \cdot H = 0 \); that is, the \( H \) and \( H' \cdot H \) matrices are orthogonal.

When the series has no separate deterministic trend, and therefore you specify the ECTREND option, the constant term should be restricted by \( \alpha' \cdot 0 = 0 \). The matrix \( \alpha' \) is a \( k \times (k - r) \) full-rank matrix orthogonal to \( \alpha \), such that \( \text{rank}(\alpha') = k - r \) and \( \alpha' \cdot \alpha = 0 \). The \( \tilde{\beta} \) becomes \( (\beta', \beta_0)' \) or \( \tilde{\beta} = (\beta_{11}, \beta_{21}, \beta_{31}, \beta_{41}, \beta_{11}^{0(0)})' \). As for the previous test of \( \beta_{11} + \beta_{21} = 0 \) (that is, \( H' \cdot \tilde{\beta} = 0 \), where \( H \cdot (1 - 1 0 0 0)' \)), you can specify the restriction matrix \( H \) as follows:

model y1-y4 / p=2;
cointeg rank=1 ectrend
    h=(1 0 0 0, -1 0 0 0, 0 1 0 0, 0 0 1 0, 0 0 0 1);

Because the dimension is changed in the \( H' \cdot H \) matrix, the dimension of \( H \) matrix has to be adjusted accordingly.

When the cointegrated system contains three dependent variables and the RANK=2 option is specified, the test of \( \beta_{1j} = -\beta_{2j} \) for \( j = 1, 2 \) can be run with the following restriction matrix \( H \), where \( H' \cdot \tilde{\beta} = 0 \):

cointeg rank=2 h=(1 0, -1 0, 0 1);

There are many ways to achieve a matrix that is orthogonal to a particular matrix. The following statements illustrate how to obtain the orthogonal matrix through QR decomposition:

proc iml;
    /* For a given matrix H_dot, */
    H_dot = {1 1 0}';
    /* get its QR decomposition, i.e., H_dot = QR. */
    call qr(Q, R, piv, lindep, H_dot);
    /* Then, the matrix orthogonal to H_dot can be extracted from Q. */
    H = Q[,ncol(H_dot)+1:nrow(H_dot)];
    /* Finally, normalize each column of H if necessary. */
    do i = 1 to ncol(H);
        k = 0;
        do j = nrow(H) to 1 by -1;
            if (H[j,i]^=0) then k=j;
        end;
        if (k=0) then
            print "Error: H is not full rank!";
        else
            do j = nrow(H) to 1 by -1;
                H[j,i] = H[j,i] / H[k,i];
            end;
    end;
print "The given matrix is:"
print H_dot;
print "The matrix orthogonal to it is:"
print H;
quit;

J=(matrix)
specifies the restrictions J on the k × r adjustment matrix α such that α = Jψ, where J is known and ψ is unknown. The k × m matrix J is specified by using this option, where k is the number of dependent variables, m is r ≤ m < k, and r is defined in the RANK=r option.

For example, suppose the system contains four variables, the RANK=1 option is specified, and you want to test α_j = 0 for j = 2, 3, 4—that is, J'_\perp α = 0, where

\[J_{\perp} = \begin{pmatrix} 0 & 0 & 0 \\ 1 & 0 & 0 \\ 0 & 1 & 0 \\ 0 & 0 & 1 \end{pmatrix}\]

Then you can specify the restriction matrix J as follows:

cointeg rank=1 j=(1, 0, 0, 0);

Suppose the system contains three variables, the RANK=2 option is specified, and you want to test α_{2j} = 0 for j = 1, 2—that is, J'_\perp α = 0, where J_{\perp} = (0 1 0)'. Then you can specify the restriction matrix J as follows:

cointeg rank=2 j=(1 0, 0 0, 0 1);

NLC
specifies the nonlinear constraints that α and β are full column rank. Although the constraints are required for a well-defined VECM, only the TECH=QUANEW and TECH=NMSIMP optimization methods in the NLOPTIONS statement support nonlinear constraints. The full-rank constraints are not imposed by default so that other optimization methods, such as TECH=CONGRA or TECH=TRUREG, can be tried. The NLC option works only when numerical optimization is used for estimating VECM (for example, when the BOUND, INITIAL, or RESTRICT statement is specified, or the VEC-ARMA or VEC-ARMA-GARCH model is estimated). That is, the NLC option is ignored if the closed-form solution of parameter estimates and maximum likelihood analysis, which is provided in Johansen and Juselius (1990) and Johansen (1995a, b), can be applied.

NORMALIZE=variable
specifies a single dependent (endogenous) variable whose cointegrating vectors are normalized. If the variable is different from the variable specified in the CointTest=(JOHANSEN=) or ECM= option in the MODEL statement, the variable in this option is used. If this option is not specified, cointegrating vectors are not normalized.

If the EXOGENITY, H=, J=, or NORMALIZE= option is specified, the BOUND, GARCH, INITIAL, and RESTRICT statements are all ignored, and the Q= option in the MODEL statement is also ignored.
GARCH Statement

GARCH options ;

The GARCH statement specifies a GARCH-type multivariate conditional heteroscedasticity model.

You can specify the following options:

**CORRCONSTANT=ESTIMATE | EXPECT**

specifies how to calculate the constant or unconditional correlation matrix in the CCC or DCC GARCH model, respectively. If you specify CORRCONSTANT=EXPECT, the constant conditional correlation matrix in the CCC GARCH model or the unconditional correlation matrix in the DCC GARCH model is calculated through the standardized residuals, given the other parameters. After parameter estimates are output, the constant or unconditional correlation matrix for the CCC or DCC GARCH model is output in the CCCCorrConstant or DCCCorrConstant ODS table, respectively. If you specify CORRCONSTANT=ESTIMATE, the correlation matrix is estimated like all other parameters in the model. By default, CORRCONSTANT=ESTIMATE.

**FORM=value**

specifies the representation for a GARCH model. Valid values are as follows:

- **BEKK** specifies a BEKK representation. This is the default.
- **CCC** specifies a constant conditional correlation representation.
- **DCC** specifies a dynamic conditional correlation representation.

**OUTHT=SAS-data-set**

writes the conditional covariance matrix to an output data set.

**P=number**

**P=(number-list)**

specifies the order of the process or the subset of GARCH terms to be fitted. For example, you can specify the P=(1,3) option. The P=3 option is equivalent to the P=(1,2,3) option. By default, P=0.

**Q=number**

**Q=(number-list)**

specifies the order of the process or the subset of ARCH terms to be fitted. This option is required in the GARCH statement. For example, you can specify the Q=(2) option. The Q=2 option is equivalent to the Q=(1,2) option.

**SUBFORM=value**

specifies the type of the univariate GARCH model for each innovation in the CCC or DCC GARCH model. If you specify the FORM=BEKK option, the SUBFORM= option is ignored. The values of the SUBFORM= option are as follows:

- **EGARCH** specifies the exponential GARCH, or EGARCH, model.
- **GARCH** specifies the GARCH model with no constraints.
- **GJR | TGARCH** specifies the GJR GARCH (also called threshold GARCH, or TGARCH) model.
**ID Statement**

**ID** variable INTERVAL=value < ALIGN=value> ;

The ID statement specifies a variable that identifies observations in the input data set. The datetime variable specified in the ID statement is included in the OUT= data set if the OUTPUT statement is specified. The ID variable is usually a SAS datetime variable. The values of the ID variable are extrapolated for the forecast observations based on the value of the INTERVAL= option.

**ALIGN= value**

controls the alignment of SAS dates used to identify output observations. The ALIGN= option allows the following values: BEGINNING | BEG | B, MIDDLE | MID | M, and ENDING | END | E. The default is BEGINNING. The ALIGN= option is used to align the ID variable to the beginning, middle, or end of the time ID interval specified by the INTERVAL= option.

**INTERVAL=value**

specifies the time interval between observations. This option is required in the ID statement. The INTERVAL= option is used in conjunction with the ID variable to check that the input data are in order and have no missing periods. The INTERVAL= option is also used to extrapolate the ID values past the end of the input data when the OUTPUT statement is specified.

The following is an example of the ID statement:

```
ID y1 INTERVAL=1;  
```

**PGARCH** specifies the power GARCH, or PGARCH, model.

**QGARCH** specifies the quadratic GARCH, or QGARCH, model.

By default, SUBFORM=GARCH.

If you specify the ECM=(NORMALIZE=) or PRIOR= option in the MODEL statement, or if you specify the EXOGENEITY, H=, J=, or NORMALIZE= option in the COINTEG statement, the GARCH statement is ignored.

For the VAR(1)–ARCH(1) model,

```plaintext
model y1 y2 / p=1;  
garch q=1 form=bekk;  
```

For the multivariate GARCH(1,1) model,

```plaintext
model y1 y2;  
garch q=1 p=1 form=ccc;  
```

Other multivariate GARCH-type models are

```plaintext
model y1 y2 = x1 / xlag=1;  
garch q=1;  
model y1 y2 / q=1;  
garch q=1 p=1;  
```

For more information, see the section “Multivariate GARCH Modeling” on page 3135.
The INITIAL statement sets up the initial parameter values for nonlinear optimization when the maximum likelihood method is applied to the estimation of VARMAX, VECM, VARMAX-GARCH, or VEC-ARMAX-GARCH models. Only one INITIAL statement is allowed. If you specify more than one equation, separate them with commas. The equations are specified in the same manner as the restrictions in the RESTRICT statement. For information about how to define equations by using matrix expressions, operators, and functions, see the section “RESTRICT Statement” on page 3050.

To use the INITIAL statement, you need to know the form of the model. If you do not specify the GARCH statement, the COINTEG statement, or the ECM=, P=, Q=, or XLAG= option in the MODEL statement, then the INITIAL statement is not applicable. If you specify the ECM=(NORMALIZE=), METHOD=LS, or PRIOR= option in the MODEL statement, or if you specify the EXOGENEITY, H=, J=, or NORMALIZE= option in the COINTEG statement, the INITIAL statement is ignored. Nonlinear restrictions on parameters are not supported.

The initial parameter values are the solution of the specified linear equations. If you do not specify initial values for all parameters, the default initial value for any parameter that is not specified in the INITIAL statement is 0, except for the following:

- The diagonal elements of the COV parameter matrix are set to ones if the COV parameter matrix is to be estimated.
- The diagonal elements of the GCHC parameter matrix are set to ones if the GCHC parameter matrix is to be estimated and the SUBFORM=EGARCH option is not specified.
- The diagonal elements of the PACH parameter matrix are set to ones if the SUBFORM=PGARCH option is specified.

The following is an example of the INITIAL statement for a bivariate \(k=2\) zero-mean VARMA(1,1) model, which is estimated by the maximum likelihood method by default because a moving average (MA) term is present:

```plaintext
proc varmax data=one;
    model y1 y2 / noint p=1 q=1;
    initial AR = 0, MA = 0,
        COV={1 0.5, 0.5 4};
run;
```

Like the RESTRICT statement, the preceding INITIAL statement can be abbreviated as follows:
initial AR = MA = 0,
    COV={1 0.5, 0.5 4};

or

initial AR, MA, COV={1 0.5, 0.5 4};

Furthermore, you can omit AR and MA in the INITIAL statement as follows, because by default the AR and MA matrices are set to zeros if they are not specified in the INITIAL statement:

initial COV={1 0.5, 0.5 4};

If you use the INITIAL statement for a vector error correction model (VECM), you must specify initial values for both the ALPHA and BETA matrices and make sure they are both full rank; otherwise, the INITIAL statement is ignored.

In the following example, the INITIAL statement is ignored because initial values for ALPHA and BETA are not specified:

```
proc varmax data=one;
    model y1 y2 / noint p=1;
    cointeg rank=1;
    initial cov=I(2)*4;
run;
```

In the following example, the INITIAL statement is ignored because initial values for ALPHA are not specified:

```
proc varmax data=one;
    model y1 y2 / noint p=1;
    cointeg rank=1;
    initial beta=1;
run;
```

In the following example, the INITIAL statement is ignored because the initial BETA matrix is not full rank:

```
proc varmax data=one;
    model y1 y2 y3 / noint p=1;
    cointeg rank=2;
    initial alpha={1 0, 0 1, 0 0},
        beta ={1 2, 2 4, 3 6};
run;
```

In the following example, the INITIAL statement works fine because the specified initial ALPHA and BETA matrices are both full rank:

```
proc varmax data=one;
    model y1 y2 y3 / noint p=1;
    cointeg rank=2;
    initial alpha={1 0, 0 1, 0 0},
        beta ={1 2, 2 4, 3 5};
run;
```
MODEL Statement

MODEL  dependents = regressors
       <, dependents = regressors > ...
       < / options > ;

The MODEL statement specifies dependent (endogenous) variables and independent (exogenous) variables for the VARMAX model. The multivariate model can have the same or different independent variables corresponding to the dependent variables. As a special case, the VARMAX procedure allows you to analyze one dependent variable. Only one MODEL statement is allowed.

For example, the following statements are equivalent ways of specifying the multivariate model for the vector \((y_1, y_2, y_3)\):

```
model y1 y2 y3 </options>;
model y1-y3 </options>;
```

The following statements are equivalent ways of specifying the multivariate model with independent variables, where \(y_1, y_2, y_3\), and \(y_4\) are the dependent variables and \(x_1, x_2, x_3, x_4\), and \(x_5\) are the independent variables:

```
model y1 y2 y3 y4 = x1 x2 x3 x4 x5 </options>;
model y1 y2 y3 y4 = x1-x5 </options>;
model y1 = x1-x5, y2 = x1-x5, y3 y4 = x1-x5 </options>;
model y1-y4 = x1-x5 </options>;
```

When the multivariate model has different independent variables that correspond to each of the dependent variables, equations are separated by commas (,) and the model can be specified as illustrated by the following MODEL statement:

```
model y1 = x1-x3, y2 = x3-x5, y3 y4 = x1-x5 </options>;
```

The following options can be used in the MODEL statement after a forward slash (/):

**CENTER**

centers the dependent (endogenous) variables by subtracting their means. Note that centering is done after differencing when the DIF= or DIFY= option is specified. If there are exogenous (independent) variables, this option is not applicable.

```
model y1 y2 / p=1 center;
```

**DIF(variable (number-list) <... variable (number-list)>)**

```
DIF=(variable (number-list) <... variable (number-list)>)
```

specifies the degrees of differencing to be applied to the specified dependent or independent variables. The number-list must contain one or more numbers, each of which should be greater than zero. The differencing can be the same for all variables, or it can vary among variables. For example, the \(\text{DIF}=(y_1(1,4) \ y_3(1) \ x_2(2))\) option specifies that the series \(y_1\) is differenced at lag 1 and at lag 4, which is

\[
(1 - B^4)(1 - B)y_{1t} = (y_{1t} - y_{1,t-1}) - (y_{1,t-4} - y_{1,t-5})
\]
the series $y_3$ is differenced at lag 1, which is $(y_{3t} - y_{3,t-1})$; and the series $x_2$ is differenced at lag 2, which is $(x_{2t} - x_{2,t-2})$.

The following uses the data $dy_1$, $y_2$, $x_1$, and $dx_2$, where $dy_1 = (1 - B)y_{1t}$ and $dx_2 = (1 - B)^2x_{2t}$:

```
model y1 y2 = x1 x2 / p=1 dif=(y1(1) x2(2));
```

**DIFX(number-list)**

*DIFX=*(*number-list*)

specifies the degrees of differencing to be applied to all independent variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For example, the DIFX=(1) option specifies that all of the independent series are differenced once at lag 1. The DIFX=(1,4) option specifies that all of the independent series are differenced at lag 1 and at lag 4. If independent variables are specified in the DIF= option, then the DIFX= option is ignored.

The following statement uses the data $y_1$, $y_2$, $dx_1$, and $dx_2$, where $dx_1 = (1 - B)x_{1t}$ and $dx_2 = (1 - B)^2x_{2t}$:

```
model y1 y2 = x1 x2 / p=1 difx(1);
```

**DIFY(number-list)**

*DIFY=*(*number-list*)

specifies the degrees of differencing to be applied to all dependent (endogenous) variables. The *number-list* must contain one or more numbers, each of which should be greater than zero. For more information, see the DIFX= option. If dependent variables are specified in the DIF= option, then the DIFY= option is ignored.

```
model y1 y2 / p=1 dify(1);
```

**FI**

specifies that the vector autoregressive fractionally integrated moving average model with exogenous variables will be used.

```
model y1 y2 / fi method = ML;
```

**METHOD=value**

requests the type of estimates to be computed. The possible values of the METHOD= option are as follows:

- **LS** specifies least squares estimates.
- **ML** specifies maximum likelihood estimates.
- **CML** specifies conditional maximum likelihood estimates.

For VARX models, you can apply least squares method, maximum likelihood method, or conditional maximum likelihood method; for VARMAX models, you can apply either maximum likelihood method or conditional maximum likelihood method; for other type of models, namely, vector error correction models, GARCH models, and Bayesian models, the default maximum likelihood method is applied.
**Chapter 43: The VARMAX Procedure**

```plaintext
model y1 y2 / p=1 method=ml;
```

**NOCURRENTX**

suppresses the current values $x_t$ of the independent variables. In general, the VARX($p, s$) model is

$$y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t$$

where $p$ is the number of lags of the dependent variables included in the model, and $s$ is the number of lags of the independent variables included in the model, including the contemporaneous values of $x_t$.

A VARX(1,2) model can be specified as:

```plaintext
model y1 y2 = x1 x2 / p=1 xlag=2;
```

If the NOCURRENTX option is specified, it suppresses the current values $x_t$ and starts with $x_{t-1}$. The VARX($p, s$) model is redefined as:

$$y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \sum_{i=1}^{s} \Theta_i^* x_{t-i} + \epsilon_t$$

This model with $p = 1$ and $s = 2$ can be specified as:

```plaintext
model y1 y2 = x1 x2 / p=1 xlag=2 nocurrentx;
```

**NOINT**

suppresses the intercept parameter $\delta$.

```plaintext
model y1 y2 / p=1 noint;
```

**NSEASON=number**

specifies the number of seasonal periods. When the NSEASON=number option is specified, ($number - 1$) seasonal dummies are added to the regressors. If the NOINT option is specified, the NSEASON=option is not applicable. For more information, see the section “Seasonal Dummies and Time Trends” on page 3098.

```plaintext
model y1 y2 / p=1 nseason=4;
```

**SCENTER**

centers seasonal dummies specified by the NSEASON= option. The centered seasonal dummies are generated by $c - (1/s)$, where $c$ is a seasonal dummy generated by the NSEASON=s option.
MODEL Statement  ➤  307

MODEL Statement

model y1 y2 / p=1 nseason=4 scenter;

TREND=value
specifies the degree of deterministic time trend included in the model. Valid values are as follows:

LINEAR  includes a linear time trend as a regressor.
QUAD    includes linear and quadratic time trends as regressors.

The TREND=QUAD option is not applicable for a cointegration analysis. For more information, see the section “Seasonal Dummies and Time Trends” on page 3098.

model y1 y2 / p=1 trend=linear;

VARDEF=value
corrects for the degrees of freedom of the denominator for computing an error covariance matrix for the METHOD=LS option. If the METHOD=ML option is specified, the VARDEF=N option is always used. Valid values are as follows:

DF      specifies that the number of nonmissing observation minus the number of regressors be used.
N       specifies that the number of nonmissing observation be used.

model y1 y2 / p=1 vardef=n;

Printing Control Options

LAGMAX=number
specifies the maximum number of lags for which results are computed and displayed by the PRINT=(CORRX CORRY COVX COVY IARR IMPULSE= IMPULSX= PARCOEF PCANCORR PCORR) options. This option is also used to limit the printed results for the cross covariances and cross-correlations of residuals. The default is LAGMAX=min(12, T-2), where T is the number of nonmissing observations.

model y1 y2 / p=1 lagmax=6;

NOPRINT
suppresses all printed output.

model y1 y2 / p=1 noprint;
PRINTALL requests all printing control options. The options set by the option PRINTALL are DFTEST=, MINIC=, PRINTFORM=BOTH, and PRINT=(CORRB CORRX CORRY COVB COVPE COVX COVY DECOMPOSE DYNAMIC IARR IMPULSE=(ALL) IMPULSX=(ALL) PARCOEF PCAN-CORR PCORR ROOTS YW).

You can also specify this option as the option ALL.

```plaintext
model y1 y2 / p=1 printall;
```

PRINTFORM=value requests the printing format of the output generated by the PRINT= option and cross covariances and cross-correlations of residuals. Valid values are as follows:

- **BOTH** prints output in both MATRIX and UNIVARIATE forms.
- **MATRIX** prints output in matrix form. This is the default.
- **UNIVARIATE** prints output by variables.

```plaintext
model y1 y2 / p=1 print=(impulse) printform=univariate;
```

**Printing Options**

**PRINT=(options)**

The following options can be used in the PRINT=( ) option. The options are listed within parentheses. If a number in parentheses follows an option listed below, then the option prints the number of lags specified by number in parentheses. The default is the number of lags specified by the LAGMAX=number option.

- **CORRB** prints the estimated correlations of the parameter estimates.

- **CORRX(number)** prints the cross-correlation matrices of exogenous (independent) variables. The number should be greater than zero.

- **CORRY(number)** prints the cross-correlation matrices of dependent (endogenous) variables. The number should be greater than zero.

- **COVB** prints the estimated covariances of the parameter estimates.
COVPE

COVPE(number)

prints the covariance matrices of number-ahead prediction errors for the VARMAX(p,q,s) model. The number should be greater than zero. If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. For more information, see the section “Forecasting” on page 3082.

COVX

COVX(number)

prints the cross-covariance matrices of exogenous (independent) variables. The number should be greater than zero.

COVY

COVY(number)

prints the cross-covariance matrices of dependent (endogenous) variables. The number should be greater than zero.

DECOMPOSE

DECOMPOSE(number)

prints the decomposition of the prediction error covariances using up to the number of lags specified by number in parentheses for the VARMA(p,q) model. The number should be greater than zero. It can be interpreted as the contribution of innovations in one variable to the mean squared error of the multistep forecast of another variable. The DECOMPOSE option also prints proportions of the forecast error variance.

If the DIF= or DIFY= option is specified, the covariance matrices of multistep prediction errors are computed based on the differenced data. This option is not applicable when the PRIOR= option is specified. For more information, see the section “Forecasting” on page 3082.

DIAGNOSE

prints the residual diagnostics and model diagnostics.

DYNAMIC

prints the contemporaneous relationships among the components of the vector time series.

ESTIMATES

prints the coefficient estimates and a schematic representation of the significance and sign of the parameter estimates.

IARR

IARR(number)

prints the infinite order AR representation of a VARMA process. The number should be greater than zero. If the ECM= option or the COINTEG statement is specified, then the reparameterized AR coefficient matrices are printed.
**IMPULSE**

**IMPULSE**(number)

**IMPULSX**(number)

prints the impulse response function. The number should be greater than zero. It investigates the response of one variable to an impulse in another variable in a system that involves a number of other variables as well. It is an infinite order MA representation of a VARMA process. For more information, see the section “Impulse Response Function” on page 3071.

You can specify the following options within parentheses:

**ACCUM** prints the accumulated impulse response function.

**ALL** is equivalent to specifying SIMPLE, ACCUM, ORTH, and STDERR.

**ORTH** prints the orthogonalized impulse response function.

**SIMPLE** prints the impulse response function. This is the default.

**STDERR** prints the standard errors of the impulse response function, the accumulated impulse response function, or the orthogonalized impulse response function.

**IMPULSX**(number)

prints the impulse response function related to exogenous (independent) variables. The number should be greater than zero. For more information, see the section “Impulse Response Function” on page 3071.

You can specify the following options within parentheses:

**ACCUM** prints the accumulated impulse response matrices for the transfer function.

**ALL** is equivalent to specifying SIMPLE, ACCUM, and STDERR.

**SIMPLE** prints the impulse response matrices for the transfer function.

**STDERR** prints the standard errors of the simple impulse response function or the accumulated impulse response function.

By default, IMPULSX(number)=(SIMPLE).

**PARCOEF**

**PARCOEF**(number)

prints the partial autoregression coefficient matrices, \( \Phi_{mm} \) up to the lag number. The number should be greater than zero. With a VAR process, this option is useful for the identification of the order since the \( \Phi_{mm} \) have the property that they equal zero for \( m > p \) under the hypothetical assumption of a VAR(p) model. For more information, see the section “Tentative Order Selection” on page 3087.

**PCANCORR**

**PCANCORR**(number)

prints the partial canonical correlations of the process at lag \( m \) and the test for testing \( \Phi_m = 0 \) for \( m > p \) up to the lag number. The number should be greater than zero. The lag \( m \) partial canonical correlations are the canonical correlations between \( y_t \) and \( y_{t-m} \), after adjustment for the dependence of these variables on the intervening values \( y_{t-1}, \ldots, y_{t-m+1} \). For more information, see the section “Tentative Order Selection” on page 3087.
PCORR
PCORR(number)
prints the partial correlation matrices. The number should be greater than zero. With a VAR process, this option is useful for a tentative order selection by the same property as the partial autoregression coefficient matrices, as described in the PRINT=(PARCOEF) option. For more information, see the section “Tentative Order Selection” on page 3087.

ROOTS
prints the eigenvalues of the $kp \times kp$ companion matrix associated with the AR characteristic function $\Phi(B)$, where $k$ is the number of dependent (endogenous) variables, and $\Phi(B)$ is the finite order matrix polynomial in the backshift operator $B$, such that $B^i y_t = y_{t-i}$. These eigenvalues indicate the stationary condition of the process since the stationary condition on the roots of $|\Phi(B)| = 0$ in the VAR($p$) model is equivalent to the condition in the corresponding VAR(1) representation that all eigenvalues of the companion matrix be less than one in absolute value. Similarly, you can use this option to check the invertibility of the MA process. In addition, when the GARCH statement is specified, this option prints the roots of the GARCH characteristic polynomials to check covariance stationarity for the GARCH process.

YW
prints Yule-Walker estimates of the preliminary autoregressive model for the dependent (endogenous) variables. The coefficient matrices are printed using the maximum order of the autoregressive process.

Some examples of the PRINT= option are as follows:

```
model y1 y2 / p=1 print=(covy(10) corry(10));
model y1 y2 / p=1 print=(parcoef pcancorr pcorr);
model y1 y2 / p=1 print=(impulse(8) decompose(6) covpe(6));
model y1 y2 / p=1 print=(dynamic roots yw);
```

Lag Specification Options

P=number
P=(number-list)
specifies the order of the vector autoregressive process. Subset models of vector autoregressive orders can be specified by listing the desired set of lags. For example, you can specify the P=(1,3,4) option. The P=3 option is equivalent to the P=(1,2,3) option. The default is P=0.

If P=0 and there are no exogenous (independent) variables, then the AR polynomial order is automatically determined by minimizing an information criterion. If P=0 and the PRIOR= or ECM= option or COINTEG statement are specified, then the AR polynomial order is determined automatically.

If the ECM= option or the COINTEG statement is specified, then subset models of vector autoregressive orders are not allowed and the AR maximum order specified is used.

Examples illustrating the P= option follow:

```
model y1 y2 / p=3;
model y1 y2 / p=(1, 3);
model y1 y2 / p=(1, 3) prior;
```
**Chapter 43: The VARMAX Procedure**

**Q=** *number*

**Q=(** *number-list**)

specifies the order of the moving-average error process. Subset models of moving-average orders can be specified by listing the desired set of lags. For example, you can specify the **Q=(1,5)** option. The default is **Q=0**.

```latex
  \text{model } y_1 \ y_2 / p=1 \ q=1;
  \text{model } y_1 \ y_2 / q=(2);
```

**XLAG=** *number*

**XLAG=(** *number-list**)

specifies the lags of exogenous (independent) variables. Subset models of distributed lags can be specified by listing the desired set of lags. For example, **XLAG=(2)** selects only a lag 2 of the exogenous variables. The default is **XLAG=0**. To exclude the present values of exogenous variables from the model, the **NOCURRENTX** option must be used.

```latex
  \text{model } y_1 \ y_2 = x_1-x_3 / xlag=2 \ nocurrentx;
  \text{model } y_1 \ y_2 = x_1-x_3 / p=1 \ xlag=(2);
```

**Tentative Order Selection Options**

**MINIC**

**MINIC=(** **P=** *number** \ **PERROR=** *number** \ **Q=** *number** \ **TYPE=** *value** )**

prints the information criterion for the appropriate AR and MA tentative order selection.

You can specify the following options within parentheses in the **MINIC=** option:

**P=** *number*

**P=(** *p_{min} : p_{max}**)

specifies the range of AR orders to be considered in the tentative order selection. The default is **P=(0:5)**. **P=3** is equivalent to **P=(0:3)**.

**PERROR=** *number*

**PERROR=(** *p_{e,min} : p_{e,max}**)

specifies the range of AR orders for obtaining the error series. The default is **PERROR=(p_{max} : p_{max} + q_{max})**.

**Q=** *number*

**Q=(** *q_{min} : q_{max}**)

specifies the range of MA orders to be considered in the tentative order selection. The default is **Q=(0:5)**.

**TYPE=** **AIC** | **AICC** | **FPE** | **HQC** | **SBC**

specifies the criterion for the model order selection. Valid criteria are as follows:
AIC specifies Akaike’s information criterion.
AICC specifies the corrected Akaike’s information criterion.
FPE specifies the final prediction error criterion.
HQC specifies the Hanna-Quinn criterion.
SBC specifies the Schwarz Bayesian criterion. You can also specify this value as TYPE=BIC.

By default, TYPE=AICC.

The following examples show how to use the MINIC or MINIC= option:

model y1 y2 / minic;
model y1 y2 / minic=(type=aic p=13);

In the selection of AR and MA orders, the model that has the smallest criterion value is chosen. For
the definitions of the information criteria used in the MINIC option, see the section “The Minimum
Information Criterion (MINIC) Method” on page 3091.

Cointegration Related Options

Two options are related to integrated time series; one is the DFTEST option to test for a unit root and the
other is the COINTTEST option to test for cointegration.

DFTEST
DFTEST=(DLAG=number)
DFTEST=(DLAG=(number) ...(number))
prints the Dickey-Fuller unit root tests. The DLAG=(number) ...(number) option specifies the regular
or seasonal unit root test. Supported values of number are in 1, 2, 4, 12. If the number is greater than
one, a seasonal Dickey-Fuller test is performed. If the TREND= option is specified, the seasonal unit
root test is not available. The default is DLAG=1.

For example, the DFTEST=(DLAG=(1)(12)) option produces two tables: the Dickey-Fuller regular
unit root test and the seasonal unit root test.

Some examples of the DFTEST= option follow:

model y1 y2 / p=2 dftest;
model y1 y2 / p=2 dftest=(dlag=4);
model y1 y2 / p=2 dftest=(dlag=(1)(12));
model y1 y2 / p=2 dftest cointtest;

COINTTEST
COINTTEST=(JOHANSEN <(=options) > SW <(=options) > SIGLEVEL=number )
specifies the cointegration tests.

You can specify the following options within parentheses in the COINTTEST= option:
Chapter 43: The VARMAX Procedure

JOHANSEN

JOHANSEN=(TYPE=value | ORDER=number | NORMALIZE=variable)

prints the cointegration rank test for multivariate time series based on Johansen’s method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 64. For more information, see the section “Vector Error Correction Modeling” on page 3115.

The VARX(p,s) model can be written as the error correction model

\[ \Delta y_t = \Pi y_{t-1} + \sum_{i=1}^{p-1} \Phi_i \Delta y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta_i x_{t-i} + \epsilon_t \]

where \( \Pi, \Phi_i, A, \) and \( \Theta_i \) are coefficient parameters and \( D_t \) is a deterministic term such as a constant, a linear trend, or seasonal dummies.

The \( I(1) \) model is defined by one reduced-rank condition. If the cointegration rank is \( r < k \), then there exist \( k \times r \) matrices \( \alpha \) and \( \beta \) of rank \( r \) such that \( \Pi = \alpha \beta' \).

The \( I(1) \) model is rewritten as the \( I(2) \) model

\[ \Delta^2 y_t = \Pi y_{t-1} - \Psi \Delta y_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta_i x_{t-i} + \epsilon_t \]

where \( \Psi = I_k - \sum_{i=1}^{p-1} \Phi_i \) and \( \Psi_i = -\sum_{j=i+1}^{p-1} \Phi_j \).

The \( I(2) \) model is defined by two reduced-rank conditions. One is that \( \Pi = \alpha \beta' \), where \( \alpha \) and \( \beta \) are \( k \times r \) matrices of full-rank \( r \). The other is that \( \alpha' \Psi \beta_{\perp} = \xi \eta' \), where \( \xi \) and \( \eta \) are \( (k - r) \times s \) matrices with \( s \leq k - r \), and \( \alpha \perp \) and \( \beta \perp \) are \( k \times (k - r) \) matrices of full-rank \( k - r \) such that \( \alpha' \alpha \perp = 0 \) and \( \beta' \beta \perp = 0 \).

You can specify the following options within parentheses in the JOHANSEN= option:

**IORDER=1 | 2**

specifies the integrated order. You can specify the following values:

1. prints the cointegration rank test for an integrated order 1 and prints the long-run parameter, \( \beta \), and the adjustment coefficient, \( \alpha \). If you specify IORDER=1, then the AR order should be greater than or equal to 1. If you specify P=0 in the MODEL statement, the value of P is set to 1 for the Johansen test.

2. prints the cointegration rank test for integrated orders 1 and 2. If you specify IORDER=2, then the AR order should be greater than or equal to 2. If you specify P=1 and IORDER=2, then the value of IORDER is set to 1; if you specify P=0 and IORDER=2, then the value of P is set to 2.

By default, IORDER=1.

**NORMALIZE=variable**

specifies the dependent (endogenous) variable whose cointegration vectors are to be normalized. If the variable is different from the variable specified in the COINTEG statement or in the ECM= option in the MODEL statement, then the value specified in the COINTEG statement is used. If you specify this option and you want to estimate an error correction
model, then the BOUND, GARCH, INITIAL, and RESTRICT statements are all ignored and the Q= option in the MODEL statement is also ignored.

**TYPE=MAX | TRACE**
specifies the type of cointegration rank test to be printed. You can specify the following values:

- **MAX** prints the cointegration maximum eigenvalue test.
- **TRACE** prints the cointegration trace test.

By default, TYPE=TRACE. If the NOINT option is not specified, PROC VARMAX prints two different cointegration rank tests in the presence of the unrestricted and restricted deterministic terms (constant or linear trend) models. If you specify IORDER=2, the procedure automatically sets the TYPE=TRACE option.

The following examples illustrate the JOHANSEN= option:

```
model y1 y2 / p=2 cointtest=(johansen=(type=max normalize=y1));
model y1 y2 / p=2 cointtest=(johansen=(iorder=2 normalize=y1));
```

**SIGLEVEL=value**
sets the size (the significance level) of the common trends tests.

The SIGLEVEL=value can be set to 0.1, 0.05, or 0.01. By default, SIGLEVEL=0.05.

```
model y1 y2 / p=2 cointtest=(sw siglevel=0.1);
model y1 y2 / p=2 cointtest=(sw siglevel=0.01);
```

**SW**
**SW=(TYPE=value LAG=number)**
prints common trends tests for a multivariate time series based on the Stock-Watson method. This test is provided when the number of dependent (endogenous) variables is less than or equal to 6. For more information, see the section “Common Trends” on page 3113.

You can specify the following options within parentheses in the SW= option:

- **LAG=number** specifies the number of lags. The default is LAG=max(1,p) for the TYPE=FILTDIF or TYPE=FILTRES option, where p is the AR maximum order specified by the P= option. The default is LAG=T^{1/4} for the TYPE=KERNEL option, where T is the number of nonmissing observations. If the specified LAG=number exceeds the default, then it is replaced by the default.

- **TYPE=FILTDIF | FILTRES | KERNEL** specifies the type of common trends test to be printed. You can specify the following values:
FILTDIF prints the common trends test based on the filtering method applied to the differenced series.

FILTRES prints the common trends test based on the filtering method applied to the residual series.

KERNEL prints the common trends test based on the kernel method.

By default, TYPE=FILTDIF.

The following examples illustrate the SW option:

```plaintext
model y1 y2 / p=2 cointtest=(sw);
model y1 y2 / p=2 cointtest=(sw=(type=kernel));
model y1 y2 / p=2 cointtest=(sw=(type=kernel lag=3));
```

Bayesian VARX Estimation Options

PRIOR

PRIOR=(prior-options)
specifies the prior value of parameters for the BVARX\((p, s)\) model. The BVARX model allows for a subset model specification. If the ECM= option or the COINTEG statement is specified with the PRIOR option, the BVECMX\((p, s)\) form is fitted. When the PRIOR option is specified, the Q= option in the MODEL statement is ignored, and the BOUND, GARCH, INITIAL, RESTRICT, and TEST statements are all ignored. For more information, see the section “Bayesian VAR and VARX Modeling” on page 3099.

The following options can be used with the PRIOR=(prior-options) option. The prior-options are listed within parentheses.

IVAR

IVAR=(variables)
specifies an integrated BVAR\((p)\) model. The variables should be specified in the MODEL statement as dependent variables. If you use the IVAR option without variables, then it sets the overall prior mean of the first lag of each variable equal to one in its own equation and sets all other coefficients to zero. If variables are specified, it sets the prior mean of the first lag of the specified variables equal to one in its own equation and sets all other coefficients to zero. When the series \(y_t = (y_1, y_2)'\) follows a bivariate BVAR(2) process, the IVAR or IVAR=(y1 y2) option is equivalent to specifying MEAN=(1 0 0 0 0 1 0 0 0).

If the PRIOR=(MEAN=) or ECM= option or the COINTEG statement is specified, the IVAR= option is ignored.

LAMBDA=value

specifies the prior standard deviation of the AR coefficient parameter matrices. It should be a positive number. The default is LAMBDA=1. As the value of the LAMBDA= option is increased, the BVAR\((p)\) model becomes closer to a VAR\((p)\) model.
**MEAN**=(vector)
specifies the mean vector in the prior distribution for the AR coefficients. If the vector is not specified, the prior value is assumed to be a zero vector. For more information, see the section “Bayesian VAR and VARX Modeling” on page 3099.

You can specify the mean vector by order of the equation. Let $(\delta, \Phi_1, \ldots, \Phi_p)$ be the parameter sets to be estimated and $\Phi = (\Phi_1, \ldots, \Phi_p)$ be the AR parameter sets. The mean vector is specified by row-wise from $\Phi$; that is, the MEAN=(vec($\Phi'$)) option.

For the PRIOR=(mean) option in the BVAR(2),

$$
\Phi = \begin{pmatrix}
\phi_{1,11} & \phi_{1,12} & \phi_{2,11} & \phi_{2,12} \\
\phi_{1,21} & \phi_{1,22} & \phi_{2,21} & \phi_{2,22}
\end{pmatrix} = \begin{pmatrix} 2 & 0.1 & 1 & 0 \\
0.5 & 3 & 0 & -1 \end{pmatrix}
$$

where $\phi_{l,ij}$ is an element of $\Phi$, $l$ is a lag, $i$ is associated with the first dependent variable, and $j$ is associated with the second dependent variable.

```plaintext
model y1 y2 / p=2 prior=(mean=(2 0.1 1 0 0.5 3 0 -1));
```

The deterministic terms and exogenous variables are considered to shrink toward zero; you must omit prior means of exogenous variables and deterministic terms such as a constant, seasonal dummies, or trends.

For a Bayesian error correction model estimated when both the ECM= option (or the COINTEG statement) and the PRIOR= option are used, a mean vector for only lagged AR coefficients, $\Phi^*_i$, in terms of regressors $\Delta y_{t-i}$, for $i = 1, \ldots, (p-1)$ is used in the VECM($p$) representation. The diffused prior variance of $\alpha$ is used, since $\beta$ is replaced by $\hat{\beta}$ estimated in a nonconstrained VECM($p$) form.

$$
\Delta y_t = \alpha z_{t-1} + \sum_{i=1}^{p-1} \Phi^*_i \Delta y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta^*_i x_{t-i} + \epsilon_t
$$

where $z_t = \beta'y_t$.

For example, in the case of a bivariate ($k = 2$) BVEC(2) form, the option

```plaintext
MEAN = (\phi^*_{1,11} \phi^*_{1,12} \phi^*_{1,21} \phi^*_{1,22})
```

where $\phi^*_{i,j}$ is the $(i,j)$ element of the matrix $\Phi^*_i$.

**NREP=number**
determines the number of repetitions that are used to compute the measure of forecast accuracy. For more information, see the equation in the section “Forecasting of BVAR Modeling” on page 3101. The default is NREP=0.5$T$, where $T$ is the number of observations. If NREP is above 0.5$T$, it is decreased to 0.5$T$; if NREP is below the value of the LEAD= option, it is increased to the value of the LEAD= option.

**THETA=value**
specifies the prior standard deviation of the AR coefficient parameter matrices. The value is in the interval (0,1). The default is THETA=0.1. As the value of the THETA= option approaches 1, the specified BVAR($p$) model approaches a VAR($p$) model.

Some examples of the PRIOR= option follow:
model y1 y2 / p=2 prior;
model y1 y2 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2 prior=(theta=0.2 lambda=5);
model y1 y2 = x1 / p=2
    prior=(theta=0.2 lambda=5 mean=(2 0.1 0 0.5 3 0 -1));

For more information, see the section “Bayesian VAR and VARX Modeling” on page 3099.

Vector Error Correction Model Options

ECM=(RANK=number < ECTREND > < NORMALIZE=variable > )
specifies a vector error correction model.

The ECM= option is obsolete. Use the COINTEG statement instead.

You must specify the following option within parentheses in the ECM= option:

RANK=number
    specifies the cointegration rank of the cointegrated system. The rank of cointegration should
    be greater than 0 and less than the number of dependent (endogenous) variables. If number is
    different from the RANK= option specified in the COINTEG statement, the value specified in the
    COINTEG statement is used for the rank.

You can also specify the following options within parentheses in the ECM= option:

ECTREND
    specifies the restriction on the drift in the VECM. This option is used in the following cases:

    • There is no separate drift in the VECM, but a constant enters only through the error correction
      term. For example, for VECM(p),

      \[ \Delta y_t = \alpha (\beta', \beta_0) (y'_{t-1} \cdot 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t \]

      An example of the ECTREND option follows:

      model y1 y2 / p=2 ecm=(rank=1 ectrend);

    • There is a separate drift and no separate linear trend in the VECM, but a linear trend enters
      only through the error correction term. For example, for VECM(p),

      \[ \Delta y_t = \alpha (\beta', \beta_1) (y'_{t-1} \cdot 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \epsilon_t \]

      An example of the ECTREND option with the TREND= option follows:

      model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
If you specify both this option and the NSEASON option in the MODEL statement, then the NSEASON option is ignored. If you specify the NOINT option in the MODEL statement, then this option is ignored.

\textbf{NORMALIZE=} \textit{variable}

specifies a single dependent (endogenous) \textit{variable} whose cointegrating vectors are normalized. If the \textit{variable} is different from the variable specified in the NORMALIZE= option in the COINTEG statement, the variable specified in the NORMALIZE= option in the COINTEG statement is used. If this option is not specified, cointegrating vectors are not normalized. If you specify this option, then the BOUND, GARCH, INITIAL, and RESTRICT statements are all ignored and the Q= option in the MODEL statement is also ignored.

The following examples illustrate the ECM= option:

\begin{verbatim}
model y1 y2 / p=2 ecm=(rank=1 normalize=y1);
model y1 y2 / p=2 ecm=(rank=1 ectrend) trend=linear;
\end{verbatim}

For more information, see the section “Vector Error Correction Modeling” on page 3115.

---

**NLOPTIONS Statement**

**NLOPTIONS options ;**

The VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks. For a list of all the options in the NLOPTIONS statement, see Chapter 6, “Nonlinear Optimization Methods.”

An example of the NLOPTIONS statement is as follows:

\begin{verbatim}
proc varmax data=one;
   nloptions tech=qn maxit=1000 pall;
   model y1 y2 / p=2;
run;
\end{verbatim}

By default, the VARMAX procedure uses the dual quasi-Newton optimization method.

---

**OUTPUT Statement**

**OUTPUT < options > ;**

The OUTPUT statement generates and prints forecasts based on the model estimated in the previous MODEL statement and, optionally, creates an output SAS data set that contains these forecasts.

When the GARCH model is estimated, the upper and lower confidence limits of forecasts are calculated according to the conditional covariance of errors.
ALPHA=number
sets the forecast confidence limit size, where number is between 0 and 1. When you specify the
ALPHA=number option, the upper and lower confidence limits define the 100(1 − α)% confidence
interval. The default is ALPHA=0.05, which produces 95% confidence intervals.

BACK=number
specifies the number of observations before the end of the data at which the multistep forecasts begin.
The BACK= option value must be less than or equal to the number of observations minus the number
of lagged regressors in the model. The default is BACK=0, which means that the forecasts start at the
end of the available data.

LEAD=number
specifies the number of multistep forecast values to compute. The default is LEAD=12.

NOPRINT
suppresses the printed forecast values of each dependent (endogenous) variable.

OUT=SAS-data-set
writes the forecast values to an output data set. If the OUT= option is not included in the OUTPUT
statement, then the output data set is named using the DATA< naming convention.

Some examples of the OUTPUT statements follow:

    proc varmax data=one;
      model y1 y2 / p=2;
      output lead=6 back=2;
    run;

    proc varmax data=one;
      model y1 y2 / p=2;
      output out=for noprint;
    run;

RESTRICT Statement

RESTRICT restriction, . . . , restriction ;

The RESTRICT statement places linear restrictions on the parameters and provides constrained estimation.
Only one RESTRICT statement is allowed. If you specify more than one restriction in a RESTRICT statement,
separate them with commas. Both equality and inequality constraints are allowed in the RESTRICT statement,
although usually equality constraints are specified in the RESTRICT statement and inequality constraints are
specified in the BOUND statement. If the least squares method is used, the inequality constraints are not
applicable.

To use the RESTRICT statement, you need to know the form of the model. If you do not specify the GARCH
statement, the COINTEG statement, or the ECM=, P=, Q=, or XLAG= option in the MODEL statement then
the RESTRICT statement is not applicable. If you specify the ECM=(NORMALIZE=) option or PRIOR=
option in the MODEL statement or if you specify the EXOGENEITY, H=, J=, or NORMALIZE= option in
the COINTEG statement, then the RESTRICT statement is ignored. Nonlinear restrictions on parameters are not supported.

Restricted parameter estimates are computed by introducing a Lagrangian parameter for each restriction (Pringle and Rayner 1971). The Lagrangian parameter measures the sensitivity of the sum of squared errors to the restriction. The estimates of these Lagrangian parameters and their significance are printed in the Restrict ODS table.

**Matrix Expression**

The RESTRICT statement operates on matrices. That is, you can specify the parameter matrices or constant matrices through the RESTRICT statement’s built-in operators and functions. You can add elements of the matrices $A$ and $B$ with the expression $A+B$, and you can perform matrix multiplication with the expression $A*B$ and elementwise multiplication with the expression $A\#B$. You can get the diagonal elements of the matrix $A$ through the function $\text{DIAG}(A)$, and you can get the $n \times n$ identity matrix through the function $I(n)$.

Each restriction is written as a matrix expression composed of constants, operators, and functions.

**Constants**

Constants are either scalar constants (such as –1.2, 0.3, and so on) or matrix constants enclosed in braces (such as the $2 \times 2$ matrix, $(\begin{smallmatrix} 1 & 2 \\ 3 & 4 \end{smallmatrix})$, or the $1 \times 3$ row vector, $(\begin{smallmatrix} -0.2 & 5.3 & 12 \end{smallmatrix})$). Constants also include the dependent variable names and exogenous variable names that represent their index values and are mostly used in the subscripts or function arguments. For example, in the following PROC VARMAX statements, the dependent and exogenous variables have the following index values (based on their orders in the MODEL statement): GDP is equal to 1, CPI to 2, M2 to 3, FFR to 1, and CP to 2. Hence, the function call $\text{AR}(2, \text{GDP}, \{\text{CPI M2}\})$ is equivalent to $\text{AR}(2,1,\{2 3\})$, and $\text{XL}(0, \text{CPI}, \{\text{FFR CP}\})$ is equivalent to $\text{XL}(0,2,\{1 2\})$. For more information about the use of $\text{AR}$ and $\text{XL}$ functions to access parameters, see the section “Functions” on page 3053.

```plaintext
proc varmax data=macrodata;
   model GDP CPI M2 = FFR CP / p=12 xlag=12;
   restrict AR(2, GDP, {CPI M2}) = 0,
       XL(0, CPI, {FFR CP}) = 0;
run;
```

The matrix constant cannot be the first item in the RESTRICT statement. For example, you cannot specify the following statement:

```plaintext
restrict \{-0.1 -0.2, -0.3 -0.4\} <= AR <= \{0.1 0.2, 0.3 0.4\};
```

However, you can put the first matrix constant in parentheses and specify the preceding example in the following way:

```plaintext
restrict ((-0.1 -0.2, -0.3 -0.4)) <= AR <= (0.1 0.2, 0.3 0.4);
```

**Operators**

Operators define the operations on operands. Table 43.2 lists all built-in operators supported by the RESTRICT statement.
Table 43.2  Operators

</tbody>
</table>

Each restriction can be a compound expression that involves several matrix operators and operands. The rules for evaluating compound expressions are as follows:

- Evaluation follows the order of operator precedence, as described in Table 43.3. Group I has the highest priority; that is, Group I operators are evaluated first. Group II operators are evaluated after Group I operators, and so on. For example, $1 + 2 * 3$ returns 7.

- If neighboring operators in an expression have equal precedence, the expression is evaluated from left to right, except for the Group I operators. For example, $1 - 2 - 3$ returns $-4$.

- All expressions in parentheses are evaluated first, following the two preceding rules. For example, $3 * (2 + 1)$ returns 9.
Functions

Functions are mainly divided into two categories: one type of function refers to parameters to be estimated, such as $\text{AR}(L, I, J)$ and $\text{CCC}(I, J)$; the other type does not, such as $\text{I}(n)$ and $\text{DIAG}(A)$.

Functions that refer to the parameters are listed in Table 43.4. The arguments for functions can be matrices. The simplest case, scalar arguments, is discussed first. For convenience, the scalar indices $i$ and $j$ refer to the position of the element in the coefficient matrix, and scalar $l$ refers to the lag value.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>ACH(l, i, j)</td>
<td>ARCH parameter of the lag $l$ value of $\epsilon_t \epsilon'_t$ in a GARCH model</td>
</tr>
<tr>
<td>ALPHA(i, j)</td>
<td>The $(i, j)$ element in the adjustment coefficient matrix $\alpha$ for the vector error correction model</td>
</tr>
<tr>
<td>AR(l, i, j)</td>
<td>Autoregressive parameter of the lag $l$ value of the $j$th dependent (endogenous) variable, $y_{jt-l}$, to the $i$th dependent variable at time $t$, $y_{it}$ for models other than error-correction models. For error correction models, $\text{AR}(l, i, j)$ is the $(i, j)$ element in $\Pi(=\alpha\beta')$ for $y_{t-1}$, and $\text{AR}(1, i, j)$, $l &gt; 1$, is the autoregressive parameter of the lag $(l-1)$ value of the $j$th differenced dependent (endogenous) variable, $\Delta y_{jt-(l-1)}$, to the $i$th differenced dependent variable at time $t$, $\Delta y_{it}$.</td>
</tr>
<tr>
<td>BETA(i, j)</td>
<td>The $(i, j)$ element in the cointegrating matrix $\beta$ for the vector error correction model</td>
</tr>
<tr>

</tr>
<tr>
<td>TACH(l,i,j)</td>
<td>Threshold ARCH parameter of the lag l value of $1_{\epsilon_{it} &lt; 0} \epsilon_{it}^2$ in the CCC or DCC GARCH model when SUBFORM=GJR is specified and i = j. If i $\neq$ j, the value is set to 0.</td>
</tr>
<tr>
<td>XL(l,i,j)</td>
<td>Exogenous parameter of the lag l value of the j-th exogenous (independent) variable, $x_{j,t-l}$, to the i-th dependent variable at time t, $y_{it}$</td>
</tr>
</tbody>
</table>

The functions that refer to parameters, as shown in Table 43.4, accept vector arguments and return the matrix that is constructed by the corresponding parameters. According to the number of arguments, the following list shows what matrix a function returns when the arguments are vectors:

- A function, FUNC0, that has zero arguments, always returns the corresponding scalar parameter. DCCA and DCCB are types of FUNC0.

- A function, FUNC1, that has one vector argument I, where $I = (i_1 \ i_2 \ \ldots \ i_{n_I})^t$, returns a vector $R = (r_1 \ r_2 \ \ldots \ r_{n_I})^t$, where $r_k = \text{FUNC1}(i_k), k = 1, \ldots, n_I$. CONST, ECCONST, ECLTREND, LAMBDA, LTREND, and QTREND are types of FUNC1.

- A function, FUNC2, that has two vector arguments I and J, where $I = (i_1 \ i_2 \ \ldots \ i_{n_I})^t$ and $J = (j_1 \ j_2 \ \ldots \ j_{n_J})^t$, returns a matrix

$$R = \begin{pmatrix} r_{1,1} & r_{1,2} & \cdots & r_{1,n_J} \\ r_{2,1} & r_{2,2} & \cdots & r_{2,n_J} \\ \vdots & \vdots & \ddots & \vdots \\ r_{n_I,1} & r_{n_I,2} & \cdots & r_{n_I,n_J} \end{pmatrix}$$

where $r_{k,m} = \text{FUNC2}(i_k, j_m), k = 1, \ldots, n_I, m = 1, \ldots, n_J$. ALPHA, BETA, CCC, COV, DCCS, GCHC, SD, and SDUMMY are types of FUNC2.
A function, \( \text{FUNC3} \), that has three vector arguments \( L, I, \) and \( J \), where \( L = (l_1\ l_2\ \ldots\ l_n)' \), \( I = (i_1\ i_2\ \ldots\ i_n)' \), and \( J = (j_1\ j_2\ \ldots\ j_n)' \), returns a matrix

\[
R = \begin{pmatrix}
    r_{1,1} & r_{1,2} & \cdots & r_{1,n_L\ n_J} \\
    r_{2,1} & r_{2,2} & \cdots & r_{2,n_L\ n_J} \\
    \vdots & \vdots & \ddots & \vdots \\
    r_{n_L\ 1} & r_{n_L\ 2} & \cdots & r_{n_L\ n_L\ n_J}
\end{pmatrix}
\]

where \( r_{k,m} = \text{FUNC3}(l_m, i_k, j_m) \), \( k = 1, \ldots, n_I \), \( m = 1, \ldots, n_L n_J \), and \( l_m \) and \( j_m \) are the quotient and remainder of \( m \) divided by \( n_J \), respectively. \( \text{ACH}, \text{AR}, \text{EACH}, \text{GCH}, \text{MA}, \text{PACH}, \text{QACH}, \text{TACH}, \text{and XL} \) are types of \( \text{FUNC3} \).

The functions that refer to parameters can accept empty arguments or omit any number of last arguments. The empty or omitted arguments are replaced with all possible values for those arguments. For example, PROC VARMAX is used to fit a bivariate \((k=2)\) VARX(1,1) model with three exogenous variables as follows:

\[
\text{model y1 y2 = x1 x2 x3 / p=1 xlag=3;}
\]

In order to restrict the third exogenous variable from having an effect on the first dependent variable, and to restrict the first exogenous variable from having an effect on the second dependent variable, you can use the following statement:

\[
\text{restrict XL}((0\ 1\ 2\ 3), 1, 3) = 0, \\
\text{XL}((0\ 1\ 2\ 3), 2, 1) = 0;
\]

Taking advantage of empty arguments, you can specify the preceding example as follows:

\[
\text{restrict XL}(( , 1, 3) = 0, \\
\text{XL}(( , 2, 1) = 0;
\]

To get all coefficients of the first lag exogenous variables on dependent variables, you can use \( \text{XL}(1, (1\ 2), (1\ 2\ 3)) \) or \( \text{XL}(1, ,) \) or \( \text{XL}(1) \). To get all coefficients of exogenous variables on dependent variables, you can use \( \text{XL}((0\ 1\ 2\ 3), (1\ 2), (1\ 2\ 3)), \) \( \text{XL}(( , ,)) \) or \( \text{XL}() \) or even just \( \text{XL} \).

Another type of function does not refer to parameters but generates useful matrices. Table 43.5 lists all built-in functions supported by the RESTRICT statement.

<table>
<thead>
<tr>
<th>Function</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>( \text{DIAG}(A) )</td>
<td>Creates a diagonal matrix from a vector or extracts the diagonal elements of a matrix</td>
</tr>
<tr>
<td>( I(n) )</td>
<td>Creates an ( n \times n ) identity matrix</td>
</tr>
<tr>
<td>( J(m, n, \text{elem}) )</td>
<td>Creates an ( m \times n ) matrix with all elements equal to ( \text{elem} )</td>
</tr>
<tr>
<td>( \text{SHAPE}(A, m, n) )</td>
<td>Creates a ( m \times n ) matrix with elements of matrix ( A )</td>
</tr>
</tbody>
</table>

For more information about each function in Table 43.5, see the section “Details of Functions” on page 3061.
Examples

The following examples show how to use the RESTRICT statement.

This example shows a bivariate \((k=2)\) VAR(2) model:

```plaintext
proc varmax data=one;
   model y1 y2 / p=2;
   restrict AR(1,1,2)=0, AR(2,1,2)=0.3;
run;
```

The \(AR(1,1,2)\) and \(AR(2,1,2)\) parameters are fixed as \(AR(1,1,2)=0\) and \(AR(2,1,2)=0.3\), respectively, and other parameters are to be estimated.

The following example shows a bivariate \((k=2)\) VAR(1) model, estimated using the ML method:

```plaintext
proc varmax data=two;
   model y1 y2 = / p=1 method=ml;
   restrict cov(1,1)=cov(2,2), cov(1,2)=0;
run;
```

The \(COV(1,1)\) and \(COV(2,2)\) parameters are equal, and the correlation between the two series is fixed at 0. You can also express the preceding restrictions in matrix expressions as follows. This approach is very convenient when the number of dependent variables is large:

```plaintext
proc varmax data=two;
   model y1 y2 = / p=1 method=ml;
   restrict cov = cov(1,1)*I(2);
run;
```

When restricting a linear combination of parameters to be 0, you can omit the equal sign. For example, the following two RESTRICT statements are equivalent:

```plaintext
restrict AR(1)[1,1]-AR(1)[2,2], 2*MA(1)[1,2]-MA(1)[2,1];
restrict AR(1)[1,1]-AR(1)[2,2] = 0, 2*MA(1)[1,2]-MA(1)[2,1] = 0;
```

The following RESTRICT statement constrains four parameter estimates to be equal:

```plaintext
restrict AR(1)[1,1] = AR(1)[1,2],
   AR(1)[1,2] = AR(1)[2,1],
   AR(1)[2,1] = AR(1)[2,2];
```

This restriction can be abbreviated as follows:

```plaintext
restrict AR(1)[1,1] = AR(1)[1,2] = AR(1)[2,1] = AR(1)[2,2];
```

Or, in matrix expressions,

```plaintext
restrict AR(1,1:2,1:2) = J(2,2,AR(1,1,1));
```

The VARMA representation \(A(L)y_t = \Theta(L)\varepsilon_t\), where \(A(L) = I_k - A_1 L - \cdots - A_p L^p\) and \(\Theta(L) = I_k - \Theta_1 L - \cdots - \Theta_q L^q\), is said to be in final equation form if \(A(L) = a(L)I_k\), where \(a(L) = 1-a_1 L - \cdots - a_p L^p\) is a scalar operator with \(a_p \neq 0\). If \(p\) and \(k\) are large, it would be difficult and inconvenient to restrict AR parameters element by element in standard form to estimate the VARMA model in final equation form. However, when you use matrix expressions, the restrictions become very simple, as shown in the following statement for a trivariate \((k = 3)\) VARMA\((p, q)\) model, where \(p\) might be any positive integer:
restrict AR = AR(1,1,1) @ I(3);

For the vector error correction models, the AR(1,,..) parameters (that is, $\Pi$) are not supported in the RESTRICT statement, because $\mathbf{AR}(1)$ is in fact the product of the estimated parameters $\mathbf{a}$ and the transpose of $\mathbf{b}$. Any linear constraints on $\mathbf{AR}(1)$ should be regarded as nonlinear constraints on the estimated parameters.

For the same reason, the $\mathbf{CONST}(..)$ or $\mathbf{LTREND}(..)$ functions are not supported in the RESTRICT statement if the ECTREND option in the COINTEG statement is specified. For example, the following statements are supported:

```plaintext
model y1-y4 / p=2;
cointeg rank=1 ectrend;
restrict ALPHA + BETA = 1.0,
     ECCONST;
```

However, neither of the following sets of statements is supported:

```plaintext
model y1-y4 / p=2;
cointeg rank=1 ectrend;
restrict AR(1,1,1) = 0;

model y1-y4 / p=2;
cointeg rank=1 ectrend;
restrict CONST(2) = 0.2;
```

### Details of Operators

This section describes all operators that are available in the RESTRICT statement. Each subsection shows how the operator is used, followed by a description of the operator.

**Addition Operator: +**

- matrix1 + matrix2
- matrix + scalar
- matrix + vector

The addition operator (+) computes a new matrix whose elements are the sums of the corresponding elements of matrix1 and matrix2. If matrix1 and matrix2 are both $n \times p$ matrices, then the addition operator adds the element in the $i$th row and $j$th column of the first matrix to the element in the $i$th row and $j$th column of the second matrix, for $i = 1, \ldots, n; j = 1, \ldots, p$. For example, $\begin{pmatrix} 1 & 2 & 3 \\ 4 & 5 & 6 \end{pmatrix} + \begin{pmatrix} 7 & 8 & 9 \\ 10 & 11 & 12 \end{pmatrix}$ results in $\begin{pmatrix} 8 & 10 & 12 \\ 14 & 16 & 18 \end{pmatrix}$.

You can also use the addition operator as follows to conveniently add a value to each element of a matrix, to each column of a matrix, or to each row of a matrix:

- When you use the matrix + scalar form, the scalar value is added to each element of the matrix.
- When you use the matrix + vector form, the vector is added to each row or column of the $n \times p$ matrix.
  - If you add an $n \times 1$ column vector, each row of the vector is added to each row of the matrix.
  - If you add a $1 \times p$ row vector, each column of the vector is added to each column of the matrix.
Chapter 43: The VARMAX Procedure

For example, you can obtain \((2, 3, 4, 5, 6, 7)\) from \((1, 2, 3, 4, 5, 6) + 1\) or \((1, 2, 3, 4, 5, 6) + (1, 1, 1)\) or \((1, 2, 3, 4, 5, 6) + (1, 1)\).

**Comparison Operators:** \(=, <, <=, >, >=\)

- `matrix1 = matrix2`
- `matrix1 < matrix2`
- `matrix1 <= matrix2`
- `matrix1 > matrix2`
- `matrix1 >= matrix2`

The comparison operators (=, <, <=, >, >=) compare two matrices element by element and return a list of equivalent restrictions on only scalar constants and parameters.

For example, the RESTRICT statement with matrix expressions

```
restrict AR(1,(1,2),(1,2)) = MA(2,(3,4),(3,4));
```

is transformed into the following equivalent RESTRICT statement with scalar parameters:

```
restrict AR(1,1,1) = MA(2,3,3),
    AR(1,1,2) = MA(2,3,4),
    AR(1,2,1) = MA(2,4,3),
    AR(1,2,2) = MA(2,4,4);
```

You can also use the comparison operators to conveniently compare all elements of a matrix with a scalar:

- If either argument is a scalar, then the VARMAX procedure performs an elementwise comparison between each element of the matrix and the scalar.

You can also compare an \(n \times p\) matrix with a row or column vector:

- If the comparison is with an \(n \times 1\) column vector, the VARMAX procedure compares each row of the vector to each row of the matrix.
- If the comparison is with a \(1 \times p\) row vector, the VARMAX procedure compares each column of the vector to each column of the matrix.

For example, the following statements are equivalent:

```
restrict AR(1,1:2,1:3) >= 0.2;
restrict AR(1,1:2,1:3) >= (0.2, 0.2);
restrict AR(1,1:2,1:3) >= (0.2, 0.2, 0.2);
```

**Concatenation Operator, Horizontal:** \(\|\)

```
matrix1 || matrix2
```

The horizontal concatenation operator (\(\|\)) produces a new matrix by horizontally joining `matrix1` and `matrix2`. The matrices must have the same number of rows, which is also the number of rows in the new
matrix. The number of columns in the new matrix is the number of columns in matrix1 plus the number of columns in matrix2.

For example, \(\{1 \ 1 \ 1, \ 7 \ 7 \ 7\} \ || \ \{0 \ 0 \ 0, \ 8 \ 8 \ 8\}\) returns \(\{1 \ 1 \ 0 \ 0 \ 0, \ 7 \ 7 \ 7 \ 8 \ 8 \ 8\}\).

**Concatenation Operator, Vertical:**  //

\[
\text{matrix1} \ // \ \text{matrix2}
\]

The vertical concatenation operator (\(||\)) produces a new matrix by vertically joining matrix1 and matrix2. The matrices must have the same number of columns, which is also the number of columns in the new matrix. The number of rows in the new matrix is the number of rows in matrix1 plus the number of rows in matrix2.

For example, \(\{1 \ 1 \ 1\} \ // \ \{0 \ 0 \ 0, \ 8 \ 8 \ 8\}\) returns \(\{1 \ 1 \ 1, \ 0 \ 0 \ 0, \ 8 \ 8 \ 8\}\).

**Direct Product Operator:**  @

\[
\text{matrix1} \ @ \ \text{matrix2}
\]

The direct product operator (@) computes a new matrix that is the direct product (also called the Kronecker product) of matrix1 and matrix2. For matrices A and B, the direct product is denoted by \(A \otimes B\). The number of rows in the new matrix equals the product of the number of rows in matrix1 and the number of rows in matrix2; the number of columns in the new matrix equals the product of the number of columns in matrix1 and the number of columns in matrix2.

Specifically, if \(A\) is an \(n \times p\) matrix and \(B\) is a \(m \times q\) matrix, then the Kronecker product \(A \otimes B\) is the following \(nm \times pq\) block matrix:

\[
A \otimes B = \begin{bmatrix}
A_{11}B & \cdots & A_{1p}B \\
\vdots & \ddots & \vdots \\
A_{n1}B & \cdots & A_{np}B
\end{bmatrix}
\]

For example, \(\{1 \ 2, \ 3 \ 4\} @ \{0 \ 2\}\) returns \(\{0 \ 2 \ 0 \ 4, \ 0 \ 6 \ 0 \ 8\}\), and \(\{0 \ 2\} @ \{1 \ 2, \ 3 \ 4\}\) returns \(\{0 \ 0 \ 2 \ 4, \ 0 \ 0 \ 6 \ 8\}\). Note that the direct product of two matrices is not commutative.

**Index Creation Operator:**  :

\[
\text{value1} : \ \text{value2}
\]

The index creation operator (:) creates a column vector whose first element is value1, whose second element is value1+1, and so on, until the last element, which is less than or equal to value2.

For example, \(3 : 6\) returns \(\{3 \ 4 \ 5 \ 6\}\). If value1 is greater than value2, a reverse-order index is created. For example, \(6 : 3\) returns \(\{6 \ 5 \ 4 \ 3\}\). Neither value1 nor value2 is required to be an integer.

**Multiplication Operator, Elementwise:**  #

\[
\text{matrix1} \ # \ \text{matrix2}
\]

\[
\text{matrix} \ # \ \text{scalar}
\]

\[
\text{matrix} \ # \ \text{vector}
\]
The elementwise multiplication operator (#) computes a new matrix whose elements are the products of the corresponding elements of `matrix1` and `matrix2`.

For example, \((1 \ 2, \ 3 \ 4) \# (4 \ 8, \ 0 \ 5)\) returns \((4 \ 16, \ 0 \ 20)\).

In addition to multiplying matrices that have the same dimensions, you can use the elementwise multiplication operator to multiply a matrix and a scalar:

- When either argument is a scalar, each element in `matrix` is multiplied by the scalar value.

When you use the `matrix # vector` form, each row or column of the \(n \times p\) matrix is multiplied by a corresponding element of the vector:

- If you multiply by an \(n \times 1\) column vector, each row of the matrix is multiplied by the corresponding row of the vector.
- If you multiply by a \(1 \times p\) row vector, each column of the matrix is multiplied by the corresponding column of the vector.

For example, a \(2 \times 3\) matrix can be multiplied on either side by a \(2 \times 3\), \(1 \times 3\), \(2 \times 1\), or \(1 \times 1\) scalar.

The product of elementwise multiplication is also known as the Schur or Hadamard product. Elementwise multiplication (which uses the # operator) should not be confused with matrix multiplication (which uses the * operator).

**Multiplication Operator, Matrix:** *

\[ \text{matrix1} \ast \text{matrix2} \]

The matrix multiplication operator (*) computes a new matrix by performing matrix multiplication. The first matrix must have the same number of columns as the second matrix has rows. The new matrix has the same number of rows as the first matrix and the same number of columns as the second matrix. That is, if \(A\) is an \(n \times p\) matrix and \(B\) is a \(p \times m\) matrix, then the product \(A \ast B\) is an \(n \times m\) matrix. The \((i, j)\) element of the product is the sum \(\sum_{k=1}^{p} A_{ik} B_{kj}\).

For example, \((1 \ 2, \ 3 \ 4) \ast (1, \ 2)\) returns \((5, \ 11)\).

**Sign Reversal Operator:** –

\[- \text{matrix}\]

The sign reversal operator (−) computes a new matrix whose elements are formed by reversing the sign of each element in `matrix`. The sign reversal operator is also called the unary minus operator.

For example, \((-(-1 \ 7 \ 6, \ 2 \ 0 \ -8)\) returns \((1 \ -7 \ -6, \ -2 \ 0 \ 8)\).

**Subscripts:** []

\[ \text{matrix}[\text{rows, columns}] \]

\[ \text{matrix}[\text{elements}] \]

Subscripts are used with matrices to select submatrices, where `rows`, `columns`, and `elements` are expressions that evaluate to scalars or vectors. If these expressions are numeric, they must contain valid subscript values of rows and columns, or the indices, in the argument matrix.
For example, \((1 \ 2 \ 3, \ 4 \ 5 \ 6, \ 7 \ 8 \ 9)[2,3]\) returns 6, \((1 \ 2 \ 3, \ 4 \ 5 \ 6, \ 7 \ 8 \ 9)[2,1:3]\) returns \((4 \ 5 \ 6)\), and \((1 \ 2 \ 3, \ 4 \ 5 \ 6, \ 7 \ 8 \ 9)[3]\) returns \((3, \ 6, \ 9)\). Because the VARMAX procedure stores matrices in row-major order, \((11 \ 22 \ 33, \ 44 \ 55 \ 66, \ 77 \ 88 \ 99)[(3 \ 5 \ 9)]\) returns \((33, \ 55, \ 99)\).

**Subtraction Operator:** –
- matrix1 – matrix2
- matrix – scalar
- matrix – vector

The subtraction operator (–) computes a new matrix whose elements are formed by subtracting the corresponding elements of matrix2 from those of matrix1.

In addition to subtracting conformable matrices, you can also use the subtraction operator to subtract a scalar from a matrix or subtract a vector from a matrix:

- When either argument is a scalar, the VARMAX procedure performs the subtraction between the scalar and each element of the matrix argument. For example, when you use the matrix – scalar form, the scalar value is subtracted from each element of the matrix.

- When you use the matrix – vector form, the vector is subtracted from each row or column of the \(n \times p\) matrix.
  - If you subtract an \(n \times 1\) column vector, each row of the vector is subtracted from each row of the matrix.
  - If you subtract a \(1 \times p\) row vector, each column of the vector is subtracted from each column of the matrix.

For example, \((1 \ 2 \ 3, \ 4 \ 5 \ 6) – (1 \ 1 \ 1, \ 1 \ 1 \ 1)\) returns \((0 \ 1 \ 2, \ 3 \ 4 \ 5)\). The same results can be obtained by \((1 \ 2 \ 3, \ 4 \ 5 \ 6) – 1\) or \((1 \ 2 \ 3, \ 4 \ 5 \ 6) – (1 \ 1 \ 1)\) or \((1 \ 2 \ 3, \ 4 \ 5 \ 6) – (1, \ 1)\).

**Transpose Operator:** `
- matrix`

The transpose operator, denoted by the backquote character (’), exchanges the rows and columns of matrix, producing the transpose of matrix. If \(v\) is the value in the \(i\)th row and \(j\)th column of matrix, then the transpose of matrix contains \(v\) in the \(j\)th row and \(i\)th column. If matrix contains \(n\) rows and \(p\) columns, the transpose has \(p\) rows and \(n\) columns.

For example, \((1 \ 2, \ 3 \ 4, \ 5 \ 6)'\) returns \((1 \ 3 \ 5, \ 2 \ 4 \ 6)\).

**Details of Functions**

**DIAG Function**
- DIAG(matrix)

The DIAG function creates a diagonal matrix from a vector or extracts the diagonal elements of a matrix. The matrix argument can be either a square matrix or a vector.

If matrix is a vector, the DIAG function creates a matrix whose diagonal elements are the values in the vector. All off-diagonal elements are zeros.
If \textbf{matrix} is a square matrix, the \textbf{DIAG} function creates a vector from the diagonal elements of the matrix.

For example, \texttt{DIAG([1 2 3, 4 5 6, 7 8 9])} returns \{1, 5, 9\}. Also, \texttt{DIAG([1 5 9])} or \texttt{DIAG(DIAG([1 2 3, 4 5 6, 7 8 9]))} returns \{1 0 0, 0 5 0, 0 0 9\}.

\textbf{I Function}
\begin{align*}
\texttt{I(dim)}
\end{align*}

The \texttt{I} function creates an identity matrix that contains \texttt{dim} rows and columns. The diagonal elements of an identity matrix are ones; all other elements are zeros. The value of \texttt{dim} must be an integer greater than or equal to 1. Noninteger operands are rounded to the nearest integer.

For example, \texttt{I(3)} returns \{1 0 0, 0 1 0, 0 0 1\}.

\textbf{J Function}
\begin{align*}
\texttt{J(nrow, ncol, value)}
\end{align*}

The \texttt{J} function creates a matrix that contains \texttt{nrow} rows and \texttt{ncol} columns, in which all elements are equal to \texttt{value}.

The arguments \texttt{nrow} and \texttt{ncol} are both integers; \texttt{value} can be any expression that returns a linear combination of scalar constants and parameters.

For example, \texttt{J(2, 3, 1)} returns \{1 1 1, 1 1 1\}. \texttt{J(2, 3, 5+2*AR(1,1,1))} returns the same result as \texttt{J(2, 3, 1) * (5+2*AR(1,1,1))}.

\textbf{SHAPE Function}
\begin{align*}
\texttt{SHAPE(matrix, nrow, ncol)}
\end{align*}

The \texttt{SHAPE} function creates a new matrix from data in \texttt{matrix}. The values \texttt{nrow} and \texttt{ncol} specify the number of rows and columns, respectively, in the new matrix. The \texttt{SHAPE} function produces the result matrix by traversing the argument matrix in row-major order until it reaches the specified number of elements. If necessary, the \texttt{SHAPE} function reuses elements.

For example, \texttt{SHAPE([1 2 3, 4 5 6], 3, 2)} returns \{1 2, 3 4, 5 6\}; \texttt{SHAPE([1 2 3, 4 5 6], 5, 2)} returns \{1 2, 3 4, 5 6, 1 2, 3 4\}; and \texttt{SHAPE([1 2 3, 4 5 6], 1, 4)} returns \{1 2 3 4\}.

\textbf{TEST Statement}
\begin{align*}
\texttt{TEST restriction, \ldots, restriction ;}
\end{align*}

The TEST statement performs the Wald test for the joint linear hypothesis that is specified in the statement. Each restriction specifies a linear hypothesis to be tested. If you specify more than one \texttt{restriction}, separate them with commas. Specify the \texttt{restrictions} in the same manner as in the RESTRICT statement. For information about how to define restriction by using matrix expressions, operators, and functions, see the section “RESTRICT Statement” on page 3050. You can specify any number of TEST statements.
To use the TEST statement, you need to know the form of the model. If you do not specify the GARCH statement, the COINTEG statement, or the ECM=, P=, Q=, or XLAG= option in the MODEL statement, then the TEST statement is not applicable. Nonlinear restrictions on parameters are not supported.

For information about the Wald test, see the section “Granger Causality Test” on page 3095.

The following is an example of the TEST statement for a bivariate \((k=2)\) VAR(2) model:

```latex
proc varmax data=one;
  model y1 y2 / p=2;
  test AR(1,1,2) = 0, AR(2,1,2) = 0;
run;
```

After estimating the parameters, the TEST statement tests the null hypothesis that \(AR(1,1,2)=0\) and \(AR(2,1,2)=0\). Like the RESTRICT statement, the preceding TEST statement can be abbreviated as follows:

```latex
test AR(1,1,2) = AR(2,1,2) = 0;
```

or

```latex
test AR(1,1,2), AR(2,1,2);
```

Note that the following statements are different from the preceding statement:

```latex
  test AR(1,1,2);
  test AR(2,1,2);
```

These two TEST statements are to test two null hypotheses separately: one is \(AR(1,1,2)=0\), and the other is \(AR(2,1,2)=0\).

For the vector error correction models, you can test the hypothesis on the \(AR(1,.,.)\) parameters (that is, \(\Pi\)) by using the TEST statement, because asymptotically these parameters follow a normal distribution and the Wald test can be applied. For the same reason, you can use the CONST(.) or LTREND(.) function in the TEST statement if the ECTREND option in the COINTEG statement is specified. However, the BETA(.,.), ECCONST(.), and ECLTREND(.) functions are not supported in the TEST statement. For example, the following statements are supported:

```latex
model y1-y4 / p=2;
  cointeg rank=1 ectrrend;
  test AR(1,1,1);
  test CONST(2);
```

However, the following statements are not supported:

```latex
model y1-y4 / p=2;
  cointeg rank=1 ectrrend;
  test BETA(1,1) = BETA(2,1) = 0;
```

or

```latex
model y1-y4 / p=2;
  cointeg rank=1 ectrrend;
  test ECCONST(1) = 0.2;
```
Details: VARMAX Procedure

Missing Values

The VARMAX procedure currently does not support missing values. PROC VARMAX uses the first contiguous group of observations that have no missing values for any of the MODEL statement variables. Observations at the beginning of the data set that have missing values for any MODEL statement variables are not used or included in the output data set. At the end of the data set, observations can have dependent (endogenous) variables with missing values and independent (exogenous) variables with nonmissing values.

VARMAX Model

The vector autoregressive moving-average model with exogenous variables is called the VARMAX\((p,q,s)\) model. The form of the model can be written as

\[
y_t = \sum_{i=1}^{p} \Phi_i y_{t-i} + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t - \sum_{i=1}^{q} \Theta_i \epsilon_{t-i}
\]

where the output variables of interest, \(y_t = (y_{1t}, \ldots, y_{kt})'\), can be influenced by other input variables, \(x_t = (x_{1t}, \ldots, x_{rt})'\), which are determined outside of the system of interest. The variables \(y_t\) are referred to as dependent, response, or endogenous variables, and the variables \(x_t\) are referred to as independent, input, predictor, regressor, or exogenous variables. The unobserved noise variables, \(\epsilon_t = (\epsilon_{1t}, \ldots, \epsilon_{kt})'\), are a vector white noise process.

The VARMAX\((p,q,s)\) model can be written

\[
\Phi(B) y_t = \Theta^*(B) x_t + \Theta(B) \epsilon_t
\]

where

\[
\Phi(B) = I - \Phi_1 B - \cdots - \Phi_p B^p
\]

\[
\Theta^*(B) = \Theta_0^* + \Theta_1^* B + \cdots + \Theta_s^* B^s
\]

\[
\Theta(B) = I - \Theta_1 B - \cdots - \Theta_q B^q
\]

are matrix polynomials in \(B\) in the backshift operator, such that \(B^i y_t = y_{t-i}\), the \(\Phi_i\) and \(\Theta_i\) are \(k \times k\) matrices, and the \(\Theta_i^*\) are \(k \times r\) matrices.

The following assumptions are made:

- \(\mathbb{E}(\epsilon_t) = 0\), \(\mathbb{E}(\epsilon_t \epsilon_t') = \Sigma\), which is positive-definite, and \(\mathbb{E}(\epsilon_t \epsilon_s') = 0\) for \(t \neq s\).

- For stationarity and invertibility of the VARMAX process, the roots of \(|\Phi(z)| = 0\) and \(|\Theta(z)| = 0\) are outside the unit circle.
The exogenous (independent) variables $x_t$ are not correlated with residuals $\epsilon_t$, $E(x_t\epsilon_t') = 0$. The exogenous variables can be stochastic or nonstochastic. When the exogenous variables are stochastic and their future values are unknown, forecasts of these future values are needed to forecast the future values of the endogenous (dependent) variables. On occasion, future values of the exogenous variables can be assumed to be known because they are deterministic variables. The VARMAX procedure assumes that the exogenous variables are nonstochastic if future values are available in the input data set. Otherwise, the exogenous variables are assumed to be stochastic and their future values are forecasted by assuming that they follow the VARMA($p,q$) model, prior to forecasting the endogenous variables, where $p$ and $q$ are the same as in the VARMAX($p,q,s$) model.

**State Space Representation**

Another representation of the VARMAX($p,q,s$) model is in the form of a state variable or a state space model, which consists of a state equation

$$z_t = Fz_{t-1} + Kx_t + G\epsilon_t$$

and an observation equation

$$y_t = Hz_t$$

where

$$z_t = \begin{bmatrix} y_t \\ \vdots \\ y_{t-p+1} \\ x_t \\ \vdots \\ x_{t-s+1} \\ \epsilon_t \\ \vdots \\ \epsilon_{t-q+1} \end{bmatrix}, \quad K = \begin{bmatrix} 0_{k \times r} \\ 0_{k \times r} \\ 0_{r \times r} \\ 0_{r \times r} \\ 0_{r \times r} \\ 0_{k \times r} \end{bmatrix}, \quad G = \begin{bmatrix} I_k \\ 0_{k \times k} \\ 0_{r \times k} \\ 0_{r \times k} \\ 0_{k \times k} \end{bmatrix}$$

$$F = \begin{bmatrix} \Phi_1 & \cdots & \Phi_{p-1} & \Phi_p & \Theta_1^* & \cdots & \Theta_{r-1}^* & \Theta_r^* & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\ I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & \cdots & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & \cdots & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & \cdots & 0 \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & I_k \\ \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots & \vdots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & I_k \end{bmatrix}$$

and

$$H = [I_k, 0_{k \times k}, \ldots, 0_{k \times k}, 0_{k \times r}, \ldots, 0_{k \times r}, 0_{k \times k}, \ldots, 0_{k \times k}]$$
On the other hand, it is assumed that \( x_t \) follows a VARMA\((p,q)\) model

\[
x_t = \sum_{i=1}^{p} A_i x_{t-i} + a_t - \sum_{i=1}^{q} C_i a_{t-i}
\]

The model can also be expressed as

\[ A(B)x_t = C(B)a_t \]

where \( A(B) = I_r - A_1 B - \cdots - A_p B^p \) and \( C(B) = I_r - C_1 B - \cdots - C_q B^q \) are matrix polynomials in \( B \), and the \( A_i \) and \( C_i \) are \( r \times r \) matrices. Without loss of generality, the AR and MA orders can be taken to be the same as the VARMAX\((p,q,s)\) model, and \( a_t \) and \( \epsilon_t \) are independent white noise processes.

Under suitable conditions such as stationarity, \( x_t \) is represented by an infinite order moving-average process

\[
x_t = (A(B)^{-1}C(B))a_t = \Psi^x(B)a_t = \sum_{j=0}^{\infty} \Psi^x_j a_{t-j}
\]

where \( \Psi^x(B) = (A(B)^{-1}C(B)) = \sum_{j=0}^{\infty} \Psi^x_j B^j \).

The optimal minimum mean squared error (minimum MSE) \( i \)-step-ahead forecast of \( x_{t+i} \) is

\[
x_{t+i|t} = \sum_{j=i}^{\infty} \Psi^x_j a_{t+i-j}
\]

\[ x_{t+i|t+1} = x_{t+i|t} + \Psi^x_{i-1} a_{t+1} \]

For \( i > q \),

\[
x_{t+i|t} = \sum_{j=1}^{p} A_j x_{t+i-j|t}
\]

The VARMAX\((p,q,s)\) model has an absolutely convergent representation as

\[
y_t = \Phi(B)^{-1}\Theta^*(B)x_t + \Phi(B)^{-1}\Theta(B)\epsilon_t
\]

\[ = \Psi^*(B)\Psi^x(B)a_t + \Phi(B)^{-1}\Theta(B)\epsilon_t
\]

\[ = V(B)a_t + \Psi(B)\epsilon_t
\]

or

\[
y_t = \sum_{j=0}^{\infty} V_j a_{t-j} + \sum_{j=0}^{\infty} \Psi_j \epsilon_{t-j}
\]

where \( \Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j \), \( \Psi^*(B) = \Phi(B)^{-1}\Theta^*(B) \), and \( V(B) = \Psi^*(B)\Psi^x(B) = \sum_{j=0}^{\infty} V_j B^j \).

The optimal (minimum MSE) \( i \)-step-ahead forecast of \( y_{t+i} \) is

\[
y_{t+i|t} = \sum_{j=i}^{\infty} V_j a_{t+i-j} + \sum_{j=i}^{\infty} \Psi_j \epsilon_{t+i-j}
\]

\[ y_{t+i|t+1} = y_{t+i|t} + V_{i-1} a_{t+1} + \Psi_{i-1} \epsilon_{t+1} \]
for $i = 1, \ldots, v$ with $v = \max(p, q + 1)$. For $i > q$,

$$y_{t+i|t} = \sum_{j=1}^{p} \Phi_j y_{t+i-j|t} + \sum_{j=0}^{s} \Theta_j^* x_{t+i-j|t}$$

$$= \sum_{j=1}^{p} \Phi_j y_{t+i-j|t} + \Theta_0^* x_{t+i|t} + \sum_{j=1}^{s} \Theta_j^* x_{t+i-j|t}$$

$$= \sum_{j=1}^{p} \Phi_j y_{t+i-j|t} + \Theta_0^* \sum_{j=1}^{p} A_j x_{t+i-j|t} + \sum_{j=1}^{s} \Theta_j^* x_{t+i-j|t}$$

$$= \sum_{j=1}^{p} \Phi_j y_{t+i-j|t} + \sum_{j=1}^{u} (\Theta_0^* A_j + \Theta_j^*) x_{t+i-j|t}$$

where $u = \max(p, s)$.

Define $\Pi_j = \Theta_0^* A_j + \Theta_j^*$. For $i = v > q$ with $v = \max(p, q + 1)$, you obtain

$$y_{t+v|t} = \sum_{j=1}^{p} \Phi_j y_{t+v-j|t} + \sum_{j=1}^{u} \Pi_j x_{t+v-j|t} \quad \text{for } u \leq v$$

$$y_{t+v|t} = \sum_{j=1}^{p} \Phi_j y_{t+v-j|t} + \sum_{j=1}^{r} \Pi_j x_{t+v-j|t} \quad \text{for } u > v$$

From the preceding relations, a state equation is

$$z_{t+1} = F z_t + K x_t^* + G e_{t+1}$$

and an observation equation is

$$y_t = H z_t$$

where

$$z_t = \begin{bmatrix} y_t \\ y_{t+1|t} \\ \vdots \\ y_{t+v-1|t} \\ x_t \\ x_{t+|t} \\ \vdots \\ x_{t+v-1|t} \end{bmatrix}, \quad x_t^* = \begin{bmatrix} x_{t+v-u} \\ x_{t+v-u+1} \\ \vdots \\ x_{t-1} \end{bmatrix}, \quad e_{t+1} = \begin{bmatrix} a_{t+1} \\ e_{t+1} \end{bmatrix}$$
In the econometrics literature, the VARMAX(p,q,s) model is sometimes written in a form that is slightly different than the one shown in the previous section. This alternative form is referred to as a dynamic simultaneous equations model or a dynamic structural equations model.

Because $\Sigma(\varepsilon_t\varepsilon'_t) = \Sigma$ is assumed to be positive-definite, there exists a lower triangular matrix $A_0$ that has ones on the diagonals such that $A_0\Sigma A'_0 = \Sigma^d$, where $\Sigma^d$ is a diagonal matrix that has positive diagonal elements.

$$A_0y_t = \sum_{i=1}^{p} A_i y_{t-i} + \sum_{i=0}^{s} C_i^* x_{t-i} + A_0\varepsilon_t - \sum_{i=1}^{q} C_i A_0\varepsilon_{t-i}$$

where $A_i = A_0\Phi_i$, $C_i^* = A_0\Theta_i^*$, and $C_i = A_0\Theta_i A_0^{-1}$. 
As an alternative form,

\[ A_0 y_t = \sum_{i=1}^{p} A_i y_{t-i} + \sum_{i=0}^{s} C_i^* x_{t-i} + a_t - \sum_{i=1}^{q} C_i a_{t-i} \]

where \( A_i = A_0 \Phi_i, C_i^* = A_0 \Theta_i^*, C_i = A_0 \Theta_i A_0^{-1}, \) and \( a_t = A_0 \epsilon_t. \) The covariance matrix of \( a_t \) is the diagonal matrix \( \Sigma^d. \) The PRINT=(DYNAMIC) option returns the parameter estimates that result from estimating the model in this form.

A dynamic simultaneous equations model involves a leading (lower triangular) coefficient matrix for \( y_t \) at lag 0 or a leading coefficient matrix for \( \epsilon_t \) at lag 0. Such a representation of the VARMAX\((p,q,s)\) model can be more useful in certain circumstances than the standard representation. From the linear combination of the dependent variables obtained by \( A_0 y_t, \) you can easily see the relationship between the dependent variables in the current time.

The following statements provide the dynamic simultaneous equations of the VAR(1) model:

```plaintext
proc iml;
    sig = {1.0 0.5, 0.5 1.25};
    phi = {1.2 -0.5, 0.6 0.3};
    /* simulate the vector time series */
    call varmasim(y,phi) sigma = sig n = 100 seed = 34657;
    cn = {'y1' 'y2'};
    create simull from y[colname=cn];
    append from y;
    quit;

data simull;
    set simull;
    date = intnx( 'year', '01jan1900'd, _n_-1 );
    format date year4. ;
    run;

proc varmax data=simull;
    model y1 y2 / p=1 noint print=(dynamic);
    run;
```

This is the same data set and model used in the section “Getting Started: VARMAX Procedure” on page 2982. You can compare the results of the VARMA model form and the dynamic simultaneous equations model form.

In Figure 43.4 in the section “Getting Started: VARMAX Procedure” on page 2982, the covariance of $\epsilon_t$ estimated from the VARMAX model form is

$$
\Sigma_\epsilon = \begin{pmatrix}
1.28875 & 0.39751 \\
0.39751 & 1.41839
\end{pmatrix}
$$

Figure 43.44 shows the results from estimating the model as a dynamic simultaneous equations model. By the decomposition of $\Sigma_\epsilon$, you get a diagonal matrix ($\Sigma_a$) and a lower triangular matrix ($A_0$) such as $\Sigma_a = A_0 \Sigma_\epsilon A_0'$ where

$$
\Sigma_a = \begin{pmatrix}
1.28875 & 0 \\
0 & 1.29578
\end{pmatrix}
$$

and

$$
A_0 = \begin{pmatrix}
1 & 0 \\
-0.30845 & 1
\end{pmatrix}
$$

The lower triangular matrix ($A_0$) is shown in the left side of the simultaneous equations model. The parameter estimates in equations system are shown in the right side of the two-equations system.
The simultaneous equations model is written as

$$\begin{pmatrix} 1 & 0 \\ -0.30845 & 1 \end{pmatrix} y_t = \begin{pmatrix} 1.15977 & -0.51058 \\ 0.18861 & 0.54247 \end{pmatrix} y_{t-1} + a_t$$

The resulting two-equation system can be written as

$$y_{1t} = 1.15977y_{1,t-1} - 0.51058y_{2,t-1} + a_{1t}$$
$$y_{2t} = 0.30845y_{1t} + 0.18861y_{1,t-1} + 0.54247y_{2,t-1} + a_{2t}$$

---

**Impulse Response Function**

**Simple Impulse Response Function (IMPULSE=SIMPLE Option)**

The VARMAX\((p,q,s)\) model has a convergent representation

$$y_t = \Psi^*(B)x_t + \Psi(B)\epsilon_t$$

where $$\Psi^*(B) = \Phi(B)^{-1}\Theta^*(B) = \sum_{j=0}^{\infty} \Psi_j B^j$$ and $$\Psi(B) = \Phi(B)^{-1}\Theta(B) = \sum_{j=0}^{\infty} \Psi_j B^j$$.

The elements of the matrices $$\Psi_j$$ from the operator $$\Psi(B)$$, called the impulse response, can be interpreted as the response of a variable to a shock in another variable. Let $$\psi_{j,n}$$ be the \((i,n)\) element of $$\Psi_j$$ at lag \(j\), where \(n\) is the index for the impulse variable, and \(i\) is the index for the response variable (impulse \(\rightarrow\) response); that is to say, $$\psi_{j,n}$$ shows the reaction of the \(i\)-th variable to a unit shock in variable \(n\), \(j\) periods ago, assuming that the effect is not contaminated by other shocks (Lütkepohl 1993). For instance, $$\psi_{j,11}$$ is an impulse response to $$y_{1t} \rightarrow y_{1t}$$, and $$\psi_{j,12}$$ is an impulse response to $$y_{2t} \rightarrow y_{1t}$$.

**Accumulated Impulse Response Function (IMPULSE=ACCUM Option)**

The accumulated impulse response function is the cumulative sum of the impulse response function, $$\Psi^a_l = \sum_{j=0}^{l} \Psi_j$$.

**Orthogonalized Impulse Response Function (IMPULSE=ORTH Option)**

The MA representation of a VARMA\((p,q)\) model with a standardized white noise innovation process offers another way to interpret a VARMA\((p,q)\) model. Since $$\Sigma$$ is positive-definite, there is a lower triangular matrix \(P\) such that $$\Sigma = PP'$$ . The alternate MA representation of a VARMA\((p,q)\) model is written as

$$y_t = \Psi^0(B)u_t$$

where $$\Psi^0(B) = \sum_{j=0}^{\infty} \Psi_j^0 B^j$$, $$\Psi_j^0 = \Psi_j P$$, and $$u_t = P^{-1}\epsilon_t$$.

The elements of the matrices $$\Psi_j^0$$, called the orthogonal impulse response, can be interpreted as the effects of the components of the standardized shock process \(u_t\) on the process \(y_t\) at lag \(j\).
Impulse Response of Transfer Function (IMPULSX=SIMPLE Option)

The coefficient matrix \( \Psi_j^* \) from the transfer function operator \( \Psi^*(B) \) can be interpreted as the effects that changes in the exogenous variables \( x_t \) have on the output variable \( y_t \) at lag \( j \); it is called an impulse response matrix in the transfer function.

Accumulated Impulse Response of Transfer Function (IMPULSX=ACCUM Option)

The accumulated impulse response in the transfer function is the cumulative sum of the impulse response in the transfer function, \( \Psi_{1 \ldots l}^* = \sum_{j=0}^{l} \Psi_j^* \).

The asymptotic distributions of the impulse functions can be seen in the section “VAR and VARX Modeling” on page 3092.

The following statements provide the impulse response and the accumulated impulse response in the transfer function for a VARX(1,0) model:

```plaintext
proc varmax data=grunfeld plot=impulse;
  model y1-y3 = x1 x2 / p=1 lagmax=5
              printform=univariate
              print=(impulsx=(all) estimates);
run;
```

In Figure 43.45, the variables \( x1 \) and \( x2 \) are impulses, and the variables \( y1, y2, \) and \( y3 \) are responses. The keyword STD stands for the standard errors of the elements. You can read the table that matches the impulse \( \rightarrow \) response pairs, such as \( x1 \rightarrow y1, x1 \rightarrow y2, x1 \rightarrow y3, x2 \rightarrow y1, x2 \rightarrow y2, \) and \( x2 \rightarrow y3 \). In the pair \( x1 \rightarrow y1 \), you can see the long-run responses of \( y1 \) to an impulse in \( x1 \) (the values are 1.69281, 0.35399, 0.09090, and so on for lag 0, lag 1, lag 2, and so on, respectively).

Figure 43.48 shows the accumulated responses of $y_1$, $y_2$, and $y_3$ to a forecast error impulse in $x_1$.

**Figure 43.48** Plot of Accumulated Impulse Response in Transfer Function

The following statements provide the impulse response function, the accumulated impulse response function, and the orthogonalized impulse response function with their standard errors for a VAR(1) model. Parts of the VARMAX procedure output are shown in Figure 43.49, Figure 43.51, and Figure 43.53.

```sas
proc varmax data=simul1 plot=impulse;
   model y1 y2 / p=1 noint lagmax=5
       print=(impulse=(all))
       printform=univariate;
run;
```
**Figure 43.49** is the output in a univariate format associated with the PRINT=(IMPULSE=) option for the impulse response function. The keyword STD stands for the standard errors of the elements. The matrix in terms of the lag 0 does not print since it is the identity. In Figure 43.49, the variables $y_1$ and $y_2$ of the first row are impulses, and the variables $y_1$ and $y_2$ of the first column are responses. You can read the table matching the *impulse* → *response* pairs, such as $y_1$ → $y_1$, $y_1$ → $y_2$, $y_2$ → $y_1$, and $y_2$ → $y_2$. For example, in the pair of $y_1$ → $y_1$ at lag 3, the response is 0.8055. This represents the impact on $y_1$ of one-unit change in $y_1$ after 3 periods. As the lag gets higher, you can see the long-run responses of $y_1$ to an impulse in itself.

**Figure 43.52** Plot of Accumulated Impulse Response

![Accumulated Response to Impulse in $y_1$](image)

Figure 43.53 is the output in a univariate format associated with the PRINT=(IMPULSE=) option for the orthogonalized impulse response function. The two right-hand side columns, $y_1$ and $y_2$, represent the $y_1\_innovation$ and $y_2\_innovation$ variables. These are the impulses variables. The left-hand side column contains responses variables, $y_1$ and $y_2$. You can read the table by matching the impulse $\rightarrow$ response pairs such as $y_1\_innovation \rightarrow y_1$, $y_1\_innovation \rightarrow y_2$, $y_2\_innovation \rightarrow y_1$, and $y_2\_innovation \rightarrow y_2$.

In Figure 43.4, there is a positive correlation between \( \varepsilon_{1t} \) and \( \varepsilon_{2t} \). Therefore, shock in \( y_1 \) can be accompanied by a shock in \( y_2 \) in the same period. For example, in the pair of \( y_1_{\text{innovation}} \rightarrow y_2 \), you can see the long-run responses of \( y_2 \) to an impulse in \( y_1_{\text{innovation}} \).
Figure 43.54 shows the orthogonalized responses of $y_1$ and $y_2$ to a forecast error impulse in $y_1$ with two standard errors.

\[ y_{t+l|t} = \sum_{j=1}^{p} \Phi_j y_{t+l-j|t} + \sum_{j=0}^{s} \Theta_j^* x_{t+l-j|t} - \sum_{j=l}^{q} \Theta_j \epsilon_{t+l-j}, \quad l \leq q \]

\[ y_{t+l|t} = \sum_{j=1}^{p} \Phi_j y_{t+l-j|t} + \sum_{j=0}^{s} \Theta_j^* x_{t+l-j|t}, \quad l > q \]

where $y_{t+l-j|t} = y_{t+l-j}$ and $x_{t+l-j|t} = x_{t+l-j}$ for $l \leq j$. For information about the forecasts $x_{t+l-j|t}$, see the section “State Space Representation” on page 3065.
Covariance Matrices of Prediction Errors without Exogenous (Independent) Variables

Under the stationarity assumption, the optimal (minimum MSE) $l$-step-ahead forecast of $y_{t+l}$ has an infinite moving-average form, $y_{t+l} = \sum_{j=1}^{\infty} \Psi_j \epsilon_{t+l-j}$. The prediction error of the optimal $l$-step-ahead forecast is $e_{t+l} = y_{t+l} - y_{t+l} = \sum_{j=0}^{l-1} \Psi_j \epsilon_{t+l-j}$, with zero mean and covariance matrix,

$$\Sigma(l) = \text{Cov}(e_{t+l}) = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi'_j = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi'_j$$

where $\Psi'_j = \Psi_j P$ with a lower triangular matrix $P$ such that $\Sigma = PP'$. Under the assumption of normality of the $\epsilon_t$, the $l$-step-ahead prediction error $e_{t+l}$ is also normally distributed as multivariate $N(0, \Sigma(l))$. Hence, it follows that the diagonal elements $\sigma_{ii}^2(l)$ of $\Sigma(l)$ can be used, together with the point forecasts $y_{i,t+l}$, to construct $l$-step-ahead prediction intervals of the future values of the component series, $y_{i,t+l}$.

The following statements use the COVPE option to compute the covariance matrices of the prediction errors for a VAR(1) model. The parts of the VARMAX procedure output are shown in Figure 43.55 and Figure 43.56.

```sas
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=5
    printform=both
    print=(decompose(5) impulse=(all) covpe(5));
run;
```

Figure 43.55 is the output in a matrix format associated with the COVPE option for the prediction error covariance matrices.
Figure 43.56 is the output in a univariate format associated with the COVPE option for the prediction error covariances. This printing format more easily explains the prediction error covariances of each variable.

### Covariance Matrices of Prediction Errors in the Presence of Exogenous (Independent) Variables

Exogenous variables can be both stochastic and nonstochastic (deterministic) variables. Considering the forecasts in the VARMAX(\(p,q,s\)) model, there are two cases.

#### When exogenous (independent) variables are stochastic (future values not specified):

As defined in the section “State Space Representation” on page 3065, \(y_{t+l|t}\) has the representation

\[
y_{t+l|t} = \sum_{j=1}^{\infty} V_j a_{t+l-j} + \sum_{j=1}^{\infty} \Psi_j \epsilon_{t+l-j}
\]

and hence

\[
e_{t+l|t} = \sum_{j=0}^{l-1} V_j a_{t+l-j} + \sum_{j=0}^{l-1} \Psi_j \epsilon_{t+l-j}
\]

Therefore, the covariance matrix of the \(l\)-step-ahead prediction error is given as

\[
\Sigma(l) = \text{Cov}(e_{t+l|t}) = \sum_{j=0}^{l-1} V_j \Sigma_a V'_j + \sum_{j=0}^{l-1} \Psi_j \Sigma_e \Psi'_j
\]

where \(\Sigma_a\) is the covariance of the white noise series \(a_t\), and \(\epsilon_t\) is the white noise series for the VARMA(\(p,q\)) model of exogenous (independent) variables, which is assumed not to be correlated with \(\epsilon_t\) or its lags.
When future exogenous (independent) variables are specified:

The optimal forecast $y_{t+l|t}$ of $y_t$ conditioned on the past information and also on known future values $x_{t+1}, \ldots, x_{t+l}$ can be represented as

$$y_{t+l|t} = \sum_{j=0}^{\infty} \Psi_j^* x_{t+l-j} + \sum_{j=l}^{\infty} \Psi_j \epsilon_{t+l-j}$$

and the forecast error is

$$e_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \epsilon_{t+l-j}$$

Thus, the covariance matrix of the $l$-step-ahead prediction error is given as

$$\Sigma(l) = \text{Cov}(e_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j \Sigma_e \Psi_j'$$

**Decomposition of Prediction Error Covariances**

In the relation $\Sigma(l) = \sum_{j=0}^{l-1} \Psi_j^o \Psi_j'^o$, the diagonal elements can be interpreted as providing a decomposition of the $l$-step-ahead prediction error covariance $\sigma^2_{it}(l)$ for each component series $y_{it}$ into contributions from the components of the standardized innovations $\epsilon_t$.

If you denote the $(i, n)$ element of $\Psi_j^o$ by $\psi_{j,in}$, the MSE of $y_{i,t+h|t}$ is

$$\text{MSE}(y_{i,t+h|t}) = \text{E}(y_{i,t+h} - y_{i,t+h|t})^2 = \sum_{j=0}^{l-1} \sum_{n=1}^{k} \psi_{j,in}^2$$

Note that $\sum_{j=0}^{l-1} \psi_{j,in}^2$ is interpreted as the contribution of innovations in variable $n$ to the prediction error covariance of the $l$-step-ahead forecast of variable $i$.

The proportion, $\omega_{l,in}$, of the $l$-step-ahead forecast error covariance of variable $i$ accounting for the innovations in variable $n$ is

$$\omega_{l,in} = \sum_{j=0}^{l-1} \psi_{j,in}^2 / \text{MSE}(y_{i,t+h|t})$$

The following statements use the DECOMPOSE option to compute the decomposition of prediction error covariances and their proportions for a VAR(1) model:

```
proc varmax data=simul1;
    model y1 y2 / p=1 noint print=(decompose(15))
        printform=univariate;
run;
```

The proportions of decomposition of prediction error covariances of two variables are given in Figure 43.57. The output explains that about 91.356% of the one-step-ahead prediction error covariances of the variable $y_{2t}$ is accounted for by its own innovations and about 8.644% is accounted for by $y_{1t}$ innovations.

Forecasting of the Centered Series

If the CENTER option is specified, the sample mean vector is added to the forecast.

Forecasting of the Differenced Series

If dependent (endogenous) variables are differenced, the final forecasts and their prediction error covariances are produced by integrating those of the differenced series. However, if the PRIOR option is specified, the forecasts and their prediction error variances of the differenced series are produced.

Let \( z_t \) be the original series with some appended zero values that correspond to the unobserved past observations. Let \( \Delta(B) \) be the \( k \times k \) matrix polynomial in the backshift operator that corresponds to the differencing specified by the MODEL statement. The off-diagonal elements of \( \Delta_l \) are zero, and the diagonal elements can be different. Then \( y_t = \Delta(B)z_t \).

This gives the relationship

\[
z_t = \Delta^{-1}(B)y_t = \sum_{j=0}^{\infty} \Lambda_j y_{t-j}
\]

where \( \Delta^{-1}(B) = \sum_{j=0}^{\infty} \Lambda_j B^j \) and \( \Lambda_0 = I_k \).

The \( l \)-step-ahead prediction of \( z_{t+l} \) is

\[
z_{t+l|t} = \sum_{j=0}^{l-1} \Lambda_j y_{t+l-j|t} + \sum_{j=l}^{\infty} \Lambda_j y_{t+l-j}
\]

The \( l \)-step-ahead prediction error of \( z_{t+l} \) is

\[
\sum_{j=0}^{l-1} \Lambda_j (y_{t+l-j} - y_{t+l-j|t}) = \sum_{j=0}^{l-1} \left( \sum_{u=0}^{j} \Lambda_u \Psi_{j-u} \right) \epsilon_{t+l-j}
\]
Letting $\Sigma_{z}(0) = 0$, the covariance matrix of the $l$-step-ahead prediction error of $z_{t+l}$, $\Sigma_{z}(l)$, is

$$
\Sigma_{z}(l) = \sum_{j=0}^{l-1} \left( \sum_{u=0}^{j} \Lambda_{u} \Psi_{j-u} \right) \Sigma_{\epsilon} \left( \sum_{u=0}^{j} \Lambda_{u} \Psi_{j-u} \right)'
$$

$$
= \Sigma_{z}(l-1) + \left( \sum_{j=0}^{l-1} \Lambda_{j} \Psi_{l-1-j} \right) \Sigma_{\epsilon} \left( \sum_{j=0}^{l-1} \Lambda_{j} \Psi_{l-1-j} \right)'
$$

If there are stochastic exogenous (independent) variables, the covariance matrix of the $l$-step-ahead prediction error of $z_{t+l}$, $\Sigma_{z}(l)$, is

$$
\Sigma_{z}(l) = \Sigma_{z}(l-1) + \left( \sum_{j=0}^{l-1} \Lambda_{j} \Psi_{l-1-j} \right) \Sigma_{\epsilon} \left( \sum_{j=0}^{l-1} \Lambda_{j} \Psi_{l-1-j} \right)'
$$

$$
+ \left( \sum_{j=0}^{l-1} \Lambda_{j} V_{l-1-j} \right) \Sigma_{\alpha} \left( \sum_{j=0}^{l-1} \Lambda_{j} V_{l-1-j} \right)'
$$

**Tentative Order Selection**

**Sample Cross-Covariance and Cross-Correlation Matrices**

Given a stationary multivariate time series $y_{t}$, cross-covariance matrices are

$$
\Gamma(l) = \text{E}[ (y_{t} - \mu)(y_{t+l} - \mu)' ]
$$

where $\mu = \text{E}(y_{t})$, and cross-correlation matrices are

$$
\rho(l) = D^{-1} \Gamma(l) D^{-1}
$$

where $D$ is a diagonal matrix with the standard deviations of the components of $y_{t}$ on the diagonal.

The sample cross-covariance matrix at lag $l$, denoted as $C(l)$, is computed as

$$
\hat{C}(l) = C(l) = \frac{1}{T} \sum_{t=1}^{T-l} \tilde{y}_{t} \tilde{y}'_{t+l}
$$

where $\tilde{y}_{t}$ is the centered data and $T$ is the number of nonmissing observations. Thus, the $(i,j)$ element of $\hat{C}(l)$ is $\hat{c}_{ij}(l) = c_{ij}(l)$. The sample cross-correlation matrix at lag $l$ is computed as

$$
\hat{\rho}_{ij}(l) = \hat{c}_{ij}(l)/[c_{ii}(0)c_{jj}(0)]^{1/2}, \quad i,j = 1,\ldots,k
$$

The following statements use the CORRY option to compute the sample cross-correlation matrices and their summary indicator plots in terms of +, −, and ·, where + indicates significant positive cross-correlations, − indicates significant negative cross-correlations, and · indicates insignificant cross-correlations:
proc varmax data=simul1;
   model y1 y2 / p=1 noint lagmax=3 print=(corry)
                     printform=univariate;
run;

Figure 43.58 shows the sample cross-correlation matrices of $y_{1t}$ and $y_{2t}$. As shown, the sample autocorrelation functions for each variable decay quickly, but are significant with respect to two standard errors.

**Partial Autoregressive Matrices**

For each $m = 1, 2, \ldots, p$, you can define a sequence of matrices $\Phi_{mm}$, which is called the partial autoregression matrices of lag $m$, as the solution for $\Phi_{mm}$ to the Yule-Walker equations of order $m$,

$$\Gamma(l) = \sum_{i=1}^{m} \Gamma(l-i)\Phi_{im}^{l}, \quad l = 1, 2, \ldots, m$$

The sequence of the partial autoregression matrices $\Phi_{mm}$ of order $m$ has the characteristic property that if the process follows the AR($p$), then $\Phi_{pp} = \Phi_p$ and $\Phi_{mm} = 0$ for $m > p$. Hence, the matrices $\Phi_{mm}$ have the cutoff property for a VAR($p$) model, and so they can be useful in the identification of the order of a pure VAR model.

The following statements use the PARCOEF option to compute the partial autoregression matrices:

```
proc varmax data=simul1;
   model y1 y2 / p=1 noint lagmax=3
                     printform=univariate
                     print=(corry parcoef pcorr
```
pcancorr roots);

Figure 43.59 shows that the model can be obtained by an AR order \( m = 1 \) since partial autoregression matrices are insignificant after lag 1 with respect to two standard errors. The matrix for lag 1 is the same as the Yule-Walker autoregressive matrix.

**Figure 43.59** Partial Autoregression Matrices (PARCOEF Option)

**Partial Correlation Matrices**

Define the forward autoregression

\[
y_t = \sum_{i=1}^{m-1} \Phi_{i,m-1} y_{t-i} + u_{m,t}
\]

and the backward autoregression

\[
y_{t-m} = \sum_{i=1}^{m-1} \Phi_{i,m-1}^* y_{t-m+i} + u_{m,t-m}^*
\]

The matrices \( P(m) \) defined by Ansley and Newbold (1979) are given by

\[
P(m) = \sum_{m=1}^{1/2} \Phi_{mm}^* \sum_{m=1}^{1/2}
\]

where

\[
\Sigma_{m=1} = \text{Cov}(u_{m,t}) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(-i) \Phi_{i,m-1}^*
\]
Chapter 43: The VARMAX Procedure

and

$$\Sigma_{m-1}^* = \text{Cov}(\text{u}_{m,t-m}) = \Gamma(0) - \sum_{i=1}^{m-1} \Gamma(m-i) \Phi_{m-i,m-1}^*$$

$P(m)$ are the partial cross-correlation matrices at lag $m$ between the elements of $y_t$ and $y_{t-m}$, given $y_{t-1}, \ldots, y_{t-m+1}$. The matrices $P(m)$ have the cutoff property for a VAR($p$) model, and so they can be useful in the identification of the order of a pure VAR structure.

The following statements use the PCORR option to compute the partial cross-correlation matrices:

```plaintext
proc varmax data=simul1;
  model y1 y2 / p=1 noint lagmax=3
       print=(pcorr)
       printform=univariate;
run;
```

The partial cross-correlation matrices in Figure 43.60 are insignificant after lag 1 with respect to two standard errors. This indicates that an AR order of $m = 1$ can be an appropriate choice.

**Partial Canonical Correlation Matrices**

The partial canonical correlations at lag $m$ between the vectors $y_t$ and $y_{t-m}$, given $y_{t-1}, \ldots, y_{t-m+1}$, are $1 \geq \rho_1(m) \geq \rho_2(m) \cdots \geq \rho_k(m)$. The partial canonical correlations are the canonical correlations between the residual series $u_{m,t}$ and $u_{m,t-m}^*$, where $u_{m,t}$ and $u_{m,t-m}^*$ are defined in the previous section. Thus, the squared partial canonical correlations $\rho_j^2(m)$ are the eigenvalues of the matrix

$$\{\text{Cov}(u_{m,t})\}^{-1} \text{E}(u_{m,t}^* u_{m,t-m}^*) \{\text{Cov}(u_{m,t-m}^*)\}^{-1} \text{E}(u_{m,t-m}^* u_{m,t}^*) = \Phi_{m,m}^* \Phi_{m,m}^\prime$$
It follows that the test statistic to test for $\Phi_m = 0$ in the VAR model of order $m > p$ is approximately

$$(T - m) \text{tr} \left\{ \Phi_{mm}^p \Phi_{mm}^p \right\} \approx (T - m) \sum_{i=1}^{k} \rho_i^2(m)$$

and has an asymptotic chi-square distribution with $k^2$ degrees of freedom for $m > p$.

The following statements use the PCANCORR option to compute the partial canonical correlations:

```plaintext
proc varmax data=simul1;
   model y1 y2 / p=1 noint lagmax=3 print=(pcancorr);
run;
```

Figure 43.61 shows that the partial canonical correlations $\rho_i(m)$ between $y_t$ and $y_{t-m}$ are $\{0.918, 0.773\}$, $\{0.092, 0.018\}$, and $\{0.109, 0.011\}$ for lags $m = 1$ to 3. After lag $m = 1$, the partial canonical correlations are insignificant with respect to the 0.05 significance level, indicating that an AR order of $m = 1$ can be an appropriate choice.

### The Minimum Information Criterion (MINIC) Method

The minimum information criterion (MINIC) method can tentatively identify the orders of a VARMA($p,q$) process (Spiliot 1983; Koreisha and Pukkila 1989; Quinn 1980). The first step of this method is to obtain estimates of the innovations series, $\epsilon_t$, from the VAR($p_e$), where $p_e$ is chosen sufficiently large. The choice of the autoregressive order, $p_e$, is determined by use of a selection criterion. From the selected VAR($p_e$) model, you obtain estimates of residual series

$$\hat{\epsilon}_t = y_t - \sum_{i=1}^{p_e} \hat{\Phi}_{i}^{p_e} y_{t-i} - \hat{\delta}^{p_e}, \ \ t = p_e + 1, \ldots, T$$

In the second step, you select the order ($p, q$) of the VARMA model for $p$ in ($p_{min} : p_{max}$) and $q$ in ($q_{min} : q_{max}$)

$$y_t = \delta + \sum_{i=1}^{p} \Phi_{i} y_{t-i} - \sum_{i=1}^{q} \Theta_{i} \hat{\epsilon}_{t-i} + \epsilon_t$$

which minimizes a selection criterion like SBC or HQ.

According to Lütkepohl (1993), the information criteria, namely Akaike’s information criterion (AIC), the corrected Akaike’s information criterion (AICC), the final prediction error criterion (FPE), the Hannan-Quinn criterion (HQC), and the Schwarz Bayesian criterion (SBC), are defined as
AIC = \log(\hat{\Sigma}) + 2r_bk/T \\
AICC = \log(\hat{\Sigma}) + 2r_bk/(T - r_b) \\
FPE = \left(\frac{T + r_b}{T - r_b}\right)^k \log(\hat{\Sigma}) \\
HQC = \log(\hat{\Sigma}) + 2r_bk \log(\log(T))/T \\
SBC = \log(\hat{\Sigma}) + r_bk \log(T)/T

where \( \hat{\Sigma} \) is the maximum likelihood estimate of the innovation covariance matrix \( \Sigma \), \( r_b \) is the number of parameters in each mean equation, \( k \) is the number of dependent variables, and \( T \) is the number of observations used to estimate the model. Compared to the definitions of AIC, AICC, HQC, and SBC discussed in the section “Multivariate Model Diagnostic Checks” on page 3110, the preceding definitions omit some constant terms and are normalized by \( T \). More specifically, only the parameters in each of the mean equations are counted; the parameters in the innovation covariance matrix \( \Sigma \) are not counted.

The following statements use the MINIC= option to compute a table that contains the information criterion associated with various AR and MA orders:

```plaintext
proc varmax data=simul1;
  model y1 y2 / p=1 noint minic=(p=3 q=3);
run;
```

Figure 43.62 shows the output associated with the MINIC= option. The criterion takes the smallest value at AR order 1.

**VAR and VARX Modeling**

The \( p \)th-order VAR process is written as

\[ y_t - \mu = \sum_{i=1}^{p} \Phi_i (y_{t-i} - \mu) + \epsilon_t \quad \text{or} \quad \Phi(B) (y_t - \mu) = \epsilon_t \]

with \( \Phi(B) = I_k - \sum_{i=1}^{p} \Phi_i B^i \).
Equivalently, it can be written as

$$y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \epsilon_t \quad \text{or} \quad \Phi(B)y_t = \delta + \epsilon_t$$

with $$\delta = (I_k - \sum_{i=1}^{p} \Phi_i) \mu$$.

**Stationarity**

For stationarity, the VAR process must be expressible in the convergent causal infinite MA form as

$$y_t = \mu + \sum_{j=0}^{\infty} \Psi_j \epsilon_{t-j}$$

where $$\Psi(B) = \Phi(B)^{-1} = \sum_{j=0}^{\infty} \Psi_j B^j$$ with $$\sum_{j=0}^{\infty} ||\Psi_j|| < \infty$$, where $$||A||$$ denotes a norm for the matrix $$A$$ such as $$||A||^2 = \text{tr}(A'A)$$. The matrix $$\Psi_j$$ can be recursively obtained from the relation $$\Phi(B)\Psi(B) = I$$; it is

$$\Psi_j = \Phi_1 \Psi_{j-1} + \Phi_2 \Psi_{j-2} + \cdots + \Phi_p \Psi_{j-p}$$

where $$\Psi_0 = I_k$$ and $$\Psi_j = 0$$ for $$j < 0$$.

The stationarity condition is satisfied if all roots of $$|\Phi(z)| = 0$$ are outside of the unit circle. The stationarity condition is equivalent to the condition in the corresponding VAR(1) representation, $$Y_t = \Phi Y_{t-1} + \epsilon_t$$, that all eigenvalues of the $$kp \times kp$$ companion matrix $$\Phi$$ be less than one in absolute value, where $$Y_t = (y'_t, \ldots, y'_{t-p+1})', \epsilon_t = (\epsilon'_t, 0', \ldots, 0')'$$, and

$$\Phi = \begin{bmatrix}
\Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\
I_k & 0 & \cdots & 0 & 0 \\
0 & I_k & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & I_k & 0
\end{bmatrix}$$

If the stationarity condition is not satisfied, a nonstationary model (a differenced model or an error correction model) might be more appropriate.

The following statements estimate a VAR(1) model and use the ROOTS option to compute the characteristic polynomial roots:

```plaintext
proc varmax data=simul1;
   model y1 y2 / p=1 noint print=(roots);
run;
```

Figure 43.63 shows the output associated with the ROOTS option, which indicates that the series is stationary since the modulus of the eigenvalue is less than one.
**Parameter Estimation**

Consider the stationary \( \text{VAR}(p) \) model

\[
y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \epsilon_t
\]

where \( y_{-p+1}, \ldots, y_0 \) are assumed to be available (for convenience of notation). This can be represented by the general form of the multivariate linear model,

\[
Y = XB + E \quad \text{or} \quad y = (X \otimes I_k)\beta + e
\]

where

\[
\begin{align*}
Y &= (y_1, \ldots, y_T)' \\
B &= (\delta, \Phi_1, \ldots, \Phi_p)' \\
X &= (X_0, \ldots, X_{T-1})' \\
X_t &= (1, y_t', \ldots, y_{t-p+1}')' \\
E &= (\epsilon_1, \ldots, \epsilon_T)' \\
y &= \text{vec}(Y') \\
\beta &= \text{vec}(B') \\
e &= \text{vec}(E')
\end{align*}
\]

with \( \text{vec} \) denoting the column stacking operator.

The conditional least squares estimator of \( \beta \) is

\[
\hat{\beta} = ((X'X)^{-1}X' \otimes I_k)y
\]

and the estimate of \( \Sigma \) is

\[
\hat{\Sigma} = (T - (kp + 1))^{-1} \sum_{i=1}^{T} \hat{\epsilon}_i \hat{\epsilon}_i'
\]

where \( \hat{\epsilon}_i \) is the residual vectors. Consistency and asymptotic normality of the LS estimator are that

\[
\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \Gamma_p^{-1} \otimes \Sigma)
\]

where \( X'X/T \) converges in probability to \( \Gamma_p \) and \( \xrightarrow{d} \) denotes convergence in distribution.

The (conditional) maximum likelihood estimator in the \( \text{VAR}(p) \) model is equal to the (conditional) least squares estimator on the assumption of normality of the error vectors.
Asymptotic Distributions of Impulse Response Functions

As before, vec denotes the column stacking operator and vech is the corresponding operator that stacks the elements on and below the diagonal. For any $k \times k$ matrix $A$, the commutation matrix $K_k$ is defined as $K_k \text{vec}(A) = \text{vec}(A')$; the duplication matrix $D_k$ is defined as $D_k \text{vec}(A) = \text{vec}(A)$; the elimination matrix $L_k$ is defined as $L_k \text{vec}(A) = \text{vech}(A)$.

The asymptotic distribution of the impulse response function (Lütkepohl 1993) is

$$\sqrt{T} \text{vec}(\Psi_j - \Psi_j) \overset{d}{\to} N(0, G_j \Sigma_\beta G_j') \quad j = 1, 2, \ldots$$

where $\Sigma_\beta = \Gamma_p^{-1} \otimes \Sigma$ and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \beta'} = \sum_{i=0}^{j-1} J(\Phi')^{j-1-i} \otimes \Psi_i$$

where $J = [I_k, 0, \ldots, 0]$ is a $k \times kp$ matrix and $\Phi$ is a $kp \times kp$ companion matrix.

The asymptotic distribution of the accumulated impulse response function is

$$\sqrt{T} \text{vech}(\tilde{\Psi}_1 - \Psi_1) \overset{d}{\to} N(0, F_1 \Sigma_\beta F_1') \quad l = 1, 2, \ldots$$

where $F_l = \sum_{j=1}^l G_j$.

The asymptotic distribution of the orthogonalized impulse response function is

$$\sqrt{T} \text{vec}(\hat{\Psi}_j - \Psi_j) \overset{d}{\to} N(0, C_j \Sigma_\beta C_j' + \tilde{C}_j \Sigma_{\sigma} \tilde{C}_j') \quad j = 0, 1, 2, \ldots$$

where $C_0 = 0, C_j = (\Psi_{0j}' \otimes I_k)G_j, \tilde{C}_j = (I_k \otimes \Psi_j)H$, $H = \frac{\partial \text{vec}(\Psi_{0j})}{\partial \sigma'} = (L_k (I_k k_2 + K_k) (\Psi_{0j}'^' \otimes I_k) L_k')^{-1}$

and $\Sigma_\sigma = 2D_k^+ (\Sigma \otimes \Sigma) D_k^+ \times D_k^+ (D_k' D_k)^{-1} D_k'$ and $\sigma = \text{vech}(E)$.  

Granger Causality Test

Let $y_t$ be arranged and partitioned in subgroups $y_{1t}$ and $y_{2t}$ with dimensions $k_1$ and $k_2$, respectively ($k = k_1 + k_2$); that is, $y_t = (y'_{1t}, y'_{2t})'$ with the corresponding white noise process $\epsilon_t = (\epsilon'_{1t}, \epsilon'_{2t})'$. Consider the VAR($p$) model with partitioned coefficients $\Phi_{ij}(B)$ for $i, j = 1, 2$ as follows:

$$\begin{bmatrix} \Phi_{11}(B) & \Phi_{12}(B) \\ \Phi_{21}(B) & \Phi_{22}(B) \end{bmatrix} \begin{bmatrix} y_{1t} \\ y_{2t} \end{bmatrix} = \begin{bmatrix} \delta_1 \\ \delta_2 \end{bmatrix} + \begin{bmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{bmatrix}$$

The variables $y_{1t}$ are said to cause $y_{2t}$, but $y_{2t}$ do not cause $y_{1t}$ if $\Phi_{12}(B) = 0$. The implication of this model structure is that future values of the process $y_{1t}$ are influenced only by its own past and not by the past of $y_{2t}$, where future values of $y_{2t}$ are influenced by the past of both $y_{1t}$ and $y_{2t}$. If the future $y_{1t}$ are not influenced by the past values of $y_{2t}$, then it can be better to model $y_{1t}$ separately from $y_{2t}$. 
Consider testing \( H_0: C \beta = c \), where \( C \) is a \( s \times (k^2 p + k) \) matrix of rank \( s \) and \( c \) is an \( s \)-dimensional vector where \( s = k_1 k_2 p \). Assuming that

\[
\sqrt{T}(\hat{\beta} - \beta) \xrightarrow{d} N(0, \Gamma^{-1}_p \otimes \Sigma)
\]

you get the Wald statistic

\[
T(C \hat{\beta} - c)' [C(\hat{\Gamma}^{-1}_p \otimes \hat{\Sigma})C]'^{-1}(C \hat{\beta} - c) \xrightarrow{d} \chi^2(s)
\]

For the Granger causality test, the matrix \( C \) consists of zeros or ones and \( c \) is the zero vector. For more information about the Granger causality test, see Lütkepohl (1993).

**VARX Modeling**

The vector autoregressive model with exogenous variables is called the VARX\((p,s)\) model. The form of the VARX\((p,s)\) model can be written as

\[
y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

\[
Y = XB + E \quad \text{or} \quad y = (X \otimes I_k)\beta + e
\]

where

\[
Y = (y_1, \ldots, y_T)' \quad B = (\delta, \Phi_1, \ldots, \Phi_p, \Theta_0^*, \ldots, \Theta_s^*)'
X = (X_0, \ldots, X_{T-1})'
X_t = (1, y_{t-1}', \ldots, y_{t-p+1}', x_{t+1}', \ldots, x_{t-s+1}')'
E = (\epsilon_1, \ldots, \epsilon_T)'
y = \text{vec}(Y') \quad \beta = \text{vec}(B') \quad e = \text{vec}(E')
\]

The conditional least squares estimator of \( \beta \) can be obtained by using the same method in a VAR\((p)\) modeling. If the multivariate linear model has different independent variables that correspond to dependent variables, the SUR (seemingly unrelated regression) method is used to improve the regression estimates.

The following example fits the ordinary regression model:

```sas
proc varmax data=one;
  model y1-y3 = x1-x5;
run;
```

This is equivalent to the REG procedure in the SAS/STAT software:
proc reg data=one;
    model y1 = x1-x5;
    model y2 = x1-x5;
    model y3 = x1-x5;
run;

The following example fits the second-order lagged regression model:

    proc varmax data=two;
        model y1 y2 = x / xlag=2;
    run;

This is equivalent to the REG procedure in the SAS/STAT software:

    data three;
        set two;
        xlag1 = lag1(x);
        xlag2 = lag2(x);
run;

    proc reg data=three;
        model y1 = x xlag1 xlag2;
        model y2 = x xlag1 xlag2;
    run;

The following example fits the ordinary regression model with different regressors:

    proc varmax data=one;
        model y1 = x1-x3, y2 = x2 x3;
    run;

This is equivalent to the following SYSLIN procedure statements:

    proc syslin data=one vardef=df sur;
        endogenous y1 y2;
        model y1 = x1-x3;
        model y2 = x2 x3;
    run;

From the output in Figure 43.25 in the section “Getting Started: VARMAX Procedure” on page 2982, you can see that the parameters, XL0_1_2, XL0_2_1, XL0_3_1, and XL0_3_2 associated with the exogenous variables, are not significant. The following example fits the VARX(1,0) model with different regressors:

    proc varmax data=grunfeld;
        model y1 = x1, y2 = x2, y3 / p=1 print=(estimates);
    run;

**Figure 43.64** Parameter Estimates for the VARX(1, 0) Model

<table>
<thead>
<tr>
<th>XLag</th>
<th>Lag Variable</th>
<th>x1</th>
<th>x2</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>y1</td>
<td>1.83231</td>
<td>_</td>
</tr>
<tr>
<td></td>
<td>y2</td>
<td>_</td>
<td>2.42110</td>
</tr>
<tr>
<td></td>
<td>y3</td>
<td>_</td>
<td>_</td>
</tr>
</tbody>
</table>
As you can see in Figure 43.64, the symbol ‘\_' in the elements of matrix corresponds to endogenous variables that do not take the denoted exogenous variables.

**Seasonal Dummies and Time Trends**

You can use the NSEASON= option to introduce seasonal dummies into the model, and the TREND= option to introduce linear trend or both linear and quadratic trends into the model. The definition of the seasonal dummies and trends starts from the first observation after skipping the presample and the observations that have missing values. The size of the presample is \( \max(p,s) \), where \( p \) is the maximum number of lags of AR terms and \( s \) is the maximum number of lags of exogenous variables; that is, the presample contains \( \{y_{-l+1}, x_{-l+1}, \ldots, y_0, x_0\} \), where \( l = \max(p,s) \).

The following statements fit a bivariate VARX(1, 2) model that has four seasonal periods and both linear and quadratic time trends:

```plaintext
data One;
  format date date9.;
  do obs = 1 to 100;
    date=intnx('quarter','01Jan1990'd,obs-1);
    y1 = normal(1); y2 = normal(1); x = normal(1);
    output;
  end;
run;

proc varmax data=One;
  model y1 y2 = x / nseason=4 xlag=2 p=1 trend=quad;
run;
```

In the following statements, the seasonal dummies and time trends are explicitly defined in the data set, together with the lags of dependent and exogenous variables, and then the equivalent model is fit by the REG procedure in SAS/STAT software:

```plaintext
data Two;
  set one;
  y1lag1 = lag(y1); y2lag1 = lag(y2);
  xlag1 = lag(x); xlag2 = lag2(x);
  if (obs>2) then do;
    ltrend = obs - 2;
    qtrend = ltrend * ltrend;
    const = 1;
    if (mod(ltrend-2,4)=0) then sd1 = 1;
    else sd1 = 0;
    if (mod(ltrend-3,4)=0) then sd2 = 1;
    else sd2 = 0;
    if (mod(ltrend-4,4)=0) then sd3 = 1;
    else sd3 = 0;
  end;
run;

proc reg data=Two(firstobs=3);
  model y1 = const sd1 sd2 sd3 ltrend qtrend
           x xlag1 xlag2 y1lag1 y2lag1 / noint;
```

Bayesian VAR and VARX Modeling

Consider the VAR($p$) model

$$y_t = \delta + \Phi_1 y_{t-1} + \cdots + \Phi_p y_{t-p} + \epsilon_t$$

or

$$y = (X \otimes I_k)\beta + \epsilon$$

When the parameter vector $\beta$ has a prior multivariate normal distribution with known mean $\beta^*$ and covariance matrix $V_\beta$, the prior density is written as

$$f(\beta) = \frac{1}{(2\pi)^{k^2p/2}} |V_\beta|^{-1/2} \exp\left[-\frac{1}{2} (\beta - \beta^*) V_\beta^{-1} (\beta - \beta^*) \right]$$

The likelihood function for the Gaussian process becomes

$$\ell(\beta|y) = \frac{1}{(2\pi)^{kT/2}} |I_T \otimes \Sigma|^{-1/2} \times$$

$$\exp\left[-\frac{1}{2} (y - (X \otimes I_k)\beta)' (I_T \otimes \Sigma^{-1}) (y - (X \otimes I_k)\beta) \right]$$
Chapter 43: The VARMAX Procedure

Therefore, the posterior density is derived as

\[ f(\beta|y) \propto \exp\left[ -\frac{1}{2}(\beta - \bar{\beta})' \Sigma^{-1}_\beta (\beta - \bar{\beta}) \right] \]

where the posterior mean is

\[ \bar{\beta} = [V^{-1}_\beta + (X'X \otimes \Sigma^{-1})]^{-1}[V^{-1}_\beta \beta^* + (X' \otimes \Sigma^{-1})y] \]

and the posterior covariance matrix is

\[ \Sigma_\beta = [V^{-1}_\beta + (X'X \otimes \Sigma^{-1})]^{-1} \]

In practice, the prior mean \( \beta^* \) and the prior variance \( V_\beta \) need to be specified. If all the parameters are considered to shrink toward zero, the null prior mean should be specified. According to Litterman (1986), the prior variance can be given by

\[ v_{ij}(l) = \begin{cases} \lambda^2/l^2 & \text{if } i = j \\ \lambda \sigma_{ii}/l \sigma_{jj}^2 & \text{if } i \neq j \end{cases} \]

where \( v_{ij}(l) \) is the prior variance of the \((i, j)\) element of \( \Phi_l \), \( \lambda \) is the prior standard deviation of the diagonal elements of \( \Phi_l \), \( \theta \) is a constant in the interval \((0, 1)\), and \( \sigma_{ii}^2 \) is the \(i\)th diagonal element of \( \Sigma \). The deterministic terms have diffused prior variance. In practice, you replace the \( \sigma_{ii}^2 \) by the diagonal element of the ML estimator of \( \Sigma \) in the nonconstrained model.

For example, for a bivariate BVAR(2) model,

\[
\begin{align*}
y_{1t} &= 0 + \phi_{1,11} y_{1,t-1} + \phi_{1,12} y_{2,t-1} + \phi_{2,11} y_{1,t-2} + \phi_{2,12} y_{2,t-2} + \epsilon_{1t} \\
y_{2t} &= 0 + \phi_{1,21} y_{1,t-1} + \phi_{1,22} y_{2,t-1} + \phi_{2,21} y_{1,t-2} + \phi_{2,22} y_{2,t-2} + \epsilon_{2t}
\end{align*}
\]

with the prior covariance matrix

\[ V_\beta = \text{Diag} \left( \infty, \lambda^2, (\lambda \sigma_{11}/\sigma_2)^2, (\lambda/2)^2, (\lambda \sigma_{11}/2\sigma_2)^2, \right. \]
\[ \left. \infty, (\lambda \sigma_{22}/\sigma_1)^2, \lambda^2, (\lambda \sigma_{22}/2\sigma_1)^2, (\lambda/2)^2 \right) \]

For the Bayesian estimation of integrated systems, the prior mean is set to the first lag of each variable equal to one in its own equation and all other coefficients at zero. For example, for a bivariate BVAR(2) model,

\[
\begin{align*}
y_{1t} &= 0 + y_{1,t-1} + 0 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{1t} \\
y_{2t} &= 0 + 0 y_{1,t-1} + 1 y_{2,t-1} + 0 y_{1,t-2} + 0 y_{2,t-2} + \epsilon_{2t}
\end{align*}
\]
Forecasting of BVAR Modeling

The mean squared error (MSE) is used to measure forecast accuracy (Litterman 1986). The MSE of the \( s \)-step-ahead forecast is

\[
\text{MSE}_s = \frac{1}{J - s + 1} \sum_{j=1}^{J-s+1} (A_{t_j} - F_{t_j}^s)^2
\]

where \( J \) is the number specified by \texttt{NREP=} option, \( t_j \) is the time index of the observation to be forecasted in repetition \( j \), \( A_{t_j} \) is the actual value at time \( t_j \), and \( F_{t_j}^s \) is the forecast made \( s \) periods earlier. If there are not enough observations, some MSEs might not be calculated.

Bayesian VARX Modeling

The Bayesian vector autoregressive model with exogenous variables is called the \texttt{BVARX}(\( p,s \)) model. The form of the BVARX(\( p,s \)) model can be written as

\[
y_t = \delta + \sum_{i=1}^{p} \Phi_i y_{t-i} + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]

The parameter estimates can be obtained by representing the general form of the multivariate linear model,

\[
y = (X \otimes I_k) \beta + e
\]

The prior means for the AR coefficients are the same as those specified in \texttt{BVAR}(\( p \)). The prior means for the exogenous coefficients are set to zero.

Some examples of the Bayesian VARX model are as follows:

\begin{verbatim}
model y1 y2 = x1 / p=1 xlag=1 prior;
model y1 y2 = x1 / p=(1 3) xlag=1 nocurrentx
        prior=(lambda=0.9 theta=0.1);
\end{verbatim}

VARMA and VARMAX Modeling

A zero-mean VARMA(\( p,q \)) process is written as

\[
y_t = \sum_{i=1}^{p} \Phi_i y_{t-i} + \epsilon_t - \sum_{i=1}^{q} \Theta_i \epsilon_{t-i}
\]

or

\[
\Phi(B)y_t = \Theta(B)\epsilon_t
\]

where \( \Phi(B) = I_k - \sum_{i=1}^{p} \Phi_i B^i \) and \( \Theta(B) = I_k - \sum_{i=1}^{q} \Theta_i B^i \).
Stationarity and Invertibility

For stationarity and invertibility of the VARMA process, the roots of $|\Phi(z)| = 0$ and $|\Theta(z)| = 0$ are outside the unit circle.

Parameter Estimation

Under the assumption of normality of the $\epsilon_t$ with zero-mean vector and nonsingular covariance matrix $\Sigma$, the conditional (approximate) log-likelihood function of a zero-mean VARMA($p,q$) model is considered.

Define $Y = (y_1, \ldots, y_T)'$ and $E = (\epsilon_1, \ldots, \epsilon_T)'$ with $B^i Y = (y_{1-i}, \ldots, y_{T-i})'$ and $B^i E = (\epsilon_{1-i}, \ldots, \epsilon_{T-i})'$; define $y = \text{vec}(Y')$ and $e = \text{vec}(E')$. Then

$$y - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i y = e - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i e$$

where $B^i y = \text{vec}[(B^i Y)']$ and $B^i e = \text{vec}[(B^i E)']$.

Then, the conditional (approximate) log-likelihood function can be written as (Reinsel 1997)

$$\ell = -\frac{T}{2} \log |\Sigma| - \frac{1}{2} \sum_{t=1}^T \epsilon'_t \Sigma^{-1} \epsilon_t$$

$$= -\frac{T}{2} \log |\Sigma| - \frac{1}{2} w' \Theta^{-1}(I_T \otimes \Sigma^{-1})\Theta^{-1} w$$

where $w = y - \sum_{i=1}^p (I_T \otimes \Phi_i) B^i y$ and $\Theta$ is such that $e - \sum_{i=1}^q (I_T \otimes \Theta_i) B^i e = \Theta e$. You can specify METHOD=CML in the MODEL statement to apply conditional maximum likelihood estimation.

For the exact log-likelihood function of a VARMA model, the VARMA model is transformed into the equivalent state space form and then the Kalman filtering method is applied.

The state space form of the zero-mean VARMA($p,q$) model consists of a state equation

$$z_t = F z_{t-1} + G \epsilon_t$$

and an observation equation

$$y_t = H z_t$$

where

$$z_t = (y'_t, y'_{t-1}, \ldots, y'_{t-(v-1)}, \epsilon'_t, \epsilon_{t-1}, \ldots, \epsilon'_{t-(q-1)})'$$

$$F = \begin{bmatrix}
\Phi_1 & \cdots & \Phi_{v-1} & \Phi_v & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\
I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 \\
0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 \\
0 & \cdots & 0 & 0 & I_k & \cdots & 0 & 0 \\
\vdots & \ddots & \vdots & \vdots & \ddots & \vdots & \vdots & \vdots \\
0 & \cdots & 0 & 0 & 0 & \cdots & I_k & 0 \\
\end{bmatrix}, \quad G = \begin{bmatrix}
I_k \\
0_{k(v-1)\times k} \\
I_k \\
0_{k(q-1)\times k} \\
\end{bmatrix}$$
and
\[ H = [I_k, 0_{k(v+q-1)\times k}] \]
where \( v = \max(p, 1) \) and \( \Phi_i = 0 \) for \( i > p \).

The Kalman filtering approach is used to evaluate the likelihood function. The updating equation is
\[ \hat{z}_{t|t} = \hat{z}_{t|t-1} + K_t \epsilon_{t|t-1} \]
where
\[ K_t = P_{t|t-1} H'[HP_{t|t-1} H']^{-1} \]
The prediction equation is
\[ \hat{z}_{t|t-1} = F \hat{z}_{t-1|t-1}, \quad P_{t|t-1} = FP_{t-1|t-1}F' + G \Sigma G' \]
where \( P_{t|t} = [I - K_t H] P_{t|t-1} \) for \( t = 1, 2, \ldots, n \).

The log-likelihood function can be expressed as
\[ \ell = -\frac{1}{2} \sum_{t=1}^{T} \log |\Sigma_{t|t-1}| + (y_t - \hat{y}_{t|t-1})' \Sigma_{t|t-1}^{-1} (y_t - \hat{y}_{t|t-1}) \]
where \( \hat{y}_{t|t-1} \) and \( \Sigma_{t|t-1} \) are determined recursively from the Kalman filtering method. To construct the likelihood function from Kalman filtering, you obtain \( \hat{y}_{t|t-1} = H \hat{z}_{t|t-1}, \hat{\epsilon}_{t|t-1} = y_t - \hat{y}_{t|t-1}, \) and \( \Sigma_{t|t-1} = HP_{t|t-1} H' \).

When you specify METHOD=ML in the MODEL statement, the exact log likelihood is evaluated and used in the maximum likelihood estimation.

Define the vector \( \beta \) as
\[ \beta = (\phi_1', \ldots, \phi_p', \theta_1', \ldots, \theta_q', \text{vech} (\Sigma))' \]
where \( \phi_i = \text{vec}(\Phi_i) \) and \( \theta_i = \text{vec}(\Theta_i) \). All elements of \( \beta \) are estimated through the preceding (conditional) maximum likelihood method. The estimates of \( \Phi_i, i = 1, \ldots, p \), and \( \Theta_i, i = 1, \ldots, q \), are output in the ParameterEstimates ODS table. The estimates of the covariance matrix (\( \Sigma \)) are output in the CovarianceParameterEstimates ODS table. If you specify the OUTTEST=, OUTCOV, PRINT=(COVB), or PRINT=(CORRB) option, you can see all elements of \( \beta \), including the covariance matrix \( \Sigma \), in the parameter estimates, covariance of parameter estimates, or correlation of parameter estimates. You can also apply the BOUND, INITIAL, RESTRICT, and TEST statements to any elements of \( \beta \), including the covariance matrix \( \Sigma \). For more information, see the syntax of the corresponding statement.

The (conditional) log-likelihood equations are solved by iterative numerical methods such as quasi-Newton optimization. The starting values for the AR and MA parameters are obtained from the least squares estimates. Although the small-sample properties of CML estimates might not be as good as the ML estimates, the CML method is much faster than the ML method. Depending on the sample size and number of parameters to be estimated, the CML method can be hundreds or even thousands of times faster than the ML method. In the following example code, the CML method is about 100 times faster than the ML method, with very similar estimation and forecast results:
proc iml;
phi = (0.9 * I(4)) // (-0.7 * I(4));
theta = 0.8 * I(4);
sig = I(4);
/* to simulate the vector time series */
call varmasim(y,phi,theta) sigma=sig n=400 seed=2;

cn = {'y1' 'y2' 'y3' 'y4'};
create simul6 from y[colname=cn];
append from y;
close;
quit;

proc varmax data=simul6;
model y1 y2 y3 y4 / noint p=2 q=1 method=cml;
nloptions pall maxit=5000 tech=qn;
output out=ocml back=12 lead=24;
run;

proc varmax data=simul6;
model y1 y2 y3 y4 / noint p=2 q=1 method=ml;
nloptions pall maxit=5000 tech=qn;
output out=oml back=12 lead=24;
run;

Asymptotic Distribution of the Parameter Estimates

Under the assumptions of stationarity and invertibility for the VARMA model and the assumption that $\epsilon_t$ is a white noise process, $\hat{\beta}$ is a consistent estimator for $\beta$ and $\sqrt{T}(\hat{\beta} - \beta)$ converges in distribution to the multivariate normal $N(0, V^{-1})$ as $T \rightarrow \infty$, where $V$ is the asymptotic information matrix of $\beta$.

Asymptotic Distributions of Impulse Response Functions

Defining the vector $\beta$

$$\beta = (\phi_1', \ldots, \phi_p', \theta_1', \ldots, \theta_q')'$$

the asymptotic distribution of the impulse response function for a VARMA($p, q$) model is

$$\sqrt{T} \text{vec}(\Psi_j - \Psi_j) \xrightarrow{d} N(0, G_j \Sigma_\beta G_j') \quad j = 1, 2, \ldots$$

where $\Sigma_\beta$ is the covariance matrix of the parameter estimates and

$$G_j = \frac{\partial \text{vec}(\Psi_j)}{\partial \beta'} = \sum_{i=0}^{j-1} H'(A')^{j-1-i} \otimes JA'J'$$

where $H = [I_k, 0, \ldots, 0, I_k, 0, \ldots, 0]'$ is a $k(p + q) \times k$ matrix with the second $I_k$ following after $p$ block matrices; $J = [I_k, 0, \ldots, 0]$ is a $k \times (p + q)$ matrix; $A$ is a $k(p + q) \times k(p + q)$ matrix,

$$A = \begin{bmatrix} A_{11} & A_{12} \\ A_{21} & A_{22} \end{bmatrix}$$
where

\[
A_{11} = \begin{bmatrix}
\Phi_1 & \Phi_2 & \cdots & \Phi_{p-1} & \Phi_p \\
I_k & 0 & \cdots & 0 & 0 \\
0 & I_k & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & I_k & 0
\end{bmatrix}
\quad A_{12} = \begin{bmatrix}
-\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q \\
0 & \cdots & 0 & 0 \\
0 & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots \\
0 & \cdots & 0 & 0
\end{bmatrix}
\]

\(A_{21}\) is a \(kq \times kp\) zero matrix, and

\[
A_{22} = \begin{bmatrix}
0 & 0 & \cdots & 0 & 0 \\
I_k & 0 & \cdots & 0 & 0 \\
0 & I_k & \cdots & 0 & 0 \\
\vdots & \vdots & \ddots & \vdots & \vdots \\
0 & 0 & \cdots & I_k & 0
\end{bmatrix}
\]

**An Example of a VARMA(1,1) Model**

Consider a VARMA(1,1) model with mean zero,

\[
y_t = \Phi_1 y_{t-1} + \epsilon_t - \Theta_1 \epsilon_{t-1}
\]

where \(\epsilon_t\) is the white noise process with a mean zero vector and the positive-definite covariance matrix \(\Sigma\).

The following IML procedure statements simulate a bivariate vector time series from this model to provide test data for the VARMAX procedure:

```
proc iml;
    sig = {1.0 0.5, 0.5 1.25};
    phi = {1.2 -0.5, 0.6 0.3};
    theta = {0.5 -0.2, 0.1 0.3};
    /* to simulate the vector time series */
    call varmasim(y,phi,theta) sigma=sig n=100 seed=34657;
    cn = {'y1' 'y2'};
    create simul3 from y[colname=cn];
    append from y;
run;
```

The following statements fit a VARMA(1,1) model to the simulated data. You specify the order of the autoregressive model by using the \(P=\) option and specify the order of moving-average model by using the \(Q=\) option. You specify the quasi-Newton optimization in the NLOPTIONS statement as an optimization method.

```
proc varmax data=simul3;
    nloptions tech=qn;
    model y1 y2 / p=1 q=1 noint print=(estimates);
run;
```
Figure 43.66 shows the initial values of parameters. The initial values were estimated by using the least squares method.

The fitted VARMA(1,1) model with estimated standard errors in parentheses is given as

\[
y_t = \begin{pmatrix} 1.01846 & -0.38682 \\ 0.10256 & 0.09644 \\ 0.39182 & 0.55281 \\ 0.10062 & 0.08422 \end{pmatrix} y_{t-1} + \begin{pmatrix} 0.32292 \\ 0.14524 \\ -0.16501 \\ 0.15704 \end{pmatrix} \epsilon_t - \begin{pmatrix} -0.000160 \\ (0.14203) \\ -0.16501 \\ (0.14115) \end{pmatrix} \epsilon_{t-1}
\]
and
\[ \epsilon_t \sim \text{iid } N(0, \begin{pmatrix} 1.25202 & 0.37950 \\ (0.17697) & (0.13401) \\ 0.37950 & 1.31315 \\ (0.13401) & (0.18610) \end{pmatrix}) \]

**VARMAX Modeling**

A general VARMAX\((p, q, s)\) process is written as
\[ y_t = \delta_t + \sum_{i=1}^{p} \Phi_i y_{t-i} + \epsilon_t - \sum_{i=1}^{q} \Theta_i \epsilon_{t-i} \]

or
\[ \Phi(B)y_t = \delta_t + \Theta(B)\epsilon_t \]

where \( \Phi(B) = I_k - \sum_{i=1}^{p} \Phi_i B^i \) and \( \Theta(B) = I_k - \sum_{i=1}^{q} \Theta_i B^i \). The vector \( \delta_t \) consists of all possible deterministic terms, namely constant, seasonal dummies, linear trend, quadratic trend, and exogenous variables. The vector \( \delta_t = \Delta \epsilon_t \), where \( \epsilon_t = (D', x'_t, \ldots, x'_{t-s})'; D_t = (1_{t,1}, \ldots, d_{t,n_s}, t, t^2)' \); \( d_{t,i}, i = 1, \ldots, n_s - 1 \), are seasonal dummies and \( n_s \) is based on the NSEASON= option; \( \Delta = (A \Theta_0^* \ldots \Theta_s^*) \); \( A \) is the parameter matrix corresponding to \( D_t \) and \( \Theta_i^* \) for \( x_{t-i}, i = 0, \ldots, s \).

The state space form of the VARMAX\((p,q,s)\) model consists of a state equation
\[ z_t = F z_{t-1} + w_t + G \epsilon_t \]

and an observation equation
\[ y_t = H z_t \]

where
\[ z_t = (y'_t, y'_{t-1}, \ldots, y'_{t-(v-1)}, \epsilon'_t, \epsilon_{t-1}, \ldots, \epsilon'_{t-(q-1)}, c'_{t+1})' \]

\[ F = \begin{bmatrix} \Phi_1 & \cdots & \Phi_{v-1} & \Phi_v & -\Theta_1 & \cdots & -\Theta_{q-1} & -\Theta_q & \Delta \\ I_k & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\ 0 & \cdots & I_k & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & \cdots & 0 & 0 & 0 & \cdots & 0 & 0 & 0 \\ 0 & \cdots & 0 & 0 & I_k & \cdots & 0 & 0 & 0 \\ \vdots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots & \ddots \\ 0 & \cdots & 0 & 0 & 0 & \cdots & I_k & 0 & 0 \end{bmatrix} \]

\[ G = \begin{bmatrix} I_k \\ 0_{k(v-1)\times k} \\ I_k \\ 0_{k(q-1)\times k} \\ 0_{u\times k} \end{bmatrix} \]

and
\[ H = [I_k, 0_{(k+q-1)+u} \times k] \]
where \( v = \max(p, 1) \), \( \Phi_i = 0 \) for \( i > p \), and \( u \) is the dimension of \( c_t \).

Kalman filtering is used to evaluate the likelihood function. The updating equation is
\[
\hat{z}_{t|t} = \hat{z}_{t|t-1} + K_t \epsilon_{t|t-1}
\]
where
\[
K_t = P_{t|t-1} H'[HP_{t|t-1}H']^{-1}
\]
The prediction equation is
\[
\hat{z}_{t-1|t} = F \hat{z}_{t-1|t-1} + w_t, \quad P_{t|t-1} = FP_{t-1|t-1}F' + G \Sigma G'
\]
where \( P_{t|t} = [I - K_t H]P_{t|t-1} \) for \( t = 1, 2, \ldots, n \).

The log-likelihood function can be expressed as
\[
\ell = -\frac{1}{2} \sum_{t=1}^{T} \left[ \log |\Sigma_{t|t-1}| + (y_t - \hat{y}_{t|t-1})' \Sigma_{t|t-1}^{-1} (y_t - \hat{y}_{t|t-1}) \right]
\]
where \( \hat{y}_{t|t-1} \) and \( \Sigma_{t|t-1} \) are determined recursively from Kalman filtering. To construct the likelihood function from Kalman filtering, you obtain \( \hat{y}_{t|t-1} = H \hat{z}_{t|t-1}, \hat{\epsilon}_{t|t-1} = y_t - \hat{y}_{t|t-1}, \) and \( \Sigma_{t|t-1} = HP_{t|t-1}H' \).

In the preceding state space form of a VARMAX model, the exogenous variables are treated as determined terms, which implies that the values of the exogenous variables must be provided to forecast the out-of-sample dependent variables. If you do not have the future values of the exogenous variables, either you predict the exogenous variables in a separate model, or you express both the exogenous variables and the dependent variables in one combined model and predict them together (Reinsel 1997).

The dimension of the state space vector of the Kalman filtering method for the VARMAX\((p,q,s)\) model might be large, so it might take a lot of time and memory for computing.

Two examples of VARMAX modeling follow:
```
model y1 y2 = x1 / q=1;
nloptions tech=qn;
```
```
model y1 y2 = x1 / p=1 q=1 xlag=1 nocurrentx;
nloptions tech=qn;
```

---

### Model Diagnostic Checks

#### Multivariate Model Diagnostic Checks

**Log Likelihood**

The log-likelihood function for the fitted model is reported in the LogLikelihood ODS table. The log-likelihood functions for different models are defined as follows:

- For VARMAX models that are estimated through the (conditional) maximum likelihood method, see the section “VARMA and VARMAX Modeling” on page 3101.
For Bayesian VAR and VARX models, see the section “Bayesian VAR and VARX Modeling” on page 3099.

For (Bayesian) vector error correction models, see the section “Vector Error Correction Modeling” on page 3115.

For multivariate GARCH models, see the section “Multivariate GARCH Modeling” on page 3135.

For VARFIMA and VARFIMAX models, see the section “V ARFIMA and V ARFIMAX Modeling” on page 3146.

For VAR and VARX models that are estimated through the least squares (LS) method, the log likelihood is defined as

\[ \ell = -\frac{1}{2} (T \log |\hat{\Sigma}| + kT) \]

where \( \hat{\Sigma} \) is the maximum likelihood estimate of the innovation covariance matrix, \( k \) is the number of dependent variables, and \( T \) is the number of observations used in the estimation.

**Information Criteria**

The information criteria include Akaike’s information criterion (AIC), the corrected Akaike’s information criterion (AICC), the final prediction error criterion (FPE), the Hannan-Quinn criterion (HQC), and the Schwarz Bayesian criterion (SBC, also referred to as BIC). These criteria are defined as

\[
\begin{align*}
\text{AIC} &= -2\ell + 2r \\
\text{AICC} &= -2\ell + 2r \frac{T}{(T - r - 1)} \\
\text{FPE} &= \left(\frac{T + r_b}{T - r_b}\right)^k |\hat{\Sigma}| \\
\text{HQC} &= -2\ell + 2r \log(\log(T)) \\
\text{SBC} &= -2\ell + r \log(T)
\end{align*}
\]

where \( \ell \) is the log likelihood, \( r \) is the total number of parameters in the model, \( k \) is the number of dependent variables, \( T \) is the number of observations that are used to estimate the model, \( r_b \) is the number of parameters in each mean equation, and \( \hat{\Sigma} \) is the maximum likelihood estimate of \( \Sigma \). As suggested by Burnham and Anderson (2004) for least squares estimation, the total number of parameters, \( r \), must include the parameters in the innovation covariance matrix. When comparing models, choose the model that has the smallest criterion values.

For an example of the output, see Figure 43.4 earlier in this chapter.

**Portmanteau Statistic**

The portmanteau statistic, \( Q_s \), is used to test whether correlation remains on the model residuals. The null hypothesis is that the residuals are uncorrelated. Let \( C_\varepsilon(l) \) be the residual cross-covariance matrices, \( \hat{\rho}_\varepsilon(l) \) be the residual cross-correlation matrices as

\[
C_\varepsilon(l) = T^{-1} \sum_{t=1}^{T-l} \varepsilon_t \varepsilon'_{t+l}
\]
Chapter 43: The VARMAX Procedure

and

\[ \hat{\rho}_e(l) = \hat{V}_\epsilon^{-1/2}C_\epsilon(l)\hat{V}_\epsilon^{-1/2} \quad \text{and} \quad \hat{\rho}_e(-l) = \hat{\rho}_e(l)' \]

where \( \hat{V}_\epsilon = \text{Diag}(\hat{\sigma}_{11}^2, \ldots, \hat{\sigma}_{kk}^2) \) and \( \hat{\sigma}_{ii}^2 \) are the diagonal elements of \( \hat{\Sigma} \). The multivariate portmanteau test defined in Hosking (1980) is

\[ Q_s = T^2 \sum_{l=1}^s (T - l)^{-1} \text{tr} \{ \hat{\rho}_e(l)\hat{\rho}_e(0)^{-1} \hat{\rho}_e(-l)\hat{\rho}_e(0)^{-1} \} \]

The statistic \( Q_s \) has approximately the chi-square distribution with \( k^2(s - p - q) \) degrees of freedom. An example of the output is displayed in Figure 43.7.

Univariate Model Diagnostic Checks

There are various ways to perform diagnostic checks for a univariate model. For more information, see the section “Testing for Nonlinear Dependence: Heteroscedasticity Tests” on page 403 in Chapter 8, “The AUTOREG Procedure.” An example of the output is displayed in Figure 43.8 and Figure 43.9.

- Durbin-Watson (DW) statistics: The DW test statistics test for the first order autocorrelation in the residuals.
- Jarque-Bera normality test: This test is helpful in determining whether the model residuals represent a white noise process. This tests the null hypothesis that the residuals have normality.
- \( F \) tests for autoregressive conditional heteroscedastic (ARCH) disturbances: \( F \) test statistics test for the heteroscedastic disturbances in the residuals. This tests the null hypothesis that the residuals have equal covariances.
- \( F \) tests for AR disturbance: These test statistics are computed from the residuals of the univariate AR(1), AR(1,2), AR(1,2,3), and AR(1,2,3,4) models to test the null hypothesis that the residuals are uncorrelated.

Cointegration

This section briefly introduces the concepts of cointegration (Johansen 1995a).

Definition 1. (Engle and Granger 1987): If a series \( y_t \) with no deterministic components can be represented by a stationary and invertible ARMA process after differencing \( d \) times, the series is integrated of order \( d \), that is, \( y_t \sim I(d) \).

Definition 2. (Engle and Granger 1987): If all elements of the vector \( y_t \) are \( I(d) \) and there exists a cointegrating vector \( \beta \neq 0 \) such that \( \beta' y_t \sim I(d - b) \) for any \( b > 0 \), the vector process is said to be cointegrated \( CI(d, b) \).
A simple example of a cointegrated process is the following bivariate system:

\[
\begin{align*}
y_{1t} &= γy_{2t} + ε_{1t} \\
y_{2t} &= y_{2,t-1} + ε_{2t}
\end{align*}
\]

with $ε_{1t}$ and $ε_{2t}$ being uncorrelated white noise processes. In the second equation, $y_{2t}$ is a random walk, $Δy_{2t} = ε_{2t}$, $Δ ≡ 1 - B$. Differencing the first equation results in

\[
Δy_{1t} = γΔy_{2t} + Δε_{1t} = γε_{2t} + ε_{1t} - ε_{1,t-1}
\]

Thus, both $y_{1t}$ and $y_{2t}$ are $I(1)$ processes, but the linear combination $y_{1t} - γy_{2t}$ is stationary. Hence $y_t = (y_{1t}, y_{2t})'$ is cointegrated with a cointegrating vector $β = (1, -γ)'$.

In general, if the vector process $y_t$ has $k$ components, then there can be more than one cointegrating vector $β'$. It is assumed that there are $r$ linearly independent cointegrating vectors with $r < k$, which make the $k \times r$ matrix $β$. The rank of matrix $β$ is $r$, which is called the cointegration rank of $y_t$.

**Common Trends**

This section briefly discusses the implication of cointegration for the moving-average representation. Let $y_t$ be cointegrated $CI(1, 1)$, then $Δy_t$ has the Wold representation:

\[
Δy_t = δ + Ψ(B)ε_t
\]

where $ε_t$ is iid$(0, Σ)$, $Ψ(B) = \sum_{j=0}^{∞} Ψ_j B^j$ with $Ψ_0 = I_k$, and $\sum_{j=0}^{∞} j |Ψ_j| < ∞$.

Assume that $ε_t = 0$ if $t ≤ 0$ and $y_0$ is a nonrandom initial value. Then the difference equation implies that

\[
y_t = y_0 + δt + Ψ(1) \sum_{i=0}^{t} ε_i + Ψ^*(B)ε_t
\]

where $Ψ^*(B) = (1 - B)^{-1}(Ψ(B) - Ψ(1))$ and $Ψ^*(B)$ is absolutely summable.

Assume that the rank of $Ψ(1)$ is $m = k - r$. When the process $y_t$ is cointegrated, there is a cointegrating $k \times r$ matrix $β$ such that $β'y_t$ is stationary.

Premultiplying $y_t$ by $β'$ results in

\[
β'y_t = β'y_0 + β'Ψ^*(B)ε_t
\]

because $β'Ψ(1) = 0$ and $β'δ = 0$.

Stock and Watson (1988) showed that the cointegrated process $y_t$ has a common trends representation derived from the moving-average representation. Since the rank of $Ψ(1)$ is $m = k - r$, there is a $k \times r$ matrix $H_1$ with rank $r$ such that $Ψ(1)H_1 = 0$. Let $H_2$ be a $k \times m$ matrix with rank $m$ such that $H_2'H_1 = 0$; then $A = C(1)H_2$ has rank $m$. The $H = (H_1, H_2)$ has rank $k$. By construction of $H$,

\[
Ψ(1)H = [0, A] = AS_m
\]
where $S_m = (0_{m \times r}, I_m)$. Since $\beta' \Psi(1) = 0$ and $\beta' \delta = 0$, $\delta$ lies in the column space of $\Psi(1)$ and can be written

$$\delta = \Psi(1) \tilde{\delta}$$

where $\tilde{\delta}$ is a $k$-dimensional vector. The common trends representation is written as

$$y_t = y_0 + \Psi(1) [\tilde{\delta} t + \sum_{i=0}^{t} \epsilon_i] + \Psi^*(B) \epsilon_t$$

$$= y_0 + \Psi(1) H^{-1} \tilde{\delta} t + H^{-1} \sum_{i=0}^{t} \epsilon_i + a_t$$

$$= y_0 + A \tau_t + a_t$$

and

$$\tau_t = \pi + \tau_{t-1} + v_t$$

where $a_t = \Psi^*(B) \epsilon_t$, $\pi = S_m H^{-1} \tilde{\delta}$, $\tau_t = S_m [H^{-1} \tilde{\delta} t + H^{-1} \sum_{i=0}^{t} \epsilon_i]$, and $v_t = S_m H^{-1} \epsilon_t$. Stock and Watson showed that the common trends representation expresses $y_t$ as a linear combination of $m$ random walks ($\tau_t$) with drift $\pi$ plus $I(0)$ components ($a_t$).

**Test for the Common Trends**

Stock and Watson (1988) proposed statistics for common trends testing. The null hypothesis is that the $k$-dimensional time series $y_t$ has $m$ common stochastic trends, where $m \leq k$ and the alternative is that it has $s$ common trends, where $s < m$. The test procedure of $m$ versus $s$ common stochastic trends is performed based on the first-order serial correlation matrix of $y_t$. Let $\beta_\perp$ be a $k \times m$ matrix orthogonal to the cointegrating matrix such that $\beta_\perp \beta = 0$ and $\beta_\perp^t \beta_\perp = I_m$. Let $z_t = \beta'_t y_t$ and $w_t = \beta'_\perp y_t$. Then

$$w_t = \beta'_\perp y_0 + \beta'_\perp \delta t + \beta'_\perp \Psi(1) \sum_{i=0}^{t} \epsilon_i + \beta'_\perp \Psi^*(B) \epsilon_t$$

Combining the expression of $z_t$ and $w_t$,

$$\begin{bmatrix} z_t \\ w_t \end{bmatrix} = \begin{bmatrix} \beta'_t y_0 \\
\beta'_\perp y_0 \end{bmatrix} + \begin{bmatrix} 0 \\
\beta'_t \delta \end{bmatrix} t + \begin{bmatrix} 0 \\
\beta'_\perp \Psi(1) \end{bmatrix} \sum_{i=1}^{t} \epsilon_i$$

$$+ \begin{bmatrix} \beta'_t \Psi^*(B) \\
\beta'_\perp \Psi^*(B) \end{bmatrix} \epsilon_t$$

The Stock-Watson common trends test is performed based on the component $w_t$ by testing whether $\beta'_\perp \Psi(1)$ has rank $m$ against rank $s$.

The following statements perform the Stock-Watson test for common trends:
Vector Error Correction Modeling

This section discusses the implication of cointegration for the autoregressive representation.

Consider the vector autoregressive process that has Gaussian errors defined by

\[ y_t = \sum_{i=1}^{p} \Phi_i y_{t-i} + \epsilon_t \]
or
\[
\Phi(B)y_t = \epsilon_t
\]
where the initial values, \(y_{-p+1}, \ldots, y_0\), are fixed and \(\epsilon_t \sim N(0, \Sigma)\). The AR operator \(\Phi(B)\) can be re-expressed as
\[
\Phi(B) = \Phi^+(B)(1 - B) + \Phi(1)B
\]
where
\[
\Phi(1) = I_k - \Phi_1 - \Phi_2 - \cdots - \Phi_p, \quad \Phi^+(B) = I_k - \sum_{i=1}^{p-1} \Phi_i^* B^i, \quad \Phi_i^* = - \sum_{j=i+1}^{p} \Phi_j
\]
The vector error correction model (VECM), also called the vector equilibrium correction model, is defined as
\[
\Phi^+(B)(1 - B)y_t = \alpha \beta' y_{t-1} + \epsilon_t
\]
or
\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t
\]
where \(\alpha \beta' = -\Phi(1)\).

**Granger Representation Theorem**
Engle and Granger (1987) define
\[
\Pi(z) \equiv (1 - z)I_k - \alpha \beta' z - \sum_{i=1}^{p-1} \Phi_i^* (1 - z) z^i
\]
and the following assumptions hold:

1. \(|\Pi(z)| = 0 \Rightarrow |z| > 1\) or \(z = 1\).
2. The number of unit roots, \(z = 1\), is exactly \(k - r\).
3. \(\alpha\) and \(\beta\) are \(k \times r\) matrices, and their ranks are both \(r\).

Then \(y_t\) has the representation
\[
y_t = C \sum_{i=1}^{t} \epsilon_i + C^+(B) \epsilon_t + y_0^*
\]
where the Granger representation coefficient, \(C\), is
\[
C = \beta_\perp \left[ \alpha_\perp^* \Phi(1) \beta_\perp^* \right]^{-1} \alpha_\perp^*
\]
where the full-rank \( k \times (k - r) \) matrix \( \beta_\perp \) is orthogonal to \( \beta \) and the full-rank \( k \times (k - r) \) matrix \( \alpha_\perp \) is orthogonal to \( \alpha \). \( C^*(B)\epsilon_t = \sum_{j=1}^{\infty} C_j^* \epsilon_{t-j} \) is an \( I(0) \) process, and \( y_0^* \) depends on the initial values.

The Granger representation coefficient \( C \) can be defined only when the \( (k - r) \times (k - r) \) matrix \( \alpha_\perp^* \Phi(1) \beta_\perp \) is invertible.

One motivation for the VECM(\( p \)) form is to consider the relation \( \beta'y_t = \epsilon \) as defining the underlying economic relations. Assume that agents react to the disequilibrium error \( \beta'y_t - \epsilon \) through the adjustment coefficient \( \alpha \) to restore equilibrium. The cointegrating vector, \( \beta \), is sometimes called the long-run parameter.

Consider a vector error correction model that has a deterministic term, \( D_t \), which can contain a constant, a linear trend, and seasonal dummy variables. Exogenous variables can also be included in the model. The model has the form

\[
\Delta y_t = \Pi y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]

where \( \Pi = \alpha \beta' \).

The alternative vector error correction representation considers the error correction term at lag \( t - p \) and is written as

\[
\Delta y_t = \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \Pi^\beta y_{t-p} + AD_t + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]

If the matrix \( \Pi \) has a full rank (\( r = k \)), all components of \( y_t \) are \( I(0) \). On the other hand, \( y_t \) are stationary in difference if \( \text{rank}(\Pi) = 0 \). When the rank of the matrix \( \Pi \) is \( r < k \), there are \( k - r \) linear combinations that are nonstationary and \( r \) stationary cointegrating relations. Note that the linearly independent vector \( z_t = \beta'y_t \) is stationary and this transformation is not unique unless \( r = 1 \). There does not exist a unique cointegrating matrix \( \beta \) because the coefficient matrix \( \Pi \) can also be decomposed as

\[
\Pi = \alpha MM^{-1} \beta' = \alpha^* \beta^*'
\]

where \( M \) is an \( r \times r \) nonsingular matrix.

**Test for Cointegration**

The cointegration rank test determines the linearly independent columns of \( \Pi \). Johansen and Juselius proposed the cointegration rank test by using the reduced rank regression (Johansen 1988, 1995b; Johansen and Juselius 1990).

**Different Specifications of Deterministic Trends**

When you construct the VECM(\( p \)) form from the VAR(\( p \)) model, the deterministic terms in the VECM(\( p \)) form can differ from those in the VAR(\( p \)) model. When there are deterministic cointegrated relationships among variables, deterministic terms in the VAR(\( p \)) model are not present in the VECM(\( p \)) form. On the other hand, if there are stochastic cointegrated relationships in the VAR(\( p \)) model, deterministic terms appear in the VECM(\( p \)) form via the error correction term or as an independent term in the VECM(\( p \)) form. There are five different specifications of deterministic trends in the VECM(\( p \)) form.
• **Case 1:** There is no separate drift in the VECM($p$) form.

\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t
\]

• **Case 2:** There is no separate drift in the VECM($p$) form, but a constant enters only via the error correction term.

\[
\Delta y_t = \alpha (\beta', \beta_0)(y'_{t-1}, 1)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t
\]

• **Case 3:** There is a separate drift and no separate linear trend in the VECM($p$) form.

\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \epsilon_t
\]

• **Case 4:** There is a separate drift and no separate linear trend in the VECM($p$) form, but a linear trend enters only via the error correction term.

\[
\Delta y_t = \alpha (\beta', \beta_1)(y'_{t-1}, t)' + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \delta_1 t + \epsilon_t
\]

• **Case 5:** There is a separate linear trend in the VECM($p$) form.

\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \delta_0 + \delta_1 t + \epsilon_t
\]

First, focus on Cases 1, 3, and 5 to test the null hypothesis that there are at most $r$ cointegrating vectors. Let

\[
\begin{align*}
Z_{0t} & = \Delta y_t \\
Z_{1t} & = y_{t-1} \\
Z_{2t} & = [\Delta y'_{t-1}, \ldots, \Delta y'_{t-p+1}, D_t]' \\
Z_0 & = [Z_{01}, \ldots, Z_{0T}]' \\
Z_1 & = [Z_{11}, \ldots, Z_{1T}]' \\
Z_2 & = [Z_{21}, \ldots, Z_{2T}]'
\end{align*}
\]

where $D_t$ can be empty for Case 1, 1 for Case 3, and $(1, t)$ for Case 5.

In Case 2, $Z_{1t}$ and $Z_{2t}$ are defined as

\[
\begin{align*}
Z_{1t} & = [y'_{t-1}, 1]' \\
Z_{2t} & = [\Delta y'_{t-1}, \ldots, \Delta y'_{t-p+1}]'
\end{align*}
\]
In Case 4, $Z_{1t}$ and $Z_{2t}$ are defined as

$$
Z_{1t} = [y'_{t-1}, 1]' \\
Z_{2t} = [\Delta y'_{t-1}, \ldots, \Delta y'_{t-p+1}, 1]'
$$

Let $\Psi$ be the matrix of parameters consisting of $\Phi^*_1, \ldots, \Phi^*_{p-1}, A, \Theta^*_0, \ldots, \Theta^*_s$, where parameter $A$ corresponds with the regressors $D_t$. Then the VECM($p$) form is rewritten in these variables as

$$
Z_{0t} = \alpha \beta' Z_{1t} + \Psi Z_{2t} + \epsilon_t
$$

The log-likelihood function is given by

$$
\ell = -\frac{kT}{2} \log 2\pi - \frac{T}{2} \log |\Sigma| - \frac{1}{2} \sum_{i=1}^{T} (Z_{0t} - \alpha \beta' Z_{1t} - \Psi Z_{2t})' \Sigma^{-1} (Z_{0t} - \alpha \beta' Z_{1t} - \Psi Z_{2t})
$$

The residuals, $R_{0t}$ and $R_{1t}$, are obtained by regressing $Z_{0t}$ and $Z_{1t}$ on $Z_{2t}$, respectively. The regression equation of residuals is

$$
R_{0t} = \alpha \beta' R_{1t} + \hat{\epsilon}_t
$$

The crossproducts matrices are computed

$$
S_{ij} = \frac{1}{T} \sum_{i=1}^{T} R_{it} R'_{jt}, \ i, j = 0, 1
$$

Then the maximum likelihood estimator for $\beta$ is obtained from the eigenvectors that correspond to the $r$ largest eigenvalues of the following equation:

$$
|\lambda S_{11} - S_{10} S^{-1}_{00} S_{01}| = 0
$$

The eigenvalues of the preceding equation are squared canonical correlations between $R_{0t}$ and $R_{1t}$, and the eigenvectors that correspond to the $r$ largest eigenvalues are the $r$ linear combinations of $y_{t-1}$, which have the largest squared partial correlations with the stationary process $\Delta y_t$ after correcting for lags and deterministic terms. Such an analysis calls for a reduced rank regression of $\Delta y_t$ on $y_{t-1}$ corrected for $(\Delta y_{t-1}, \ldots, \Delta y_{t-p+1}, D_t)$, as discussed by Anderson (1951). Johansen (1988) suggests two test statistics to test the null hypothesis that there are at most $r$ cointegrating vectors

$$
H_0: \lambda_i = 0 \text{ for } i = r + 1, \ldots, k
$$
**Trace Test**
The trace statistic for testing the null hypothesis that there are at most $r$ cointegrating vectors is as follows:

$$
\lambda_{\text{trace}} = -T \sum_{i=r+1}^{k} \log(1 - \lambda_i)
$$

The asymptotic distribution of this statistic is given by

$$
\text{tr} \left\{ \int_0^1 (dW)^{\prime} \left( \int_0^1 \tilde{W} \tilde{W}^\prime dr \right)^{-1} \int_0^1 \tilde{W} (dW)^{\prime} \right\}
$$

where $\text{tr}(A)$ is the trace of a matrix $A$, $W$ is the $k - r$ dimensional Brownian motion, and $\tilde{W}$ is the Brownian motion itself, or the demeaned or detrended Brownian motion according to the different specifications of deterministic trends in the vector error correction model.

**Maximum Eigenvalue Test**
The maximum eigenvalue statistic for testing the null hypothesis that there are at most $r$ cointegrating vectors is as follows:

$$
\lambda_{\text{max}} = -T \log(1 - \lambda_{r+1})
$$

The asymptotic distribution of this statistic is given by

$$
\max_i \int_0^1 (dW)^{\prime} \tilde{W}_i^\prime \left( \int_0^1 \tilde{W} \tilde{W}^\prime dr \right)^{-1} \int_0^1 \tilde{W} (dW)^{\prime}
$$

where $\max(A)$ is the maximum eigenvalue of a matrix $A$. Osterwald-Lenum (1992) provided detailed tables of the critical values of these statistics.

The following statements use the JOHANSEN option to compute the Johansen cointegration rank trace test of integrated order 1:

```plaintext
proc varmax data=simul2;
  model y1 y2 / p=2 cointest=(johansen=(normalize=y1));
run;
```

Figure 43.72 shows the output based on the model specified in the MODEL statement. An intercept term is assumed. In the “Cointegration Rank Test Using Trace” table, the column Drift in ECM indicates that there is no separate drift in the error correction model, and the column Drift in Process indicates that the process has a constant drift before differencing. The “Cointegration Rank Test Using Trace” table shows the trace statistics and $p$-values based on Case 3, and the “Cointegration Rank Test Using Trace under Restriction” table shows the trace statistics and $p$-values based on Case 2. For a specified significance level, such as 5%, the output indicates that the null hypothesis that the series are not cointegrated (H0: Rank = 0) can be rejected, because the $p$-values for both Case 2 and Case 3 are less than 0.05. The output also shows that the null hypothesis that the series are cointegrated with rank 1 (H0: Rank = 1) cannot be rejected for either Case 2 or Case 3, because the $p$-values for these tests are both greater than 0.05.
Figure 43.72  Cointegration Rank Test (COINTTEST=(JOHANSEN=) Option)

Figure 43.73 shows which result, either Case 2 (the hypothesis H0) or Case 3 (the hypothesis H1), is appropriate depending on the significance level. Since the cointegration rank is chosen to be 1 by the result in Figure 43.72, look at the last row that corresponds to rank=1. Since the *p*-value is 0.054, the Case 2 cannot be rejected at the significance level 5%, but it can be rejected at the significance level 10%. For modeling of the two Case 2 and Case 3, see Figure 43.76 and Figure 43.77.

</tbody>
</table>
Using the NORMALIZE= option, the first row of the “Beta” table has 1. Considering that the cointegration rank is 1, the long-run relationship of the series is

\[
\begin{align*}
\beta^\prime y_t &= \left[ \begin{array}{c} 1 \\ -2.04869 \end{array} \right]
\begin{bmatrix}
y_1 \\
y_2 \\
\end{bmatrix} \\
&= y_{1t} - 2.04869y_{2t} \\
y_{1t} &= 2.04869y_{2t}
\end{align*}
\]

Figure 43.75 shows the estimates of long-run parameter (Beta) and adjustment coefficients (Alpha) based on Case 2.

<table>
<thead>
<tr>

<tr>
<td>y1</td>
</tr>
<tr>
<td>y2</td>
</tr>
</tbody>
</table>

Considering that the cointegration rank is 1, the long-run relationship of the series is

\[
\begin{align*}
\beta^\prime y_t &= \left[ \begin{array}{c} 1 \\ -2.04366 \\ 6.75919 \end{array} \right]
\begin{bmatrix}
y_1 \\
y_2 \\
1 \\
\end{bmatrix} \\
&= y_{1t} - 2.04366y_{2t} + 6.75919 \\
y_{1t} &= 2.04366y_{2t} - 6.75919
\end{align*}
\]

**Estimation of Vector Error Correction Model**

The preceding log-likelihood function is maximized for

\[
\begin{align*}
\hat{\beta} &= S_{11}^{-1/2}[v_1, \ldots, v_r] \\
\hat{\alpha} &= S_{01}\hat{\beta}(\hat{\beta}'S_{11}\hat{\beta})^{-1} \\
\hat{\Gamma} &= \hat{\alpha}\hat{\beta}' \\
\hat{\Psi}' &= (Z_2'Z_2)^{-1}Z_2'(Z_0 - Z_1\hat{\Gamma}') \\
\hat{\Sigma} &= (Z_0 - Z_2\hat{\Psi}' - Z_1\hat{\Gamma}')'(Z_0 - Z_2\hat{\Psi}' - Z_1\hat{\Gamma}')/T
\end{align*}
\]

The estimators of the orthogonal complements of \(\alpha\) and \(\beta\) are

\[
\hat{\beta}_{\perp} = S_{11}[v_{r+1}, \ldots, v_k]
\]
and
\[ \hat{\alpha}_\perp = S_{00}^{-1} S_{01} [v_r+1, \ldots, v_k] \]

Let \( \theta \) denote the parameter vector \( (\text{vec}(\alpha, \Psi)', \text{vech}(\Sigma)'')' \). The covariance of parameter estimates \( \hat{\theta} \) is obtained as the inverse of the negative Hessian matrix \( H = \frac{\partial^2 F}{\partial \theta \partial \theta'} \). Because \( \hat{\Pi} = \hat{\alpha} \hat{\beta}' \), the variance of \( \hat{\Pi} \) and the covariance between \( \hat{\Pi} \) and \( \hat{\theta} \) are calculated as follows:

\[
cov(\text{vec}(\hat{\Pi}), \text{vec}(\hat{\Pi})) = (\hat{\beta} \otimes I_k) \text{cov}(\text{vec}(\hat{\alpha}), \text{vec}(\hat{\alpha}))(\hat{\beta} \otimes I_k)'
\]
\[
cov(\text{vec}(\hat{\Pi}), \hat{\theta}) = (\hat{\beta} \otimes I_k) \text{cov}(\text{vec}(\hat{\alpha}), \hat{\theta})
\]

For Case 2 (Case 4), because the coefficient vector \( \hat{\delta}_0 (\hat{\delta}_1) \) for the constant term (the linear trend term) is the product of \( \hat{\alpha} \) and \( \hat{\beta}_0 (\hat{\beta}_1) \), the variance of \( \hat{\delta}_0 (\hat{\delta}_1) \) and the covariance between \( \hat{\delta}_0 (\hat{\delta}_1) \) and \( \hat{\theta} \) are calculated as follows:

\[
cov(\hat{\delta}_i, \hat{\delta}_i) = (\hat{\beta}_i' \otimes I_k) \text{cov}(\text{vec}(\hat{\alpha}), \text{vec}(\hat{\alpha}))(\hat{\beta}_i' \otimes I_k)', \ i = 0 \text{ or } 1
\]
\[
cov(\hat{\delta}_i, \hat{\theta}) = (\hat{\beta}_i' \otimes I_k) \text{cov}(\text{vec}(\hat{\alpha}), \hat{\theta}), \ i = 0 \text{ or } 1
\]

The following statements are examples of fitting the five different cases of the vector error correction models mentioned in the previous section.

For fitting Case 1,

```
model y1 y2 / p=2 noint;
cointeg rank=1 normalize=y1;
```

For fitting Case 2,

```
model y1 y2 / p=2;
cointeg rank=1 normalize=y1 ectrend;
```

For fitting Case 3,

```
model y1 y2 / p=2;
cointeg rank=1 normalize=y1;
```

For fitting Case 4,

```
model y1 y2 / p=2 trend=linear;
cointeg rank=1 normalize=y1 ectrend;
```

For fitting Case 5,

```
model y1 y2 / p=2 trend=linear;
cointeg rank=1 normalize=y1;
```

In the previous example, the output from the COINTTEST=(JOHANSEN) option shown in Figure 43.73 indicates that you can fit the model by using either Case 2 or Case 3 because the test of the restriction was not significant at the 0.05 level, but was significant at the 0.10 level. Following both models are fit to show the differences in the displayed output. Figure 43.76 is for Case 2, and Figure 43.77 is for Case 3.
For Case 2,

```
proc varmax data=simul2;
    model y1 y2 / p=2 print=(estimates);
    cointeg rank=1 normalize=y1 ectrend;
run;
```

Figure 43.77 can be reported as follows:

$$\Delta y_t = \begin{bmatrix} -0.46421 & 0.95103 \\ 0.17535 & -0.35923 \end{bmatrix} y_{t-1} + \begin{bmatrix} -0.74052 \\ 0.34820 \end{bmatrix} \Delta y_{t-1} + \begin{bmatrix} -2.60825 \\ 3.43005 \end{bmatrix} + \epsilon_t$$

**A Test for the Long-Run Relations**

Consider the example with the variables $m_t$ log real money, $y_t$ log real income, $i_t^d$ deposit interest rate, and $i_t^b$ bond interest rate. It seems a natural hypothesis that in the long-run relation, money and income have equal coefficients with opposite signs. This can be formulated as the hypothesis that the cointegrated relation contains only $m_t$ and $y_t$ through $m_t - y_t$. For the analysis, you can express these restrictions in the
parameterization of $H$ such that $\beta = H\phi$, where $H$ is a known $k \times s$ matrix and $\psi$ is the $s \times r (r \leq s < k)$ parameter matrix to be estimated. For this example, $H$ is given by

$$
H = \begin{bmatrix}
1 & 0 & 0 \\
-1 & 0 & 0 \\
0 & 1 & 0 \\
0 & 0 & 1
\end{bmatrix}
$$

**Restriction $H_0$: $\beta = H\phi$**

When the linear restriction $\beta = H\phi$ is given, it implies that the same restrictions are imposed on all cointegrating vectors. You obtain the maximum likelihood estimator of $\beta$ by reduced rank regression of $\Delta y_t$ on $H y_{t-1}$ corrected for $(\Delta y_{t-1}, \ldots, \Delta y_{t-p+1}, D_t)$, solving the following equation,

$$
|\rho H'S_{11}H - H'S_{10}S_{00}^{-1}S_{01}H| = 0
$$

for the eigenvalues $1 > \rho_1 > \cdots > \rho_s > 0$ and eigenvectors $(v_1, \ldots, v_s)$. $S_{ij}$ given in the preceding section. Then choose $\hat{\phi} = (v_1, \ldots, v_r)$ that corresponds to the $r$ largest eigenvalues, and the $\hat{\beta}$ is $H \hat{\phi}$.

The test statistic for $H_0$: $\beta = H\phi$ is given by

$$
T \sum_{i=1}^{r} \log \{(1 - \rho_i)/(1 - \lambda_i)\} \overset{d}{\rightarrow} \chi^2_{r(k-s)}
$$

If the series has no deterministic trend, the constant term should be restricted by $a' \delta = 0$ as in Case 2. Then $H$ is given by

$$
H = \begin{bmatrix}
1 & 0 & 0 & 0 \\
-1 & 0 & 0 & 0 \\
0 & 1 & 0 & 0 \\
0 & 0 & 1 & 0 \\
0 & 0 & 0 & 1
\end{bmatrix}
$$

The following statements test that $2 \beta_1 + \beta_2 = 0$:

```plaintext
proc varmax data=simul2;
    model y1 y2 / p=2;
    cointeg rank=1 h=(1,-2) normalize=y1;
run;
```

Figure 43.78 shows the results of testing $H_0: 2\beta_1 + \beta_2 = 0$. The input $H$ matrix is $H = (1 - 2)'$. The adjustment coefficient is reestimated under the restriction, and the test indicates that you cannot reject the null hypothesis.
Test for the Weak Exogeneity and Restrictions of Alpha

Consider a vector error correction model:

\[ \Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + AD_t + \epsilon_t \]

Divide the process \( y_t \) into \((y'_1, y'_2)'\) with dimension \( k_1 \) and \( k_2 \) and the \( \Sigma \) into

\[ \Sigma = \begin{bmatrix} \Sigma_{11} & \Sigma_{12} \\ \Sigma_{21} & \Sigma_{22} \end{bmatrix} \]

Similarly, the parameters can be decomposed as follows:

\[ \alpha = \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix}, \quad \Phi_i^* = \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix}, \quad A = \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} \]

Then the VECM(\( p \)) form can be rewritten by using the decomposed parameters and processes:

\[ \begin{bmatrix} \Delta y_{1t} \\ \Delta y_{2t} \end{bmatrix} = \begin{bmatrix} \alpha_1 \\ \alpha_2 \end{bmatrix} \beta' y_{t-1} + \sum_{i=1}^{p-1} \begin{bmatrix} \Phi_{1i}^* \\ \Phi_{2i}^* \end{bmatrix} \Delta y_{t-i} + \begin{bmatrix} A_1 \\ A_2 \end{bmatrix} D_t + \begin{bmatrix} \epsilon_{1t} \\ \epsilon_{2t} \end{bmatrix} \]

The conditional model for \( y_{1t} \) given \( y_{2t} \) is

\[ \Delta y_{1t} = \omega \Delta y_{2t} + (\alpha_1 - \omega \alpha_2) \beta' y_{t-1} + \sum_{i=1}^{p-1} (\Phi_{1i}^* - \omega \Phi_{2i}^*) \Delta y_{t-i} \\
+ (A_1 - \omega A_2) D_t + \epsilon_{1t} - \omega \epsilon_{2t} \]
and the marginal model of $y_{2t}$ is

$$\Delta y_{2t} = \alpha_2 \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_{2i}^* \Delta y_{t-i} + A_2 D_t + \epsilon_{2t}$$

where $\omega = \Sigma_{12} \Sigma_{22}^{-1}$.

The test of weak exogeneity of $y_{2t}$ for the parameters $(\alpha_1, \beta)$ determines whether $\alpha_2 = 0$. Weak exogeneity means that there is no information about $\beta$ in the marginal model or that the variables $y_{2t}$ do not react to a disequilibrium.

**Restriction $H_0$: $\alpha = J \psi$**

Consider the null hypothesis $H_0: \alpha = J \psi$, where $J$ is a $k \times m$ matrix with $r \leq m < k$.

From the previous residual regression equation

$$R_{0t} = \alpha \beta' R_{1t} + \hat{\epsilon}_t = J \psi \beta' R_{1t} + \hat{\epsilon}_t$$

you can obtain

$$\tilde{J}' R_{0t} = \psi \beta' R_{1t} + \tilde{J}' \hat{\epsilon}_t$$

$$J'_\perp R_{0t} = J'_\perp \hat{\epsilon}_t$$

where $\tilde{J} = J(J' J)^{-1}$ and $J'_\perp$ is orthogonal to $J$ such that $J'_\perp J = 0$.

Define

$$\Sigma_{J J'_\perp} = \tilde{J}' \Sigma J'_\perp \quad \text{and} \quad \Sigma_{J'_\perp J'_\perp} = J'_\perp \Sigma J'_\perp$$

and let $\omega = \Sigma_{J J'_\perp} \Sigma_{J'_\perp J'_\perp}^{-1}$. Then $\tilde{J}' R_{0t}$ can be written as

$$\tilde{J}' R_{0t} = \psi \beta' R_{1t} + \omega J'_\perp R_{0t} + \tilde{J}' \hat{\epsilon}_t - \omega J'_\perp \hat{\epsilon}_t$$

Using the marginal distribution of $J'_\perp R_{0t}$ and the conditional distribution of $\tilde{J}' R_{0t}$, the new residuals are computed as

$$\tilde{R}_{J t} = \tilde{J}' R_{0t} - S_{J J'_\perp} S^{-1}_{J'_\perp J'_\perp} J'_\perp R_{0t}$$

$$\tilde{R}_{1t} = R_{1t} - S_{J'_\perp J'_\perp} S^{-1}_{J'_\perp J'_\perp} J'_\perp R_{0t}$$

where

$$S_{J J'_\perp} = \tilde{J}' S_{00} J'_\perp, \quad S_{J'_\perp J'_\perp} = J'_\perp S_{00} J'_\perp, \quad \text{and} \quad S_{J'_\perp 01} = J'_\perp S_{01}$$

In terms of $\tilde{R}_{J t}$ and $\tilde{R}_{1t}$, the MLE of $\beta$ is computed by using the reduced rank regression. Let

$$S_{i j, J'_\perp} = \frac{1}{T} \sum_{t=1}^{T} \tilde{R}_{i t} \tilde{R}_{j t}' \text{ for } i, j = 1, J$$
Under the null hypothesis $H_0: \alpha = J\psi$, the MLE $\tilde{\beta}$ is computed by solving the equation

$$|\rho S_{11,J\perp} - S_{1J,J\perp} S_{J,J\perp}^{-1} S_{J1,J\perp}| = 0$$

Then $\tilde{\beta} = (v_1, \ldots, v_r)$, where the eigenvectors correspond to the $r$ largest eigenvalues and are normalized such that $\tilde{\beta}' S_{11,J\perp} \tilde{\beta} = I_r$; $\tilde{\alpha} = JS_{J1,J\perp} \tilde{\beta}$. The likelihood ratio test for $H_0: \alpha = J\psi$ is

$$T \sum_{i=1}^r \log\{(1 - \rho_i)/(1 - \lambda_i)\} \xrightarrow{d} \chi^2_r(k-m)$$

For more information, see Theorem 6.1 in Johansen and Juselius (1990).

The test of weak exogeneity of $y_{2t}$ is a special case of the test $\alpha = J\psi$, considering $J = (I_{k1}, 0)'$. Consider the previous example with four variables ($m_t, y_t, i^b_t, i^d_t$). If $r = 1$, you formulate the weak exogeneity of $(y_t, i^b_t, i^d_t)$ for $m_t$ as $J = [0, I_3]'$ and the weak exogeneity of $i^d_t$ for $(m_t, y_t, i^b_t)$ as $J = [I_3, 0]'$.

The following statements test the weak exogeneity of other variables, assuming $r = 1$:

```sas
proc varmax data=simul2;
  model y1 y2 / p=2;
  cointeg rank=1 exogeneity normalize=y1;
run;
```

Figure 43.79 shows that each variable is not the weak exogeneity of other variable.

**General Tests and Restrictions on Parameters**

The previous sections discuss some special forms of tests on $\beta$ and $\alpha$, namely the long-run relations that are expressed in the form $H_0: \beta = H\phi$, the weak exogeneity test, and the null hypotheses on $\alpha$ in the form $H_0: \alpha = J\psi$. In fact, with the help of the RESRICT and BOUND statements, you can estimate the models that have linear restrictions on any parameters to be estimated, which means that you can implement the likelihood ratio (LR) test for any linear relationship between the parameters.

The restricted error correction model must be estimated through numerical optimization. You might need to use the NLOPTIIONS statement to try different options for the optimizer and the INITIAL statement to try different starting points. This is essentially important because the $\alpha$ and $\beta$ are usually not identifiable.

You can also use the TEST statement to apply the Wald test for any linear relationships between parameters that are not long-run. Even more, you can test the constraints on $\Pi (= \alpha\beta')$ and $\delta_0 (= \alpha\beta_0)$ in Case 2 or $\delta_1 (= \alpha\beta_1)$ in Case 4 when the constant term or linear trend is restricted to the error correction term.
For more information and examples, see the section “Example 43.3: Analysis of Restricted Cointegrated Systems” on page 3189.

**Forecasting of the VECM**

Consider the cointegrated moving-average representation of the differenced process of $y_t$

$$\Delta y_t = \delta + \Psi(B)\epsilon_t$$

Assume that $y_0 = 0$. The linear process $y_t$ can be written as

$$y_t = \delta t + \sum_{i=1}^{t} \sum_{j=0}^{t-i} \Psi_j \epsilon_i$$

Therefore, for any $l > 0$,

$$y_{t+l} = \delta(t + l) + \sum_{i=1}^{t} \sum_{j=0}^{t+l-i} \Psi_j \epsilon_i + \sum_{i=1}^{l} \sum_{j=0}^{l-i} \Psi_j \epsilon_{t+i}$$

The $l$-step-ahead forecast is derived from the preceding equation:

$$y_{t+l|t} = (t + l) + \sum_{i=1}^{t} \sum_{j=0}^{t+l-i} \Psi_j \epsilon_i$$

Note that

$$\lim_{l \to \infty} \beta' y_{t+l|t} = 0$$

since $\lim_{l \to \infty} \sum_{j=0}^{t+l-i} \Psi_j = \Psi(1)$ and $\beta'\Psi(1) = 0$. The long-run forecast of the cointegrated system shows that the cointegrated relationship holds, although there might exist some deviations from the equilibrium status in the short-run. The covariance matrix of the predict error $e_{t+l|t} = y_{t+l} - y_{t+l|t}$ is

$$\Sigma(l) = \sum_{i=1}^{l} \sum_{j=0}^{l-i} \Psi_j \Sigma(\sum_{j=0}^{l-i} \Psi_j')$$

When the linear process is represented as a VECM($p$) model, you can obtain

$$\Delta y_t = \Pi y_{t-1} + \sum_{j=1}^{p-1} \Phi_j^* \Delta y_{t-j} + \delta + \epsilon_t$$

The transition equation is defined as

$$z_t = Fz_{t-1} + e_t$$
where \(z_t = (y'_{t-1}, \Delta y'_t, \Delta y'_{t-1}, \ldots, \Delta y'_{t-p+2})'\) is a state vector and the transition matrix is

\[
F = \begin{bmatrix}
I_k & I_k & 0 & \cdots & 0 \\
\Pi & (\Pi + \Phi_1^*) & \Phi_2^* & \cdots & \Phi_{p-1}^* \\
0 & I_k & 0 & \cdots & 0 \\
\vdots & \vdots & \vdots & \ddots & \vdots \\
0 & 0 & \cdots & I_k & 0
\end{bmatrix}
\]

where 0 is a \(k \times k\) zero matrix. The observation equation can be written

\[y_t = \delta t + Hz_t\]

where \(H = [I_k, I_k, 0, \ldots, 0]\).

The \(l\)-step-ahead forecast is computed as

\[y_{t+l|t} = \delta(t + l) + HF^l z_t\]

### Cointegration with Exogenous Variables

The error correction model with exogenous variables can be written as follows:

\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]

The following statements demonstrate how to fit VECMX\((p,s)\), where \(p = 2\) and \(s = 1\) from the P=2 and XLAG=1 options:

```plaintext
proc varmax data=simul3;
    model y1 y2 = x1 / p=2 xlag=1;
    cointeg rank=1;
run;
```

The following statements demonstrate how to BVECMX\((2,1)\):

```plaintext
proc varmax data=simul3;
    model y1 y2 = x1 / p=2 xlag=1
    prior=(lambda=0.9 theta=0.1);
    cointeg rank=1;
run;
```

### I(2) Model

The VARX\((p,s)\) model can be written in the error correction form:

\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta_i^* x_{t-i} + \epsilon_t
\]
Let $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$. If $\alpha$ and $\beta$ have full-rank $r$, and $\text{rank}(\alpha' \Phi^* \beta') = k - r$, then $y_t$ is an $I(1)$ process.

If the condition $\text{rank}(\alpha' \Phi^* \beta') = k - r$ fails and $\alpha' \Phi^* \beta'$ has reduced-rank $\alpha' \Phi^* \beta' = \xi \eta'$ where $\xi$ and $\eta$ are $(k - r) \times s$ matrices with $s \leq k - r$, then $\alpha_\perp$ and $\beta_\perp$ are defined as $k \times (k - r)$ matrices of full rank such that $\alpha' \alpha_\perp = 0$ and $\beta' \beta_\perp = 0$.

If $\xi$ and $\eta$ have full-rank $s$, then the process $y_t$ is $I(2)$, which has the implication of $I(2)$ model for the moving-average representation.

$$y_t = B_0 + B_1 t + C_2 \sum_{j=1}^{t} \sum_{i=1}^{j} \epsilon_i + C_1 \sum_{i=1}^{t} \epsilon_i + C_0(B) \epsilon_t$$

The matrices $C_1$, $C_2$, and $C_0(B)$ are determined by the cointegration properties of the process, and $B_0$ and $B_1$ are determined by the initial values. For more information, see Johansen (1995b).

The implication of the $I(2)$ model for the autoregressive representation is given by

$$\Delta^2 y_t = \Pi y_{t-1} - \Phi^* \Delta y_{t-1} + \sum_{i=1}^{p-2} \Psi_i \Delta^2 y_{t-i} + AD_t + \sum_{i=0}^{s} \Theta_i \epsilon_{t-i} + \epsilon_t$$

where $\Psi_i = -\sum_{j=i+1}^{p-1} \Phi_i^*$ and $\Phi^* = I_k - \sum_{i=1}^{p-1} \Phi_i^*$.

**Test for I(2)**

The $I(2)$ cointegrated model is given by the following parameter restrictions:

$$H_{r,s}; \Pi = \alpha \beta' \text{ and } \alpha_\perp \Phi^* \beta_\perp = \xi \eta'$$

where $\xi$ and $\eta$ are $(k - r) \times s$ matrices with $0 \leq s \leq k - r$. Let $H_0^0$ represent the $I(1)$ model where $\alpha$ and $\beta$ have full-rank $r$, let $H_0^0$ represent the $I(2)$ model where $\xi$ and $\eta$ have full-rank $s$, and let $H_{r,s}$ represent the $I(2)$ model where $\xi$ and $\eta$ have rank $\leq s$. Table 43.6 shows the relation between the $I(1)$ models and the $I(2)$ models.

Johansen (1995b) proposed the two-step procedure to analyze the $I(2)$ model. In the first step, the values of $(r, \alpha, \beta)$ are estimated using the reduced rank regression analysis, performing the regression analysis $\Delta^2 y_t$.
\( \Delta y_{t-1}, \) and \( y_{t-1} \) on \( \Delta^2 y_{t-1}, \ldots, \Delta^2 y_{t-p+2}, \) and \( D_t. \) This gives residuals \( R_0t, R_1t, \) and \( R_2t, \) and residual product moment matrices

\[
M_{ij} = \frac{1}{T} \sum_{t=1}^{T} R_{it} R'_{jt} \quad \text{for} \quad i, j = 0, 1, 2
\]

Perform the reduced rank regression analysis \( \Delta^2 y_t \) on \( y_{t-1} \) corrected for \( \Delta y_{t-1}, \Delta^2 y_{t-1}, \ldots, \Delta^2 y_{t-p+2}, \) and \( D_t, \) and solve the eigenvalue problem of the equation

\[
|\lambda M_{22.1} - M_{20.1} M^{-1}_{00.1} M_{02.1}| = 0
\]

where \( M_{ij,1} = M_{ij} - M_{i1} M^{-1}_{11} M_{1j} \) for \( i, j = 0, 2. \)

In the second step, if \((r, \alpha, \beta)\) are known, the values of \((s, \xi, \eta)\) are determined using the reduced rank regression analysis, regressing \( \hat{\alpha}' \Delta^2 y_t \) on \( \hat{\beta}' \Delta y_{t-1} \) corrected for \( \Delta^2 y_{t-1}, \ldots, \Delta^2 y_{t-p+2}, D_t, \) and \( \beta' \Delta y_{t-1}. \)

The reduced rank regression analysis reduces to the solution of an eigenvalue problem for the equation

\[
|\rho M_{\beta' \beta} - M_{\beta' \alpha} M^{-1}_{\alpha' \alpha} M_{\alpha' \beta}| = 0
\]

where

\[
M_{\beta' \beta} = \beta' (M_{11} - M_{11} \beta' M_{11} \beta) M_{\alpha' \alpha}^{-1} \beta M_{11} \beta \quad \text{and} \quad M_{\alpha' \beta} = \alpha' (M_{01} - M_{01} \beta' M_{11} \beta) M_{\alpha' \beta} \quad \text{and} \quad M_{\alpha' \alpha}^{-1} \beta M_{10} \alpha \quad \text{and} \quad M_{\alpha' \beta} = \alpha' (M_{00} - M_{01} \beta' M_{11} \beta) M_{\alpha' \beta} \quad \text{and} \quad M_{\alpha' \alpha}^{-1} \beta M_{10} \alpha
\]

where \( \hat{\alpha} = (\alpha' \alpha)^{-1}. \)

The solution gives eigenvalues \( 1 > \rho_1 > \cdots > \rho_s > 0 \) and eigenvectors \((v_1, \ldots, v_s).\) Then, the ML estimators are

\[
\hat{\eta} = (v_1, \ldots, v_s) \quad \text{and} \quad \hat{\xi} = M_{\alpha' \beta} \hat{\eta}
\]

The likelihood ratio test for the reduced rank model \( H_{r,s} \) with rank \( \leq s \) in the model \( H_{r,k-r} = H_r^0 \) is given by

\[
Q_{r,s} = -T \sum_{i=s+1}^{k-r} \log(1 - \rho_i), \quad s = 0, \ldots, k - r - 1
\]

The following statements simulate an I(2) process and compute the rank test to test for cointegrated order 2:

```plaintext
proc iml;
  alpha = { 1, 1 };  * alphaOrthogonal = { 1, -1 };  
  beta = { 1, -0.5 };  * betaOrthogonal = { 1, 2 };  
  * alphaOrthogonal' * phiStar * betaOrthogonal = 0;  
  phiStar = { 1 0, 0 0.5 };  
  A1 = 2 * I(2) + alpha * beta - phiStar;
```
A2 = phiStar - I(2);
phi = A1 // A2;
sig = I(2);
/* to simulate the vector time series */
call varmasim(y,phi) sigma=sig n=200 seed=2;
cn = {'y1' 'y2'};
create simul4 from y[colname=cn];
append from y;
close;
quit;

proc varmax data=simul4;
  model y1 y2 /noint p=2 cointtest=(johansen=(iorder=2));
run;

The last two columns in Figure 43.80 explain the cointegration rank test with integrated order 1. For a specified significance level, such as 5%, the output indicates that the null hypothesis that the series are not cointegrated (H0: r = 0) is rejected, because the p-value for this test, shown in the column Pr > Trace of I(1), is less than 0.05. The results also indicate that the null hypothesis that there is a cointegrated relationship with cointegration rank 1 (H0: r = 1) cannot be rejected at the 5% significance level, because the p-value for the test statistic, 0.7961, is greater than 0.05. Because of this latter result, the rows in the table that are associated with r = 1 are further examined. The test statistic, 0.0257, tests the null hypothesis that the series are cointegrated order 2. The p-value that is associated with this test is 0.8955, which indicates that the null hypothesis cannot be rejected at the 5% significance level.

**Vector Error Correction Model in ARMA Form**

The vector error correction model in ARMA form (the VEC-ARMA model) introduces MA terms and is defined as follows:

\[
\Delta y_t = \alpha \beta' y_{t-1} + \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \epsilon_t - \sum_{i=1}^{q} \Theta_i \epsilon_{t-i}
\]

The determined terms and the exogenous variables can also be introduced into the model. Similar to the VECM that has only AR terms, the constant term is constrained in the error correction term in Case 2 and the linear trend term is similarly constrained in Case 4.

The model is estimated through the maximum likelihood method. The log likelihood of the model is defined as
\[ \ell = -\frac{T}{2} \log |\Sigma| - \frac{1}{2} T \sum_{t=1}^{T} e_t^\prime \Sigma^{-1} e_t \]

where

\[ e_t = \Delta y_t - \alpha \beta^\prime y_{t-1} - \sum_{i=1}^{p-1} \Phi_i^* \Delta y_{t-i} + \sum_{i=1}^{q} \Theta_i e_{t-i} \]

conditional on the presample \( \{y_0, \ldots, y_{1-p}\} \), and \( e_s = 0, s \leq 0 \).

You can specify a VEC-ARMA(2,1) model with cointegration rank 2 on the three-dimensional time series by the following statements:

```plaintext
model y1-y3 / p=2 q=1;
cointeg rank=2;
```

For more information about modeling the cointegrated VARMA processes, see Lütkepohl (2007, Chapter 14).

---

**Multivariate GARCH Modeling**

Stochastic volatility modeling is important in many areas, particularly in finance. To study the volatility of time series, GARCH models are widely used because they provide a good approach to conditional variance modeling.

**BEKK Representation**

Engle and Kroner (1995) propose a general multivariate GARCH model and call it a BEKK representation. Let \( \mathcal{F}(t-1) \) be the sigma field generated by the past values of \( \epsilon_t \), and let \( H_t \) be the conditional covariance matrix of the \( k \)-dimensional random vector \( \epsilon_t \). Let \( H_t \) be measurable with respect to \( \mathcal{F}(t-1) \); then the multivariate GARCH model can be written as

\[ \epsilon_t | \mathcal{F}(t-1) \sim N(0, H_t) \]

\[ H_t = C + \sum_{i=1}^{q} A_i' \epsilon_{t-i} \epsilon_{t-i}^\prime A_i + \sum_{i=1}^{p} G_i' H_{t-i} G_i \]

where \( C, A_i, \) and \( G_i \) are \( k \times k \) parameter matrices.

Consider the bivariate GARCH(1,1) model

\[ H_t = \begin{bmatrix} c_{11} & c_{12} \\ c_{12} & c_{22} \end{bmatrix} + \begin{bmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{bmatrix} \begin{bmatrix} \epsilon_{1,t-1}^2 & \epsilon_{1,t-1} \epsilon_{2,t-1} \\ \epsilon_{2,t-1} \epsilon_{1,t-1} & \epsilon_{2,t-1}^2 \end{bmatrix} \begin{bmatrix} \alpha_{11} & \alpha_{12} \\ \alpha_{21} & \alpha_{22} \end{bmatrix} + \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix} H_{t-1} \begin{bmatrix} g_{11} & g_{12} \\ g_{21} & g_{22} \end{bmatrix} \]

or, representing the univariate model,
For the BEKK representation of the bivariate GARCH(1,1) model, the SAS statements are

```sas
model y1 y2;
garch q=1 p=1 form=bekk;
```

The multistep forecast of the conditional covariance matrix, \( \mathbf{H}_{t+h|t} \), \( h = 1, 2, \ldots \), is obtained recursively through the formula

\[
\mathbf{H}_{t+h|t} = \mathbf{C} + \sum_{i=1}^{h-1} \mathbf{A}_i \mathbf{H}_{t+h-i|t} \mathbf{A}_i^\prime + \sum_{i=h}^{q} \mathbf{A}_i \mathbf{\epsilon}_{t+h-i} \mathbf{\epsilon}_{t+h-i}^\prime \mathbf{A}_i + \sum_{i=1}^{p} \mathbf{G}_i \mathbf{H}_{t+h-i|t} \mathbf{G}_i^\prime
\]

where \( \mathbf{H}_{s|t} = \mathbf{H}_s \) for \( s \leq t \).

### CCC Representation

Bollerslev (1990) proposes a multivariate GARCH model with time-varying conditional variances and covariances but constant conditional correlations.

The conditional covariance matrix \( \mathbf{H}_t \) consists of

\[
\mathbf{H}_t = \mathbf{D}_t \mathbf{S} \mathbf{D}_t
\]

where \( \mathbf{D}_t \) is a \( k \times k \) stochastic diagonal matrix with element \( \sigma_{i,t} \) and \( \mathbf{S} \) is a \( k \times k \) time-invariant correlation matrix with the typical element \( s_{ij} \).

The element of \( \mathbf{H}_t \) is

\[
h_{ij,t} = s_{ij} \sigma_{i,t} \sigma_{j,t} \quad i, j = 1, \ldots, k
\]

Note that \( h_{ii,t} = \sigma_{i,t}^2, i = 1, \ldots, k \).

If you specify CORRCONSTANT=EXPECT, the element \( s_{ij} \) of the time-invariant correlation matrix \( \mathbf{S} \) is

\[
s_{ij} = \frac{1}{T} \sum_{t=1}^{T} \frac{\mathbf{\epsilon}_{i,t}}{\sqrt{h_{ii,t}}} \frac{\mathbf{\epsilon}_{j,t}}{\sqrt{h_{jj,t}}}
\]

where \( T \) is the sample size.
By default, or when you specify SUBFORM=GARCH, $\sigma_{i,t}^2$ follows a univariate GARCH process,

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^{q} a_{ii,l} \epsilon_{i,t-l}^2 + \sum_{l=1}^{p} g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \ldots, k$$

As shown in many empirical studies, positive and negative innovations have different impacts on future volatility. There is a long list of variations of univariate GARCH models that consider the asymmetry. Four typical variations follow:

- exponential GARCH (EGARCH) model (Nelson and Cao 1992)
- quadratic GARCH (QGARCH) model (Engle and Ng 1993)
- threshold GARCH (TGARCH) model (Glosten, Jaganathan, and Runkle 1993; Zakoian 1994)
- power GARCH (PGARCH) model (Ding, Granger, and Engle 1993)

For more information about the asymmetric GARCH models, see Engle and Ng (1993). You can choose the type of GARCH model of interest by specifying the SUBFORM= option.

The EGARCH model was proposed by Nelson (1991). Nelson and Cao (1992) argue that the nonnegativity constraints in the GARCH model are too restrictive. The GARCH model, implicitly or explicitly, imposes the nonnegative constraints on the parameters, whereas these parameters have no restrictions in the EGARCH model. In the EGARCH model, the conditional variance is an asymmetric function of lagged disturbances,

$$\ln(\sigma_{i,t}^2) = c_i + \sum_{l=1}^{q} a_{ii,l} \left( b_{ii,l} \frac{\epsilon_{i,t-l}}{\sigma_{i,t-l}} + |\epsilon_{i,t-l}| - \sqrt{\frac{2}{\pi}} \right) + \sum_{l=1}^{p} g_{ii,l} \ln(\sigma_{i,t-l}^2) \quad i = 1, \ldots, k$$

In the QGARCH model, the lagged errors’ centers are shifted from zero to some constant values,

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^{q} a_{ii,l} (\epsilon_{i,t-l} - b_{ii,l})^2 + \sum_{l=1}^{p} g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \ldots, k$$

In the TGARCH model, each lagged squared error has an extra slope coefficient,

$$\sigma_{i,t}^2 = c_i + \sum_{l=1}^{q} (a_{ii,l} + 1_{\epsilon_{i,t-l} < 0} b_{ii,l}) \epsilon_{i,t-l}^2 + \sum_{l=1}^{p} g_{ii,l} \sigma_{i,t-l}^2 \quad i = 1, \ldots, k$$

where the indicator function $1_{\epsilon_{i,t} < 0}$ is one if $\epsilon_{i,t} < 0$ and zero otherwise.
The PGARCH model not only considers the asymmetric effect but also provides a way to model the long memory property in the volatility,

$$\sigma_{i,t}^{2\lambda_i} = c_i + \sum_{l=1}^{q} a_{ii,l}((\epsilon_{i,t-l} - b_{i,i,l})^{2\lambda_i} + \sum_{l=1}^{p} g_{ii,l}\sigma_{i,t-l}^{2\lambda_i} i = 1, \ldots, k$$

where $\lambda_i > 0$ and $|b_{i,i,l}| \leq 1, l = 1, \ldots, q, i = 1, \ldots, k$.

Note that the implemented TGARCH model is also well known as GJR-GARCH (Glosten, Jagannathan, and Runkle 1993), which is similar to the threshold GARCH model proposed by Zakoian (1994) but not exactly the same. In Zakoian’s model, the conditional standard deviation is a linear function of the past values of the white noise. Zakoian’s model can be regarded as a special case of the PGARCH model when $\lambda_i = 1/2$.

The following formulas are recursively implemented to obtain the multistep forecast of conditional error variance $\sigma_{i,t+h\mid t}^{2}$, $i = 1, \ldots, k$ and $h = 1, 2, \ldots$:

- for the GARCH($p$, $q$) model:

$$\sigma_{i,t+h\mid t}^{2} = c_i + \sum_{l=1}^{h-1} a_{ii,l}\sigma_{i,t+h-l\mid t}^{2} + \sum_{l=h}^{q} a_{ii,l}\epsilon_{i,t+h-l\mid t}^{2} + \sum_{l=1}^{p} g_{ii,l}\sigma_{i,t+h-l\mid t}^{2}$$

- for the EGARCH($p$, $q$) model:

$$\ln(\sigma_{i,t+h\mid t}^{2}) = c_i + \sum_{l=h}^{q} a_{ii,l} \left( b_{i,i,l} \frac{\epsilon_{i,t+h-l\mid t}}{\sigma_{i,t+h-l\mid t}} + \frac{|\epsilon_{i,t+h-l\mid t}| - \sqrt{2/\pi}}{\sigma_{i,t+h-l\mid t}} \right) + \sum_{l=1}^{p} g_{ii,l}\ln(\sigma_{i,t+h-l\mid t}^{2})$$

- for the QGARCH($p$, $q$) model:

$$\sigma_{i,t+h\mid t}^{2} = c_i + \sum_{l=1}^{h-1} a_{ii,l}\left(\sigma_{i,t+h-l\mid t}^{2} + b_{i,i,l}^{2}\right) + \sum_{l=h}^{q} a_{ii,l}(\epsilon_{i,t+h-l\mid t} - b_{i,i,l})^{2} + \sum_{l=1}^{p} g_{ii,l}\sigma_{i,t+h-l\mid t}^{2}$$

- for the TGARCH($p$, $q$) model:

$$\sigma_{i,t+h\mid t}^{2} = c_i + \sum_{l=1}^{h-1} (a_{ii,l} + b_{i,i,l}/2)\sigma_{i,t+h-l\mid t}^{2} + \sum_{l=h}^{q} (a_{ii,l} + 1_{\epsilon_{i,t-l} < 0}b_{i,i,l})\epsilon_{i,t-l}^{2} + \sum_{l=1}^{p} g_{ii,l}\sigma_{i,t+h-l\mid t}^{2}$$
for the PGARCH\((p, q)\) model:

\[
\sigma_{i,t+h|t}^{2\lambda_i} = c_i + \sum_{l=1}^{h-1} a_{i,l} ((1 + b_{i,l})^{2\lambda_i} + (1 - b_{i,l})^{2\lambda_i}) \sigma_{i,t+h-l|t}/2
\]

\[+ \sum_{l=h}^{q} a_{i,l} (|\epsilon_{i,t-l}| - b_{i,l} \epsilon_{i,t-l})^{2\lambda_i} + \sum_{l=1}^{p} g_{i,l} \sigma_{i,t+h-1|t}^{2\lambda_i} \]

In the preceding equations, \(\sigma_{i,s|t} = \sigma_{i,s}\) for \(s \leq t\). Then, the multistep forecast of conditional covariance matrix \(H_{t+h|t}, h = 1, 2, \ldots\), is calculated by

\[H_{t+h|t} = D_{t+h|t} SD_{t+h|t}\]

where \(D_{t+h|t}\) is the diagonal matrix with element \(\sigma_{i,t+h|t}, i = 1, \ldots, k\).

**DCC Representation**

Engle (2002) proposes a parsimonious parametric multivariate GARCH model that has time-varying conditional covariances and correlations.

The conditional covariance matrix \(H_t\) consists of

\[H_t = D_t \Gamma_t D_t\]

where \(D_t\) is a \(k \times k\) stochastic diagonal matrix with the element \(\sigma_{i,t}\) and \(\Gamma_t\) is a \(k \times k\) time-varying matrix with the typical element \(\rho_{ij,t}\).

The element of \(H_t\) is

\[h_{ij,t} = \rho_{ij,t} \sigma_{i,t} \sigma_{j,t} \quad i, j = 1, \ldots, k\]

Note that \(h_{ii,t} = \sigma_{i,t}^2, i = 1, \ldots, k\).

As in the CCC GARCH model, you can choose the type of GARCH model of interest by specifying the `SUBFORM=` option.

In the GARCH model,

\[\sigma_{i,t}^2 = c_i + \sum_{l=1}^{q} a_{i,l} \epsilon_{i,t-l}^2 + \sum_{l=1}^{p} g_{i,l} \sigma_{i,t-l}^2 \quad i = 1, \ldots, k\]

In the EGARCH model, the conditional variance is an asymmetric function of lagged disturbances,

\[\ln(\sigma_{i,t}^2) = c_i + \sum_{l=1}^{q} a_{i,l} \left( b_{i,l} \epsilon_{i,t-l} + \frac{\epsilon_{i,t-l}}{\sigma_{i,t-l}} - \sqrt{\frac{2}{\pi}} \right) + \sum_{l=1}^{p} g_{i,l} \ln(\sigma_{i,t-l}^2) \quad i = 1, \ldots, k\]
In the QGARCH model, the lagged errors’ centers are shifted from zero to some constant values,

\[
\sigma^2_{i,t} = c_i + \sum_{l=1}^{q} a_{ii,l}(\epsilon_{i,t-l} - b_{ii,l})^2 + \sum_{l=1}^{p} g_{ii,l}\sigma^2_{i,t-l} \quad i = 1, \ldots, k
\]

In the TGARCH model, each lagged squared error has an extra slope coefficient,

\[
\sigma^2_{i,t} = c_i + \sum_{l=1}^{q} (a_{ii,l} + 1\epsilon_{i,t-l} < 0 b_{ii,l})\epsilon_{i,t-l}^2 + \sum_{l=1}^{p} g_{ii,l}\sigma^2_{i,t-l} \quad i = 1, \ldots, k
\]

where the indicator function \(1_{\epsilon_{i,t} < 0}\) is one if \(\epsilon_{i,t} < 0\) and zero otherwise.

The PGARCH model not only considers the asymmetric effect but also provides another way to model the long memory property in the volatility,

\[
\sigma^{2\lambda_i}_{i,t} = c_i + \sum_{l=1}^{q} a_{ii,l}(|\epsilon_{i,t-l}| - b_{ii,l}\epsilon_{i,t-l})^{2\lambda_i} + \sum_{l=1}^{p} g_{ii,l}\sigma^{2\lambda_i}_{i,t-l} \quad i = 1, \ldots, k
\]

where \(\lambda_i > 0\) and \(|b_{ii,l}| \leq 1\), \(l = 1, \ldots, q\); \(i = 1, \ldots, k\).

The conditional correlation estimator \(\rho_{ij,t}\) is

\[
\rho_{ij,t} = \frac{q_{ij,t}}{\sqrt{q_{ii,t}q_{jj,t}}} \quad i, j = 1, \ldots, k
\]

\[
q_{ij,t} = (1 - \alpha - \beta)s_{ij} + \alpha \frac{\epsilon_{i,t-1}}{\sigma_{i,t-1}} \frac{\epsilon_{j,t-1}}{\sigma_{j,t-1}} + \beta q_{ij,t-1}
\]

where \(s_{ij}\) is the element of \(S\), the unconditional correlation matrix.

If you specify \(\text{CORRCONSTANT=EXPECT}\), the element \(s_{ij}\) of the unconditional correlation matrix \(S\) is

\[
s_{ij} = \frac{1}{T} \sum_{t=1}^{T} \frac{\epsilon_{i,t} \epsilon_{j,t}}{\sigma_{i,t} \sigma_{j,t}}
\]

where \(T\) is the sample size.

As shown in the CCC GARCH models, the following formulas are recursively implemented to obtain the multistep forecast of conditional error variance \(\sigma^2_{i,t+h|t}\), \(i = 1, \ldots, k\) and \(h = 1, 2, \ldots\):

- for the GARCH\((p, q)\) model:

\[
\sigma^2_{i,t+h|t} = c_i + \sum_{l=1}^{h-1} a_{ii,l}\sigma^2_{i,t+h-l|t} + \sum_{l=h}^{q} a_{ii,l}\epsilon^2_{i,t+h-l} + \sum_{l=1}^{p} g_{ii,l}\sigma^2_{i,t+h-1|t}
\]
Multivariate GARCH Modeling

- for the EGARCH\((p, q)\) model:

\[
\ln(\sigma^2_{i,t+h|t}) = c_i + \sum_{l=h}^{q} a_{ii,l} \left( b_{i,l} \frac{\epsilon_{i,t+h-l}}{\sigma_{i,t+h-l}} + |\frac{\epsilon_{i,t+h-l}}{\sigma_{i,t+h-l}}| - \frac{2}{\pi} \right) + \sum_{l=1}^{p} g_{i,l} \ln(\sigma^2_{i,t+h-l|t})
\]

- for the QGARCH\((p, q)\) model:

\[
\sigma^2_{i,t+h|t} = c_i + \sum_{l=1}^{h-1} a_{ii,l} (\sigma^2_{i,t+h-l|t} + b_{i,l}^2) + \sum_{l=h}^{q} a_{ii,l} (\epsilon_{i,t+h-l} - b_{i,l})^2
\]

\[
+ \sum_{l=1}^{p} g_{i,l} \sigma^2_{i,t+h-1|t}
\]

- for the TGARCH\((p, q)\) model:

\[
\sigma^2_{i,t+h|t} = c_i + \sum_{l=1}^{h-1} a_{ii,l} (\epsilon_{i,t+h-l} + b_{i,l}/2)\sigma^2_{i,t+h-l|t} + \sum_{l=h}^{q} (a_{ii,l} + 1)\epsilon_{i,t+l-\alpha}b_{i,l}\epsilon_{i,t-l}^2
\]

\[
+ \sum_{l=1}^{p} g_{i,l} \sigma^2_{i,t+h-1|t}
\]

- for the PGARCH\((p, q)\) model:

\[
\sigma_{i,t+h|t}^{2\lambda_i} = c_i + \sum_{l=1}^{h-1} a_{ii,l} \left( (1 + b_{i,l})^{2\lambda_i} + (1 - b_{i,l})^{2\lambda_i} \right)\sigma_{i,t+h-l|t}^{2\lambda_i}
\]

\[
+ \sum_{l=h}^{q} a_{ii,l} (\epsilon_{i,t-l} - b_{i,l}\epsilon_{i,t-l})^{2\lambda_i} + \sum_{l=1}^{p} g_{i,l} \sigma_{i,t+h-1|t}^{2\lambda_i}
\]

In the preceding equations, \(\sigma_{i,s|t} = \sigma_{i,s} \) for \(s \leq t\). Then, the multistep forecast of conditional covariance matrix \(H_{t+h|t}, h = 1, 2, \ldots\), is calculated by

\[
H_{t+h|t} = D_{t+h|t}\Gamma_{t+h|t} D_{t+h|t}
\]

where \(D_{t+h|t}\) is the diagonal matrix with element \(\sigma_{i,t+h|t}, i = 1, \ldots, k\), and \(\Gamma_{t+h|t}\) is the matrix with element \(\rho_{ij,t+h|t}, i, j = 1, \ldots, k\),

\[
\rho_{ij,t+h|t} = \frac{q_{ij,t+h|t}}{\sqrt{q_{ii,t+h|t}q_{jj,t+h|t}}}
\]

\[
q_{ij,t+h|t} = \begin{cases}
(1 - \alpha - \beta)s_{ij} + \alpha \frac{\epsilon_{i,t} \epsilon_{j,t}}{\sigma_{i,t} \sigma_{j,t}} + \beta q_{ij,t} & h = 1 \\
(1 - \alpha - \beta)s_{ij} + \alpha q_{ij,t+h-1|t} + \beta q_{ij,t+h-1|t} & h > 1
\end{cases}
\]
Estimation of GARCH Model

The log-likelihood function of the multivariate GARCH model is written without a constant term as

\[ \ell = -\frac{1}{2} \sum_{t=1}^{T} [\log |H_t| + \epsilon_t' H_t^{-1} \epsilon_t] \]

where \( \epsilon_t \) is calculated from the first-moment model (that is, the VARMAX model or VEC-ARMA model). The log-likelihood function is maximized by an iterative numerical method such as quasi-Newton optimization. The starting values for the regression parameters are obtained from the least squares estimates. The covariance of \( \epsilon_t \) is used as the starting value for the GARCH constant parameters, and the starting values for the other GARCH parameters are either \( 10^{-6} \) or \( 10^{-3} \), depending on the GARCH model’s representation.

Prediction of Endogenous (Dependent) Variables

In multivariate GARCH models, the optimal (minimum MSE) \( l \)-step-ahead forecast of endogenous variables \( y_{t+l|t} \) uses the same formula as shown in the section “Forecasting” on page 3082. However, the exogenous (independent) variables, if present, are always assumed to be nonstochastic (deterministic); that is, to predict the endogenous variables, you must specify the future values of the exogenous variables. The prediction error of the optimal \( l \)-step-ahead forecast is \( \epsilon_{t+l|t} = y_{t+l} - y_{t+l|t} = \sum_{j=0}^{l-1} \Psi_j \epsilon_{t+l-j} \), with zero mean and covariance matrix,

\[ \Sigma(l) = \text{Cov}(\epsilon_{t+l|t}) = \sum_{j=0}^{l-1} \Psi_j H_{t+l-j|t} \Psi_j' \]

where \( H_{t+h|t} \), \( h = 1, \ldots, l \), is the \( h \)-step-ahead forecast of the conditional covariance matrix. As emphasized by the subscript \( t \), \( \Sigma(l) \) is time-dependent. In the OUT= data set, the forecast standard errors and prediction intervals are constructed according to \( \Sigma(l) \). If you specify the COVPE option, the prediction error covariances that are output in the CovPredictError and CovPredictErrorByVar ODS tables are based on the time-independent formula

\[ \Sigma(l) = \sum_{j=0}^{l-1} \Psi_j \Sigma \Psi_j' \]

where \( \Sigma \) is the unconditional covariance matrix of innovations. The decomposition of the prediction error covariances is also based on \( \Sigma(l) \).

Covariance Stationarity

Define the multivariate GARCH process as

\[ h_t = \sum_{i=1}^{\infty} G(B)^i \theta_i + A(B) \eta_t \]
where $h_t = \text{vec}(H_t)$, $c = \text{vec}(C_0)$, and $\eta_t = \text{vec}(\epsilon_t \epsilon_t')$. This representation is equivalent to a GARCH$(p, q)$ model by the following algebra:

\[
    h_t = c + A(B)\eta_t + \sum_{i=2}^{\infty} G(B)^{i-1}[c + A(B)\eta_t]
\]

\[
    = c + A(B)\eta_t + G(B) \sum_{i=1}^{\infty} G(B)^{i-1}[\eta_t]
\]

\[
    = c + A(B)\eta_t + G(B)h_t
\]

Defining $A(B) = \sum_{i=1}^{q} (A_i \otimes A_i)' B^i$ and $G(B) = \sum_{i=1}^{p} (G_i \otimes G_i)' B^i$ gives a BEKK representation.

The necessary and sufficient conditions for covariance stationarity of the multivariate GARCH process are that all the eigenvalues of $A(1) + G(1)$ are less than 1 in modulus.

### An Example of a VAR(1)–ARCH(1) Model

The following DATA step simulates a bivariate vector time series to provide test data for the multivariate GARCH model:

```r
data garch;
    retain seed 16587;
    esq1 = 0; esq2 = 0;
    ly1 = 0; ly2 = 0;
    do i = 1 to 1000;
        ht = 6.25 + 0.5*esq1;
        call rannor(seed,ehat);
        e1 = sqrt(ht)*ehat;
        ht = 1.25 + 0.7*esq2;
        call rannor(seed,ehat);
        e2 = sqrt(ht)*ehat;
        y1 = 2 + 1.2*ly1 - 0.5*ly2 + e1;
        y2 = 4 + 0.6*ly1 + 0.3*ly2 + e2;
        if i>500 then output;
        esq1 = e1*e1; esq2 = e2*e2;
        ly1 = y1; ly2 = y2;
    end;
    keep y1 y2;
run;
```

The following statements fit a VAR(1)–ARCH(1) model to the data. For a VAR-ARCH model, you specify the order of the autoregressive model with the P=1 option in the MODEL statement and the Q=1 option in the GARCH statement. In order to produce the initial and final values of parameters, the TECH=QN option is specified in the NLOPTIONS statement.

```r
proc varmax data=garch;
    model y1 y2 / p=1
        print=(roots estimates diagnose);
    garch q=1;
    nloptions tech=qn;
run;
```
Figure 43.81 through Figure 43.85 show the details of this example. Figure 43.81 shows the initial values of parameters.

**VARFIMA and VARFIMAX Modeling**

VAR and VARMA series are short-range dependent (SRD) in the sense that their autocovariance function dies out exponentially fast with the increasing lag. However, in many financial and macroeconomics applications, stationary yet persistent series arise, calling for models that have a slowly decaying autocovariance function and that are therefore more suitable to capture long-range dependence in the data.

The VARFIMA model captures both long-range and short-range dependence dynamics in a multivariate series. For a $k$-dimensional series $y_t = (y_{1t}, \ldots, y_{kt})'$, $t = 1, \ldots, T$, the VARFIMA($p, D, q$) model is defined as

$$\Phi(B)y_t = (I - B)^{-D}\Theta(B)\epsilon_t$$

where $B$ and $I$ are the backshift and identity operators; $D = \text{diag}(d_j)$ $d_j \in (-1/2, 1/2)$, are the LRD parameters of the component series $\{y_{jt}\}_{t \in \mathbb{Z}}$, $j = 1, \ldots, k$; and $\{\epsilon_t\}_{t \in \mathbb{Z}}$ is a $k$-dimensional white noise series with zero mean $E\epsilon_t = 0$ and covariance $E\epsilon_t\epsilon_t' = \Sigma$.

The fractional integration operator $(I - B)^{-D}$ allows for long memory in the series. On the other hand, $\Phi(z)$ and $\Theta(z)$, which are the typical autoregressive and moving average matrix polynomials of orders $p$ and $q$, respectively, capture the short-range dependence.

The VARFIMA($p, D, q$) series satisfies the multivariate long-range dependence definitions given in Kechagias and Pipiras (2015). Moreover, each component series $\{y_{jt}\}_{t \in \mathbb{Z}}$, $j = 1, \ldots, k$, satisfies the univariate time and frequency domain LRD definitions given in Beran et al. (2013). The following sections briefly review these definitions and show how you can detect long-range dependence in the data before fitting a VARFIMA model.

**Autocorrelation and Spectral Density of VARFIMA Series**

The diagonal components of the autocorrelation matrix function of a VARFIMA($p, D, q$) series satisfy the univariate LRD time domain definition

$$\rho_i(n) \sim c_i n^{2d_i - 1}, \quad i = 1, \ldots, k, \quad \text{as} \quad n \to \infty$$
where \(a_n \sim b_n\) implies that \(\lim_{n \to \infty} a_n/b_n = 1\) and \(c_1 > 0\). Similarly, the diagonal components of the spectral density matrix function of a VARFIMA\((p, D, q)\) series satisfy

\[ f_i(\lambda) \sim c_2 \lambda^{-2d_i}, \quad i = 1, \ldots, k, \quad \text{as} \quad \lambda \to 0^+ \]

for some \(c_2 > 0\).

To obtain preliminary estimates of the LRD parameters, you can plot the logged periodogram values against the log of the Fourier frequencies \(\lambda_j = 2\pi j/T, \quad j = 1, \ldots, T/2\), and then fit a line for frequencies near 0. The slope of this line is expected to be equal to \(-2d_i\) (the exponent in the right-hand side of the preceding relation). The following statements demonstrate this procedure for a synthetic VARFIMA\((1, D, 1)\) series with \(T = 2,000\) and true parameters \(d_1 = 0.4, d_2 = 0.3, \Phi_{11} = \Sigma_{11} = \Sigma_{22} = 3, \Sigma_{12} = 0.5, \Phi_{11} = 0.8, \Phi_{12} = 0.3, \Phi_{21} = -0.2, \Phi_{22} = 0.1, \Theta_{11} = 0.2, \Theta_{12} = 0.4, \Theta_{21} = 0, \text{and} \Theta_{22} = 0.3\):

```plaintext

    model logpdg1 = logfreq;  
  run;
  /* Introduce weights where regression will be performed */
  data logspectra;
    set spectra(firstobs=2);  
    /* compute Fourier frequencies */
    j = _N_;  
    pi = constant('pi');  
    logfreq = log(2*pi*j/2000);  
    logpdg1 = log(P_01);  
    logpdg2 = log(P_02);  
    wt = (1<= j <=100);  
    keep wt logfreq logpdg1 logpdg2;
  run;
  /* Regression for log-periodogram of y1*/
  proc autoreg data = logspectra(obs = 100);  
    model logpdg1 = logfreq;  
  run;
```
Chapter 43: The VARMAX Procedure

/* Regression for log-periodogram of y1*/
proc autoreg data = logspectra(obs = 100);
   model logpdg2 = logfreq;
run;

The output from the two regressions is shown in Figure 43.86 and Figure 43.87.

**Figure 43.86** Regression Estimates for y1

The AUTOREG Procedure

| Variable | DF | Estimate | Standard Error | t Value | Approx Pr > |t| |
|----------|----|----------|----------------|---------|-------------|---|
| Intercept | 1  | 4.3279   | 0.2885         | 15.00   | <.0001      |   |
| logfreq  | 1  | -0.9051  | 0.1245         | -7.27   | <.0001      |   |

**Figure 43.87** Regression Estimates for y2

The AUTOREG Procedure

| Variable | DF | Estimate | Standard Error | t Value | Approx Pr > |t| |
|----------|----|----------|----------------|---------|-------------|---|
| Intercept | 1  | 2.0811   | 0.3172         | 6.56    | <.0001      |   |
| logfreq  | 1  | -0.5227  | 0.1369         | -3.82   | 0.0002      |   |

The following statements produce log-log plots of the two periodograms along with the regression lines:

/*Plot the periodograms in log-log scale*/
ods graphics on;

proc sgplot data = logspectra;
   series x = logfreq y = logpdg1 / lineattrs = (pattern = solid);
   reg y = logpdg1 x = logfreq / nomarkers weight = wt lineattrs =
      (thickness = 1 color = 'red' );
   inset "Slope = -0.905" / position = topright textattrs = (color = 'red');
   xaxis label = 'log-frequency';
   yaxis label = 'log-periodogram';
   title 'Log-periodogram of y1';
run;

proc sgplot data = logspectra;
   series x = logfreq y = logpdg2 / lineattrs = (pattern = solid);
   reg y = logpdg2 x = logfreq / nomarkers weight = wt lineattrs =
      (thickness = 1 color = 'red' );
   inset "Slope = -0.523" / position = topright textattrs = (color = 'red');
   xaxis label = 'log-frequency';
   yaxis label = 'log-periodogram';
   title 'Log-periodogram of y2';
run;

The final plots are shown in Figure 43.88.
Dividing the slopes by 2 and removing the negative signs yields preliminary estimates for the LRD parameters, 
\( \hat{d}_1 = 0.45 \) and \( \hat{d}_2 = 0.26 \).

**Estimation**

Estimation of all the parameters in the VARFIMA model is performed using the conditional likelihood
Durbin-Levinson (CLDL) algorithm of Tsay (2010). This method uses the multivariate Durbin-Levinson
algorithm, whose order of complexity is \( O(T^2) \), making it computationally feasible for small or medium
sample sizes.

The initial values of the LRD parameters are obtained by the semiparametric estimator of Geweke and
Porter-Hudak (1983). The initial values of the AR and MA parameters are obtained from least squares
estimation on the fractionally differenced series \((I - B)^D y_t\). The LRD parameters are restricted in the range
\((-1/2, 1/2)\). If an initial LRD parameter estimate is outside this range, then the chosen starting value is
either \(-1/2 + 10^{-6}\) or \(1/2 - 10^{-6}\) for negative or positive initial semiparametric estimates, respectively.

**Forecasting**

One-step-ahead and multi-step-ahead forecasts for the VARFIMA series are based on a finite past. However,
the \(h\)-step-ahead forecast errors for \(h > 1\) are based on the infinite past except for VARFIMA series that have
only MA components. In the latter case, the forecast errors are also based on a finite past.

The following statements plot the \(h\)-step-ahead forecasts, \(h = 1, \ldots, 36\), for a bivariate synthetic
VARFIMA(1, D, 1) series with \( T = 400 \) and true parameters \( d_1 = 0.4, d_2 = 0.3, \Phi_{11} = \Sigma_{11} = \Sigma_{22} = 3, \Sigma_{12} = 0.5, \Phi_{11} = 0.8, \Phi_{12} = 0.3, \Phi_{21} = -0.2, \Phi_{22} = 0.1, \Theta_{11} = 0.2, \Theta_{12} = 0.4, \Theta_{21} = 0, \) and \( \Theta_{22} = 0.3 \). The statements also specify initial values for \(d_1 \) and \(d_2 \) close to the true parameter values.

```plaintext
data VARFIMA1D1N4;
  time = _N_;  
  input y1 y2; 
  datalines; 
  0.55596529 2.114409393  
  -1.842925215 3.415027987  
  ... more lines ...
```

The BACK option in the preceding SAS statements is used to specify the point where the historical data ends and multi-step-ahead forecasting begins. Note that the BACK option does not affect estimation. The latter is performed using the whole data set, even when you specify the BACK option.

Impulse Response Functions

The impulse response functions of the VARFIMA series are calculated using the methodology of Chung (2001). The following statements produce the first 12 simple, accumulated and orthogonal impulse response functions and their corresponding standard errors for the VARFIMA(1, D, 1) series of the preceding example.

```
proc varmax data = VARFIMA1D1N4 plots = (impulse);
  model y1 y2 / noint fi p=1 q=1 print = (impulse = (all));
run;
```

VARFIMAX Modeling

The VARFIMAX(p, D, q, s) series is defined as

$$
\Phi(B)y_t + \Theta^*(B)x_t = (I - B)^{-D} \Theta(B)\epsilon_t
$$

where $x_t = (x_{1t}, \ldots, x_{rt})'$, $t = 1, \ldots, T$, is an r-dimensional time series vector of exogenous variables and $\Theta^*(z)$ is the order s matrix polynomial defined as $\Theta^*(z) = \Theta_0^* + \Theta_1^*z + \cdots + \Theta_s^*z^s$ for some $k \times r$ real matrices $\Theta_i^*$, $i = 1, \ldots, s$.

The following statements estimate a bivariate VARFIMAX(1, D, 1, 0) model:

```
model y1 y2 = x1 / fi p=1 q=1;
```
Output Data Sets

The VARMAX procedure can create the OUT=, OUTTEST=, OUTHT=, and OUTSTAT= data sets. In general, if processing fails, the output is not recorded or is set to missing in the relevant output data set, and appropriate error and/or warning messages are recorded in the log.

OUT= Data Set

The OUT= data set contains the forecast values produced by the OUTPUT statement. The following output variables can be created:

- the BY variables
- the ID variable
- the MODEL statement dependent (endogenous) variables. These variables contain the actual values from the input data set.
- FORi, numeric variables that contain the forecasts. The FORi variables contain the forecasts for the i\textsuperscript{th} endogenous variable in the MODEL statement list. Forecasts are one-step-ahead predictions until the end of the data or until the observation specified by the BACK= option. Multistep forecasts can be computed after that point based on the LEAD= option.
- RESi, numeric variables that contain the residual for the forecast of the i\textsuperscript{th} endogenous variable in the MODEL statement list. For multistep forecast observations, the actual values are missing and the RESi variables contain missing values.
- STDi, numeric variables that contain the standard deviation for the forecast of the i\textsuperscript{th} endogenous variable in the MODEL statement list. The values of the STDi variables can be used to construct univariate confidence limits for the corresponding forecasts.
- LCIi, numeric variables that contain the lower confidence limits for the corresponding forecasts of the i\textsuperscript{th} endogenous variable in the MODEL statement list.
- UCIi, numeric variables that contain the upper confidence limits for the corresponding forecasts of the i\textsuperscript{th} endogenous variable in the MODEL statement list.

The OUT= data set contains the values shown in Table 43.7 and Table 43.8 for a bivariate case.

### OUTEST= Data Set

The OUTEST= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created:

- **BY** variables
- **NAME**, a character variable that contains the name of the endogenous (dependent) variables or the name of the parameters for the covariance of the matrix of the parameter estimates if you specify the OUTCOV option
- **TYPE**, a character variable that contains the value EST for parameter estimates, the value STD for standard error of parameter estimates, and the value COV for the covariance of the matrix of the parameter estimates if you specify the OUTCOV option
• CONST, a numeric variable that contains the estimates of constant parameters and their standard errors

• SEASON\_i, a numeric variable that contains the estimates of seasonal dummy parameters and their standard errors, where \( i = 1, \ldots, (nseason - 1) \), and \( nseason \) is based on the NSEASON= option

• LTREND, a numeric variable that contains the estimates of linear trend parameters and their standard errors

• QTREND, a numeric variable that contains the estimates of quadratic trend parameters and their standard errors

• XL\_l\_i, numeric variables that contain the estimates of exogenous parameters and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, r \), where \( r \) is the number of exogenous variables

• AR\_l\_i, numeric variables that contain the estimates of autoregressive parameters and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, k \), where \( k \) is the number of endogenous variables

• MA\_l\_i, numeric variables that contain the estimates of moving-average parameters and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, k \), where \( k \) is the number of endogenous variables

• COV\_i, numeric variables that contain the estimates of the covariance of innovations parameters when the maximum likelihood method is applied, where \( i = 1, \ldots, k \)

• DCCAB, a numeric variable that contains the estimates of \( \alpha \) or \( \beta \) in the correlation equation for DCC representation and their standard errors

• CCC\_i, numeric variables that contain the estimates of the conditional constant correlation parameters for CCC representation, where \( i = 2, \ldots, k \)

• DCCS\_i, numeric variables that contain the estimates of the unconditional correlation parameters for DCC representation, where \( i = 2, \ldots, k \)

• GCHC\_i, numeric variables that contain the estimates of the constant parameters of the covariance matrix and their standard errors, where \( i = 1, \ldots, k \) for BEKK representation, \( k \) is the number of endogenous variables, and \( i = 1 \) for CCC and DCC representations

• ACH\_l\_i, numeric variables that contain the estimates of the ARCH parameters of the covariance matrix and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, k \) for BEKK, CCC, and DCC representations, where \( k \) is the number of endogenous variables

• EACH\_l\_i, numeric variables that contain the estimates of the exponential ARCH parameters of the covariance matrix and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, k \) for CCC and DCC representations, where \( k \) is the number of endogenous variables

• PACH\_l\_i, numeric variables that contain the estimates of the power ARCH parameters of the covariance matrix and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, k \) for CCC and DCC representations, where \( k \) is the number of endogenous variables

• QACH\_l\_i, numeric variables that contain the estimates of the quadratic ARCH parameters of the covariance matrix and their standard errors, where \( l \) is the lag \( l \)th coefficient matrix and \( i = 1, \ldots, k \) for CCC and DCC representations, where \( k \) is the number of endogenous variables
• TACH\(_i\), numeric variables that contain the estimates of the threshold ARCH parameters of the covariance matrix and their standard errors, where \(l\) is the lag \(l\)th coefficient matrix and \(i = 1, \ldots, k\) for CCC and DCC representations, where \(k\) is the number of endogenous variables

• GCH\(_i\), numeric variables that contain the estimates of the GARCH parameters of the covariance matrix and their standard errors, where \(l\) is the lag \(l\)th coefficient matrix and \(i = 1, \ldots, k\) for BEKK, CCC, and DCC representations, where \(k\) is the number of endogenous variables

• LAMBDA, a numeric variable that contains the estimates of power parameters in the PGARCH model for CCC and DCC representations and their standard errors

The OUTEST= data set contains the values shown in Table 43.9 for a bivariate case.

Consider the following example:

```plaintext
proc varmax data=simul2 outest=est;
  model y1 y2 / p=2 noint noprint;
  cointeg rank=1 normalize=y1;
run;

proc print data=est;
run;
```

The output in Figure 43.91 shows the results of the OUTEST= data set.

### OUTHT= Data Set

The OUTHT= data set contains predictions of conditional covariance matrices of innovations of the fitted GARCH model that the GARCH statement produces. The following output variables can be created:
• the BY variables, if BY-group processing is performed
• the ID variable, if the ID statement is specified
• $H_{i,j}$, numeric variables that contain the prediction of covariance, where $1 \leq i \leq j \leq k$, where $k$ is the number of dependent variables

The OUTHT= data set contains the values shown in Table 43.10 for a bivariate case.

<table>
<thead>
<tr>
<th>Obs</th>
<th>H1_1</th>
<th>H1_2</th>
<th>H2_2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>h111</td>
<td>h121</td>
<td>h221</td>
</tr>
<tr>
<td>2</td>
<td>h112</td>
<td>h122</td>
<td>h222</td>
</tr>
<tr>
<td>...</td>
<td></td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The OUTHT= data set has the same number of observations as the OUT= data set. Both the OUTHT= and OUT= data sets include any observations at the beginning of the data set that are skipped because of the DIF=, DIFY=, DIFX=, P=, or XLAG= option and include the predicted observations at the end of the data set, which correspond with the LEAD= specification. If you specify an ID statement together with the OUTHT= and OUT= options, then the values of the ID variable in the two data sets correspond with one another.

Consider the following example of the OUTHT= option:

```plaintext
data garch;
set garch;
date = intnx( 'month', '01may1972'd, _n_-1);
format date yymms.;
run;

proc varmax data=garch;
id date interval=month;
model y1 y2 / p=1;
garch q=1 outht=ht;
output out=og lead=6;
run;

proc print data=og(obs=8);
var date y1 for1 std1 lci1 uci1 y2 for2 std2 lci2 uci2;
run;

proc print data=ht(obs=8);
run;

proc print data=og(firstobs=499);
var date y1 for1 std1 lci1 uci1 y2 for2 std2 lci2 uci2;
run;

proc print data=ht(firstobs=499);
run;
```
The output in Figure 43.92 and Figure 43.93 shows the first eight observations in the OUT= and OUTHT= data sets, respectively. The first observation is skipped in the GARCH model estimation because of the P=1 option, resulting in the missing values in the first observations in the OUT= and OUTHT= data sets. The output in Figure 43.94 and Figure 43.95 shows the last eight observations in the OUT= and OUTHT= data sets, respectively. In the OUT= data set, the standard deviations of the forecast of dependent variables are time-variant. The last six observations in OUTHT= data set are the multistep forecast of conditional covariance matrices of innovations.

OUTSTAT= Data Set

The OUTSTAT= data set contains estimation results of the fitted model produced by the VARMAX statement. The following output variables can be created. The subindex $i$ is $1, \ldots, k$, where $k$ is the number of endogenous variables.

- the BY variables
- NAME, a character variable that contains the name of endogenous (dependent) variables
- SIGMA$_i$, numeric variables that contain the estimate of the innovation covariance matrix
- AICC, a numeric variable that contains the corrected Akaike’s information criterion value
- HQC, a numeric variable that contains the Hannan-Quinn’s information criterion value
- AIC, a numeric variable that contains the Akaike’s information criterion value
- SBC, a numeric variable that contains the Schwarz Bayesian’s information criterion value
- FPEC, a numeric variable that contains the final prediction error criterion value
- FValue, a numeric variable that contains the $F$ statistics
- PValue, a numeric variable that contains $p$-value for the $F$ statistics

If the JOHANSEN= option is specified, the following items are added:

- Eigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1
- RestrictedEigenvalue, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1 when the NOINT option is not specified
- Beta$_i$, numeric variables that contain long-run effect parameter estimates, $\beta$
• **Alpha_i**, numeric variables that contain adjustment parameter estimates, \( \alpha \)

If the JOHANSEN=(IORDER=2) option is specified, the following items are added:

• **EValueI2_i**, numeric variables that contain eigenvalues for the cointegration rank test of integrated order 2

• **EValueI1**, a numeric variable that contains eigenvalues for the cointegration rank test of integrated order 1

• **Eta_i**, numeric variables that contain the parameter estimates in integrated order 2, \( \eta \)

• **Xi_i**, numeric variables that contain the parameter estimates in integrated order 2, \( \xi \)

The OUTSTAT= data set contains the values shown Table 43.11 for a bivariate case.

Printed Output

The default printed output produced by the VARMAX procedure is described in the following list:

- descriptive statistics, which include the number of observations used, the names of the variables, their means and standard deviations (STD), their minimums and maximums, the differencing operations used, and the labels of the variables
- a type of model to fit the data and an estimation method
- a table of parameter estimates that shows the following for each parameter: the variable name for the left-hand side of equation, the parameter name, the parameter estimate, the approximate standard error, $t$ value, the approximate probability ($Pr > |t|$), and the variable name for the right-hand side of equations in terms of each parameter
- the innovation covariance matrix
- the information criteria

If PRINT=ESTIMATES is specified, the VARMAX procedure prints the following list with the default printed output:

- the estimates of the constant vector (or seasonal constant matrix), the trend vector, the coefficient matrices of the distributed lags, the AR coefficient matrices, and the MA coefficient matrices
- the ALPHA and BETA parameter estimates for the error correction model
- the schematic representation of parameter estimates

If PRINT=DIAGNOSE is specified, the VARMAX procedure prints the following list with the default printed output:

- the cross-covariance and cross-correlation matrices of the residuals
- the tables of test statistics for the hypothesis that the residuals of the model are white noise:
  - Durbin-Watson (DW) statistics
– $F$ test for autoregressive conditional heteroscedastic (ARCH) disturbances
– $F$ test for AR disturbance
– Jarque-Bera normality test
– portmanteau test

### ODS Table Names

The VARMAX procedure assigns a name to each table that it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 43.12.

**ODS Graphics**

This section describes the use of ODS for creating statistical graphs with the VARMAX procedure.

When ODS GRAPHICS are in effect, the VARMAX procedure produces a variety of plots for each dependent variable.

The plots available are as follows:

- The procedure displays the following plots for each dependent variable in the MODEL statement with the PLOT= option in the VARMAX statement:
  - impulse response function
  - impulse response of the transfer function
  - time series and predicted series
  - prediction errors
  - distribution of the prediction errors
  - normal quantile of the prediction errors
  - ACF of the prediction errors
  - PACF of the prediction errors
  - IACF of the prediction errors
  - log scaled white noise test of the prediction errors

- The procedure displays forecast plots for each dependent variable in the OUTPUT statement with the PLOT= option in the VARMAX statement.

**ODS Graph Names**

The VARMAX procedure assigns a name to each graph it creates by using ODS. You can use these names to reference the graphs when using ODS. The names are listed in Table 43.13.

Computational Issues

Computational Method

The VARMAX procedure uses numerous linear algebra routines and frequently uses the sweep operator (Goodnight 1979) and the Cholesky root (Golub and Van Loan 1983).

In addition, the VARMAX procedure uses the nonlinear optimization (NLO) subsystem to perform nonlinear optimization tasks for the maximum likelihood estimation. The optimization requires intensive computation.

Convergence Problems

For some data sets, the computation algorithm can fail to converge. Nonconvergence can result from a number of causes, including flat or ridged likelihood surfaces and ill-conditioned data.

If you experience convergence problems, the following points might be helpful:

- Data that contain extreme values can affect results in PROC VARMAX. Rescaling the data can improve stability.
- Changing the TECH=, MAXITER=, and MAXFUNC= options in the NLOPTIONS statement can improve the stability of the optimization process.
- Specifying a different model that might fit the data more closely and might improve convergence.

Memory

Let $T$ be the length of each series, $k$ be the number of dependent variables, $p$ be the order of autoregressive terms, and $q$ be the order of moving-average terms. The number of parameters to estimate for a VARMA($p,q$) model is

$$k + (p + q)k^2 + k \times (k + 1)/2$$
As $k$ increases, the number of parameters to estimate increases very quickly. Furthermore, the memory requirement for VARMA($p, q$) quadratically increases as $k$ and $T$ increase.

For a VARMAX($p, q, s$) model and GARCH-type multivariate conditional heteroscedasticity models, the number of parameters to estimate and the memory requirements are considerable.

**Computing Time**

PROC VARMAX is computationally intensive, and execution times can be long. Extensive CPU time is often required to compute the maximum likelihood estimates.

---

**Examples: VARMAX Procedure**

**Example 43.1: Analysis of United States Economic Variables**

Consider the following four-dimensional system of US economic variables. Quarterly data for the years 1954 to 1987 are used (Lütkepohl 1993, Table E.3.).

```plaintext
title 'Analysis of US Economic Variables';
data us_money;
    date=intnx('qtr', '01jan54'd, _n_-1);
    format date yyq.;
    input y1 y2 y3 y4 @@;
    y1=log(y1);
    y2=log(y2);
    label y1='log(real money stock M1)'
         y2='log(GNP in bil. of 1982 dollars)'
         y3='Discount rate on 91-day T-bills'
         y4='Yield on 20-year Treasury bonds';
datalines;
450.9 1406.8 0.010800000 0.026133333
453.0 1401.2 0.0081333333 0.025233333
459.1 1418.0 0.0087000000 0.024900000
... more lines ...
```

The following statements plot the series:

```plaintext
proc sgplot data=us_money;
    series x=date y=y1 / lineattrs=(pattern=solid);
    series x=date y=y2 / lineattrs=(pattern=dash);
yaxis label="Series";
run;
```
Output 43.1.1 shows the plot of the variables $y_1$ and $y_2$.

\begin{figure}[h]
\centering
\includegraphics[width=\textwidth]{plot.png}
\caption{Plot of Data}
\end{figure}

The following statements plot the variables $y_3$ and $y_4$:

\begin{verbatim}
proc sgplot data=us_money;
   series x=date y=y3 / lineattrs=(pattern=solid);
   series x=date y=y4 / lineattrs=(pattern=dash);
   yaxis label="Series";
run;
\end{verbatim}
Output 43.1.2 shows the plot of the variables $y_3$ and $y_4$.

**Output 43.1.2 Plot of Data**

The following statements perform the Dickey-Fuller test for stationarity, the Johansen cointegrated test integrated order 2, and the exogeneity test. The VECM(2) is fit to the data.

```
proc varmax data=us_money;
  id date interval=qtr;
  model y1-y4 / p=2 lagmax=6 df test
     print=(iarr(3) estimates diagnose)
     cointest=(johansen=(iorder=2));
  cointeg rank=1 normalize=y1 exogeneity;
run;
```

From the outputs shown in Output 43.1.5, you can see that the series has unit roots and is cointegrated in
The fitted VECM(2) is given as

$$
\Delta y_t = \begin{pmatrix}
0.0408 \\
0.0860 \\
0.0052 \\
-0.0144
\end{pmatrix}
+ \begin{pmatrix}
-0.0140 & 0.0065 & -0.2026 & 0.1306 \\
-0.0281 & 0.0131 & -0.4080 & 0.2630 \\
-0.0022 & 0.0010 & -0.0312 & 0.0201 \\
0.0051 & -0.0024 & 0.0741 & -0.0477
\end{pmatrix}
y_{t-1}

+ \begin{pmatrix}
0.3460 & 0.0913 & -0.3535 & -0.9690 \\
0.0994 & 0.0379 & 0.2390 & 0.2866 \\
0.1812 & 0.0786 & 0.0223 & 0.4051 \\
0.0322 & 0.0496 & -0.0329 & 0.1857
\end{pmatrix}
\Delta y_{t-1} + \epsilon_t
$$

The $\Delta$ prefixed to a variable name implies differencing.

Output 43.1.3 through Output 43.1.16 show the details. Output 43.1.3 shows the descriptive statistics.

</tbody>
</table>
The Johansen cointegration rank test shows whether the series is integrated order either 1 or 2 as shown in Output 43.1.5. The last two columns in Output 43.1.5 explain the cointegration rank test with integrated order 1. The results indicate that there is a cointegrated relationship with cointegration rank 1 with respect to the 0.05 significance level because the test statistic for the null hypothesis $H_0: r = 0$ is 55.9633 and its corresponding $p$-value is 0.0072, less than 0.05 (indicating that $H_0: r = 0$ should be rejected), and the test statistic for the null hypothesis $H_0: r = 1$ is 20.6542 and its corresponding $p$-value is 0.3775, greater than 0.05 (indicating that $H_0: r = 1$ cannot be rejected). Now, look at the row associated with $r = 1$. All $p$-values of the tests for the null hypothesis that the series are integrated order 2 are zeros, less than 0.05 significance level (indicating that the null hypothesis should be rejected).

Output 43.1.8 shows that the VECM(2) is fit to the data. The RANK=1 option in the COINTEG statement produces the estimates of the long-run parameter, $\beta$, and the adjustment coefficient, $\alpha$.

Output 43.1.13 shows the innovation covariance matrix estimates, the log-likelihood, the various information criteria results, and the tests for white noise residuals. According to the portmanteau test results, the residuals have significant correlations at lag 2 and 3, indicating that a VECM(3) model might be a better fit than the VECM(2) model.

Example 43.1: Analysis of United States Economic Variables  ➤ 3177
Output 43.1.16 shows whether each variable is the weak exogeneity of other variables. The variable $y_1$ is not the weak exogeneity of other variables, $y_2$, $y_3$, and $y_4$; the variable $y_2$ is not the weak exogeneity of other variables, $y_1$, $y_3$, and $y_4$; the variables $y_3$ and $y_4$ are the weak exogeneity of other variables.

Example 43.2: Analysis of German Economic Variables

This example considers a three-dimensional VAR(2) model. The model contains the logarithms of a quarterly, seasonally adjusted West German fixed investment, disposable income, and consumption expenditures. The data used are in Lütkepohl (1993, Table E.1).

```sas
title 'Analysis of German Economic Variables';
data west;
  date = intnx('qtr', '01jan60'd, _n_-1);
  format date yyq.;
  input y1 y2 y3 @@;
y1 = log(y1);
y2 = log(y2);
y3 = log(y3);
  label y1 = 'logarithm of investment'
            y2 = 'logarithm of income'
            y3 = 'logarithm of consumption';
datalines;
180 451 415 179 465 421 185 485 434 192 493 448
211 509 459 202 520 458 207 521 479 214 540 487
... more lines ...
data use;
  set west;
  where date < '01jan79'd;
  keep date y1 y2 y3;
run;
proc varmax data=use;
  id date interval=qtr;
  model y1-y3 / p=2 dify=(1)
       print=(decompose(6) impulse=(stderr) estimates diagnose)
       printform=both lagmax=3;
  causal group1=(y1) group2=(y2 y3);
  output lead=5;
run;
```
Example 43.2: Analysis of German Economic Variables

First, the differenced data are modeled as a VAR(2) with the following result:

\[
\Delta y_t = \left(\begin{array}{c}
-0.01672 \\
0.01577 \\
0.01293
\end{array}\right) + \left(\begin{array}{ccc}
-0.31963 & 0.14599 & 0.96122 \\
0.04393 & -0.15273 & 0.28850 \\
-0.00242 & 0.22481 & -0.26397
\end{array}\right) \Delta y_{t-1} \\
+ \left(\begin{array}{ccc}
-0.16055 & 0.11460 & 0.93439 \\
0.05003 & 0.01917 & -0.01020 \\
0.03388 & 0.35491 & -0.02223
\end{array}\right) \Delta y_{t-2} + \epsilon_t
\]

The parameter estimates AR1_1_2, AR1_1_3, AR2_1_2, and AR2_1_3 are insignificant, and the VARX model is fitted in the next step.

The detailed output is shown in Output 43.2.1 through Output 43.2.8.

Output 43.2.1 shows the descriptive statistics.

The proportions of decomposition of the prediction error covariances of three variables are given in Output 43.2.7. If you see the $y_3$ variable in the first column, then the output explains that about 64.713% of the one-step-ahead prediction error covariances of the variable $y_{3t}$ is accounted for by its own innovations, about 7.995% is accounted for by $y_{1t}$ innovations, and about 27.292% is accounted for by $y_{2t}$ innovations.

Test 1: Group 1 Variables: \(y_1\)
Group 2 Variables: \(y_2 y_3\)

The following SAS statements show that the variable \(y_1\) is the exogenous variable and fit the VARX(2,1) model to the data:

```sas
proc varmax data=use;
  id date interval=qtr;
  model y2 y3 = y1 / p=2 dify=(1) difx=(1) xlag=1 lagmax=3
            print=(estimates diagnose);
run;
```

The fitted VARX(2,1) model is written as

\[
\begin{pmatrix}
\Delta y_{2t} \\
\Delta y_{3t}
\end{pmatrix} = \begin{pmatrix}
0.01542 \\
0.01319
\end{pmatrix} + \begin{pmatrix}
0.02520 \\
0.05130
\end{pmatrix} \Delta y_{1t} + \begin{pmatrix}
0.03870 \\
0.00363
\end{pmatrix} \Delta y_{1,t-1}
\]

\[
+ \begin{pmatrix}
-0.12258 & 0.25811 \\
0.24367 & -0.31809
\end{pmatrix} \begin{pmatrix}
\Delta y_{2,t-1} \\
\Delta y_{3,t-1}
\end{pmatrix}
\]

\[
+ \begin{pmatrix}
0.01651 & 0.03498 \\
0.34921 & -0.01664
\end{pmatrix} \begin{pmatrix}
\Delta y_{2,t-2} \\
\Delta y_{3,t-2}
\end{pmatrix} + \begin{pmatrix}
\epsilon_{1t} \\
\epsilon_{2t}
\end{pmatrix}
\]

The detailed output is shown in **Output 43.2.10** through **Output 43.2.13**.

**Output 43.2.10** shows the parameter estimates in terms of the constant, the current and the lag one coefficients of the exogenous variable, and the lag two coefficients of the dependent variables.

Output 43.2.13 describes how well each univariate equation fits the data. The residuals are off from the normality, but have no ARCH and AR effects.
Example 43.3: Analysis of Restricted Cointegrated Systems

The structural relationships between economic time series have been of interest for decades. Because of the cointegration, the vector error correction model (VECM), introduced by Engle and Granger (1987), is one of the most important tools for performing such analysis. Although there exist analytical solutions for a nonrestricted VECM and some restricted VECMs in special forms, the estimation of a generally restricted VECM relies on numerical methods. This section illustrates how to use the RESTRICT (or BOUND) and TEST statements, together with the COINTEG statement, to estimate the restricted VECM and perform the statistical tests. For more information about this topic, see Boswijk and Doornik (2004) and references therein.

The data are simulated based on the VECM,

\[
\Delta y_t = \alpha \beta' y_{t-1} + \Phi_t^* \Delta y_{t-1} + \Theta_0^* x_t + \epsilon_t
\]

where \( I_4 \) is the \( 4 \times 4 \) identity matrix.
The following statements implement the simulation:

```sql
title 'Analysis of Restricted Cointegrated Systems';
proc iml;
   alpha = {0.01 -0.02, -0.03 0.04, 0.05 -0.06, 0 0};
   beta = {1 0, 0 1, -1 0, 0 -1};
   phiStar = {-0.01 0.03 0.05 -0.02,
               0.02 -0.04 0.06 0.03,
               0 0 0.10 0,
               0 0 0 0.04};
   Pi = alpha * beta` ;
   A1 = I(4) + Pi+ phiStar;
   A2 = -phiStar;
   phi = A1 // A2;
   sig = I(4);

   /* to simulate the vector time series */
   T = 600;
   myseed = 2;
   call varmasim(y,phi) sigma=sig n=T seed=myseed;
   x = J(T,1,0);
   do i = 1 to T;
      x[i] = normal(myseed);
   end;
   y = y || x;
   cn = {'y1' 'y2' 'y3' 'y4' 'x'};
   create simul5 from y[colname=cn];
   append from y;
   close;
quit;
```

**Weak Exogeneity Tests**

This example shows different methods for checking weak exogeneity.

The first method uses the EXOGENEITY option in the following statements, and the test results are shown in Output 43.3.1:

```sql
   /* Method 1 -- To use the EXOGENEITY option */
   ods output LogLikelihood = tbl_ll_g;
   proc varmax data=simul5;
      model y1 y2 y3 y4 = x / noint p=2;
      cointeg rank=2 exogeneity;
   run;
```
Output 43.3.1 Test Weak Exogeneity with the EXOGENEITY Option

Analysis of Restricted Cointegrated Systems

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Variable</th>
<th>DF</th>
<th>Chi-Square</th>
<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>y1</td>
<td>2</td>
<td>102.96</td>
<td>&lt;.0001</td>
</tr>
<tr>
<td>y2</td>
<td>2</td>
<td>116.12</td>
<td>&lt;.0001</td>
</tr>
<tr>
<td>y3</td>
<td>2</td>
<td>200.80</td>
<td>&lt;.0001</td>
</tr>
<tr>
<td>y4</td>
<td>2</td>
<td>3.99</td>
<td>0.1357</td>
</tr>
</tbody>
</table>

The second method uses the RESTRICT statement and then the likelihood ratio (LR) test in the following statements. The results are shown in Output 43.3.2. In theory, the first and second methods should have exactly same statistics and p-values because they implement the same LR tests. However, because of the difference between the analytical solution and the numerical solution for the restricted VECM, the statistics are a little different, although for the 0.05 significance level they lead to the same correct conclusion: the variable y1 is not the weak exogeneity of variables y2, y3, and y4; the variable y2 is not the weak exogeneity of variables y1, y3, and y4; the variable y3 is not the weak exogeneity of variables y1, y2, and y4; the variable y4 is the weak exogeneity of variables y1, y2, and y3.

/* Method 2 -- Use the RESTRICT statement and implement LR test */
%macro LRTestForVECM();
  %do i = 1 %to 4;
    ods output LogLikelihood = tbl_ll_r1_&i.;
    proc varmax data=simul5;
      model y1 y2 y3 y4 = x / noint p=2;
      cointeg rank=2;
      restrict alpha(&i.,1:2) = 0;
    run;
  %end;
  proc iml;
    use tbl_ll_g;
    read all var {nValue1} into ll_g;
    close;
    %do i = 1 %to 4;
      use tbl_ll_r1_&i.;
      read all var {nValue1} into ll_r_&i.;
      close;
    %end;
    DF = J(4,1,2);
    ll_r = ll_r_1 // ll_r_2 // ll_r_3 // ll_r_4;
    Stat = -2*(ll_r - ll_g);
    pValue = 1-cdf("CHISQUARE", Stat, DF);
    Test = {"H0: Alpha(1,)=0"} // {"H0: Alpha(2,)=0"}
      // {"H0: Alpha(3,)=0"} // {"H0: Alpha(4,)=0"};
    print Test DF Stat pValue;
  quit;
%mend;
%LRTestForVECM();
**Output 43.3.2** Test Weak Exogeneity with the RESTRICT Statement and LR Tests

**Analysis of Restricted Cointegrated Systems**

<table>
<thead>
<tr>
<th>Test</th>
<th>DF</th>
<th>Stat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>H0: Alpha(1,)=0</td>
<td>2</td>
<td>109.05157</td>
<td>0</td>
</tr>
<tr>

<td>0</td>
</tr>
<tr>
<td>H0: Alpha(3,)=0</td>
<td>2</td>
<td>238.35505</td>
<td>0</td>
</tr>
<tr>
<td>H0: Alpha(4,)=0</td>
<td>2</td>
<td>5.0877699</td>
<td>0.0785606</td>
</tr>
</tbody>
</table>

The third method uses the TEST statement, which implements the Wald tests. Asymptotically, the Wald test has the same distribution as the LR test.

```sas
/* Method 3 -- To use the TEST statement and the Wald test */
proc varmax data=simul5;
  model y1 y2 y3 y4 = x / noint p=2;
  cointeg rank=2;
  test alpha(1,1:2) = 0;
  test alpha(2,1:2) = 0;
  test alpha(3,1:2) = 0;
  test alpha(4,1:2) = 0;
run;
```

Based on the test results shown in **Output 43.3.3**, the same correct conclusion can be obtained at the 0.05 significance level: the variable $y_1$ is not the weak exogeneity of variables $y_2$, $y_3$, and $y_4$; the variable $y_2$ is not the weak exogeneity of variables $y_1$, $y_3$, and $y_4$; the variable $y_3$ is not the weak exogeneity of variables $y_1$, $y_2$, and $y_4$; the variable $y_4$ is the weak exogeneity of variables $y_1$, $y_2$, and $y_3$.

**Output 43.3.3** Test Weak Exogeneity with the TEST Statement, Wald Tests

**Analysis of Restricted Cointegrated Systems**

<table>

<td>4.81</td>
<td>0.0903</td>
</tr>
</tbody>
</table>

**Identification**

This example shows how important it is to identify $\alpha$ and $\beta$ when applying the Wald test on $\alpha$. First, in the following statements, there are no constraints on $\beta$:

```sas
proc varmax data=simul5;
  model y1 y2 y3 y4 = x / noint p=2;
  cointeg rank=2;
  test alpha(1,2) = alpha(2,2) + alpha(3,2);
run;
```
As shown in Output 43.3.4, based on the test results, the null hypothesis $H_0: \alpha_1 = \alpha_2 + \alpha_3$ should be rejected at the 0.05 significance level, although the true parameter values for the data generating process indicate that $H_0$ is correct.

**Output 43.3.4** Importance of Identifying $\alpha$ and $\beta$ in the Wald Test

**Analysis of Restricted Cointegrated Systems**

The **VARMAX Procedure**

<table>
<thead>
<tr>
<th>Test</th>
<th>DF</th>
<th>Chi-Square</th>
<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>21.44</td>
<td>&lt;.0001</td>
</tr>
</tbody>
</table>

In the following statements, $r^2$ constraints are now imposed on $\beta$, where $r$ is the cointegration rank:

```
proc varmax data=simul5;
   model y1 y2 y3 y4 = x / noint p=2;
   cointeg rank=2;
   restrict beta(3:4,1:2) = -I(2);
   test alpha(1,2) = alpha(2,2) + alpha(3,2);
run;
```

As shown in Output 43.3.5, the null hypothesis cannot be rejected at 0.05 significance level; that is to say, the correct conclusion is achieved.

**Output 43.3.5** Importance of Identifying $\alpha$ and $\beta$ in the Wald Test, Continued

**Analysis of Restricted Cointegrated Systems**

The **VARMAX Procedure**

<table>
<thead>
<tr>
<th>Test</th>
<th>DF</th>
<th>Chi-Square</th>
<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>0.18</td>
<td>0.6750</td>
</tr>
</tbody>
</table>

Besides $\alpha$, other short-run parameters in a VECM can also be tested by using the TEST statement. Because short-run parameters other than $\alpha$ are identified in a VECM, it is not necessary to impose additional constraints on $\alpha$ and $\beta$. The following statements test the null hypothesis $H_0: \Phi_1^* = 0$:

```
proc varmax data=simul5;
   model y1 y2 y3 y4 = x / noint p=2;
   cointeg rank=2;
   test ar(2);
run;
```

According to the results shown in Output 43.3.6, the null hypothesis should be rejected at the 0.05 significance level.
Output 43.3.6  Wald Tests for Short-Run Parameters

Analysis of Restricted Cointegrated Systems

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Test DF</th>
<th>Chi-Square</th>
<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>32.79</td>
<td>0.0079</td>
</tr>
</tbody>
</table>

The following statements test the null hypothesis $H_0: \Theta_0^* = 0$:

```
proc varmax data=simul5;
  model y1 y2 y3 y4 = x / noint p=2;
  cointeg rank=2;
  test xl;
run;
```

According to the results shown in Output 43.3.7, the null hypothesis cannot be rejected at the 0.05 significance level.

Output 43.3.7  Wald Tests for Short-Run Parameters, Continued

Analysis of Restricted Cointegrated Systems

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Test DF</th>

<th>Pr &gt; ChiSq</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>6.01</td>
<td>0.1982</td>
</tr>
</tbody>
</table>

Besides the parameters that are estimated in a VECM, you can also use the TEST statement on $\alpha\delta_0$ and $\alpha\delta_1$ for Case 2 or 4 when the constant or linear trend, respectively, is restricted in the error correction term. However, keep in mind that the covariance matrix for these parameter estimates is singular when the cointegration rank is less than the number of dependent variables; hence, you might not get the results for some tests.

```
proc varmax data=simul5;
  model y1 y2 y3 y4 = x / noint p=2;
  cointeg rank=2;
  test ar(1,4,1:4);
  test ar(1,4,{1 3});
run;
```

As shown in Output 43.3.8, the first test on $H_0: \Pi[4,] = 0$ cannot be calculated, whereas the second test on $H_0: \Pi[4, 1] = \Pi[4, 3] = 0$ can be.
**Output 43.3.8** Wald Tests for $\Pi$

Tests for Long-Run Parameter

This example focuses on testing the relationships on the long-run parameter $\beta$. Here, only the following specific form of hypothesis is discussed,

$$H_0: \beta = (H, \phi)$$

where $H$ is a known $k \times r_1$ matrix, $\phi$ is a freely varying $k \times (r - r_1)$ parameter matrix, $k$ is the number of dependent variables, $r$ is the cointegration rank, and $0 \leq r_1 \leq r$. Other forms of hypothesis—for example, $H_0: \beta = (H_1 \phi_1, \ldots, H_r \phi_r)$ or $H_0: H \text{vec}(\beta) = h$—are omitted, although they can also be implemented in the same logic. The following statements test the null hypothesis that $(1 \, 0 \, -1 \, 0)'$ is in the cointegrating space that is spanned by $\beta$:

```plaintext
/* Use the RESTRICT statement and LR test for restrictions on Beta. */
/* H0: Beta = [ H, phi ] where H is known and phi is free */
ods output LogLikelihood = tbl_ll_r2;
proc varmax data=simul5;
   model y1 y2 y3 y4 = x / noint p=2;
   cointeg rank=2;
   restrict beta(,1) = {1, 0, -1, 0};
   nloptions tech=qn maxit=5000;
run;

proc iml;
   use tbl_ll_g;
   read all var {nValue1} into ll_g;
   close;
   use tbl_ll_r2;
   read all var {nValue1} into ll_r;
   close;
   DF = (4-2)*1; /* DF = (k-r)*r_1 */
   Stat = -2*(ll_r - ll_g);
   pValue = 1-cdf("CHISQUARE", stat, df);
   Test = "H0: Beta[1,1:4] = (1 0 -1 0)';"
   print Test DF Stat pValue;
quit;
```

According to the result shown in Output 43.3.9, the null hypothesis cannot be rejected at the 0.05 significance level.
Output 43.3.9  LR Tests on Long-Run Parameter $\beta$

Analysis of Restricted Cointegrated Systems

<table>
<thead>
<tr>
<th>Test</th>
<th>DF</th>
<th>Stat</th>
<th>pValue</th>
</tr>
</thead>
<tbody>
<tr>
<td>$H_0: \beta[1:4] = {1 \ 0 \ -1 \ 0}'$</td>

<td>0.2747891</td>
</tr>
</tbody>
</table>

The following statements test the null hypothesis that the cointegrating space is spanned by $(1 \ 0 \ -1 \ 0 \ 0 \ 1 \ -1 \ 0 \ -1)'$:

```plaintext
/* H0: Beta = H, where H is the true Beta for DGP */
ods output LogLikelihood = tbl_ll_r3;
proc varmax data=simul5;
   model y1 y2 y3 y4 = x / noint p=2;
   cointeg rank=2;
   restrict beta = I(2) // (-I(2));
   nloptions tech=qn maxit=5000;
run;

proc iml;
   use tbl_ll_g;
   read all var {nValue1} into ll_g;
   close;
   use tbl_ll_r3;
   read all var {nValue1} into ll_r;
   close;
   DF = (4-2)*2; /* DF = (k-r)*r_1 */
   Stat = -2*(ll_r - ll_g);
   pValue = 1-cdf("CHISQUARE", stat, df);
   Test = "H0: Beta = {1 0, 0 1, -1 0, 0 -1}";
   print Test DF Stat pValue;
quit;
```

According to the result shown in Output 43.3.10, the null hypothesis cannot be rejected at the 0.05 significance level.

Output 43.3.10  LR Tests on Long-Run Parameter $\beta$, Continued

Analysis of Restricted Cointegrated Systems

<table>

</tr>
</tbody>
</table>

The following statements test the null hypothesis that the cointegrating space is spanned by $(1 \ 0 \ 1 \ 0 \ 0 \ 1 \ 0 \ 1)'$, the orthogonal matrix to the true $\beta$ for the data generating process:

```plaintext
/* H0: Beta = H, where H is the matrix orthogonal to the true Beta for DGP */
ods output LogLikelihood = tbl_ll_r4;
proc varmax data=simul5;
   model y1 y2 y3 y4 = x / noint p=2;
   cointeg rank=2;
```

The following statements test the null hypothesis that the cointegrating space is spanned by $(1 \ 0 \ 1 \ 0 \ 0 \ 1 \ 0 \ 1)'$.
Example 43.4: Analysis of Euro Foreign Exchange Reference Rates

```
restrict beta = {1 0, 0 1, 1 0, 0 1};
nloptions tech=qn maxit=5000;
run;

proc iml;
    use tbl_ll_g;
    read all var {nValue1} into ll_g;
    close;
    use tbl_ll_r4;
    read all var {nValue1} into ll_r;
    close;
    DF = (4-2)*2; /* DF = (k-r)*r_1 */
    Stat = -2*(ll_r - ll_g);
    pValue = 1-cdf("CHISQUARE", stat, df);
    Test = "H0: Beta = {1 0, 0 1, 1 0, 0 1}";
    print Test DF Stat pValue;
quit;
```

According to the result shown in Output 43.3.11, the null hypothesis should be rejected at the 0.05 significance level.

For the VECM, the BOUND statement can be regarded as an alias of the RESTRICT statement; that is, you can directly replace any RESTRICT statement with a BOUND statement and get the same result. The linear inequality constraints in the restricted cointegrated systems are not discussed in this section, although they are also supported in the BOUND and RESTRICT statements. For more information, see the sections “BOUND Statement” on page 3024 and “RESTRICT Statement” on page 3050.

Obtaining the numerical solution for the restricted VECM is not an easy task in most cases. You might need to use the INITIAL and NLOPTIONS statements to tune the process. For more information, see the sections “INITIAL Statement” on page 3032 and “NLOPTIONS Statement” on page 3049.

**Example 43.4: Analysis of Euro Foreign Exchange Reference Rates**

This example illustrates how to use and select the VARMA-GARCH model for exchange rates, a general type of financial data. As shown in much of the literature, the financial variables are cross-correlated and autocorrelated not only on first moments, but also on second moments. The VARMA-GARCH model and the vector error correction GARCH model are often used to catch the stylized fact.

The data, downloaded from European Central Bank website (https://www.ecb.europa.eu), consist of four pairs of daily foreign exchange reference rates: the euro and the Australian dollar (AUD), the euro and the British pound sterling (GBP), the euro and the Japanese yen (JPY), and the euro and the US dollar (USD). The full sample covers the period from January 4, 1999, to February 12, 2015 (4,127 days). In the following statements, the series are logarithmically transformed, and the returns (in percentage) are calculated:
title 'Analysis of Euro Foreign Exchange Reference Rates';
data eurofxrr;
  input date : MMDDYY10. aud gbp jpy usd;
  label aud='The euro and the Australian dollar'
    usd='The euro and the U.S. dollar'
    jpy='The euro and the Japanese yen'
    gbp='The euro and the British pound sterling';
  logAUD = log(AUD); logGBP = log(GBP);
  logJPY = log(JPY); logUSD = log(USD);
  rAUD = (logAUD - lag(logAUD))*100;
  rGBP = (logGBP - lag(logGBP))*100;
  rJPY = (logJPY - lag(logJPY))*100;
  rUSD = (logUSD - lag(logUSD))*100;
datalines;
01/04/1999  1.9100  0.71110  133.73  1.1789
01/05/1999  1.8944  0.71220  130.96  1.1790
01/06/1999  1.8820  0.70760  131.42  1.1743
01/07/1999  1.8474  0.70585  129.43  1.1632
... more lines ...
02/10/2015  1.4522  0.74200  134.67  1.1297
02/11/2015  1.4606  0.73960  135.50  1.1314
02/12/2015  1.4761  0.73760  135.72  1.1328
;
Although it is well known that unit roots exist in the exchange rate series and they are not cointegrated, you
 can use the following statements to verify:

/**--- Unit Roots and Cointegration in Log Exchange Rates ---*/

proc varmax data=eurofxrr;
  model logAUD logGBP logJPY logUSD / p=2 df test cointest;
run;

According to the results of the Dickey-Fuller unit root tests shown in Output 43.4.1, the null hypothesis that
there is a unit root in each series cannot be rejected at the 5% significance level. The results of the Johansen
cointegration rank trace tests shown in Output 43.4.2 confirm that there is no cointegration between series
because the null hypothesis that the cointegration rank is 0, in both unrestricted and restricted cases, cannot
be rejected at the 5% significance level. Because there is no cointegration, you do not need to consider vector
error correction models; otherwise, the final selected model might be a vector error correction GARCH
model, instead of a VARMA-GARCH model.

<td>2</td>
<td>16</td>
<td>59.42</td>
</tr>
<tr>
<td></td>
<td>3</td>
<td>16</td>
<td>15.67</td>
</tr>
</tbody>
</table>

The null hypothesis that the constant term is 0 and the null hypothesis that the second lag AR term is 0 are both accepted at the 5% significance level. However, the null hypothesis that the first lag AR term is 0 is rejected at the 5% significance level. In the remaining model selection process, only the first lag AR term is considered.

The following statements estimate a zero-mean VAR(1) model and also print some diagnostic results:

```plaintext
/*--- VAR Model ---*/

proc varmax data=eurofxrr;
  model rAUD rGBP rJPY rUSD / noint p=1 print=(diagnose);
run;
```
Output 43.4.5 shows the information criteria for the estimated zero-mean VAR(1) model. In this example, AICC is used as the criterion for model selection: the smaller the AICC, the better the model.

**Output 43.4.5** Information Criteria for the VAR Model

**Analysis of Euro Foreign Exchange Reference Rates**

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Information Criteria</th>
</tr>
</thead>
<tbody>
<tr>
<td>AICC -1745.29</td>
</tr>
<tr>

<td></td>
</tr>
<tr>
<td>rUSD                      1.99959 1398.54 &lt;.0001 157.85 &lt;.0001</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

To find the right GARCH model, you can start with the VAR(1)-CCC-GARCH(1,1) model (which is usually the fastest one to be estimated) as in the following statement:

```plaintext
/*---- VAR CCC GARCH Model ----*/

proc varmax data=eurofxrr;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=ccc;
run;
```

Compared to the AICC for the zero-mean VAR(1) model (shown in Output 43.4.5), the AICC for VAR(1)-CCC-GARCH(1,1) model, as shown in Output 43.4.7, dramatically decreases, which means that the ARCH effects do play an important role and should be modeled.
Output 43.4.7  Information Criteria for VAR CCC GARCH Model

Analysis of Euro Foreign Exchange Reference Rates

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Information Criteria</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AICC</td>
<td>-4646.77</td>
</tr>
<tr>
<td>HQC</td>
<td>-4571.24</td>
</tr>
<tr>
<td>AIC</td>
<td>-4647.35</td>
</tr>
<tr>
<td>SBC</td>
<td>-4432.31</td>
</tr>
<tr>
<td>FPEC</td>
<td>0.011966</td>
</tr>
</tbody>
</table>

As indicated by its name, a basic assumption of the CCC GARCH model is that the conditional correlation is time-invariant, which might not be true. The following statements estimate a BEKK GARCH model to see whether modeling the conditional correlation could improve the model performance:

```plaintext
/**** VAR BEKK GARCH Model ****/
proc varmax data=eurofxrr outest=odiagbekk;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=bekk;
run;
```

As shown in Output 43.4.8, the AICC for the VAR BEKK GARCH model does get smaller than the AICC for the CCC GARCH model (shown in Output 43.4.7). The smaller AICC implies that the assumption of the CCC GARCH model might be inaccurate.

Output 43.4.8  Information Criteria for VAR BEKK GARCH Model

Analysis of Euro Foreign Exchange Reference Rates

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Information Criteria</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AICC</td>
<td>-5667.7</td>
</tr>
<tr>
<td>HQC</td>
<td>-5539.55</td>

</tr>
<tr>
<td>SBC</td>
<td>-5302.54</td>
</tr>
<tr>
<td>FPEC</td>
<td>0.011979</td>
</tr>
</tbody>
</table>

One shortcoming of the BEKK GARCH model is that it has too many parameters. In practice, especially for a large number of dependent variables, the scalar BEKK GARCH model and the diagonal BEKK GARCH model are often applied, as shown in the following statements. In the RESTRICT statement, matrix operations are used; using matrix operations is much more concise than restricting tens of ARCH and GARCH parameters one by one.
Example 43.4: Analysis of Euro Foreign Exchange Reference Rates

/** VAR Scalar BEKK GARCH Model ***/

```
proc varmax data=eurofxrr outest=odiagbekk;
    model rAUD rGBP rJPY rUSD / noint p=1;
    garch p=1 q=1 form=bekk;
    restrict ach(1)=ach(1,1,1)*I(4), gch(1)=gch(1,1,1)*I(4);
run;
```

/** VAR Diagonal BEKK GARCH Model ***/

```
proc varmax data=eurofxrr outest=odiagbekk;
    model rAUD rGBP rJPY rUSD / noint p=1;
    garch p=1 q=1 form=bekk;
    restrict ach(1)=ach(1)#I(4), gch(1)=gch(1)#I(4);
run;
```

The AICCs for the scalar and diagonal BEKK GARCH models are shown in Output 43.4.9 and Output 43.4.10, respectively, and both of them are larger than the AICC for the BEKK GARCH model (shown in Output 43.4.8). Hence, so far, the VAR BEKK GARCH model is the best.

**Output 43.4.9** Information Criteria for VAR Scalar BEKK GARCH Model

**Analysis of Euro Foreign Exchange Reference Rates**

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Information Criteria</th>

</tr>
</tbody>
</table>

Another type of multivariate GARCH model that is suitable for modeling the time-varying conditional correlation is the dynamic conditional correlation (DCC) GARCH model, as indicated by its name. The following statements estimate the DCC GARCH model:
Chapter 43: The VARMAX Procedure

/*--- VAR DCC GARCH Model ---*/

proc varmax data=eurofxrr;
  model rAUD rGBP rJPY rUSD / noint p=1;
  garch p=1 q=1 form=dcc;
run;

As shown in Output 43.4.11, the AICC for the VAR DCC GARCH model is smaller than the AICC for the VAR BEKK GARCH model (shown in Output 43.4.8), implying that the best model should be in the class of DCC GARCH models.

Output 43.4.11 Information Criteria for VAR DCC GARCH Model

Analysis of Euro Foreign Exchange Reference Rates

The VARMAX Procedure

<table>
<thead>
<tr>
<th>Information Criteria</th>
<th>Value</th>
</tr>
</thead>
<tbody>
<tr>
<td>AICC</td>

<tr>
<td>AIC</td>
<td>-5690.08</td>
</tr>
<tr>
<td>SBC</td>
<td>-5462.39</td>
</tr>
<tr>
<td>FPEC</td>
<td>0.011973</td>
</tr>
</tbody>
</table>

Could the DCC GARCH model be more parsimonious? The following statements use the sample correlation matrix of the standardized residuals (saving six parameters) to calculate the unconditional correlation matrix in the DCC GARCH model:

/*--- Parsimonious VAR DCC GARCH Model ---*/

proc varmax data=eurofxrr;
  model rAUD rGBP rJPY rUSD / noint p=1;
  garch p=1 q=1 form=dcc corrconst=expect;
run;

The AICC of the parsimonious VAR DCC GARCH model, as shown in Output 43.4.12, becomes a little smaller. Hence, the best model so far is the parsimonious VAR DCC GARCH model.

Output 43.4.12 Information Criteria for the Parsimonious VAR DCC GARCH Model

Analysis of Euro Foreign Exchange Reference Rates

</tbody>
</table>
Another way to refine the model is to try different subforms of GARCH models for each series. The following statements estimate the VAR DCC EGARCH model and produce Output 43.4.13:

```plaintext
/**** VAR DCC EGARCH Model ****/

proc varmax data=eurofxrr;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=dcc subform=egarch corrconst=expect;
   nloptions maxit=5000 pall;
run;
```

The following statements estimate the VAR DCC PGARCH model and produce Output 43.4.14:

```plaintext
/**** VAR DCC PGARCH Model ****/

proc varmax data=eurofxrr;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=dcc subform=pgarch corrconst=expect;
   nloptions maxit=5000 pall;
run;
```

The following statements estimate the VAR DCC QGARCH model and produce Output 43.4.15:

```plaintext
/**** VAR DCC QGARCH Model ****/

proc varmax data=eurofxrr;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=dcc subform=qgarch corrconst=expect;
   nloptions maxit=5000 pall;
run;
```

The following statements estimate the VAR DCC TGARCH model and produce Output 43.4.16:

```plaintext
/**** VAR DCC TGARCH Model ****/

proc varmax data=eurofxrr;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=dcc subform=tgarch corrconst=expect;
   nloptions maxit=5000 pall;
run;
```

Comparing the AICCs shown in Output 43.4.13 through Output 43.4.16, you find that the AICC for the VAR DCC PGARCH model is the smallest. Hence, the best model becomes the zero-mean VAR(1)-DCC-PGARCH(1,1) model, whose unconditional correlation matrix is estimated by the sample correlation matrix of the standardized residuals.

</table>

The following statements estimate the VAR DCC PGARCH model without those insignificant parameters:

```plaintext
/*--- VAR DCC PGARCH Model w/o Insignificant Parameters ---*/
proc varmax data=eurofxrr;
   model rAUD rGBP rJPY rUSD / noint p=1;
   garch p=1 q=1 form=dcc subform=pgarch corrconst=expect;
   nloptions maxit=5000 pall;
   restrict ar(1, 1, 2:4), ar(1, 2, 3), ar(1, 3, 3:4), ar(1, 4, 2:4);
run;
```

As shown in Output 43.4.19, the AICC does improve and decrease. Further refining the model is possible but beyond the scope of this example. Hence, the best model, according to the AICC, is the zero-mean VAR(1)-DCC-PGARCH(1,1) model without insignificant AR parameters, and its unconditional correlation matrix is estimated by the sample correlation matrix of the standardized residuals.

This example focuses only on using the information criterion to distinguish models. In practice, the forecast performance of the model might be more important. The VARMAX procedure supports multistep forecasting in both VARMAX-GARCH models and vector error correction GARCH models. Hence, although it is not covered in this example, you can also use the VARMAX procedure and a criterion based on out-of-sample forecast to perform model selection.
Example 43.5: Numerous Examples

The following are examples of syntax for model fitting:

```sas
/* Data 'a' Generated Process */
proc iml;
    sig = {1.0 0.5, 0.5 1.25};
    phi = {1.2 -0.5, 0.6 0.3};
    call varmasim(y,phi) sigma = sig n = 100 seed = 46859;
    cn = {'y1' 'y2'};
    create a from y[colname=cn];
    append from y;
run;

/* when the series has a linear trend */
proc varmax data=a;
    model y1 y2 / p=1 trend=linear;
run;

/* Fit subset of AR order 1 and 3 */
proc varmax data=a;
    model y1 y2 / p=(1,3);
run;

/* Check if the series is nonstationary */
proc varmax data=a;
    model y1 y2 / p=1 dfptest print=(roots);
run;

/* Fit VAR(1) in differencing */
proc varmax data=a;
    model y1 y2 / p=1 print=(roots) dify=(1);
run;

/* Fit VAR(1) in seasonal differencing */

/* Weak Exogenous Testing for each variable */
proc varmax data=b outstat=bbb;
  model y1-y4 / p=2 lagmax=4;
  cointeg rank=3 exogeneity normalize=y1;
run;

/* Hypotheses Testing for long-run and adjustment parameter */
proc varmax data=b outstat=bbb;
  model y1-y4 / p=2 lagmax=4;
  cointeg rank=3 normalize=y1
    h=(1 0 0, 0 1 0, -1 0 0, 0 0 1)
    j=(1 0 0, 0 1 0, 0 0 1, 0 0 0);
run;

/* ordinary regression model */
proc varmax data=grunfeld;
  model y1 y2 = x1-x3;
run;

/* Ordinary regression model with subset lagged terms */
proc varmax data=grunfeld;
  model y1 y2 = x1 / xlag=(1,3);
run;

/* VARX(1,1) with no current time Exogenous Variables */
proc varmax data=grunfeld;
  model y1 y2 = x1 / p=1 xlag=1 nocurrentx;
run;
Example 43.6: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. For information about the graphics available in the VARMAX procedure, see the section “ODS Graphics” on page 3165.

The following statements use the SASHELP.WORKERS data set to study the time series of electrical workers and its interaction with the series of masonry workers. The series and predict plots, the residual plot, and the forecast plot are created in Output 43.6.1 through Output 43.6.3. These are a selection of the plots created by the VARMAX procedure.

```sas
title "Illustration of ODS Graphics";
proc varmax data=sashelp.workers plot(unpack)=(residual model forecasts);
   id date interval=month;
   model electric masonry / dify=(1,12) noint p=1 oint lead=12;
run;
```

Overview: X11 Procedure

The X11 procedure, an adaptation of the U.S. Bureau of the Census X-11 Seasonal Adjustment program, seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set containing the adjusted time series and intermediate calculations.

The X11 procedure also provides the X-11-ARIMA method developed by Statistics Canada. This method fits an ARIMA model to the original series, then uses the model forecast to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

The X11 procedure incorporates sliding spans analysis. This type of analysis provides a diagnostic for determining the suitability of seasonal adjustment for an economic series.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, \( O_t, t = 1, \ldots, n \), and separated from trend cycle, trading-day, and irregular fluctuations. The seasonal component of this time series, \( S_t \), is defined as the intrayear variation that is repeated constantly or in an evolving fashion from year to year. The trend cycle component, \( C_t \), includes variation due to the long-term trend, the business cycle, and other long-term cyclical factors. The trading-day component, \( D_t \), is the variation that can be attributed to the composition of the calendar. The irregular component, \( I_t \), is the residual variation. Many economic time series are related in a multiplicative fashion (\( O_t = S_t C_t D_t I_t \)). A seasonally adjusted time series, \( C_t I_t \), consists of only the trend cycle and irregular components.

Getting Started: X11 Procedure

The most common use of the X11 procedure is to produce a seasonally adjusted series. Eliminating the seasonal component from an economic series facilitates comparison among consecutive months or quarters. A plot of the seasonally adjusted series is often more informative about trends or location in a business cycle than a plot of the unadjusted series.

The following example shows how to use PROC X11 to produce a seasonally adjusted series, \( C_t I_t \), from an original series \( O_t = S_t C_t D_t I_t \).
In the multiplicative model, the trend cycle component $C_t$ keeps the same scale as the original series $O_t$, while $S_t$, $D_t$, and $I_t$ vary around 1.0. In all printed tables and in the output data set, these latter components are expressed as percentages, and thus will vary around 100.0 (in the additive case, they vary around 0.0).

The naming convention used in PROC X11 for the tables follows the original U.S. Bureau of the Census X-11 Seasonal Adjustment program specification (Shiskin, Young, and Musgrave 1967). Also, see the section “Printed Output” on page 3256. This convention is outlined in Figure 44.1.

The tables corresponding to parts A–C are intermediate calculations. The final estimates of the individual components are found in the D tables: Table D10 contains the final seasonal factors, Table D12 contains the final trend cycle, and Table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you only need to look at Table D11, the final seasonally adjusted series.

For more information about the X-11-ARIMA tables, see Ladiray and Quenneville (2001).

---

Suppose you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the MONTHLY statement, which associates a SAS date value to each observation. To see the results of the seasonal adjustment, you must request table D11, the final seasonally adjusted series, in a TABLES statement.

```sas
data sales;
  input sales @@;
  date = intnx('month', '01sep1978'd, _n_-1);
  format date monyy7.;
datalines;
112 118 132 129 121 135 148 148 136 119 104 118
... more lines ...
/**** X-11 ARIMA ****/
proc x11 data=sales;
  monthly date=date;
  var sales;
  tables d11;
run;
```
Figure 44.1 Basic Seasonal Adjustment

The X11 Procedure

Seasonal Adjustment of - sales

X-11 Seasonal Adjustment Program
U. S. Bureau of the Census
Economic Research and Analysis Division
November 1, 1968

The X-11 program is divided into seven major parts.

Part  Description
A.  Prior adjustments, if any
B.  Preliminary estimates of irregular component weights and regression trading day factors
C.  Final estimates of above
D.  Final estimates of seasonal, trend-cycle and irregular components
E.  Analytical tables
F.  Summary measures
G.  Charts

Series - sales
Type of run: multiplicative seasonal adjustment.
Selected Tables or Charts.
Sigma limits for graduating extreme values are 1.5 and 2.5
Irregular values outside of 2.5-sigma limits are excluded from trading day regression

Total: 40324  Mean: 280.03  S.D.: 111.31
You can compare the original series, Table B1, and the final seasonally adjusted series, Table D11, by plotting them together. These tables are requested and named in the OUTPUT statement.

title 'Monthly Retail Sales Data (in $1000)';

Figure 44.3 Plot of Original and Seasonally Adjusted Data
An inherent problem with the X-11 method is the revision of the seasonal factor estimates as new data become available. The X-11 method uses a set of centered moving averages to estimate the seasonal components. These moving averages apply symmetric weights to all observations except those at the beginning and end of the series, where asymmetric weights have to be applied. These asymmetric weights can cause poor estimates of the seasonal factors, which then can cause large revisions when new data become available.

While large revisions to seasonally adjusted values are not common, they can happen. When they do happen, it undermines the credibility of the X-11 seasonal adjustment method.

A method to address this problem was developed at Statistics Canada (Dagum 1980, 1982a). This method, known as X-11-ARIMA, applies an ARIMA model to the original data (after adjustments, if any) to forecast the series one or more years. This extended series is then seasonally adjusted, allowing symmetric weights to be applied to the end of the original data. This method was tested against a large number of Canadian economic series and was found to greatly reduce the amount of revisions as new data were added.

The X-11-ARIMA method is available in PROC X11 through the use of the ARIMA statement. The ARIMA statement extends the original series either with a user-specified ARIMA model or by an automatic selection process in which the best model from a set of five predefined ARIMA models is used.

The following example illustrates the use of the ARIMA statement. The ARIMA statement does not contain a user-specified model, so the best model is chosen by the automatic selection process. Forecasts from this best model are then used to extend the original series by one year. The following partial listing shows parameter estimates and model diagnostics for the ARIMA model chosen by the automatic selection process:

```plaintext
proc x11 data=sales;
   monthly date=date;
   var sales;
   arima;
run;
```

The X11 Procedure

Seasonal Adjustment of - sales

Conditional Least Squares Estimation

Approx. Std Error
Syntax: X11 Procedure

The X11 procedure uses the following statements:

```
PROC X11 options;
   ARIMA options;
   BY variables;
   ID variables;
   MACURVES option;
   MONTHLY options;
   OUTPUT OUT=dataset options;
   PDWEIGHTS option;
   QUARTERLY options;
   SSPAN options;
   TABLES tablenames;
   VAR variables;
```

Either the MONTHLY or QUARTERLY statement must be specified, depending on the type of time series data you have. The PDWEIGHTS and MACURVES statements can be used only with the MONTHLY statement. The TABLES statement controls the printing of tables, while the OUTPUT statement controls the creation of the OUT= data set.

---

Criteria Summary for Model 2: (0,1,2)(0,1,1)s, Log Transform

- Box-Ljung Chi-square: 22.03 with 21 df Prob= 0.40  
  (Criteria prob > 0.05)
- Test for over-differencing: sum of MA parameters = 0.57  
  (must be < 0.90)
- MAPE - Last Three Years: 2.84 (Must be < 15.00 %)
  - Last Year: 3.04
  - Next to Last Year: 1.96
  - Third from Last Year: 3.51

Table D11 (final seasonally adjusted series) is now constructed using symmetric weights on observations at the end of the actual data. This should result in better estimates of the seasonal factors and, thus, smaller revisions in Table D11 as more data become available.

## Functional Summary

The statements and options controlling the X11 procedures are summarized in Table 44.1.

PROC X11 Statement

PROC X11 options ;

The following options can appear in the PROC X11 statement:

DATA=SAS-data-set
specifies the input SAS data set used. If it is omitted, the most recently created SAS data set is used.

OUTEXTRAP
adds the extra observations used in ARIMA processing to the output data set.

When ARIMA forecasting/backcasting is requested, extra observations are appended to the ends of the series, and the calculations are carried out on this extended series. The appended observations are not normally written to the OUT= data set. However, if OUTEXTRAP is specified, these extra observations are written to the output data set. If a DATE= variable is specified in the MONTHLY/QUARTERLY statement, the date variable is extrapolated to identify forecasts/backcasts. The OUTEXTRAP option can be abbreviated as OUTEX.
NO PRINT  

suppresses any printed output. The NOPRINT option overrides any PRINTOUT=, CHARTS=, or TABLES statement and any output associated with the ARIMA statement.

OUTSPAN=SAS-data-set  

specifies the output data set to store the sliding spans analysis results. Tables A1, C18, D10, and D11 for each span are written to this data set. For more information, see the section “The OUTSPAN= Data Set” on page 3254.

OUTSTB=SAS-data-set  

specifies the output data set to store the stable seasonality test results (Table D8). All the information in the analysis of variance table associated with the stable seasonality test is contained in the variables written to this data set. For more information, see the section “OUTSTB= Data Set” on page 3254.

OUTTDR=SAS-data-set  

specifies the output data set to store the trading-day regression results (Tables B15 and C15). All the information in the analysis of variance table associated with the trading-day regression is contained in the variables written to this data set. This option is valid only when TDREGR=PRINT, TEST, or ADJUST is specified in the MONTHLY statement. For more information, see the section “OUTTDR= Data Set” on page 3255.

YRAHEADOUT  

adds one-year-ahead forecast values to the output data set for Tables C16, C18, and D10. The original purpose of this option was to avoid recomputation of the seasonal adjustment factors when new data became available. While computing costs were an important factor when the X-11 method was developed, this is no longer the case and this option is obsolete. For more information, see the section “The YRAHEADOUT Option” on page 3250.

ARIMA Statement  

ARIMA options ;  

The ARIMA statement applies the X-11-ARIMA method to the series specified in the VAR statement. This method uses an ARIMA model estimated from the original data to extend the series one or more years. The ARIMA statement options control the ARIMA model used and the estimation, forecasting, and printing of this model.

There are two ways of obtaining an ARIMA model to extend the series. A model can be given explicitly with the MODEL= and TRANSFORM= options. Alternatively, the best-fitting model from a set of five predefined models is found automatically whenever the MODEL= option is absent. For more information, see the section “Details of Model Selection” on page 3251.

BACKCAST=n  

specifies the number of years to backcast the series. The default is BACKCAST=0. For more information, see the section “Effect of Backcast and Forecast Length” on page 3250.
CHICR= value
specifies the criteria for the significance level for the Box-Ljung chi-square test for lack of fit when
testing the five predefined models. The default is CHICR=0.05. The CHICR= option values must be
between 0.01 and 0.90. The hypothesis being tested is that of model adequacy. Nonrejection of the
hypothesis is evidence for an adequate model. Making the CHICR= value smaller makes it easier to
accept the model. For more information about the CHICR= option, see the section “Criteria Details”
on page 3252.

CONVERGE= value
specifies the convergence criterion for the estimation of an ARIMA model. The default value is 0.001.
The CONVERGE= value must be positive.

FORECAST= n
specifies the number of years to forecast the series. The default is FORECAST=1. For more informa-
tion, see the section “Effect of Backcast and Forecast Length” on page 3250.

MAPECR= value
specifies the criteria for the mean absolute percent error (MAPE) when testing the five predefined
models. A small MAPE value is evidence for an adequate model; a large MAPE value results in the
model being rejected. The MAPECR= value is the boundary for acceptance/rejection. Thus a larger
MAPECR= value would make it easier for a model to pass the criteria. The default is MAPECR=15.
The MAPECR= option values must be between 1 and 100. For more information about the MAPECR=
option, see the section “Criteria Details” on page 3252.

MAXITER= n
specifies the maximum number of iterations in the estimation process. MAXITER must be between 1
and 60; the default value is 15.

METHOD=CLS
METHOD=ULS
METHOD=ML
specifies the estimation method. ML requests maximum likelihood, ULS requests unconditional least
squares, and CLS requests conditional least squares. METHOD=CLS is the default. The maximum
likelihood estimates are more expensive to compute than the conditional least squares estimates. In
some cases, however, they can be preferable. For further information about the estimation methods,
see the section “Estimation Details” on page 250 in Chapter 7, “The ARIMA Procedure.”

MODEL= ( P=n1 Q=n2 SP=n3 SQ=n4 DIF=n5 SDIF=n6 < NOINT > < CENTER >)
specifies the ARIMA model. The AR and MA orders are given by P=n1 and Q=n2, respectively, while
the seasonal AR and MA orders are given by SP=n3 and SQ=n4, respectively. The lag corresponding
to seasonality is determined by the MONTHLY or QUARTERLY statement. Similarly, differencing
and seasonal differencing are given by DIF=n5 and SDIF=n6, respectively.

For example,

    arima model=( p=2 q=1 sp=1 dif=1 sdif=1 );

specifies a (2,1,1)(1,1,0)s model, where s, the seasonality, is either 12 (monthly) or 4 (quarterly). For
more examples of the MODEL= syntax, see the section “Details of Model Selection” on page 3251.
NOINT
suppresses the fitting of a constant (or intercept) parameter in the model. (That is, the parameter $\mu$ is omitted.)

CENTER
centers each time series by subtracting its sample mean. The analysis is done on the centered data. Later, when forecasts are generated, the mean is added back. Note that centering is done after differencing. The CENTER option is normally used in conjunction with the NOCONSTANT option of the ESTIMATE statement.

For example, to fit an AR(1) model on the centered data without an intercept, use the following ARIMA statement:

```
arima model=( p=1 center noint );
```

NOPRINT
suppresses the normal printout generated by the ARIMA statement. Note that the effect of specifying the NOPRINT option in the ARIMA statement is different from the effect of specifying the NOPRINT in the PROC X11 statement, since the former only affects ARIMA output.

OVDIFCR=value
specifies the criteria for the over-differencing test when testing the five predefined models. When the MA parameters in one of these models sum to a number close to 1.0, this is an indication of over-parameterization and the model is rejected. The OVDIFCR= value is the boundary for this rejection; values greater than this value fail the over-differencing test. A larger OVDIFCR= value would make it easier for a model to pass the criteria. The default is OVDIFCR=0.90. The OVDIFCR= option values must be between 0.80 and 0.99. For more information about the OVDIFCR= option, see the section “Criteria Details” on page 3252.

PRINTALL
provides the same output as the default printing for all models fit and, in addition, prints an estimation summary and chi-square statistics for each model fit. For more information, see the “Printed Output” on page 3256.

PRINTFP
prints the results for the initial pass of X11 made to exclude trading-day effects. This option has an effect only when the TDREGR= option specifies ADJUST, TEST, or PRINT. In these cases, an initial pass of the standard X11 method is required to get rid of calendar effects before doing any ARIMA estimation. Usually this first pass is not of interest, and by default no tables are printed. However, specifying PRINTFP in the ARIMA statement causes any tables printed in the final pass to also be printed for this initial pass.

TRANSFORM= (LOG) | LOG
TRANSFORM= ( constant ** power )
The ARIMA statement in PROC X11 allows certain transformations on the series before estimation. The specified transformation is applied only to a user-specified model. If TRANSFORM= is specified and the MODEL= option is not specified, the transformation request is ignored and a warning is printed.
The LOG transformation requests that the natural log of the series be used for estimation. The resulting forecast values are transformed back to the original scale.

A general power transformation of the form $X_t \rightarrow (X_t + a)^b$ is obtained by specifying

```
transform= ( a ** b )
```

If the constant $a$ is not specified, it is assumed to be zero. The specified ARIMA model is then estimated using the transformed series. The resulting forecast values are transformed back to the original scale.

**BY Statement**

```
BY variables ;
```

A BY statement can be used with PROC X11 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

**ID Statement**

```
ID variables ;
```

If you are creating an output data set, use the ID statement to put values of the ID variables, in addition to the table values, into the output data set. The ID statement has no effect when an output data set is not created. If the DATE= variable is specified in the MONTHLY or QUARTERLY statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from ARIMA forecasting or backcasting, or from YRAHEADOUT) are extrapolated, while all other ID variables are missing.

**MACURVES Statement**

```
MACURVES month=option . . . ;
```

The MACURVES statement specifies the length of the moving-average curves for estimating the seasonal factors for any month. This statement can be used only with monthly time series data.

The `month=option` specifications consist of the month name (or the first three letters of the month name), an equal sign, and one of the following option values:

- `'3'` specifies a three-term moving average for the month
- `'3X3'` specifies a three-by-three moving average
- `'3X5'` specifies a three-by-five moving average
- `'3X9'` specifies a three-by-nine moving average
- `STABLE` specifies a stable seasonal factor (average of all values for the month)

For example, the statement
macurves jan='3' feb='3x3' march='3x5' april='3x9';

uses a three-term moving average to estimate seasonal factors for January, a $3 \times 3$ (a three-term moving average of a three-term moving average) for February, a $3 \times 5$ (a three-term moving average of a five-term moving average) for March, and a $3 \times 9$ (a three-term moving average of a nine-term moving average) for April.

The numeric values used for the weights of the various moving averages and a discussion of the derivation of these weights are given in Shiskin, Young, and Musgrave (1967). A general discussion of moving average weights is given in Dagum (1985).

If the specification for a month is omitted, the X11 procedure uses a three-by-three moving average for the first estimate of each iteration and a three-by-five average for the second estimate.

---

**MONTHLY Statement**

```
MONTHLY options;
```

The MONTHLY statement must be used when the input data to PROC X11 are a monthly time series. The MONTHLY statement specifies options that determine the computations performed by PROC X11 and what is included in its output. Either the DATE= or START= option must be used.

The following options can appear in the MONTHLY statement:

**ADDITIVE**

performs additive adjustments. If the ADDITIVE option is omitted, PROC X11 performs multiplicative adjustments.

**CHARTS=STANDARD**

**CHARTS=FULL**

**CHARTS=NONE**

specifies the charts produced by the procedure. The default is CHARTS=STANDARD, which specifies 12 monthly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE.

The TABLES statement can also be used to specify particular monthly charts to be printed. If no CHARTS= option is given, and a TABLES statement is given, the TABLES statement overrides the default value of CHARTS=STANDARD; that is, no charts (or tables) are printed except those specified in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. You would specify the following statements:
monthly date=date;
tables g1 g4;

**DATE=** variable

specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have 12 years of monthly data (144 observations, no missing values) beginning in January 1970 and ending in December 1981, and you wanted to seasonally adjust only six years beginning in January 1974. Specifying

```
monthly date=date start=jan1974 end=dec1979;
```

would seasonally adjust only this subset of the data. If instead you wanted to adjust the last eight years of data, only the START= option is needed:

```
monthly date=date start=jan1974;
```

**END=** mmmyyyy

specifies that only the part of the input series ending with the month and year given be adjusted (for example, END=DEC1970). For information about using the START= and END= options to subset a series for processing, see the DATE= variable option.

**EXCLUDE=value**

excludes from the trading-day regression any irregular values that are more than value standard deviations from the mean. The EXCLUDE=value must be between 0.1 and 9.9, with the default value being 2.5.

**FULLWEIGHT=value**

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= value (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The FULLWEIGHT=value must be between 0.1 and 9.9 but must be less than the ZEROWEIGHT=value. The default is FULLWEIGHT=1.5.

**LENGTH**

includes length-of-month allowance in computing trading-day factors. If this option is omitted, length-of-month allowances are included with the seasonal factors.
**NDEC=n**
specifies the number of decimal places shown in the printed tables in the listing. This option has no effect on the precision of the variable values in the output data set.

**PMFACTOR=variable**
specifies a variable containing the prior monthly factors. Use this option if you have previous knowledge of monthly adjustment factors. The PMFACTOR= option can be used to make the following adjustments:

- adjust the level of all or part of a series with discontinuities
- adjust for the influence of holidays that fall on different dates from year to year, such as the effect of Easter on certain retail sales
- adjust for unreasonable weather influence on series, such as housing starts
- adjust for changing starting dates of fiscal years (for budget series) or model years (for automobiles)
- adjust for temporary dislocating events, such as strikes

For more information and examples using the PMFACTOR= option, see the section “Prior Daily Weights and Trading-Day Regression” on page 3248.

**PRINTOUT=STANDARD | LONG | FULL | NONE**
specifies the tables to be printed by the procedure. If the PRINTOUT=STANDARD option is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=None results in no tables being printed; however, charts are still printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also be used to specify particular monthly tables to be printed. If no PRINTOUT= option is specified, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are specified, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

**START=mmyyyy**
adjusts only the part of the input series starting with the specified month and year. When the DATE= option is not used, the START= option gives the year and month of the first input observation—for example, START=JAN1966. START= must be specified if DATE= is not given. If START= is specified (and no DATE= option is given), and an OUT= data set is requested, a variable named _DATE_ is added to the data set, giving the date value for each observation. For information about using the START= and END= options to subset a series, see the DATE= variable option.

**SUMMARY**
specifies that the data are already seasonally adjusted and the procedure is to produce summary measures. If the SUMMARY option is omitted, the X11 procedure performs seasonal adjustment of the input data before calculating summary measures.
**TDCOMPUTE=**year

uses the part of the input series beginning with January of the specified year to derive trading-day weights. If this option is omitted, the entire series is used.

**TDREGR=NONE | PRINT | ADJUST | TEST**

specifies the treatment of trading-day regression. TDREG=NONE omits the computation of the trading-day regression. TDREG=PRINT computes and prints the trading-day regressions but does not adjust the series. TDREG=ADJUST computes and prints the trading-day regression and adjusts the irregular components to obtain preliminary weights. TDREG=TEST adjusts the final series if the trading-day regression estimates explain significant variation on the basis of an F test (or residual trading-day variation if prior weights are used). The default is TDREGR=NONE.

For more information and examples using the TDREGR= option, see the section “Prior Daily Weights and Trading-Day Regression” on page 3248.

If ARIMA processing is requested, any value of TDREGR other than the default TDREGR=NONE will cause PROC X11 to perform an initial pass (see the section “Details: X11 Procedure” on page 3241 and the PRINTFP option).

The significance level reported in Table C15 should be viewed with caution. The dependent variable in the trading-day regression is the irregular component formed by an averaging operation. This induces a correlation in the dependent variable and hence in the residuals from which the F test is computed. Hence the distribution of the trading-day regression F statistics differs from an exact F; for more information, see Cleveland and Devlin (1980).

**TRENDADJ**

modifies extreme irregular values prior to computing the trend cycle estimates in the first iteration. If the TRENDADJ option is omitted, the trend cycle is computed without modifications for extremes.

**TRENDMA=9 | 13 | 23**

specifies the number of terms in the moving average to be used by the procedure in estimating the variable trend cycle component. The value of the TRENDMA= option must be 9, 13, or 23. If the TRENDMA= option is omitted, the procedure selects an appropriate moving average. For information about the number of terms in the moving average, see Shiskin, Young, and Musgrave (1967).

**ZEROWEIGHT=value**

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the ZEROWEIGHT= option are assigned zero weights. Values that fall between the two limits (ZEROWEIGHT= and FULLWEIGHT=) are assigned weights linearly graduated between 0 and 1. For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The ZEROWEIGHT=value must be between 0.1 and 9.9 but must be greater than the FULLWEIGHT=value. The default is ZEROWEIGHT=2.5.

The ZEROWEIGHT option can be used in conjunction with the FULLWEIGHT= option to adjust outliers from a monthly or quarterly series. For an illustration of this use, see Example 44.3 later in this chapter.
OUTPUT Statement

```
OUTPUT OUT= SAS-data-set tablename=var1 var2 . . . ;
```

The OUTPUT statement creates an output data set containing specified tables. The data set is named by the OUT= option.

**OUT=SAS-data-set**

If OUT= is omitted, the SAS System names the new data set by using the DATA convention.

For each table to be included in the output data set, write the X11 table identification keyword, an equal sign, and a list of new variable names:

```
tablename = var1 var2 . . .
```

The tablename keywords that can be used in the OUTPUT statement are listed in the section “Printed Output” on page 3256. The following is an example of a VAR statement and an OUTPUT statement:

```
var z1 z2 z3;
output out=out_x11 b1=s d11=w x y;
```

The variable s contains the Table B1 values for the variable z1, while the Table D11 values for variables z1, z2, and z3 are contained in variables w, x, and y, respectively. As this example shows, the list of variables following a tablename= keyword can be shorter than the VAR variable list.

In addition to the variables named by tablename =var1 var2 . . ., the ID variables, and BY variables, the output data set contains a date identifier variable. If the DATE= option is given in the MONTHLY or QUARTERLY statement, the DATE= variable is the date identifier. If no DATE= option is given, a variable named _DATE_ is the date identifier.

PDWEIGHTS Statement

```
PDWEIGHTS day=w . . . ;
```

The PDWEIGHTS statement can be used to specify one to seven daily weights. The statement can only be used with monthly series that are seasonally adjusted using the multiplicative model. These weights are used to compute prior trading-day factors, which are then used to adjust the original series prior to the seasonal adjustment process. Only relative weights are needed; the X11 procedure adjusts the weights so that they sum to 7.0. The weights can also be corrected by the procedure on the basis of estimates of trading-day variation from the input data.

For more information and examples using the PDWEIGHTS statement, see the section “Prior Daily Weights and Trading-Day Regression” on page 3248.

Each day=w option specifies a weight (w) for the named day. The day can be any day, Sunday through Saturday. The day keyword can be the full spelling of the day, or the three-letter abbreviation. For example, SATURDAY=1.0 and SAT=1.0 are both valid. The weights w must be a numeric value between 0.0 and 10.0.

The following is an example of a PDWEIGHTS statement:
pdweights sun=.2 mon=.9 tue=1 wed=1 thu=1 fri=.8 sat=.3;

Any number of days can be specified with one PDWEIGHTS statement. The default weight value for any day that is not specified is 0. If you do not use a PDWEIGHTS statement, the program computes daily weights if TDREGR=ADJUST is specified. For more information, see Shiskin, Young, and Musgrave (1967).

**QUARTERLY Statement**

```plaintext
QUARTERLY options;
```

The QUARTERLY statement must be used when the input data are quarterly time series. This statement includes options that determine the computations performed by the procedure and what is in the printed output. The DATE= option or the START= option must be used.

The following options can appear in the QUARTERLY statement:

- **ADDITIVE**
  - performs additive adjustments. If this option is omitted, the procedure performs multiplicative adjustments.

- **CHARTS=STANDARD**
- **CHARTS=FULL**
- **CHARTS=NONE**
  - specifies the charts to be produced by the procedure. The default value is CHARTS=STANDARD, which specifies four quarterly seasonal charts and a trend cycle chart. If you specify CHARTS=FULL (or CHARTS=ALL), the procedure prints additional charts of irregular and seasonal factors. To print no charts, specify CHARTS=NONE. The TABLES statement can also be used to specify particular charts to be printed. The presence of a TABLES statement overrides the default value of CHARTS=STANDARD; that is, if a TABLES statement is specified, and no CHARTS=option is specified, no charts (nor tables) are printed except those given in the TABLES statement. However, if both the CHARTS= option and a TABLES statement are given, the charts corresponding to the CHARTS= option and those requested by the TABLES statement are printed.

For example, suppose you wanted only charts G1, the final seasonally adjusted series and trend cycle, and G4, the final irregular and final modified irregular series. This is accomplished by specifying the following statements:

```plaintext
quarterly date=date;
  tables g1 g4;
```

- **DATE=** variable
  - specifies a variable that gives the date for each observation. The starting and ending dates are obtained from the first and last values of the DATE= variable, which must contain SAS date values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly. This variable is automatically added to the OUTPUT= data set if one is requested, and extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

The DATE= option and the START= and END= options can be used in combination to subset a series for processing. For example, suppose you have a series with 10 years of quarterly data (40 observations,
no missing values) beginning in ‘1970Q1’ and ending in ‘1979Q4’, and you want to seasonally adjust only four years beginning in ‘1974Q1’ and ending in ‘1977Q4’. Specifying

```
quarterly date=variable start='1974q1' end='1977q4';
```

seasonally adjusts only this subset of the data. If instead you wanted to adjust the last six years of data, only the START= option is needed:

```
quarterly date=variable start='1974q1';
```

END=‘yyyyQq’
specifies that only the part of the input series ending with the quarter and year given be adjusted (for example, END=‘1973Q4’). The specification must be enclosed in quotes, and q must be 1, 2, 3, or 4. For information about using the START= and END= options to subset a series, see the DATE= variable option.

FULLWEIGHT=value
assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values less than the FULLWEIGHT= value (in standard deviation units) are assigned full weights of 1, values that fall between the ZEROWEIGHT= and FULLWEIGHT= limits are assigned weights linearly graduated between 0 and 1, and values greater than the ZEROWEIGHT= limit are assigned a weight of 0.

For example, if ZEROWEIGHT=2 and FULLWEIGHT=1, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is FULLWEIGHT=1.5.

NDEC=n
specifies the number of decimal places shown on the output tables. This option has no effect on the precision of the variables in the output data set.

PRINTOUT=STANDARD
PRINTOUT=LONG
PRINTOUT=FULL
PRINTOUT=NONE
specifies the tables to print. If PRINTOUT=STANDARD is specified, between 17 and 27 tables are printed, depending on the other options that are specified. PRINTOUT=LONG prints between 27 and 39 tables, and PRINTOUT=FULL prints between 44 and 59 tables. Specifying PRINTOUT=NONE results in no tables being printed. The default is PRINTOUT=STANDARD.

The TABLES statement can also specify particular quarterly tables to be printed. If no PRINTOUT= is given, and a TABLES statement is given, the TABLES statement overrides the default value of PRINTOUT=STANDARD; that is, no tables (or charts) are printed except those given in the TABLES statement. However, if both the PRINTOUT= option and a TABLES statement are given, the tables corresponding to the PRINTOUT= option and those requested by the TABLES statement are printed.

START=‘yyyyQq’
adjusts only the part of the input series starting with the quarter and year given. When the DATE= option is not used, the START= option gives the year and quarter of the first input observation (for
example, \( \text{START}='1967Q1' \)). The specification must be enclosed in quotes, and \( q \) must be 1, 2, 3, or 4. \( \text{START} \) must be specified if the \( \text{DATE} \) option is not given. If \( \text{START} \) is specified (and no \( \text{DATE} \) is given), and an \( \text{OUTPUT} \) data set is requested, a variable named \(_{\text{DATE}}\) is added to the data set, giving the date value for a given observation. For information about using the \( \text{START} \) and \( \text{END} \) options to subset a series, see the \( \text{DATE} \) option.

**SUMMARY**

specifies that the input is already seasonally adjusted and that the procedure is to produce summary measures. If this option is omitted, the procedure performs seasonal adjustment of the input data before calculating summary measures.

**TRENDADJ**

modifies extreme irregular values prior to computing the trend cycle estimates. If this option is omitted, the trend cycle is computed without modification for extremes.

**ZEROWEIGHT=value**

assigns weights to irregular values based on their distance from the mean in standard deviation units. The weights are used for estimating seasonal and trend cycle components. Irregular values beyond the standard deviation limit specified in the **ZEROWEIGHT** option are assigned zero weights. Values that fall between the two limits (**ZEROWEIGHT** and **FULLWEIGHT**) are assigned weights linearly graduated between 0 and 1. For example, if **ZEROWEIGHT=2** and **FULLWEIGHT=1**, a value 1.3 standard deviations from the mean would be assigned a graduated weight. The default is **ZEROWEIGHT=2.5**.

The **ZEROWEIGHT** option can be used in conjunction with the **FULLWEIGHT** option to adjust outliers from a monthly or quarterly series. For an illustration of this use, see Example 44.3 later in this chapter.

---

**SSPAN Statement**

**SSPAN options ;**

The SSPAN statement applies sliding spans analysis to determine the suitability of seasonal adjustment for an economic series.

The following options can appear in the SSPAN statement:

**NDEC=n**

specifies the number of decimal places shown on selected sliding span reports. This option has no effect on the precision of the variables values in the OUTSPAN output data set.

**CUTOFF=value**

gives the percentage value for determining an excessive difference within a span for the seasonal factors, the seasonally adjusted series, and month-to-month and year-to-year differences in the seasonally adjusted series. The default value is 3.0. The use of the **CUTOFF=value** in determining the maximum percent difference (MPD) is described in the section “Computational Details for Sliding Spans Analysis” on page 3246. Caution should be used in changing the default **CUTOFF=value**. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when value is changed.
**TDCUTOFF=value**
gives the percentage value for determining an excessive difference within a span for the trading-day factors. The default value is 2.0. The use of the TDCUTOFF=value in determining the maximum percent difference (MPD) is described in the section “Computational Details for Sliding Spans Analysis” on page 3246. Caution should be used in changing the default TDCUTOFF=value. The empirical threshold ranges found by the U.S. Census Bureau no longer apply when the value is changed.

**NOPRINT**
suppresses all sliding span reports. For more information about sliding span reports, see the section “Computational Details for Sliding Spans Analysis” on page 3246.

**PRINT**
prints the summary sliding span reports S 0 through S 6.E.

**PRINTALL**
prints the summary sliding spans report S 0 through S 6.E, along with detail reports S 7.A through S 7.E.

---

**TABLES Statement**

```
TABLES tablenames;
```

The TABLES statement prints the tables specified in addition to the tables that are printed as a result of the PRINTOUT= option in the MONTHLY or QUARTERLY statement. Table names are listed in Table 44.4 later in this chapter.

To print only selected tables, omit the PRINTOUT= option in the MONTHLY or QUARTERLY statement and list the tables to be printed in the TABLES statement. For example, to print only the final seasonal factors and final seasonally adjusted series, use the statement

```
tables d10 d11;
```

---

**VAR Statement**

```
VAR variables;
```

The VAR statement is used to specify the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those appearing in a BY or ID statement or the variable named in the DATE= option in the MONTHLY or QUARTERLY statement.
Historical Development of X-11

This section briefly describes the historical development of the standard X-11 seasonal adjustment method and the later development of the X-11-ARIMA method. Most of the following discussion is based on a comprehensive article by Bell and Hillmer (1984), which describes the history of X-11 and the justification of using seasonal adjustment methods, such as X-11, given the current availability of time series software. For further discussions about statistical problems associated with the X-11 method, see Ghysels (1990).

Seasonal adjustment methods began to be developed in the 1920s and 1930s, before there were suitable analytic models available and before electronic computing devices were in existence. The lack of any suitable model led to methods that worked the same for any series—that is, methods that were not model-based and that could be applied to any series. Experience with economic series had shown that a given mathematical form could adequately represent a time series only for a fixed length; as more data were added, the model became inadequate. This suggested an approach that used moving averages. For further analysis of the properties of X-11 moving averages, see Cleveland and Tiao (1976).

The basic method was to break up an economic time series into long-term trend, long-term cyclical movements, seasonal movements, and irregular fluctuations.

Early investigators found that it was not possible to uniquely decompose the trend and cycle components. Thus, these two were grouped together; the resulting component is usually referred to as the “trend cycle component.”

It was also found that estimating seasonal components in the presence of trend produced biased estimates of the seasonal components, but, at the same time, estimating trend in the presence of seasonality was difficult. This eventually lead to the iterative approach used in the X-11 method.

Two other problems were encountered by early investigators. First, some economic series appear to have changing or evolving seasonality. Secondly, moving averages were very sensitive to extreme values. The estimation method used in the X-11 method allows for evolving seasonal components. For the second problem, the X-11 method uses repeated adjustment of extreme values.

All of these problems encountered in the early investigation of seasonal adjustment methods suggested the use of moving averages in estimating components. Even with the use of moving averages instead of a model-based method, massive amounts of hand calculations were required. Only a small number of series could be adjusted, and little experimentation could be done to evaluate variations on the method.

With the advent of electronic computing in the 1950s, work on seasonal adjustment methods proceeded rapidly. These methods still used the framework previously described; variants of these basic methods could now be easily tested against a large number of series.

Much of the work was done by Julian Shiskin and others at the U.S. Bureau of the Census beginning in 1954 and culminating after a number of variants into the X-11 Variant of the Census Method II Seasonal Adjustment Program, which PROC X11 implements.

References for this work during this period include Shiskin and Eisenpress (1957), Shiskin (1958), and Marris (1961). The authoritative documentation for the X-11 Variant is in Shiskin, Young, and Musgrave (1967). This document is not equivalent to a program specification; however, the FORTRAN code that implements

Development of the X-11-ARIMA Method

The X-11 method uses symmetric moving averages in estimating the various components. At the end of the series, however, these symmetric weights cannot be applied. Either asymmetric weights have to be used, or some method of extending the series must be found.

While various methods of extending a series have been proposed, the most important method to date has been the X-11-ARIMA method developed at Statistics Canada. This method uses Box-Jenkins ARIMA models to extend the series.

The Time Series Research and Analysis Division of Statistics Canada investigated 174 Canadian economic series and found five ARIMA models out of twelve that fit the majority of series well and reduced revisions for the most recent months. References that give details of various aspects of the X-11-ARIMA methodology include Dagum (1980, 1982a, c, 1983, 1988), Laniel (1985), Lothian and Morry (1978a), and Huot et al. (1986).

Differences between X11ARIMA/88 and PROC X11

The original implementation of the X-11-ARIMA method was by Statistics Canada in 1980 (Dagum 1980), with later changes and enhancements made in 1988 (Dagum 1988). The calculations performed by PROC X11 differ from those in X11ARIMA/88, which will result in differences in the final component estimates provided by these implementations.

There are three areas where Statistics Canada made changes to the original X-11 seasonal adjustment method in developing X11ARIMA/80 (Monsell 1984). These are (a) selection of extreme values, (b) replacement of extreme values, and (c) generation of seasonal and trend cycle weights.

These changes have not been implemented in the current version of PROC X11. Thus the procedure produces results identical to those from previous versions of PROC X11 in the absence of an ARIMA statement.

Additional differences can result from the ARIMA estimation. X11ARIMA/88 uses conditional least squares (CLS), while CLS, unconditional least squares (ULS) and maximum likelihood (ML) are all available in PROC X11 by using the METHOD= option in the ARIMA statement. Generally, parameters estimates will differ for the different methods.

Implementation of the X-11 Seasonal Adjustment Method

The following steps describe the analysis of a monthly time series using multiplicative seasonal adjustment. Additional steps used by the X-11-ARIMA method are also indicated. Equivalent descriptions apply for an additive model if you replace divide with subtract where applicable.

In the multiplicative adjustment, the original series $O_t$ is assumed to be of the form

$$O_t = C_t S_t I_t P_t D_t$$

where $C_t$ is the trend cycle component, $S_t$ is the seasonal component, $I_t$ is the irregular component, $P_t$ is the prior monthly factors component, and $D_t$ is the trading-day component.
The trading-day component can be further factored as

\[ D_t = D_{rr,t} D_{tr,t} \]

where \( D_{rr,t} \) are the trading-day factors derived from the prior daily weights, and \( D_{tr,t} \) are the residual trading-day factors estimated from the trading-day regression. For further information about estimating trading day variation, see Young (1965).

**Additional Steps When Using the X-11-ARIMA Method**

The X-11-ARIMA method consists of extending a given series by an ARIMA model and applying the usual X-11 seasonal adjustment method to this extended series. Thus in the simplest case in which there are no prior factors or calendar effects in the series, the ARIMA model selection, estimation, and forecasting are performed first, and the resulting extended series goes through the standard X-11 steps described in the next section.

If prior factor or calendar effects are present, they must be eliminated from the series before the ARIMA estimation is done because these effects are not stochastic.

Prior factors, if present, are removed first. Calendar effects represented by prior daily weights are then removed. If there are no further calendar effects, the adjusted series is extended by the ARIMA model, and this extended series goes through the standard X-11 steps without repeating the removal of prior factors and calendar effects from prior daily weights.

If further calendar effects are present, a trading-day regression must be performed. In this case it is necessary to go through an initial pass of the X-11 steps to obtain a final trading-day adjustment. In this initial pass, the series, adjusted for prior factors and prior daily weights, goes through the standard X-11 steps. At the conclusion of these steps, a final series adjusted for prior factors and all calendar effects is available. This adjusted series is then extended by the ARIMA model, and this extended series goes through the standard X-11 steps again, without repeating the removal of prior factors and calendar effects from prior daily weights and trading-day regression.

**The Standard X-11 Seasonal Adjustment Method**

The standard X-11 seasonal adjustment method consists of the following steps. These steps are applied to the original data or the original data extended by an ARIMA model.

1. In step 1, the data are read, ignoring missing values until the first nonmissing value is found. If prior monthly factors are present, the procedure reads prior monthly \( P_t \) factors and divides them into the original series to obtain \( O_t/P_t = C_t S_t I_t D_{rr,t} D_{tr,t} \).

Seven daily weights can be specified to develop monthly factors to adjust the series for trading-day variation, \( D_{tr,t} \); these factors are then divided into the original or prior adjusted series to obtain \( C_t S_t I_t D_{tr,t} \).

2. In steps 2, 3, and 4, three iterations are performed, each of which provides estimates of the seasonal \( S_t \), trading-day \( D_{tr,t} \), trend cycle \( C_t \), and irregular components \( I_t \). Each iteration refines estimates of the extreme values in the irregular components. After extreme values are identified and modified, final estimates of the seasonal component, seasonally adjusted series, trend cycle, and irregular components are produced. Step 2 consists of three substeps:
a) During the first iteration, a centered, 12-term moving average is applied to the original series $O_t$ to provide a preliminary estimate $\hat{C}_t$ of the trend cycle curve $C_t$. This moving average combines 13 (a 2-term moving average of a 12-term moving average) consecutive monthly values, removing the $S_t$ and $I_t$. Next, it obtains a preliminary estimate $\hat{S}_t I_t$ by

$$\hat{S}_t I_t = \frac{O_t}{\hat{C}_t}$$

b) A moving average is then applied to the $\hat{S}_t I_t$ to obtain an estimate $\hat{S}_t$ of the seasonal factors. $\hat{S}_t I_t$ is then divided by this estimate to obtain an estimate $\hat{I}_t$ of the irregular component. Next, a moving standard deviation is calculated from the irregular component and is used in assigning a weight to each monthly value for measuring its degree of extremeness. These weights are used to modify extreme values in $\hat{S}_t I_t$. New seasonal factors are estimated by applying a moving average to the modified value of $\hat{S}_t I_t$. A preliminary seasonally adjusted series is obtained by dividing the original series by these new seasonal factors. A second estimate of the trend cycle is obtained by applying a weighted moving average to this seasonally adjusted series.

c) The same process is used to obtain second estimates of the seasonally adjusted series and improved estimates of the irregular component. This irregular component is again modified for extreme values and then used to provide estimates of trading-day factors and refined weights for the identification of extreme values.

3. Using the same computations, a second iteration is performed on the original series that has been adjusted by the trading-day factors and irregular weights developed in the first iteration. The second iteration produces final estimates of the trading-day factors and irregular weights.

4. A third and final iteration is performed using the original series that has been adjusted for trading-day factors and irregular weights computed during the second iteration. During the third iteration, PROC X11 develops final estimates of seasonal factors, the seasonally adjusted series, the trend cycle, and the irregular components. The procedure computes summary measures of variation and produces a moving average of the final adjusted series.

**Sliding Spans Analysis**

The motivation for sliding spans analysis is to answer the question, When is an economic series unsuitable for seasonal adjustment? There have been a number of past attempts to answer this question: stable seasonality $F$ test; moving seasonality $F$ test, $Q$ statistics, and others.

Sliding spans analysis attempts to quantify the stability of the seasonal adjustment process, and hence quantify the suitability of seasonal adjustment for a given series.

It is based on a very simple idea: for a stable series, deleting a small number of observations should not result in greatly different component estimates compared with the original, full series. Conversely, if deleting a small number of observations results in drastically different estimates, the series is unstable. For example, a drastic difference in the seasonal factors (Table D10) might result from a dominating irregular component or sudden changes in the seasonally component. When the seasonal component estimates of a series is unstable in this manner, they have little meaning and the series is likely to be unsuitable for seasonal adjustment.

Sliding spans analysis, developed at the Statistical Research Division of the U.S. Census Bureau (Findley et al. 1990; Findley and Monsell 1986), performs a repeated seasonal adjustment on subsets or spans of the
full series. In particular, an initial span of the data, typically eight years in length, is seasonally adjusted, and the Tables C18, the trading-day factors (if trading-day regression performed), D10, the seasonal factors, and D11, the seasonally adjusted series are retained for further processing. Next, one year of data is deleted from the beginning of the initial span and one year of data is added. This new span is seasonally adjusted as before, with the same tables retained. This process continues until the end of the data is reached. The beginning and ending dates of the spans are such that the last observation in the original data is also the last observation in the last span. This is discussed in more detail in the following paragraphs.

The following notation for the components or differences computed in the sliding spans analysis follows Findley et al. (1990). The meaning for the symbol $X_t(k)$ is component $X$ in month (or quarter) $t$, computed from data in the $k$th span. These components are now defined.

- **Seasonal Factors (Table D10):** $S_t(k)$
- **Trading-Day Factors (Table C18):** $TD_t(k)$
- **Seasonally Adjusted Data (Table D11):** $SA_t(k)$
- **Month-to-Month Changes in the Seasonally Adjusted Data:** $MM_t(k)$
- **Year-to-Year Changes in the Seasonally Adjusted Data:** $YY_t(k)$

The key measure is the maximum percent difference across spans. For example, consider a series that begins in January 1972, ends in December 1984, and has four spans, each of length 8 years (see Figure 1 in Findley et al. (1990), p. 346). Consider $S_t(k)$ the seasonal factor (Table D10) for month $t$ for span $k$, and let $N_t$ denote the number of spans containing month $t$; that is,

$$N_t = \{k : \text{span } k \text{ contains month } t\}$$

In the middle years of the series there is overlap of all four spans, and $N_t$ will be 4. The last year of the series will have only one span, while the beginning can have 1 or 0 spans depending on the original length.

Since we are interested in how much the seasonal factors vary for a given month across the spans, a natural quantity to consider is

$$\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)$$

In the case of the multiplicative model, it is useful to compute a percentage difference; define the maximum percentage difference (MPD) at time $t$ as

$$MPD_t = \frac{\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)}{\min_{k \in N_t} S_t(k)}$$

The seasonal factor for month $t$ is then unreliable if $MPD_t$ is large. While no exact significance level can be computed for this statistic, empirical levels have been established by considering over 500 economic series (Findley et al. 1990; Findley and Monsell 1986). For these series it was found that for four spans, stable series typically had less than 15% of the MPD values exceeding 3.0%, while in marginally stable series, between 15% and 25% of the MPD values exceeded 3.0%. A series in which 25% or more of the MPD values exceeded 3.0% is almost always unstable.

While these empirical values cannot be considered an exact significance level, they provide a useful empirical basis for deciding if a series is suitable for seasonal adjustment. These percentage values are shifted down when fewer than four spans are used.
Computational Details for Sliding Spans Analysis

Length and Number of Spans

The algorithm for determining the length and number of spans for a given series was developed at the U.S. Bureau of the Census, Statistical Research Division. A summary of this algorithm is as follows.

First, an initial length based on the MACURVE month=option specification is determined, and then the maximum number of spans possible using this length is determined. If this maximum number exceeds four, set the number of spans to four. If this maximum number is one or zero, there are not enough observations to perform the sliding spans analysis. In this case a note is written to the log and the sliding spans analysis is skipped for this variable.

If the maximum number of spans is two or three, the actual number of spans used is set equal to this maximum. Finally, the length is adjusted so that the spans begin in January (or the first quarter) of the beginning year of the span.

The remainder of this section gives the computation formulas for the maximum percentage difference (MPD) calculations along with the threshold regions.

Seasonal Factors (Table D10)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)$$

For the multiplicative model, the MPD is

$$\text{MPD}_t = \frac{\max_{k \in N_t} S_t(k) - \min_{k \in N_t} S_t(k)}{\min_{k \in N_t} S_t(k)}$$

A series for which less than 15% of the MPD values of D10 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% is unstable. Span reports S 2.A through S 2.C give the various breakdowns for the number of times the MPD exceeded these levels.

Trading Day Factor (Table C18)

For the additive model, the MPD is defined as

$$\max_{k \in N_t} TD_t(k) - \min_{k \in N_t} TD_t(k)$$

For the multiplicative model, the MPD is

$$\text{MPD}_t = \frac{\max_{k \in N_t} TD_t(k) - \min_{k \in N_t} TD_t(k)}{\min_{k \in N_t} TD_t(k)}$$

The U.S. Census Bureau currently gives no recommendation concerning MPD thresholds for the trading-day factors. Span reports S 3.A through S 3.C give the various breakdowns for MPD thresholds. When TDREGR=NONE is specified, no trading-day computations are done, and this table is skipped.
Seasonally Adjusted Data (Table D11)

For the additive model, the MPD is defined as
\[
\max_{k \in N_1} SA_t(k) - \min_{k \in N_1} SA_t(k)
\]

For the multiplicative model, the MPD is
\[
\text{MPD}_t = \frac{\max_{k \in N_1} SA_t(k) - \min_{k \in N_1} SA_t(k)}{\min_{k \in N_1} SA_t(k)}
\]

A series for which less than 15% of the MPD values of D11 exceed 3.0% is stable; between 15% and 25% is marginally stable; and greater than 25% is unstable. Span reports S 4.A through S 4.C give the various breakdowns for the number of times the MPD exceeded these levels.

Month-to-Month Changes in the Seasonally Adjusted Data

Some additional notation is needed for the month-to-month and year-to-year differences. Define \( N_1_t \) as
\[
N_1_t = \{ k : \text{span } k \text{ contains month } t \text{ and } t - 1 \}
\]

For the additive model, the month-to-month change for span \( k \) is defined as
\[
\text{MM}_t(k) = SA_t - SA_{t-1}
\]

while for the multiplicative model
\[
\text{MM}_t(k) = \frac{SA_t - SA_{t-1}}{SA_{t-1}}
\]

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined as
\[
\text{MPD}_t = \max_{k \in N_1} \text{MM}_t(k) - \min_{k \in N_1} \text{MM}_t(k)
\]

The current recommendation of the U.S. Census Bureau is that if 35% or more of the MPD values of the month-to-month differences of D11 exceed 3.0%, then the series is usually not stable; 40% exceeding this level clearly marks an unstable series. Span reports S 5.A.1 through S 5.C give the various breakdowns for the number of times the MPD exceeds these levels.

Year-to-Year Changes in the Seasonally Adjusted Data

First define \( N_{12} \) as
\[
N_{12} = \{ k : \text{span } k \text{ contains month } t \text{ and } t - 12 \}
\]

(Appropriate changes in notation for a quarterly series are obvious.)

For the additive model, the month-to-month change for span \( k \) is defined as
\[
\text{YY}_t(k) = SA_t - SA_{t-12}
\]
while for the multiplicative model

$$YY_t(k) = \frac{SA_t - SA_{t-12}}{SA_{t-12}}$$

Since this quantity is already in percentage form, the MPD for both the additive and multiplicative model is defined as

$$\text{MPD}_t = \max_{k \in N_1} YY_t(k) - \min_{k \in N_1} YY_t(k)$$

The current recommendation of the U.S. Census Bureau is that if 10% or more of the MPD values of the month-to-month differences of D11 exceed 3.0%, then the series is usually not stable. Span reports S 6.A through S 6.C give the various breakdowns for the number of times the MPD exceeds these levels.

**Data Requirements**

The input data set must contain either quarterly or monthly time series, and the data must be in chronological order. For the standard X-11 method, there must be at least three years of observations (12 for quarterly time series or 36 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

For the X-11-ARIMA method, there must be at least five years of observations (20 for quarterly time series or 60 for monthly) in the input data sets or in each BY group in the input data set if a BY statement is used.

**Missing Values**

Missing values at the beginning of a series to be adjusted are skipped. Processing starts with the first nonmissing value and continues until the end of the series or until another missing value is found.

Missing values are not allowed for the DATE= variable. The procedure terminates if missing values are found for this variable.

Missing values found in the PMFACTOR= variable are replaced by 100 for the multiplicative model (default) and by 0 for the additive model.

Missing values can occur in the output data set. If the time series specified in the OUTPUT statement is not computed by the procedure, the values of the corresponding variable are missing. If the time series specified in the OUTPUT statement is a moving average, the values of the corresponding variable are missing for the first \(n\) and last \(n\) observations, where \(n\) depends on the length of the moving average. Additionally, if the time series specified is an irregular component modified for extremes, only the modified values are given, and the remaining values are missing.

**Prior Daily Weights and Trading-Day Regression**

Suppose that a detailed examination of retail sales at ZXY Company indicates that certain days of the week have higher amounts of sales. In particular, Thursday, Friday, and Saturday have approximately twice the
amount of sales as Monday, Tuesday, and Wednesday, and no sales occur on Sunday. This means that months with five Saturdays would have higher amounts of sales than months with only four Saturdays.

This phenomenon is called a calendar effect; it can be handled in PROC X11 by using the PDWEIGHTS (prior daily weights) statement or the TDREGR=option (trading-day regression). The PDWEIGHTS statement and the TDREGR=option can be used separately or together.

If the relative weights are known (as in the preceding) it is appropriate to use the PDWEIGHTS statement. If further residual calendar variation is present, TDREGR=ADJUST should also be used. If you know that a calendar effect is present, but know nothing about the relative weights, use TDREGR=ADJUST without a PDWEIGHTS statement.

In this example, it is assumed that the calendar variation is due to both prior daily weights and residual variation. Thus both a PDWEIGHTS statement and TDREGR=ADJUST are specified.

Note that only the relative weights are needed; in the actual computations, PROC X11 normalizes the weights to sum to 7.0. If a day of the week is not present in the PDWEIGHTS statement, it is given a value of zero. Thus “sun=0” is not needed.

```
proc x11 data=sales;
  monthly date=date tdregr=adjust;
  var sales;
  tables a1 a4 b15 b16 c14 c15 c18 d11;
  pdweights mon=1 tue=1 wed=1 thu=2 fri=2 sat=2;
  output out=x11out a1=a1 a4=a4 b1=b1 c14=c14
               c16=c16 c18=c18 d11=d11;
run;
```

Tables of interest include A1, A4, B15, B16, C14, C15, C18, and D11. Table A4 contains the adjustment factors derived from the prior daily weights; Table C14 contains the extreme irregular values excluded from trading-day regression; Table C15 contains the trading-day-regression results; Table C16 contains the monthly factors derived from the trading-day regression; and Table C18 contains the final trading-day factors derived from the combined daily weights. Finally, Table D11 contains the final seasonally adjusted series.

---

**Adjustment for Prior Factors**

Suppose now that a strike at ZXY Company during July and August of 1988 caused sales to decrease an estimated 50%. Since this is a one-time event with a known cause, it is appropriate to prior adjust the data to reflect the effects of the strike. This is done in PROC X11 through the use of PMFACTOR=varname (prior monthly factor) in the MONTHLY statement.

In the following example, the PMFACTOR variable is named PMF. Since the estimate of the decrease in sales is 50%, PMF has a value of 50.0 for the observations corresponding to July and August 1988, and a value of 100.0 for the remaining observations.

This prior adjustment on SALES is performed by replacing SALES with the calculated value (SALES/PMF) * 100.0. A value of 100.0 for PMF leaves SALES unchanged, while a value of 50.0 for PMF doubles SALES. This value is the estimate of what SALES would have been without the strike. The following example shows how this prior adjustment is accomplished:
data sales2;
    set sales;
    if '01jul1988'd <= date <= '01aug1988'd then pmf = 50;
    else pmf = 100;
run;

proc x11 data=sales2;
    monthly date=date pmfactor=pmf;
    var sales;
    tables a1 a2 a3 d11;
    output out=x11out a1=a1 a2=a2 a3=a3 d11=d11;
run;

Table A2 contains the prior monthly factors (the values of PMF), and Table A3 contains the prior adjusted series.

---

The **YRAHEADOUT Option**

For monthly data, the YRAHEADOUT option affects only Tables C16 (regression trading-day adjustment factors), C18 (trading-day factors from combined daily weights), and D10 (seasonal factors). For quarterly data, only Table D10 is affected. Variables for all other tables have missing values for the forecast observations. The forecast values for a table are included only if that table is specified in the OUTPUT statement.

Tables C16 and C18 are calendar effects that are extrapolated by calendar composition. These factors are independent of the data once trading-day weights have been calculated. Table D10 is extrapolated by a linear combination of past values. If \( N \) is the total number of nonmissing observations for the analysis variable, this linear combination is given by

\[
D10_t = \frac{1}{2} (3 \times D10_{t-12} - D10_{t-24}), \quad t = N + 1, \ldots, N + 12
\]

If the input data are monthly time series, 12 extra observations are added to the end of the output data set. (If a BY statement is used, 12 extra observations are added to the end of each BY group.) If the input data are a quarterly time series, four extra observations are added to the end of the output data set. (If a BY statement is used, four extra observations are added to each BY group.)

The DATE= variable (or _DATE_) is extrapolated for the extra observations generated by the YRAHEADOUT option, while all other ID variables will have missing values.

If ARIMA processing is requested, and if both the OUTEXTRAP and YRAHEADOUT options are specified in the PROC X11 statement, an additional 12 (or 4) observations are added to the end of output data set for monthly (or quarterly) data after the ARIMA forecasts, using the same linear combination of past values as before.

---

Effect of Backcast and Forecast Length

Based on a number of empirical studies (Dagum 1982a, b, c; Dagum and Laniel 1987), one year of forecasts minimize revisions when new data become available. Two and three years of forecasts show only small gains.
Backcasting improves seasonal adjustment but introduces permanent revisions at the beginning of the series and also at the end for series of length 8, 9, or 10 years. For series shorter than 7 years, the advantages of backcasting outweigh the disadvantages (Dagum 1988).

Other studies (Pierce 1980; Bobbitt and Otto 1990; Buszuwski 1987) suggest “full forecasting”—that is, using enough forecasts to allow symmetric weights for the seasonal moving averages for the most current data. For example, if a $3 \times 9$ seasonal moving average was specified for one or more months by using the MACURVES statement, five years of forecasts would be required. This is because the seasonal moving averages are performed on calendar months separately, and the $3 \times 9$ is an 11-term centered moving average, requiring five observations before and after the current observation. Thus

```plaintext
macurves dec='3x9';
```

would require five additional December values to compute the seasonal moving average.

---

**Details of Model Selection**

If an ARIMA statement is present but no MODEL= is given, PROC X11 estimates and forecasts five predefined models and selects the best. This section describes the details of the selection criteria and the selection process.

The five predefined models used by PROC X11 are the same as those used by X11ARIMA/88 from Statistics Canada. These particular models, shown in Table 44.2, were chosen on the basis of testing a large number of economics series (Dagum 1988) and should provide reasonable forecasts for most economic series.

### Table 44.2 Five Predefined Models

<table>
<thead>
<tr>
<th>Model #</th>
<th>Specification</th>
<th>Multiplicative</th>
<th>Additive</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>(0,1,1)(0,1,1)s</td>
<td>Log transform</td>
<td>No transform</td>

<td>Log transform</td>
<td>No transform</td>
</tr>
<tr>
<td>5</td>
<td>(2,1,2)(0,1,1)s</td>
<td>No transform</td>
<td>No transform</td>
</tr>
</tbody>
</table>

The selection process proceeds as follows. The five models are estimated and one-step-ahead forecasts are produced in the order shown in Table 44.2. As each model is estimated, the following three criteria are checked:

- The mean absolute percent error (MAPE) for the last three years of the series must be less than 15%.
- The significance probability for the Box-Ljung chi-square for up to lag 24 for monthly (8 for quarterly) must greater than 0.05.
- The over-differencing criteria must not exceed 0.9.

The descriptions of these three criteria are given in the section “Criteria Details” on page 3252. The default values for these criteria are those used by X11ARIMA/88 from Statistics Canada; these defaults can be changed by the MAPECR=, CHICR=, and OVDIFCR= options.
A model that fails any one of these three criteria is excluded from further consideration. In addition, if the ARIMA estimation fails for a given model, a warning is issued, and the model is excluded. The final set of all models considered consists of those that pass all three criteria and are estimated successfully. From this set, the model with the smallest MAPE for the last three years is chosen.

If all five models fail, ARIMA processing is skipped for the variable being processed, and the standard X-11 seasonal adjustment is performed. A note is written to the log with this information.

The chosen model is then used to forecast the series one or more years (determined by the FORECAST= option in the ARIMA statement). These forecasts are appended to the original data (or the prior and calendar-adjusted data).

If a BACKCAST= option is specified, the chosen model form is used, but the parameters are reestimated using the reversed series. Using these parameters, the reversed series is forecast for the number of years specified by the BACKCAST= option. These forecasts are then reversed and appended to the beginning of the original series, or the prior and calendar-adjusted series, to produce the backcasts.

Note that the final selection rule (the smallest MAPE using the last three years) emphasizes the quality of the forecasts at the end of the series. This is consistent with the purpose of the X-11-ARIMA methodology, which is to improve the estimates of seasonal factors and thus minimize revisions to recent past data as new data become available.

**Criteria Details**

**Mean Absolute Percent Error (MAPE)**
For the MAPE criteria testing, only the last three years of the original series (or prior and calendar adjusted series) are used in computing the MAPE.

Let $y_t, t = 1, \ldots, n$, be the last three years of the series, and denote its one-step-ahead forecast by $\hat{y}_t$, where $n = 36$ for a monthly series and $n = 12$ for a quarterly series.

With this notation, the MAPE criteria are computed as

$$MAPE = \frac{100}{n} \sum_{t=1}^{n} \frac{|y_t - \hat{y}_t|}{|y_t|}$$

**Box-Ljung Chi-Square**
The Box-Ljung chi-square is a lack-of-fit test based on the model residuals. This test statistic is computed using the Ljung-Box formula

$$\chi^2_m = n(n + 2) \sum_{k=1}^{m} \frac{r_k^2}{(n - k)}$$

where $n$ is the number of residuals that can be computed for the time series, and

$$r_k = \frac{\sum_{t=1}^{n-k} a_t a_{t+k}}{\sum_{t=1}^{n} a_t^2}$$

where the $a_t$'s are the residual sequence. This formula has been suggested by Ljung and Box (1978) as yielding a better fit to the asymptotic chi-square distribution. Some simulation studies of the finite sample properties of this statistic are given by Davies, Triggs, and Newbold (1977) and by Ljung and Box (1978).

For monthly series, $m = 24$, while for quarterly series, $m = 8$. 

**Over-differencing Test**

From Table 44.2 you can see that all models have a single seasonal MA factor and at most two nonseasonal MA factors. Also, all models have seasonal and nonseasonal differencing. Consider model 2 applied to a monthly series $y_t$ with $E(y_t) = \mu$:

$$(1 - B^1)(1 - B^{12})(y_t - \mu) = (1 - \theta_1 B - \theta_2 B^2)(1 - \theta_3 B^{12})a_t$$

If $\theta_3 = 1.0$, then the factors $(1 - \theta_3 B^{12})$ and $(1 - B^{12})$ will cancel, resulting in a lower-order model.

Similarly, if $\theta_1 + \theta_2 = 1.0$,

$$(1 - \theta_1 B - \theta_2 B^2) = (1 - B)(1 - \alpha B)$$

for some $\alpha \neq 0.0$. Again, this results in cancellation and a lower-order model.

Since the parameters are not exact, it is not reasonable to require that

$$\theta_3 < 1.0 \text{ and } \theta_1 + \theta_2 < 1.0$$

Instead, an approximate test is performed by requiring that

$$\theta_3 \leq 0.9 \text{ and } \theta_1 + \theta_2 \leq 0.9$$

The default value of 0.9 can be changed by the OVDIFCR= option. Similar reasoning applies to the other models.

**ARIMA Statement Options for the Five Predefined Models**

Table 44.3 lists the five predefined models and gives the equivalent MODEL= parameters in a PROC X11 ARIMA statement.

In all models except the fifth, a log transformation is performed before the ARIMA estimation for the multiplicative case; no transformation is performed for the additive case. For the fifth model, no transformation is done for either case.

The multiplicative case is assumed in Table 44.3. The indicated seasonality $s$ in the specification is either 12 (monthly) or 4 (quarterly). The MODEL statement assumes a monthly series.

<table>

</tr>
</tbody>
</table>
OUT= Data Set

The OUT= data set specified in the OUTPUT statement contains the BY variables, if any; the ID variables, if any; and the DATE= variable if the DATE= option is given, or _DATE_ if the DATE= option is not specified. In addition, the variables specified by the option

\[ \text{tablename=} \ var1 \ var2 \ldots \ varn \]

are placed in the OUT= data set. A list of tables available for monthly and quarterly series is given later, in Table 44.4.

The OUTSPAN= Data Set

The OUTSPAN= option is specified in the PROC statement, and writes the sliding spans results to the specified output data set. The OUTSPAN= data set contains the following variables:

- **A1**, a numeric variable that is a copy of the original series truncated to the current span. Note that overlapping spans will contain identical values for this variable.
- **C18**, a numeric variable that contains the trading-day factors for the seasonal adjustment for the current span
- **D10**, a numeric variable that contains the seasonal factors for the seasonal adjustment for the current span
- **D11**, a numeric variable that contains the seasonally adjusted series for the current span
- **DATE**, a numeric variable that contains the date within the current span
- **SPAN**, a numeric variable that contains the current span. The first span is the earliest span—that is, the one with the earliest starting date.
- **VARNAME**, a character variable containing the name of each variable in the VAR list. A separate sliding spans analysis is performed on each variable in the VAR list.

OUTSTB= Data Set

The output data set produced by the OUTSTB= option of the PROC X11 statement contains the information in the analysis of variance on Table D8 (Final Unmodified S-I Ratios). This analysis of variance, following Table D8 in the printed output, tests for stable seasonality (Shiskin, Young, and Musgrave 1967, Appendix A). These data contain the following variables:

- **VARNAME**, a character variable containing the name of each variable in the VAR list
• **TABLE**, a character variable specifying the table from which the analysis of variance is performed. When ARIMA processing is requested, and two passes of PROC X11 are required (when TDREGR=PRINT, TEST, or ADJUST), Table D8 and the stable seasonality test are computed twice: once in the initial pass, then again in the final pass. Both of these computations are put in the OUTSTB data set and are identified by D18.1 and D18.2, respectively.

• **SOURCE**, a character variable corresponding to the “source” column in the analysis of variance table following Table D8

• **SS**, a numeric variable containing the sum of squares associated with the corresponding source term

• **DF**, a numeric variable containing the degrees of freedom associated with the corresponding source term

• **MS**, a numeric variable containing the mean square associated with the corresponding source term. MS is missing for the source term “Total.”

• **F**, a numeric variable containing the $F$ statistic for the “Between” source term. $F$ is missing for all other source terms.

• **PROBF**, a numeric variable containing the significance level for the $F$ statistic. PROBF is missing for the source terms “Total” and “Error.”

---

**OUTTDR= Data Set**

The trading-day regression results (Tables B15 and C15) are written to the OUTTDR= data set, which contains the following variables:

- **VARNAME**, a character variable containing the name of the VAR variable being processed

- **TABLE**, a character variable containing the name of the table. It can have only the value B15 (Preliminary Trading-Day Regression) or C15 (Final Trading-Day Regression).

- **_TYPE_**, a character variable whose value distinguishes the three distinct table format types. These types are (a) the regression, (b) the listing of the standard error associated with length-of-month, and (c) the analysis of variance. The first seven observations in the OUTTDR= data set correspond to the regression on days of the week; thus the _TYPE_ variable is given the value “REGRESS” (day-of-week regression coefficient). The next four observations correspond to 31-, 30-, 29-, and 28-day months and are given the value _TYPE_=LOM_STD (length-of-month standard errors). Finally, the last three observations correspond to the analysis of variance table, and _TYPE_=ANOVA.

- **PARM**, a character variable, further identifying the nature of the observation. PARM is set to blank for the three _TYPE_=ANOVA observations.

- **SOURCE**, a character variable containing the source in the regression. This variable is missing for all _TYPE_=REGRESS and LOM_STD.

- **CWGT**, a numeric variable containing the combined trading-day weight (prior weight + weight found from regression). The variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.
• PRWGT, a numeric variable containing the prior weight. The prior weight is 1.0 if PDWEIGHTS are not specified. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

• COEFF, a numeric variable containing the calculated regression coefficient for the given day. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

• STDERR, a numeric variable containing the standard errors. For observations with _TYPE_=REGRESS, this is the standard error corresponding to the regression coefficient. For observations with _TYPE_=LOM_STD, this is standard error for the corresponding length-of-month. This variable is missing for all _TYPE_=ANOVA.

• T1, a numeric variable containing the $t$ statistic corresponding to the test that the combined weight is different from the prior weight. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

• T2, a numeric variable containing the $t$ statistic corresponding to the test that the combined weight is different from 1.0. This variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

• PROBT1, a numeric variable containing the significance level for $t$ statistic T1. The variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

• PROBT2, a numeric variable containing the significance level for $t$ statistic T2. The variable is missing for all _TYPE_=LOM_STD and _TYPE_=ANOVA.

• SS, a numeric variable containing the sum of squares associated with the corresponding source term. This variable is missing for all _TYPE_=REGRESS and LOM_STD.

• DF, a numeric variable containing the degrees of freedom associated with the corresponding source term. This variable is missing for all _TYPE_=REGRESS and LOM_STD.

• MS, a numeric variable containing the mean square associated with the corresponding source term. This variable is missing for the source term ‘Total’ and for all _TYPE_=REGRESS and LOM_STD.

• F, a numeric variable containing the $F$ statistic for the ‘Regression’ source term. The variable is missing for the source terms ‘Total’ and ‘Error’ and for all _TYPE_=REGRESS and LOM_STD.

• PROBF, a numeric variable containing the significance level for the $F$ statistic. This variable is missing for the source term ‘Total’ and ‘Error’ and for all _TYPE_=REGRESS and LOM_STD.

Printed Output

The output from PROC X11, both printed tables and the series written to the OUT= data set, depends on whether the data are monthly or quarterly. For the printed tables, the output depends further on the value of the PRINTOUT= option and the TABLE statement, along with other options specified.

The printed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X11 procedure are as follows:
Table 44.4 describes the individual tables and charts. Most tables apply to both quarterly and monthly series. Those that apply only to a monthly time series are indicated by an “M” in the notes section, while “P” indicates that the table is not a time series, and is only printed, not output to the OUT= data set.

</table>
The PRINTOUT= Option

The PRINTOUT= option controls printing for groups of tables. For information about specifying individual tables, see the section “TABLES Statement” on page 3240. The following list gives the tables printed for each value of the PRINTOUT= option:

STANDARD (26 tables) A1–A4, B1, C13–C19, D8–D13, E1–E6, F1, F2
LONG (40 tables) A1–A5, A13–A15, B1, B2, B7, B10, B13–B15, C1, C7, C10, C13–C19, D1, D7–D11, D13, E1–E6, F1, F2
FULL (62 tables) A1–A5, A13–A15, B1–B11, B13–B19, C1–C11, C13–C19, D1, D2, D4–D12, E1–E6, F1, F2

The actual number of tables printed depends on the options and statements specified. If a table is not computed, it is not printed. For example, if TDREGR=NONE is specified, none of the tables associated with the trading-day are printed.

The CHARTS= Option

Of the four charts listed in Table 44.4, G1 and G2 are printed by default (CHARTS=STANDARD). Charts G3 and G4 are printed when CHARTS=FULL is specified. For information about specifying individual charts, see the section “TABLES Statement” on page 3240.

Stable, Moving, and Combined Seasonality Tests on the Final Unmodified SI Ratios (Table D8)

PROC X11 displays four tests used to identify stable seasonality and moving seasonality and to measure identifiable seasonality. These tests are displayed after Table D8. They are “Stable Seasonality Test,” “Moving Seasonality Test,” “Nonparametric Test for the Presence of Seasonality Assuming Stability,” and “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” The motivation, interpretation, and statistical details of all these tests are now given.

**Motivation**

The seasonal component of this time series, $S_t$, is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality). If the increase in the seasonal factors from year to year is too large, then the seasonal factors will introduce distortion into the model. It is important to determine if seasonality is identifiable without distorting the series.

To determine if stable seasonality is present in a series, PROC X11 computes a one-way analysis of variance by using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use because the removal of the trend cycle is equivalent to detrending. PROC X11 prints this test, labeled “Stable Seasonality Test,” immediately after the Table D8.

The X11 seasonal adjustment method tests for moving seasonality. Moving seasonality can be a source of distortion when seasonal factors are used in the model. PROC X11 computes and prints a test for moving seasonality. The test is a two-way analysis of variance that uses months (or quarters) and years. As in the “Stable Seasonality Test,” this analysis of variance is performed on the Final Unmodified SI Ratios (Table D8). PROC X11 prints this test, labeled “Moving Seasonality Test,” after the “Stable Seasonality Test.”

PROC X11 next computes a nonparametric Kruskal-Wallis chi-squared test for stable seasonality. “Nonparametric Test for the Presence of Seasonality Assuming Stability.” The Kruskal-Wallis test is performed on the
The results of the preceding three tests are combined into a joint test to measure identifiable seasonality, “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” This test combines the two $F$ tests previously described, along with the Kruskal-Wallis chi-squared test for stable seasonality, to determine “identifiable” seasonality. This test is printed after “Nonparametric Test for the Presence of Seasonality Assuming Stability.”

**Interpretation and Statistical Details**

The “Stable Seasonality Test” is a one-way analysis of variance on the “Final Unmodified SI Ratios” with seasons (months or quarters) as the factor.

To determine whether stable seasonality is present in a series, PROC X11 computes a one-way analysis of variance by using the seasons (months or quarters) as the factor on the Final Unmodified SI Ratios (Table D8). This is the appropriate table to use because the removal of the trend cycle is similar to detrending.

A large $F$ statistic and a small significance level are evidence that a significant amount of variation in the SI-ratios is due to months or quarters, which in turn is evidence of seasonality; the null hypothesis of no month/quarter effect is rejected.

Conversely, a small $F$ statistic and a large significance level (close to 1.0) are evidence that variation due to month or quarter could be due to random error, and the null hypothesis of no month/quarter effect is not rejected. The interpretation and utility of seasonal adjustment are problematic under such conditions.

The $F$ test for moving seasonality is performed by a two-way analysis of variance. The two factors are seasons (months or quarters) and years. The years effect is tested separately; the null hypothesis is no effect due to years after accounting for variation due to months or quarters. For more information about the moving seasonality test, see Lothian (1984a, b, 1978) and Higginson (1975).

The significance level reported in both the moving and stable seasonality tests are only approximate. Table D8, the Final Unmodified SI Ratios, is constructed from an averaging operation that induces a correlation in the residuals from which the $F$ test is computed. Hence the computed $F$ statistic differs from an exact $F$ statistic; for more information, see Cleveland and Devlin (1980).

The test for identifiable seasonality is performed by combining the $F$ tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The following description is based on Lothian and Morry (1978b); for more information, see Dagum (1988, 1983).

Let $F_s$ and $F_m$ denote the $F$ value for the stable and moving seasonality tests, respectively. The combined test is performed as shown in Table 44.5 and as follows:

1. If the null hypothesis of no stable seasonality is not rejected at the 0.10% significance level ($P_S \geq 0.001$), then the series is considered to be nonseasonal. PROC X11 returns the conclusion, “Identifiable Seasonality Not Present.”

2. If the null hypothesis in step 1 is rejected, then PROC X11 computes the following quantities:

\[
T_1 = \frac{7}{F_s} \\
T_2 = \frac{3F_m}{F_s}
\]
Let $T$ denote the simple average of $T_1$ and $T_2$:

$$T = \frac{(T_1 + T_2)}{2}$$

If the null hypothesis of no moving seasonality is rejected at the 5.0% significance level ($P_M < 0.05$) and if $T \geq 1.0$, the null hypothesis of identifiable seasonality not present is not rejected and PROC X11 returns the conclusion, “Identifiable Seasonality Not Present.”

3. If the null hypothesis of identifiable seasonality not present has not been accepted, but $T_1 \geq 1.0$, $T_2 \geq 1.0$, or the Kruskal-Wallis chi-squared test fails to reject at the 0.10% significance level ($P_{KW} \geq 0.001$), then PROC X11 returns the conclusion “Identifiable Seasonality Probably Not Present.”

4. If the null hypotheses of no stable seasonality associated with the $F_S$ and Kruskal-Wallis chi-squared tests are rejected and if none of the combined measures described in steps 2 and 3 fail, then the null hypothesis of identifiable seasonality not present is rejected and PROC X11 returns the conclusion “Identifiable Seasonality Present.”
Figure 44.5 Combined Seasonality Test Flowchart

Combined test for identifiable seasonality

- \( P_s \geq 0.001 \) → Stable seasonality test
- \( P_s < 0.001 \)

No evidence of stable seasonality at the 0.1 per cent level

Seasonality present at the 0.1 per cent level

- \( P_m < 0.05 \) → Moving seasonality test
- \( P_m \geq 0.05 \)

Moving seasonality present at the five percent level OR Moving seasonality present at the one percent level

No evidence of moving seasonality at the five percent level

- \( T \geq 1 \) → Test: \( T = 1 \)
- \( T < 1 \)

- \( T_1 \geq 1 \) or \( T_2 \geq 1 \)
- \( T_1 < 1 \) and \( T_2 < 1 \)

\( P_{KW} \geq 0.001 \) → Kruskal-Wallis test

\( P_{KW} < 0.001 \)

Identifiable seasonality not present

Identifiable seasonality probably not present

Identifiable seasonality present
Tables Written to the OUT= Data Set

All tables that are time series can be written to the OUT= data set. However, depending on the specified options and statements, not all tables are computed. When a table is not computed, but is requested in the OUTPUT statement, the resulting variable has all missing values.

For example, if the PMFACTOR= option is not specified, Table A2 is not computed, and requesting this table in the OUTPUT statement results in the corresponding variable having all missing values.

The trading-day regression results, Tables B15 and C15, although not written to the OUT= data set, can be written to an output data set; for more information, see the OUTTDR= option.

Printed Output Generated by Sliding Spans Analysis

**Table S 0.A**
Table S 0.A gives the variable name, the length and number of spans, and the beginning and ending dates of each span.

**Table S 0.B**
Table S 0.B gives the summary of the two $F$ tests performed during the standard X11 seasonal adjustments for stable and moving seasonality on Table D8, the final SI ratios. These tests are described in the section “Printed Output” on page 3256.

**Table S 1.A**
Table S 1.A gives the range analysis of seasonal factors. This includes the means for each month (or quarter) within a span, the maximum percentage difference across spans for each month, and the average. The minimum and maximum within a span are also indicated.

For example, for a monthly series and an analysis with four spans, the January row would contain a column for each span, with the value representing the average seasonal factor (Table D10) over all January calendar months occurring within the span. Beside each span column is a character column with either a MIN, MAX, or blank value, indicating which calendar month had the minimum and maximum value over that span.

Denote the average over the $j$th calendar month in span $k$, $k = 1, \ldots, 4$, by $\bar{S}_j(k)$; then the maximum percent difference (MPD) for month $j$ is defined by

$$
\text{MPD}_j = \frac{\max_{k=1,\ldots,4} \bar{S}_j(k) - \min_{k=1,\ldots,4} \bar{S}_j(k)}{\min_{k=1,\ldots,4} \bar{S}_j(k)}
$$

The last numeric column of Table S 1.A is the average value over all spans for each calendar month, with the minimum and maximum row flagged as in the span columns.

**Table S 1.B**
Table S 1.B gives a summary of range measures for each span. The first column, Range Means, is calculated by computing the maximum and minimum over all months or quarters in a span, then taking the difference. The next column is the range ratio means, which is simply the ratio of the previously described maximum and minimum. The next two columns are the minimum and maximum seasonal factors over the entire span, while the range sf column is the difference of these. Finally, the last column is the ratio of the Max SF and Min SF columns.
Chapter 44: The X11 Procedure

Breakdown Tables
Table S 2.A.1 begins the breakdown analysis for the various series considered in the sliding spans analysis. The key concept here is the MPD described earlier in the section “Table S 1.A” on page 3263 and in the section “Computational Details for Sliding Spans Analysis” on page 3246. For a month or quarter that appears in two or more spans, the maximum percentage difference is computed and tested against a cutoff level. If it exceeds this cutoff, it is counted as an instance of exceeding the level. It is of interest to see if such instances fall disproportionately in certain months and years. Tables S 2.A.1 through S 6.A.3 display this breakdown for all series considered.

Table S 2.A.1
Table S 2.A.1 gives the monthly (quarterly) breakdown for the seasonal factors (Table D10). The first column identifies the month or quarter. The next column is the number of times the MPD for D10 exceeded 3.0%, followed by the total count. The last is the average maximum percentage difference for the corresponding month or quarter.

Table S 2.A.2
Table S 2.A.2 gives the same information as Table S 2.A.1, but on a yearly basis.

Table S 2.A.3
The description of Table S 2.A.3 requires the definition of “Sign Change” and “Turning Point.”

First, some motivation. Recall that for a highly stable series, adding or deleting a small number of observations should not affect the estimation of the various components of a seasonal adjustment procedure.

Consider Table D10, the seasonal factors in a sliding spans analysis that uses four spans. For a given observation \( t \), looking across the four spans, we can easily pick out large differences if they occur. More subtle differences can occur when estimates go from above to below (or vice versa) a base level. In the case of multiplicative model, the seasonal factors have a base level of 100.0. So it is useful to enumerate those instances where both a large change occurs (an MPD value exceeding 3.0%) and a change of sign (with respect to the base) occur.

Let \( B \) denote the base value (which in general depends on the component being considered and the model type, multiplicative or additive). If, for span 1, \( S_t(1) \) is below \( B \) (that is, \( S_t(1) - B \) is negative) and for some subsequent span \( k \), \( S_t(k) \) is above \( B \) (that is, \( S_t(k) - B \) is positive), then a positive “Change in Sign” has occurred at observation \( t \). Similarly, if, for span 1, \( S_t(1) \) is above \( B \), and for some subsequent span \( k \), \( S_t(k) \) is below \( B \), then a negative “Change in Sign” has occurred. Both cases, positive or negative, constitute a “Change in Sign”; the actual direction is indicated in tables S 7.A through S 7.E, which are described below.

Another behavior of interest occurs when component estimates increase then decrease (or vice versa) across spans for a given observation. Using the preceding example, the seasonal factors at observation \( t \) could first increase, then decrease across the four spans.

This behavior, combined with an MPD exceeding the level, is of interest in questions of stability.

Again, consider Table D10, the seasonal factors in a sliding spans analysis that uses four spans. For a given observation \( t \) (containing at least three spans), note the level of D10 for the first span. Continue across the spans until a difference of 1.0% or greater occurs (or no more spans are left), noting whether the difference is up or down. If the difference is up, continue until a difference of 1.0% or greater occurs downward (or no more spans are left). If such an up-down combination occurs, the observation is counted as an up-down turning point. A similar description occurs for a down-up turning point. Tables S 7.A through S 7.E, described
below, show the occurrence of turning points, indicating whether up-down or down-up. Note that it requires at least three spans to test for a turning point. Hence Tables S 2.A.3 through S 6.A.3 show a reduced number in the “Turning Point” row for the “Total Tested” column, and in Tables S 7.A through S 7.E, the turning points symbols can occur only where three or more spans overlap.

With these descriptions of sign change and turning point, we now describe Table S 2.A.3. The first column gives the type or category, the second column gives the total number of observations falling into the category, the third column gives the total number tested, and the last column gives the percentage for the number found in the category.

The first category (row) of the table is for flagged observations—that is, those observations where the MPD exceeded the appropriate cutoff level (3.0% is default for the seasonal factors). The second category is for level changes, while the third category is for turning points. The fourth category is for flagged sign changes—that is, for those observations that are sign changes, how many are also flagged. Note the total tested column for this category equals the number found for sign change, reflecting the definition of the fourth category.

The fifth column is for flagged turning points—that is, for those observations that are turning points, how many are also flagged.

The footnote to Table S 2.A.3 gives the U.S. Census Bureau recommendation for thresholds, as described in the section “Computational Details for Sliding Spans Analysis” on page 3246.

**Table S 2.B**
Table S 2.B gives the histogram of flagged for seasonal factors (Table D10) using the appropriate cutoff value (default 3.0%). This table looks at the spread of the number of times the MPD exceeded the corresponding level. The range is divided up into four intervals: 3.0%–4.0%, 4.0%–5.0%, 5.0%–6.0%, and greater than 6.0%. The first column shows the symbol used in Table S 7.A, the second column gives the range in interval notation, and the last column gives the number found in the corresponding interval. Note that the sum of the last column should agree with the “Number Found” column of the “Flagged MPD” row in Table S 2.A.3.

**Table S 2.C**
Table S 2.C gives selected percentiles for the MPD for the seasonal factors (Table D10).

**Tables S 3.A.1 through S 3.A.3**
These table relate to the trading-day factors (Table C18) and follow the same format as Tables S 2.A.1 through S 2.A.3. The only difference between these tables and Tables S 2.A.1 through S 2.A.3 is the default cutoff value of 2.0% instead of the 3.0% used for the seasonal factors.

**Tables S 3.B, S 3.C**
These tables, applied to the trading-day factors (Table C18), are the same format as Tables S 2.B through S 2.C. The default cutoff value is different, with corresponding differences in the intervals in S 3.B.

**Tables S 4.A.1 through S 4.A.3**
These tables relate to the seasonally adjusted series (Table D11) and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.
Chapter 44: The X11 Procedure

Tables S 4.B, S 4.C
These tables, applied to the seasonally adjusted series (Table D11), are the same format as Tables S 2.B through S 2.C.

Tables S 5.A.1 through S 5.A.3
These tables relate to the month-to-month (or quarter-to-quarter) differences in the seasonally adjusted series, and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

Tables S 5.B, S 5.C
These tables, applied to the month-to-month (or quarter-to-quarter) differences in the seasonally adjusted series, are the same format as Tables S 2.B through S 2.C. The same default cutoff value of 3.0% is used.

Tables S 6.A.1 through S 6.A.3
These tables relate to the year-to-year differences in the seasonally adjusted series, and follow the same format as Tables S 2.A.1 through S 2.A.3. The same default cutoff value of 3.0% is used.

These tables, applied to the year-to-year differences in the seasonally adjusted series, are the same format as Tables S 2.B through S 2.C. The same default cutoff value of 3.0% is used.

Table S 7.A
Table S 7.A gives the entire listing of the seasonal factors (Table D10) for each span. The first column gives the date for each observation included in the spans. Note that the dates do not cover the entire original data set. Only those observations included in one or more spans are listed.

The next $N$ columns (where $N$ is the number of spans) are the individual spans starting at the earliest span. The span columns are labeled by their beginning and ending dates.

Following the last span is the “Sign Change” column. As explained in the description of Table S 2.A.3, a sign change occurs at a given observation when the seasonal factor estimates go from above to below, or below to above, a base level. For the seasonal factors, 100.0 is the base level for the multiplicative model, 0.0 for the additive model. A blank value indicates no sign change, a “U” indicates a movement “upward” from the base level and a “D” indicates a movement “downward” from the base level.

The next column is the “Turning Point” column. As explained in the description of Table S 2.A.3, a turning point occurs when there is an upward then downward movement, or downward then upward movement, of sufficient magnitude. A blank value indicates no turning point, a “U-D” indicates a movement “upward then downward,” and a “D-U” indicates a movement “downward then upward.”

The next column is the maximum percentage difference (MPD). This quantity, described in the section “Computational Details for Sliding Spans Analysis” on page 3246, is the main computation for sliding spans analysis. A measure of how extreme the MPD value is given in the last column, the “Level of Excess” column. The symbols used and their meaning are described in Table S 2.A.3. If a given observation has exceeded the cutoff, the level of excess column is blank.
Table S 7.B
Table S 7.B gives the entire listing of the trading-day factors (Table C18) for each span. The format of this table is exactly like that of Table S 7.A.

Table S 7.C
Table S 7.C gives the entire listing of the seasonally adjusted data (Table D11) for each span. The format of this table is exactly like that of Table S 7.A except for the “Sign Change” column, which is not printed. The seasonally adjusted data have the same units as the original data; there is no natural base level as in the case of a percentage. Hence the sign change is not appropriate for D11.

Table S 7.D
Table S 7.D gives the entire listing of the month-to-month (or quarter-to-quarter) changes in seasonally adjusted data for each span. The format of this table is exactly like that of Table S 7.A.

Table S 7.E
Table S 7.E gives the entire listing of the year-to-year changes in seasonally adjusted data for each span. The format of this table is exactly like that of Table S 7.A.

Printed Output from the ARIMA Statement
The information printed by default for the ARIMA model includes the parameter estimates, their approximate standard errors, $t$ ratios, and variances, the standard deviation of the error term, and the AIC and SBC statistics for the model. In addition, a criteria summary for the chosen model is given that shows the values for each of the three test criteria and the corresponding critical values.

If the PRINTALL option is specified, a summary of the nonlinear estimation optimization and a table of Box-Ljung statistics is also produced. If the automatic model selection is used, this information is printed for each of the five predefined models. Finally, a model selection summary is printed, showing the final model chosen.

ODS Table Names
PROC X11 assigns a name to each table it creates. You can use these names to reference the table when using the Output Delivery System (ODS) to select tables and create output data sets. These names are listed in Table 44.5.

Note: For monthly and quarterly tables, use the ODS names MonthlyTables and QuarterlyTables; For brevity, only the MonthlyTables are listed here; the QuarterlyTables are simply duplicates. Printing of individual tables can be specified by using the TABLES table_name, which is not listed here. Printing groups of tables is specified in the MONTHLY and QUARTERLY statements by specifying the option PRINTOUT=NONE||STANDARD||LONG||FULL. The default is PRINTOUT=STANDARD.

Examples: X11 Procedure

Example 44.1: Component Estimation—Monthly Data

This example computes and plots the final estimates of the individual components for a monthly series. In the first plot (Output 44.1.1), an overlaid plot of the original and seasonally adjusted data is produced. The trend in the data is more evident in the seasonally adjusted data than in the original data. This trend is even more clear in Output 44.1.3, the plot of Table D12, the trend cycle. Note that both the seasonal factors and the irregular factors vary around 100, while the trend cycle and the seasonally adjusted data are in the scale of the original data.

From Output 44.1.2 the seasonal component appears to be slowly increasing, while no apparent pattern exists for the irregular series in Output 44.1.4.

Example 44.3: Outlier Detection and Removal

PROC X11 can be used to detect and replace outliers in the irregular component of a monthly or quarterly series.

The weighting scheme used in measuring the “extremeness” of the irregulars is developed iteratively; thus the statistical properties of the outlier adjustment method are unknown.

In this example, the data are simulated by generating a trend plus a random error. Two periods in the series were made “extreme” by multiplying one generated value by 2.0 and another by 0.10. The additive model is appropriate based on the way the data were generated. Note that the trend in the generated data was modeled automatically by the trend cycle component estimation.

The detection of outliers is accomplished by considering Table D9, the final replacement values for extreme S-I ratios. This table indicates which observations had irregular component values more than FULLWEIGHT= standard deviation units from 0.0 (1.0 for the multiplicative model). The default value of the FULLWEIGHT= option is 1.5; a larger value would result in fewer observations being declared extreme.

In this example, FULLWEIGHT=3.0 is used to isolate the extreme inflated and deflated values generated in the DATA step. The value of ZEROWEIGHT= must be greater than FULLWEIGHT; it is given a value of 3.5.

A plot of the original and modified series, Output 44.3.2, shows that the deviation from the trend line for the modified series is greatly reduced compared with the original series.
Example 44.3: Outlier Detection and Removal

```sas
proc x11 data=a;
  monthly date=date additive
     fullweight=3.0 zeroweight=3.5;
  var x;
  table d9;
  output out=b b1=original e1=e1;
run;

proc sgplot data=b;
  series x=date y=original / markers
     markerattrs=(color=red symbol='asterisk')
     lineattrs=(color=red)
     legendlabel="unmodified" ;
  series x=date y=e1 / markers
     markerattrs=(color=blue symbol='circle')
     lineattrs=(color=blue)
     legendlabel="modified" ;
  yaxis label='Original and Outlier Adjusted Time Series';
run;
```

Overview: X12 Procedure

The X12 procedure is an adaptation of the US Bureau of the Census X-12-ARIMA seasonal adjustment program (US Bureau of the Census 2010). The X-12-ARIMA program was developed by the Time Series Staff of the Statistical Research Division, US Census Bureau. The X-12-ARIMA seasonal adjustment program contains components developed from Statistics Canada’s X-11-ARIMA program. The X-12-ARIMA automatic modeling method is based on the work of Gómez and Maravall (1997a, b).

The Time Series Staff of the Statistical Research Division, US Census Bureau, has recently developed a new program, X-13ARIMA-SEATS (US Bureau of the Census 2013). This program incorporates the X-12-ARIMA functionality along with the SEATS functionality that was developed by Gómez and Maravall (1997a, b). The X12 procedure includes improvements on X-12-ARIMA methods that are incorporated into the X-13ARIMA-SEATS program.

Because the US Census Bureau has focused its new development on the X-13ARIMA-SEATS program, a new X13 procedure has been developed to incorporate the X-13ARIMA-SEATS method.

NOTE: The functionality previously available in the X12 procedure is included in the new X13 procedure. You can specify either of the following with the same results:

```
proc x12 ...
proc x13 ...
```

For documentation of the PROC X12 syntax and a description of its details, see Chapter 46, “The X13 Procedure.”

Overview: X13 Procedure

The X13 procedure is an adaptation of the US Bureau of the Census X-13ARIMA-SEATS seasonal adjustment program (US Bureau of the Census 2013c). The X-13ARIMA-SEATS program was developed by the Time Series Staff of the Statistical Research Division, US Census Bureau, by incorporating the SEATS method into the X-12-ARIMA seasonal adjustment program. The X-12-ARIMA seasonal adjustment program contains components developed from Statistics Canada’s X-11-ARIMA program (US Bureau of the Census 2010). The X-12-ARIMA automatic modeling method and the SEATS method are based on the work of Gómez and Maravall (1997a, b).

The new X-13ARIMA-SEATS program incorporates the X-12-ARIMA functionality. It also incorporates improvements on X-12-ARIMA methods. Because the X-12-ARIMA methods and improvements are available in X-13ARIMA-SEATS, the new X13 procedure and the existing X12 procedure use the same X-13ARIMA-SEATS methodology, and PROC X12 and PROC X13 are aliases for the same procedure.

The version of PROC X13 documented here was produced by converting the US Census Bureau’s FORTRAN code to the SAS development language and adding typical SAS procedure syntax. This conversion work was performed by SAS and resulted in the X13 procedure. Although several features were added during the conversion, credit for the statistical aspects and general methodology of the X13 procedure belongs to the US Census Bureau.
The X13 procedure seasonally adjusts monthly or quarterly time series. The procedure makes additive or multiplicative adjustments and creates an output data set that contains the adjusted time series and intermediate calculations.

The X-13ARIMA-SEATS program includes the X-12-ARIMA program, which combines the capabilities of the X-11 program (Shiskin, Young, and Musgrave 1967) and the X-11-ARIMA/88 program (Dagum 1988) and also introduces some new features (Findley et al. 1998). One of the main enhancements in the X-12-ARIMA program involves the use of a regARIMA model, a regression model with ARIMA (autoregressive integrated moving average) errors. Thus, the X-12-ARIMA program contains methods developed by both the US Census Bureau and Statistics Canada. In addition, the X-12-ARIMA automatic modeling routine is based on the TRAMO (time series regression with ARIMA noise, missing values, and outliers) method (Gómez and Maravall 1997a, b). The four major components of the X-12-ARIMA program are regARIMA modeling, model diagnostics, seasonal adjustment that uses enhanced X-11 methodology, and post-adjustment diagnostics. Statistics Canada’s X-11 method fits an ARIMA model to the original series, and then uses the model forecasts to extend the original series. This extended series is then seasonally adjusted by the standard X-11 seasonal adjustment method. The extension of the series improves the estimation of the seasonal factors and reduces revisions to the seasonally adjusted series as new data become available.

Seasonal adjustment of a series is based on the assumption that seasonal fluctuations can be measured in the original series, \( O_t, t = 1, \ldots, n \), and separated from trend cycle, trading day, and irregular fluctuations. The seasonal component of this time series, \( S_t \), is defined as the intrayear variation that is repeated consistently or evolves slowly from year to year (Hillmer and Tiao 1982). The trend cycle component, \( C_t \), includes variation that is attributed to the long-term trend, the business cycle, and other long-term cyclical factors. The trading day component, \( D_t \), is the variation that can be attributed to the composition of the calendar. The irregular component, \( I_t \), is the residual variation. Many economic time series are related in a multiplicative fashion (\( O_t = S_t C_t D_t I_t \)). Other economic series are related in an additive fashion (\( O_t = S_t + C_t + D_t + I_t \)). A seasonally adjusted time series, \( C_t I_t \) or \( C_t + I_t \), consists of only the trend cycle and irregular components. For more information about the X-11 seasonal adjustment method, see Ladiray and Quenneville (2001).

Graphics are now available with the X13 procedure. For more information, see the section “ODS Graphics” on page 3355.
The naming convention used in PROC X13 for the tables follows the convention used in the Census Bureau’s X-13ARIMA-SEATS program; see *X-13ARIMA-SEATS Reference Manual* (US Bureau of the Census 2013c), *X-13ARIMA-SEATS Quick Reference for DOS* (US Bureau of the Census 2013a), and *X-13ARIMA-SEATS Quick Reference for UNIX/Linux* (US Bureau of the Census 2013b). Also see the section “Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords” on page 3350. The table names are outlined in Table 46.15.

The tables that correspond to parts A through C are intermediate calculations. The final estimates of the individual components are found in the D tables: Table D10 contains the final seasonal factors, Table D12 contains the final trend cycle, and Table D13 contains the final irregular series. If you are primarily interested in seasonally adjusting a series without consideration of intermediate calculations or diagnostics, you need to look only at Table D11, the final seasonally adjusted series. Tables in part E contain information about extreme values and changes in the original and seasonally adjusted series. The tables in part F are seasonal adjustment quality measures. Spectral analysis is performed in part G. For more information about the tables produced by the X11 statement, see Ladiray and Quenneville (2001).

## Basic Seasonal Adjustment

Suppose that you have monthly retail sales data starting in September 1978 in a SAS data set named SALES. At this point, you do not suspect that any calendar effects are present, and there are no prior adjustments that need to be made to the data.

In this simplest case, you need only specify the DATE= variable in the PROC X13 statement and request seasonal adjustment in the X11 statement as shown in the following statements:

```sas
data sales;
  set sashelp.air;
  sales = air;
  date = intnx( 'month', '01sep78'd, _n_-1 );
  format date monyy.;
run;

proc x13 data=sales date=date;
  var sales;
  x11;
  ods select d11;
run;
```

The results of the seasonal adjustment are in Table D11 (the final seasonally adjusted series) in the displayed output shown in Figure 46.1.

You can compare the original series (Table A1) and the final seasonally adjusted series (Table D11) by plotting them together as shown in Figure 46.2. These tables are requested in the OUTPUT statement and are written to the OUT= data set. Note that the default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

```plaintext
proc x13 data=sales date=date noprint;
  var sales;
  x11;
  output out=out a1 d11;
run;

proc sgplot data=out;
  series x=date y=sales_A1 / name = "A1" markers
    markerattrs=(color=red symbol='asterisk')
    lineattrs=(color=red);
  series x=date y=sales_D11 / name = "D11" markers
    markerattrs=(symbol='circle')
    lineattrs=(color=blue);
  yaxis label='Original and Seasonally Adjusted Time Series';
run;
```
Figure 46.2  Plot of Original and Seasonally Adjusted Data
The statements used by PROC X13 perform basically the same function as the Census Bureau’s X-13ARIMA-SEATS specs (specifications). Specs are used in X-13ARIMA-SEATS to control the computations and output. The PROC X13 statement performs some of the same functions as the Series spec in the Census Bureau’s X-13ARIMA-SEATS software. The ADJUST statement performs some of the same functions as the Transform spec. The ARIMA, AUTOMDL, CHECK, ESTIMATE, FORECAST, IDENTIFY, OUTLIER, PICKMDL, REGRESSION, TRANSFORM, and X11 statements are designed to perform the same functions as the corresponding X-13ARIMA-SEATS specs, although full compatibility is not yet available. The Census Bureau documentation X-13ARIMA-SEATS Reference Manual (US Bureau of the Census 2009) provides added insight to the functionality of these statements. The SEATSDECOMP statement provides a SEATS (signal extraction in ARIMA time series) seasonal decomposition for the B1 series that uses the same ARIMA model as is used to model the series. For more information about SEATS, see Gómez and Maravall (1997a, b).

#### Date Information Options
- Specifies the date variable
  - PROC X13 DATE=
- Specifies the date of the first observation
  - PROC X13 START=
- Specifies the beginning or ending date or both of the subset
  - PROC X13 SPAN=
- Specifies the interval of the time series
  - PROC X13 INTERVAL=
- Specifies the interval of the time series
  - PROC X13 SEASONS=

#### Declaring the Role of Variables
- Specifies BY-group processing
  - BY
- Specifies identifying variables
  - ID
- Specifies the variables to be seasonally adjusted
  - VAR
- Specifies the user-defined variables that are available for regression
  - USERDEFINED

#### Controlling the Table Computations
- Suppresses trimming of leading and trailing missing values (if they exist)
  - PROC X13 NOTRIMMISS
- Transforms or prior-adjusts the series
  - TRANSFORM FUNCTION=
- Transforms or prior-adjusts the series
  - TRANSFORM POWER=
- Adjusts the series by using a predefined adjustment variable
  - ADJUST PREDEFINED=
- Specifies the likelihood function to be used for estimating AR and MA parameters
  - ESTIMATE EXACT=
- Specifies the maximum number of iterations for estimating AR and MA parameters
  - ESTIMATE MAXITER
- Specifies the convergence tolerance for nonlinear estimation
  - ESTIMATE TOL=
- Specifies size of forecast confidence limits
  - FORECAST ALPHA=
- Specifies the number of backcasts by which to extend the series for seasonal adjustment
  - FORECAST NBACKCAST=
- Specifies the number of forecasts by which to extend the series for seasonal adjustment
  - FORECAST LEAD=
- Specifies that one-step-ahead forecasts be computed
  - FORECAST OUT1STEP

Chapter 46: The X13 Procedure

PROC X13 Statement

PROC X13 options ;

The PROC X13 statement provides information about the time series to be processed by PROC X13. Either the DATE= or the START= option must be specified. If both options are specified, then a syntax error results and the X13 procedure is not executed.

The original series is displayed in Table A1. If there are missing values in the original series and a regARIMA model is specified or automatically selected, then Table MV1 is displayed. Table MV1 contains the original series with missing values replaced by the predicted values from the fitted model. If outliers are identified and Table A19 is added in the TABLES statement, then the outlier adjusted series is displayed in Table A19. Table B1 is displayed when the original data are altered (for example, through an ARIMA model estimation, prior adjustment factor, or regression) or the series is extended with forecasts.

Although the X-13ARIMA-SEATS method handles missing values, there are some restrictions. In order for PROC X13 to process the series, no month or quarter can contain missing values for all years. For instance, if the third quarter contained only missing values for all years, then processing is skipped for that series. In addition, if more than half the values for a month or a quarter are missing, then a warning message is displayed in the log file, and other errors might occur later in processing. If a series contains many missing values, other methods of missing value replacement should be considered prior to seasonally adjusting the series.

You can specify the following options in the PROC X13 statement:

**AUXDATA=SAS-data-set**

specifies an auxiliary input data set that contains user-defined variables, which are specified in the INPUT statement, the USERVAR= option in the REGRESSION statement, or the USERDEFINED statement. The AUXDATA= data set can also contain the date variable, which is specified in the DATE= option in the PROC X13 statement. If the date variable is present, then the date variable is used to align the observations in the auxiliary data set to the observations in the series that is being processed. The date values must be sorted in ascending order with no gaps or duplications, and the interval must match the interval of the series. If the date variable is not present or valid, then observations in the auxiliary data set are matched by observation number to the series that is being processed. The auxiliary data set does not support BY-group processing. The variables in the auxiliary data set are applied to all BY groups, where the dates of the BY group correspond to the dates of the auxiliary data set. Example 46.11 shows the use of the AUXDATA= data set.

**DATA=SAS-data-set**

specifies the input SAS data set to use. If this option is omitted, the most recently created SAS data set is used.

**DATE=variable**

**DATEVAR=variable**

specifies a variable that gives the date for each observation. Unless specified in the SPAN= option, the starting and ending dates are obtained from the first and last values of the BY group for the DATE= variable, which must contain SAS date or datetime values. The procedure checks values of the DATE= variable to ensure that the input observations are sequenced correctly in ascending order. If the INTERVAL= option or the SEASONS= option is specified, the values of the date variable must be consistent with the specified seasonality or interval. If neither the INTERVAL= option nor the
SEASONS= option is specified, then the procedure tries to determine the type of data from the values of the date variable. This variable is automatically added to the OUT= data set if a data set is requested in an OUTPUT statement, and the date values for the variable are extrapolated if necessary. If the DATE= option is not specified, the START= option must be specified.

INEVENT=SAS-data-set
specifies the input data set that defines any user-defined event variables. This option can be omitted if events are not specified or if only SAS predefined events are specified in an EVENT statement. For more information about the format of this data set, see the section “INEVENT= Data Set” on page 3360.

INTERVAL=interval
specifies the frequency of the input time series. If the input data consist of quarterly observations, then INTERVAL=QTR should be used. If the input data consist of monthly observations, then INTERVAL=MONTH should be used. If the INTERVAL= option is not specified and SEASONS=4, then INTERVAL=QTR is assumed; likewise, SEASONS=12 implies INTERVAL=MONTH. If both the INTERVAL= option and the SEASONS= option are specified, the values should not be conflicting. If neither the INTERVAL= option nor the SEASONS= option is specified and the START= option is specified, then the data are assumed to be monthly. If a date variable is specified using the DATE= option, it is not necessary to specify the INTERVAL= option or the SEASONS= option; however, if specified, the values of the INTERVAL= option or the SEASONS= option should not be in conflict with the values of the date variable. For more information about intervals, see Chapter 4, “Date Intervals, Formats, and Functions.”

MDLINFOIN=SAS-data-set
specifies an optional input data set that contains model information that overrides information that is contained in one or more of the TRANSFORM, REGRESSION, ARIMA, and AUTOMDL statements. The SAS-data-set can contain BY-group, series names, and other information. For more information about this data set, see the section “MDLINFOIN= and MDLINFOOUT= Data Sets” on page 3358.

You can supply the following model information in SAS-data-set:

- a single model for each series that is used to forecast the series.
- multiple models for each series. If multiple models are specified for a series, the PICKMDL method is used to select from among the candidate models, and the selected model will be used to generate the forecasts. For more information, see the “PICKMDL Model Selection” on page 3348.

The MDLINFOIN= data set can include a variable that identifies different models. All observations that have the same value for the model identification variable are considered to be relevant to the same model. A single model can be considered to consist of all the observations for a BY group that consists of the BY variables (if any), the _NAME_ variable if it exists, and the model identification variable (whose default is _MODEL_). Even if the PICKMDL statement is not specified, but the MDLINFOIN= data set contains a _MODEL_ variable and more than one model for a series, then the PICKMDL method is automatically invoked to choose a model for that series.

MDLINFOOUT=SAS-data-set
specifies the optional output data set that contains the transformation, regression, and ARIMA information related to each seasonally adjusted series. The data set is sorted by the BY-group variables, if any, and by series names. The MDLINFOOUT= data set can be used as input for the MDLINFOIN= option.
option. For more information, see the section “MDLINFOIN= and MDLINFOOUT= Data Sets” on page 3358.

NOPRINT
suppresses any printed output.

NOTRIMMISS
suppresses the default, by which leading and trailing missing values are trimmed from each variable listed (or implied) in the VAR statement. If you specify the NOTRIMMISS option, PROC X13 treats leading and trailing missing values in the same manner as it treats embedded missing values. For information about the treatment of embedded missing values, see the section “Missing Values” on page 3340. Missing values are not supported in the regression variables that you specify in the REGRESSION, INPUT, or USERDEFINED statement; therefore, leading and trailing missing values are always trimmed from user-defined regressors even if you specify NOTRIMMISS.

OUTSTAT=SAS-data-set
specifies an optional output data set which contains the summary statistics that related to each seasonally adjusted series. The data set is sorted by the BY-group variables, if any, and by series names. For more information, see the section “OUTSTAT= Data Set” on page 3362.

PERIODOGRAM
specifies that the PERIODOGRAM rather than the spectrum of the series be plotted in the G tables and plots. If PERIODOGRAM is not specified, then the spectrum is plotted in the G tables.

PLOTS= (global-plot-options) > <= plot-request < (options)>>
controls the plots that are produced through ODS Graphics. When you specify only one plot request, you can omit the parentheses around the plot request.

Following are some examples of the PLOTS= option:

plots=none
plots=all
plots=residual(none)
plots(only)=(series(acf pacf) residual(hist))

ODS Graphics must be enabled before you request plots. For example:

   ods graphics on;
   proc x13 data=sales date=date;
     var sales;
     identify diff=(0,1) sdiff=(0,1);
   run;

Since no specific plot is requested in this program, the default plots associated with the PROC X13 and IDENTIFY statements are produced.

For general information about ODS Graphics, see Chapter 21, “Statistical Graphics Using ODS” (SAS/STAT User’s Guide). If you have enabled ODS Graphics but do not specify any specific plot
request, then the default plots that are associated with each of the PROC X13 statements used in the program are produced. Line printer plots are suppressed when ODS Graphics is enabled.

If NONE is specified in an option, then no plots are produced for that option. If ALL is specified without NONE in an option, then all plots are produced for that option.

Global Plot Options
The global-plot-options apply to all relevant plots that are generated by the X13 procedure. The following global-plot-option is supported:

ONLY
suppresses the default plots. Only the plots specifically requested are produced.

Specific Plot Options
The following list describes the specific plots and their options:

ALL
produces all plots that are appropriate for the particular analysis.

NONE
suppresses all plots.

ADJUSTED(<sa-plot-options>)
produces plots of the seasonally adjusted series that results from the decomposition specified in the X11 statement. The SPECTRUM plot is produced by default.

The following sa-plot-options are available:

ALL
produces all seasonally adjusted plots.

NONE
suppresses all seasonally adjusted plots.

SPECTRUM
produces the spectral plot of Table G1. Table G1 is calculated based on the modified seasonally adjusted series (Table E2). The data are first-differenced and transformed as specified in the TRANSFORM statement. By default, the type of spectral estimate used to calculate the spectral plot is the spectrum. If the PERIODGRAM option is specified in the PROC X13 statement, then the periodogram of the series is used to calculate the spectral plot.

FORECAST(<forecast-plot-options>)
produces the regARIMA model forecast plots if the FORECAST statement is specified. The FORECAST plot is produced by default. The following forecast-plot-options are available:
ALL
produces all the forecast plots that are appropriate for the particular analysis.

FORECAST
plots the actual time series and its one-step-ahead forecast over the historical period, and
plots the forecast and its confidence bands over the forecast horizon. The OUT1STEP option
must be specified in the FORECAST statement in order for the X13 procedure to calculate
the one-step-ahead forecasts.

FORECASTONLY
plots the forecast and its confidence bands over the forecast horizon only.

MODELFORECASTS
plots the one-step-ahead model forecast and its confidence bands in the historical period;
plots the forecast and its confidence bands over the forecast horizon. The OUT1STEP option
must be specified in the FORECAST statement in order for the X13 procedure to calculate
the one-step-ahead forecasts.

MODELS
plots the one-step-ahead model forecast and its confidence bands in the historical period.
The OUT1STEP option must be specified in the FORECAST statement in order for the X13
procedure to calculate the one-step-ahead forecasts.

NONE
suppresses all the forecast plots.

TRANSFORECAST
plots the transformed time series and its one-step-ahead forecast over the historical period;
plots the forecast and its confidence bands over the forecast horizon. The OUT1STEP option
must be specified in the FORECAST statement in order for the X13 procedure to calculate
the one-step-ahead forecasts. The TRANSFORECAST plot is available only if the data have
been transformed using the TRANSFORM statement.

TRANSFORECASTONLY
plots the forecast of the transformed series and its confidence bands over the forecast horizon
only. The TRANSFORECASTONLY plot is available only if the data have been transformed
using the TRANSFORM statement.

TRANSMODELFORECASTS
plots the one-step-ahead model forecast of the transformed series and its confidence bands
in the historical period; plots the forecast and its confidence bands over the forecast horizon.
The OUT1STEP option must be specified in the FORECAST statement in order for the X13
procedure to calculate the one-step-ahead forecasts. The TRANSMODELFORECASTS plot is available only if the data have been transformed using the TRANSFORM statement.

TRANSMODELS
plots the one-step-ahead model forecast of the transformed series and its confidence bands in
the historical period. The OUT1STEP option must be specified in the FORECAST statement
in order for the X13 procedure to calculate the one-step-ahead forecasts. The TRANSMODELS plot is available only if the data have been transformed using the TRANSFORM statement.
IRREGULAR(<ic-plot-options>)
IC(<ic-plot-options>)
produces plots of the irregular series that results from the decomposition specified in the X11 statement. The SPECTRUM plot is produced by default.

The following ic-plot-options are available:

ALL
produces all irregular plots.

NONE
suppresses all irregular plots.

SPECTRUM
produces the spectral plot of Table G2. Table G2 is calculated based on the modified irregular series (Table E3). The data are first-differenced and transformed as specified in the TRANSFORM statement. By default, the type of spectral estimate used to calculate the spectral plot is the spectrum. If the PERIODOGRAM option is specified in the PROC X13 statement, then the periodogram of the series is used to calculate the spectral plot.

RESIDUAL(<residual-plot-options>)
produces the regARIMA model residual series plots if the CHECK statement is specified. The ACF, PACF, HIST, SQACF, and SPECTRUM plots are produced by default. The following residual-plot-options are available:

ACF
produces the plot of residual autocorrelations.

ALL
produces all the residual diagnostics plots that are appropriate for the particular analysis.

HIST
produces the histogram of the residuals and also the residual outliers and residual statistics tables that describe the residual histogram.

NONE
suppresses all the residual diagnostics plots.

PACF
produces the plot of residual partial-autocorrelations if PRINT=PACF is specified in the CHECK statement.

SPECTRUM
produces the spectral plot of Table GRs. Table GRs is calculated based on the regARIMA model residual series. By default, the type of spectral estimate used to calculate the spectral plot is the spectrum. If the PERIODOGRAM option is specified in the PROC X13 statement, then the periodogram of the series is used to calculate the spectral plot.

SQACF
produces the plot of squared residual autocorrelations.
SERIES(<series-plot-options>)
produces plots that are associated with the identification stage of the modeling. The ACF, PACF, and SPECTRUM plots are produced by default. The following series-plot-options are available:

ACF
produces the plot of autocorrelations.

ALL
produces all the plots that are associated with the identification stage.

NONE
suppresses all plots that are associated with the identification stage.

PACF
produces the plot of partial-autocorrelations.

SPECTRUM
produces the spectral plot of Table G0. Table G0 is calculated based on either Table A1, A19, B1, or E1, as specified by the SPECTRUMSERIES= option. The original data are first-differenced and transformed as specified in the TRANSFORM statement. By default, the type of spectral estimate that is used to calculate the spectral plot is the spectrum. If the PERIODOGRAM option is specified in the PROC X13 statement, then the periodogram of the series is used to calculate the spectral plot.

SEASONS= number
specifies the number of observations in a seasonal cycle. If the SEASONS= option is not specified and INTERVAL=QTR, then SEASONS=4 is assumed. If the SEASONS= option is not specified and INTERVAL=MONTH, then SEASONS=12 is assumed. If the SEASONS= option is specified, its value should not conflict with the values of the INTERVAL= option or the values of the date variable. For more information, see the descriptions of the START=, DATE=, and INTERVAL= options.

SPAN=(mmmyy,mmmyy)
SPAN=(‘yyQq’,‘yyQq’)
specifies the dates of the first and last observations to define a subset for processing. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use SPAN=(,mmmyy). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set or BY group is assumed. Because the dates are input as strings and the quarterly dates begin with a numeric character, the specification for a quarterly date must be enclosed in quotation marks. A four-digit year can be specified; if a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies.

SPECTRUMSERIES= table-name
specifies the table name of the series that is used in the spectrum of the original series (Table G0). The table names that can be specified are A1, A19, B1, or E1. The default is B1.

START= mmmyy
START= ‘yyQq’
STARTDATE= mmmyy
STARTDATE= ‘yyQq’
specifies the date of the first observation. Unless the SPAN= option is used, the starting and ending dates are the dates of the first and last observations, respectively. Either this option or the DATE= option is required. When using this option, use either the INTERVAL= option or the SEASONS= option to specify monthly or quarterly data. If neither the INTERVAL= option nor the SEASONS= option
is present, monthly data are assumed. Because the dates are input as strings and the quarterly dates begin with a numeric character, the specification for a quarterly date must be enclosed in quotation marks. A four-digit year can be specified; if a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies. When using the START= option with BY processing, the start date is applied to the first observation in each BY group.

### ADJUST Statement

**ADJUST option** ;

The ADJUST statement adjusts the series for leap year and length-of-period factors prior to estimating a regARIMA model. The “Prior Adjustment Factors” table is associated with the ADJUST statement.

The following option can appear in the ADJUST statement:

**PREDEFINED=LOM | LOQ | LPYEAR**

specifies length-of-month adjustment, length-of-quarter adjustment, or leap year adjustment. PREDEFINED=LOM and PREDEFINED=LOQ are equivalent because the actual adjustment is determined by the interval of the time series. Also, because leap year adjustment is a limited form of length-of-period adjustment, only one type of predefined adjustment can be specified. The PREDEFINED= option should not be used in conjunction with PREDEFINED=TD or PREDEFINED=TD1COEF in the REGRESSION statement or MODE=ADD or MODE=PSEUDOADD in the X11 statement. PREDEFINED=LPYEAR cannot be specified unless the series is log transformed.

If the series is to be transformed by using a Box-Cox or logistic transformation, the series is first adjusted according to the ADJUST statement, and then it is transformed.

In the case of a length-of-month adjustment for the series with observations $Y_t$, each observation is first divided by the number of days in that month, $m_t$, and then multiplied by the average length of month ($30.4375$), resulting in $30.4375 \times \frac{Y_t}{m_t}$. Length-of-quarter adjustments are performed in a similar manner, resulting in $91.3125 \times \frac{Y_t}{q_t}$, where $q_t$ is the length in days of quarter $t$.

Forecasts of the transformed and adjusted data are transformed and adjusted back to the original scale for output.

### ARIMA Statement

**ARIMA option** ;

The ARIMA statement specifies the ARIMA part of the regARIMA model. This statement defines a pure ARIMA model if no REGRESSION statements, INPUT statements, or EVENT statements are specified. The ARIMA part of the model can include multiplicative seasonal factors.

The following option can appear in the ARIMA statement:
MODEL=\((p \; d \; q) \; (P \; D \; Q)s\)

specifies the ARIMA model. The format follows standard Box-Jenkins notation (Box, Jenkins, and Reinsel 1994). The nonseasonal AR and MA orders are given by \(p\) and \(q\), respectively, while the seasonal AR and MA orders are given by \(P\) and \(Q\). The number of differences and seasonal differences are given by \(d\) and \(D\), respectively. The notation \((p \; d \; q)\) and \((P \; D \; Q)\) can also be specified as \((p, \; d, \; q)\) and \((P, \; D, \; Q)\). The maximum lag of any AR or MA parameter is 36. The maximum value of a difference order, \(d\) or \(D\), is 144. All values for \(p\), \(d\), \(q\), \(P\), \(D\), and \(Q\) should be nonnegative integers. The seasonality parameter, \(s\), should be a positive integer. If \(s\) is omitted, it is set equal to the value that is specified in the SEASONS= option in the PROC X13 statement.

For example, the following statements specify an ARIMA \((2,1,1)(1,1,0)12\) model:

```plaintext
proc x13 data=ICMETI seasons=12 start=jan1968;
  arima model=((2,1,1)(1,1,0));
```

**AUTOMDL Statement**

AUTOMDL options;

The AUTOMDL statement invokes the automatic model selection procedure of the X-13ARIMA-SEATS method. This method is based largely on the TRAMO (time series regression with ARIMA noise, missing values, and outliers) method by Gómez and Maravall (1997a, b). If the AUTOMDL statement is used without the OUTLIER statement, then only missing values regressors are included in the regARIMA model. If both the AUTOMDL and the OUTLIER statements are used, then both missing values regressors and regressors for automatically identified outliers are included in the regARIMA model. For more information about missing value regressors, see the section “Missing Values” on page 3340.

If both the AUTOMDL statement and the ARIMA statement are present, the ARIMA statement is ignored. The ARIMA statement specifies the model, but the AUTOMDL statement allows the X13 procedure to select the model. If the AUTOMDL statement is specified and a data set is specified in the MDLINFOIN= option in the PROC X13 statement, then the AUTOMDL statement is ignored if the specified data set contains a model specification for the series. If no model for the series is specified in the MDLINFOIN= data set, the AUTOMDL or ARIMA statement is used to determine the model. Thus, it is possible to give a specific model for some series and automatically identify the model for other series by using both the MDLINFOIN= option and the AUTOMDL statement.

The AUTOMDL statement cannot be specified when the PICKMDL statement is also specified. The AUTOMDL and PICKMDL statements each specify different methods of automatic model selection. So, either one method must be used or the other method must be used to select a model.

When the AUTOMDL statement is specified, the X13 procedure compares a model selected using a TRAMO method to a default model. The TRAMO method is implemented first, and involves two parts: identifying the orders of differencing and identifying the ARIMA model. The table “ARIMA Estimates for Unit Root Identification” provides details about the identification of the orders of differencing, and the table “Results of Unit Root Test for Identifying Orders of Differencing” shows the orders of differencing selected by TRAMO. The table “Models Estimated by Automatic ARIMA Model Selection Procedure” provides details regarding the TRAMO automatic model selection, and the table “Best Five ARIMA Models Chosen by Automatic Modeling” ranks the best five models estimated using the TRAMO method. The “Comparison
of Automatically Selected Model and Default Model” table compares the model selected by the TRAMO method to a default model. At this point in the processing, if the default model is selected over the TRAMO model, then PROC X13 displays a note. No note is displayed if the TRAMO model is selected. The Ljung-Box $Q$ statistic is then checked for acceptance, and the results are displayed in the “Check of the Residual Ljung-Box Q Statistic” table. The initial model selected at this point is displayed in the “Initial Automatic Model Selection” table. PROC X13 then performs final checks for unit roots, over differencing, and insignificant ARMA coefficients. The results of the final checks are displayed in the “Final Checks for Identified Model” table, which also indicates changes to the model order if the orders are changed. The last table, “Final Automatic Model Selection,” shows the results of the automatic model selection; if the orders have been altered during the final checks, the Orders Altered column displays a value of Yes. An example of the automatic modeling selection procedure is shown in Example 46.4.

The following options can appear in the AUTOMDL statement:

**ACCEPTDEFAULT**
specifies that the default model be chosen if its Ljung-Box $Q$ is acceptable.

**ARMACV=value**
specifies the threshold value for the $t$ statistics that are associated with the highest-order ARMA coefficients. As a check of model parsimony, the parameter estimates and $t$ statistics of the highest-order ARMA coefficients are examined to determine whether the coefficient is insignificant. An ARMA coefficient is considered to be insignificant if the $t$ value that is displayed in the table “Exact ARMA Maximum Likelihood Estimation” is below the value specified in the ARMACV= option and the absolute value of the parameter estimate is reliably close to zero. The absolute value is considered to be reliably close to zero if it is below 0.15 for 150 or fewer observations or is below 0.1 for more than 150 observations. If the highest-order ARMA coefficient is found to be insignificant, then the order of the ARMA model is reduced. For example, if AUTOMDL identifies a $(3 1 1)(0 0 1)$ model and the parameter estimate of the seasonal MA lag of order 1 is –0.09 and its $t$ value is –0.55, then the ARIMA model is reduced to at least $(3 1 1)(0 0 0)$. After the model is reestimated, the check for insignificant coefficients is performed again. If ARMACV=0.54 is specified in the preceding example, then the coefficient is not found to be insignificant and the model is not reduced.

If a constant is allowed in the model and if the $t$ value associated with the constant parameter estimate is below the ARMACV= critical value, then the constant is considered to be insignificant and is removed from the model. Note that if a constant is added to or removed from the model and then the ARIMA model changes, then the $t$ statistic for the constant parameter estimate also changes. Thus, changing the ARMACV= value does not necessarily add or remove a constant term from the model.

The value specified in the ARMACV= option should be greater than zero. The default value is 1.0.

**BALANCED**
specifies that the automatic modeling procedure prefer balanced models over unbalanced models. A balanced model is one in which the sum of the AR, seasonal AR, differencing, and seasonal differencing orders equals the sum of the MA and seasonal MA orders. Specifying BALANCED gives the same preference as the TRAMO program. If BALANCED is not specified, all models are given equal consideration.

**DIFFID=CONDITIONAL | EXACT | EXACTFIRST** (Experimental)
specifies the estimation to be used in automatic difference identification when Hannen-Rissanen fails. You can specify the following values:
**CONDITIONAL** uses conditional likelihood estimation.

**EXACT** uses exact likelihood estimation.

**EXACTFIRST** attempts to estimate the parameters by using exact likelihood for the first `diffiditer` iterations, where `diffiditer` is specified in the DIFFIDITER= option. If the estimation does not converge within `diffiditer` iterations, then conditional likelihood is used to estimate the parameters.

The effects of this option are displayed in the Estimation Method column in the “ARIMA Estimates for Unit Root Identification” table. By default, DIFFID=EXACTFIRST.

**DIFFIDITER=** `diffiditer` (Experimental)

specifies the maximum number of exact likelihood estimation iterations when DIFFID=EXACTFIRST is specified. If the number of iterations exceeds `diffiditer`, then conditional likelihood is used to estimate the remaining iterations. The default value is 500; this default differs from the default value of 200 in the US Census Bureau’s implementation of X-13ARIMA-SEATS.

**DIFFORDER=** `(nonseasonal-order, seasonal-order)`

specifies the fixed orders of differencing to be used in the automatic ARIMA model identification procedure. When the DIFFORDER= option is used, only the AR and MA orders are automatically identified. Acceptable values for the regular (nonseasonal) differencing orders are 0, 1, and 2; acceptable values for the seasonal differencing orders are 0 and 1. If the MAXDIFF= option is also specified, then the DIFFORDER= option is ignored. There are no default values for DIFFORDER. If neither the DIFFORDER= option nor the MAXDIFF= option is specified, then the default is MAXDIFF=(2,1).

**HRINITIAL**

specifies that Hannan-Rissanen estimation be done before exact maximum likelihood estimation to provide initial values. If the HRINITIAL option is specified, then models for which the Hannan-Rissanen estimation has an unacceptable coefficient are rejected.

**LJUNGBOXLIMIT=value**

specifies acceptance criteria for the confidence coefficient of the Ljung-Box $Q$ statistic. If the Ljung-Box $Q$ for a final model is greater than this value, the model is rejected, the outlier critical value is reduced, and outlier identification is redone with the reduced value. For more information, see the REDUCECV option. The value specified in the LJUNGBOXLIMIT= option must be greater than 0 and less than 1. The default value is 0.95.

**MAXDIFF=** `(nonseasonal-order, seasonal-order)`

specifies the maximum orders of regular and seasonal differencing for the automatic identification of differencing orders. When MAXDIFF is specified, the differencing orders are identified first, and then the AR and MA orders are identified. Acceptable values for the regular differencing orders are 1 and 2. The only acceptable value for the seasonal differencing order is 1. If both the MAXDIFF= option and the DIFFORDER option= are specified, then the DIFFORDER= option is ignored. If neither the DIFFORDER= nor the MAXDIFF= option is specified, then the default is MAXDIFF=(2,1).

**MAXORDER=** `(nonseasonal-order, seasonal-order)`

specifies the maximum orders of nonseasonal and seasonal ARMA polynomials for the automatic ARIMA model identification procedure. The maximum order for the nonseasonal ARMA parameters is 4, and the maximum order for the seasonal ARMA is 2.
NOINT
suppresses the fitting of a constant or intercept parameter in the model.

PRINT=(option-list)
specifies the tables to be displayed in the output. You can specify one or more of the following options (parentheses are optional; use a space between options):

NONE suppresses all automatic modeling output.
ALL includes all automatic modeling tables in the output if NONE is not specified in the option-list.
ONLY specifies that only the listed tables be output.
AUTOCHOICE displays the tables titled “Comparison of Automatically Selected Model and Default Model” and “Final Automatic Model Selection.” The “Comparison of Automatically Selected Model and Default Model” table compares a default model to the model chosen by the TRAMO-based automatic modeling method. The “Final Automatic Model Selection” table indicates which model has been chosen automatically. These tables are output by default unless NONE or ONLY is specified in the option-list.
AUTOCHOICEMDL displays the table “Models Estimated by Automatic ARIMA Model Selection Procedure.” This table summarizes the various models that were considered by the TRAMO automatic model selection method and their measures of fit.
AUTOLJUNGBOX displays the table “Check of the Residual Ljung-Box Q Statistic.” This table is displayed only if the model is not accepted because the Ljung-Box Q statistic is greater than the acceptance limit. The details of the test and the changes made either to the model or to the model selection method are displayed.
BEST5MODEL displays the table “Best Five ARIMA Models Chosen by Automatic Modeling.” This table ranks the five best models that were considered by the TRAMO automatic modeling method.
FINALCHECKS displays the table “Final Checks for Identified Model.” This table displays the results of the final checks for model adequacy. The final checks can result in the orders of the initially identified model being altered. Any order changes or changes in the constant term are included in this table. This table is output by default unless NONE or ONLY is specified in the option-list.
INITCHOICEMDL displays the table “Initial Automatic Model Selection.” The “Comparison of Automatically Selected Model and Default Model” table compares a default model to the model chosen by the TRAMO-based automatic modeling method. The chosen model can then be altered if the model fails the Ljung-Box Q statistic test. The “Initial Automatic Model Selection” table indicates which model has been chosen automatically after the Ljung-Box Q statistic test. This table is output by default unless NONE or ONLY is specified in the option-list.
UNITROOTTEST displays the table titled “Results of Unit Root Test for Identifying Orders of Differencing.” This table displays the orders that were automatically selected by the AUTOMDL statement. Unless the nonseasonal and seasonal
differences are specified using the DIFFORDER= option, the AUTOMDL statement automatically identifies the orders of differencing. This table is output by default unless NONE or ONLY is specified in the option-list.

UNITROOTTESTMDL displays the table titled “ARIMA Estimates for Unit Root Identification.” This table summarizes the various models that were considered by the TRAMO automatic selection method while it identified the orders of differencing and the statistics associated with those models. The unit root identification method first attempts to obtain the coefficients by using the Hannan-Rissanen method. If Hannan-Rissanen estimation cannot be performed, the algorithm attempts to obtain the coefficients by using conditional likelihood estimation.

By default, PRINT=(UNITROOTTEST AUTOCHOICE INITCHOICEMDL FINALCHECKS).

REDUCECV=value specifies the percentage by which the outlier critical value be reduced when a final model is found to have an unacceptable confidence coefficient for the Ljung-Box $Q$ statistic. This value should be between 0 and 1. The default value is 0.14286.

### BY Statement

BY variables;

A BY statement can be used with PROC X13 to obtain separate analyses on observations in groups defined by the BY variables. When a BY statement appears, the procedure expects the input DATA= data set to be sorted in order of the BY variables.

### CHECK Statement

CHECK options;

The CHECK statement produces statistics for diagnostic checking of residuals from the estimated regARIMA model.

The following tables that are associated with diagnostic checking are displayed in the output: “Autocorrelation of regARIMA Model Residuals,” “Partial Autocorrelation of regARIMA Model Residuals,” “Autocorrelation of Squared regARIMA Model Residuals,” “Outliers of the Unstandardized Residuals,” “Summary Statistics for the Unstandardized Residuals,” “Normality Statistics for regARIMA Model Residuals,” and “Table G Rs: 10*LOG(SPECTRUM) of the regARIMA Model Residuals.” If ODS graphics is enabled, the following plots that are associated with diagnostic checking output are produced: the autocorrelation function (ErrorACF) plot of the residuals, the partial autocorrelation function (ErrorPACF) plot of the residuals, the autocorrelation function (SqErrorACF) plot of the squared residuals, a histogram (ResidualHistogram) of the residuals, and a spectral plot (SpectralPlot) of the residuals. For more information about controlling the display of plots, see the PLOTS=RESIDUAL option in the PROC X13 statement.

The residual histogram displayed by the X13 procedure shows the distribution of the unstandardized, uncentered regARIMA model residuals; the residual histogram displayed by the US Census Bureau’s X-13ARIMA-SEATS seasonal adjustment program displays standardized and mean-centered residuals.
The following *options* can appear in the CHECK statement:

**MAXLAG=value**

specifies the number of lags for the residual sample autocorrelation function (ACF) and partial autocorrelation function (PACF). The default is 36 for monthly series and 12 for quarterly series. The minimum value for MAXLAG= is 1.

For the table “Autocorrelation of Squared regARIMA Model Residuals” and the corresponding SqErrorACF plot, the maximum number of lags calculated is 12 for monthly series and 4 for quarterly series. The MAXLAG= option can only reduce the number of lags for this table and plot.

**PRINT=(option-list)**

specifies the diagnostic checking tables to be displayed. You can specify one or more of the following *options* (parentheses are optional; use a space between *options*):

- **NONE** suppresses diagnostic checking output. If PRINT=NONE is specified and no other PRINT= option is specified, then none of the tables that are associated with diagnostic checking are displayed. However, PRINT=NONE has no effect if other PRINT= options are specified in the CHECK statement.
- **ALL** specifies that all tables related to diagnostic checking be displayed.
- **ACF** displays the table titled “Autocorrelation of regARIMA Model Residuals.”
- **ACFSQUARED** displays the table titled “Autocorrelation of Squared regARIMA Model Residuals.”
- **NORM** displays the table titled “Normality Statistics for regARIMA Model Residuals.” Measures of normality included in this table are skewness, Geary’s a statistic, and kurtosis.
- **PACF** displays the table titled “Partial Autocorrelation of regARIMA Model Residuals.”
- **RESIDUALOUTLIER** displays the table titled “Outliers of the Unstandardized Residuals” if the residuals contain outliers. You can specify this option either as PRINT=RESIDUALOUTLIER or PRINT=RESOUTLIER.
- **RESIDUALSTATISTICS** displays the table titled “Summary Statistics for the Unstandardized Residuals.” You can specify this option either as PRINT=RESIDUALSTATISTICS or PRINT=RESSTAT.
- **SPECRESIDUAL** displays the table titled “Table G Rs: 10*LOG(SPECTRUM) of the regARIMA Model Residuals.”

By default, PRINT=(ACF ACFSQUARED NORM RESIDUALOUTLIER RESIDUALSTATISTICS SPECRESIDUAL).

---

**ESTIMATE Statement**

**ESTIMATE options ;**

The ESTIMATE statement estimates the regARIMA model. The regARIMA model is specified by the REGRESSION, INPUT, EVENT, and ARIMA statements or by the MDLINFOIN= data set in the PROC
X13 statement. Estimation output includes point estimates and standard errors for all estimated AR, MA, and regression parameters; the maximum likelihood estimate of the variance $\sigma^2$; $t$ statistics for individual regression parameters; $\chi^2$ statistics for assessing the joint significance of the parameters associated with certain regression effects (if included in the model); and likelihood-based model selection statistics (if the exact likelihood function is used). The regression effects for which $\chi^2$ statistics are produced are fixed seasonal effects.

The following options can appear in the ESTIMATE statement:

**EXACT=ARMA | MA | NONE** *(Experimental)*

specifies the likelihood function for estimation, likelihood evaluation, and forecasting. You can specify the following values:

- **ARMA** uses the likelihood function that is exact for both AR and MA parameters.
- **MA** uses the likelihood function that is exact for MA parameters, but conditional for AR parameters.
- **NONE** uses the likelihood function that is conditional for both AR and MA parameters.

The ARMA estimation iterations are displayed in the “Iteration History” table, which is available when the ITPRINT option is specified. By default, EXACT=ARMA.

**ITPRINT**

displays the “Iteration History” table. This table includes detailed output for estimation iterations, including log-likelihood values, parameters, counts of function evaluations, and iterations. It is useful to examine the “Iteration History” table when errors occur within estimation iterations. By default, only successful iterations are displayed, unless the PRINTERR option is specified. An unsuccessful iteration is an iteration that is restarted due to a problem such as a root inside the unit circle. Successful iterations have a status of 0. If restarted iterations are displayed, a note at the end of the table gives definitions for status codes that indicate a restarted iteration. For restarted iterations, the number of function evaluations and the number of iterations is –1, which is displayed as missing. If regression parameters are included in the model, then both IGLS and ARMA iterations are included in the table. The number of function evaluations is a cumulative total.

**MAXITER=value**

specifies the maximum number of iterations used in estimating the AR and MA parameters. For models that include regression variables, this limit applies to the total number of ARMA iterations over all iterations of the iterative generalized least squares (IGLS) algorithm. For models without regression variables, value is the maximum number of iterations allowed for the set of ARMA iterations. By default, MAXITER=1500.

**PRINTERR**

causes restarted iterations to be included in the “Iteration History” table if ITPRINT is specified; creates the “Restarted Iterations” table if ITPRINT is not specified. Whether or not PRINTERR is specified, a WARNING message is printed to the log file if any iteration is restarted during estimation.
**TOL=** specified the convergence tolerance for the nonlinear estimation. Absolute changes in the log-likelihood are compared to the TOL= value to check convergence of the estimation iterations. For models with regression variables, the TOL= value is used to check convergence of the IGLS iterations (where the regression parameters are reestimated for each new set of AR and MA parameters). For models without regression variables, there are no IGLS iterations, and the TOL= value is then used to check convergence of the nonlinear iterations that are used to estimate the AR and MA parameters. The default value is TOL=0.00001. The minimum tolerance value is a positive value based on the machine precision and the length of the series. If a tolerance less than the minimum supported value is specified, an error message is displayed and the series is not processed.

**EVENT Statement**

**EVENT variables < / options > ;**

The EVENT statement specifies events to be included in the regression portion of the regARIMA model. Multiple EVENT statements can be specified. Dummy variable values for EVENT variables are generated by the X13 procedure, however, the EVENT variables are input as user-defined regression effects to the X-13ARIMA-SEATS method. Thus, the EVENT variables are treated in the same manner as it treats variables specified in the USERVAR= option in the REGRESSION statement. If a MDLINFOIN= data set is not specified in the PROC X13 statement, then all variables specified in the EVENT statements are applied to all BY groups and all time series that are processed. If a MDLINFOIN= data set is specified, then the EVENT statements apply only if no regression information for the BY group and series is available in the MDLINFOIN= data set. The events specified in the EVENT statements either must be SAS predefined events or must be defined in the data set specified in the INEVENT= option in the PROC X13 statement. For a summary of SAS predefined events, see the section “SAS Predefined Events” on page 3341.

The EVENT statement can also be used to include outlier, level-shift, and temporary change regressors that are available as predefined US Census Bureau variables in the X-13ARIMA-SEATS program. For example, the following statements specify an additive outlier in January 1970 and a level-shift that begins in July 1971:

```
proc x13 data=ICMETI seasons=12 start=jan1968;
  event AO01JAN1970D CBLS01JUL1971D;
```

The following statements specify an additive outlier in the second quarter 1970 and a temporary change that begins in the fourth quarter 1971:

```
proc x13 data=ICMETI seasons=4 start='1970q1';
  event AO01APR1970D TC01OCT1971D;
```

The following **options** can appear in the EVENT statement:

**B=(value <F> . . .)**

specifies initial or fixed values for the EVENT parameters in the order in which they appear in **variables**. Each B= list applies to the variable list that immediately precedes the slash.

For example, the following statements set an initial value of 1 for the event, x:

```
  event y ;
  event x / b=1 2 ;
```

In this example, the B= option applies only to the second EVENT statement. The value 2 is discarded because there is only one variable in the variable list.
To assign an initial value of 1 to the y regressor and 2 to the x regressor, use the following statements:

```plaintext
event y / b=1;
event x / b=2;
```

An F immediately following the numerical value indicates that this is not an initial value, but a fixed value. For an example that uses fixed parameters, see Example 46.8. In PROC X13, individual parameters can be fixed while other parameters in the same model are estimated.

**USERTYPE=(values)**

enables a user-defined variable to be processed in the same manner as a US Census predefined variable. You can specify the following values: AO, CONSTANT, EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, LS, RP, SCEASTER, SEASONAL, TC, TD, TDSTOCK, THANKS, or USER. For example, the US Census Bureau EASTER(w) regression effects are included in the “RegARIMA Holiday Component” table (A7). Specify USERTYPE=EASTER to include an event variable that is processed exactly as the US Census predefined EASTER(w) variable, including inclusion in the A7 table. The NOAPPLY= option in the REGRESSION statement also changes the processing of variables based on the USERTYPE= value. Table 46.4 shows the regression types that are associated with each regression effects table.

Each USERTYPE= list applies to the variable list that immediately precedes the slash. The same rules for assigning B= values to regression variables apply for USERTYPE= options. For example, the following statements specify that the event in the variable MyEaster be processed exactly as the US Census predefined LOM variable:

```plaintext
event MyLOM;
event MyEaster / usertype=LOM EASTER;
```

In this example, the USERTYPE= option applies only to the MyEaster variable in the second EVENT statement. The USERTYPE value EASTER is discarded because there is only one variable in the variable list.

To assign the USERTYPE value LOM to the MyLOM variable and EASTER to the MyEaster variable, use the following statements:

```plaintext
event MyLOM / usertype=LOM;
event MyEaster / usertype=EASTER;
```

The following USERTYPE= options specify that the regression effect be removed from the seasonally adjusted series: EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, SCEASTER, SEASONAL, TD, TDSTOCK, THANKS, and USER. When a regression effect is removed from the seasonally adjusted series, the level (mean) of the seasonally adjusted series can be altered. It is often desirable to use a zero-mean (mean-adjusted) regressor for effects that are to be removed from the seasonally adjusted series. For an example showing the effects of specifying a zero-mean regressor, see Example 46.6.
The FORECAST statement uses the estimated model to forecast the time series. The output contains point forecasts and forecast statistics for the transformed and original series. Whenever forecasts or backcasts (or both) are generated and seasonal adjustment is performed, the forecasts and backcasts are appended to the original series, and the seasonal adjustment procedures are applied to the forecast or backcast (or both) extended series. If the FORECAST statement is not specified, but a regARIMA model is specified using either the ARIMA or AUTOMDL statement, then the series is extended one year ahead by default.

Tables that contain forecasts, standard errors, and confidence limits are displayed in association with the FORECAST statement. If the data are transformed, then two tables are displayed: one table for the original data, and one table for the transformed data. Data from these tables can be output to a SAS data set using ODS. The auxiliary variable `_SCALE_` is included in forecast data sets that are output using ODS. The value of `_SCALE_` is “Original” or “Transformed” to indicate the scale of the data. The auxiliary variable can also be used in ODS SELECT and ODS OUTPUT statements. For example, you can specify the following statements to output the forecasts on the original scale to a data set `forecasts` and the forecasts on the transformed scale to a data set `Tforecasts`:

```sas
ods output Original.ForecastCL=forecasts;
ods output Transformed.ForecastCL=Tforecasts;
```

The following `options` can appear in the FORECAST statement:

- **ALPHA=\(\alpha\)** specifies the size of the upper and lower confidence limits, which are calculated as \(1 - \alpha\), where \(\alpha\) must be between 0 and 1. By default, ALPHA=0.05, which produces 95% confidence intervals.

- **LEAD=value** specifies the number of periods ahead to forecast for regARIMA extension of the series. The default is the number of periods in a year (4 or 12), and the maximum is 120. Setting LEAD=0 specifies that the series not be extended by forecasts for seasonal adjustment. The LEAD= value also controls the number of forecasts that are displayed in Table D10.A. However, if the series is not extended by forecasts (LEAD=0), then the default year of forecasts is displayed in Table D10.A. Forecast values in Table D10.A are calculated using the method shown on page 148 of Ladiray and Quenneville (2001) based on values that are displayed in Table D10. The regARIMA forecasts affect the D10.A forecasts only indirectly through the impact of the regARIMA forecasts on the seasonal factors that are shown in Table D10. If the SEATSDECOMP statement is specified, then value is increased to the minimum required for SEATS decomposition. For more information, see the section “SEATS Decomposition” on page 3349.

- **NBACKCAST=value**
- **BACKCAST=value**
- **NBACK=value**

specifies the number of periods to backcast for regARIMA extension of the series. The default is NBACKCAST=0, which specifies that the series not be extended with backcasts. The maximum number of backcasts is 120. When the OUTBACKCAST option is specified, the NBACKCAST= value also controls the number of backcasts that are output to the OUT= data set specified in the OUTPUT statement. If the SEATSDECOMP statement is specified, then value is increased to the minimum required for SEATS decomposition.
required for SEATS decomposition. For more information, see the section “SEATS Decomposition” on page 3349.

**OUT1STEP**

specifies that the one-step-ahead forecasts be computed and displayed in addition to the multistep forecasts. The default is to compute and display only the multistep forecasts beginning at the forecast horizon.

**OUTBACKCAST**

**OUTBKCAST**

determines whether backcasts are included in certain tables sent to the output data set. If OUTBACKCAST is specified, then backcast values are included in the output data set for tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, and D18. The default is not to include backcasts.

**OUTFCST**

**OUTFORECAST**

determines whether forecasts are included in certain tables sent to the output data set. If OUTFORECAST is specified, then forecast values are included in the output data set for Tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, D18, and E18. The default is not to include forecasts. The OUTFORECAST option can be specified in either the X11 statement or the FORECAST statement with identical results.

### ID Statement

**ID variables ;**

If you are creating an output data set, use the ID statement to copy values of the ID variables, in addition to the table values, into the output data set. Or, if the VAR statement is omitted, all numeric variables that are not identified as BY variables, ID variables, the DATE= variable, or user-defined regressors are processed as time series. The ID statement has no effect when a VAR statement is specified and an output data set is not created. If the DATE= variable is specified in the PROC X13 statement, this variable is included automatically in the OUTPUT data set. If no DATE= variable is specified, the variable _DATE_ is added.

The date variable (or _DATE_) values outside the range of the actual data (from forecasting) are extrapolated, while all other ID variables are missing in the forecast horizon.

### IDENTIFY Statement

**IDENTIFY options ;**

The IDENTIFY statement produces plots of the sample autocorrelation function (ACF) and partial autocorrelation function (PACF) for identifying the ARIMA part of a regARIMA model. The sample ACF and PACF are produced for all combinations of the nonseasonal and seasonal differences of the data specified by the DIFF= and SDIFF= options.

The original series is first transformed as specified in the TRANSFORM statement.

If the model includes a regression component (specified using the REGRESSION, INPUT, and EVENT statements or the MDLINFOIN= data set in the PROC X13 statement), both the transformed series and
the regressors are differenced at the highest order that is specified in the DIFF= and SDIFF= option. The parameter estimates are calculated using the differenced data. Then the undifferenced regression effects (with the exception of a constant term) are removed from the undifferenced data to produce undifferenced regression residuals. The ACFs and PACFs are calculated for the specified differences of the undifferenced regression residuals.

If the model does not include a regression component, then the ACFs and PACFs are calculated for the specified differences of the transformed data.

Tables displayed in association with identification are “Autocorrelation of Model Residuals” and “Partial Autocorrelation of Model Residuals.” If the model includes a regression component (specified using the REGRESSION, INPUT, and EVENT statements or the MDLINFOIN= data set in the PROC X13 statement), then the “Regression Model Parameter Estimates” table is also displayed if the PRINTREG option is specified.

The following options can appear in the IDENTIFY statement:

**DIFF=(order, order, order)**
specifies orders of nonseasonal differencing to use in model identification. The value 0 specifies no differencing, the value 1 specifies one nonseasonal difference \((1 - B)\), the value 2 specifies two nonseasonal differences \((1 - B)^2\), and so forth. The ACFs and PACFs are produced for all orders of nonseasonal differencing specified, in combination with all orders of seasonal differencing that are specified in the SDIFF= option. The default is DIFF=(0). You can specify up to three values for nonseasonal differences.

**MAXLAG=value**
specifies the number of lags for the sample autocorrelation function (ACF) and partial autocorrelation function (PACF) of the regression residuals for model identification. The default is 36 for monthly series and 12 for quarterly series. MAXLAG applies to both tables and plots. The minimum value for MAXLAG= is 1.

**PRINTREG**
causes the “Regression Model Parameter Estimates” table to be printed if the REGRESSION statement is present. By default, this table is not printed.

**SDIFF=(order, order, order)**
specifies orders of seasonal differencing to use in model identification. The value 0 specifies no seasonal differencing, the value 1 specifies one seasonal difference \((1 - B^s)\), the value 2 specifies two seasonal differences \((1 - B^s)^2\), and so forth. The value for \(s\) corresponds to the period specified in the SEASONS= option in the PROC X13 statement. The value of the SEASONS= option is supplied explicitly or is implicitly supplied through the INTERVAL= option or the values of the DATE= variable. The ACFs and PACFs are produced for all orders of seasonal differencing specified, in combination with all orders of nonseasonal differencing specified in the DIFF= option. The default is SDIFF=(0). You can specify up to three values for seasonal differences.

For example, the following statement produces ACFs and PACFs for two levels of differencing: \((1 - B)\) and \((1 - B)(1 - B^3)\):

\[
\text{identify diff=(1) sdiff=(0, 1)};
\]
INPUT Statement

**INPUT** variables < / options > ;

The INPUT statement specifies variables in the DATA= or AUXDATA= data set (which are specified in the PROC X13 statement) that are to be used as regressors in the regression portion of the regARIMA model. The variables in the data set should contain the values for each observation that define the regressor. Past values of regression variables should also be included in the DATA= or AUXDATA= data set if the time series listed in the VAR statement is to be extended with regARIMA backcasts. Similarly, future values of regression variables should also be included in the DATA= or AUXDATA= data set if the time series listed in the VAR statement is to be extended with regARIMA forecasts.

You can specify multiple INPUT statements. If you do not specify a MDLINFOIN= data set in the PROC X13 statement, then all variables listed in the INPUT statements are applied to all BY groups and all time series that are processed. If you specify a MDLINFOIN= data set, then the INPUT statements apply only if no regression information for the BY group and series is available in the MDLINFOIN= data set.

The INPUT statement provides the same functionality as the USERVAR= option in the REGRESSION statement. For more information about specifying user-defined regression variables, see the section “User-Defined Regression Variables” on page 3344, Example 46.6, and Example 46.11.

The following **options** can appear in the INPUT statement:

- **B=(value < F > ...)**
  - specifies initial or fixed values for the regression parameters in the order in which they appear in variables. Each B= list applies to the variable list that immediately precedes the slash.
  - For example, the following statements set an initial value of 1 for the user-defined regressor, x:

    ```
    input y ;
    input x / b=1 2 ;
    ```

    In this example, the B= option applies only to the second INPUT statement. The value 2 is discarded because there is only one variable in the variable list.

    To assign an initial value of 1 to the y regressor and 2 to the x regressor, use the following statements:

    ```
    input y / b=1;
    input x / b=2 ;
    ```

  - An F immediately following the numerical value indicates that this is not an initial value, but a fixed value. For an example that uses fixed parameters, see Example 46.8. In PROC X13, individual parameters can be fixed while other parameters in the same model are estimated.

- **USERTYPE=(values)**
  - enables a user-defined variable to be processed in the same manner as a US Census predefined variable. You can specify the following values: AO, CONSTANT, EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, LS, RP, SCEASTER, SEASONAL, TC, TD, TDSTOCK, THANKS, or USER. For example, the US Census Bureau EASTER(w) regression effects are included in the “RegARIMA Holiday Component” table (A7). Specify USERTYPE=EASTER to include a user-defined variable that is processed exactly as the US Census predefined EASTER(w) variable, including
inclusion in the A7 table. The NOAPPLY= option in the REGRESSION statement also changes the processing of variables based on the USERTYPE= value. Table 46.4 shows the regression types that are associated with each regression effects table.

Each USERTYPE= list applies to the variable list that immediately precedes the slash. The same rules for assigning B= values to regression variables apply for USERTYPE= options. For example, the following statements specify that the user-defined regressor in the variable MyEaster be processed exactly as the US Census predefined LOM variable:

```
input MyLOM;
input MyEaster / usertype=LOM EASTER;
```

In this example, the USERTYPE= option applies only to the MyEaster variable in the second INPUT statement. The USERTYPE value EASTER is discarded because there is only one variable in the variable list.

To assign the USERTYPE value LOM to the MyLOM variable and EASTER to the MyEaster variable, use the following statements:

```
input MyLOM / usertype=LOM;
input MyEaster / usertype=EASTER;
```

The following USERTYPE= options specify that the regression effect be removed from the seasonally adjusted series: EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, SCEASTER, SEASONAL, TD, TDSTOCK, THANKS, and USER. When a regression effect is removed from the seasonally adjusted series, the level (mean) of the seasonally adjusted series can be altered. It is often desirable to use a zero-mean (mean-adjusted) regressor for effects that are to be removed from the seasonally adjusted series. For an example that specifies a zero-mean regressor, see Example 46.6.

**OUTLIER Statement**

```
OUTLIER options ;
```

The OUTLIER statement specifies that the X13 procedure perform automatic detection of additive point outliers, temporary change outliers, level-shifts, or any combination of the three when using the specified model. After outliers are identified, the appropriate regression variables are incorporated into the model as “Automatically Identified Outliers,” and the model is reestimated. This procedure is repeated until no additional outliers are found.

The OUTLIER statement also identifies potential outliers and lists them in the “Potential Outliers” table in the displayed output. Potential outliers are identified by decreasing the critical value by the value that is specified in the ALMOST= option.

In the output, the initial critical values used for outlier detection in a given analysis are displayed in the table “Critical Values to Use in Outlier Detection.” Outliers that are detected and incorporated into the model are displayed in the output in the table “Regression Model Parameter Estimates,” where the regression variable is listed as “Automatically Identified.”

You can specify the following options:
ALMOST=value

specifies the difference between the critical value for an automatically identified outlier and a potential outlier that is “almost” identified. value is subtracted from the critical value that is used to identify outliers to form a critical value that more aggressively identifies potential outliers. Potential outliers are not included in the regARIMA model. However, potential outliers are displayed in the “Potential Outliers” table. value must be greater than 0. By default, ALMOST=0.5.

ALPHA=value

specifies the significance level to use for outlier identification, where critical values are calculated based on value. Any critical value that is specified in the CV=, AOCV=, LSCV=, or TCCV= option overrides the critical values that are calculated based on this option. value must be greater than 0 and less than or equal to 0.1. If you do not specify this option or the CV= option, the X-13ARIMA-SEATS method calculates the default initial critical value by assuming ALPHA=0.05.

AOCV=value

specifies a critical value to use for additive point outliers. If you specify this option, it overrides any default initial critical value for AO outliers. For more information, see the CV= option.

CV=value

specifies a default initial critical value to use for detecting all types of outliers. The absolute value of the t statistic that is associated with an outlier parameter estimate is compared with value to determine the significance of the outlier. If you do not specify this option, then the default initial critical value is computed based on the ALPHA= option, the CVMETHOD= option, and the number of observations for the model span that is used in the analysis. Table 46.2 shows initial critical values for various series lengths, which are based on the default values of the ALPHA= option and CVMETHOD= option. Increasing the critical value decreases the sensitivity of the outlier detection routine and can reduce the number of observations that are treated as outliers. The automatic model identification process might decrease the critical value by a certain percentage if the automatic model identification process fails to identify an acceptable model.

**CVMETHOD=CORRECTED | LJUNG**

specifies the method to use to calculate the default initial critical value, based on the **ALPHA=** value and the number of observations for the model span that is used in the analysis. You can specify the following values:

**CORRECTED**

uses a method that is a modification of the Ljung method in which critical values are interpolated based on the number of observations in the model span.

**LJUNG**

uses a method that is based on the asymptotic formula described in Ljung (1993).

By default, CVMETHOD=CORRECTED.

**LSCV=value**

specifies a critical value to use for level-shift outliers. If you specify this option, it overrides any default initial critical value for LS outliers. For more information, see the **CV=** option.

**LSRUN=value**

specifies the maximum number of successive level-shift outliers to combine to form a temporary level-shift. Valid values for this option are 0 to 5, inclusive. If LSRUN=0 or LSRUN=1, no temporary level-shifts are evaluated. The evaluation of the temporary level-shifts is displayed in the “Tests for Cancellation of Level Shifts” table. By default, LSRUN=0.

**METHOD=ADDALL | ADDONE**

specifies whether to add outliers one at a time for each model estimation iteration or to add all outliers at once for each model estimation iteration. You can specify the following values:

**ADDALL**

includes all significant outliers as regressors in the model, and then reestimates the model.

**ADDONE**

adds the most significant outlier as a regressor in the model, and then reestimates the model.
For both methods, all candidate points for outliers are evaluated at each iteration and model estimation iterations continue until no remaining outliers are identified. By default, METHOD=ADDOONE.

\[ \text{SPAN}=(\text{mmmyy }, \text{mmmyy}) \]
\[ \text{SPAN}=(\text{yyQq'}, \text{yyQq'}) \]

specifies the dates of the first and last observations to define a subset for searching for outliers. A single date in parentheses is interpreted to be the starting date of the subset. To specify only the ending date, use SPAN=(,mmmyy) or SPAN=(,yyQq'). If the starting or ending date is omitted, then the first or last date, respectively, of the input data set or BY group is assumed. Because the dates are input as strings and the quarterly dates begin with a numeric character, the specification for a quarterly date must be enclosed in quotation marks. A four-digit year can be specified. If a two-digit year is specified, the value specified in the YEARCUTOFF= SAS system option applies.

\[ \text{TCCV}=\text{value} \]

specifies a critical value to use for temporary change (TC) outliers. If you specify this option, it overrides any default initial critical value for TC outliers. For more information, see the CV= option.

\[ \text{TCRATE}=\text{value} \]

specifies the rate of decay for temporary change outliers. value must be greater than 0 and less than 1. The default value is \((0.7)^{\frac{12}{\text{period}}}, \) where period is the number of observations in one year.

\[ \text{TYPE}=\text{NONE} \]
\[ \text{TYPE}=\text{(outlier types)} \]

lists the outlier types to be detected by the automatic outlier identification method. TYPE=NONE turns off outlier detection. The valid outlier types are AO, LS, and TC. The default is TYPE=(AO LS).

---

**OUTPUT Statement**

```
OUTPUT OUT=SAS-data-set < YEARSEAS > tablename1 tablename2 . . . ;
```

The OUTPUT statement creates an output data set that contains specified tables. The data set is named by the OUT= option.

\[ \text{OUT}=\text{SAS-data-set} \]

names the data set to contain the specified tables. If the OUT= option is omitted, the data set is named using the default DATA_ convention.

\[ \text{YEARSEAS} \]
\[ \text{YRSEAS} \]

specifies that two additional variables be added to the OUT= data set. The two additional variables are the variables _YEAR_ and _SEASON_. The variable _YEAR_ contains the year of the date identifying the observation. The variable _SEASON_ contains the month for monthly data, or quarter for quarterly data, of the date that identifies the observation. For monthly data, the value of _SEASON_ is between 1 and 12. For quarterly data, the value of _SEASON_ is between 1 and 4. The _YEAR_ and _SEASON_ variables are useful when creating seasonal plots.
tablename1 tablename2 . . .
specify X13 tablenames that correspond to the title label used by the US Census Bureau X-13ARIMA-SEATS software. Specify one tablename for each table to be included in the output data set. Currently available tablenames are A1, A2, A6, A7, A8, A8AO, A8LS, A8TC, A9, A10, A19, B1, B7, B13, B17, B20, C1, C17, C20, D1, D7, D8, D8B, D8BX, D8BO, D8BL, D9, D10, D10B, D10D, D11, D11A, D11F, D11R, D12, D13, D16, D16B, D18, E1, E2, E3, E5, E6, E6A, E6R, E7, E8, E18, and MV1. Specifying D8B is equivalent to specifying D8, D8BX, D8BO, and D8BL because Table D8.B displays the D8 series along with labels for extremes (D8BX), outliers (D8BO), and level shifts (D8BL). If no table is specified in the OUTPUT statement, Table A1 is output to the OUT= data set by default.

The tablenames that can be used in the OUTPUT statement are listed in the section “Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords” on page 3350. The following is an example of a VAR statement and an OUTPUT statement:

```
var sales costs;
output out=out_x13 b1 d11;
```

The default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name. The variable `sales_B1` contains the Table B1 values for the variable `sales`, the variable `costs_B1` contains the Table B1 values for the variable `costs`, the variable `sales_D11` contains the Table D11 values for the variable `sales`, and the variable `costs_D11` contains the Table D11 values for the variable `costs`. If necessary, the variable name is shortened so that the table name can be added. If the DATE= variable is specified in the PROC X13 statement, then that variable is included in the output data set; otherwise, a variable named _DATE_ is written to the OUT= data set as the date identifier.

---

**PICKMDL Statement (Experimental)**

```
PICKMDL options;
```

The PICKMDL statement enables you to specify a variety of options for the PICKMDL method. The PICKMDL method uses models that are specified in the MDLINFOIN= data set to choose a regARIMA model. If the MDLINFOIN= option is not specified, then the PICKMDL method chooses a model from the list shown in Table 46.14. Example 46.9 demonstrates the use of the PICKMDL statement.

The PICKMDL statement cannot be specified when the AUTOMDL statement is also specified. The AUTOMDL and PICKMDL statements each specify different methods of automatic model selection. So only one of these methods can be used to select a model.

For more information about using the US Census Bureau’s PICKMDL method for model selection, see the section “PICKMDL Model Selection” on page 3348.

You can specify the following options in the PICKMDL statement:

**ARIMAMISS= ARIMASTMT | ZEROORDERS**

specifies the method for interpreting missing ARIMA information in a model that is present in the MDLINFOIN= data set. You can specify the following values:
Chapter 46: The X13 Procedure

**ARIMASTMT** interprets missing information as the model that is specified in the MODEL= option of the ARIMA statement. This option should not be specified if the MDLINFOOUT= data set from a previous X13 procedure call is being used to replicate previous results. However, the (0 0 0)(0 0 0) model is not always the most appropriate model to use as a default when no model has been specified. This option enables you to specify default model orders.

**ZEROORDERS** interprets missing information as the (0 0 0)(0 0 0) model. This method is compatible with the output from the MDLINFOOUT= option.

By default, ARIMAMISS=ZEROORDERS.

**MDLVAR=** `variable`
specifies the variable in the MDLINFOIN= data set that identifies the models. A model identification variable is not required in the data set if fewer than two models are specified for each series. By default, MDLVAR= `_MODEL_`.

**METHOD=** `BEST | FIRST` specifies the method for choosing the regARIMA model. You can specify the following values:

- **BEST** chooses the best model.
- **FIRST** chooses the first acceptable model.

By default, METHOD=FIRST.

---

**REGRESSION Statement**

**REGRESSION** `regression-group-options`;

**REGRESSION PREDEFINED=** `variables < / B=(value < F > . . . )>`;

**REGRESSION USERVAR=** `variables < / B=(value < F > . . . ) USERTYPE=(values) >`;

The REGRESSION statement includes regression variables in a regARIMA model or specifies regression variables whose effects are to be removed by the IDENTIFY statement to aid in ARIMA model identification. Include the PREDEFINED= option to select predefined regression variables. Include the USERVAR= option to specify user-defined regression variables.

Table 46.3 shows the X-13ARIMA-SEATS tables that contain regression factors. Tables A8AO, A8LS, and A8TC are available only when more than one outlier type is present in the model.

</table>
Missing values in the span of an input series automatically create missing value regressors. For more information about missing values, see the NOTRIMMISS option in the PROC X13 statement and the section “Missing Values” on page 3340.

Combining your model with additional predefined regression variables can result in a singularity problem. To successfully perform the regression if a singularity occurs, you might need to alter either the model or the choices of the regressors.

To seasonally adjust a series that uses a regARIMA model, the factors derived from regression are used as multiplicative or additive factors, depending on the mode of seasonal decomposition. Therefore, regressors that are appropriate to the mode of the seasonal decomposition should be defined, so that meaningful combined adjustment factors can be derived and adjustment diagnostics can be generated. For example, if a regARIMA model is applied to a log-transformed series, then the regression factors are expressed as ratios, which match the form of the seasonal factors that are generated by the multiplicative or log-additive adjustment modes. Conversely, if a regARIMA model is fit to the original series, then the regression factors are measured on the same scale as the original series, which matches the scale of the seasonal factors that are generated by the additive adjustment mode. Note that the default transformation (no transformation) and the default seasonal adjustment mode (multiplicative) are in conflict. Thus, when you specify the X11 statement and any of the REGRESSION, INPUT, or EVENT statements, you must also either use the TRANSFORM statement to specify a transformation or use the MODE= option in the X11 statement to specify a different mode to seasonally adjust the data that uses the regARIMA model.

According to Ladiray and Quenneville (2001), “X-12-ARIMA is based on the same principle [as the X-11 method] but proposes, in addition, a complete module, called Reg-ARIMA, that allows for the initial series to be corrected for all sorts of undesirable effects. These effects are estimated using regression models with ARIMA errors (Findley et al. [23]).” The REGRESSION, INPUT, and EVENT statements specify these regression effects. Predefined effects that can be corrected in this manner are listed in the PREDEFINED= option. You can create your own definitions to remove other effects by using the USERVAR= option and the EVENT statement.

You can specify either the PREDEFINED= option or the USERVAR= option, but not both, in a single REGRESSION statement. You can use multiple REGRESSION statements.

You can specify the following regression-group-options in the REGRESSION statement. The regression-group-options apply to all regression variables in a regression group. For predefined regression variables, the regression group is predefined. For user-defined regression variables, you can specify the regression group in the USERTYPE= option.

AICTEST=(EASTER | TD | TD1COEF | TD1NOLPYEAR | TDNOLPYEAR | TDSTOCK | USER)

specifies that an AIC-based selection be used to determine whether a given set of regression variables are to be included with the specified regARIMA model. For example, if you specify a trading day model selection, then AIC values (with a correction for the length of the series, henceforth referred to as AICC) are derived for models with and without the specified trading day variable. By default, the
model with a smaller AICC is used to generate forecasts, identify outliers, and so on. If you specify more than one type of regressor, the AIC tests are performed sequentially in this order: (a) trading day regressors, (b) Easter regressors, (c) user-defined regressors. If there are several variables of the same type (for example, several trading day regressors), then AIC-based selection is applied to them as a group. That is, either all variables of this type or none are included in the final model. If you do not specify this option, no automatic AIC-based selection is performed.

If you use the AUTOMDL statement to identify the model and you also specify this option, then this option affects the model selection process in the following manner:

- AIC-based selection tests are performed on the default model.
- A new series is created by removing the regression effects that are identified in the default model from the original series. The automatic model identification process attempts to identify a model that is based on the new series.
- After a model is automatically identified, AIC-based selection tests that use the automatically identified model are performed on the original series.
- The default model, including regressors that are identified by using AIC-based selection, is compared to the automatically identified model, which also might include regressors that are identified by using AIC-based selections. The regressors for the two models can differ.

**EASTERMEANS=** *(YR400 | YR500 | SPAN)*

specifies how the monthly means, which are used to remove seasonality from the EASTER predefined regressor, are calculated. When **PREDEFINED=EASTER(w)** is specified in the REGRESSION statement, monthly means are computed internally over the 500-year range from 1600 to 2099 by default. These monthly means are then used to remove seasonality from the Easter effect prior to calculating the Easter regression coefficient. The EASTERMEANS= option is ignored if no predefined EASTER regressor is included in the regression model or if SCEASTER(w) is the only predefined Easter regressor specified. You can specify the following values:

- **SPAN** computes short-term monthly means rather than long-term monthly means to remove seasonality in the Easter effect. In this case, the monthly means are computed over the same span of data that is used to calculate the coefficient of the EASTER(w) regressor.
- **YR400** computes monthly means over the 400-year range from 1583 to 1982. This method was used in earlier versions of the X-13ARIMA-SEATS methodology.
- **YR500** computes monthly means over the 500-year range from 1600 to 2099.

By default, EASTERMEANS=**YR500**.
NOAPPLY=(AO | HOLIDAY | LS | TC | TD | USER | USERSEASONAL)

specifies a list of the types of regression effects whose model-estimated values are not to be removed from the original series before performing the seasonal adjustment calculations that are specified by the X11 statement. The NOAPPLY= option applies to the regression component values displayed in the X11 seasonal adjustment method regARIMA component tables as shown in Table 46.4.

You can specify the following regression variable specification options in the REGRESSION statement.

PREDEFINED=CONSTANT | EASTER(value) | LABOR(value) | LOM | LOMSTOCK | LOQ | LPYEAR
PREDEFINED=SCEASTER(value) | SEASONAL | SINCOS(value . . .) | TD | TD1COEF
PREDEFINED=TD1NOLPYEAR | TDNOLPYEAR | TDSTOCK(value) | THANK(value)

lists the predefined regression variables to be included in the model. Data values for these variables are calculated by the program, mostly as functions of the calendar. Table 46.5 gives definitions for the available predefined variables. The values LOM and LOQ are equivalent: the actual regression is controlled by the SEASONS= option in the PROC X13 statement. You can specify multiple predefined regression variables. The syntax for using both a length-of-month and a seasonal regression can be in one of the following forms:

```
regression predefined=lom seasonal;
regression predefined=(lom seasonal);
regression predefined=lom predefined=seasonal;
```

The following restrictions apply when you use more than one predefined regression variable:

- You can specify only one of TD, TDNOLPYEAR, TD1COEF, or TD1NOLPYEAR.
- You cannot specify LPYEAR with TD, TD1COEF, LOM, LOMSTOCK, or LOQ.
- You cannot specify LOM or LOQ with TD or TDICOEF.
- If you specify the SINCOS predefined regression variable, then you must also specify the INTERVAL= option or the SEASONS= option in the PROC X13 statement because there are restrictions on this regression variable that are based on the frequency of the data.

The predefined regression variables, EASTER, LABOR, SCEASTER, SINCOS, TDSTOCK, and THANK, require extra parameters. Only one TDSTOCK regressor can be implemented in the regression model. If you specify multiple TDSTOCK variables, PROC X13 uses the last TDSTOCK variable specified. For EASTER, LABOR, SCEASTER, SINCOS, and THANK, you can specify the variables with different parameters to implement multiple regressors in the model. For example, the following statement specifies two EASTER regressors with widths 7 and 14:

```r
regression predefined=easter(7) easter(14);
```

For SINCOS, specifying a parameter includes both the sine and the cosine regressor except for the highest order allowed (2 for quarterly data and 6 for monthly data.) For quarterly data, the following statement is the most common use of the SINCOS variable; it includes three regressors in the model:

```r
regression predefined=sincos(1,2);
```

For monthly data, the following statement is the most common use of the SINCOS variable; it includes 11 regressors in the model:

```r
regression predefined=sincos(1,2,3,4,5,6);
```

| Leap year (monthly and quarterly flow) | $LY_t = \begin{cases} 
0.75 & \text{in leap year February (first quarter)} \\
-0.25 & \text{in other Februaries (first quarter)} \\
0 & \text{otherwise} 
\end{cases}$ |
|----------------------------------------|--------------------------------------------------|

Statistics Canada Easter (monthly or quarterly flow)  
Statistics Canada Easter ($SCEASTER(w)$)  
If Easter falls before April $w$, let $n_E$ be the number of the $w$ days on or before Easter that fall in March. Then:

$$E(w, t) = \begin{cases} 
\frac{n_E}{w} & \text{in March} \\
-\frac{n_E}{w} & \text{in April} \\
0 & \text{otherwise} 
\end{cases}$$  
If Easter falls on or after April $w$, then $E(w, t) = 0$.  
(Note: This variable is 0 except in March and April (or first and second quarter).) Restriction: $1 \leq w \leq 24$.  

Fixed seasonal  
Fixed seasonal ($SEASONAL$)  
$$M_{1,t} = \begin{cases} 
1 & \text{in January} \\
-1 & \text{in December} \\
0 & \text{otherwise} 
\end{cases}$$  
$$\ldots, M_{11,t} = \begin{cases} 
1 & \text{in November} \\
-1 & \text{in December} \\
0 & \text{otherwise} 
\end{cases}$$

Fixed seasonal  
Fixed seasonal ($SINCOS(j)$)  
where $w_j = 2\pi j/s, 1 \leq j \leq s/2$, and $s$ is the seasonal period  
(drop $\sin(w_j t)$ for $j = s/2$)  
Restrictions: $1 \leq j_i \leq s/2, 1 \leq n \leq s/2$.

</tbody>
</table>

**USERVAR=(variables)**

specifies variables in the DATA= or AUXDATA= data set (which are specified in the PROC X13 statement) that are to be used as regressors. The variables in the data set should contain the values for each observation that define the regressor. Regression variables should also include future values in the data set for the forecast horizon if the time series is to be extended with regARIMA forecasts. Regression variables should include past values if the time series is to be extended with regARIMA backcasts. Missing values are not permitted within the data span, including backcasts and forecasts, of the user-defined regressors. Example 46.6 shows how to create an input data set that contains both the series to be seasonally adjusted and a user-defined input variable. Example 46.11 shows how to create an auxiliary data set that contains a user-defined input variable. For more information about specifying user-defined regression variables, see the section “User-Defined Regression Variables” on page 3344.

All regression variables in the USERVAR= option apply to all time series to be seasonally adjusted unless the MDLINFOIN= data set specifies different regression information. You cannot specify the PREDEFINED= option and the USERVAR= option in the same REGRESSION statement; however, you can specify multiple REGRESSION statements.

You can specify the following **options** for individual regression variables. Individual regression variable options are specified in the PREDEFINED= and USERVAR= options after the slash. The B= option can be specified in both the PREDEFINED= and USERVAR= options. Because the regression group is predefined for predefined variables, you can specify the USERTYPE= option only in the USERVAR= option.
Chapter 46: The X13 Procedure

\[ \text{B=} (\text{value} < \text{F} > \ldots) \]

specifies initial or fixed values for the regression parameters in the order in which they appear in a PREDEFINED= or USERVAR= option. Each B= list applies to the PREDEFINED= or USERVAR= variable list that immediately precedes the slash.

For example, the following statements set an initial value of 1 for the user-defined regressor, \( x \):

\[
\begin{align*}
\text{regression predefined=} & \text{LOM ;} \\
\text{regression uservar=} & \text{x / b=}1\ 2;
\end{align*}
\]

In this example, the B= option applies only to the USERVAR= option. The value 2 is discarded because there is only one variable in the USERVAR= list.

To assign an initial value of 1 to the LOM regressor and 2 to the \( x \) regressor, use the following statements:

\[
\begin{align*}
\text{regression predefined=} & \text{LOM / b=}1; \\
\text{regression uservar=} & \text{x / b=}2;
\end{align*}
\]

An F immediately following the numerical value indicates that this is not an initial value, but a fixed value. For an example that uses fixed parameters, see Example 46.8. In PROC X13, individual parameters can be fixed while other parameters in the same model are estimated.

\text{USERTYPE=} (values)

enables a variable that you define to be processed in the same manner as a US Census predefined variable. You can specify the following values: AO, CONSTANT, EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, LS, RP, SCEASTER, SEASONAL, TC, TD, TDSTOCK, THANKS, or USER. For example, the US Census Bureau EASTER(\( w \)) regression effects are included the “RegARIMA Holiday Component” table (A7). Specify USERTYPE=EASTER to define a variable that is processed exactly as the US Census predefined EASTER(\( w \)) variable, including inclusion in the A7 table. Each USERTYPE= list applies to the USERVAR= variable list that immediately precedes the slash. USERTYPE= does not apply to US Census predefined variables.

The same rules for assigning B= values to regression variables apply for USERTYPE= options. For example, the following statements specify that the user-defined regressor in the variable \( \text{MyEaster} \) be processed exactly as the US Census predefined LOM variable:

\[
\begin{align*}
\text{regression uservar=} & \text{MyLOM ;} \\
\text{regression uservar=} & \text{MyEaster / usertype=} \text{LOM EASTER ;}
\end{align*}
\]

In this example, the USERTYPE= option applies only to the \( \text{MyEaster} \) variable in the second REGRESSION statement. The USERTYPE value EASTER is discarded because there is only one variable in the USERVAR= list.

To assign the USERTYPE value LOM to the \( \text{MyLOM} \) variable and EASTER to the \( \text{MyEaster} \) variable, use the following statements:
The following USERTYPE= options specify that the regression effect be removed from the seasonally adjusted series: EASTER, HOLIDAY, LABOR, LOM, LOMSTOCK, LOQ, LPYEAR, SCEASTER, SEASONAL, TD, TDSTOCK, THANKS, and USER. When a regression effect is removed from the seasonally adjusted series, the level (mean) of the seasonally adjusted series can be altered. It is often desirable to use a zero-mean (mean-adjusted) regressor for effects that are to be removed from the seasonally adjusted series. For an example that specifies a zero-mean regressor, see Example 46.6.

**SEATSDECOMP Statement (Experimental)**

```
SEATSDECOMP OUT= SAS-data-set < options > ;
```

The SEATSDECOMP statement creates an output data set (named by the OUT= option) that contains the SEATS decomposition series.

The following is an example of a VAR statement and a SEATSDECOMP statement:

```
var sales costs;
seatsdecomp out=SEATS_DECOMP;
```

The default variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name. Because the B1 series is used as the original input series for the SEATS decomposition, the output data set SEATS_DECOMP from the example will contain the seasonal decomposition variables in the following order:

- **sales_OS** contains the Table B1 values for the variable sales.
- **sales_SC** contains the SEATS decomposition seasonal component for the variable sales.
- **sales_TC** contains the SEATS trend component values for the variable sales.
- **sales_SA** contains the SEATS seasonally adjusted series for the variable sales.
- **sales_IC** contains the SEATS irregular component for the variable sales.
- **costs_OS** contains the Table B1 values for the variable costs.
- **costs_SC** contains the SEATS decomposition seasonal component for the variable costs.
- **costs_TC** contains the SEATS trend component values for the variable costs.
- **costs_SA** contains the SEATS seasonally adjusted series for the variable costs.
- **costs_IC** contains the SEATS irregular component for the variable costs.

If necessary, the variable name is shortened so that the component name can be added. If you specify the DATE= variable in the PROC X13 statement, then that variable is included in the output data set; otherwise, a variable named _DATE_ is written to the OUT= data set as the date identifier. For more information about the output data set, see the section “SEATSDECOMP OUT= Data Set” on page 3357.

You can specify the following options in the SEATSDECOMP statement:
LEAD=value

specifies the number of periods ahead to forecast for a regARIMA extension of the series. The default is twice the number of periods in a year (8 or 24), and the maximum is 120. In the SEATS computations, the number of backcasts and forecasts are the same, and the minimum number is also dependent on the ARIMA model orders. For more information, see the section “SEATS Decomposition” on page 3349. If you specify a LEAD= value that is less than the default, then the number of forecasts specified in the LEAD= option are displayed in the OUT= data set. If the value of the LEAD= option and NBACKCAST= options in the FORECAST statement are less than the required number for SEATS decomposition, then the values of the LEAD= and NBACKCAST= options in the FORECAST statement are increased.

NBACKCAST=value

specifies the number of periods to backcast for a regARIMA extension of the series. The default is twice the number of periods in a year (8 or 24), and the maximum is 120. In the SEATS computations, the number of backcasts and forecasts are the same, and the minimum number is also dependent on the ARIMA model orders. For more information, see the section “SEATS Decomposition” on page 3349. If you specify a NBACKCAST= value that is less than the default, then the number of backcasts specified in the NBACKCAST= option are displayed in the OUT= data set. If the value of the LEAD= option and NBACKCAST= option specified in the FORECAST statement are less than the required number for SEATS decomposition when SEATSDECOMP is specified, then the value of LEAD= and NBACKCAST= in the FORECAST statement will be increased.

OUT=SAS-data-set

names the data set to contain the SEATS decomposition series: original series, seasonal component, trend component, seasonally adjusted series, irregular component. If the OUT= option is omitted, the data set is named using the default DATA%n convention.

YEARSEAS

specifies that two additional variables be added to the OUT= data set: _YEAR_ and _SEASON_. The variable _YEAR_ contains the year of the date that identifies the observation. The variable _SEASON_ contains the month for monthly data, or quarter for quarterly data, of the date that identifies the observation. For monthly data, the value of _SEASON_ is between 1 and 12. For quarterly data, the value of _SEASON_ is between 1 and 4. The _YEAR_ and _SEASON_ variables are useful when you create seasonal plots.
TABLES Statement

TABLES tablename1 tablename2 . . . options ;

The TABLES statement enables you to alter the display of the PROC X13 tables. You can specify the display of tables that are not displayed by default by PROC X13, and the NOSUM option enables you to suppress the printing of the period summary line in the time series tables.

tablename1 tablename2 . . .
specifies X13 tablenames that correspond to the title label used by the US Census Bureau X-13ARIMA-SEATS software. For each table to be included in the displayed output, you must specify the X13 tablename keyword. Currently available tables are A19, B7, B13, B17, B20, C1, C20, D1, D7, E1, E2, and E3. Although these tables are not displayed by default, their values are sometimes useful in understanding the X-13ARIMA-SEATS method. For more information about the available tables, see the section “Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords” on page 3350.

NOSUM
NOSUMMARY
NOSUMMARYLINE
applies to the tables available for output in the OUTPUT Statement. By default, these tables include a summary line that gives the average, total, or standard deviation for the historical data by period. The NOSUM option suppresses the display of the summary line in the listing. Also, if the tables are output with ODS, the summary line is not an observation in the data set. Thus, the output to the data set is only the time series, both the historical data and the forecast data, if available.

TRANSFORM Statement

TRANSFORM options ;

The TRANSFORM statement transforms or adjusts the series prior to estimating a regARIMA model. With this statement, the series can be Box-Cox (power) transformed. The “Prior Adjustment Factors” table is associated with the TRANSFORM statement.

Only one of the following options can appear in the TRANSFORM statement:

POWER= value
transforms the input series, $Y_t$, by using a Box-Cox power transformation,

$$ Y_t \rightarrow y_t = \begin{cases} \log(Y_t) & \lambda = 0 \\ \lambda^2 + (Y_t^\lambda - 1)/\lambda & \lambda \neq 0 \end{cases} $$
The power $\lambda$ must be specified (for example, POWER=0.33). The default is no transformation ($\lambda = 1$); that is, POWER=1. The log transformation (POWER=0), square root transformation (POWER=0.5), and the inverse transformation (POWER=-1) are equivalent to the corresponding FUNCTION= option.

**Table 46.6** Power Values Related to the Census Bureau Function Argument

<table>
<thead>
<tr>
<th>FUNCTION=</th>
<th>Transformation</th>
<th>Range for $Y_t$</th>
<th>Equivalent Power Argument</th>
</tr>
</thead>
<tbody>
<tr>
<td>NONE</td>
<td>$Y_t$</td>

<td>$\log(Y_t)$</td>
<td>$Y_t &gt; 0$ for all $t$</td>
<td>POWER=0</td>
</tr>
<tr>
<td>SQRT</td>
<td>$2(\sqrt{Y_t} - 0.875)$</td>
<td>$Y_t \geq 0$ for all $t$</td>
<td>POWER=0.5</td>
</tr>
<tr>
<td>INVERSE</td>
<td>$2 - \frac{1}{Y_t}$</td>
<td>$Y_t \neq 0$ for all $t$</td>
<td>POWER=-1</td>
</tr>
<tr>
<td>LOGISTIC</td>
<td>$\log\left(\frac{Y_t}{1-Y_t}\right)$</td>
<td>$0 &lt; Y_t &lt; 1$ for all $t$</td>
<td>No equivalent</td>
</tr>
</tbody>
</table>

FUNCTION=NONE | LOG | SQRT | INVERSE | LOGISTIC | AUTO

specifies the transformation to be applied to the series prior to estimating a regARIMA model. The transformation used by FUNCTION=NONE, LOG, SQRT, INVERSE, or LOGISTIC is related to the POWER= option as shown in Table 46.6. FUNCTION=AUTO uses selection based on Akaike’s information criterion (AIC) to decide between a log transformation and no transformation. The default is FUNCTION=NONE.

However, the FUNCTION= and POWER= options are not completely equivalent. In some cases, using the FUNCTION= option causes the program to automatically select other options. For example, FUNCTION=NONE causes the default mode to be MODE=ADD in the X11 statement. Also, the choice of transformation invoked by the FUNCTION=AUTO option can impact the default mode of the X11 statement.

There are restrictions on the value used in the POWER= and FUNCTION= options when preadjustment factors for seasonal adjustment are generated from a regARIMA model. When seasonal adjustment is requested with the X11 statement, any value of the POWER option can be used for the purpose of forecasting the series with a regARIMA model. However, this is not the case when factors generated from the regression coefficients are used to adjust either the original series or the final seasonally adjusted series. In this case, the only accepted transformations are the log transformation, which can be specified as POWER=0 for multiplicative or log-additive seasonal adjustments, and no transformation, which can be specified as POWER=1 for additive seasonal adjustments. If no seasonal adjustment is performed, any POWER transformation can be used. The preceding restrictions also apply when FUNCTION=NONE and FUNCTION=LOG are specified.
USERDEFINED Statement

USERDEFINED variables ;

The USERDEFINED statement is used to identify the variables in the input data set or auxiliary data set that are available for user-defined regression. Only numeric variables can be specified. Specifying variables in the USERDEFINED statement does not include the variables as regressors. If a variable is specified in the INPUT statement or USERVAR= option in the REGRESSION statement, it is not necessary to include that variable in the USERDEFINED statement. However, if a variable is specified in the MDLINFOIN= data set in the PROC X13 statement and is not specified in an INPUT statement or in the USERVAR= option in the REGRESSION statement, then the variable should be specified in the USERDEFINED statement in order to make the variable available for regression.

VAR Statement

VAR variables ;

The VAR statement specifies the variables in the input data set that are to be analyzed by the procedure. Only numeric variables can be specified. If the VAR statement is omitted, all numeric variables are analyzed except those that appear in a BY statement, ID statement, INPUT statement, or USERDEFINED statement; in the USERVAR= option in the REGRESSION statement; or in the DATE= option in the PROC X13 statement.

X11 Statement

X11 options ;

The X11 statement is an optional statement for invoking seasonal adjustment by an enhanced version of the methodology of the US Census Bureau X-11 and X-11Q programs. You can control the type of seasonal adjustment decomposition calculated with the MODE= option. The output includes the final tables and diagnostics for the X-11 seasonal adjustment method listed in Table 46.7. Tables B7, B13, B17, B20, C1, E1, E2, E3, C20, D1, and D7 are not displayed by default; however, you can display these tables by requesting them in the TABLES statement.
### Table 46.7  Tables Related to X11 Seasonal Adjustment

</table>
For more information about the X-11 seasonal adjustment diagnostics, see Shiskin, Young, and Musgrave (1967), Lothian and Morry (1978a), and Ladiray and Quenneville (2001).

You can specify the following options in the X11 statement:

**FINAL=AO | LS | TC | USER | ALL**

**FINAL=(options)**

- **FINAL** lists the types of prior adjustment factors, obtained from the EVENT, REGRESSION, and OUTLIER statements, that are to be removed from the final seasonally adjusted series. Additive outliers are removed by specifying FINAL=AO. Level change and ramp outliers are removed by specifying FINAL=LS. Temporary change outliers are removed by specifying FINAL=TC. User-defined regressors or events (USERTYPE=USER) are removed by specifying FINAL=USER. All the preceding are removed by specifying FINAL=ALL or by specifying all the options in parentheses, FINAL=(AO LS TC USER). If this option is not specified, the final seasonally adjusted series contains these effects.

**FORCE=TOTALS | ROUND | BOTH**

- **FORCE** specifies that the seasonally adjusted series be modified to: (a) force the yearly totals of the seasonally adjusted series and the original series to be the same (FORCE=TOTALS), (b) adjust the seasonally adjusted values for each calendar year so that the sum of the rounded seasonally adjusted series for any year equals the rounded annual total (FORCE=ROUND), or (c) first force the yearly totals, then round the adjusted series (FORCE=BOTH). When FORCE=TOTALS is specified, the differences between the annual totals is distributed over the seasonally adjusted values in a way that approximately preserves the month-to-month (or quarter-to-quarter) movements of the original series. For more information, see Huot (1975) and Cholette (1979). This forcing procedure is not recommended if the seasonal pattern is changing or if trading day adjustment is performed. Forcing the seasonally adjusted totals to be the same as the original series annual totals can degrade the quality of the seasonal adjustment, especially when the seasonal pattern is undergoing change. It is not natural if trading day adjustment is performed because the aggregate trading day effect over a year is variable and moderately different from zero.

**MODE=ADD | MULT | LOGADD | PSEUDOADD**

- **MODE** determines the mode of the seasonal adjustment decomposition to be performed. The four option choices correspond to additive, multiplicative, log-additive, and pseudo-additive decomposition, respectively. If this option is omitted, the procedure performs multiplicative adjustments. Table 46.8 shows the values of the MODE= option and the corresponding models for the original (O) and the seasonally adjusted (SA) series.

<table>
<thead>
<tr>
<th>Value of Mode Option</th>
<th>Name</th>

<td>( SA = C \times I )</td>
</tr>
<tr>
<td>LOGADD</td>
<td>Log-additive</td>
<td>( \log(O) = C + S + I )</td>
<td>( SA = \exp(C + I) )</td>
</tr>
</tbody>
</table>
OUTFORECAST
OUTFCST
determines whether forecasts are included in certain tables sent to the output data set. If OUTFORECAST is specified, then forecast values are included in the output data set for Tables A6, A7, A8, A9, A10, B1, D10, D10B, D10D, D16, D16B, D18, and E18. The default is not to include forecasts. The OUTFORECAST option can be specified in either the X11 statement or the FORECAST statement with identical results.

SEASONALMA=S3X1 | S3X3 | S3X5 | S3X9 | S3X15 | STABLE | X11DEFAULT | MSR
SEASONALMA=(filter-list-by-period)
specifies which seasonal moving average (also called “seasonal filter”) to use to estimate the seasonal factors. These seasonal moving averages are \( n \times m \) moving averages, meaning that an \( n \)-term simple average is taken of a sequence of consecutive \( m \)-term simple averages. X11DEFAULT is the method used by the US Census Bureau’s X-11-ARIMA program.

You can specify either a single filter option or a list. A single option indicates that all periods will use the same filter or the same method of identifying the filter. Alternately, you can specify the seasonal filters for each seasonal period by specifying \( \text{SEASONALMA}=(\text{filter-list-by-period}) \), where \( (\text{filter-list-by-period}) \) lists the moving average filter for each period. For quarterly data, you must specify four filters; for monthly data, you must specify 12 filters. In the \( (\text{filter-list-by-period}) \), you can specify S3X1, S3X3, S3X5, S3X9, or S3X15. For example, the following statement assigns a \( 3 \times 1 \) moving average filter to the first quarter of a quarterly series and a \( 3 \times 3 \) moving average to the second, third, and fourth quarters:

\[
\text{X11 SEASONALMA}=( \text{S3X1 S3X3 S3X3 S3X3} );
\]

Table 46.9 describes the seasonal filter options available for the entire series:

<table>
<thead>
<tr>
<th>Filter Name</th>
<th>Description of Filter</th>
</tr>
</thead>
<tbody>
<tr>
<td>S3X1</td>
<td>A ( 3 \times 1 ) moving average</td>
</tr>
<tr>
<td>S3X3</td>
<td>A ( 3 \times 3 ) moving average</td>
</tr>
<tr>
<td>S3X5</td>
<td>A ( 3 \times 5 ) moving average</td>
</tr>
<tr>
<td>S3X9</td>
<td>A ( 3 \times 9 ) moving average</td>
</tr>
<tr>
<td>S3X15</td>
<td>A ( 3 \times 15 ) moving average</td>
</tr>
<tr>
<td>STABLE</td>
<td>Stable seasonal filter: a single seasonal factor for each calendar month or quarter is generated by calculating the simple average of all the values for each month or quarter (taken after detrending and outlier adjustment)</td>
</tr>
<tr>
<td>X11DEFAULT</td>
<td>Uses a ( 3 \times 3 ) moving average to calculate the initial seasonal factors in each iteration and a ( 3 \times 5 ) moving average to calculate the final seasonal factors</td>
</tr>
<tr>
<td>MSR</td>
<td>Filter chosen automatically by using the moving seasonality ratio of X-11-ARIMA/88 (Dagum 1988)</td>
</tr>
</tbody>
</table>

By default, \( \text{SEASONALMA} \)=MSR, which is the methodology of Statistic Canada’s X-11-ARIMA/88 program.
**SIGMALIM=(lower limit, upper limit)**

**SIGMALIM=(lower limit)**

**SIGMALIM=(, upper limit)**

specifies the lower and upper sigma limits in standard deviation units which are used to identify and down-weight extreme irregular values in the internal seasonal adjustment computations. One or both limits can be specified. The lower limit must be greater than 0 and not greater than the upper limit. If the lower sigma limit is not specified, then it defaults to a value of 1.5. The default upper sigma limit is 2.5. The comma must be used if the upper limit is specified.

Table 46.10 shows the effect of the SIGMALIM= option on the weights that are applied to the internal irregular values.

<table>
<thead>
<tr>
<th>Weight</th>
<th>Sigma Limit</th>
</tr>
</thead>
<tbody>
<tr>
<td>0</td>
<td>If ( \frac{</td>
</tr>
<tr>
<td>Partial weight</td>
<td>If lower limit ( &lt; \frac{</td>
</tr>
<tr>
<td>1</td>
<td>If ( \frac{</td>
</tr>
</tbody>
</table>

In Table 46.10, \( \mu \) is the theoretical mean of the irregular component, and \( \sigma_1,I_t \) and \( \sigma_2,I_t \) are the respective estimates of the standard deviation of the irregular component before and after extreme values are removed. The estimates of the standard deviation \( \sigma_1,I_t \) and \( \sigma_2,I_t \) vary with respect to \( t \), and they are the same if no extreme values are removed. If they are different (\( \sigma_2,I_t < \sigma_1,I_t \)), then the first line in Table 46.10 is reevaluated with \( \sigma_2,I_t \). In the special case where the lower limit equals the upper limit, the weight is 1 for \( \frac{|I_t-\mu|}{\sigma_2,I_t} \leq \text{lower limit} \), and 0 otherwise. For more information about how extreme irregular values are handled in the X11 computations, see Ladiray and Quenneville 2001, pp. 53–68, 122–125.

**TRENDMA=value**

specifies which Henderson moving average is used to estimate the final trend cycle. Any odd number greater than one and less than or equal to 101 can be specified (for example, TRENDMA=23). If the TRENDMA= option is not specified, the program selects a trend moving average based on statistical characteristics of the data. For monthly series, a 9-, 13-, or 23-term Henderson moving average is selected. For quarterly series, the program chooses either a 5- or a 7-term Henderson moving average is selected. For quarterly series, the program chooses either a 5- or a 7-term Henderson moving average.

**TYPE=SA | SUMMARY | TREND**

specifies the method used to calculate the final seasonally adjusted series (Table D11). The default method is TYPE=SA. This method assumes that the original series has not been seasonally adjusted. For method TYPE=SUMMARY, the trend cycle, irregular, trading day, and holiday factors are calculated, but not removed from the seasonally adjusted series. Thus, for TYPE=SUMMARY, Table D11 is the same as the original series. For TYPE=TREND, trading day, holiday, and prior adjustment factors are removed from the original series to calculate the seasonally adjusted series (Table D11) and also are used in the calculation of the final trend (Table D12).
Details: X13 Procedure

Data Requirements

The input data set must contain either quarterly or monthly time series, and the data must be sorted in chronological order within each BY group. For the standard X-13ARIMA-SEATS method, there must be at least three years of observations (12 for quarterly time series or 36 for monthly).

If an ARIMA model is specified in the ARIMA statement, AUTOMDL statement, PICKMDL statement, or the MDLINFOIN= data set, then more than three years of observations might be required in order to fit the ARIMA model and perform the computations associated with the seasonal decomposition and other diagnostics.

The minimum number of observations applies to each series listed in the VAR statement and within each BY group and is determined after any missing values are trimmed from the series.

Missing Values

PROC X13 can process a series with missing values.

Types of Missing Values

Missing values in a series are considered to be one of two types:

- A leading or trailing missing value occurs before the first nonmissing value or after the last nonmissing value, respectively, in the span of a series. The span of a series can be determined either explicitly by the SPAN= option or implicitly by the START= or DATE= option in the PROC X13 statement. By default, leading and trailing missing values are ignored. If you specify the NOTRIMMISS option in the PROC X13 statement, PROC X13 processes leading and trailing missing values according to the X-13ARIMA-SEATS missing value method.

- An embedded missing value occurs between the first nonmissing value and the last nonmissing value in the span of the series. PROC X13 processes embedded missing values according to the X-13ARIMA-SEATS missing value method.

X-13ARIMA-SEATS Missing Value Method

When the X-13ARIMA-SEATS method encounters a missing value, it inserts an additive outlier for the missing observation into the set of regression variables for the model of the series and then replaces the missing observation with a value large enough to be considered an outlier during model estimation. After the regARIMA model is estimated, the X-13ARIMA-SEATS method adjusts the original series by using factors that are generated from these missing value outlier regressors. The adjusted values are estimates of the missing values, and the adjusted series is displayed in Table MV1. The X-13ARIMA-SEATS missing value method requires the use of a regARIMA model to replace the missing values. Thus, either an ARIMA or AUTOMDL statement or the MDLINFOIN= option in the PROC X13 statement must be specified if there are embedded missing values in the time series.
SAS Predefined Events

SAS predefined events are summarized in this section. For complete details about SAS predefined events, see the section “EVENTKEY Statement” in SAS Forecast Studio: User’s Guide.

Table 46.11 shows a summary of the SAS predefined event keywords. Table 46.12 lists the holiday date keywords that can be used as SAS predefined events. Table 46.13 lists the seasonal date keywords that can be used as SAS predefined events.

</tr>
</tbody>
</table>

### User-Defined Regression Variables

The X-13ARIMA-SEATS method enables you to define regression variables to be included in the regARIMA model. A user-defined regression variable is composed of a value at each time series observation that you provide; the entire variable is implemented as a regressor in the regARIMA model. The regARIMA model is used in the seasonal decomposition process to extend the series prior to X11 decomposition. Because the X-13ARIMA-SEATS method does not impute, forecast, nor backcast user-defined regression variables, you must provide a nonmissing value at each observation in the span of the time series to be modeled and also provide a nonmissing value at each observation to be forecast or backcast.

A user-defined regression variable can be included in either the PROC X13 DATA= or AUXDATA= data set. You can supply the values for the user-defined regression variable by one of the following methods:

- You can include them in an auxiliary data set. The auxiliary data set should have a date variable that corresponds to the date variable in the DATA= data set. The name of the auxiliary data set is specified in the AUXDATA= option in the PROC X13 statement. The name of the date variable that exists in both the DATA= and AUXDATA= data sets is specified in the DATE= option in the PROC X13 statement. The observations in the auxiliary data set must span the entire series plus any forecast and backcast period.
You can include them in the DATA= data set. Because the number of observations and the date values are exactly the same for both user-defined regressors and time series values, you need to include forecast and backcast values for user-defined regression variables beyond the span of the time series in one of the following ways:

- You must specify leading missing values in the series to be seasonally adjusted for backcast periods. You must specify trailing missing values in the series to be seasonally adjusted for forecast periods. You must not use the NOTRIMMISS option in this case. The span of the series to be seasonally adjusted that is implied by trimming the leading and trailing missing values will be less than the span of the date values in the DATA= data set. Using this method, forecast error cannot be computed for the forecast and backcast periods.

- You can use the SPAN= option in the PROC X13 statement to alter the span of the series to be seasonally adjusted to allow for backcast and forecast periods within the span of the date values in the DATA= data set. Using this method, forecast error can be computed for the forecast and backcast periods.

These methods of including user-defined regression variables in the regARMIA model are illustrated in Example 46.6 and Example 46.11.

If missing values for the user-defined regression variable are present within the span of the time series, including backcast and forecast observations, then an error message is displayed and the time series is not processed. If the span of the user-defined regression variable, or the span after leading and trailing missing values are trimmed, is not sufficient to cover the span of the series to be seasonally adjusted, including any backcasts and forecasts, then an error message is also displayed, and the time series is not processed.

Combined Test for the Presence of Identifiable Seasonality

The seasonal component of a time series, \( S_t \), is defined as the intrayear variation that is repeated constantly (stable) or in an evolving fashion from year to year (moving seasonality). If the increase in the seasonal factors from year to year is too large, then the seasonal factors introduce distortion into the model. It is important to determine whether seasonality is identifiable without distorting the series.

For seasonality to be identifiable, the series should be identified as seasonal by using the “Test for the Presence of Seasonality Assuming Stability” and “Nonparametric Test for the Presence of Seasonality Assuming Stability.” Also, since the presence of moving seasonality can cause distortion, it is important to evaluate the moving seasonality in conjunction with the stable seasonality to determine whether the seasonality is identifiable. The results of these tests are displayed in “\( F \) tests for Seasonality” (Table D8.A) in the X13 procedure.

The test for identifiable seasonality is performed by combining the \( F \) tests for stable and moving seasonality, along with a Kruskal-Wallis test for stable seasonality. The following description is based on Lothian and Morry (1978b). Other details can be found in Dagum (1988, 1983).

Let \( F_s \) and \( F_m \) denote the \( F \) value for the stable and moving seasonality tests, respectively. The combined test is performed as follows (see also Figure 46.3):
1. If the null hypothesis of no stable seasonality is not rejected at the 0.10% significance level ($P_S \geq 0.001$), then the series is considered to be nonseasonal. PROC X13 returns the conclusion, “Identifiable Seasonality Not Present.”

2. If the null hypothesis in step 1 is rejected, then PROC X13 computes the following quantities:

   \[ T_1 = \frac{7}{F_s} \]

   \[ T_2 = \frac{3F_m}{F_s} \]

   Let $T$ denote the simple average of $T_1$ and $T_2$:

   \[ T = \frac{(T_1 + T_2)}{2} \]

   If the null hypothesis of no moving seasonality is rejected at the 5.0% significance level ($P_M < 0.05$) and if $T \geq 1.0$, the null hypothesis of identifiable seasonality not present is not rejected and PROC X13 returns the conclusion, “Identifiable Seasonality Not Present.”

3. If the null hypothesis of identifiable seasonality not present has not been accepted, but $T_1 \geq 1.0$, $T_2 \geq 1.0$, or the Kruskal-Wallis chi-squared test fails to reject at the 0.10% significance level ($P_{KW} \geq 0.001$), then PROC X13 returns the conclusion “Identifiable Seasonality Probably Not Present.”

4. If the null hypotheses of no stable seasonality associated with the $F_S$ and Kruskal-Wallis chi-squared tests are rejected and if none of the combined measures described in steps 2 and 3 fail, then the null hypothesis of identifiable seasonality not present is rejected and PROC X13 returns the conclusion “Identifiable Seasonality Present.”

Included in the displayed output of Table D8A is the table “Summary of Results and Combined Test for the Presence of Identifiable Seasonality.” This table displays the $T_1$, $T_2$, and $T$ values and the significance levels for the stable seasonality test, the moving seasonality test, and the Kruskal-Wallis test. The last item in the table is the result of the combined test for identifiable seasonality.
Figure 46.3 Combined Seasonality Test Flowchart

Combined test for identifiable seasonality

- \( P_3 \geq 0.01 \)
- \( P_3 < 0.01 \)

- Stable seasonality test
  - No evidence of stable seasonality at the 0.1 per cent level

- Seasonality present at the 0.1 per cent level
  - \( P_M < 0.05 \)
    - Moving seasonality test
      - Moving seasonality present at the five percent level OR Moving seasonality present at the one percent level
      - \( T \geq 1 \) or \( T < 1 \)
        - Test: \( T \geq 1 \)

- \( P_M \geq 0.05 \)
  - No evidence of moving seasonality at the five percent level

- \( T_1 \geq 1 \) or \( T_2 \geq 1 \)
  - Test: \( T_1 \geq 1 \) or \( T_2 \geq 1 \)

- \( P_{KW} \geq 0.001 \)
  - Kruskal-Wallis test
  - \( P_{KW} < 0.001 \)

- Identifiable seasonality not present
- Identifiable seasonality probably not present
- Identifiable seasonality present
Chapter 46: The X13 Procedure

Computations

For more information about the computations used in PROC X13, see the X-13ARIMA-SEATS Reference Manual (US Bureau of the Census 2009).

For more information about the X-11 method of decomposition, see Seasonal Adjustment with the X-11 Method (Ladiray and Quenneville 2001).

PICKMDL Model Selection

You can request that the X-13ARIMA-SEATS method select a model in a manner similar to the method used in X-11-ARIMA (Dagum 1988, 1983). Information about this model selection (PICKMDL) is based on the description in the X-13ARIMA-SEATS Reference Manual (US Bureau of the Census 2009). You can request the PICKMDL method in one of the following ways:

- by specifying the PICKMDL statement
- by specifying more than one value for the _MODEL_ variable in the MDLINFOIN= data set (subset by BY group and series)

The default settings for the PICKMDL automatic model selection method classify a model as acceptable if all of the following conditions are true:

- The absolute average percentage error of the extrapolated values within the last three years of data is less than 15%.
- The $p$-value is greater than 5% for the fitted model’s Ljung-Box $Q$ statistic test of the lack of correlation in the model’s residuals.
- There are no signs of overdifferencing. Overdifferencing is indicated if the sum of the nonseasonal MA parameter estimates (for models with at least one nonseasonal difference) is greater than 0.9.

If a data set is specified in the MDLINFOIN= option and the data set contains more than one model for a series to be forecast, then the models described in the data set are candidates for the PICKMDL method of model selection. If the MDLINFOIN= option is not specified, then the candidate models are shown in Table 46.14, along with the order in which the models are considered. The order in which the model is considered is important when METHOD-FIRST is specified in the PICKMDL statement.

Table 46.14  PICKMDL Method Default ARIMA Models

<table>

<td>(0 2 2)(0 1 1)</td>
</tr>
<tr>
<td>5</td>
<td>(2 1 2)(0 1 1)</td>
</tr>
</tbody>
</table>
No model is selected when none of the models in the MDLINFO= data set are acceptable. For more information about the output when no model is selected, see the section “Final Automatic Model Selection Table” on page 3353.

The regARIMA model consists of a transformation, a regression component, and an ARIMA model component. For each series, the following conditions hold:

- If no regression is specified in the MDLINFO= data set model but regressors are specified using the INPUT, EVENT, or REGRESSION statements, then the ARIMA models from the MDLINFO= data set are tested in conjunction with the regression variables specified in the INPUT, EVENT, and REGRESSION statements.

- If no ARIMA model is specified in the MDLINFO= data set but an ARIMA model is specified using an ARIMA statement or TRANSFORM statement, then the regression information from each model specified in the MDLINFO= data set is used in conjunction with the ARIMA model specified by the TRANSFORM and ARIMA statements.

- If no model information is specified in the MDLINFO= data set, then any model information specified by the TRANSFORM, INPUT, REGRESSION, EVENT, and ARIMA statements is used, and the PICKMDL statement is not in effect for that series.

SEATS Decomposition

PROC X13 can decompose the B1 series by using the SEATS decomposition method described in Gómez and Maravall (1997a, b). The SEATS decomposition method is planned for inclusion in the US Census Bureau’s X13 program, which is not yet available for release.

The SEATS method requires the series to be extended with the same number of backcast and forecast observations. The number of observations backcast and forecast must meet the following minimum criteria:

- The number of forecast and backcast observations must be at least twice the number of observations in a year, with a minimum of 8.

- The number of forecast and backcast observations must be at least $2 \times (q + Q \times s)$, where the ARIMA model used to extend the series is $(pdq)(PDQ)s$ in standard Box-Jenkins notation.

- The number of forecast and backcast observations must be at least $p + d + q + (P + D + Q) \times s$, where the ARIMA model used to extend the series is $(pdq)(PDQ)s$ in standard Box-Jenkins notation.

If you specify the SEATSDECOMP statement and the number of forecasts or backcasts (either the default number or the number you specify) is not sufficient for SEATS decomposition, then the number of forecasts or backcasts is increased to the minimum required.
Chapter 46: The X13 Procedure

Displayed Output, ODS Table Names, and OUTPUT Tablename Keywords

The options specified in PROC X13 control both the tables produced by the procedure and the tables available for output to the OUT= data set specified in the OUTPUT statement.

The displayed output is organized into tables identified by a part letter and a sequence number within the part. The seven major parts of the X13 procedure are as follows:

A  prior adjustments and regARIMA components (optional)
B  preliminary estimates of irregular component weights and trading day regression factors (X-11 method)
C  final estimates of irregular component weights and trading day regression factors
D  final estimates of seasonal, trend cycle, and irregular components
E  analytical tables
F  summary measures
G  charts

Table 46.15 describes the individual tables and charts. “P” indicates that the table is only displayed and is not available for output to the OUT= data set. Data from displayed tables can be extracted into data sets by using the Output Delivery System (ODS). For more information about the SAS Output Delivery System, see the SAS Output Delivery System: User's Guide. For more information about the features of the ODS Graphics system, including the many ways that you can control or customize the plots that are produced by SAS procedures, see Chapter 21, “Statistical Graphics Using ODS” (SAS/STAT User's Guide).

When tables available through the OUTPUT statement are output using ODS, the summary line is included in the ODS output by default. The summary line gives the average, standard deviation, or total by each period. The value –1 for YEAR indicates that the summary line is a total; the value –2 for YEAR indicates that the summary line is an average; and the value –3 for YEAR indicates that the line is a standard deviation. The value of YEAR for historical and forecast values is greater than or equal to zero. Thus, a negative value indicates a summary line. You can suppress the summary line altogether by specifying the NOSUM option in the TABLES statement. However, the NOSUM option also suppresses the display of the summary line in the displayed table.

“T” indicates that the table is available using the OUTPUT statement, but is not displayed by default; you must request that these tables be displayed by using the TABLES Statement. If there is no notation in the “Notes” column, then the table is available directly using the OUTPUT statement, without specifying the TABLES statement. If a table is not computed, then it is not displayed; if it is requested in the OUTPUT statement, then the variable in the OUT= data set contains missing values. The actual number of tables displayed depends on the options and statements specified.

Final Automatic Model Selection Table

When the PICKMDL statement is specified and no model is selected, then the model in the “Final Automatic Model Selection” table is displayed as “(*, *, *) (*, *, *)” and an error message is displayed in both the log file and the output. If the “Final Automatic Model Selection” table is output to a data set, the model orders are output as –1, indicating the failure to select a model. For more information about PICKMDL model selection, see the section “PICKMDL Model Selection” on page 3348.

Table D 8.B

Table D8B displays the same series as Table D8. However, additional information is provided about the D8 series. The following values are displayed as labels for each observation of the series:

- The first label column indicates whether the D8 series value is extreme as determined by the X-11 extreme value method. An extreme observation is marked with an asterisk in the first label column. This data value is 0 or 1. If D8B or D8BX is specified in the OUTPUT statement, this value is output as the D8BX series to the data set that is specified in the OUT= option in the OUTPUT statement.
Chapter 46: The X13 Procedure

- The second label column contains the number of AO, TC, or RP outliers, if any, that affect the observation. This data value is 0 if no outliers affect the observation. Only the nonzero values are displayed in the table. If D8B or D8BO is specified in the OUTPUT statement, the number of outliers is output as the D8BO series to the data set that is specified in the OUT= option in the OUTPUT statement.

- The third label column indicates whether the observation is affected by level shift outliers as determined by an X-13ARIMA-SEATS method. This data value contains the number of level shifts that affect the observation. A nonzero value is displayed as “L”. If D8B or D8BL is specified in the OUTPUT statement, the data values are output as the D8BL series to the data set that is specified in the OUT= option in the OUTPUT statement.

If any observations in Table D 8.B are affected by extremes, outliers, or level shifts, then notes that indicate the number of observations affected in each category are displayed at the end of the table.

Using Auxiliary Variables to Subset Output Data Sets

The X13 procedure can produce more than one table with the same name. For example, the following IDENTIFY statement produces ACF and PACF tables for two levels of differencing:

```plaintext
identify diff=(1) sdiff=(0, 1);
```

Auxiliary variables in the output data can be used to subset the data. In this example, the auxiliary variables Diff and SDiff specify the levels of regular and seasonal differencing that are used to compute the ACF. The following statements show how to retrieve the ACF results for the first differenced series:

```plaintext
ods select acf;
ods output acf=acf;
proc x13 data=sashelp.air date=date;
    identify diff=(1) sdiff=(0,1);
run;
title "Regular Difference=1 Seasonal Difference=0";
data acfd1D0;
    set acf(where=(Diff=1 and Sdiff=0));
run;
```

In addition to any BY variables, the auxiliary variables in the ACF and PACF data sets are _NAME_, _TYPE_, Transform, Adjust, Regressors, Diff, and SDiff. Auxiliary variables can be related to the group as shown in the Results Viewer (for example, BY variables, _NAME_, and _TYPE_). However, they can also be variables in the template where printing is suppressed by using PRINT=OFF. Auxiliary variables such as Transform, Adjust, and Regressors are not displayed in the ACF and PACF tables because similar information is displayed in the ModelDescription table that immediately precedes the ACF and PACF tables. The variables Diff and SDiff are not displayed because the levels of differencing are included in the title of the ACF and PACF tables.

The BY variables and the _NAME_ variable are available for all ODS OUTPUT data sets that are produced by the X13 procedure. The _TYPE_ variable is available for all ODS OUTPUT data sets that are produced during the model identification and model estimation stages. The _TYPE_ variable enables you to determine whether data in a table, such as the ModelDescription table, originated from the model identification stage or the model estimation stage.
The forecast data sets contain the auxiliary variable `_SCALE_`. The value of `_SCALE_` is “Original” or “Transformed” to indicate the scale of the data. The auxiliary variable `_SCALE_` is the same as the group in the Results Viewer. It is not displayed in the forecast tables because the table titles indicate the scale of the data.

**ODS Graphics**

Before you create graphs, ODS Graphics must be enabled (for example, with the ODS GRAPHICS ON statement). For more information about enabling and disabling ODS Graphics, see the section “Enabling and Disabling ODS Graphics” in that chapter.

The overall appearance of graphs is controlled by ODS styles. Styles and other aspects of using ODS Graphics are discussed in the section “A Primer on ODS Statistical Graphics” in that chapter.

This section describes the use of ODS for creating graphics with the X13 procedure.

The graphs available through ODS Graphics are ACF plots, PACF plots, a residual histogram, spectral graphs, and forecasting plots. ACF and PACF plots for regARIMA model identification are not available unless the IDENTIFY statement is used. ACF plots, PACF plots, the residual histogram, and the residual spectral graph for diagnosis of the regARIMA model residuals are not available unless the CHECK statement is used. Forecasting plots are not available unless the FORECAST statement is used. A spectral plot of the original series is always available; however, additional spectral plots are provided when the X11 statement and CHECK statement are used. When ODS Graphics is not enabled, the ACF, PACF, and spectral analysis are displayed as columns of a table. The residual histogram is available only when ODS Graphics is enabled. To obtain a table that contains values related to the residual histogram, use the ODS OUTPUT statement.

**ODS Graph Names**

PROC X13 assigns a name to each graph it creates by using ODS. You can use these names to selectively reference the graphs. The names are listed in Table 46.16.

<table>

### OUT= Data Set

You can use the OUTPUT statement to output the component series computed in the X-13ARIMA-SEATS decomposition.

The OUT= data set specified in the OUTPUT statement contains the BY variables (if any), the ID variables (if any), and the DATE= variable if the DATE= option is specified or the variable _DATE_ if the DATE= option is not specified. If user-defined regressor variables or EVENT variables are specified, they are included. In addition, the various components specified by the table names in the OUTPUT statement are included in the OUT= data set.

The OUTPUT OUT= data set can contain the following variables:

**BY variables** are the BY variables used to subset the series by BY groups. The BY variables included in this data set match the BY variables, if any, used to process the series in the DATA= data set.
ID variables enable the series observations to be identified using further information. The ID variables included in this data set match the ID variables, if any, specified in the ID statement and input from the DATA= data set.

DATE variable is the time ID variable used to process the time series. It is either the variable specified in the DATE= option in the PROC X13 statement or the variable _DATE_ generated by the START= option in the PROC X13 statement.

_YEAR_ variable contains a value for the year of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.

_SEASON_ variable contains a value for the month or quarter of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.

User-defined variables are variables specified in the INPUT statement or the USERVAR= option in the REGRESSION statement. The values of these variables are copied from the DATA= data set or from the AUXDATA= data set.

EVENT variables are variables specified in the EVENT statement. The values of these variables are computed based on the event definition and the dates of the time series observations.

Table variables contains the data from the X-13ARIMA-SEATS decomposition tables: A1, A2, A6, A7, A8, A8AO, A8LS, A8TC, A9, A10, A19, B1, B7, B13, B17, B20, C1, C17, C20, D1, D7, D8, D8BX, D8BO, D8BL, D9, D10, D10B, D10D, D11, D11A, D11F, D11R, D12, D13, D16, D16B, D18, E1, E2, E3, E5, E6, E6A, E6R, E7, E8, E18, and MV1. The variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

----------

SEATSDECOMP OUT= Data Set

You can use the SEATSDECOMP statement to output the component series that is computed using the SEATS method of seasonal decomposition.

The OUT= data set specified in the SEATSDECOMP statement contains the BY variables (if any), the ID variables (if any), and either the DATE= variable if the DATE= option is specified or the variable _DATE_ if the DATE= option is not specified. If user-defined regressor variables or EVENT variables are specified, they are included. In addition, the five components computed by the SEATS decomposition method are included in the OUT= data set for each series.

The SEATSDECOMP OUT= data set can contain the following variables:

BY variables are the BY variables used to subset the series by BY groups. The BY variables included in this data set match the BY variables (if any) that are used to process the series in the DATA= data set.

ID variables enable the series observations to be identified using further information. The ID variables included in this data set match the ID variables (if any) that are specified in the ID statement and input from the DATA= data set.

DATE variable is the time ID variable used to process the time series. It is either the variable specified in the DATE= option in the PROC X13 statement or the variable _DATE_ that is generated by the START= option in the PROC X13 statement.
Chapter 46: The X13 Procedure

_YEAR_ variable contains a value for the year of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.

_SEASON_ variable contains a value for the month or quarter of the date variable for the observation. This variable is included in the OUT= data set if YEARSEAS is specified in the OUTPUT statement.

User-defined variables are variables specified in the INPUT statement or the USERVAR= option in the REGRESSION statement. The values of these variables are copied from the DATA= data set or from the AUXDATA= data set.

EVENT variables are variables that are specified in the EVENT statement. The values of these are computed based on the event definition and the dates of the time series observations.

Component variables contains the data from the SEATS decomposition tables. The variable name used in the output data set is the input variable name followed by an underscore and the corresponding table name.

_SOS_ contains the original series for SEATS decomposition. This is the B1 series from the X-13ARIMA-SEATS method.

_SC contains the seasonal component series that is calculated by SEATS decomposition.

_TC contains the trend component series that is calculated by SEATS decomposition.

_SA contains the seasonally adjusted series that is calculated by SEATS decomposition.

_IC contains the irregular series that is calculated by SEATS decomposition.

Special Data Sets

The X13 procedure can read a MDLINFOIN= input data set and output a MDLINFOOUT= data set. The structure of both of these data sets is the same. The difference is that when the MDLINFOIN= data set is read, only information relative to specifying a model is processed, whereas the MDLINFOOUT= data set contains the results of estimating a model. The X13 procedure can also read data sets that contain event definition data. The structure of these data sets is the same as in the SAS High-Performance Forecasting system.

MDLINFOIN= and MDLINFOOUT= Data Sets

The MDLINFOIN= and MDLINFOOUT= data sets can contain one or more of the following variables:

BY variables enable the model information to be specified by BY groups. BY variables can be included in this data set that match the BY variables used to process the series. If no BY variables are included, then the models specified by _NAME_ in the MDLINFOIN= data set apply to all BY groups in the DATA= data set.

_NAME_ contains the variable name of the time series to which a particular model is to be applied. Omit the _NAME_ variable if you are specifying the same model for all series in a BY group.

_MODEL_ contains a name to identify the model for this observation. You can specify a name other than _MODEL_ in the MDLVAR= option in the PICKMDL statement. The _MODEL_ variable is an ID variable; all observations that have the same value of this variable
belong to the same model. This variable is used to identify different model candidates when the PICKMDL method is used to choose a model; it is not needed if only a single model is specified.

_MODELTYPE_ specifies whether the observation contains regression or ARIMA information. The value of _MODELTYPE_ should be either REG to supply regression information or ARIMA to supply model information. If valid regression information exists in the MDLINFOIN= data set for a BY group and series being processed, then the REGRESSION, INPUT, and EVENT statements are ignored for that BY group and series. Likewise, if valid ARIMA model information exists in the data set, then the AUTOMDL, ARIMA, and TRANSFORM statements are ignored. Valid values for the other variables in the data set depend on the value of the _MODELTYPE_ variable. Although other values of _MODELTYPE_ might be permitted in other SAS procedures, PROC X13 recognizes only REG and ARIMA.

_MODELPART_ further qualifies the regression information in the observation. For _MODELTYPE_=REG, valid values of _MODELPART_ are INPUT, EVENT, and PREDEFINED. A value of INPUT indicates that this observation refers to the user-defined variable whose name is given in _DSVAR_. Likewise, a value of EVENT indicates that the observation refers to the SAS or user-defined event whose name is given in _DSVAR_. PREDEFINED indicates that the name given in _DSVAR_ is a predefined US Census Bureau variable. If only ARIMA model information is included in the data set (that is, all observations have _MODELTYPE_=ARIMA), then the _MODELPART_ variable can be omitted. For observations where _MODELTYPE_=ARIMA, valid values for _MODELPART_ are FORECAST, \text{"."}, or blank.

_COMPONENT_ further qualifies the regression or ARIMA information in the observation. For _MODELTYPE_=REG, the only valid value of _COMPONENT_ is SCALE. For _MODELTYPE_=ARIMA, the valid values of _COMPONENT_ are TRANSFORM, CONSTANT, NONSEASONAL, and SEASONAL. TRANSFORM indicates that the observation contains the information that would be supplied in the TRANSFORM statement. CONSTANT is specified to control the constant term in the model. NONSEASONAL and SEASONAL refer to the AR, MA, and differencing terms in the ARIMA model.

_PARMTYPE_ further qualifies the regression or ARIMA information in the observation. For _MODELTYPE_=REG, the value of _PARMTYPE_ is the same as the value of the USERTYPE= option in the REGRESSION statement. Since the USERTYPE= option applies only to user-defined events and variables, the value of _PARMTYPE_ does not alter processing in observations where _MODELPART_=PREDEFINED. However, it is consistent to use a value for _PARMTYPE_ that matches the US Census Bureau predefined variable. For the constant term in the model information, _PARMTYPE_ should be SCALE. For transformation information, the value of _PARMTYPE_ should be NONE, LOG, LOGIT, SQRT, or BOXCOX. For _MODELTYPE_=ARIMA, valid values of _PARMTYPE_ are AR, MA, and DIF.

_DSVAR_ specifies the variable name associated with the current observation. For _MODELTYPE_=REG, the value of _DSVAR_ is the name of the user-defined variable, the event, or the US Census Bureau predefined variable. For _MODELTYPE_=ARIMA, _DSVAR_ should match the name of the series being processed. If the ARIMA model information applies to more than one series, then _DSVAR_ can be blank or \text{"."}, equivalently.

_VALUE_ contains a numerical value that is used as a parameter for certain types of information. For example, the PREDEFINED=EASTER(6) option in the REGRESSION statement is implemented in the MDLINFOIN= data set by using _DSVAR_=EASTER and
For a BOXCOX transformation, VALUE is set equal to the λ parameter value. For COMPONENT=SEASONAL, if VALUE is nonmissing, then VALUE is used as the seasonal period. If VALUE is missing for COMPONENT=SEASONAL, then the seasonal period is determined by the interval of the series.

FACTOR applies only to the AR and MA portions of the ARIMA model. The value of FACTOR identifies the factor of the given AR or MA term. Therefore, the value of FACTOR is the same for all observations that are related to the same factor.

LAG identifies the degree for differencing and AR and MA lags. If COMPONENT=SEASONAL, then the value in LAG is multiplied by the seasonal period indicated by the value of VALUE.

SHIFT contains the shift value for transfer functions. This value is not processed by PROC X13, but it might be processed by other procedures in which transfer functions can be specified.

NOEST indicates whether a parameter associated with the observation is to be estimated. For example, the NOINT option is indicated by COMPONENT=CONSTANT with NOEST=1 and EST=0. NOEST=1 indicates that the value in EST is a fixed value. NOEST pertains to the constant term, to AR and MA parameters, and to regression parameters.

EST contains an initial or fixed value for a parameter associated with the observation that is to be estimated. NOEST=1 indicates the value in EST is a fixed value. EST pertains to the constant term, to AR and MA parameters, and to regression parameters.

STDERR contains output information about estimated parameters. The variable STDERR is not processed by the MDLINFOIN= data set for PROC X13. In the MDLINFOOUT= data set, STDERR contains the standard error that pertains to the estimated parameter in the variable EST.

TVALUE contains output information about estimated parameters. The variable TVALUE is not processed by the MDLINFOIN= data set for PROC X13. In the MDLINFOOUT= data set, TVALUE contains the t value that pertains to the estimated parameter in the variable EST.

PVALUE contains output information about estimated parameters. The variable PVALUE is not processed by the MDLINFOIN= data set for PROC X13. In the MDLINFOOUT= data set, PVALUE contains the p-value that pertains to the estimated parameter in the variable EST.

LABEL contains a character string. The value of the variable LABEL does not affect the model that is input when the data set is specified in the MDLINFOIN= option. The user can store any string in the variable LABEL. If a model is selected from the MDLINFOIN= data set, then the value of the variable LABEL (if any) for the first observation corresponding to that model is output to the MDLINFOOUT= data set (if specified).

INEVENT= Data Set

The INEVENT= data set can contain the following variables. When a variable is omitted from the data set, that variable is assumed to have the default value for all observations. The default values are specified in the list.
_NAME_ specifies the event variable name. _NAME_ is displayed with the case preserved. Since _NAME_ is a SAS variable name, the event can be referenced by using any case. The _NAME_ variable is required; there is no default.

_CLASS_ specifies the class of event: SIMPLE, COMBINATION, PREDEFINED. The default for _CLASS_ is SIMPLE.

_KEYNAME_ contains either a date keyword (SIMPLE EVENT), a predefined event variable name (PREDEFINED EVENT), or an event name (COMBINATION EVENT). All _KEYNAME_ values are displayed in upper case. However, if the _KEYNAME_ value refers to an event name, then the actual name can be of mixed case. The default for _KEYNAME_ is no keyname, designated by "".

.STARTDATE_ contains either the date timing value or the first date timing value to use in a do-list. The default for _STARTDATE_ is no date, designated by a missing value.

. ENDDATE_ contains the last date timing value to use in a do-list. The default for _ENDDATE_ is no date, designated by a missing value.

_DATEINTRVL_ contains the interval for the date do-list. The default for _DATEINTRVL_ is no interval, designated by "".

.STARTDT_ contains either the datetime timing value or the first datetime timing value to use in a do-list. The default for _STARTDT_ is no datetime, designated by a missing value.

. ENDDT_ contains the last datetime timing value to use in a do-list. The default for _ENDDT_ is no datetime, designated by a missing value.

 DTINTRVL_ contains the interval for the datetime do-list. The default for _DTINTRVL_ is no interval, designated by "".

.STARTOBS_ contains either the observation number timing value or the first observation number timing value to use in a do-list. The default for _STARTOBS_ is no observation number, designated by a missing value.

. ENDOBS_ contains the last observation number timing value to use in a do-list. The default for _ENDOBS_ is no observation number, designated by a missing value.

_OBSINTRVL_ contains the interval length of the observation number do-list. The default for _OBSINTRVL_ is no interval, designated by "".

.TYPE_ specifies the type of event. The valid values of _TYPE_ are POINT, LS, RAMP, TR, TEMPRAMP, TC, LIN, LINEAR, QUAD, CUBIC, INV, INVERSE, LOG, and LOGARITHMIC. The default for _TYPE_ is POINT.

.VALUE_ specifies the value for nonzero observation. The default for _VALUE_ is 1.0.

.PULSE_ specifies the interval that defines the units for the duration values. The default for _PULSE_ is no interval, designated by "".

.DUR_BEF_ specifies the number of durations before the timing value. The default for _DUR_BEF_ is 0.

.DUR_AFT_ specifies the number of durations after the timing value. The default for _DUR_AFT_ is 0.

.SLOPE_BEF_ determines whether the curve is GROWTH or DECAY before the timing value for _TYPE_=RAMP, _TYPE_=TEMPRAMP, and _TYPE_=TC. Valid values are GROWTH and DECAY. The default for _SLOPE_BEF_ is GROWTH.
determines whether the curve is GROWTH or DECAY after the timing value for TYPE RAMP, TYPE TEMP RAMP, and TYPE TC. Valid values are GROWTH and DECAY. The default for SLOPE_AFT is GROWTH unless TYPE = TC; then the default is DECAY.

Specifies the number of PULSE intervals to shift the timing value. The shift can be positive (forward in time) or negative (backward in time). If PULSE is not specified, then the shift is in observations. The default for SHIFT is 0.

Specifies the parameter for EVENT of TYPE TC. The default for TCPARM is 0.5.

Specifies the rule to use when combining events or when timing values of an event overlap. The valid values of RULE are ADD, MAX, MIN, MINNZ, MINMAG, and MULT. The default for RULE is ADD.

Specifies the frequency interval at which the event should be repeated. If this value is missing, then the event is not periodic. The default for PERIOD is no interval, designated by “.”.

Specifies the label or description for the event. If a label is not specified, then the default label value is displayed as “.”. For events that produce dummy variables, either the user-supplied label or the default label is used. For COMPLEX events, the LABEL value is merely a description of the group of events.

OUTSTAT= Data Set

The OUTSTAT= data set can contain the following variables:

BY variables sorts the statistics into BY groups. BY variables are included in this data set that match the BY variables used to process the series.

NAME specifies the variable name of the time series to which the statistics apply.

STAT describes the statistic that is stored in VALUE or CVALUE. STAT takes the following values:

- **Period**: the period of the series, 4 or 12.
- **Mode**: the mode of the seasonal adjustment from the X11 statement. Possible values are ADD, MULT, LOGADD, and PSEUDOADD.
- **Start**: the beginning of the model span expressed as monyyyy for monthly series or yyyyQq for quarterly series.
- **End**: the end of the model span expressed as monyyyy for monthly series or yyyyQq for quarterly series.
- **NbFct**: the number of forecast observations.
- **SigmaLimLower**: the lower sigma limit in standard deviation units.
- **SigmaLimUpper**: the upper sigma limit in standard deviation units.
- **pLBQ_24**: the Ljung-Box Q statistic of the residuals at lag 24, for monthly series. Note that lag 12 (pLBQ_12) and lag 16 (pLBQ_16) are included in the data set for quarterly series.
- **D8Fs**: the stable seasonality F test value from Table D8.
D8Fm the moving seasonality $F$ test value from Table D8.
ISRatio the final irregular-to-seasonal ratio from Table F 2.H.
SMA_ALL the final seasonal moving average filter for all periods.
RSF the residual seasonality $F$ test value for Table D11 for the entire series.
RSF3 the residual seasonality $F$ test value for Table D11 for the last three years.
RSFA the residual seasonality $F$ test value for Table D11.A for the entire series.
RSF3A the residual seasonality $F$ test value for Table D11.A for the last three years.
RSFR the residual seasonality $F$ test value for Table D11.R for the entire series.
RSF3R the residual seasonality $F$ test value for Table D11.R for the last three years.
TMA the Henderson trend moving average filter selected.
ICRatio the final irregular-to-trend cycle ratio from Table F 2.H.
E5sd the standard deviation from Table E5.
E6sd the standard deviation from Table E6.
E6Asd the standard deviation from Table E6.A.
MCD months of cyclical dominance.
Q the overall level Q from Table F3.
Q2 Q overall level without M2 from Table F3.

FMT indicates whether the format is numeric or character. FMT="NUM" if the value is numeric and stored in the VALUE variable. FMT="CHAR" if the value is a string and stored in the CVALUE variable.

VALUE contains the numerical value of the statistic or missing if the statistic is of type character.
CVALUE contains the character value of the text statistic or blank if the statistic is of type numeric.
Example 46.1: ARIMA Model Identification

This example shows typical PROC X13 statements that are used for ARIMA model identification. This example invokes the X13 procedure and uses the TRANSFORM and IDENTIFY statements. It specifies the time series data, takes the logarithm of the series (TRANSFORM statement), and generates ACFs and PACFs for the specified levels of differencing (IDENTIFY statement). The ACFs and PACFs for DIFF=1 and SDIFF=1 are shown in Output 46.1.1, Output 46.1.2, Output 46.1.3, and Output 46.1.4. The data set is the same as in the section “Basic Seasonal Adjustment” on page 3288.

The graphical displays are available when ODS Graphics is enabled. For more information about the graphics available in the X13 procedure, see the section “ODS Graphics” on page 3355.

```plaintext
proc x13 data=sales date=date;
  var sales;
  transform power=0;
  identify diff=(0,1) sdiff=(0,1);
run;
```

**Example 46.2: Model Estimation**

After studying the output from Example 46.1 and identifying the ARIMA part of the model as, for example, \((0\ 1\ 1)(0\ 1\ 1)\ 12\), you can replace the IDENTIFY statement with the ARIMA and ESTIMATE statements as follows:

```plaintext
proc x13 data=sales date=date;
  var sales;
  transform power=0;
  arima model=( (0,1,1)(0,1,1) );
  estimate;
run;
```

The parameter estimates and estimation summary statistics are shown in **Output 46.2.1**.
Output 46.2.1  Estimation Data

Example 46.3: Seasonal Adjustment

Assuming that the model in Example 46.2 is satisfactory, a seasonal adjustment that uses forecast extension can be performed by adding the X11 statement to the procedure. By default, the data are forecast one year ahead at the end of the series.

```plaintext
ods output D8A#1=SalesD8A_1;
ods output D8A#2=SalesD8A_2;
ods output D8A#3=SalesD8A_3;
ods output D8A#4=SalesD8A_4;

\]

Combined Test of Identifiable Seasonality: Present

The four ODS statements in the preceding example direct output from the D8A tables into four data sets: SalesD8A_1, SalesD8A_2, SalesD8A_3, and SalesD8A_4. It is best to direct the output to four different data sets because the four tables associated with Table D8A have varying formats. The ODS data sets are shown in Output 46.3.2, Output 46.3.3, Output 46.3.4, and Output 46.3.5.

Example 46.4: RegARIMA Automatic Model Selection

This example demonstrates regARIMA modeling and TRAMO-based automatic model selection, which is available with the AUTOMDL statement. ODS SELECT statements are used to limit the displayed output to the model selection and estimation stages. The same data set is used as in the previous examples.

```sas
title 'TRAMO Automatic Model Identification';
ods select UnitRootTestModel
   UnitRootTest
   AutoChoiceModel
   Best5Model
   AutomaticModelChoice
   InitialModelChoice
   FinalModelChecks
   FinalModelChoice
   AutomdlNote;
proc x13 data=sales date=date;
   var sales;
   transform function=log;
   regression predefined=td;
   automdl maxorder=(1,1)
     print=all;
   estimate;
   x11;
   output out=out a1 a2 a6 b1 c17 c20 d1 d7 d8 d9 d10
d11 d12 d13 d16 d18;
run;
proc print data=out(obs=21);
   title 'Output Variables Related to Trading Day Regression';
run;
```

The automatic model selection output is shown in Output 46.4.1, Output 46.4.2, and Output 46.4.3. The first table, “ARIMA Estimate for Unit Root Identification” in Output 46.4.1, gives details of the method that TRAMO uses to automatically select the orders of differencing. The second table, “Results of Unit Root Test for Identifying Orders of Differencing” in Output 46.4.1, shows that a regular difference order of 1 and a seasonal difference order of 1 has been determined by TRAMO. The third table, “Models Estimated by Automatic ARIMA Model Selection Procedure” in Output 46.4.2, shows all the models examined by the TRAMO-based method. The fourth table, “Best Five ARIMA Models Chosen by Automatic Modeling” in Output 46.4.3, shows the top five models in order of rank and their BIC2 statistic. The fifth table, “Comparison of Automatically Selected Model and Default Model” in Output 46.4.3, compares the model selected by the TRAMO model to the default regARIMA model of the X-13ARIMA-SEATS method. The sixth table, “Initial Automatic Model Selection” in Output 46.4.3, shows which model was selected between the two models that are compared in the table “Comparison of Automatically Selected Model and Default Model.” (When available, the table “Check of the Residual Ljung-Box Q Statistic” in Output 46.4.3 contains additional information about the initial model choice.) The seventh table, “Final Checks for Identified Model” in Output 46.4.3, displays the results of the final model checks for model adequacy. The eighth table, “Final Automatic Model Selection” in Output 46.4.3, shows which model was actually selected.

Example 46.5: Automatic Outlier Detection

This example demonstrates the use of the OUTLIER statement to automatically detect and remove outliers from a time series to be seasonally adjusted. The data set is the same as in the section “Basic Seasonal Adjustment” on page 3288 and the previous examples. Adding the OUTLIER statement to Example 46.3 requests that outliers be detected by using the default critical value as described in the section “OUTLIER Statement” on page 3317. The tables associated with outlier detection for this example are shown in Output 46.5.1. The first table shows the critical values; the second table shows that a single potential outlier was identified; the third table shows the estimates for the ARMA parameters. Since no outliers are included in the regression model, the “Regression Model Parameter Estimates” table is not displayed. Because only a potential outlier was identified, and not an actual outlier, in this case the A1 series and the B1 series are identical.

```
title 'Automatic Outlier Identification';
proc x13 data=sales date=date;
  var sales;
  transform function=log;
  arima model=( (0,1,1)(0,1,1) );
  outlier;
  estimate;
  x11;
  output out=nooutlier a1 b1 d10;
run ;
```

</tr>
</tbody>
</table>

Note: The following time series values might later be identified as outliers when data are added or revised. They were not identified as outliers in this run either because their test t-statistics were slightly below the critical value or because they were eliminated during the backward deletion step of the identification procedure, when a non-robust t-statistic is used.

Output 46.5.1 continued

| Parameter   | Lag | Estimate | Standard Error | t Value | Pr > |t| |
|-------------|-----|----------|----------------|---------|------|---|
| Nonseasonal MA | 1   | 0.40181  | 0.07887        | 5.09    | <.0001 |
| Seasonal MA   | 12  | 0.55695  | 0.07626        | 7.30    | <.0001 |

In the next example, reducing the critical value to 3.3 causes the outlier identification routine to more aggressively identify outliers as shown in Output 46.5.2. The first table shows the critical values. The second table shows that three additive outliers and a level-shift have been included in the regression model. The third table shows how the inclusion of outliers in the model affects the ARMA parameters.

```
proc x13 data=sales date=date;
  var sales;
  transform function=log;
  arima model=((0,1,1) (0,1,1));
  outlier cv=3.3;
  estimate;
  x11;
  output out=outlier a1 a8 a8ao a8ls b1 d10;
run;

proc print data=outlier(obs=45);
run;
```

| Seasonal MA  | 12  | 0.49647 | 0.07676 | 6.47 | <.0001 |

The first 45 observations of the A1, A8, A8AO, A8LS, B1, and D10 series are displayed in Output 46.5.3. You can confirm the following relationships from the data:

\[ A8 = A8AO \times A8LS \]

\[ B1 = A1/A8 \]

The seasonal factors are stored in the variable sales_D10.

From the two previous examples, you can examine how outlier detection affects the seasonally adjusted series. Output 46.5.4 shows a plot of A1 versus B1 in the series where outliers are detected. B1 has been adjusted for the additive outliers and the level-shift.

```
proc sgplot data=outlier;
    series x=date y=sales_A1 / name='A1' markers
        markerattrs=(color=red symbol='circle')
        lineattrs=(color=red);
    series x=date y=sales_B1 / name='B1' markers
        markerattrs=(color=black symbol='asterisk')
        lineattrs=(color=black);
    yaxis label='Original and Outlier Adjusted Time Series';
run;
```

**Output 46.5.4** Original Series and Outlier Adjusted Series
Output 46.5.5 compares the seasonal factors (Table D10) of the series unadjusted for outliers to the series adjusted for outliers. The seasonal factors are based on the B1 series.

```
data both;
    merge nooutlier(rename=(sales_D10=unadj_D10)) outlier;
run;

title 'Results of Outlier Identification on Final Seasonal Factors';
proc sgplot data=both;
    series x=date y=unadj_D10 / name='unadjusted' markers
        markerattrs=(color=red symbol='circle')
        lineattrs=(color=red)
        legendlabel='Unadjusted for Outliers';
    series x=date y=sales_D10 / name='adjusted' markers
        markerattrs=(color=blue symbol='asterisk')
        lineattrs=(color=blue)
        legendlabel='Adjusted for Outliers';
yaxis label='Final Seasonal Factors';
run;
```

Output 46.5.5 Seasonal Factors Based on Original and Outlier Adjusted Series
Example 46.6: User-Defined Regressors

This example demonstrates the use of the `USERVAR=` option in the REGRESSION statement to include user-defined regressors in the regARIMA model. The user-defined regressors must be defined as nonmissing values for the span of the series being modeled plus any backcast or forecast values. Suppose you have the data set `SALESDATA` with 132 monthly observations beginning in January 1949.

```sas
title 'Data Set to be Seasonally Adjusted';
data salesdata;
   set sashelp.air(obs=132);
run;
```

Because the regARIMA model forecasts one year ahead, you must define the regressor for 144 observations that start in January 1949. You can construct a simple length-of-month regressor by using the following DATA step:

```sas
title 'User-defined Regressor for Data to be Seasonally Adjusted';
data regressors(keep=date LengthOfMonth);
   set sashelp.air;
   LengthOfMonth = INTNX('MONTH',date,1) - date;
run;
```

In this example, the two data sets are merged to use them as input to PROC X13. You can also use the AUXDATA= data set to input user-defined regressors. For more information, see Example 46.11. The BY statement is used to align the regressors with the time series by the time ID variable `DATE`.

```sas
title 'Data Set Containing Series and Regressors';
data datain;
   merge regressors salesdata;
   by date;
run;
proc print data=datain(firstobs=121);
run;
```
The last 24 observations of the input data set are displayed in Output 46.6.1. The regressor variable is defined for one year (12 observations) beyond the span of the time series to be seasonally adjusted.

**Output 46.6.1** PROC X13 Input Data Set with User-Defined Regressor

Data Set Containing Series and Regressors

The DATAIN data set is now ready to be used as input to PROC X13. The DATE= variable and the user-defined regressors are automatically excluded from the variables to be seasonally adjusted.

```plaintext
    title 'regARIMA Model with User-defined Regressor';
    proc x13 data=datain date=DATE interval=MONTH plots=none;
        transform function=log;
        regression uservar=LengthOfMonth / usertype=lom;
        automdl;
        x11;
        output out=out a1 d11;
    run;
```
Example 46.6: User-Defined Regressors

The parameter estimates for the regARIMA model are shown in Output 46.6.2

Output 46.6.2 PROC X13 Output for User-Defined Regression Parameter

regARIMA Model with User-defined Regressor

The X13 Procedure

Regression Model Parameter Estimates
For Variable AIR

| Type         | Parameter | NoEst | Estimate | Standard Error | t Value | Pr > |t| |
|--------------|-----------|-------|----------|----------------|---------|------|------|
| User Defined | LengthOfMonth | Est   | 0.04683  | 0.01834        | 2.55    | 0.0119 |

Exact ARMA Maximum Likelihood Estimation
For Variable AIR

| Parameter         | Lag | Estimate | Standard Error | t Value | Pr > |t| |
|-------------------|-----|----------|----------------|---------|------|------|
| Nonseasonal MA    | 1   | 0.33678  | 0.08506        | 3.96    | 0.0001 |
| Seasonal MA       | 12  | 0.54078  | 0.07726        | 7.00    | <.0001 |

Another way to include user-defined regressors in the regARIMA model is to specify the SPAN= option in the PROC X13 statement. The following user-defined regressor is similar to the one defined previously. However, this length-of-month regressor is mean adjusted. Using a zero-mean regressor prevents the regressor from altering the level of the series. In this instance, the series to be seasonally adjusted, AIR, and the regression variable, LengthOfMonth, have nonmissing observations at all time periods in the data set DATAIN.

title 'User-defined Regressor for Data to be Seasonally Adjusted, Mean Adjusted';
data datain(keep=date AIR LengthOfMonth);
   set sashelp.air;
   LengthOfMonth = INTNX('MONTH',date,1) - date - 30.4375;
run;

Because the default forecast period is one year ahead, the span of the series must be limited to one year before the end of the regression variable definition to forecast using the regression variable LengthOfMonth,

title 'regARIMA Model with Zero-Mean User-defined Regressor';
proc x13 data=datain date=DATE interval=MONTH span=(,DEC1959) plots=none;
   transform function=log;
   regression uservar=LengthOfMonth / usertype=lom;
   automdl;
   x11;
   output out=outzm a1 d11;
run;

The parameter estimates for the regARIMA model that are estimated using a zero-mean regressor are shown in Output 46.6.3
Output 46.6.3 PROC X13 Output for Zero-Mean User-Defined Regression Parameter

regARIMA Model with Zero-Mean User-defined Regressor

The X13 Procedure

Regression Model Parameter Estimates
For Variable AIR

| Type          | Parameter | NoEst | Estimate | Standard Error | t Value | Pr > |t| |
|---------------|-----------|-------|----------|----------------|---------|------|------|
| User Defined  | LengthOfMonth | Est   | 0.04683  | 0.01834        | 2.55    | 0.0119 |     |

Exact ARMA Maximum Likelihood Estimation
For Variable AIR

| Parameter                | Lag | Estimate | Standard Error | t Value | Pr > |t| |
|--------------------------|-----|----------|----------------|---------|------|------|
| Nonseasonal MA           | 1   | 0.33678  | 0.08506        | 3.96    | 0.0001 |     |
| Seasonal MA              | 12  | 0.54078  | 0.07726        | 7.00    | <.0001 |     |

Specifying USERTYPE=LOM causes the regression effect to be removed from the seasonally adjusted series. The effect of the mean of the regression variable on the seasonally adjusted series can be seen by examining the plots of the original series and the seasonally adjusted series.

```
title 'regARIMA Model with Non-Zero-Mean User-Defined Regressor';
proc sgplot data=out;
    series x=date y=air_A1 / name = "A1" markers
        markerattrs=(color=red symbol='asterisk')
        lineattrs=(color=red);
    series x=date y=air_D11 / name= "D11" markers
        markerattrs=(symbol='circle')
        lineattrs=(color=blue);
    yaxis label='Original and Seasonally Adjusted Time Series';
run;
```

```
title 'regARIMA Model with Zero-Mean User-Defined Regressor';
proc sgplot data=outzm;
    series x=date y=air_A1 / name = "A1" markers
        markerattrs=(color=red symbol='asterisk')
        lineattrs=(color=red);
    series x=date y=air_D11 / name= "D11" markers
        markerattrs=(symbol='circle')
        lineattrs=(color=blue);
    yaxis label='Original and Seasonally Adjusted Time Series';
run;
```

The graph of the original and seasonally adjusted series in Output 46.6.4 shows that the level of the seasonally adjusted series has been altered due to the user-defined regressor. The graph of the original and seasonally adjusted series in Output 46.6.5 shows that the level of the seasonally adjusted series is the same as the original series since the user-defined regressor has zero-mean.
Output 46.6.4 Plot of Original and Seasonally Adjusted Data

![Graph showing regARIMA model with non-zero-mean user-defined regressor.](image)

- Table A 1: Time Series Data (for the Span Analyzed)
- Table D 11: Final Seasonally Adjusted Data
When actual values are available for the forecast periods, information about forecast error is available in the output. **Output 46.6.6** shows the table “Forecasts and Standard Errors of the Transformed Data on the Original Scale” for a series with missing values in the forecast period. **Output 46.6.7** shows the table “Forecasts and Standard Errors of the Transformed Data on the Original Scale” for a series with actual values in the forecast period. Thus, it is more desirable to use SPAN= option to limit the span of a series if the actual values are available for the forecast period.

Suppose that after examining the output from the preceding example, you decide that an Easter regressor should be added to the model. The following statements create a data set with the model identified above and adds a US Census Bureau Predefined Easter(25) regressor. The new model data set to be used as input in the MDLINFOIN= option is displayed in the data set shown in Output 46.7.3.

```plaintext
data pluseaster;
  _NAME_ = 'y';
  _MODELTYPE_ = 'REG';
  _MODELPART_ = 'PREDEFINED';
  _COMPONENT_ = 'SCALE';
  _PARMTYPE_ = 'EASTER';
  _DSVAR_ = 'EASTER';
  _VALUE_ = 25;
run;

data mdlpluseaster;
  set mdl;
run;

proc append base=mdlpluseaster data=pluseaster force;
run;

proc print data=mdlpluseaster;
run;
```
**Output 46.7.3**  MDLINFOIN= Data Set Model with Easter(25) Regression Added

The following statements estimate the regression and ARIMA parameters by using the model described in the new data set mdlpluseaster. The results of estimating the new model are shown in **Output 46.7.4**.

```plaintext
proc x13 data=b1 start='1980q1' interval=qtr
   MdlInfoIn=mdlpluseaster MdlInfoOut=mdl2;
   estimate;
run;
```

The new model estimation results are displayed in the data set mdl2 shown in **Output 46.7.5**.

```plaintext
proc print data=mdl2;
run;
```
Example 46.8: Setting Regression Parameters

This example illustrates the use of fixed regression parameters in PROC X13. Suppose that you have the same data set as in the section “Basic Seasonal Adjustment” on page 3288. You can specify the following statements to use TRAMO to automatically identify a model that includes a US Census Bureau Easter(25) regressor:

```plaintext
title 'Estimate Easter(25) Parameter';
proc x13 data=sales date=date MdlInfoOut=mdlout1;
var sales;
  regression predefined=easter(25);
  automdl;
run;
```

The displayed results are shown in Output 46.8.1.

Output 46.8.1  Automatic Model ID with Easter(25) Regression

Estimate Easter(25) Parameter

The X13 Procedure

Regression Model Parameter Estimates
For Variable sales

| Type  | Parameter  | NoEst | Estimate | Error   | t Value | Pr > |t| |
|-------|------------|-------|----------|---------|---------|------|---|
| Easter| Easter[25] | Est   | -5.09298 | 3.50786 | -1.45   | 0.1489 |

The MDLINFOOUT= data set, mdlout1, that contains the model and parameter estimates is shown in Output 46.8.2.

```plaintext
proc print data=mdlout1;
run;
```

**Output 46.8.2** MDLINFOOUT= Data Set, Estimation of Automatic Model ID with Easter(25) Regression

| Estimate Easter(25) Parameter
|-----------------------------|
| _NAME_ _MODELTYPE_ _MODELPART_ _COMPONENT_ _PARMTYPE_ _DSVAR_ _VALUE_ _FACTOR_
| sales REG PREDEFINED SCALE EASTER EASTER 25 . |

To fix the Easter(25) parameter while adding a regressor that is weighted according to the number of Saturdays in a month, either use the REGRESSION and EVENT statements or create a MDLINFOIN= data set. The following statements show the method for using the REGRESSION statement to fix the EASTER parameter and the EVENT statement to add the SATURDAY regressor. The output is shown in **Output 46.8.3**.
Example 46.8: Setting Regression Parameters

To fix the EASTER regressor and add the new SATURDAY regressor by using a DATA step, you can create the data set mdlin2 as shown. The data set mdlin2 is displayed in Output 46.8.4.

title 'Use a SAS DATA Step to Create a MdlInfoIn= Data Set';
data plusSaturday;
  _NAME_ = 'sales';
  _MODELTYPE_ = 'REG';
  _MODELPART_ = 'EVENT';
  _COMPONENT_ = 'SCALE';
  _PARMTYPE_ = 'USER';
  _DSVAR_ = 'SATURDAY';
run;

data mdlin2;
  set mdlout1;
  if ( _DSVAR_ = 'EASTER' ) then do;
    _NOEST_ = 1;
    _EST_ = -5.029298;
  end;
run;

proc append base=mdlin2 data=plusSaturday force;
run;

proc print data=mdlin2;
run;
Output 46.8.4 MDLINFOIN= Data Set, Fixed Easter(25) and Added Saturday Regression, Previously Identified Model

Use a SAS DATA Step to Create a MdlInfoIn= Data Set

The data set mdlin2 can be used to replace the regression and model information contained in the REGRESSION, EVENT, and AUTOMDL statements. Note that the model specified in the mdlin2 data set is the same model as the automatically identified model. The following example uses the mdlin2 data set as input; the results are displayed in Output 46.8.5:

```sas
title 'Use Updated Data Set to Alter Model';
proc x13 data=sales date=date MdlInfoIn=mdlin2 MdlInfoOut=mdlout2DS;
  var sales;
  estimate;
run;
```
Output 46.8.5  Estimate MDLINFO= File for Model with Fixed Easter(25) and Saturday Regression, Previously Identified Model

Use Updated Data Set to Alter Model

The X13 Procedure

Regression Model Parameter Estimates
For Variable sales

| Type            | Parameter | NoEst | Estimate | Standard Error | t Value | Pr > |t| |
|-----------------|-----------|-------|----------|----------------|---------|------|---|
| User Defined    | SATURDAY  | Est   | 3.41762  | 1.07641        | 3.18    | 0.0019|

Exact ARMA Maximum Likelihood Estimation
For Variable sales

| Parameter       | Lag | Estimate | Standard Error | t Value | Pr > |t| |
|-----------------|-----|----------|----------------|---------|------|---|
| Nonseasonal AR  | 1   | 0.62225  | 0.09175        | 6.78    | <.0001|
|                 | 2   | 0.30429  | 0.10109        | 3.01    | 0.0031|
|                 | 3   | -0.14862 | 0.08859        | -1.68   | 0.0958|
| Nonseasonal MA  | 1   | 0.97125  | 0.03798        | 25.57   | <.0001|
| Seasonal MA     | 12  | 0.11691  | 0.10000        | 1.17    | 0.2445|

The following statements specify almost the same information as contained in the data set mdlin2. The ARIMA statement specifies the lags of the model. However, the initial AR and MA parameter values are the default. When using the mdlin2 data set as input, the initial values can be specified. The results are displayed in Output 46.8.6.

```
title 'Use SAS Statements to Alter Model';
proc x13 data=sales date=date MdlInfoOut=mdlout3grm;
  var sales;
  regression predefined=easter(25) / b=-5.029298 F;
  event Saturday;
  arima model=((3 1 1)(0 1 1));
  estimate;
run;
```

```
proc print data=mdlout3grm;
run;
```

The MDLINFOOUT= data set provides a method for comparing the results of the model identification. The data set mdlout3grm that results from using the MODEL= option in the ARIMA statement can be compared to the data set mdlout2DS that results from using the MDLINFOIN= data set with initial values for the AR and MA parameters. The mdlout2DS data set is shown in Output 46.8.7, and the results of the comparison are shown in Output 46.8.8. The slight difference in the estimated parameters can be attributed to the difference in the initial values for the AR and MA parameters.

```sas
proc print data=mdlout2DS;
run;
```
Output 46.8.7  MDLINFOOUT= Data Set, Fixed Easter(25) and Added Saturday Regression, Previously Identified Model

Example 46.9: Creating an MDLINFO= Data Set for Use with the PICKMDL Statement

This example illustrates how you can create a data set for use in the PICKMDL statement that contains five commonly used ARIMA models:

- ARIMA \((0 \, 1 \, 1)(0 \, 1 \, 1)s\)
- ARIMA \((0 \, 1 \, 2)(0 \, 1 \, 1)s\)
- ARIMA \((2 \, 1 \, 0)(0 \, 1 \, 1)s\)
- ARIMA \((0 \, 2 \, 2)(0 \, 1 \, 1)s\)
- ARIMA \((2 \, 1 \, 2)(0 \, 1 \, 1)s\)

The following macro code creates a MDLINFOIN= data set for a general ARIMA model:

```sas
%macro makemodel(name,p,d,q,sp,sd,sq,model);
data "&name" (keep= _MODELTYPE_ _MODELPART_ _COMPONENT_ _DSVAR_ _PARMTYPE_ _FACTOR_ _LAG_ _LABEL_);
length _MODELTYPE_ _MODELPART_ _COMPONENT_ _DSVAR_ _PARMTYPE_ _FACTOR_ _LAG_ 8;
length _LABEL_ $32;

_MODELTYPE_="ARIMA";
_MODELPART_="FORECAST";
_DSVAR_=".";

_LABEL_="\\("||"&p"||"\\"|"||"&d"||"\\"|"||"&q"||\")\\("||"&sp"||"\\"|"||"&sd"||"\\"|"||"&sq"||\")s";

/* nonseasonal AR factors */
_COMPONENT_="NONSEASONAL";
_PARMTYPE_="AR";
_FACTOR_=_1;
do _LAG_=_1 to &p;
   output;
end;

/* seasonal AR factors */
_COMPONENT_="SEASONAL";
_PARMTYPE_="AR";
_FACTOR_=_2;
do _LAG_=_1 to &sp;
   output;
end;
```

Example 46.9: Creating an MDLINFO= Data Set for Use with the PICKMDL Statement

```sas
/* nonseasonal MA factors */
_COMPONENT_="NONSEASONAL"
_PARMTYPE_="MA"
_FACTOR_ =1;
do _LAG_=1 to &q;
   output;
   end;

/* seasonal MA factors */
_COMPONENT_="SEASONAL"
_PARMTYPE_="MA"
_FACTOR_ =2;
do _LAG_=1 to &sq;
   output;
   end;

/* nonseasonal DIF */
_COMPONENT_="NONSEASONAL"
_PARMTYPE_="DIF"
_FACTOR_ =1;
_LAG_ =1;
do i_=1 to &d;
   output;
   end;

/* seasonal DIF */
_COMPONENT_="SEASONAL"
_PARMTYPE_="DIF"
_FACTOR_ =2;
_LAG_ =1;
do i_=1 to &sd;
   output;
   end;

run;
data sasuser.&name;
   length _MODEL_ $32;
   set &name;
   _MODEL_ = "&model";
run;
%mend makemodel;
```
Chapter 46: The X13 Procedure

The following SAS statements use the macro to generate a data set with some commonly used models for use in the PICKMDL statement:

```sas
%makemodel(x13mdl1, 0, 1, 1, 0, 1, 1, Model1);
%makemodel(x13mdl2, 0, 1, 2, 0, 1, 1, Model2);
%makemodel(x13mdl3, 2, 1, 0, 0, 1, 1, Model3);
%makemodel(x13mdl4, 0, 2, 2, 0, 1, 1, Model4);
%makemodel(x13mdl5, 2, 1, 2, 0, 1, 1, Model5);
```

```sas
data Models;
  length _NAME_ $32;
  set sasuser.x13mdl1 sasuser.x13mdl2 sasuser.x13mdl3
       sasuser.x13mdl4 sasuser.x13mdl5;
  _NAME_ = 'sales';
run;
```

The Models data set is shown in Output 46.9.1.

```sas
title '5 Commonly Used Models';
proc print data=Models;
run ;
```
Output 46.9.1 A Data Set That Contains Models for Use with the PICKMDL Statement

## 5 Commonly Used Models

Example 46.9: Creating an MDLINFO= Data Set for Use with the PICKMDL Statement

The following statements reverse the order of the models in the input data set. The default METHOD=FIRST option is used to select the model. The chosen model is shown in the mdlchosen data set in Output 46.9.3. With METHOD=FIRST, a different model is chosen because the order is changed.

```plaintext
data Models;
  length _NAME_ $32;
  set sasuser.x13mdl5 sasuser.x13mdl4 sasuser.x13mdl3
      sasuser.x13mdl2 sasuser.x13mdl1 ;
  _NAME_ = 'sales';
run;

proc x13 data=sales date=date mdlinfoin=Models mdlinfoout=mdlchosen;
  var sales;
  transform function=log;
  pickmdl method=first;
run;

title 'Chosen Model';
proc print data=mdlchosen;
run;
```

Output 46.9.3 The Model Chosen from the Five Commonly Used Models, Reversed Order

<table>
<thead>

</table>

The following example shows the use of PICKMDL statement option METHOD=BEST to select the model. The chosen model is shown in the mdlchosen data set in Output 46.9.4. With METHOD=BEST, a different model is chosen than either of the previous models chosen. Because the order in which the models occur in the MDLINFOIN= data set affects model selection when METHOD=FIRST is specified, it is a common practice to list models from the simplest model to the most complex in the MDLINFOIN= data set that is used in conjunction with the PICKMDL statement.
Chapter 46: The X13 Procedure

```sas
proc x13 data=sales date=date mdlinfoin=Models mdlinfoout=mdlchosen;
   var sales;
   transform function=log;
   pickmdl method=best;
run;

title 'Chosen Model';
proc print data=mdlchosen;
run;
```

### Example 46.10: Illustration of ODS Graphics

This example illustrates the use of ODS Graphics. Using the same data set as in the section “Basic Seasonal Adjustment” on page 3288 and the previous examples, a spectral plot of the original series is displayed in Output 46.10.1.

The graphical displays are available when ODS Graphics is enabled. For specific information about the graphics available in the X13 procedure, see the section “ODS Graphics” on page 3355.

```sas
proc x13 data=sales date=date;
   var sales;
run;
```
Example 46.11: AUXDATA= Data Set

This example demonstrates the use of the AUXDATA= data set to input user-defined regressors for use in the regARIMA model. User-defined regressors are often economic indicators, but in this example a user-defined regressor is generated in the following statements:

```
data auxreg(keep=date lengthofmonth);
  set sales;
  lengthofmonth = (INTNX('MONTH',date,1) - date) - (365/12);
  format date monyy.;
run;
```

When you use the AUXDATA= data set, it is not necessary to merge the user-defined regressor data set with the DATA= data set. The following statements input the regressor lengthofmonth in the data set auxreg. The regressor lengthofmonth is specified in the REGRESSION statement, and the data set auxreg is specified in the AUXDATA= option in the PROC X13 statement.
title 'Align lengthofmonth Regressor from Auxreg to First Three Years';
ods select regParameterEstimates;
proc x13 data=sales(obs=36) date=date auxdata=auxreg;
  var sales;
  regression uservar=lengthofmonth;
  arima model=((0 1 1) (0 1 1));
  estimate;
run;

title 'Align lengthofmonth Regressor from Auxreg to Second Three Years';
ods select regParameterEstimates;
proc x13 data=sales(firstobs=37 obs=72) date=date auxdata=auxreg;
  var sales;
  regression uservar=lengthofmonth;
  arima model=((0 1 1) (0 1 1));
  estimate;
run;

Output 46.11.1 and Output 46.11.2 display the parameter estimates for the two series.

**Output 46.11.1** Using Regressors in the AUXDATA= Data for the First Three Years of Series

Align lengthofmonth Regressor from Auxreg to First Three Years

The X13 Procedure

<table>
<thead>
<tr>
<th>Type</th>
<th>Parameter</th>
<th>NoEst</th>
<th>Estimate</th>
<th>Standard Error</th>
<th>t Value</th>
<th>Pr &gt;</th>
<th>t</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>
<td>User Defined</td>
<td>lengthofmonth</td>
<td>Est</td>
<td>2.98046</td>
<td>5.36251</td>
<td>0.56</td>
<td>0.5840</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

**Output 46.11.2** Using Regressors in the AUXDATA= Data for the Second Three Years of Series

Align lengthofmonth Regressor from Auxreg to Second Three Years

The X13 Procedure

<table>
<thead>
<tr>
<th>Type</th>
<th>Parameter</th>
<th>NoEst</th>
<th>Estimate</th>
<th>Standard Error</th>
<th>t Value</th>
<th>Pr &gt;</th>
<th>t</th>
<th></th>
</tr>
</thead>
<tbody>
<tr>

<td>-0.51215</td>
<td>8.43145</td>
<td>-0.06</td>
<td>0.9521</td>
<td></td>
<td></td>
</tr>
</tbody>
</table>

The X13 procedure uses the date variable in the sales data set and the auxreg data set to align the user-defined regressors.

In the following example, the DATA= data set salesby contains BY groups. The X13 procedure aligns the regressor in the auxreg data set to each BY group in the salesby data set according to the variable date that is specified by the DATE= option in the PROC X13 statement. The variable date must be present in the auxreg data set to align the values.
data salesby;
  set sales(obs=72);
  if (_n_ < 37 ) then by=1;
  else by=2;
run;
ods select regParameterEstimates;
title 'Align lengthofmonth Regressor from Auxreg to BY Groups';
proc x13 data=salesby date=date auxdata=auxreg;
  var sales;
  by by;
  regression uservar=lengthofmonth;
  arima model=((0 1 1) (0 1 1));
  estimate;
run;

The results in Output 46.11.3 match the previous results in Output 46.11.1 and Output 46.11.2.

Overview: SASECRSP Interface Engine

Introduction

The SASECRSP interface engine in SAS/ETS software enables SAS users to access and process time series, events, portfolios, and group data that reside in Center for Research in Security Prices databases (CRSPAccess data). It also provides a seamless interface between CRSP and SAS data processing. Currently, the SASECRSP engine supports access of CRSP US Stock Databases and CRSP Indices Databases.

Opening a Database

The SASECRSP interface engine uses the LIBNAME statement to enable you to specify which CRSPAccess database you want to access and how you want to select time series or events from that database.

To specify the database, you supply the combination of a physical path to indicate the location of the CRSPAccess data files and a set identifier (SETID) to identify the selected database from those available at the physical path. Specify one SETID from Table 47.1. Notice that the CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars that provide the time ID variables and enable the libref to be assigned successfully. If your database SETID is 250, use the SASEXCCM interface to access your data. For more information about the SASEXCCM interface engine, see Chapter 55, “The SASEXCCM Interface Engine.” Because CRSP no longer supports the CPZ data format, the SASECRSP engine no longer supports the SETID 200 (CRSP/Compustat Merged, CCM) data access.

<table>
<thead>
<tr>
<th>SETID</th>
<th>Data Set</th>
</tr>

</tr>
<tr>
<td>440</td>
<td>CRSP Indices data, daily index groups</td>
</tr>
<tr>
<td>460</td>
<td>CRSP Indices data, daily index series</td>
</tr>
</tbody>
</table>

Usually you do not want to open the entire CRSPAccess database, so for efficiency and ease of use, the SASECRSP engine supports a variety of options for performing data selection on your CRSPAccess database by using the LIBNAME statement. These options enable you to open and retrieve data for only the portion of the database that you want. The availability of some of these options depends on the type of database that you open.
**CRSP US Stock Databases**

When accessing the CRSP US Stock Databases, you can select which securities to access by specifying their PERMNOs with the PERMNO= option. A PERMNO is CRSP’s unique permanent issue identification number and the primary key for its stock databases. Alternatively, a number of secondary keys can be used to select stock data. For example, you can use the PERMCO= option to read selected securities based on CRSP’s unique permanent company identification number, PERMCO. A full list of possible keys for accessing CRSP Stock data is shown in Table 47.2.

<table>
<thead>

</tr>
</tbody>
</table>

**CRSP/Compustat Merged Databases—No Longer Supported by the SASECRSP Engine**

Use the SASEXCCM interface engine instead of the SASECRSP interface engine to access your Xpressfeed CCM data. The SASEXCCM interface engine provides data item handling access methods by using CRSPAccess version 3.23. For a detailed description of this new SAS/ETS interface engine, see Chapter 55, “The SASEXCCM Interface Engine.”

Because CRSPAccess version 3.23 does not support CPZ data (legacy Compustat data format for SETID 200), the SASECRSP engine issues the following error messages when you specify the SETID=200 option and/or the CRSPLINKPATH= option:

**ERROR:** Use the SASEXCCM engine instead of the SASECRSP engine for CCM access. The CPZ data format needed for SETID=200 and the CRSPLINKPATH= options was last shipped in July 2011 and is no longer supported by CRSP. Use of the SASECRSP engine for this purpose is not allowed: Depreciated calendar configurations can result in fatal errors, corrupted memory, tracebacks, exceptions, or incorrect results for all libref assignments that follow the deassignment of a CCM/CRSPLINKPATH libref.

**ERROR:** Engine is unable to open crspdb CPZ200606 with SETID 200. Check that your CRSP database contains the crsp_ca_ref_2.bin file.

**CRSP Indices Databases**

When accessing the CRSP Indices Databases, you can select which indices to access by specifying their INDNOs. INDNO is the primary key for the CRSP Indices Databases. You can specify which INDNO to use by specifying the INDNO= option. No secondary key access is supported for CRSP Indices. A full list of possible keys for accessing CRSP Indices data is shown in Table 47.3.
### Table 47.3  Keys for Accessing CRSP Indices Data

<table>
<thead>
<tr>
<th>Key</th>
<th>Access By</th>
</tr>
</thead>
<tbody>
<tr>
<td>INDNO</td>
<td>CRSP’s unique permanent index identifier number. This is the primary key for CRSP Indices Databases. It enables you to specify which index series or groups you want to select.</td>
</tr>
</tbody>
</table>

Regardless of which database you access, you can always use the `INSET=` and `RANGE=` options for subsetting and selection. The `RANGE=` option subsets the data by date. The `INSET=` option enables you to specify which issues or companies to select from the CRSP Indices data by using an input SAS data set.

### Using Your Opened Database

After the libref is assigned, the database is opened. You can retrieve data for any member that you want in the opened database. For a complete description of available data sets and their fields, see the section “Data Elements Reference: SASECRSP Interface Engine” on page 3431. You can also use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. Because CRSP and SAS use three different date representations, you can use the CRSP date formats, informats, and functions that the SASECRSP engine provides for your data processing needs. For more information about dates in the SASECRSP engine, see the section “Understanding CRSP Date Formats, Informats, and Functions” on page 3427 and Example 47.6 later in this chapter.

The SASECRSP engine supports Linux X64 (64-bit), Solaris Sun Ultra Sparc, Solaris on Intel x86, and Windows. Windows no longer requires you to install the CRSPAccess API, because it is now distributed automatically by your SAS/ETS installation. Prior to running SASECRSP, your Windows setup requires that the environment variable, `CRSPDB_SASCAL`, be set to the path where your database calendar files reside.

### Getting Started: SASECRSP Interface Engine

#### Structure of a SAS Data Set That Contains Time Series Data

SAS requires time series data to be in a specific form that is recognizable by the SAS System. This form is a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain points in time. The time at which observations are recorded can be included in the data set as a time ID variable. Because CRSP sets the date at the end of a time period instead of at the beginning, the SASECRSP interface engine follows this convention. For example, the time ID variable for any particular month in a monthly time series is set to the last trading day of that month.

The SASECRSP engine provides several different time ID variables, depending on the data member that is opened. For most members, a time ID variable named `CALDT` is provided. `CALDT` provides a day-based calendar date and is in a CRSP date format. The dates are stored as an offset in an array of trading days or a trading-day calendar. Five different CRSP trading-day calendars are available; which calendar is used
Reading CRSP Data Files

The SASECRSP engine supports reading time series, events, portfolios, and group data from CRSPAccess databases. The SETID that you specify determines the database that is read. For a list of possible databases, see Table 47.1. The CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars that provide the time ID variables and enable the libref to be successfully assigned.

Using the SAS DATA Step

You can store the selected series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. After the data are stored in a SAS data set, you can use them as you would use data in any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure, and you can report information about the contents of your data set by using the CONTENTS procedure.

You can also create a view of the CRSPAccess database by using the SQL procedure in conjunction with a SASECRSP libref.

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment. To do so, select the SASECRSP engine libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking the desired output data set libref in the LIBNAME window of the SAS windowing environment. Type Viewtable on the SAS command line to view any of your SASECRSP engine tables, views, or librefs for both input and output data sets.

Before you use the Viewtable command, it is recommended that you store your output data sets in a physical folder or library that is separate from the folder or library used for your input databases. (The default location for output data sets is the SAS Work library.)
Using CRSP Date Formats, Informats, and Functions

Historically, CRSP has used two different methods to represent dates, and SAS has used a third. The SASECRSP engine provides 23 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. For more information, see the section “Understanding CRSP Date Formats, Informats, and Functions” on page 3427.

Syntax: SASECRSP Interface Engine

The SASECRSP engine uses standard engine syntax. The options that the SASECRSP engine uses are summarized in Table 47.4.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>SETID=</td>
<td>Specifies which CRSP database subset to open. This option is required. See Table 47.1 for a complete list of supported SETIDs</td>
</tr>
<tr>
<td>PERMNO=</td>
<td>Specifies a CRSP PERMNO to be selected for access</td>
</tr>
<tr>
<td>PERMCO=</td>
<td>Specifies a CRSP PERMCO to be selected for access</td>
</tr>
<tr>
<td>CUSIP=</td>
<td>Specifies a current CUSIP to be selected for access</td>
</tr>
<tr>
<td>HCUSIP=</td>
<td>Specifies a historic CUSIP to be selected for access</td>
</tr>
<tr>
<td>TICKER=</td>
<td>Specifies a ticker to be selected for access (for active companies only)</td>
</tr>
<tr>
<td>SICCD=</td>
<td>Specifies a SIC code to be selected for access</td>
</tr>
<tr>
<td>INDNO=</td>
<td>Specifies a CRSP INDNO to be selected for access</td>
</tr>
<tr>
<td>RANGE=</td>
<td>Specifies the range of data to keep in format 'YYYYMMDD--YYYYMMDD'</td>
</tr>
<tr>
<td>INSET=</td>
<td>Uses a SAS data set named Setname as input for issues</td>
</tr>
</tbody>
</table>

The LIBNAME libref SASECRSP Statement

LIBNAME libref SASECRSP 'physical name' options ;

The physical name that the LIBNAME statement requires should point to the directory of CRSPAccess data files where the CRSP database that you want to open is located. Note that the physical name must end in a slash for UNIX environments and a backslash for Windows environments.

The CRSP environment variable CRSPDB_SASCAL must be defined before the SASECRSP engine can access the CRSPAccess database calendars. The CRSP environment variable CRSPDB_SASCAL is necessary for the SASECRSP libref to be assigned successfully. This environment variable should be defined automatically either by the CRSP software installation or, in later versions, by the CRSP data installation. Because occasionally the variable is not set properly, always check to ensure that the CRSPDB_SASCAL
The LIBNAME libref SASECRSP Statement

The environment variable is set to the location where your most recent CRSP data reside. Remember to include the final slash or backslash as required.

After the libref is assigned, you can access any of the available data sets or members within the opened database. For a complete description of available data sets and their fields, see the section “Data Elements Reference: SASECRSP Interface Engine” on page 3431.

You can specify the following options.

**SETID=crsp_setidnumber**

specifies the CRSP database that you want to read from. SETID= is a required option. Choose one SETID from the six possible values in Table 47.1. The SETID limits the frequency selection of time series that are included in the SAS data set.

For example, to access monthly CRSP US Stock data, you would use the following statements:

```
LIBNAME myLib sasecrsp 'physical-name'
SETID=20;
```

**PERMNO=crsp_permnumber**

enables you to select data from your CRSP database by the PERMNO (or other keys) that you specify. A PERMNO is CRSP’s unique permanent issue identification number. There is no limit to the number of crsp_permnumber options that you can use. By default, the SASECRSP engine reads all keys for the CRSPAccess database that you specified in your SASECRSP libref.

From a performance standpoint, the PERMNO= option enables efficient random access and reads only the data for the PERMNOs specified.

For example, the following LIBNAME statement reads data only for Microsoft Corporation (PERMNO=10107) and International Business Machines Corporation (PERMNO=12490) by using the primary PERMNO key and thus is very efficient:

```
LIBNAME myLib sasecrsp 'physical-name'
SETID=20
PERMNO=10107
PERMNO=12490;
```

The PERMCO=, CUSIP=, HCUSIP=, SICCD=, TICKER=, and INDNO= options behave similarly, and you can use them in conjunction with or in place of the PERMNO= option. For example, you could use the following statement to access monthly data for Microsoft and IBM:

```
LIBNAME myLib sasecrsp 'physical-name'
SETID=20
TICKER='MSFT'
CUSIP=59491810;
```

Details about the use of the other key selection options (PERMCO, CUSIP, HCUSIP, TICKER, SICCD, and INDNO) follow.

PERMNOs that you specify by using this option can select the companies or issues to keep for CRSP US Stock data, but PERMNO is not a supported option for CRSP Indices data. Use the INDNO=...
option with the CRSP Indices data and use the PERMNO= option with the CRSP US Stock data. Details about the use of key selection options for each type of database follow.

**STK Databases**

PERMNO is the primary key for CRSP Stock data. Every valid PERMNO that you specify with the PERMNO= option keeps exactly one issue.

**IND Databases**

INDNO is the primary key for accessing CRSP Indices data. PERMNO is not available as a key for the IND (CRSP Indices) Databases; use INDNO for efficient access of the IND Databases.

**PERMCO=crsp_permcompany**

is similar to the PERMNO= option in that it enables you to use the CRSP’s unique permanent company identification key (PERMCO) to select the companies or issues to keep. There is no limit to the number of **crsp_permcompany** options that you can use.

**STK Databases**

PERMCO is a secondary key for accessing CRSP US Stock data. One PERMCO can map to multiple PERMNOs. Access by a PERMCO key is equivalent to access by all mapped PERMNOs.

**IND Databases**

Use INDNO for accessing CRSP Indices data. PERMCO is not available as a key for accessing CRSP Indices data; use INDNO instead.

**CUSIP=crsp_cusip**

is similar to the PERMNO= option in that it enables you to use the CUSIP key to select the companies or issues to keep. There is no limit to the number of **crsp_cusip** options that you can use.

**STK Databases**

CUSIP is a secondary key for accessing CRSP US Stock data. One CUSIP maps to one PERMNO.

**IND Databases**

Use INDNO for accessing CRSP Indices data. CUSIP is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

**HCUSIP=crsp_hcusip**

is similar to the PERMNO= option in that it enables you to use the historical CUSIP key, HCUSIP, to select the companies or issues to keep. There is no limit to the number of **crsp_hcusip** options that you can use.

**STK Databases**

HCUSIP is a secondary key for accessing CRSP US Stock Databases. One HCUSIP maps to one PERMNO.

**IND Databases**

Use INDNO for accessing CRSP Indices Databases. HCUSIP is not available as a key for accessing CRSP Indices Databases; use INDNO instead.
TICKER=crsp_ticker
is similar to the PERMNO= option in that it enables you to use the TICKER key to select the companies or issues to keep. There is no limit to the number of crsp_ticker options that you can use.

STK Databases
TICKER is a secondary key for accessing CRSP US Stock Databases. One TICKER maps to one PERMNO. **NOTE:** Some PERMNOs are inaccessible by the TICKER key.

IND Databases
Use INDNO for accessing CRSP Indices Databases. TICKER is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

SICCD=crsp_siccd
is similar to the PERMNO= option in that it enables you to use the Standard Industrial Classification (SIC) code (SICCD) to select the companies or issues to keep. There is no limit to the number of crsp_siccd options that you can use.

STK Databases
SICCD is a secondary key for accessing CRSP US Stock Databases. One SICCD can map to multiple PERMNOs. All PERMNOs that have been classified once under the specified SICCD are mapped and the data for them are retrieved. Access by the SICCD key is equivalent to access by all PERMNOs that have ever been classified under the specified SICCD key.

IND Databases
Use INDNO for accessing CRSP Indices Databases. SICCD is not available as a key for accessing CRSP Indices Databases; use INDNO instead.

INDNO=crsp_indno
is similar to the PERMNO= option in that it enables you to use CRSP’s permanent index number INDNO to select the companies or issues to keep. There is no limit to the number of crsp_indno options that you can use.

STK Databases
INDNO is not available as a key for accessing CRSP US Stock Databases, but it can be used in the combined CRSP US Stock and Indices Databases.

IND Databases
INDNO is the primary key for accessing CRSP Indices Databases. Every INDNO that you specify keeps exactly one index series or group.

For example, you can use the following statement to access the CRSP NYSE Value-Weighted and Equal-Weighted daily market indices:

```sql
LIBNAME myLib3 sasecrsp 'physical-name'
SETID=460
INDNO=1000000 /* Value-Weighted */
INDNO=1000001; /* Equal-Weighted */
```
**RANGE='crsp_begdt-crsp_enddt'**

limits the time range of data that are read from your CRSPAccess database. Specify this option in your LIBNAME libref SASECRSP statement, where *crsp_begdt* is the beginning date of the range in 'YYYYMMDD' format and *crsp_enddt* is the ending date of the range in 'YYYYMMDD' format.

For example, to access monthly stock data for Microsoft Corporation and for International Business Machines Corporation for the first quarter of 1999, you can use the following statement:

```sas
LIBNAME myLib sasecrsp 'physical-name'
  SETID=20
  PERMNO=10107
  PERMNO=12490
  RANGE='19990101-19990331';
```

The specified beginning and ending dates are interpreted as calendar dates.

You can use the RANGE= option for all members of CRSP US Stock and Indices Databases. CRSP data members are associated with only one date, and all CRSP data members have a date resolution to the day. For example, monthly time series, although they are monthly, resolve to the last trading day of the month.

**INSET='setname[,keyfieldname,keyfieldtype,date1field,date2field]'**

specifies a SAS data set named setname as input for issues. The SASECRSP engine assumes that a default PERMNO field that contains selected CRSP PERMNOs is present in the data set. If optional parameters are used, they must all be specified. The only acceptable shorthand for dropping the parameters is to drop those at the very end, assuming they are all being omitted. Dropped parameters use their defaults.

You can specify the following parameters:

- **keyfieldname** labels the field that contains the keys to be selected. If unspecified, the default is PERMNO.
- **keyfieldtype** specifies the CRSPAccess key type of the provided keys. Possible key types are: PERMNO, PERMCO, CUSIP, HCUSIP, TICKER, SICCD, or INDNO. If unspecified, the default is “PERMNO”.
- **date1field** specifies the beginning date of the specific date range restriction being applied to this key. If either *date1field* or *date2field* is omitted, then by default there is no date range restriction.
- **date2field** specifies the ending date of the specific date range restriction being applied to this key. If either *date1field* or *date2field* is omitted, then by default there is no date range restriction.

Individual date range restrictions that you specify by using the INSET= option can be used in combination with the RANGE= option in the LIBNAME statement. In such a case, only data from the intersection of the individual date restriction and the global RANGE= option date restriction are read.
Using the INSET= Option

The following examples illustrate the use of the INSET= option.

Basic INSET= Option Use: Providing a List of PERMNOs

This example uses the INSET= option to extract monthly data for a portfolio of three companies. No date range restriction is used.

```sas
data testin1;
  permno = 10107; output;
  permno = 12490; output;
  permno = 14322; output;
run;

LIBNAME mstk sasecrsp 'physical-name'
  SETID=20
  INSET='testin1';

proc print data=mstk.stkhead (keep=permno permco begdt enddt hcomnam htick);
run;
```

General Use of the INSET= Option to Specify Lists of Keys

This example illustrates the use of the INSET= option to select a few index series from the CRSP Indices data, and securities from the CRSP US Stock data. The libref `ind2` is used for accessing the CRSP Indices data by using the two specified INDNO keys. The libref `sec3` is used to access the CRSP US Stock data by using the three specified TICKER keys. Note the use of shorthand in specifying the INSET= option. The date1field, date2field, and datetype arguments are all omitted, so the default of no range restriction applies (though the range restriction set by the RANGE= option in the LIBNAME statement still applies). For more information, including sample output, see Example 47.4.

```sas
data indices;
  indno=1000000; output;  /* NYSE Value-Weighted Market Index */
  indno=1000001; output;  /* NYSE Equal-Weighted Market Index */
run;

libname ind2 sasecrsp "%sysget(CRSP_MSTK)" setid=420
  INSET='indices,INDNO,INDNO' range='19990101-19990401';

title2 'Total Returns for NYSE Value- and Equal-Weighted Market Indices';
proc print data=ind2.tret label;
run;
```

```sas
data securities;
  ticker='BAC'; output;  /* Bank of America */
```
ticker='DUK'; output; /* Duke Energy */
ticker='GSK'; output; /* GlaxoSmithKline */
run;

libname sec3 sasecrsp "%sysget(CRSP_MSTK)" setid=20
    inset='securities,TICKER,TICKER'
    range='19970820-19970920';

title2 'PERMNOs and General Header Info of Selected TICKERs';
proc print data=sec3.stkhead (keep=permno htick htsymbol) label;
run;

title3 'Average Price for Bank of America, Duke and GlaxoSmithKline';
proc print data=sec3.prc label; run;

Key-Specific Date Range Restriction with the INSET= Option

Suppose you not only want to select keys with your INSET= option, but you also want to specify a date
range restriction for each key individually. The following statements show how to do this. Again, shorthand
enables you to omit the date1field and date2field arguments. The dates that are provided default to a calendar interpretation. For more information, including the sample output, see Example 47.5.

title2 'INSET=testin2 uses date ranges along with PERMNOs:';
title3 '10107, 12490, 14322, 25788';
title4 'Begin dates and end dates for each permno are used in the INSET';

data testin2;
    permno = 10107; date1 = 19980731; date2 = 19981231; output;
    permno = 12490; date1 = 19970101; date2 = 19971231; output;
    permno = 14322; date1 = 19950731; date2 = 19960131; output;
    permno = 25778; date1 = 19950101; date2 = 19950331; output;
run;

libname mstk2 sasecrsp "%sysget(CRSP_MSTK)" setid=20
    inset='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
    set mstk2.prc;
run;

proc print data=b;
run;

The SAS Output Data Set

You can use the SAS DATA step to write the selected CRSP data to a SAS data set. This enables you to easily analyze the data by using SAS. When you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set by using the specified name in either the SAS Work library or, if specified, the User library.
The contents of the SAS data set include the date of each observation, the series name of each series read from the CRSPAccess database, event variables, and the label or description of each series/event or array.

You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use PROC SQL with the SASECRSP engine libref to create a custom view of your data.

In general, CRSP missing values are represented as ‘.’ in the SAS data set. When accessing the CRSP US STOCK data, the SASECRSP engine uses the mapping shown in Table 47.5 for converting CRSP missing values into SAS missing codes.

Understanding CRSP Date Formats, Informats, and Functions

CRSP has historically used two different methods to represent dates, whereas SAS has used a third. The three formats are SAS dates, CRSP dates, and integer dates. The SASECRSP engine provides 23 functions, 15 informats, and 10 formats to enable you to easily translate the dates from one internal representation to another. A SASECRSP engine libref must be assigned prior to your use of the CRSP date formats, informats, and functions. See “Example 47.6: Converting Dates by Using the CRSP Date Functions” on page 3460.

SAS dates are stored internally as the number of days since January 1, 1960. The SAS method is an industry standard that provides a great deal of flexibility, including a wide variety of informats, formats, and functions.

CRSP dates are designed to ease time series storage and access. Internally, the dates are stored as an offset in an array of trading days or a trading-day calendar. There are five different CRSP trading-day calendars: Annual, Quarterly, Monthly, Weekly, and Daily. In this sense, there are five different types of CRSP dates, one for each frequency of calendar that it references. The CRSP method provides fewer missing values and makes trading period calculations very easy. However, many valid calendar dates are not available in the CRSP trading calendars, and you must be careful when you use other dates.

Integer dates are a way to represent dates that are platform-independent and maintain the correct sort order. However, the distance between dates is not maintained.

The best way to illustrate the various date formats is to use some sample data. Table 47.6 shows date representations for CRSP daily and monthly data.
Table 47.6  Date Representations for Daily and Monthly Data

<table>

<td>Dec. 31, 1998</td>
<td>14,244</td>
<td>9191</td>
<td>877</td>
<td>19981231</td>
</tr>
</tbody>
</table>

*Not available if an exact match is requested.

Having an understanding of the internal differences in representing SAS dates, CRSP dates, and CRSP integer dates helps you use the SASECRSP engine formats, informats, and functions effectively. Always keep in mind the frequency of the CRSP calendar that you are accessing when you specify a CRSP date.

The CRSP Date Formats

CRSP dates use two types of formats, and five frequencies are available for each type. The two types are exact dates (CRSPDT*) and range dates (CRSPDR*), where the ‘*’ can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The ten types are CRSPDTA, CRSPDTQ, CRSPDTM, CRSPDTW, CRSPDTD, CRSPDRA, CRSPDRQ, CRSPDRM, CRSPDRW, and CRSPDRD.

Table 47.7 shows some samples that use the monthly and daily calendar as examples. The Annual (CRSPDTA and CRSPDRA), Quarterly (CRSPDTQ and CRSPDRQ), and Weekly (CRSPDTW and CRSPDRW) formats work analogously.

Table 47.7  Sample CRSPDT Formats for Daily and Monthly Data

<table>
<thead>
<tr>
<th>Date</th>
<th>CRSP Date Daily, Monthly</th>
<th>CRSPDT Daily Date</th>
<th>CRSPDRD Daily Range</th>
<th>CRSPDTM Monthly Date</th>
<th>CRSPDRM Monthly Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>July 31, 1962</td>
<td>21, 440</td>
<td>19620731</td>
<td>19620731†</td>
<td>19620731</td>
<td>19620630, 19620731</td>
</tr>
<tr>
<td>August 31, 1962</td>
<td>44, 441</td>
<td>19620831</td>
<td>19620831†</td>
<td>19620831</td>
<td>19620801, 19620831</td>
</tr>
<tr>
<td>Dec. 30, 1998</td>
<td>9190, NA*</td>
<td>19981230†</td>
<td>19981230†</td>
<td>NA*</td>
<td>NA*</td>
</tr>
<tr>
<td>Dec. 31, 1998</td>
<td>9191, 877</td>
<td>19981231†</td>
<td>19981231†</td>
<td>19981231</td>
<td>19981201, 19981231</td>
</tr>
</tbody>
</table>

†Daily ranges look similar to monthly ranges if they are Mondays or immediately follow a trading holiday.

*When you are working with exact matches, no CRSP monthly date exists for December 30, 1998.
The @CRSP Date Informats

CRSP dates use three types of informats, and five frequencies are available for each type. The three types are exact (@CRSPDT*), range (@CRSPDR*), and backward (@CRSPDB*) dates, where the ‘*’ can be A for annual, Q for quarterly, M for monthly, W for weekly, or D for daily. The 15 formats are @CRSPDTA, @CRSPDTQ, @CRSPDTM, @CRSPDTW, @CRSPDTD, @CRSPDRA, @CRSPDRQ, @CRSPDRM, @CRSPDRW, @CRSPDRD, @CRSPDBA, @CRSPDBQ, @CRSPDBM, @CRSPDBW, and @CRSPDBD.

The five CRSPDT* informats find exact matches only. The five CRSPDR* informats look for an exact match, and if an exact match is not found, they go forward, matching the CRSPDR* formats. The five CRSPDB* informats look for an exact match, and if an exact match is not found, they go backward.

Table 47.8 shows a sample that uses only the CRSP monthly calendar as an example. The daily, weekly, quarterly, and annual frequencies work analogously.

Table 47.8 Sample @CRSP Date Informats Using Monthly Data

<table>
<thead>
<tr>
<th>Input Date (Integer Date)</th>
<th>CRSPDTM</th>
<th>CRSPDRM</th>
<th>CRSPDBM</th>
<th>CRSPDTM Monthly Date</th>
<th>CRSPDRM Monthly Range</th>
</tr>
</thead>
<tbody>
<tr>
<td>19620731</td>
<td>440</td>
<td>440</td>
<td>440</td>
<td>19620731</td>
<td>19620630 to 19620731</td>
</tr>
<tr>
<td>19620815</td>
<td>.(missing)</td>
<td>441</td>
<td>440</td>
<td>See below†</td>
<td>See below*</td>
</tr>
<tr>
<td>19620831</td>
<td>441</td>
<td>441</td>
<td>441</td>
<td>19620831</td>
<td>19620801 to 19620831</td>
</tr>
</tbody>
</table>

†Missing values are preserved. If 441, then 19620831. If 440, then 19620731.

*Missing values are preserved. If 441, then 19620801 to 19620831. If 440, then 19620630 to 19620731.

The CRSP Date Functions

Table 47.9 shows the 22 date functions that the SASECRSP engine provides. The engine uses these functions internally, but they are also available to end users. There are seven groups of functions. The first four groups have five functions each, one for each CRSP calendar frequency. The next two functions are for converting between SAS and integer date formats.

Data sets are made available based on the type of CRSP database that you open. Table 47.10 and Table 47.11 show summary views of the two types of CRSP databases (Stock and Indices) and the data sets that they make available. Tables that contain details about the data sets, including their specific fields, immediately follow the summary tables. You can also see the available data sets for an opened database via the SAS Explorer by opening a SASECRSP engine libref that you previously assigned.

Examples: SASECRSP Interface Engine

Example 47.1: Specifying PERMNOs and Range in the LIBNAME Statement

The following statements show how to set up a LIBNAME statement to extract data for certain selected PERMNOs during a specific time period. The result is shown in Output 47.1.1.

```latex
title2 'Define a range inside the data range';
title3 'My range is (19950101-19960630)';

libname _all_ clear;
libname testit1 sasecrsp "/r/tappan/vol/vol1/crsp1/data201212/MIZ201212/"
setid=20
  permno=81871 /* Desired PERMNOs are selected */
  permno=82200 /* via the libname PERMNO= option */
  permno=82224
  permno=83435
  permno=83696
  permno=83776
  permno=84788
  range='19950101-19960630';

proc print data=testit1.ask;
run;
```
**Output 47.1.1**  ASK Monthly Time Series Data with RANGE= Option

Define a range inside the data range
My range is ( 19950101-19960630 )

Example 47.2: Using the LIBNAME Statement to Access All Keys

To set up the libref to access all keys, no key options such as PERMNO=, TICKER=, or GVKEY= are specified in the LIBNAME statement and no INSET= option is used. Any of these options cause the SASECRSP engine to limit access to specified keys or specified insets. When no such options are specified, the SASECRSP engine correctly defaults to selecting all keys in the database. Other LIBNAME statement options, such as the RANGE= option, can still be used normally to limit the time span of the data—in other words, to define the date range of observations.

This example does not use key-specifying options. This forces the engine to default to all PERMNOs in the monthly STK database. The range that is specified in the LIBNAME statement behaves normally, and data are limited to the first two months of 1995.

```sql
/* Define a range inside the data range */
/* My range is (19950101-19950228) */
libname _all_ clear;
libname testit2 sasecrsp "/r/tappan/vol/vol1/crsp1/data201212/MIZ201212/"
    setid=20
    range='19950101-19950228';
data a;
    set testit2.ask(obs=30);
run;
proc print data=a;
run;
```

The result is shown in Output 47.2.1.
Output 47.2.1  All PERMNOs of ASK Monthly Time Series Data with RANGE= Option

Define a range inside the data range
My range is ( 19950101-19950228 )

Example 47.3: Accessing One PERMNO without the RANGE= Option

The SASECRSP engine defaults to providing access to the entire range of available data when you do not restrict the range (that is, when you do not use the RANGE= option).

This example shows access of the entire range of available data for one particular PERMNO extracted from the monthly data set.

```sas
title2 'Select only PERMNO = 81871';
title3 'Valid trading dates (19890131--19981231)';
title4 'No range option, leave wide open';

libname _all_ clear;
libname testit3 sasecrsp "/r/tappan/vol/vol1/crsp1/data201212/MIZ201212/"
         setid=20
         permno=81871;

data c;
   set testit3.ask;
run;

proc print data=c;
run;
```

The result is shown in Output 47.3.1.

Example 47.4: Specifying Keys by Using the INSET= Option

The INSET= option enables you to select any companies or issues for which you want data. This example selects two CRSP Index Series from the CRSP Indices data, and four securities from the CRSP US Stock data for data extraction. Note that because each CRSP database might be in a different location and must be opened separately, a total of two different librefs are used, one for each database.

```sas
data indices;
  indno=1000000; output; /* NYSE Value-Weighted Market Index */
  indno=1000001; output; /* NYSE Equal-Weighted Market Index */
run;
libname _all_ clear;
libname ind2 sasecrsp "/r/tappan/vol/vol1/crsp1/data201212/MIZ201212/"
  setid=420
  inset='indices,INDNO,INDNO'
  range='19990101-19990401';
title2 'Total Returns for NYSE Value- and Equal-Weighted Market Indices';
proc print data=ind2.tret label;
run;
```

Output 47.4.1 shows the result of selecting two CRSP Index Series from the CRSP Indices data.

**Output 47.4.1** IND Data Extracted Using INSET= Option

<table>
<thead>
<tr>

</table>
Example 47.5: Specifying Ranges for Individual Keys with the INSET= Option

Insets enable you to define options that are specific to each individual key. This example uses an inset to select four PERMNOs and specifies a different date restriction for each PERMNO.

```plaintext
title2 'INSET=testin2 uses date ranges along with PERMNOs:';
title3 '10107, 12490, 14322, 25778';
title4 'Begin dates and end dates for each permno are used in the INSET';

data testin2;
  permno = 10107; date1 = 19980731; date2 = 19981231; output;
  permno = 12490; date1 = 19970101; date2 = 19971231; output;
  permno = 14322; date1 = 19950731; date2 = 19960131; output;
  permno = 25778; date1 = 19950101; date2 = 19950331; output;
run;

libname _all_ clear;
libname mstk2 sasecrsp "/r/tappan/vol/vol1/crsp1/data201212/MIZ201212/"
  setid=20
  inset='testin2,PERMNO,PERMNO,DATE1,DATE2';

data b;
  set mstk2.prc;
run;

proc print data=b;
run;
```

Output 47.5.1 shows CRSP US Stock price time series data selected by PERMNO in the INSET= option, where each PERMNO has its own time span specified in the INSET= option.
Output 47.5.1  PRC Monthly Time Series Using the INSET= Option

INSET=testin2 uses date ranges along with PERMNOs:
10107, 12490, 14322, 25788
Begin dates and end dates for each permno are used in the INSET

Overview: SASEFAME Interface Engine

The SASEFAME interface engine provides a seamless interface between Fame and SAS data to enable SAS users to access and process time series, case series, and formulas that reside in a Fame database.

Fame is an integrated, front-to-back market data and historical database solution for storing and managing real-time and high-volume time series data that are used by leading institutions in the financial, energy, and public sectors, as well as by third-party content aggregators, software vendors, and individual investors. Fame provides real-time market data feeds and end-of-day data, a web-based desktop solution, application hosting, data delivery components, and tools for performing analytic modeling.

The SASEFAME engine uses the LIBNAME statement to enable you to specify the time series that you want to read from the Fame database and how you want to convert the selected time series to the same time scale. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEFAME interface engine supports Windows and Linux Opteron hosts that use Fame 11.5. Although SASEFAME is no longer available on the AIX and Solaris hosts, you can still get remote access to Fame data on those hosts by using SASEFAME from a Windows or Linux Opteron host to connect to the MCADBS or master server on the AIX and Solaris hosts. For more information about MarketMap (formerly Fame) servers, see Guide to MarketMap Database Servers, formerly known as Guide to Fame Database Servers.

Getting Started: SASEFAME Interface Engine

Structure of a SAS Data Set That Contains Time Series Data

The SAS System represents time series data in a two-dimensional array, called a SAS data set, whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as a time ID variable. The SASEFAME engine provides a time ID variable named DATE. The DATE variable can be represented by any of the time intervals shown in the section “Mapping Fame Frequencies to SAS Time Intervals” on page 3476.
Reading and Converting Fame Database Time Series

The SASEFAME engine supports reading and converting time series that reside in Fame databases. The SASEFAME engine uses Fame’s Work database to temporarily store the converted time series. All series that are specified by the Fame wildcard are written to the Fame Work database. For conversion of very large databases, you might want to define the FAME_TEMP environment variable to point to a location where there is ample space for the Fame Work database.

The SASEFAME engine provides seamless access to Fame databases via Fame’s C host language interface (CHLI). Fame expressions that contain formulas and Fame functions can be input to the engine via the INSET= option.

The SASEFAME engine finishes the CHLI whenever a fatal error occurs. To restart the engine after a fatal error, terminate the current SAS session and open a new SAS session.

Using the SAS DATA Step

You can store the converted series in a SAS data set by using the SAS DATA step. You can also perform other operations on your data inside the DATA step. After your data are stored in a SAS data set, you can use this data set as you would any other SAS data set.

Using SAS Procedures

You can print the output SAS data set by using the PRINT procedure and report information about the contents of your data set by using the CONTENTS procedure, as in Example 48.1. You can create a view of the Fame database by using the SQL procedure’s USING clause to reference the SASEFAME engine in your libref. See Example 48.5.

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment. To do so, select the SASEFAME engine libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking the desired output data set libref in the LIBNAME window of the SAS windowing environment. Type Viewtable on the SAS command line to view any of your SASEFAME engine tables, views, or librefs both for input and output data sets. Before you use the Viewtable command, it is recommended that you store your output data sets in a physical folder or library that is separate from the folder or library used for your input databases. (The default location for output data sets is the SAS Work library.)
Chapter 48: The SASEFAME Interface Engine

Remote Fame Data Access

The remote access feature of the SASEFAME engine uses the MarketMap (Fame) CHLI to communicate with your remote server (master or MCADBS). It is available to licensed MarketMap customers who have the CHLI on both their remote and client machines.

For an example that uses the master server, see Example 48.7, where you simply provide the frdb_m port number and node name of your Fame master server in your SASEFAME engine libref. For more information, see the section “Start the Master Server” in Guide to MarketMap Database Servers.

For an example that uses the MCADBS remote server, see Example 48.18, where you specify an explicit connection with the CONNECT=YES option, and you specify the service, host, and name of the connection by using the TO_SERVICE= option, ON_HOST= option, and AS_NAME= options, respectively. In addition, you specify the USER= and PASS= options for the connection. For more information, see the section “Start the MCADBS Server” in Guide to MarketMap Database Servers.

Creating Views of Time Series by Using SASEFAME LIBNAME Options

You can perform selection based on names of your time series simply by using Fame wildcard specifications in the SASEFAME engine WILDCARD= option.

You can limit the time span of time series data by specifying a beginning and ending date range in the SASEFAME engine RANGE= option.

It is also easy to use the SAS input data set INSET= option to create a specific view of your Fame data. You can create multiple views by using multiple LIBNAME statements with customized options that are tailored to the unique views that you want to create.

You can list the INSET variables that you want to keep in your SAS data set by using the KEEP= clause. When you use INSET variables in conjunction with the input data set that you specify in the INSET= option, the SASEFAME engine can show any or all of your expression groups in the same view or in multiple views. The INSET= option defines the valid set of expression groups that you can reference in the KEEP= clause, as shown in Example 48.16.

The INSET variables define the BY variables that enable you to view cross sections (slices) of your data. When you use INSET variables in conjunction with the WHERE clause and the CROSSLIST= option, the SASEFAME engine can show any or all of your BY groups in the same view or in multiple views. When you use the INSET= option along with a WHERE clause that specifies the BY variables that you want to use in your view, you must also use the CROSSLIST= option, as shown in Example 48.10. You can use the CROSSLIST= option without using the INSET= option, as shown in Example 48.8 and Example 48.9.

Syntax: SASEFAME Interface Engine

The SASEFAME interface engine uses standard engine syntax. Table 48.1 summarizes the options used by the SASEFAME engine.
Table 48.1  Summary of LIBNAME libref SASEFAME Statement Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AS_DB=</td>
<td>Specifies the channel name to use for a local database; used when Fame expressions or formulas need to resolve in a Fame child process.</td>
</tr>
<tr>
<td>AS_NAME=</td>
<td>Specifies the name to use for an explicit connection for remote access; used with the CONNECT=YES option.</td>
</tr>
<tr>
<td>CONNECT=</td>
<td>Specifies whether or not you want to use an explicit named connection for remote access, which you name in the AS_NAME= option.</td>
</tr>
<tr>
<td>CONVERT=</td>
<td>Specifies the Fame frequency and the Fame technique.</td>
</tr>
<tr>
<td>CROSSLIST=</td>
<td>Specifies a Fame crosslist fame_namelists to perform selection based on the crossproduct of two Fame namelists.</td>
</tr>
<tr>
<td>DBVERSION=</td>
<td>Echoes the present version number of the Fame Work database in the SAS log.</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not you need diagnostic message logging in the SAS log window.</td>
</tr>
<tr>
<td>FAMEOUT=</td>
<td>Specifies the Fame data object class/type that you want output to the SAS data set.</td>
</tr>
<tr>
<td>INSET=</td>
<td>Uses a SAS data set named setname and KEEP= fame_expression_group as selection input variables or WHERE= fame_bygroup as selection input for BY variables.</td>
</tr>
<tr>
<td>ON_HOST=</td>
<td>Specifies the remote Fame MCADBS server node name to connect to; used with the CONNECT=YES option.</td>
</tr>
<tr>
<td>PASS=</td>
<td>Specifies the password for the connection, which should match the password that you use as the adduser parameter in your Fame FRDB facsq command; used with the USER= option (for remote access).</td>
</tr>
<tr>
<td>RANGE=</td>
<td>Specifies the range of data to keep in 'ddmmyyy' – 'ddmmyyy' format.</td>
</tr>
<tr>
<td>TO_SERVICE=</td>
<td>Specifies the port number that you started the MCADBS service on, which is the same port that you specified in the -p argument in the mcadbs.exe command on your MCADBS server; used with the CONNECT=YES option (for remote access).</td>
</tr>
<tr>
<td>TUNEFAME=</td>
<td>Tunes the Fame database engine’s use of memory to reduce I/O in favor of a bigger virtual memory for caching database objects.</td>
</tr>
<tr>
<td>TUNECHLI=</td>
<td>Tunes the CHLI database engine’s use of memory to reduce I/O in favor of a bigger virtual memory for caching database objects.</td>
</tr>
<tr>
<td>USER=</td>
<td>Specifies the user name for the connection, which should match the user name you use as the adduser parameter in your Fame FRDB facsq command; used with the PASS= option (for remote access).</td>
</tr>
<tr>
<td>WILDCARD=</td>
<td>Specifies a Fame wildcard to match data object series names within the Fame database.</td>
</tr>
</tbody>
</table>
**LIBNAME libref SASEFAME Statement**

```plaintext
LIBNAME libref SASEFAME ‘physical name’ options ;
```

Because ‘physical name’ specifies the location of the folder where your Fame database resides, it should end in a backslash if you are in a Windows environment or a forward slash if you are in a UNIX environment.

If you are accessing a remote Fame database using an implicit connection in the Fame CHLI, you can use the following syntax for ‘physical name’:

```
#port_number @hostname physical_path_name
```

You can specify the following options.

- **AS_DB=fame_db_name**
- **OPEN_AS= fame_db_name**
  
  specifies the Fame database ID to use in the Fame OPEN command, which is often the same as the name of the database (without the .db extension). In Fame, you can retrieve a list of open database ID names by using the Fame command `TYPE @OPEN.DB`. Use this option when you get this error:

  ```
  ERROR: From cfmfame: Error from a FAME-like server, error from cfmferr is: \Variable{XXXX} not found
  ```

  For a more complete discussion of opening a local Fame database, see the section “Opening a Local Fame Database” on page 3472.

- **AS_NAME="fame_channel_name"**
- **NAME= "fame_channel_name"**

  specifies the Fame channel name to use in the Fame CONNECT command for remote database access. In Fame, you can retrieve a list of open channel names by using the Fame command `TYPE @OPEN.CONNECTIONS`. For a more complete discussion of opening a remote Fame database on an MCADBS server, see Example 48.18.

- **CONNECT=YES | IMPLICIT | NO**
- **CONNECTION=YES | IMPLICIT | NO**

  specifies whether or not the connection is an explicit connection.

  - **YES** specifies that the connection is explicit.
  - **IMPLICIT** specifies that the connection is implicit.
  - **NO** specifies that the connection is implicit.

  An explicit connection also requires the TO_SERVICE=, ON_HOST=, AS_NAME=, USER=, and PASS= options. When an implicit connection is specified, these additional options are not used; instead the details of the connection are given inside the physical pathname in the SASEFAME LIBNAME statement with the special syntax described in the section “LIBNAME libref SASEFAME Statement” on page 3468. For more information about implicit Fame connections, see the section “Opening Databases on Implicit Connections” in MarketMap Fame 11.5 Online Help at the following URL:

- [https://fame.sungard.com/support_secure/fame/online_help_115(commands_and_options/opening_databases_implicit_connections.htm)](https://fame.sungard.com/support_secure/fame/online_help_115(commands_and_options/opening_databases_implicit_connections.htm)
For more information about explicit Fame connections, see the section “Opening Databases on Explicit Connections” in the MarketMap Fame 11.5 Online Help at the following URL:

https://fame.sungard.com/support_secure/fame/online_help_115/commands_and_options/opening_databases_explicit_connections.htm

**LIBNAME libref SASEFAME Statement**

**CONVERT=( FREQ=fame_frequency TECH=fame_technique)**

**CONV=( FREQ=fame_frequency TECH=fame_technique)**

specifies the Fame frequency and the Fame technique, just as you would in the Fame CONVERT function. There are four possible values for fame_technique: Constant (default), Cubic, Discrete, and Linear. Table 48.2 shows the Fame frequencies that are supported by the SASEFAME engine.

For a more complete discussion of Fame frequencies and SAS time intervals, see the section “Mapping Fame Frequencies to SAS Time Intervals” on page 3476. For all possible fame_frequency values, see the section “Understanding Frequencies” in the User’s Guide to Fame. For example:

```
LIBNAME libref sasefame 'physical-name'
CONVERT=(TECH=CONSTANT FREQ=TWICEMONTHLY);
```

**CROSSLIST=(<fame_namelist1>, <fame_namelist2>)**

**CROSS=(<fame_namelist1>, <fame_namelist2>)**

performs a crossproduct of the members of the first namelist with the members of the second namelist, using a glue symbol “.” to join the two. If one of the time series that are listed in fame_namelist2 does not exist, the SASEFAME engine stops processing the remainder of the namelist. For more information, see the section “Performing the Crosslist Selection Function” on page 3479.

**DBVERSION=ON | OFF**

specifies whether or not to display the version number of the Fame Work database. DBVERSION=ON specifies that the SAS log show the version number (3 or 4) of the Fame Work database. By default, DBVERSION=OFF.

**DEBUG= ON | OFF (default)**

specifies that additional diagnostic information in the SAS log be reported. When you specify DEBUG=ON, the information about Fame commands that are outlined in the SAS log by debug tracing can be valuable for diagnosing and identifying the issues that cause errors when you are using the SASEFAME engine. By default, DEBUG=OFF. See Example 48.18 for a detailed SAS log that is created when you specify DEBUG=ON.

**FAMEOUT=fame_data_object_class_type**

specifies the class and type of the Fame data series objects to include in your SAS output data set. The possible values for fame_data_object_class_type are FORMULA, TIME, BOOLEAN, CASE, DATE, and STRING. Case series can be numeric, boolean, string, and date, or they can be generated using formulas that resolve to series. The SASEFAME engine resolves all formulas that belong to the type of series data object that you specify in the FAMEOUT= option. If the FAMEOUT= option is not specified, numeric time series are output to the SAS data set. FAMEOUT=CASE defaults to case series of numeric type. If you want another type of case series in your output, then you must specify it. Scalar data objects are not supported.
INSET=(setname KEEP=fame_expression_group)

INSET=(setname KEEPLIST=fame_expression_group)
specifies the name of a SAS data set (setname) and selects series that are generated by the expressions defined in fame_expression_group. You can define fame_expression_group by using Fame functions and Fame expressions. It is important to specify the length of the longest expression, or expressions might be truncated because the default length is the first defined variable in the DATA step. The INSET (input data set) must output each expression statement as a character string ending with a semicolon, enclosed in single quotation marks, and followed by another semicolon and an output statement. For more about using the INSET= option to define a group of selected series that are generated by Fame expressions, see the section “Performing the Keeplist Expression Function” on page 3477.

INSET=(setname WHERE=fame_bygroup)
specifies a SAS data set (setname) as input for a BY group such as a ticker, and uses the fame_bygroup to select time series that are named using the following convention. Selected variable names are glued together by the BY-group name (such as a ticker symbol) concatenated with the glue character (such as DOT) to the series name that is specified in the CROSSLIST= option or in the fame_bygroup.

For more information, see the section “Performing the Crosslist Selection Function” on page 3479.

ON_HOST="fame_hostname"
HOST= "fame_hostname"
specifies the Fame host name to use in the Fame CONNECT command, which is the name of the host or node that is running as the MCADBS server. You can see the host name when you use the MCADBS command with the show option. For a more complete discussion of using the MCADBS command with the show option, see the section “Using the MCADBS Show Function” on page 3474.

PASS="fame_password"
PASSWORD= "fame_password"
specifies the Fame password to use in the Fame CONNECT command, which is the password for the user name designated in the adduser function in the facsq access control command. For a more complete discussion about managing and monitoring your Fame server processes, see the section “Managing Fame Server Processes for Remote Access” on page 3473.

RANGE='fame_begdt'd- 'fame_enddt'd
DATERANGE='fame_begdt'd- 'fame_enddt'd
DATE='fame_begdt'd- 'fame_enddt'd
DATECASE='fame_begdt'd- 'fame_enddt'd
limits the time range of data that are read from your Fame database. The string fame_begdt is the beginning date in 'ddmmmyyyy' format, and the string fame_enddt is the ending date of the range in 'ddmmmyyyy' format; both strings must be enclosed in single quotation marks and followed by the letter 'd'.

For example, to read a series with a date range that spans the first quarter of 1999, you could use the following statement:

LIBNAME test sasefame 'physical name of test database'
    RANGE='01jan1999'd - '31mar1999'd;
TO_SERVICE="fame_service_portnumber"

SERVICE="fame_service_portnumber"
specifies the Fame service port number to use in the Fame CONNECT command, which is the same port number that you use in your MCADBS command for the name port (-n option). For a more complete discussion about managing and monitoring your Fame server processes, see the section “Managing Fame Server Processes for Remote Access” on page 3473.

TUNEFAME=NODES fameengine_size_virtual_memory_MB
specifies the number of megabytes to use for the cache size for the Fame API (CHLI). The fameengine_sizeirtual_memory_MB can range from a minimum of 0.1 MB (100 KB) to a maximum of 17,592,186,000,000 MB. For more information, see Example 48.17.

TUNECHLI=NODES famechliengine_size_virtual_memory_MB
specifies the number of megabytes to use for the cache size for the Fame API (CHLI). The famechliengine_size_virtual_memory_MB can range from a minimum of 0.1 MB (100 KB) to a maximum of 17,592,186,000,000 MB. For more information, see Example 48.17.

USER="fame_username"
USERNAME="fame_username"
specifies the Fame user name to use in the Fame CONNECT command, which corresponds to the password and user name designated in the adduser function in the facsq access control command. For a more complete discussion about managing and monitoring your Fame server processes, see the section “Managing Fame Server Processes for Remote Access” on page 3473.

WILDCARD="fame_wildcard"
WILD="fame_wildcard"
limits the time series read from the Fame database. By default, the SASEFAME engine reads all time series in the Fame database that you name in your SASEFAME libref. The fame_wildcard is a quoted string that contains the Fame wildcard you want to use. The wildcard is used for matching against the data object names of series that you want to select from the Fame database that resides in the library you are assigning.

For more information about using wildcards, see the section “Specifying Wildcards” in the User's Guide to Fame.

For example, to read all time series in the TEST library that is being accessed by the SASEFAME engine, you would specify the following statement:

    LIBNAME test sasefame 'physical name of test database'
    WILDCARD="?";

To read series that have names such as A_DATA, B_DATA, and C_DATA, you could specify the following statement:

    LIBNAME test sasefame 'physical name of test database'
    WILDCARD="^_DATA";
When you use the WILDCARD= option, you limit the number of series that are read and converted to the desired frequency. This option can help you save resources when processing large databases or when processing a large number of observations, such as daily or hourly frequencies. Because the SASEFAME engine uses the Fame Work database to store the converted time series, using wildcards is recommended to prevent your workspace from getting too large. When the FAMEOUT= option is also specified, the wildcard is applied to the type of data object series that you specify in the FAMEOUT= option.

Details: SASEFAME Interface Engine

Opening a Local Fame Database

Fame databases often contain expressions and formulas that resolve to a series. In order for Fame to resolve the expressions and formulas a channel is opened to the local database to a Fame-like server that is invoked by the SASEFAME interface engine so that the selected series are complete.

For example, the following SAS code generates the SAS log after it, which shows the OPEN command that is used to open the local training database on the Fame channel named TR, enabling the Fame Crosslist to resolve all the time series values for all the tickers included in the inset's BY group (TICK):

```sas
libname lib5 sasefame "\\tappan\crsp1\fame10"
   as_db="TR"
   debug=ON
   convert=(frequency=business technique=constant)
   inset=( inseta where=tick )
   crosslist=
       {adjust, close, high, low, open, volume, uclose, uhigh, ulow, uopen, uvolume})

data trout;
   set lib5.training;
run;
```

Here is an excerpt of the information shown in the SAS log (on Windows), which is created by using the DEBUG=ON option:

```
NOTE: The SASEFAME engine is using Version 11.43000 of the HLI.
len4=2
SIMPLE FAMECMD for local open is: "\\tappan\crsp1\fame10/training"
len4= 2
FAME COMMAND line 1004 is:
OPEN <ACCESS READ> """"\\tappan\crsp1\fame10/training"""" AS TR
```

It is important to note that the SAS SET command for local access uses the database name, training (without the .db extension), in the DATA step. This is in contrast to the SET statement for remote MCADBS server
access, which uses the channel name in the SAS SET statement, as shown in Example 48.18. For more information about opening and closing local Fame databases, see the section “Opening and Closing Local Databases” in Online Help for MarketMap Analytic Studio at the following URL:

https://fame.sungard.com/support_secure/fame/online_help/commands_and_options/opening_local_databases.htm

Managing Fame Server Processes for Remote Access

Whether you use a master server or an MCADBS server, the appropriate configuration file is necessary. For the master server, on UNIX, your configuration file might look like this:

```
cat master1.config
security access all
dbback $FAME/frdb/dbback
```

Your `master` command could look like this:

```
$FAME/frdb/master -p \#5555 -s master1.config > master1.log &
```

For more information about the `master` server command, visit the following URL:

https://fame.sungard.com/support_secure/fame/online_help_115/servers/master_server_command.htm

To manage your MCADBS Fame server processes, you can start the FACS daemon on your Fame server. On Windows, enter the `facsd` command in the command window (if that is your Fame server):

```
%FAME%\frdb\64\facsd -d U:\fame940\doc\ -p 2990 -o U:\fame940\test\facs
-s U:\fame940\doc\facsd.config
```

After you start the FACS daemon this way, you can use it for user authentication, access control, and accounting and logging facilities of Fame access control and accounting. To set up authentication, you can use the `facsq` command as follows:

```
%FAME%\frdb\64\facsq -p 2990 adduser <fame_username> <fame_password>
```

The user name and password in the `adduser` function are the same as those that are specified in the SASEFAME LIBNAME statement’s USER= and PASS= options.

For a more complete discussion of the FACS daemon and configuration file, visit the following URLs:
Next you start your Fame server. The MCADBS server command, on Windows, looks like this:

```
C:\PROGRA~2\FAME\frdb\64\mcadbs.exe -n 2960 -p 2961 -s U:\fame940\doc\mcadbs.config -o U:\fame940\doc\mcadbs.log
```

For a more complete discussion, see the section “Start the MCADBS Server” in Guide to MarketMap Database Servers.

After starting the server, you can ask for information about the MACDBS server, as shown in the following section, “Using the MCADBS Show Function” on page 3474.

---

**Using the MCADBS Show Function**

When you have the MCADBS server running, you can get detailed information about the server by using the MCADBS show function as follows:

```
C:\Users\saskff>\FAME\frdb\64\mcadbs -n 2960 show
```

This results in the following report:

```
MCADBS Release 11.4 64-bit Copyright (C) 2014 by SunGard. All rights reserved.

Default: detail
```
You can use the SAS DATA step to write the selected time series from your Fame database to a SAS data set. This enables you to easily analyze the data by using the SAS System. You can specify the name of the output data set in the DATA statement. This causes the engine supervisor to create a SAS data set by using the specified name in either the SAS Work library or, if specified, the Sasuser library. For more information about naming your SAS data set, see the section “SAS Data Sets: Data Set Names” in SAS Language Reference: Concepts.

The contents of the SAS data set that contains time series include the date of each observation, the name of each series read from the Fame database as specified by the WILDCARD= option, and the label or Fame description of each series. Missing values are represented as ‘.’ in the SAS data set. You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEFAME libref in the LIBNAME window that you have previously used in your LIBNAME statement. You can use PROC PRINT and PROC CONTENTS to print your output data set and its contents. You can use PROC SQL and the SASEFAME engine to create a view of your SAS data set. You can view your SAS output observations by double-clicking the desired output data set libref in the LIBNAME window of the SAS windowing environment.
The DATE variable in the SAS data set contains the date of the observation. For Fame weekly intervals that end on a Friday, Fame reports the date on the Friday that ends the week, whereas the SAS System reports the date on the Saturday that begins the week.

A more detailed discussion of how to map Fame frequencies to SAS time intervals follows. For other types of data, such as Boolean case series, numeric case series, date case series, string case series, and extracting source for formulas, see Example 48.11, Example 48.12, Example 48.13, Example 48.14, and Example 48.15, respectively.

### Mapping Fame Frequencies to SAS Time Intervals

Table 48.2 summarizes the mapping of Fame frequencies to SAS time intervals. Fame frequencies often have a sample unit in parentheses after the keyword frequency. This sample unit is an end-of-interval unit. SAS dates are represented by beginning-of-interval notation.

For more information about SAS time intervals, see Chapter 4, “Date Intervals, Formats, and Functions.”

For more information about Fame frequencies, see the section “Understanding Frequencies” in the User’s Guide to Fame.

Performing the Keeplist Expression Function

This section shows how to use the INSET= option to define a group of selected series that are generated by Fame expressions. It is important to use the LENGTH statement to avoid truncating the longest expression in
the group defined by the BY variable EXPRESS. **Note**: The EXPRESS variable is assigned the character string expression and is shown in Table 48.3. The following statements create an input data set, INSETA, and print it:

```plaintext
data inseta; /* Use this for training database */
   length express $52;
   express='{ibm.high,ibm.low,ibm.close}'; output;
   express='crosslist({gm,f,c},{volume});'; output;
   express='cvx.close;'; output;
   express='mave(ibm.close,30);'; output;
   express='cvx.close+ibm.close;'; output;
   express='ibm.close;'; output;
   express='close * shares/sum(close * shares);'; output;
   express='sum(pep.volume);'; output;
   express='mave(pep.close,20);'; output;
run;

proc print
   data=inseta;
run;
```

Next you can name the input data set that you want to use in the INSET= option, followed by the KEEP= variable that specifies the expression group you want to keep. Only series variables that are defined in the selected expression group are output to the output data set. You can define up to eight different expression groups in an INSET= option.

```plaintext
libname lib5 sasefame "C:\PROGRA~1\FAME10\util"
   wildcard="?"
   convert=(frequency=business technique=constant)
   range='23jul1997'd - '25jul1997'd
   inset=( inseta KEEP=express)
;

data trout;
   set lib5.trainten;
run;

title1 'TRAINING DB, Pricing Time Series for Expressions in INSET=';
title2 'OUT=TROUT from the PRINT Procedure';
proc print data=trout;
run;
```

Table 48.3 shows the eight expressions that are defined in INSETA.

<table>
<thead>
<tr>

</tr>
<tr>
<td>7</td>
<td>sum(pep.volume);</td>
</tr>
<tr>
<td>8</td>
<td>mave(pep.close,20);</td>
</tr>
</tbody>
</table>

Table 48.4 shows the output data set, TROUT. The output data set names each derived variable SASTEMPn by appending the number, n, to match the observation number of the input data set’s expression for that variable. For example, SASTEMP1 names the series derived by ‘cvx.close’ in observation 1, and SASTEMP3 names the series derived by the expression ‘mave(ibm.close,30);’ in observation 3. Because SASTEMP2 is a simple name list of three series, the original series names are used.

Table 48.4  TRAINING DB, Pricing Timeseries for Expressions in INSETA for OUT=TROUT from the PRINT Procedure

</tr>
</tbody>
</table>

Note that SASTEMP3 and SASTEMP8 have no observations in the date range July 23, 1997, to July 25, 1997, so the missing value symbol ‘.’ appears for those observations.

Performing the Crosslist Selection Function

There are two methods of performing the crosslist selection function. The first method uses two Fame namelists, and the second method uses one namelist and one BY group specified in the WHERE= clause of the INSET= option.

For example, suppose that your Fame database has a string case series named TICKER, so that when the Fame NL function is used on TICKER, it returns the following namelist:

Ticker = {AOL, C, CVX, F, GM, HPQ, IBM, INDUA, INTC, SPX, SUNW, XOM}

Also suppose your time series are named in fame_namelist2 as

{adjust, close, high, low, open, volume, uclose, uhigh, ulow, uopen, uvolume}
When you specify the following statements, the 132 variables shown in Table 48.5 are selected by the CROSSLIST= option:

```
LIBNAME test sasefame 'physical name of test database'
   RANGE='01jan1999'd - '31mar1999'd
   CROSSLIST=(nl(ticker),
               {adjust, close, high, low, open, volume,
                uclose, uhigh, ulow, uopen, uvolume})
;
```

**Table 48.5  SAS Variables Selected by CROSSLIST= Option**

</tr>
</tbody>
</table>
Instead of using two namelists, you can use the WHERE= clause in an INSET= option to perform the crossproduct of the BY variables specified in your input data set via the WHERE= clause and the members named in your namelist. The following statements define a SAS input data set named INSETA to use as input for the CROSSLIST= option instead of using the Fame namelist:

```sas
DATA INSETA;
  LENGTH tick $5;
  /* AOL, C, CVX, F, GM, HPQ, IBM, INDUA, INTC, SPX, SUNW, XOM */
  tick='AOL'; output;
  tick='C'; output;
  tick='CVX'; output;
  tick='F'; output;
  tick='GM'; output;
  tick='HPQ'; output;
  tick='IBM'; output;
  tick='INDUA'; output;
  tick='INTC'; output;
  tick='SPX'; output;
  tick='SUNW'; output;
  tick='XOM'; output;
RUN;
```

```sas
LIBNAME test sasefame 'physical name of test database'
  RANGE='01jan1999'd - '31mar1999'd
  INSET=(inseta, where=tick)
  CROSSLIST=(
    {adjust, close, high, low, open, volume,
    uclose, uhigh, ulow, uopen, uvolume})
;```

Using a SAS INSET statement with a WHERE clause and using a Fame namelist in the CROSSLIST= statement are equivalent ways of performing the same selection function. In the preceding example, the Fame ticker namelist corresponds to the SAS input data set’s BY variable named TICK.

Note that the `fame_bygroup` that you specify in the WHERE= clause must match the BY-variable name used in your input data set in order for the CROSSLIST= option to perform the desired selection. If one of the time series listed in `fame_namelist2` does not exist, the SASEFAME engine stops processing the remainder of the namelist. For complete results, make sure that your `fame_namelist2` is accurate and does not name unknown variables. The same holds true for `fame_namelist1` and the BY-variable values named in the input data set and used in the WHERE= clause.

---

**Examples: SASEFAME Interface Engine**

In this section, the examples were run on Windows, so the physical names used in the LIBNAME `libref` SASEFAME statement reflect the syntax necessary for that platform. In general, Windows environments use backslashes in their pathname, and the UNIX environments use forward slashes.
Example 48.1: Converting an Entire Fame Database

To enable conversion of all time series, no wildcard is specified, so the default “?” wildcard is used. Always consider both the number of time series and the number of observations generated by the conversion process. The converted series reside in the Fame Work database during the SAS DATA step. You can further limit your resulting SAS data set by using KEEP, DROP, or WHERE statements inside your DATA step.

The following statements convert a Fame database and print out its contents:

```sas
options pagesize=60 linesize=80 validvarname=any ;
%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);
libname famedir sasefame "%sysget(FAME_DATA)"
    convert=(freq=annual technique=constant);
libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* Read in oecd1.db data from the Organization */
    /* For Economic Cooperation and Development */
    where date between '01jan88'd and '31dec93'd;
run;

proc print data=mydir.a;
run;
```

In the preceding example, the Fame database is called OECD1.DB, and it resides in the famedir directory. The DATA statement names the SAS output data set a that will reside in mydir. All time series in the Fame OECD1.DB database will be converted to an annual frequency and reside in the mydir.a SAS data set. Because the time series variable names contain the special glue symbol ‘.’, the SAS option statement specifies VALIDVARNAME=ANY. For more information about this option, see SAS System Options: Reference. The Fame environment variable is the location of the Fame installation. In the Windows environment, the log would look like this:
Example 48.1: Converting an Entire Fame Database

1 options validvarname=any;
2 %let FAME=%sysget(FAME);
3 %put(&FAME);
(C:\PROGRA~1\FAME)
4 %let FAMETEMP=%sysget(FAME_TEMP);
5 %put(&FAMETEMP);
(\ge\U11\saskff\fametemp\}
6
7 libname famedir sasefame "&FAME\util"
8 convert=(freq=annual technique=constant);
NOTE: Libref FAMEDIR was successfully assigned as follows:
Engine: FAMECHLI
Physical Name: C:\PROGRA~1\FAME\util
9
10 libname mydir '\dntsrc\usrtmp\saskff';
NOTE: Libref MYDIR was successfully assigned as follows:
Engine: V9
Physical Name: \dntsrc\usrtmp\saskff
11
12 data mydir.a; /* add data set to mydir */
13 set famedir.oecd1;
AUS.DIRDES -- SERIES (NUMERIC by ANNUAL)
AUS.DIRDES copied to work data base as AUS.DIRDES.

For more about the glue DOT character, see the section “Gluing Names Together” in the User’s Guide to Fame. In the preceding log, the variable name AUS.DIRDES uses the glue DOT between AUS and DIRDES.

The PROC PRINT statement produces the results shown in Output 48.1.1, which displays all observations in the mydir.a SAS data set.
### Output 48.1.1 Listing of OUT=MYDIR.A of the OECD1 Fame Data

| Obs | DATE | AUS.DIRDES | AUS.HERD | AUT.DIRDES | AUT.HERD | BEL.DIRDES | BEL.HERD | CAN.DIRDES | CAN.HERD | CHE.DIRDES | CHE.HERD | DEU.DIRDES | DEU.HERD | DNK.DIRDES | DNK.HERD | ESP.DIRDES | ESP.HERD | FIN.DIRDES | FIN.HERD | FRA.DIRDES | FRA.HERD | GBR.DIRDES | GBR.HERD | GRC.DIRDES | GRC.HERD | IRL.DIRDES | IRL.HERD | ISL.DIRDES | ISL.HERD | ITA.DIRDES | ITA.HERD | JPN.DIRDES | JPN.HERD | NLD.DIRDES | NLD.HERD | NOR.DIRDES | NOR.HERD | NZL.DIRDES | NZL.HERD | PRD.DIRDES | PRD.HERD | SWE.DIRDES | SWE.HERD | TUR.DIRDES | TUR.HERD | USA.DIRDES | USA.HERD | YUG.DIRDES | YUG.HERD |
|-----|------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|------------|---------|
Example 48.2: Reading Time Series from the Fame Database

This example uses the Fame WILDCARD= option to limit the number of series converted. The following statements show how to read only series whose names begin with WSPCA:

```sas
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);

libname lib1 sasefame "%sysget(FAME_DATA)"
   wildcard="wspca?";
   convert=(technique=constant freq=twicemonthly);

libname lib2 "%sysget(FAME_TEMP)";

data lib2.twild(label='Annual Series from the FAMEECON.db');
   set lib1.subecon;
   where date between '01jan93'd and '31dec93'd;
   /* keep only */
   keep date wspca;
run;

proc contents data=lib2.twild;
run;

proc print data=lib2.twild;
run;
```

Output 48.2.1 and Output 48.2.2 show the results of using WILDCARD=“WSPCA?”.

**Output 48.2.1** Contents of OUT=LIB2.TWILD of the SUBECON Fame Data

The CONTENTS Procedure

<td>8</td>
<td>ST</td>
<td>STANDARD &amp; POOR'S WEEKLY BOND YIELD: COMPOSITE, A</td>
<td></td>
</tr>
</tbody>
</table>

The WILDCARD=“WSPCA?” option limits reading to only those series whose names begin with WSPCA. The KEEP statement further restricts the SAS data set to include only the series named WSPCA and the DATE variable. The time interval that is used for the conversion is TWICEMONTHLY.

Example 48.3: Writing Time Series to the SAS Data Set

The following statements use the DROP statement to exclude certain time series from the SAS data set. (You can also use the KEEP statement to include certain series in the SAS data set.)

```sas
options validvarname=any;
%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);
libname famedir sasefame "%sysget(FAME_DATA)"
   convert=(freq=annual technique=constant);
libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
   set famedir.oecd1;
   drop 'ita.dirdes'n--'jpn.herd'n 'tur.dirdes'n--'usa.herd'n;
   where date between '01jan88'd and '31dec93'd;
run;

title1 "OEC1: TECH=Constant, FREQ=Annual";
title2 "Drop Using N-literals";
proc print data=mydir.a;
run;
```

Output 48.3.1 shows the results.

Note that the SAS option VALIDVARNAME=ANY was used at the beginning of this example because special characters are present in the time series names. SAS variables that contain certain special characters are called n-literals and are referenced in SAS code, as shown in this example.

You can rename your SAS variables by using the RENAME statement. The following statements show how to use n-literals when selecting variables that you want to keep and how to rename some of your kept variables:

```sas
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);

libname famedir sasefame "%sysget(FAME_DATA)"
   convert=(freq=annual technique=constant);
```
libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
  set famedir.oecd1;
  /* keep and rename */
  keep date 'ita.dirdes'n--'jpn.herd'n 'tur.dirdes'n--'usa.herd'n;
  rename 'ita.dirdes'n='italy.dirdes'n 'jpn.hirdes'n='japan.dirdes'n 'tur.dirdes'n='turkey.dirdes'n 'usa.dirdes'n='united.states.of.america.dirdes'n;
run;

title1 "OECD1: TECH=Constant, FREQ=Annual";
title2 "keep statement using n-literals";
title3 "rename statement using n-literals";
proc print data=mydir.a;
run;

Output 48.3.2 shows the results.

Example 48.4: Limiting the Time Range of Data

You can also limit the time range of the data in the SAS data set by using the RANGE= option in the LIBNAME statement or the WHERE statement in the DATA step to process the time ID variable DATE only when it falls in the range you are interested in.

All data for 1988, 1989, and 1990 are included in the SAS data set that is generated by using the RANGE='01JAN1988'D - '31DEC1990'D option or the WHERE DATE BETWEEN '01JAN88'D AND '31DEC90'D statement. The difference is that the RANGE= option uses less space in the Fame Work database. If you have a very large database and you want to use less space in your Fame Work database while you are processing the OECD1 database, you should use the RANGE= option as shown in the following statements:

```sas
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);

libname famedir SASEFAME "%sysget(FAME_DATA)"
   convert=(freq=annual technique=constant)
   range='01jan1988'd - '31dec1990'd;

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
   set famedir.oecd1;
   /* range on the libref restricts the dates */
   /* read from famedir's oecd1 database */
run;

title1 "OECD1: TECH=Constant, FREQ=Annual";
proc print data=mydir.a;
run;
```

Output 48.4.1 shows the results.

Example 48.4: Limiting the Time Range of Data

The following statements show how you can use the WHERE statement in the DATA step to process the time ID variable DATE only when it falls in the range you are interested in:

```sas
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);

libname famedir SASEFAME "%sysget(FAME_DATA)"
    convert=(freq=annual technique=constant);

libname mydir "%sysget(FAME_TEMP)";

data mydir.a; /* add data set to mydir */
    set famedir.oecd1;
    /* where only */
    where date between '01jan88'd and '31dec90'd;
run;

title1 "OECD1: TECH=Constant, FREQ=Annual";
proc print data=mydir.a;
run;
```

In Output 48.4.2, you can see that the result from the WHERE statement is the same as the result in Output 48.4.1 from using the RANGE= option.

For more information about the KEEP, DROP, RENAME, and WHERE statements, see SAS Language Reference: Concepts.
Example 48.5: Creating a View Using the SQL Procedure and the SASEFAME Engine

The following statements create a view of OECD data by using the SQL procedure’s FROM and USING clauses. For more information about SQL views, see the SAS Visual Data Management and Utility Procedures Guide.

```sas
title1 'famesql5: PROC SQL Dual Embedded Libraries w/ FAME option';
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME TEMP);
%put(&FAMETEMP);

title2 'OECD1: Dual Embedded Library Allocations with FAME Option';
proc sql;
create view fameview as
  select date, 'fin.herd'n
  from lib1.oecd1
  using libname lib1 sasefame "%sysget(FAME_DATA)"
    convert=(tech=constant freq=annual),
    libname temp "%sysget(FAME TEMP)";
quit;

title2 'OECD1: Print of View from Embedded Library with FAME Option';
proc print data=fameview;
run;
```

Output 48.5.1 shows the results.

Output 48.5.1  Printout of the Fame View of OECD Data

proc print data=fameview;
run;

The SAS option VALIDVARNAMES=ANY is used at the beginning of this example because special characters
are present in the time series names. The output from this example shows how each Fame view is the
output of the SASEFAME engine’s processing. Different engine options could have been used in the USING
LIBNAME clause if desired. Output 48.5.4 shows the results.

Output 48.5.4 Printout of the Fame View of DRI Basic Economic Data

Example 48.6: Reading Other Fame Data Objects with the FAMEOUT= Option

This example shows how you can designate the data objects that are output to your SAS data set by using the FAMEOUT= option. In this example, the FAMEOUT=FORMULA option selects the formulas and their source definitions to be output. The RANGE= option is ignored because no time series are selected when FAMEOUT=FORMULA is specified.

```sas
options validvarname=any ls=90;
%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);
libname lib6 sasefame "%sysget(FAME_DATA)"
   fameout=formula
   convert=(frequency=business technique=constant)
   range='02jan1995'd - '25jul1997'd
   wildcard="?YIELD?";

data crout;
   set lib6.training;
   keep 'S.GM.YIELD.A'n -- 'S.XON.YIELD.A'n;
run;

title1 'Formulas from the TRAINING DB, FAMEOUT=FORMULA Option';
title2 'Using WILDCARD="?YIELD?"';
proc contents
   data=crout;
run;
```

Output 48.6.1 shows the results.
The CONTENTS Procedure

<table>
<thead>
<tr>
<th>#</th>
<th>Variable Type</th>
<th>Len</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>S.GM.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>S.GM_PP.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>
<td>3</td>
<td>S.HWP.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>
<td>4</td>
<td>S.IBM.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>
<td>5</td>
<td>S.INDUT.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>
<td>6</td>
<td>S.SPAL.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>

<td>S.XOM.YIELD.A Char 82</td>
<td></td>
</tr>
<tr>
<td>10</td>
<td>S.XON.YIELD.A Char 82</td>
<td></td>
</tr>
</tbody>
</table>

The FAMEOUT=FORMULA option restricts the SAS data set to include only formulas. The WILDCARD= ”?YIELD?” option further limits the selection of formulas to those whose names contain “YIELD”.

```plaintext
options validvarname=any linesize=79;

title1 'Formulas from the TRAINING DB, FAMEOUT=FORMULA Option';
title2 'Using WILDCARD= ”?YIELD?”';
proc print
data=crout noobs;
run;
```

Additional examples of the FAMEOUT= option are shown in Example 48.11, Example 48.12, Example 48.13, Example 48.14, and Example 48.15.
Example 48.7: Remote Fame Access by Using Fame CHLI

When you run Fame in a client/server environment and also have Fame CHLI capability to enable access to the server, you can access Fame remote data. Access the remote data by specifying the port number of the TCP/IP service that is defined for the frdb_m and the node name of the Fame master server in the physical path. In this example, the Fame server node name is STONES, and the port number is 5555, as was designated in the Fame master command. For more information about starting your Fame master server, see the section “Starting the Master Server” in Guide to Fame Database Servers.

```plaintext
options ls=78;
title1 "DRIECON Database, Using FAME with Remote Access via CHLI";
options validvarname=any;
libname test1 sasefame '#5555@stones $FAME/util';

data a;
  set test1.driecon;
  keep YP ZA ZB;
  where date between '01jan98'd and '31dec03'd;
run;

proc means data=a n;
run;
```

Output 48.7.1 shows the results.

**Output 48.7.1** Summary Statistics for the Remote FAME Data

DRIECON Database, Using FAME with Remote Access via CHLI

Example 48.8: Selecting Time Series by Using the CROSSLIST= Option and KEEP Statement

This example shows how to use two Fame namelists to perform selection. Note that `fame_namelist1` could be easily generated using the Fame WILDLIST function. For more about the WILDLIST function, see the section “The WILDLIST Function” in the Fame Command Reference, Volume 2, Functions. In the following statements, four tickers are selected in `fame_namelist1`, but when you use the KEEP statement, the resulting data set contains only the desired IBM ticker:

```r
options validvarname=any;
libname lib8 sasefame "%sysget(FAME_DATA)"
  convert=(frequency=business technique=constant)
  crosslist=(
    { IBM, SPALN, SUNW, XOM },
    { adjust, close, high, low, open, volume, uclose, uhigh, ulow, uopen, uvolume }
  );

data trout;
  /* eleven companies, keep only the IBM ticker this time */
  set lib8.training;
  where date between '01mar02'd and '20mar02'd;
  keep IBM: ;
run;

title1 'TRAINING DB, Pricing Timeseries for IBM Ticker in CROSSLIST=';
proc contents
  data=trout;
run;

proc print
  data=trout;
run;
```

Output 48.8.1 and Output 48.8.2 show the results.

Example 48.9: Selecting Time Series by Using the CROSSLIST= Option and Fame Namelist

This example demonstrates selection by using the CROSSLIST= option. Only the ticker “IBM” is specified in the KEEP statement from the 11 companies in the Fame ticker namelist.

```sas
options validvarname=any;
libname lib9 sasefame "%sysget(FAME_DATA)"
   convert=(frequency=business technique=constant)
   range='07jul1997'd - '25jul1997'd
crosslist=( nl(ticker),
   { adjust, close, high, low, open, volume,
     uclose, uhigh, ulow, uopen, uvolume }
   );

data crout;
   /* eleven companies in the FAME ticker namelist */
   set lib9.training;
   keep IBM: ;
run;

title1 'TRAINING DB, Pricing Timeseries for Eleven Tickers in CROSSLIST=';
title2 'Using TICKER Namelist';
proc print data=crout;
run;

proc contents data=crout;
run;
```

Output 48.9.1 and Output 48.9.2 show the results.

### Example 48.10: Selecting Time Series by Using the CROSSLIST= Option and WHERE=TICK

Instead of having a Fame namelist with the ticker symbols for companies whose data you are interested in, you can designate an input SAS data set (INSETA) that specifies the tickers to select. Specify your selection by using the WHERE clause in the INSET= option as follows:

```plaintext
options validvarname=any;

data inseta;
  length tick $5;
  tick='AOL'; output;
  tick='C'; output;
  tick='CPQ'; output;
  tick='CVX'; output;
  tick='F'; output;
  tick='GM'; output;
  tick='HWP'; output;
  tick='IBM'; output;
  tick='SPALN'; output;
  tick='SUNW'; output;
  tick='XOM'; output;
run;

libname lib10 sasefame "%sysget(FAME_DATA)"
  convert=(frequency=business technique=constant)
  range='07jul1997'd - '25jul1997'd
  inset=( inseta where=tick )
  crosslist=
    ( {adjust, close, high, low, open, volume,
    uclose, uhigh, ulow, uopen, uvolume} );
```
Example 48.10: Selecting Time Series by Using the CROSSLIST= Option and WHERE=TICK

```sas
data trout;
/* eleven companies with unique TICKs specified in INSETA */
  set lib10.training;
  keep IBM: ;
run;

%title 'TRAINING DB, Pricing Timeseries for Eleven Tickers in CROSSLIST=';
%title2 'Using INSET with WHERE=TICK';
proc print data=trout;
run;
proc contents data=trout;
run;
```

Output 48.10.1 and Output 48.10.2 show the results.

Output 48.10.1 Listing of OUT=TROUT Using CROSSLIST= and INSET= Options in the Fame TRAINING Data

TRAINING DB, Pricing Timeseries for Eleven Tickers in CROSSLIST=
Using INSET with WHERE=TICK

Example 48.11: Selecting Boolean Case Series with the FAMEOUT= Option

This example shows how to extract all Boolean case series from the Fame ALLTYPES database. The following statements write all Boolean case series to the SAS data set BOOOUT:

```
title1 '***famallt: FAMEOUT Option, Different Type Values***';
options validvarname=any;

%let FAME=%sysget(FAME);
%put(&FAME);
%let FAMETEMP=%sysget(FAME_TEMP);
%put(&FAMETEMP);

libname lib4 sasefame "%sysget(FAME_DATA)"
   fameout=boolcase wildcard="?" ;

data booout;
   set lib4.alltypes;
run;

title1 'ALLTYPES FAMEOUT=BOOLCASE for Boolean Case Series';
title2 'Using FAMEOUT=CASE BOOLEAN Option without Range';
proc contents
   data=booout;
run;

proc print
   data=booout;
run;
```

Output 48.11.1 and Output 48.11.2 show the results for the Boolean case.

**Example 48.12: Selecting Numeric Case Series with the FAMEOUT= Option**

This example extracts numeric case series. In addition to the already existing numeric case series in the Fame database, you can also have formulas that expand to numeric case series. The SASEFAME engine resolves all formulas that belong to the class and type of series data object that you specify in the FAMEOUT= option. The following statements write all numeric case series to the SAS data set CSOUT:

```
libname lib5 sasefame "%sysget(FAME_DATA)"
   fameout=case wildcard="?" ;

data csout;
   set lib5.alltypes;
run;

title1 'Using FAMEOUT=CASE Option without Range';
title2 'ALLTYPES, FAMEOUT=CASE and Open Wildcard for Numeric Case Series';
proc contents
   data=csout;
run;

proc print
   data=csout;
run;
```

Output 48.12.1 and Output 48.12.2 show the results.

**Example 48.15: Extracting Source for Formulas**

This example shows how to extract the source for all the formulas in the Fame database by using the FAMEOUT=FORMULA and WILDCARD="?" options. The following statements show the source of all formulas written to the SAS data set CFOROUT. Another example of the FAMEOUT=FORMULA option is shown in Example 48.6.

```sas
libname lib8 sasefame "%sysget(FAME_DATA)"
  fameout=formula wildcard="?" ;

data cforout;
  set lib8.alltypes;
run;

title1 'Using FAMEOUT=FORMULA Option without Range';
proc contents
data=cforout;
run;
```

Output 48.15.1 and Output 48.15.2 show the results.
Output 48.15.1  Contents of OUT=CFOROUT Using FAMEOUT=FORMULA and Open Wildcard

Using FAMEOUT=FORMULA Option without Range

S.DFRM  S.FRM1  S.FRM2
IF DBOO THEN DPRC ELSE DNUM IF BOO1 THEN NUM1 ELSE NUM2 IF BOO0 THEN DAT1 ELSE DAT2

If you want all series of every type, you can merge the resulting data sets. For more information about merging SAS data sets, see SAS Language Reference: Concepts.

Example 48.16: Reading Time Series by Defining Fame Expression Groups in the INSET= Option with the KEEP= Clause

To keep all the numeric time series that are listed in the expressions given in the input data set, INSETA, use the INSET=( setname KEEPLIST=fame_expression_group ) and WILDCARD="?" options. The following statements show how to select time series that are specified in a KEEP expression group and are written to the SAS output data set:

data inseta; /* Use this for d8690 training database */
length express $52;
express='cvx.close;'; output;
express='{ibm.high,ibm.low,ibm.close};'; output;
express='mave(ibm.close,30);'; output;
express='crosslist({gm,f,c},{volume});'; output;
express='cvx.close+ibm.close;'; output;
express='ibm.close;'; output;
express='sum(pep.volume);'; output;
express='mave(pep.close,20);'; output;
run;
title1 'TRAINING DB, Pricing Timeseries for Expressions in INSET=';
proc print
data=inseta;
run;

Output 48.16.1 shows the expressions that are stored as observations in the input data set, INSETA.

Output 48.16.1 Listing of INSETA Defining Fame Expression Group

TRAINING DB, Pricing Timeseries for Expressions in INSET=

<table>
<thead>
<tr>
<th>Obs</th>
<th>express</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>cvx.close;</td>
</tr>
<tr>
<td>2</td>
<td>{ibm.high,ibm.low,ibm.close};</td>
</tr>
<tr>
<td>3</td>
<td>mave(ibm.close,30);</td>
</tr>
<tr>
<td>4</td>
<td>crosslist({gm,f,c},{volume});</td>
</tr>
<tr>
<td>5</td>
<td>cvx.close+ibm.close;</td>
</tr>
<tr>
<td>6</td>
<td>ibm.close;</td>
</tr>
<tr>
<td>7</td>
<td>sum(pep.volume);</td>
</tr>
<tr>
<td>8</td>
<td>mave(pep.close,20);</td>
</tr>
</tbody>
</table>

The following statements show how to use the INSET= option to keep all time series that are represented in the input data set, INSETA, as the group variable EXPRESS:

libname libX sasefame "%sysget(FAME_DATA)"
   wildcard="?"
   convert=(frequency=business technique=constant)
   range='23jul1997'd - '25jul1997'd
   inset=( inseta KEEP=express)
;

data trout;
   set libX.trainten;
run;

title1 'TRAINING DB, Pricing Timeseries for Expressions in INSET=';
proc print data=trout;
run;

proc contents data=trout;
run;

Output 48.16.2 and Output 48.16.3 show the results.
Example 48.17: Optimizing Cache Sizes with the TUNEFAME= and TUNECHLI= Options

This example shows how to use the TUNEFAME= option, the TUNECHLI= option, and a RANGE= option to select pricing time series in the TRAINTEN database. The selected time series are written to the SAS output data set. The Fame database engine’s virtual memory is given in megabytes (MB), so this example sets the cache size to 100 MB. The Fame CHLI engine’s virtual memory is also given in megabytes (MB), so this example sets the CHLI cache size to 100 MB. These two settings correspond to the default settings. Both the Fame 4GL engine and the Fame CHLI engine can use a cache size that ranges from 0.1 MB to 17,592,186,000,000 MB.
libname lib5 sasefame "%sysget(FAME_DATA)"
    wildcard=’?UHIGH’
    tunefame=nodes 100
    tunechli=nodes 100
    convert=(frequency=business technique=constant)
    range='23jul1997'd - '25jul1997'd
;

data trout(drop=C:);
    set lib5.trainten;
run;
title1 'TRAINTEN DB, Pricing Time Series, TUNEFAME=NODES and TUNECHLI=NODES Options';
proc print data=trout;
run;

proc contents data=trout;
run;

Output 48.17.1 and Output 48.17.2 show the results.

Output 48.17.1 Listing of TRAINING DB, Pricing Time Series, TUNEFAME=NODES, and TUNECHLI=NODES Options

<table>

For more information about tuning the use of virtual memory, read about TUNE CACHE nodes in the section “TUNE CACHE Option” in the online document Fame 10 Online Help.

Example 48.18: Remote Access Using the MCADBS Server

Instead of accessing the local Fame training database, as shown in Example 48.10, this example shows how to access the remote Fame training database that is located on a remote Fame MCADBS server whose host name is “txa006”. First, specify an explicit connection by using the CONNECT=YES option. Then name the connection in the AS_NAME= option, specify the host name of the remote MCADBS server in the ON_HOST= option, and specify the service to use in the TO_SERVICE= option. In addition, specify the user name and password for the connection by using the USER= and PASS= options. Designate an input SAS data set (INSETZ) that specifies the tickers to select, and specify your selection by using the WHERE clause in the INSET= option as follows:
Chapter 48: The SASEFAME Interface Engine

```sas
option validvarname=any;

data insetz;
length tick $6;
/* need $6 so DJ30IN is not truncated */
  tick='C'; output;
  tick='CVX'; output;
  tick='DJ30IN'; output;
  tick='F'; output;
  tick='HPQ'; output;
  tick='IBM'; output;
  tick='INTC'; output;
  tick='KO'; output;
  tick='ORCL'; output;
  tick='PEP'; output;
  tick='SPX'; output;
  tick='XOM'; output;
  tick='YUM'; output;
run;

libname lib10 sasefame "C:\PROGRA~1\FAME\util"
  debug=on
  connect=yes to_service="2961" on_host="txa006" as_name="C"
  user="famekff" pass="XXXXXXXXX"
  convert=(frequency=business technique=constant)
  range='07jul1997'd - '25jul1997'd
  inset=( insetz where=tick )
  crosslist=
    ( {adjust, close, high, low, open, volume,
        uclose, uhigh, ulow, uopen, uvolume} );

data trout;
/* thirteen companies with unique TICKs specified in INSETZ */
/* Use tr since this is the MCADBS dbid for the training.db */
  keep DATE IBM: ; /* only keep IBM for brevity of output results */
run;

   title1 'TRAINING DB, Pricing Timeseries for IBM';
   title2 'Using INSET with WHERE=TICK.';
   proc print data=trout;
run;

   proc contents data=trout;
run;
```

Output 48.18.1 and Output 48.18.2 show the results.

The DEBUG=ON option gives tracing information in the SAS log that shows the Fame CHLI commands that are used to communicate with the remote server. This debugging information can be useful in explaining the communication between the client and server machines. An abbreviated version of the SAS log follows:

NOTE: Libref LIB10 was successfully assigned as follows:

<table>

Example 48.18: Remote Access Using the MCADBS Server

Because you specify the DEBUG=ON option, the SAS log includes the Fame commands and reports the status of the Fame CHLI commands that are issued during the execution of the SAS DATA step. The first Fame command shown is OPEN; it is important to note that instead of using training in the SAS SET statement, it is necessary to use the database ID, tr. For the MCADBS server, a list of databases is given in the mcadbs.config file, which for the host txa006 contains the following information:

# The databases to open
OPEN %OL% %FAME%\util\training.db TR
    # Clients refer to this as TR.

The first OPEN command listed in the SAS log (inside the FAME command) refers to the named connection, C:

OPEN <ACCESS READ> tr ON C;

So the connection is named C, which is specified in the AS_NAME= option in the SASEFAME LIBNAME statement.
References

Overview: SASEFRED Interface Engine

The SASEFRED interface engine enables SAS users to retrieve economic data from the FRED website, which is hosted by the Economic Research Division of the Federal Reserve Bank of St. Louis. FRED stands for Federal Reserve Economic Data. The FRED databases contain more than 61,000 economic data time series from 48 national and international sources, both public and private. These time series are updated at annual, quarterly, monthly, weekly, and daily intervals. The economic time series on the FRED website contain observation or measurement periods that are associated with data values.

The SASEFRED interface engine uses the LIBNAME statement to enable you to specify how to subset your FRED data and how to aggregate the selected time series at the same update frequency. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEFRED interface engine supports 64-bit Windows and Linux X64 (LAX) platforms.

Note that the SASEFRED engine uses the FRED API, but it is not endorsed or certified by the Federal Reserve Bank of St. Louis, and that by using the SASEFRED interface, you are agreeing to comply with the FRED terms of use, which are described on the web page at the following URL: https://api.stlouisfed.org/terms_of_use.html.

Getting Started: SASEFRED Interface Engine

You can query the Federal Reserve Economic Data (FRED) databases to retrieve the observations or data values for a list of economic time series by specifying the series ID of each time series that you want to read into SAS and by specifying your unique FRED API key. To obtain your own unique API key, visit the FRED website at the following URL:

https://api.stlouisfed.org/api_key.html

The FRED API key is a 32-character alphanumeric lowercase string, such as ‘abcdefgijklmnpqrstuvwxy213456’, and is represented by ’XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX’ in the APIKEY= option in the following example. In addition, the example URLs in this section and in the section “Details: SASEFRED Interface Engine” on page 3538 use the same FRED API key as the argument your_fred_apikey.

After you have your assigned FRED API key and you have agreed to the terms of use, before downloading any copyright-protected data series, be aware that you are solely responsible for obtaining copyright permissions for any copyright-protected time series that you download (other than for personal use). To obtain a list of the copyright-protected data series, visit the web page at the following URL:

https://api.stlouisfed.org/fred/series/search?search_text=copyright&api_key=your_fred_apikey

Now that you are informed about the terms of use of the FRED data, you can use your FRED API key to access the FRED data, as shown in the following example. In the following example, and “Examples: SASEFRED Interface Engine” on page 3544, use the SAS option SSLCALISTLOC=<specify the location of your CA certificates here>. The specification shown as SSLCALISTLOC="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem" is for demonstration purposes only. Specify your own location of your trusted certificates inside the double quotes.
The following statements enable you to access the exports of goods and services time series data from January 1, 1960, to January 1, 2012, on an annual basis. The observations are sorted by the time ID variable DATE.

```
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Data for the Exports of Goods and Services';
libname _all_ clear;

libname fred sasefred "%sysget(FRED)"
   OUTXML=exportgs
   XMLMAP="%sysget(FRED)exportgs.map"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
   IDLIST='bopxgsa';

data export_gsa;
   set fred.exportgs ;
run;

proc contents data=export_gsa; run;
proc print data=export_gsa(obs=15); run;
```

The XML data that the FRED website returns are placed in a file named by the OUTXML= option, in this case, `EXPORTGS.xml`. Note that the XML file extension is excluded from the filename given in the OUTXML= option. When the SET statement is executed, the XML data is read into a SAS data set named `Exportgs.sas7bdat`, which resides in the location given inside the string enclosed in double quotation marks in the SASEFRED LIBNAME statement. So, in the preceding example, if the FRED environment variable is set to
then the SAS data set created from reading the downloaded XML file is placed into

/sasusr/playpens/saskff/fred/test/exportgs.sas7bdat

An equivalent LIBNAME statement that does not use any environment variables could be as follows:

Libname fred sasefred "/sasusr/playpens/saskff/fred/test/"
    OUTXML=exportgs
    XMLMAP="/sasusr/playpens/saskff/fred/test/exportgs.map"
    APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    IDLIST='bopxgsa';

You could also use either a SAS macro variable or a system environment variable to store the value of your FRED API key so that the key does not appear explicitly in your SAS code. The XML map that is created is assigned the full pathname specified by the XMLMAP= option. The IDLIST= option specifies the list of time series that you want to retrieve. This option accepts a string, enclosed in single quotation marks, that denotes a list of one or more time series that you select (keep) in the resulting SAS data set. The result, Export_gsa, is named in the DATA step and is shown in Figure 49.1. It is more efficient to use the DATA step to store your FRED data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC GPLOT statement, but you can also refer to the SASEFRED libref directly, as in the following statement:

proc print data=fred.exportgs; run;

This statement uses the member name, exportgs, in the PROC PRINT statement; this usage corresponds to specifying the OUTXML=EXPORTGS option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASEFRED libref, the FRED interface reads the entire XML file again into SAS. It is best to refer to the SAS data set repeatedly rather than invoking the interface engine repeatedly. For another example that uses more SASEFRED LIBNAME statement options, see the section “Reading Price Data by Using Indices” on page 3542.

Syntax: SASEFRED Interface Engine

The SASEFRED interface engine uses standard engine syntax to read the observations or data values for one or more economic time series. Table 49.1 summarizes the options that the SASEFRED engine uses. There are two required options: APIKEY='fred_apikey' and ID_LIST='fred_idlist'.
### Table 49.1 Summary of LIBNAME libref SASEFRED Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AGG=</td>
<td>Specifies the aggregation method used for frequency aggregation. The valid aggregation arguments are ‘avg’, ‘sum’, and ‘eop’; the default is ‘avg’.</td>
</tr>
<tr>
<td>APIKEY=</td>
<td>Specifies the required FRED access key that enables you to access the data that the FRED website provides.</td>
</tr>
<tr>
<td>AUTOMAP=</td>
<td>Specifies whether or not to overwrite the existing XML map file.</td>
</tr>
<tr>
<td>CONNECT=</td>
<td>Specifies whether or not you need the connect method for a secure connection via a proxy server. You must specify the PROXY= option when you use the CONNECT=ON option. See the PROXY= option.</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not you need diagnostic message logging in the SAS log window.</td>
</tr>
<tr>
<td>END=</td>
<td>Specifies the end date for the observation period (‘YYYY-MM-DD’ formatted string, optional; the default is 1776-07-04 (earliest available)).</td>
</tr>
<tr>
<td>FORMAT=</td>
<td>Specifies a file extension that indicates the type of file to retrieve. Only XML is supported.</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies the reporting frequency of the selected data (lower frequency to aggregate values to): ‘m’ for monthly, ‘d’ for daily. The FRED frequency aggregation feature converts higher-frequency data series to lower-frequency time series (such as converting a monthly time series to an annual time series). For the complete list of frequencies, see Table 49.2.</td>
</tr>
<tr>
<td>IDLIST=</td>
<td>Specifies a list of time series IDs for accessing FRED data. To select more than one time series, list the unique time series IDs, separated by commas.</td>
</tr>
<tr>
<td>LIMIT=</td>
<td>Specifies the maximum number of observations (rows) to return (integer between 1 and 100,000, optional; the default is 100,000).</td>
</tr>
<tr>
<td>MAPREF=</td>
<td>Specifies the fileref used for the map file assignment.</td>
</tr>
<tr>
<td>OFFSET=</td>
<td>Specifies the number of rows (observations) to skip in the returned data set.</td>
</tr>
<tr>
<td>OUTPUT=</td>
<td>Specifies an output type. The valid output arguments are ‘1’ for Observations by Real-Time Period; ‘2’ for Observations by Vintage Date, All Observations; ‘3’ for Observations by Vintage Date, New and Revised Observations Only; and ‘4’ for Observations, Initial Release Only (integer, optional; the default is ‘1’).</td>
</tr>
<tr>
<td>OUTXML=</td>
<td>Specifies the name of the output SAS data set and the XML file(s) requested by the IDLIST= option. When more than one time series ID is listed in the IDLIST= option, then the SASEFRED engine appends the positional integer (‘1’ for the first time series ID, ‘2’ for the second time series ID, and so on) to the name specified by the OUTXML= option.</td>
</tr>
<tr>
<td>PROXY=</td>
<td>Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, use the CONNECT=ON option in addition to the PROXY= option. See the CONNECT= option.</td>
</tr>
<tr>
<td>RTSTART=</td>
<td>Specifies the real-time start date for the observation period (‘YYYY-MM-DD’ formatted string, optional; the default is today).</td>
</tr>
<tr>
<td>RTEND=</td>
<td>Specifies the real-time end date for the observation period (‘YYYY-MM-DD’ formatted string, optional; the default is today).</td>
</tr>
<tr>
<td>SORT=</td>
<td>Specifies the order of the results in ascending or descending observation_date order. The valid sort arguments are ‘asc’ and ‘desc’; the default is ‘asc’.</td>
</tr>
<tr>
<td>Option</td>
<td>Description</td>
</tr>
<tr>
<td>---------</td>
<td>-------------</td>
</tr>
<tr>
<td>START=</td>
<td>Specifies the start date for the observation period ('YYYY-MM-DD' formatted string, optional; the default is 9999-12-31 (latest available))</td>
</tr>
<tr>
<td>UNITS=</td>
<td>Specifies a data value transformation. The valid units arguments are ‘lin’, ‘chg’, ‘ch1’, ‘pch’, ‘pc1’, ‘cca’, ‘cch’, ‘pc1’, and ‘log’; the default is ‘lin’. For more information about units, see Table 49.3.</td>
</tr>
<tr>
<td>URL=</td>
<td>Specifies a URL from which to request useful information about available releases, vintage dates, tags, categories, sources, and series. The information is downloaded from the specified URL and stored in the XFREDTPU data set (a temporary utility data set), which can then be saved or renamed to a permanent SAS data set.</td>
</tr>
<tr>
<td>USER=</td>
<td>Specifies the location of the writable folder where you permanently store data sets that have one-level names</td>
</tr>
<tr>
<td>VINTAGE=</td>
<td>Specifies one or more dates in history. Vintage dates are used to download data as they existed on that specific date in history ('YYYY-MM-DD' formatted string, optional; by default no vintage dates are set). You can request one or many vintage dates at a time; dates are in 'YYYY-MM-DD' format and are separated by commas (no blanks allowed). For multiple vintage dates, specify OUTPUT=2 for all observations or OUTPUT=3 for only new or revised observations.</td>
</tr>
<tr>
<td>XMLMAP=</td>
<td>specifies the fully qualified name of the location where the XMLmap file is automatically stored. By default, XMLMAP=Fred.map.</td>
</tr>
</tbody>
</table>

The LIBNAME libref SASEFRED Statement

```
LIBNAME libref SASEFRED 'physical-name' options ;
```

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of FRED data files in which the downloaded FRED XML data are stored.

You must specify the following arguments:

**“physical name”**

specifies the location of the folder where your FRED XML data reside. Enclose the `physical name` in double quotation marks, and end it with a backslash if the folder is in a Windows environment or a forward slash if it is in a UNIX environment.

**APIKEY='fred_apikey'**

specifies the FRED access key that enables you to access the data provided by the FRED website. The FRED access key is a 32-character alphanumeric lowercase string. You can request your `fred_apikey` by visiting the website at the following URL:

https://api.stlouisfed.org/api_key.html

**IDLIST='fred_idlist'**

specifies the list of time series to be included in the output SAS data set. This list is comma-delimited and must be enclosed in single quotation marks.

You can also specify the following options.
AGG='AVG' | 'EOP' | 'SUM'
specifies the aggregation method used for frequency aggregation. You can specify the following values:

'AVG'  aggregates by averaging the frequencies.
'EOP'  aggregates by summing the frequencies.
'SUM'  aggregates by using the end of the period.

By default, AGG='AVG'. This option has no effect if the frequency option (FREQ=) is not specified.

AUTOMAP=REPLACE | REUSE
specifies which XMLmap file to use. You can specify the following values:

REPLACE  overwrites the existing XMLmap file and uses the most current XMLmap that is generated by the SASEFRED engine and named in the XMLMAP= option.
REUSE  uses a preexisting XMLmap file that is named in the XMLMAP= option.

CONNECT=ON | OFF
specifies whether or not to use the connect method along with the PROXY= option. **Note:** You must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option when you want to use the connect method. For more information about a secure connection, see the PROXY= option.

DEBUG=ON | OFF
specifies whether or not to include diagnostic message logging in the SAS log window. This information can be very useful for troubleshooting a problem. DEBUG=OFF redirects the SAS debug logging to a temporary file in the current working folder. You can specify a different folder to store the resulting log information (in the USER folder) when you specify the USER= option. DEBUG=OFF is the default. Use DEBUG=ON to see all the log messages (including debug information) in the SAS log. For more information about the USER folder, see the USER= option.

END='fred_enddate'
specifies the end date for the time series in the format 'YYYY-MM-DD'. The default is 9999-12-31 (latest available).

FORMAT='fred_xmlformat'
specifies the format of the file to be received from the FRED website. Although FRED can report data in many formats, the SASEFRED engine for 9.4 supports the XML format (default).

FREQ='fred_frequency'
specifies a lower frequency to aggregate values to. The FRED frequency aggregation feature converts higher-frequency time series to lower-frequency time series (such as converting a daily time series to a monthly time series). In FRED, the highest frequency is daily, and the lowest frequency is annual. There is no default value for no frequency aggregation. The valid frequency arguments are presented in Table 49.2.

**Note:** An error is returned if you specify a frequency that is higher than the native frequency of the series. For example, if a series has the native frequency ‘Annually’, it is not possible to aggregate the series to the higher ‘Monthly’ frequency by using the frequency parameter value ‘m’. To find the
native frequency of an economic time series, enter the following URL in your web browser. The output includes the ‘Frequency’ field, which shows native frequency of that time series.

https://api.stlouisfed.org/fred/series?series_id=DJCA&api_key=your_fred_apikey

**NOTE:** When a single time series is specified in the IDLIST= option and the FREQ= option is not specified or is an empty string, then the native frequency of that time series is used as the reporting frequency. When multiple time series are specified in the IDLIST= option, then the ‘Annual’ frequency is used as the reporting frequency unless the reporting frequency is specified in the FREQ= option. If any time series in the IDLIST= option list have a lower native frequency than the requested frequency, then those time series are dropped from the list and excluded from the output.

### Table 49.2  FRED Frequency Codes

<td>bwem</td>
<td>Displays data on a biweekly (ending Monday) basis</td>
</tr>
</tbody>
</table>

**LIMIT=** *fred_limit*  
specifies the maximum number of rows (time series observations) to return, where *fred_limit* is an integer between 1 and 100,000. LIMIT= is optional, and the default is LIMIT=100000.

**MAPREF=** *fred_xmlmapref*  
specifies the fileref used for the map assignment. For an example of the SASEFRED engine that uses the MAPREF= and the XMLMAP= options in the FILENAME statement to assign a filename, as in the following, see the section “Reading Price Data by Using Indices” on page 3542:

FILENAME MyMap "/sasusr/playpens/saskff/fred/test/gstart.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file, and to name your SAS data set created from reading the XML data into SAS. The resulting
SAS data set is placed in the folder designated by ‘physical-name’, and you can reference it by using the myLib libref in your SASEFRED LIBNAME statement. This is shown in the section “Getting Started: SASEFRED Interface Engine” on page 3528, inside the DATA step in the SET statement. The SET statement reads observations from the input data set myLib.gstart and stores them in a SAS data set named Company_pvol.

OFFSET=\fred_offset

specifies the number of rows (time series observations) to skip before reading the time series observations from the FRED database, where \fred_offset is an optional nonnegative integer. If you specify both the OFFSET= and LIMIT= options, the number of rows specified in the OFFSET= option is skipped before the count begins of the number of rows (specified in the LIMIT= option) that are returned. By default, OFFSET=0.

OUTPUT=1 | 2 | 3 | 4

specifies the type of the file to be received from the FRED website. You can specify the following values:

1 specifies the type Observations by Real-Time Period.
2 specifies the type Observations by Vintage Date, All Observations.
3 specifies the type Observations by Vintage Date, New and Revised Observations Only.
4 specifies the type Observations, Initial Release Only.

If OUTPUT=1 and UNITS='lin', then you must specify a START= date that is later than the series observation start date, Obs_Start. If OUTPUT=3 or OUTPUT=4, then you must specify UNITS='lin'.

OUTXML=\fred_xmlfile

specifies the name of both the XML file (downloaded) and the SAS data set created when the XML data are read into SAS. Each FRED time series that is listed in the IDS= option is given a positional numeral: 1 for the first time series ID in the ID= option, 2 for the second time series ID, and so on. The SASEFRED engine appends this numeral to the filename of the XML of each data set that the website returns. When all the XML files are retrieved, the data are merged into a SAS data set. When only one FRED time series ID is specified in the ID= option, the filename has the numeral 1 appended to the OUTXML filename. By default, OUTXML=FRED, which creates a file named FRED1.xml in the current working directory. The SAS data set created when the XML data are read into SAS is placed in the folder specified by the physical path in the LIBNAME libref SASEFRED statement.

PROXY="\fred_proxyserver"

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused error or a connection-timed-out error occurs. For \fred_proxyserver, specify the server’s HTTP address followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY="http://inetgw.unx.sas.com:8118". See also the CONNECT= option.

RTEND='\fred_rtenddate'

specifies the real-time end date for the time series in the format 'YYYY-MM-DD'. When you use the OUTPUT=4 option, it is important to specify RTSTART='1776-07-04' and RTEND='9999-12-31' to get the available observations for the initial release of the data. Failure to do so can result in no observations being returned for the requested series. The default is today.
RTSTART='fred_rtdstartdate'
specifies the real-time start date for the time series in the format 'YYYY-MM-DD'. When you use the OUTPUT=4 option, it is important to specify RTSTART='1776-07-04' and RTEND='9999-12-31' to get the available observations for the initial release of the data. Failure to do so can result in no observations being returned for the requested series. The default is today.

SORT='ASC' | 'DSC'
specifies the order of the time series observations. You can specify the following values:

'ASC' specifies that the time series observations are in ascending order.

'DSC' specifies that the time series observations are in descending order.

By default, SORT='ASC'.

START='fred_startdate'
specifies the start date for the time series in the format 'YYYY-MM-DD'. The default is 1776-07-04 (earliest available). When you use the OUTPUT=1 option (observation by real-time period) and the UNITS='chg' option, it is important to specify a date in the START= option that is later than the series observation start date, Obs_Start. Failure to do so forces the SASEFRED interface engine to change UNITS='chg' to UNITS='lin'.

UNITS='fred_units'
specifies the data value transformation. The valid units arguments are 'lin', 'chg', 'ch1', 'pch', 'pc1', 'pca', 'cch', 'cca', and 'log'. the default is UNITS='lin' (for no transformation). The details of the arguments and the corresponding formulas are presented in Table 49.3. When you specify UNITS='chg' and OUTPUT=1 (observation by real-time period), it is important to specify a date in the START= option that is later than the series observation start date, Obs_Start. Failure to do so forces the SASEFRED interface engine to change UNITS='chg' to UNITS='lin'.

</tbody>
</table>

$x_t$ is the value of series $x$ at time period $t$. $N$ is the number of observations per year that differs by frequency: daily ($N=260$), annual ($N=1$), monthly ($N=12$), quarterly ($N=4$), biweekly ($N=26$), and weekly ($N=52$).
The LIBNAME libref SASEFRED Statement

URL="fred_url_link/\texttt{query_type?query_option=value}>><\texttt{LIMIT=limit}>"

queries for useful information (such as categories, tags, groups, and releases) and stores the information in a temporary utility data set named XFREDTPU. Specify the following fields within double quotation marks:

fred_url_link/

specifies the base FRED URL that you want to use. The \texttt{fred_url_link} in the following example is ‘https://api.stlouisfed.org/fred/’. The required APIKEY= option completes the FRED URL request. An example follows:

\begin{verbatim}
URL="https://api.stlouisfed.org/fred/series/vintagedates\?series_id=N500C1A027NBEA"
APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
\end{verbatim}

\texttt{query_type?query_option}

specifies the type of information that you want to query. You can specify the following \texttt{query_types} and \texttt{query_options}:

series/vintagedates?series_id=series_id

requests the vintage dates for the specified \texttt{series_id}, which you must also specify in the IDLIST= option. For an example of this type of query, see Example 49.7.

release/series?release_id=release

requests a list of the available series for the specified \texttt{release}. For an example of this type of query, see Example 49.8.

source/releases?

source/releases?source_id=source_id

requests a list of the releases available today or available for a specified \texttt{source_id}. For an example of this type of query, see Example 49.14.

You can also narrow this type of query by specifying the \texttt{source_id}; then only the releases that are available for the specified source are stored in the XFREDTPU data set. For an example of this type of query, see Example 49.11.

tags/series?tags_names=value-list

requests a list of the series that are available and whose tag names match the specified \texttt{value-list}. For an example of this type of query, see Example 49.9.

category/series?category_id=category_id

requests a list of the series that are available and whose category ID matches the specified \texttt{category_id}. For an example of this type of query, see Example 49.12.

sources?

requests a list of the sources available for today’s date. For an example of this type of query, see Example 49.13.

series/categories?series_id=series_ID

requests a list of the categories available for a specified \texttt{series_ID}. For an example of this type of query, see Example 49.10.
**LIMIT=limit**
limits the number of query results that are returned, where limit must be an integer between 1 and 100,000, inclusive. By default, LIMIT=1000 for releases and release date requests and LIMIT=100,000 for time series requests.

**USER=“user-folder-location”**
specifies the location of the writable folder where you permanently store SAS data sets that have one-level names. Enclose the user-folder-location in double quotation marks, and end it with a backslash if the folder is in a Windows environment or a forward slash if it is in a UNIX environment. Use the USER= option to redirect the current working folder when you see this error: Insufficient authorization to access. This error can occur if your SAS environment does not allow you to have write access in the current working folder.

**VINTAGE=‘fred_vintage_date1,fred_vintage_date2,…,fred_vintage_dateN’**
specifies one or more vintage dates in history. The fred_vintage_dates are represented in 'YYYY-MM-DD' format and are used to download the data for a time series as it existed on that specific date in history. The dates in the list are separated by commas (no blanks are allowed). When requesting multiple vintage dates, specify OUTPUT=2 to retrieve all observations or OUTPUT=3 to retrieve only new or revised observations. The default setting is no vintage dates.

Archival Federal Reserve economic data (ALFRED) enable you to retrieve vintage versions of economic data that were available on specific dates in history. To retrieve vintage versions of various time series, enter the following URL in your web browser:

https://alfred.stlouisfed.org/

To see a list of available vintage dates for each series, refer to the FRED documentation at the web page with the following URL:

https://api.stlouisfed.org/docs/fred/series_vintagedates.html

**XMLMAP=fred_xmlmapfile**
specifies the fully qualified name of the location where the XMLmap file is automatically stored. By default, XMLMAP=Fred.map.

---

**Details: SASEFRED Interface Engine**

The SASEFRED interface engine enables SAS users to access both Archival Federal Reserve Economic Data (ALFRED) and FRED data that are provided by the FRED website. Normal use is called FRED mode, for which the real-time period is the current day (today). In FRED mode, you are using the current facts: the information about the past that is available today. Economic data sources, releases, series, and observations can change their names or their observation data values over time. The real-time period marks when information was true or when information was known until it changed. Economic data sources, releases, series, and observations are all assigned a real-time period. For most URL requests, the default real-time period is today. This can be thought of as FRED mode. ALFRED users can change the real-time period to retrieve information that was known as of a point in history. ALFRED uses vintage dates, which are release dates for a series, excluding the release dates when the data values did not change.
Available Sources That Provide FRED Time Series Data

To obtain a list of the available sources of economic data, enter the following URL in your web browser. Table 49.4 shows some of the sources available.

https://api.stlouisfed.org/fred/sources?api_key=your_fred_apikey

You can use the URL= option to store today’s available sources (and associated information about the sources) in a SAS data set. For more information, see the sources query option. For an example see Example 49.13.

You can also use the URL= option to store today’s available releases (and associated information about the releases) in a SAS data set. For more information, see the releases query option. For an example see Example 49.14.

FRED API Key

The API key that is used in these examples, ‘abcdefghijklmnopqrstuvwxyz123456’, is for demonstration purposes only. To successfully download data from the FRED website, use your own FRED API key, which is a 32-character alphanumeric lowercase string. You can request your own API key by visiting the website at the following URL:

https://api.stlouisfed.org/api_key.html

Available Releases for Each Source That Provides FRED Time Series Data

Each of the FRED sources might have several releases. To get a list of the releases for a specific source, enter the following URL in your web browser and specify the ID that corresponds to that source. For example, the response to this request retrieves a list of all releases for Dow Jones & Company (source_ID=11).

https://api.stlouisfed.org/fred/source/releases?source_id=11&api_key=your_fred_apikey
Table 49.5 shows the list of releases for Dow Jones & Company.

### Table 49.5  Releases for Dow Jones & Company

<table>
<thead>
<tr>
<th>Release ID</th>
<th>Name</th>
<th>URL</th>
</tr>
</thead>
<tbody>
<tr>
<td>72</td>
<td>Daily Treasury Inflation-Indexed Securities</td>
<td>--</td>
</tr>
<tr>
<td>197</td>
<td>Dow Jones Averages</td>
<td><a href="http://www.djaverages.com">http://www.djaverages.com</a></td>
</tr>
</tbody>
</table>

#### Available Time Series for Each Release ID

Each release of economic sources contains several time series. To get the list of time series for a specific release, enter the following URL in your web browser and specify the ID that corresponds to that release. For example, the following URL retrieves a list of all time series for the Dow Jones Averages release (release_ID=197):

https://api.stlouisfed.org/fred/release/series?release_id=197&api_key=your_fred_apikey

Table 49.6 shows all the time series that are included in the Dow Jones Averages release.

### Table 49.6  Time Series for the Release of Dow Jones Averages

<table>
<thead>
<tr>
<th>Series ID</th>
<th>Title</th>
<th>Start</th>
<th>End</th>
<th>Frequency</th>

</tr>
<tr>
<td>DJUA</td>
<td>Dow Jones Utility Average</td>
<td>1929-01-02</td>
<td>2012-11-23</td>
<td>Daily</td>
</tr>
</tbody>
</table>

You can use the URL= option to store the list of available time series for a particular release in a SAS data set. For more information, see the release/series query option.

#### Available Native Frequency for Each Series ID

To find the native frequency of an economic time series, enter the following URL in your web browser. The output includes the “Frequency” field, which shows the native frequency of that time series.

https://api.stlouisfed.org/fred/series?series_id=DJCA&api_key=your_fred_apikey

The response to the preceding request follows. As the response shows, the native frequency of the Dow Jones Composite Average (DJCA) time series is Daily (frequency=Daily).

<series id="DJCA" realtime_start="2012–11–26" realtime_end="2012–11–26" title="Dow Jones Composite Average" observation_start="1934–01–02" observation_end="2012–11–23" frequency="Daily, Close" frequency_short="D" units="Index" units_short="Index" seasonal_adjustment="Not Seasonally Adjusted" seasonal_adjustment_short="NSA" last_updated="2012–11–26 09:05:12–06" popularity="48">
Vintage Dates for Each Series ID

Vintage dates are the release dates for a time series, excluding those releases in which the data did not change. To obtain a list of vintage dates for a particular series, you can enter the following URL in your web browser and specify the series ID of the series that you are interested in. For example, the following URL retrieves a list of all vintage dates for the MICH series, showing the median expected price change (the next 12 months from the Survey of Consumers):

https://api.stlouisfed.org/fred/series/vintagedates?series_id=MICH&api_key=your_fred_apikey

The resulting list of observations is too long to show here—172 vintage dates, ranging from 1999-02-26 to 2013-05-31. You can get only the vintage dates that you want by specifying the VINTAGE= option.

You can use the URL= option to store the list of available vintage dates for a particular time series in a SAS data set. For more information, see the series/vintagedates query option.

SAS Output Data Set

You can use the SAS DATA step to write the selected FRED data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the User library.

The contents of the SAS data set include the date of each observation and the series name of each series that is read from the FRED data source.

The SASEFRED interface engine maintains the sort order, so the time series are sorted in the resulting SAS data set by the order specified in the SORT= option, by date (time ID), and by variable (time series item name).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASEFRED libref to create a custom view of your data.

SAS OUTXML File

The SAS XML (XML format) data that are returned from the FRED website are placed in a file named by the OUTXML= option. The SAS XML data file is placed in the current working directory, but the SAS data set created by reading the XML data into SAS is placed in the location that is specified by the physical-name in the LIBNAME libref SASEFRED statement, which is described in the section “The LIBNAME libref SASEFRED Statement” on page 3532.

SAS XML Map File

The XML map that (by default) is automatically created is assigned the full pathname given by the XMLMAP= option in your LIBNAME libref SASEFRED statement. The map file is either reused (not overwritten) if
you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE (the default). The SASEFRED engine invokes the XMLV2 engine to create the map and to read the data into SAS.

---

**XFREDTPU SAS Data Set**

You can use the URL= option to query for useful information such as categories, tags, groups, and releases and store the information in a temporary utility data set named XFREDTPU. After you have this information, you can use it for selecting the data you want to include in a subsequent SASEFRED libref statement. For more information about the seven possible types of XFREDTPU contents, see the URL= option.

---

**Reading Price Data by Using Indices**

The following statements enable you to access the S&P 500 Stock Price Index (IDLIST=SP500) and the Wilshire 5000 Price Index (IDLIST=WILL5000PR) on a monthly basis:

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'FRED Data: SP500 Stock Index and Wilshire 5000 Price Index';
LIBNAME myLib sasefred "%sysget(FRED)"
   OUTXML=gstart
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="%sysget(FRED)gstart.map"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
   IDLIST='sp500,will5000pr'
   START='2011-01-01'
   END='2012-01-01'
   FREQ='m'
   FORMAT=xml
   ;

data stock_price;
   set myLib.gstart ;
run;

proc contents data=stock_price; run;
proc print data=stock_price; run;
```
The SASEFRED interface engine supports the XML format. The XML data that the FRED website returns are placed in a file named by the OUTXML= option. The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option. In the preceding example, the SASEFRED engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename:

FILENAME MyMap "/sasusr/playpens/saskff/fred/test/gstart.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file and to name your SAS data set created when reading the XML data into SAS; it is described in the section “SAS OUTXML File” on page 3541. The SAS data set is placed in the folder designated by ‘physical-name’, which is described in the section “The LIBNAME libref SASEFRED Statement” on page 3532. You can refer to your data by using the myLib libref in your SASEFRED LIBNAME statement. The myLib libref is shown inside the DATA step in the SET statement. The SET statement reads observations from the input data set myLib.gstart and stores them in a SAS data set named stock_price, as shown in Figure 49.2. You can also use the SAS DATA step to perform further processing and to store the resulting time series in a SAS data set; this process is described in the section “SAS Output Data Set” on page 3541.

To specify the list of time series that you want to retrieve, use the IDLIST= option. This option accepts a string enclosed in single quotation marks that denotes a list of time series that you select for the resulting SAS data set. The series IDs are separated by commas, so valid time series IDs cannot contain embedded commas or quotes. The stock_price data set contains two time series variables, sp500 and will5000pr, as specified in the IDLIST= option, and the observation range is controlled by the START= and END= options. The stock_price data set contains observations that range from January 1, 2011, to January 1, 2012, as specified by the START= and END= options. The frequency of the data is monthly, as indicated by the ‘m’ in the FREQ= option.

NOTE: The ‘%20’ is a special character for URL encoding of blanks. If the time series ID that you name in the IDLIST= option contains a blank, you must use the ‘%20’ wherever the blank appears in the time series name. If the time series ID contains an underscore, then you must use an underscore in the time series name. The underscore and the blank are not equivalent in the FRED databases, so make sure that you use the ‘%20’ (URL encoded space) to designate blank characters.
Examples: SASEFRED Interface Engine

Example 49.1: Retrieving Data for Multiple Time Series

This example shows how to use multiple time series IDs to retrieve the average balance of payment basis data for the exports (BOPXGS) and imports (BOPMGS) of goods and services for the last 15 years, starting 1997-01-01 and ending 2011-01-01, with an annual frequency.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Balance of Payment Data for the Exports and Imports';
libname _all_ clear;

libname fred sasefred "%sysget(FRED)"
   OUTXML=fredex01
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="%sysget(FRED)fredex01.map"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
   IDLIST='bopxgs,bopmgs'
   START='1997-01-01'
   END='2011-01-01'
   FREQ='a'
   OUTPUT=1
   AGG='avg'
   FORMAT=xml;

data export_import;
   set fred.fredex01 ;
run;

proc contents data=export_import; run;
proc print data=export_import; run;
```
**Example 49.2: Retrieving Data by Using the Vintage Date**

This example shows how to use the vintage date to retrieve data for exports of goods and services as they existed on that specific date in history. OUTPUT=3 retrieves the new and revised observations only, by the vintage date (VINTAGE=2012-06-14). If OUTPUT=3, then you must specify UNITS='lin'. In this example, the UNITS= option is not specified, so it assumes its default value, which is 'lin'. Specifying a different argument for the UNITS= option (such as 'chg') is invalid for OUTPUT=3, so 'chg' is replaced by the default value ('lin').

```plaintext
options validvarname=any
   ssllistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem"
   title 'Retrieve Data for the Exports of Goods and Service by Using Vintage Date';
   libname _all_ clear;

libname fred sasefred "%sysget(FRED)"
   OUTXML=fredex02
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="%sysget(FRED)frefex02.map"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
   IDLIST='bopxgsa'
   VINTAGE='2012-06-14'
   OUTPUT=3
   FORMAT=xml;

data export_vin;
   set fred.fredex02 ;
run;

proc contents data=export_vin; run;
proc print data=export_vin; run;
```
Output 49.2.1 Retrieve Data for the Exports of Goods and Services by Using the Vintage Date

Retrieve Data for the Exports of Goods and Services by Using the Vintage Date

Example 49.3: Selecting Time Series When Native Frequency Is Less Than Requested Frequency

This example shows how to retrieve data for multiple time series that have different default frequencies. The time series are Domestic Financial Commercial Paper Outstanding (DFINCP), Domestic Nonfinancial Commercial Paper Outstanding (DNFINCP), Foreign Financial Commercial Paper Outstanding (FFINCP), Foreign Nonfinancial Commercial Paper Outstanding (FNFINCP), and Total Credit Market Assets Held by Domestic Financial Sectors (ABSITCMAHDFS). The native frequency of the first four time series is ‘Weekly’, and the native frequency of the last time series (ABSITCMAHDFS) is ‘Quarterly’. Note that the requested frequency as it is specified by the FREQ= option is ‘Weekly’ (FREQ=w). The native frequency of the last time series (ABSITCMAHDFS) is lower than the requested frequency. Therefore, this time series is excluded from the list, and only the observations that correspond to the first four time series are presented. If you want to retrieve the observations for all five time series, then the value of the FREQ= option needs to be less than or equal to all the native frequencies (here, weekly and quarterly). In this case, the valid frequency parameters would be ‘q’, ‘sa’, and ‘a’. See Example 49.4.

options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Selecting Time Series When Native Frequency Is Less Than Requested Frequency';
libname _all_ clear;

libname fred sasefred "%sysget(FRED)"
   OUTXML=fredex03
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="%sysget(FRED)fredex03.map"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
   IDLIST='dfincp,dnfincp,ffincp,fnfincp,absitcmahdfs'
   START='2010-01-01'
   END='2010-05-20'
   FREQ='w'
   OUTPUT=1
   FORMAT=xml;

data diffNative_freqw;
   set fred.fredex03 ;
run;

proc contents data=diffNative_freqw; run;
proc print data=diffNative_freqw; run;
Example 49.4: Selecting Time Series When Native Frequency Is Greater Than Requested Frequency

This example shows how to retrieve data for multiple time series that have different default frequencies. The time series are Domestic Financial Commercial Paper Outstanding (DFINCP), Domestic Nonfinancial Commercial Paper Outstanding (DNFINCP), Foreign Financial Commercial Paper Outstanding (FFINCP), Foreign Nonfinancial Commercial Paper Outstanding (FNFINCP), and Total Credit Market Assets Held by Domestic Financial Sectors (ABSITCMAHDFS). The native frequency of the first four time series is ‘Weekly’, and the native frequency of the last time series (ABSITCMAHDFS) is ‘Quarterly’. The requested frequency as it is specified by the FREQ= option is ‘Quarterly’ (FREQ=q). The native frequency of all five time series is either greater than or equal to the requested frequency. Hence, the output includes the data for all time series.

options validvarname=any
       sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Selecting Time Series When Native Frequency Is Greater Than Requested Frequency';
libname _all_ clear;

libname fred sasefred "%sysget(FRED)"
       OUTXML=fredex04
       AUTOMAP=replace
       MAPREF=MyMap
Example 49.5: Specifying One Series ID with Multiple Vintage Dates for the OUTPUT=2 Option

This example demonstrates how to request the CBI time series, which show the change in private industries for three different vintage dates: 1947-08-17, 1966-08-11, and 1994-08-26. Using the early range of START='1942-01-01' and END='1947-04-01', you can get an idea of how the changes show up for each vintage date. If you specify OUTPUT=2, each time series is named by concatenating the series ID to the vintage date with an underscore.
Example 49.6: Specifying Two Series IDs with Multiple Vintage Dates and Descending Sort Order

This example demonstrates how to request the ADJRES and ADJRESN time series, which show the St. Louis adjusted reserves, the first of which is seasonally adjusted and the second of which is not seasonally adjusted. The request is made for three different vintage dates, but only 2006-08-31 and 2013-06-13 yield data when you use the range of START='2004-01-01’ and END='2012-12-01’. If you specify OUTPUT=2, each time series is named by concatenating the series ID to the vintage date with an underscore. For brevity, Output 49.6.1 shows only the first 10 and last 10 observations. The sort order is descending; that is why the dates start with the most recent observation and continue in biweekly (ending Wednesday) periods to the least recent.

Example 49.7: Vintage Dates for a Specific Series with the URL= Option

The following statements demonstrate how to use the URL= option to obtain the VINTAGE_DATE and VINTAGE_DATES data sets for a specified series and how to create a permanent data set named VINDAT1 in the MyLib SAS library. You must specify the series in both the URL= option and the IDLIST= option.

```sas
options validvarname=any
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem"
    title 'Specifying the URL= Option to Create the VINTAGE_DATES Data Set';
libname _all_ clear;
libname mylib "\sasusr\playpens\saskff\fred\doc/";
libname fred1 sasefred "%sysget(FRED)"
```

1Disclaimer: SAS may reference other websites or content or resources for use at Customer’s sole discretion. SAS has no control over any websites or resources that are provided by companies or persons other than SAS. Customer acknowledges and agrees that SAS is not responsible for the availability or use of any such external sites or resources, and does not endorse any advertising, products, or other materials on or available from such websites or resources. Customer acknowledges and agrees that SAS is not liable for any loss or damage that may be incurred by Customer or its end users as a result of the availability or use of those external sites or resources, or as a result of any reliance placed by Customer or its end users on the completeness, accuracy, or existence of any advertising, products, or other materials on, or available from, such websites or resources.
The list of available vintage dates for the N5005C1A027NBEA series is read from the XFREDtpu.xml file that is downloaded by the SASEFRED engine. The contents are shown in Output 49.7.1. The engine automatically maps the data in the XML file and reads the data into the XFREDTPU data set when the SET statement is executed. When the DATA step runs, the data in the temporary utility data set are read and stored in the permanent data set named vindat1.sas7bdat in the MyLib library. A side effect of the DATA step is the automatic creation of two SAS data sets, named vintage_date.sas7bdat and vintage_dates.sas7bdat, in the FRED1 library's location.

Example 49.8: Series for a Specific Release with the URL= Option

The following statements demonstrate how to use the URL= option to obtain the SERIES and SERIESS data sets for a specified release and how to create a permanent data set named SERIES2 in the MyLib SAS library:

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Specifying the URL= Option to Create the SERIES Data Set';
libname _all_ clear;

libname fred2 sasefred "%sysget(FRED)"
   URL="https://api.stlouisfed.org/fred/release/series?release_id=51"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX' ;

data series2;
   set fred2.XFREDtpu;
run;

proc contents
   data=series2;
run;

%macro pri10nom(datname);
   data lastob;
      set &datname nobs=last;
      last5=last-4;
      if last>10 then
         call symput('print5',last5);
      else
         call symput('print5',9);
   run;
   data getall10;
      set &datname(obs=5) &datname(firstobs=&print5);
   run;
   proc print data=getall10; run;
%mend pri10nom;

title3 "First 5/Last 5 Obs, SERIES2 Data Set";
%pri10nom(series2);
```

The returned data are stored in the XFREDTPU data set and are copied to the permanent data set named series2.sas7bdat in the MyLib library. A side effect of the DATA step is the automatic creation of two SAS data sets, named series.sas7bdat and seriess.sas7bdat, in the FRED2 library’s location. Fifty-seven series are returned for release_id=51; Output 49.8.1 shows the first and last five observations of the SERIES data set.

Example 49.9: Series for Specific Tags with the URL= Option

The following statements demonstrate how to use the URL= option to obtain the SERIES and SERIESS data sets for specified tag names and how to create a permanent data set named TAGS_SERIES4 in the MyLib SAS library:

```sas
options validvarname=any
  sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Specifying the URL= Option to Create the TAGS_SERIES4 Data Set.';
libname _all_ clear;
libname mylib "'/sasusr/playpens/saskff/fred/doc/";
libname fred4 sasefred "'/sasusr/playpens/saskff/fred/test/"
  debug=on
  URL="https://api.stlouisfed.org/fred/tags/series?tag_names=slovenia;food;oecd"
  APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
;
data mylib.tags_series4;
  set fred4.XFREDtpu;
run;

proc print
  data=mylib.tags_series4(obs=2);
run;

proc contents
  data=mylib.tags_series4;
run;
```

The returned data are stored in the XFREDTPU data set and are copied to the permanent data set named tags_series4.sas7bdat in the MyLib library. A side effect of the DATA step is the automatic creation of two SAS data sets, named series.sas7bdat and seriess.sas7bdat, in the FRED4 library’s location. Eighteen series are returned for the specified tag names; the OBS=2 option in the DATA statement in the PROC PRINT step prints only two of them. Output 49.9.1 shows the first two observations of the TAGS_SERIES4 data set.

5Disclaimer: SAS may reference other websites or content or resources for use at Customer’s sole discretion. SAS has no control over any websites or resources that are provided by companies or persons other than SAS. Customer acknowledges and agrees that SAS is not responsible for the availability or use of any such external sites or resources, and does not endorse any advertising, products, or other materials on or available from such websites or resources. Customer acknowledges and agrees that SAS is not liable for any loss or damage that may be incurred by Customer or its end users as a result of the availability or use of those external sites or resources, or as a result of any reliance placed by Customer or its end users on the completeness, accuracy, or existence of any advertising, products, or other materials on, or available from, such websites or resources.
Example 49.12: Series for a Specific Category with the URL= Option

The following statements demonstrate how to use the URL= option to obtain the SERIES data set for a specific category and how to create a permanent data set named SERIES_CAT5 in the MyLib SAS library:

```sas
options validvarname=any sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Specifying the URL= Option to Create the SERIES_CAT5 Data Set';
libname _all_ clear;
libname mylib "/sasusr/playpens/saskff/fred/doc/";

libname fred5 sasefred "/sasusr/playpens/saskff/fred/test/"
  debug=on
  URL="https://api.stlouisfed.org/fred/category/series?category_id=125"
  APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
;

data mylib.series_cat5;
  set fred5.XFREDtpu;
run;

proc print data=mylib.series_cat5;
run;

proc contents data=mylib.series_cat5;
run;
```

The returned data are stored in the XFREDTPU data set and are copied to the permanent data set named series_cat5.sas7bdat in the MyLib library. A side effect of the DATA step is the automatic creation of two SAS data sets, named series.sas7bdat and seriess.sas7bdat, in the FRED5 library’s location. Forty-five series are returned for the specified category ID, as shown in Output 49.12.1.

---

6Disclaimer: SAS may reference other websites or content or resources for use at Customer’s sole discretion. SAS has no control over any websites or resources that are provided by companies or persons other than SAS. Customer acknowledges and agrees that SAS is not responsible for the availability or use of any such external sites or resources, and does not endorse any advertising, products, or other materials on or available from such websites or resources. Customer acknowledges and agrees that SAS is not liable for any loss or damage that may be incurred by Customer or its end users as a result of the availability or use of those external sites or resources, or as a result of any reliance placed by Customer or its end users on the completeness, accuracy, or existence of any advertising, products, or other materials on, or available from, such websites or resources.

Example 49.13: Sources for Today’s Date with the URL= Option

The following statements demonstrate how to use the URL= option to obtain the first 10 sources (LIMIT=10) for the SOURCES6 data set for today’s date and how to create a permanent data set named SOURCES6 in the MyLib SAS library:

```sas
options validvarname=any sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Specifying the URL= Option to Create the SOURCES6 Data Set';
libname _all_ clear;
libname mylib "sasuser/playpens/saskff/fred/doc/";
libname fred6 sasefred "sasuser/playpens/saskff/fred/test/"
   debug=on
   URL="https://api.stlouisfed.org/fred/sources?limit=10"
   APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX';

data mylib.sources6;
   set fred6.XFREDtpu;
run;

proc print
data=mylib.sources6;
run;

proc contents
data=mylib.sources6;
run;
```

The returned data are stored in the XFREDTPU data set and are copied to the permanent data set named SOURCES6.sas7bdat in the MyLib library. A side effect of the DATA step is the automatic creation of two SAS data sets, named SOURCE.sas7bdat and SOURCES.sas7bdat, in the FRED6 library’s location. Sixty-eight sources could be returned for today’s date, but the LIMIT=10 option obtains only the first 10 sources, as shown in Output 49.13.1.

---

7Disclaimer: SAS may reference other websites or content or resources for use at Customer’s sole discretion. SAS has no control over any websites or resources that are provided by companies or persons other than SAS. Customer acknowledges and agrees that SAS is not responsible for the availability or use of any such external sites or resources, and does not endorse any advertising, products, or other materials on or available from such websites or resources. Customer acknowledges and agrees that SAS is not liable for any loss or damage that may be incurred by Customer or its end users as a result of the availability or use of those external sites or resources, or as a result of any reliance placed by Customer or its end users on the completeness, accuracy, or existence of any advertising, products, or other materials on, or available from, such websites or resources.
Example 49.14: Releases Available for Today’s Date with the URL= Option

The following statements demonstrate how to use the URL= option to obtain the first 10 observations (LIMIT=10) of the REL3 data set for today’s date and how to create a permanent data set named REL3 in the MyLib SAS library:<sup>8</sup>

```sas
options validvarname=any
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem"

title 'Specifying the URL= Option to Create the REL3 Data Set';
libname _all_ clear;
libname mylib '/sasusr/playpens/saskff/fred/doc/';
libname fred3 sasefred '/sasusr/playpens/saskff/fred/test/"
   debug=on
```

<sup>8</sup>Disclaimer: SAS may reference other websites or content or resources for use at Customer’s sole discretion. SAS has no control over any websites or resources that are provided by companies or persons other than SAS. Customer acknowledges and agrees that SAS is not responsible for the availability or use of any such external sites or resources, and does not endorse any advertising, products, or other materials on or available from such websites or resources. Customer acknowledges and agrees that SAS is not liable for any loss or damage that may be incurred by Customer or its end users as a result of the availability or use of those external sites or resources, or as a result of any reliance placed by Customer or its end users on the completeness, accuracy, or existence of any advertising, products, or other materials on, or available from, such websites or resources.
Chapter 49: The SASEFRED Interface Engine

```sas
URL="https://api.stlouisfed.org/fred/releases?limit=10"
APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
;

data mylib.rel3;
  set fred3.XFREDtpu;
run;

proc print
data=mylib.rel3;
run;

proc contents
data=mylib.rel3;
run;
```

The returned data are stored in the XFREDTPU data set and are copied to the permanent data set named rel3.sas7bdat in the MyLib library. A side effect of the DATA step is the automatic creation of two SAS data sets, named release.sas7bdat and releases.sas7bdat, in the FRED3 library's location. More than 200 available releases could be returned for today, but the LIMIT=10 option obtains only the first 10 releases, as shown in Output 49.14.1.

Overview: SASEHAVR Interface Engine

The SASEHAVR interface engine is a seamless interface between Haver Analytics and SAS data processing that enables SAS users to read economic and financial time series data that reside in a Haver Analytics DLX (Data Link Express) database. The Haver Analytics DLX economic and financial database offerings include U.S. economic indicators, specialized databases, and financial indicators; data about industry, industrial countries, emerging markets, and international organizations; forecasts and as-reported data; and data about U.S. regional services. For more information, see the section “Data Elements Reference: Haver Analytics DLX Database Profile” on page 3590.

The SASEHAVR engine uses the LIBNAME statement to enable you to specify how to subset your Haver data and how to aggregate the selected time series at the same frequency. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEHAVR engine supports both 32-bit and 64-bit Windows hosts. Haver Analytics supplies two versions of the DLX application programming interface (API), one for 32-bit applications (dlxapi32.dll) and one for 64-bit applications (dlxapi64.dll). Choose the appropriate application, either 32-bit or 64-bit, for your platform. You can follow the instructions for setting up your installation of the Haver API in the section “Setting Up the Haver Analytics DLX Application Programming Interface” on page 3578.

Getting Started: SASEHAVR Interface Engine

Setting Up the Haver Analytics DLX Application Programming Interface

If this is your first time using the SASEHAVR interface engine on your Windows machine, then it is necessary to follow these setup instructions. If you have already used the SASEHAVR interface, then just check the file version number of your already installed dlxapi32.dll (or dlxapi64.dll). For 32-bit installations, the file version is 1.1.9.0, and for 64-bit installations, the file version is 2.0.0.1. The Haver API version number appears in the SAS log the first time you assign a SASEHAVR libref. In Windows Explorer, you can see a file’s properties, including its version number, by hovering the mouse pointer over the file icon. Alternatively, you can right-click on the file icon to bring up the properties and click the Details tab to see the version number.

To set up the Haver Analytics API on your machine, visit the SAS Technical Support download site at the following URL:

First, create a folder on your system drive (usually designated as C:), and name the folder HAVER. Create an environment variable named HAVER as follows:

```
HAVER=C:\HAVER\n```

If your SAS system is 32-bit, then download the files dlxapi32.h, dlxapi32.dll, and dlxapi32.lib to your HAVER folder. If your SAS system is 64-bit, then download the files dlxapi64.h, dlxapi64.dll, and dlxapi64.lib to your HAVER folder. Second, prepend the location of your HAVER folder to the system environment variable (%PATH%) as follows, so that the SASEHAVR engine can find your downloaded Haver API files:
PATH=C:\HAVER\;%PATH%

Reboot your system to complete the Haver API setup.

---

**Structure of a SAS Data Set That Contains Time Series Data**

SAS represents time series data in a two-dimensional array called a SAS data set whose columns correspond to series variables and whose rows correspond to measurements of these variables at certain time periods. The time periods at which observations are recorded can be included in the data set as time ID variables. The SASEHAVR engine provides a time ID variable called DATE. The DATE variable can be represented in any of the time intervals shown in the section “Mapping Haver Frequencies to SAS Time Intervals” on page 3586.

---

**Reading and Converting Haver DLX Time Series**

The SASEHAVR engine supports reading and converting all selected time series that reside in Haver DLX databases. The SASEHAVR engine enables you to limit the range of data by specifying the START= and END= options in the LIBNAME statement. Start dates and end dates are recommended to help save resources when you are processing large databases or a large number of observations.

The SASEHAVR engine enables you to convert or aggregate all selected time series to a desired frequency. By default, the SASEHAVR engine selects the time series variables that match the frequency of the first selected variable. To select variables of one specific frequency, use the FREQ= option. If no selection criteria are specified, the first selected variable is the first physical DLX record read from the Haver database. To force aggregation of all selected variables to the frequency specified by the FREQ= option, use the FORCE=FREQ option. The AGGMODE= option enables you to specify a strict or relaxed aggregation method; by default, AGGMODE=RELAXED. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. If a conversion to a more frequent frequency is attempted, all missing values are returned by the Haver DLX API. For more information, see the section “Aggregating to Quarterly Frequency Using the FORCE=FREQ Option” on page 3589. The FORCE= option is ignored if the FREQ= option is not specified.

---

**Using the SAS DATA Step**

If desired, you can store your selected time series in a SAS data set by using the SAS DATA step. You can further subset your data by using the WHERE, KEEP, or DROP statement in your DATA step.

For more efficient subsetting of time series by Haver variables, Haver groups, Haver sources, Haver short sources, Haver long sources, or Haver geographic codes, you can use the corresponding KEEP=, GROUP=, SOURCE=, SHORTSOURCE=, LONGSOURCE=, GEOGCODE1=, or GEOGCODE2= option in the LIBNAME libref SASEHAVR statement. To see the available Haver selection key values, including geographic codes, short sources, and long sources for your database, specify the OUTSELECT=ON option. From the OUTSELECT= option output, you can use convenient wildcard symbols to create the selection list for your next LIBNAME libref SASEHAVR statement.
There are three wildcard symbols: ‘*’, ‘?’, and ‘#’. The ‘*’ wildcard corresponds to any character string and includes any string pattern that corresponds to that position in the matching variable name. The ‘?’ stands for any single alphanumeric character. Lastly, the ‘#’ wildcard corresponds to a single numeric character.

You can also deselect time series by Haver variables, by Haver groups, by Haver sources, by Haver short sources, by Haver long sources, or by Haver geographic codes, by using the corresponding DROP=, DROPGROUP=, DROPSOURCE=, DROPSHORT=, DROPLONG=, DROPGEOG1=, or DROPGEOG2= option. These options also support wildcards.

After your selected data are stored in a SAS data set, you can use these data as you would any other SAS data set.

Using the SAS Windowing Environment

You can see the available data sets in the SAS LIBNAME window of the SAS windowing environment by selecting the SASEHAVR libref in the LIBNAME window that you have previously defined in your LIBNAME statement. You can view your SAS output observations by double-clicking on the desired output data set libref in the LIBNAME window of the SAS windowing environment. You can type Viewtable on the SAS command line to view your SASEHAVR tables, views, or librefs.

Before you use Viewtable, it is recommended that you store your output data sets in a physical folder or library that is separate from the folder or library used for your input databases. (The default location for output data sets is the SAS Work library.) If you do not follow this guideline, you will receive the following error message for each input database that does not have the selected options in the SASEHAVR libref that you double-clicked:

ERROR: No variable selected with current options.

Syntax: SASEHAVR Interface Engine

The SASEHAVR engine uses standard engine syntax. Table 50.1 summarizes the options used in the LIBNAME libref SASEHAVR statement.

<table>
<thead>

**LIBNAME libref SASEHAVR Statement**

LIBNAME libref sasehavr ‘physical name’ options;

The ‘physical name’ specifies the location of the folder where your Haver DLX database resides.

You can use the following options in the LIBNAME libref SASEHAVR statement:
Chapter 50: The SASEHAVR Interface Engine

FREQ=\textit{haver\_frequency}
FREQUENCY=\textit{haver\_frequency}
INTERVAL=\textit{haver\_frequency}

specifies the Haver frequency. All Haver frequencies are supported by the SASEHAVR engine. Accepted frequency values are annual, year, yearly, quarter, quarterly, qtr, monthly, month, mon, week.1, week.2, week.3, week.4, week.5, week.6, week.7, weekly, week, daily, and day.

START=\textit{start\_date}
STARTDATE=\textit{start\_date}
STDATE=\textit{start\_date}
BEGIN=\textit{start\_date}

specifies the start date for the time series in the form YYYYMMDD.

END=\textit{end\_date}
ENDDATE=\textit{end\_date}
ENDATE=\textit{end\_date}

specifies the end date for the time series in the form YYYYMMDD.

KEEP=“\textit{haver\_variable\_list}”

specifies the list of Haver variables to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

DROP=“\textit{haver\_variable\_list}”

specifies the list of Haver variables to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GROUP=“\textit{haver\_group\_list}”
KEEPSOURCE=“\textit{haver\_source\_list}”

specifies the list of Haver groups to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GROUP=“\textit{haver\_group\_list}”
KEEPSOURCE=“\textit{haver\_source\_list}”

specifies the list of Haver groups to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GROUP=“\textit{haver\_group\_list}”
KEEPSOURCE=“\textit{haver\_source\_list}”

specifies the list of Haver sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GROUP=“\textit{haver\_group\_list}”
KEEPSOURCE=“\textit{haver\_source\_list}”

specifies the list of Haver sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GROUP=“\textit{haver\_shortsource\_list}”
KEEPSHORT=“\textit{haver\_shortsource\_list}”

specifies the list of Haver short sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.
DROPSHORT="haver_shortsource_list"
DROPSHORTSOURCE="haver_shortsource_list"

specifies the list of Haver short sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

LONG="haver_longsource_list"
KEEPLONG="haver_longsource_list"
LONGSOURCE="haver_longsource_list"

specifies the list of Haver long sources to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

DROPLONG="haver_longsource_list"
DROPLONGSOURCE="haver_longsource_list"

specifies the list of Haver long sources to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GEOG1="haver_geographycode1_list"
KEEPGEOG1="haver_geographycode1_list"
GEOGCODE1="haver_geographycode1_list"

specifies the list of Haver geography1 codes to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

DROPGEOG1="haver_geographycode1_list"
DROPGEOGCODE1="haver_geographycode1_list"

specifies the list of Haver geography1 codes to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

GEOG2="haver_geographycode2_list"
KEEPGEOG2="haver_geographycode2_list"
GEOGCODE2="haver_geographycode2_list"

specifies the list of Haver geography2 codes to be included in the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

DROPGEOG2="haver_geographycode2_list"
DROPGEOGCODE2="haver_geographycode2_list"

specifies the list of Haver geography2 codes to be excluded from the output SAS data set. This list is comma-delimited and must be surrounded by double quotation marks.

OUTSELECT=ON | OFF

specifies what the output data set shows. OUTSELECT=ON specifies that the output data set show values of selection keys (such as geography codes, groups, sources, short sources, and long sources) for each selected variable name (time series) in the database. OUTSELECT=OFF specifies that the output data set show the observations in the range for all selected time series. The default is OUTSELECT=OFF.

AGGMODE=STRICT | RELAXED

specifies whether the SASEHAVR engine uses a strict or relaxed aggregation method when converting time series from a higher to lower frequency.
A strict aggregation method returns a missing value whenever there is a missing observation in a time period. For instance, if a monthly time series has a missing value for the month of February 2005, then attempting to aggregate to a quarterly frequency results in a missing value for the first quarter of 2005. The SAS log reports the status of this option.

When a relaxed aggregation method is used, some observations can be missing, but the relaxed method returns an aggregated value calculated from the nonmissing data points according to the series aggregation type (average, sum, or end of period). Average type only needs one valid (nonmissing) data point to calculate the average. Sum type needs all the data points to be available in order to sum the values. End of period type calculates the end of period value if there is at least one valid (nonmissing) data point in the aggregated span. It returns the last available valid data point in the aggregated span. The default is AGGMODE=RELAXED.

**FORCE=FREQ**
specifies that the selected variables be aggregated to the frequency in the FREQ= option. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. For sample output and suggested error recovery from attempting a conversion that yields missing values when a higher frequency conversion is specified, see the section “Aggregating to Quarterly Frequency Using the FORCE=FREQ Option” on page 3589. This option is ignored if the FREQ= option is not set. For a more complete discussion of Haver frequencies and SAS time intervals, see the section “Mapping Haver Frequencies to SAS Time Intervals” on page 3586.

Following is an example of the LIBNAME libref SASEHAVR statement:

```
LIBNAME libref sasehavr 'physical-name'
    FREQ=MONTHLY;
```

By default, the SASEHAVR engine reads all time series in the Haver database that you reference by `libref`. The start date is specified in the form YYYYMMDD. The start date is used to delimit the data to a specified start date.

For example, to read the time series in the TEST library starting on July 4, 1996, specify the following statement:

```
LIBNAME test sasehavr 'physical-name'
    STARTDATE=19960704;
```

When you use the START= option, you limit the range of observations that are read from the time series and that are converted to the desired frequency. Start dates can help save resources when processing large databases or when processing a large number of observations. It is also possible to select specific variables to be included or excluded from the SAS data set by using the KEEP= or DROP= option, respectively.

```
LIBNAME test sasehavr 'physical-name'
    KEEP="ABC*, XYZ??";
```

```
LIBNAME test sasehavr 'physical-name'
    DROP="*SC*, #T#";
```

When the KEEP= or DROP= option is used, the resulting SAS data set keeps or drops the variables that you select in that option. Three wildcards are available: ‘*’, ‘?’, and ‘#’. The ‘*’ wildcard corresponds to any character string and includes any string pattern that corresponds to that position in the matching variable name. The ‘?’ means that any single alphanumeric character is valid. The ‘#’ wildcard corresponds to a single numeric character. You can also select time series in your data by using the GROUP=, SOURCE=, SHORT=,
LONG=, GEOG1=, or GEOG2= option to select on the group name, source name, short source name, long source name, geography1 code, or geography2 code, respectively. Alternatively, you can deselect time series by using the DROPGROUP=, DROPSOURCE=, DROPSHORT=, DROPLONG=, DROPGEOG1=, or DROPGEOG2= option, respectively.

Following are examples that perform variable selection (or deselection) based on groups or sources:

```sas
LIBNAME test sasehavr 'physical-name'
GROUP="CBA, ZYX";

LIBNAME test sasehavr 'physical-name'
DROPGROUP="TKN*, XCZ?";

LIBNAME test sasehavr 'physical-name'
SOURCE="FRB";

LIBNAME test sasehavr 'physical-name'
DROPSOURCE="NYSE";
```

The SASEHAVR engine selects only the variables that are of the specified frequency in the FREQ= option. If this option is not specified, the SASEHAVR engine selects the variables that match the frequency of the first selected variable. If no other selection criteria are specified, by default the first selected variable is the first physical DLX record read from the Haver database. You can specify the FORCE=FREQ option to force the aggregation of all variables selected to be of the frequency specified in the FREQ= option. Aggregation is supported only from a more frequent time interval to a less frequent time interval, such as from weekly to monthly. For suggested recovery from using a frequency that does not aggregate the data appropriately, see the section “Aggregating to Quarterly Frequency Using the FORCE=FREQ Option” on page 3589. The FORCE= option is ignored if the FREQ= option is not specified. The AGGMODE= STRICT option is used when a strict aggregation method is desired. The default value for AGGMODE is RELAXED, the same method that was used in prior releases of the SASEHAVR engine.

---

**Details: SASEHAVR Interface Engine**

**SAS Output Data Set**

You can use the SAS DATA step to write the Haver converted series to a SAS data set so that you can easily analyze the data using the SAS System. You can specify the name of the output data set in the DATA statement. This causes the engine supervisor to create a SAS data set with the specified name in either the SAS Work library or, if specified, the Sasuser library.

When OUTSELECT=OFF (the default), the contents of the SAS data set include the date of each observation, the name of each series read from the Haver database, and the label or Haver description of each series. Missing values are represented as '.' in the SAS data set. You can use the PRINT procedure and the CONTENTS procedure to print your output data set and its contents. You can use the SQL procedure along with the SASEHAVR engine to create a view of your SAS data set.

The DATE variable in the SAS data set contains the date of the observation. The SASEHAVR engine automatically maps the Haver intervals to the appropriate corresponding SAS intervals.
When OUTSELECT=ON, the OUT= data set does not contain the observations of all time series. Instead, each observation contains the name of the time series, the source of the time series, the geography1 code, the geography2 code, the short source, and the long source for that time series. In addition, the contents of the OUT= data set shows every selected time series name and label. For more information about the OUTSELECT=ON option, see Output 50.11.1 and Output 50.11.2.

A more detailed discussion of how to map Haver frequencies to SAS time intervals follows.

**Mapping Haver Frequencies to SAS Time Intervals**

Table 50.2 summarizes the mapping of Haver frequencies to SAS time intervals. For more information, see Chapter 4, “Date Intervals, Formats, and Functions.”

**Error Recovery for the SASEHAVR Interface Engine**

Common errors are easy to avoid by noting the valid dates that are specified in the warning messages in your SAS log. Often you can get rid of errors by removing the date restriction (START= and END= options), by removing the FORCE=FREQ option, or by deleting the FREQ= option so that the frequency defaults to the original frequency rather than attempting a conversion.

Following are some common error scenarios and how to handle them.

**Using the Optimum Range for Best Output Results**

Suppose you see the following warnings in your SAS log:
libname kgs2 sasehavr "%sysget(HAVER_DATA)"
    start= 19550101 end=19600105
    keep="FCSEED, FCSEEI, FCSEEM, BGSX, BGSM, FXDUSBC"
    group="I01, F56, M02, R30"
    source="JPM,CEN,OMB" ;

NOTE: Libref KGS2 was successfully assigned as follows:
    Engine: SASEHAVR
    Physical Name: C:\haver

data kgse9;
    set kgs2.haver;
    NOTE: Defaulting to MONTHLY frequency.
WARNING: Start date (19550101) is not a valid date.
    Engine is ignoring your start date and using default. Setting the default Haver start date to 7001.
WARNING: End date (19600105) is not a valid date.
    Engine is ignoring your end date and using default. Setting the default Haver end date to 10103.
run;

NOTE: There were 375 observations read from the data set KGS2.HAVER.
NOTE: The data set WORK.KGSE9 has 375 observations and 4 variables.

The important diagnostic to note here is the warning message that tells you that the data start in January 1970 (Haver date 7001) and end in March 2001 (Haver date 10103). Since the specified range falls outside the range of data, no observations are in range. So the engine uses the default range stated in the warning messages. Change the START= and END= options to overlap the results in data that span from JAN1970 to MAR2001. To view the entire range of selected data, remove the START= and END= options from the LIBNAME statement:

libname kgs sasehavr "%sysget(HAVER_DATA)"
    keep="FCSEED, FCSEEI, FCSEEM, BGSX, BGSM, FXDUSBC"
    group="I01, F56, M02, R30"
    source="JPM,CEN,OMB" ;

NOTE: Libref KGS was successfully assigned as follows:
    Engine: SASEHAVR
    Physical Name: C:\haver

data kgse5;
    set kgs.haver;
    NOTE: Defaulting to MONTHLY frequency.
    run;

NOTE: There were 375 observations read from the data set KGS.HAVER.
NOTE: The data set WORK.KGSE5 has 375 observations and 4 variables.

Using a Valid Range of Data with START= and END= Options

In this example, an error about an invalid range is issued:
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Weekly
start=20060301 end=20060531;
NOTE: Libref LIB1 was successfully assigned as follows:
  Engine: SASEHAVR
  Physical Name: C:\haver
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
  Engine: V9
  Physical Name: \dntsrc\usrtmp\saskff
data lib2.wweek;
  set lib1.intwkly;
ERROR: No observations found inside RANGE.
  The valid range for HAVER dates is (610104–1050318).
ERROR: No observations found in specified range.
    keep date m11: ;
  run;
WARNING: The variable date in the DROP, KEEP, or RENAME list
  has never been referenced.
WARNING: The variable m11: in the DROP, KEEP, or RENAME list
  has never been referenced.
NOTE: The SAS System stopped processing this step because of errors.
WARNING: The data set LIB2.WEEK may be incomplete.
    When this step was stopped there were 0
  observations and 0 variables.
WARNING: Data set LIB2.WEEK was not replaced because this step was stopped.
The important diagnostic message is the first error statement, which tells you that the range of Haver dates
is not valid for the specified frequency. A valid range is one that overlaps the dates (610104–1050318).
Removing the range altogether causes the engine to output the entire range of data.

libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Weekly;

NOTE: Libref LIB1 was successfully assigned as follows:
  Engine: SASEHAVR
  Physical Name: C:\haver
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
  Engine: V9
  Physical Name: \dntsrc\usrtmp\saskff
data lib2.wweek;
  set lib1.intwkly;
  keep date m11: ;
  run;

NOTE: There were 2307 observations read from the data set LIB1.INTWKLY.
NOTE: The data set LIB2.WEEK has 2307 observations and 35 variables.

Since the START= and END= options give day-based dates, it is important to use dates that correspond to the
FREQ= option when giving a range of dates, especially with weekly frequencies such as WEEK.1–WEEK.7.
Since FREQ=WEEK.4 selects weeks that begin on Wednesday, the start and end dates need to be specified as
Wednesday dates.
libname lib1 sasehavr "%sysget(HAVER_DATA)" freq=Week.4
  start=20050302 end=20050309;
NOTE: Libref LIB1 was successfully assigned as follows:
  Engine: SASEHAVR
    Physical Name: \tappan\crsp1\haver
title2 'Weekly dataset with freq=week.4 range is small';
libname lib2 "\\dntsrc\usrtmp\saskff" ;
NOTE: Libref LIB2 was successfully assigned as follows:
  Engine: V9
    Physical Name: \dntsrc\usrtmp\saskff

data lib2.wweek;
  set lib1.intwkly;
  keep date m11: ;
run;
NOTE: There were 2 observations read from the data set LIB1.INTWKLY.
NOTE: The data set LIB2.WWEEK has 2 observations and 25 variables.

Giving bad dates (for example, Tuesday dates) for a Wednesday FREQ=WEEK.4 results in the following error:

ERROR: Fatal error in GetDate routine.
  Remove the range statement or change the START= date to be consistent with the freq=option.
ERROR: No observations found in specified range.

Aggregating to Quarterly Frequency Using the FORCE=FREQ Option

In the next example, six time series are selected by the KEEP= option. Their frequencies are annual, monthly, and quarterly, so when the FREQ=WEEKLY and FORCE=FREQ options are used, a diagnostic appears in the log stating that the engine is forcing the frequency to QUARTERLY for better date alignment of observations. The first selected variable is BALO, which is a quarterly time series and causes the default choice of FREQ to be quarterly.

title1 '***HAVKWC.SAS: KEEP= option tests with wildcards***';

%setup( ets );

/*----------------*/
/* Wildcard: * */
/*----------------*/

title2 "keep=B*, G*, I*";
title3 "6 valid variables are: BALO BGSM BGSX BPBCA G IUM";
libname lib1 sasehavr 'C:\haver\' keep="B*, G*, I*"
    freq=weekly force=freq;
NOTE: Libref LIB1 was successfully assigned as follows:
  Engine: SASEHAVR
    Physical Name: C:\haver

data wc;
  set lib1.haver;
WARNING: Earliest Start Date in DLX Database matches QUARTERLY frequency better than the specified WEEKLY frequency. Engine is forcing the frequency to QUARTERLY for better date alignment of observations.

run;

NOTE: There were 221 observations read from the data set LIB1.HAVER. NOTE: The data set WORK.WC has 221 observations and 7 variables.

Note that the time series IUM is an annual frequency. The attempt to convert to a quarterly frequency produces all missing values in the output range because aggregation produces only missing values when forced to go from a lower frequency to a higher frequency.

Data Elements Reference: Haver Analytics DLX Database Profile

The Haver DLX economic and financial database offerings include U.S. economic indicators, specialized databases, financial indicators, industry, industrial countries, emerging markets, international organizations, forecasts and as-reported data, and U.S. regional service. Table 50.3 is a list of available databases and the corresponding description of each.

Examples: SASEH AVR Interface Engine

Before running the following sample code, set your HAVER_DATA environment variable to point to the SAS/ETS SASMISC folder that contains sample Haver databases. The provided sample data files are HAVERD.DAT, HAVERD.IDX, HAVERW.IDX, and HAVERW.DAT. In the following example, the Haver database is called haverw, and it resides in the directory lib1. The DATA statement names the SAS output data set hwouty, which will reside in the Work library.

Example 50.1: Examining the Contents of a Haver Database

To see which time series are in your Haver database, use the CONTENTS procedure with the SASEH AVR LIBNAME statement to read the contents.

```
libname lib1 sasehavr "%sysget(HAVER_DATA)"
   freq=yearly start=19920101
   end=20041231
   force(freq);

data hwouty;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, HAVERW.DAT';
title2 'PROC CONTENTS for Time Series converted to yearly frequency';
proc contents data=hwouty;
run;
```

All time series in the Haver haverw database are listed alphabetically in Output 50.1.1.

Output 50.1.1 Examining the Contents of Haver Analytics Database, haverw.dat

Haver Analytics Database, HAVERW.DAT
PROC CONTENTS for Time Series converted to yearly frequency

The CONTENTS Procedure

<table>

</tbody>
</table>

You could also use the following SAS statements to create a SAS data set named hwouty and to print its contents:
Example 50.2: Viewing Quarterly Time Series from a Haver Database

The following statements specify a quarterly frequency conversion of all time series for the period spanning April 1, 2001, to December 31, 2004:

```
libname lib1 sasehavr "%sysget(HAVER_DATA)"
  freq=quarterly
  start=20010401
run;
```

```
Haver Analytics Database, Frequency=quarterly, infile=haverw.dat
Define a range inside the data range for OUT= dataset,;
Using the START=20010401 END=20041231 LIBNAME options.
```

```
proc print data=hwoutq;
run;
```

The preceding LIBNAME Lib1 statement specifies that all time series in the haverw database be converted to a quarterly frequency but to select only the range of data from April 1, 2001, to December 31, 2004. The resulting SAS data set, hwoutq, is shown in Output 50.1.2.

**Output 50.1.2** Defining a Range inside the Data Range for Quarterly Time Series

Chapter 50: The SASEHAVR Interface Engine

```sas
end=20041231
force=freq;

data hwoutq;
   set lib1.haverw;
run;

title1 'Haver Analytics Database, Frequency=quarterly, infile=haverw.dat';
title2 'Define a range inside the data range for OUT= dataset';
title3 'Using the START=20010401 END=20041231 LIBNAME options.';
proc print data=hwoutq;
run;
```

The resulting SAS data set `hwoutq` is shown in Output 50.2.1.

### Output 50.2.1 Defining a Range inside the Data Range for Quarterly Time Series

**Haver Analytics Database, Frequency=quarterly, infile=haverw.dat**
Define a range inside the data range for OUT= dataset
Using the START=20010401 END=20041231 LIBNAME options.

Example 50.3: Viewing Monthly Time Series from a Haver Database

The following statements convert weekly time series to a monthly frequency:

```sas
libname lib1 sasehavr "%sysget(HAVER_DATA)"
   freq=monthly
   start=20040401
   end=20041231
   force=freq;

data hwoutm;
   set lib1.haverw;
run;
```
Example 50.4: Viewing Weekly Time Series from a Haver Database

The following statements show weekly data that span from September 1, 2004, to December 31, 2004:

    libname lib1 sasehavr "%sysget(HAVER_DATA)"
    freq=weekly
    start=20040901
    end=20041231;

    data hwoutw;
      set lib1.haverw;
    run;

    title1 'Haver Analytics Database, Frequency=weekly, infile=haverw.dat';
    title2 ' Define a range inside the data range for OUT= dataset';
    title3 ' Using the START=20040901 END=20041231 LIBNAME options.';

    proc print data=hwoutw;
    run;

Output 50.4.1 shows the output.

---

The result from using the range of April 1, 2004, to December 31, 2004, is shown in Output 50.3.1.

Example 50.5: Viewing Daily Time Series from a Haver Database

Consider viewing the Haver Analytics daily database named haverd. The contents of this database can be seen by submitting the following DATA step:

```plaintext
libname lib1 sasehavr "%sysget(HAVER_DATA)"
   freq=daily
   start=20041201
   end=20041231;

data hwoutd;
   set lib1.haverd;
run;

title1 'Haver Analytics Database, HAVERD.DAT';
title2 'PROC CONTENTS for Time Series converted to daily frequency';
proc contents data=hwoutd;
run;
```
Output 50.5.1 shows the output of PROC CONTENTS with the time ID variable DATE followed by the time series variables FCM10, FCM1M, FFED, FFP1D, FXAUS, and TCC with their corresponding attributes such as type, length, format, and label.

**Output 50.5.1** Examining the Contents of a Daily Haver Analytics Database, haerdl.dat

**Example 50.6: Limiting the Range of Time Series from a Haver Database**

The following statements limit the range of data to the month of December:

```sas
libname lib1 sasehavr "%sysget(HAVER_DATA)"
  freq=daily
  start=20041201
  end=20041231;

data hwoutd;
  set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haerdl.dat';
title2 ' Define a range inside the data range for OUT= dataset';
title3 ' Using the START=20041201 END=20041231 LIBNAME options.';

proc print data=hwoutd;
run;
```

Note that **Output 50.6.1** for daily conversion shows the frequency as the SAS time interval for WEEKDAY.
Output 50.6.1  Defining a Range inside the Data Range for Daily Time Series

Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041201 END=20041231 LIBNAME options.

Example 50.7: Using the WHERE Statement to Subset Time Series from a Haver Database

Using a WHERE statement in the DATA step can be useful for further subsetting.

```plaintext
libname lib1 sasehavr "%sysget(HAVER_DATA)"
   freq=daily start=20041101 end=20041231;

data hwoutd;
   set lib1.haverd;
   where date between '01nov2004'd and '01dec2004'd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 'Define a range inside the data range for OUT= dataset';
title3 'Using the START=20041101 END=20041231 LIBNAME options.';
title4 'Subset further: where date between 01nov2004 and 31dec2004.';
proc print data=hwoutd;
run;
```
Output 50.7.1 shows that the time slice of November 1, 2004, to December 31, 2004, is narrowed further by the DATE test in the WHERE statement to stop at December 1, 2004.

**Output 50.7.1** Defining a Range Using the WHERE Statement, START=20041101, and END=20041231

Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041231 LIBNAME options.
Subset further: where date between 01nov2004 and 31dec2004.

Example 50.8: Using the KEEP Option to Subset Time Series from a Haver Database

To select specific time series, you can use the KEEP= or DROP= option as follows:

```plaintext
libname lib1 sasehavr "sysget(HAVER_DATA)"
    freq=daily
    start=20041101
    end=20041231
    keep="FCM*";

data hwoutd;
    set lib1.haverd;
run;
```

Output 50.8.1 shows two series that are selected by using KEEP="FCM*" in the LIBNAME statement.
Output 50.8.1 Using the KEEP Option and Defining a Range Using START=20041101 and END=20041231

Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041231 LIBNAME options.
Subset further: Using keep="FCM*" LIBNAME option

</table>
You can use the DROP option to drop specific variables from a Haver database. To specify this option, use DROP= instead of KEEP=.

Example 50.9: Using the SOURCE Option to Subset Time Series from a Haver Database

You can use the SOURCE= or DROPSOURCE= option to select specific variables that belong to a certain source, similar to the way you use the KEEP= or DROP= option.

```sas
libname lib1 sasehavr "%sysget(HAVER_DATA)"
    freq=daily
    start=20041101
    end=20041223
    source="FRB";

data hwoutd;
    set lib1.haverd;
run;

title1 'Haver Analytics Database, Frequency=daily, infile=haverd.dat';
title2 'Define a range inside the data range for OUT= dataset';
title3 'Using the START=20041101 END=20041231 LIBNAME options.';
title4 'Subset further: Using keep="FCM***" LIBNAME option';
proc print data=hwoutd;
run;
```

Output 50.9.1 shows two series that are selected by using SOURCE="FRB" in the LIBNAME statement.
### Output 50.9.1 Using the SOURCE Option and Defining a Range Using START=20041101 and END=20041223

Haver Analytics Database, Frequency=daily, infile=haverd.dat
Define a range inside the data range for OUT= dataset
Using the START=20041101 END=20041223 LIBNAME options.
Subset further: Using source="FRB" LIBNAME option

Example 50.10: Using the GROUP Option to Subset Time Series from a Haver Database

You can use the GROUP= or DROPGROUP= option to select specific variables that belong to a certain group, similar to the way you use the KEEP= or DROP= option.

Output 50.10.1, Output 50.10.2, and Output 50.10.3 show three different cross sections of the same database, haverw, by specifying three unique GROUP= options: GROUP="F*" in LIBNAME LIB1, GROUP="M*" in LIBNAME LIB2, and GROUP="E*" in LIBNAME LIB3.

The following statements specify GROUP="F*" in the LIBNAME LIB1 statement:

```
libname lib1 sasehavr "%sysget(HAVER_DATA)"
   freq=week.6
   force=freq
   start=20040102
   end=20041001
   group="F*";

data hwoutwA;
   set lib1.haverw;
run;
```

```
title1 'Haver Analytics Database, Frequency=week.6, infile=haverw.dat';
title2 'Define a range inside the data range for OUT= dataset';
title3 'Using the START=20040102 END=20041001 LIBNAME options.';
title4 'Subset further: Using group="F*" LIBNAME option';
proc print data=hwoutwA;
run;
```

Output 50.10.1 shows the output.
**Example 50.10: Using the GROUP Option to Subset Time Series from a Haver Database**

**Output 50.10.1** Using the GROUP=F* Option and Defining a Range

Haver Analytics Database, Frequency=week.6, infile=haverw.dat

Define a range inside the data range for OUT= dataset

Using the START=20040102 END=20041001 LIBNAME options.

Subset further: Using group="F*" LIBNAME option

Example 50.11: Using the OUTSELECT=ON Option to View the Key Selection Variables in a Haver Database

Suppose you want to select your time series based on geography codes or source codes. To construct your wildcard for selection, first run with the OUTSELECT=ON option to see the possible values for each selection key.

```sas
Libname lib1 sasehavr "%sysget(HAVER_DATA)";
outselect=on ;

data validD1;
  set lib1.haverd;
run;

title1 'OUTSELECT=ON, Print the OUT= Data Set';
title2 'Shows the Values for Key Selection Variables:';
title3 'Name, Source, Geog1, Geog2, Shortsrc, Longsrc';
title4 'OUTSELECT=ON, the CONTENTS Procedure with Variable Names and Labels';
proc print data=validD1;
run;

proc contents data=validD1;
run;
```

Output 50.11.1 shows the output values for each key selection variable.

Output 50.11.1 OUTSELECT=ON Option Shows the Values for Key Selection Variables

<table>

</tr>
</tbody>
</table>

If you also want to see a list of all the variables and their corresponding labels for this OUTSELECT=ON data set, you can run the CONTENTS procedure.

Output 50.11.2 shows the contents of the output data set.
Example 50.12: Selecting Variables Based on Short Source Key Code

Using the information from Example 50.11, you can now select time series by using selection keys such as the SHORT=, GEOG1=, or GEOG2= option. Since the short source values are nontrivial in the database haverd, it is best in this case to use the SHORT= option. For more information about using geography codes as selection keys, see Output 50.13.1 for the GEOG1= option and Output 50.13.2 for the GEOG2= option.

```
Libname lib1 sasehavr "%sysget(HAVER_DATA)"
   short="GOLDMAN, FRB, CRB"
   data validE2;
         set lib1.haverd;
         where date between '18jan2005'd and '29mar2005'd;
   run;

   title1 'SHORT= option list: GOLDMAN, FRB, CRB';
   title2 'Should contain these time series:';
   title3 'FCM10, FCM1M, FFED, FFP1D';
   title4 'SHORT= option, Print the OUT= ValidE2 Data Set';
   proc print data=validE2;
   run;

   title4 'SHORT= option, Print the Contents of OUT= ValidE2 Data Set';
   proc contents data=validE2;
   run;
```

Output 50.12.1 shows the output for the SHORT= option.
Output 50.12.1  SHORT= Option Shows the Selected Variables

SHORT= option list: GOLDMAN, FRB, CRB
Should contain these time series:
FCM10, FCM1M, FFED, FFP1D
SHORT= option, Print the OUT= ValidE2 Data Set

Example 50.13: Selecting Variables Based on Geography Key Codes

Since the hadver database did not have interesting geography codes, the following statements access the INTWKLY database by using its more complete geography key codes to select the desired time series from the specified geography codes:

```
Libname lib1 sasehavr "%sysget(HAVER_DATA_NEW)"
   outselect=on
   keep="R273RF3,X924USBE,R023DF,R273G1,F023A,F158FBS,F023ACR,X156VEB,F023ACE";

data valid1(keep=NAME SOURCE GEOG1 GEOG2 SHORTSRC LONGSRC);
   set lib1.intwkly;
run;
```

```
title1 'OUTSELECT=ON, Print the OUT= Data Set';
title2 'Shows the Values for Key Selection Variables:';
title3 'Name, Source, Geo1, Geo2, Shorts, Longs';
title4 'OUTSELECT=ON, the CONTENTS Procedure with Variable Names and Labels';
proc print data=valid1;
```
run;

Libname lib2 sasehavr "%sysget(HAVER_DATA_NEW)"
  geog1="156";

data valid2(
  keep=date R273RF3 X924USBE R023DF R273G1 F023A F158FBS F023ACR X156VEB F023ACE);
  set lib2.intwkly;
run;

  title1 'Only one GEOG1 Code, 156, contains time series X156VEB';
  title2 'Select Geography Code 1 Option:';
  title3 'GEOG1= option';
  title4 'Only Time Series X156VEB has Geog1 = 156';

proc contents
  data=valid2;
run;

Libname lib3 sasehavr "%sysget(HAVER_DATA_NEW)"
  geog2="299";

data valid3(
  keep=date R273RF3 X924USBE R023DF R273G1 F023A F158FBS F023ACR X156VEB F023ACE);
  set lib3.intwkly;
run;

  title1 'Only one GEOG2 Code, 299, contains time series X156VEB';
  title2 'Select Geography Code 2 Option:';
  title3 'GEOG2= option';
  title4 'Only Time Series X156VEB has Geog2 = 299';

proc contents
  data=valid3;
run;

  title1 'Compare GEOG1 Code 156';
  title2 'Over nonmissing values range';
  title3 'With GEOG2 Code 299';
  title4 'Over nonmissing values range';

proc compare listall briefsummary criterion=1.0e-5
  base=valid2(    
    where=( date between '09jan1998'd and '28dec2007'd ))
  compare=valid3(    
    where=( date between '09jan1998'd and '28dec2007'd ));
run;

Overview: SASENOAA Interface Engine

The SASENOAA interface engine enables SAS programmers to retrieve severe weather data from the National Oceanic and Atmospheric Administration (NOAA) Severe Weather Data Inventory (SWDI) web service, which is hosted jointly by the NOAA’s National Environmental Satellite Data and Information Service (NESDIS), the US Department of Commerce National Climatic Data Center (NCDC), the University of North Carolina at Asheville’s National Environmental Modeling and Analysis Center (NEMAC), and the Renaissance Computing Institute (RENCI) at UNC Asheville.

The SWDI web service offers access to severe weather data such as tornado vortex signatures; mesocyclone signatures; the digital mesocyclone detection algorithm; hail data; storm cell structure; preliminary local storm reports; and severe thunderstorm, tornado, flash flood, and special marine warnings. The SWDI lightning data are not accessible to the public, so they are not supported by the SASENOAA interface engine.

It is important to note that the absence of SWDI weather data for a geographic region or time period does not necessarily indicate that severe weather did not occur at that place or time; instead, the interpretation should be that severe weather was not detected or reported by NOAA’s SWDI data sources. In addition, because much of the SWDI’s information is derived from radar data, its usefulness is primarily that it provides data that indicates probable conditions for an event rather than confirming the actual occurrence of an event.

The SASENOAA interface engine uses the LIBNAME statement to enable you to specify how to retrieve your NOAA Severe Weather data and which weather data time series or storm events you want to retrieve based on date range and weather station location. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set or in map files (such as Google Earth’s KMZ files or Esri shapefiles). You can perform more analysis (if desired) either in the same SAS session or in a later session. You can map your results in Google Maps by importing the resulting KML file, or you can map your results in SAS by using PROC MAPIMPORT and PROC GMAP to create a map from the resulting Esri shapefiles (which have the filename extension .shp).

The SASENOAA interface engine is supported on SAS running on Linux X64 (LAX) and Windows. Although the SASENOAA engine uses the NOAA SWDI API, it is not endorsed or certified by either NOAA or the National Weather Service. By using the SASENOAA interface engine, you are agreeing to comply with the NOAA SWDI terms of use, which are described on the web page at the following URL:

http://www.weather.gov/disclaimer/

Getting Started: SASENOAA Interface Engine

You can query the SWDI data sets to retrieve the observations or data values for a list of time series or events by specifying the data format (FORMAT= option), the data set to access (NOAASET= option), and the date range (RANGE= option).

The SASENOAA engine’s FORMAT= option supports three formats: XML (default), SHP, and KMZ. The XML format stores the weather data results in a SAS data set (.sas7bdat) named in the OUTXML= option, and when applicable, in two additional data sets: one for message text output (_M.sas7bdat), and another for statistics output (_S.sas7bdat).
The SHP format produces a ZIP file that contains four Esri shapefiles (with the extensions .shp, .shx, .dbf, and .prj). The SASENOAA interface unzips the SHP ZIP file to surface the four Esri files. The KMZ format produces a ZIP file (with the extension .kmz) that can be opened in virtual globe software such as Google Earth. The SASENOAA engine unzips the KMZ file to produce the resulting KML file, which can then be imported into Google Maps to create a detailed map of the SWDI time series data.

The NOAASET= option is required. You can specify one of the following Next-Generation Radar (NEXRAD) Level III types: nx3tvs (tornado vortex signatures), nx3meso (mesocyclone signatures), nx3mda (digital mesocyclone detection algorithm), nx3hail (hail signatures), or nx3structure (storm cell structure information). You can also specify two other types: plsr (preliminary local storm reports) and warn (severe thunderstorm, tornado, flash flood, and special marine warnings).

After you specify both the NOAASET= option and the format, you must also use the RANGE= option to specify the date range of the data that you are selecting for output, as shown in the following example.

The statements that follow enable you to access the severe weather tornado vortex signature (TVS) events that are recorded in the nx3tvs database for the date range beginning May 5, 2006, and ending May 6, 2006. The observations are sorted in chronological order (the datetime variable is ztime). The output is shown in Figure 51.1.

```sas
options validvarname=any
        sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Tornado Vortex Signature Data for the Range 20060505:20060506';
libname _all_ clear;

libname mylib "'/sasusr/playpens/saskff/noaa/doc/";
libname noaa sasenoaa "'/sasusr/playpens/saskff/noaa/test/"
   NOAASET=nx3tvs
   RANGE='20060505:20060506'
   OUTXML=cinco
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="/sasusr/playpens/saskff/noaa/test/cinco.map"
   FORMAT=xml;

data mylib.mycinco;
   set noaa.cinco;
run;

proc contents data=mylib.mycinco; run;
proc print data=mylib.mycinco(obs=10); run;
```

</table>

The XML data that the NOAA SWDI web service returns are placed in a file that is named by the OUTXML= option—in this case, CINCO1.xml. Note that the SASENOAA engine appends a numeral to the XML filename, and the file extension (.xml) is excluded from the filename that appears in the OUTXML= option. This XML data file resides in the location that is given inside the string enclosed in double quotation marks in the SASENOAA LIBNAME statement. So, in the preceding example, if the NOAA_DATA environment variable is set to /sasusr/playpens/saskff/noaa/test/, then the downloaded XML file is located at /sasusr/playpens/saskff/noaa/test/CINCO1.xml. An equivalent LIBNAME statement that does not use any environment variables could be as follows:

```
libname noaa sasenoaa "/sasusr/playpens/saskff/noaa/test/"
  NOAASET=nx3tvs
  RANGE='20060505:20060506'
  OUTXML=cinco
  XMLMAP="/sasusr/playpens/saskff/noaa/test/cinco.map"
  AUTOMAP=replace
  MAPREF=MyMap
  FORMAT=xml;
```

The XML map that is created is assigned the full pathname that the XMLMAP= option specifies. The SASENOAA engine appends a numeral to the XML filename to prevent filenames from being overwritten during multiple read requests.
The RANGE= option specifies the start date and end date for the range of days for which you want to retrieve data. This option accepts a string, enclosed in single quotation marks, that gives start and end dates (in 'YYYYMMDD' format) so that only the recorded severe weather events from the selected dates are included. The result, MYCINCO, is named in the DATA step and is shown in Figure 51.1.

It is more efficient to use the DATA step to store your NOAA SWDI data in a SAS data set and then refer to the SAS data set directly in your PROC statements. You can also refer to the SASENOAA libref directly, as in the statement

   proc print data=noaa.cinco(obs=10);

The PROC PRINT statement uses the member name, CINCO; this usage corresponds to the OUT-XML=CINCO option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASENOAA libref, the SASENOAA interface engine reads the entire XML file into SAS again. So it is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly.

The SASENOAA interface engine supports the XML format by placing the XML data that the NOAA SWDI web service returns in a file named by the OUTXML= option. The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option. In the preceding sample code, the SASENOAA engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename:

   FILENAME MyMap "/sasusr/playpens/saskff/noaa/test/cinco.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file; it is described in the section “SAS OUTXML File” on page 3643. The XML data file is placed in the folder that is designated by physical-name, which is described in the section “The LIBNAME libref SASENOAA Statement” on page 3631. You can refer to your data by using the NOAA libref defined in your SASENOAA LIBNAME statement. The NOAA libref is shown inside the DATA step in the SET statement. The SET statement reads observations from the input data set Noaa.cinco and stores them in a SAS data set named Mycinco, as shown in Figure 51.1. You can also use the SAS DATA step to perform further processing and to store the resulting time series in a SAS data set; this process is described in the section “SAS Output Data Set” on page 3641.

In summary, to specify the NOAA SWDI data set that you want to retrieve, use the NOAASET= option. This required option accepts a string that names the desired NOAA data set, in this case, NOAASET=NX3TVS. The RANGE= option is also required and selects the date range based on the ztime variable, which is the time ID variable for the resulting SAS data set. The Mycinco data set contains the NX3TVS data variables whose observation range is controlled by the RANGE= option. The Mycinco data set contains observations that start May 5, 2006, and end the same day, as specified by the end date May 6, 2006, which is excluded from the selected data. NOTE: The begin date on the RANGE= option is inclusive, but the end date is exclusive of the data.
Chapter 51: The SASENOAA Interface Engine

The SASENOAA interface engine uses standard engine syntax to read the observations or data values for NOAA SWDI data sets that can each contain one or more events or time series. Table 51.1 summarizes the options that the SASENOAA engine uses.

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMAP=</td>
<td>Specifies whether or not to overwrite the existing XML map file.</td>
</tr>
<tr>
<td>BBOX=</td>
<td>Specifies the geographic area to report on by defining a bounding box in the format 'minLon,minLat,maxLon,maxLat' for minimum longitude, minimum latitude, maximum longitude, maximum latitude. For example: BBOX='(-91,30,-90,31)'.</td>
</tr>
<tr>
<td>CENTER=</td>
<td>Specifies the center point ('longitude,latitude)' (to nearest tenth of a degree) of the geographic area to retrieve data for. Use this option with the RADIUS= option to complete the specification.</td>
</tr>
<tr>
<td>CONNECT=</td>
<td>Specifies whether or not you need the connect method for a secure connection via a proxy server. You must specify the PROXY= option when you specify CONNECT=ON.</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not you need diagnostic message logging in the SAS log window.</td>
</tr>
<tr>
<td>FILTERBY=</td>
<td>Specifies the weather station to retrieve data for.</td>
</tr>
<tr>
<td>FILTERBYCONDITION=</td>
<td>Specifies the condition for selection of the weather station.</td>
</tr>
<tr>
<td>FORMAT=</td>
<td>Specifies a file extension that indicates the type of file to retrieve. Only XML, SHP, and KMZ file types are supported for the SASENOAA engine.</td>
</tr>
<tr>
<td>ID=</td>
<td>Specifies an ID to retrieve the text message in the warning or the preliminary local storm report databases.</td>
</tr>
<tr>
<td>KMZMAP=</td>
<td>Specifies the fully qualified filename for the KMZ map that the SASENOAA engine creates. This filename is usually the same as the one in the OUTKMZ= option.</td>
</tr>
<tr>
<td>LIMIT=</td>
<td>Specifies the maximum number of observations to use in the report.</td>
</tr>
<tr>
<td>NOAASET=</td>
<td>Specifies the required NOAA data set name to access in the Severe Weather Data Inventory.</td>
</tr>
<tr>
<td>OFFSET=</td>
<td>Specifies the offset to the number of observations to start the report.</td>
</tr>
<tr>
<td>OUTKMZ=</td>
<td>Specifies the name for the downloaded KMZ file. The SASENOAA engine also unzips the KMZ file and gives the KML file this name.</td>
</tr>
<tr>
<td>OUTSHP=</td>
<td>Specifies the name for the downloaded SHP ZIP file. The SASENOAA engine also unzips the SHP file and uses this name for the four Esri shapefiles.</td>
</tr>
<tr>
<td>OUTXML=</td>
<td>Specifies the name for the XML data that are downloaded from the SWDI web service containing the time series/event data. This name is also used to create the SAS data sets that contain the SWDI data.</td>
</tr>
<tr>
<td>PROXY=</td>
<td>Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, use the CONNECT=ON option in addition to the PROXY= option. See the CONNECT= option.</td>
</tr>
</tbody>
</table>
Table 51.1  continued

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>RADIUS=</td>
<td>Specifies the radius (in miles, measured from the CENTER= option value’s</td>
</tr>
<tr>
<td></td>
<td>coordinates) of the geographic area to retrieve data for. This option must</td>
</tr>
<tr>
<td></td>
<td>be used with the CENTER= option.</td>
</tr>
<tr>
<td>RANGE=</td>
<td>Specifies the start date and end date for reading the severe weather data in</td>
</tr>
<tr>
<td></td>
<td>'YYYYMMDD:YYYYMMDD' format. The range must be within the same calendar year</td>
</tr>
<tr>
<td></td>
<td>unless you are requesting statistics only by also specifying the STAT= option.</td>
</tr>
<tr>
<td></td>
<td>The start date is inclusive of the data, but the end date is exclusive of the data. There is a special option (PERIODOFRECORD) that returns the valid range availability of data for the requested data set specified in the NOAASET= option.</td>
</tr>
<tr>
<td>SHPMAP=</td>
<td>Specifies the fully qualified filename for the SHP map that the SASENOAA engine creates. This filename is usually the same as the one in the OUTSHP= option.</td>
</tr>
<tr>
<td>STAT=</td>
<td>Specifies the statistical operation that you want to perform on the requested severe weather data</td>
</tr>
<tr>
<td>TILE=</td>
<td>Specifies the coordinates of a geographic location to the nearest tenth of a degree. For the earlier example of –95.45,36.88, the matching tile would contain values from –95.4500 to –95.5499 and from 36.8500 to 36.9499.</td>
</tr>
<tr>
<td>XMLMAP=</td>
<td>Specifies the fully qualified filename for the XML map that the SASENOAA engine creates. This filename is usually the same as the one in the OUTXML= option.</td>
</tr>
</tbody>
</table>

The LIBNAME libref SASENOAA Statement

```
LIBNAME libref SASENOAA 'physical-name' options ;
```

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory where you want the NOAA Severe Weather Data Inventory (SWDI) files to be downloaded and stored. The required `physical-name` argument specifies the location of the folder where your SWDI XML or data shapefiles reside. The `physical-name` should end with a backslash if you are in a Windows environment and a forward slash if you are in a UNIX environment. The designated folder that is specified in the `physical-name` argument must already exist before you submit the LIBNAME libref SASENOAA statement.

You can specify the following `options` in the LIBNAME libref SASENOAA statement.

**AUTOMAP=REPLACE | REUSE**

- **REPLACE** specifies whether or not to overwrite the existing XML map file.
- **REUSE** specifies that the XML map file not be overwritten, and ensures that a pre-existing XML map file that is named by the XMLMAP= option is used.

By default, AUTOMAP=REPLACE. The AUTOMAP= option is used only with the XML format (the default).
BBOX='noaa_bbox_coordinates'
specifies the coordinates that define the bounding box in the format 'minLon,minLat,maxLon,maxLat'. This option enables you to select the severe weather data that lie within the geographic area bounded by the box that is defined within the intersections of the specified paired sets of parallels and meridians.

CENTER='noaa_center_coordinates'
specifies the center coordinates (longitude, latitude) of a geographic area that, when used along with the RADIUS= option, enable you to select the severe weather data from within the circle whose center is at the specified coordinates (CENTER= option) and of the specified radius (RADIUS= option). An example request follows for “Get all nx3tvs occurring on May 6, 2006, within 15 miles of latitude = 32.7 and longitude = –102.0 and return as XML”:

```
LIBNAME libref sasenoaa 'physical-name'
FORMAT=xml
NOAASET=nx3tvs
RANGE='20060506:20060507'
RADIUS='15.0'
CENTER='-102.0,32.7'
OUTXML=mytvs;
```

CONNECT=ON | OFF
specifies whether or not to use the connect method along with the PROXY= option. NOTE: You must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option when you want to use the connect method. For more information about a secure connection, see the PROXY= option.

DEBUG=ON | OFF
specifies whether or not to include diagnostic message logging in the SAS log window. This information can be very useful for troubleshooting a problem.

FILTERBY='noaa_filterby_column_value_pair'
specifies the column name and column value, separated by a colon, to filter the data by. Most often, the column name is WSR_ID and the column value is one of the NEXRAD III weather station ICAO codes shown in Table 51.2.

FILTERBYCONDITION='noaa_filterbyCond_column_cond_pair'
specifies the column name and condition value, separated by a colon, to filter the data by. Most often, the column name is WSR_ID and the condition is AND | OR. An example request follows:

```
LIBNAME libref sasenoaa 'physical-name'
FORMAT=xml
NOAASET=nx3hail
RANGE='20110521:20110522'
FILTERBY='WSR_ID:KFWS'
FILTERBYCONDITION='WSR_ID:or'
OUTXML=byNexR;
```

See also the FILTERBY= option.
The LIBNAME libref SASENOAA Statement  ➤  3633

**FORMAT=XML | KMZ | SHP**

specifies the format of the file to be retrieved from the NOAA SWDI web service. Although this service can report data in many formats, the SASENOAA engine supports only the XML, SHP, and KMZ formats. When you specify FORMAT=XML, the downloaded data file is named by the OUTXML= option and mapped using the fully designated physical filename specified in the XMLMAP= option. Similarly, when you specify FORMAT=KMZ, use the OUTKMZ= and KMZMAP= options to name your results; and when you specify FORMAT=SHP, use the OUTSHP= and SHPMAP= options to name your results. **NOTE:** Only one format specification is allowed in each SASENOAA LIBNAME statement.

**ID='noaa_id_messageno'**

specifies the message number to retrieve the complete text of the message for the data set specified in the NOAASET= option. ID numbers can be read from the ID column in the results data set (named in the OUTXML= option) for either the warn or plsr data set. The ID= option is used with either the warn or plsr data set to retrieve the entire message that matches the message number indicated in the ID= option for the desired data set, either the NOAA severe storm warnings (warn data set) or the preliminary local storm reports (plsr data set). See Example 51.1 for sample code that shows that the output from the ID= option is placed in the SAS data set named by appending _M to the member name specified in the OUTXML= option.

**KMZMAP=noaa_kmzmapfile**

specifies the fully qualified name of the location where the KMZ map file (zipped KML map file) is automatically stored.

**LIMIT=noaa_limit**

limits the number of observations in the results data set. Specify a number from 1 to 10,000,000.

**MAPREF=noaa_xmlmapref**

specifies the fileref to use for the map assignment. For an example of the SASENOAA engine that uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename, as in the following, see the section “Getting Started: SASENOAA Interface Engine” on page 3626:

```
FILENAME MyMap "/sasusr/playpens/saskff/noaa/test/gstart.map"
```

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file. It is placed in the folder that is designated by physical-name in your SASENOAA LIBNAME statement, and you can reference it by using the myLib libref. This is shown in the section “Getting Started: SASENOAA Interface Engine” on page 3626, inside the DATA step in the SET statement. The SET statement reads observations from the input data set myLib.GSTART and stores them in a SAS data set named ShearV.

**NOAASET=noaa_data set_SWDI_dsname**

specifies the name of the NOAA SWDI data set that you want to access. Use one of the following names: nx3tvs, nx3meso, nx3mda, nx3hail, nx3structure, plsr, or warn. For a complete description of each data set, see the section “Details: SASENOAA Interface Engine” on page 3636.
OFFSET=\texttt{noaa\_offset}

specifies a starting row number (offset) in the results to use as your first observation in the results data set.

OUTKMZ=\texttt{noaa\_kmzfile}

specifies the name of the file where the KMZ data (FORMAT=KMZ) that are returned from the SWDI web service are stored. It is recommended that you specify the OUTKMZ= option when the FORMAT=KMZ option is specified. In cases where the two options do not correspond, the FORMAT= option overrides the designated OUTKMZ= option.

\textbf{NOTE:} The KMZ format produces a ZIP file whose name contains the corresponding file extension (.kmz). The SASENOAA engine automatically unzips the KMZ file to produce a KML map file. The KMZMAP= option gives the name and location of the resulting .kml file.

OUTSHP=\texttt{noaa\_shpfile}

specifies the name of the file where the SHP data (FORMAT=SHP) that are returned from the SWDI web service are stored. It is recommended that you specify the OUTSHP= option when the FORMAT=SHP option is specified. In cases where the two options do not correspond, the FORMAT= option overrides the designated OUTSHP= option.

\textbf{NOTE:} The SHP format produces a ZIP file whose name contains the corresponding file extension (.shp). The SASENOAA engine automatically unzips the SHP file to produce four Esri map files with the file extensions .dbf, .prj, .shp, and .shx. For example, if OUTSHP=MYSBY and FORMAT=SHP, then the files that contain the SWDI data are named MYSBY.dbf, MYSBY.prj, MYSBY.shp, and MYSBY.shx.

OUTXML=\texttt{noaa\_xmlfile}

specifies the name of the file where the XML data (FORMAT=XML), KMZ data (FORMAT=KMZ), or SHP data (FORMAT=SHP) that are returned from the SWDI web service are stored. When FORMAT=XML, additional SAS data sets are provided by the SASENOAA engine, depending on two options: ID= and STAT=. When an ID= option is also specified, the engine appends _M to the OUTXML= specification to name the resulting SAS data set that contains the message text that the SWDI web service returns. When the STAT= option is also specified, the engine appends _S to the OUTXML= specification to name the resulting data set that contains the counts from the statistical operation that is performed.

It is recommended that you specify the OUTXML= option when the FORMAT=XML option is specified. In cases where the two options do not correspond, the FORMAT= option overrides the designated OUTXML= option.

PROXY="\texttt{noaa\_proxyserver}"

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused error or a connection-timed-out error occurs. For \texttt{noaa\_proxyserver}, specify the server’s HTTP address followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY="http://inetgw.unx.sas.com:8118". See also the CONNECT= option.
RADIUS='noaa_radius'
specifies the search radius (in miles) of the area to retrieve the severe weather data for. The current limit for the search radius is 15 miles. This option must be used with the CENTER= option.

RANGE='noaa_range'
specifies the date range to report severe (past) weather for. The format for noaa_range is 'YYYYMMDD:YYYYMMDD'. The range must fall within the period of record for the desired data set. The NOAA SWDI data web service returns the period of record for the requested data set (in this case, nx3hail) at the following URL:

http://www.ncdc.noaa.gov/swdiws/xml/nx3hail/periodOfRecord

It also returns a begin date and end date, giving the available time range of data to choose from. Although the limit for a range is one year, often only a few days of data are requested, unless the STAT= option is used. More than one year is allowed in the RANGE= option when you also use the STAT= option to request the COUNT, which returns only the number of observations in the results data set.

SHPMAP=noaa_shpmapfile
specifies the fully qualified name of the location where the SHP map file (zipped Esri shapefiles) is automatically stored.

STAT='noaa_stat_op'
specifies the statistical operation that you want to perform on the requested severe weather data. You can specify one of the following values for noaa_stat_op within single quotes:

COUNT
returns number of results only (no actual data).

COUNTGROUPBY:WSR_ID
returns number of results for each BY group (each WSR_ID that returns data).

TILESUM:longitude,latitude
returns daily feature counts for a tenth-of-a-degree grid centered at the specified coordinates.

Although the SASENOAA engine automatically checks the statistics to make sure there is a nonzero observation count before requesting the specified data, it is often useful to use the STAT= option to determine the best geographic area and the best date range to retrieve severe weather data that are of the most interest. Output from the STAT= option is placed in the SAS data set named by appending _S to the member name specified in the OUTXML= option.

TILE='noaa_tile_coordinates'
specifies that you want to search for severe weather data in the geographic area within a 0.1 degree tile that is centered at the specified coordinates (longitude, latitude).

XMLMAP=noaa_xmlmapfile
specifies the fully qualified name of the location where the XML map file is automatically stored.
Details: SASENOAA Interface Engine

The SASENOAA interface engine enables SAS programmers to access the NOAA Severe Weather Data Inventory (SWDI) data sets. All dates and times are in Greenwich mean time (GMT), and all latitude and longitude values for input parameters and output data are in the World Geodetic System 1984 (WGS84) datum, the standard for geospatial information.

NOAA Severe Weather Data Inventory Data Sets

The following data sets are supported:

- **NX3TVS**: NEXRAD level III tornado vortex signatures
- **NX3MESO**: NEXRAD level III mesocyclone signatures
- **NX3MDA**: NEXRAD level III digital mesocyclone detection algorithm
- **NX3HAIL**: NEXRAD level III hail signatures
- **NX3STRUCTURE**: NEXRAD level III storm cell structure information
- **PLSR**: Preliminary local storm reports
- **WARN**: Severe thunderstorm, tornado, flash flood, and special marine warnings

To display details about the available inventory for the NEXRAD level III data sets, enter the following URL in your browser:

http://www.ncdc.noaa.gov/swdiws/xml

The result is a list of available SWDI web service data sets, each with a description, begin date, end date, tile summary allowed (yes or no), and ID query allowed (yes or no). The web page at the following URL describes the column definitions and units for each NEXRAD III product and includes a discussion about accuracy:

http://www.ncdc.noaa.gov/swdiws/csv/nx3hail:inv

NOAA NEXRAD Sites and Their ICAO Codes and Coordinates

A list of the NEXRAD sites and their corresponding WSR_ID codes, also known as International Civil Aviation Organization (ICAO) codes, is given in Table 51.2. For examples of how to use this important BY variable, WSR_ID, to subset and gather statistics about NOAA SWDI data, see Example 51.6 and Example 51.4.

SAS Output Data Set

You can use a SAS DATA step to write the selected NOAA Severe Weather Data Inventory data to a SAS data set. This enables you to use SAS software to easily perform data analysis. If you specify the name of the output data set in the DATA statement, the SAS engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the SAS User library.

The contents of the SAS data sets are described in the section “Examples: SASENOAA Interface Engine” on page 3644 and summarized in Table 51.3 through Table 51.7. Each type of SWDI data set contains its own columns and variables, and the resulting SAS data set is named by the OUTXML= option specification. When the ID= option is used, another SAS data set is created with _M appended to the original data set name, and if the STAT= option is used, then another data set is created with _S appended to the original data set name.

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASENOAA engine libref to create a custom view of your data.

</tbody>
</table>

The storm cell identification and tracking (SCIT) algorithm is an enhanced WSR-88D algorithm that is outside the scope of this chapter, but this section briefly summarizes some of the variables in the NX3MDA
data set. Storm-relative depth is the ratio (expressed in percentage) of meso-depth divided by the storm depth as determined by the SCIT algorithm’s cell. Strength ranking and mesocyclone strength index (MSI) are nondimensional numbers that provide a way to determine the 3D-integrated intensity value of the detection.

Max_rv_kft is the height (in kilofeet) at which maximum rotational velocity was detected; it might or might not be associated with the lowest radar elevation angle. Max_rv_kts is the rotational velocity in knots; it might or might not be associated with the lowest radar elevation angle. The variables ll_rot_vel, ll_dv, and ll_base are always associated with the lowest elevation angle, so max_ and ll_ values are sometimes identical.

**SAS OUTXML File**

The SAS XML (XML format) data that are returned by the NOAA SWDI web service are placed in a file that is named by the OUTXML= option. The SASENOAA interface engine creates a separate XML file for each SAS data set that is created. By default, OUTXML=NOAA, which creates a file named NOAA.xml in the current working directory. The SAS data set created when the XML data are read into SAS is placed in the folder specified by the physical path in the LIBNAME libref SASENOAA statement, which is described in the section “The LIBNAME libref SASENOAA Statement” on page 3631. The name that you specify in the OUTXML= option is also used to form the names of other data sets, but a suffix is added to the name to maintain the identity of the file, such as _M for the message file data set (ID= option) and _S for the statistics results data set (STAT= option).

**SAS XML Map File**

The XML map that (by default) is automatically created is assigned the full pathname that is given by the XMLMAP= option in your LIBNAME libref SASENOAA statement. The map file is either reused (not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE (the default). The SASENOAA interface engine invokes the XMLV2 engine to create the map and to read the data into SAS.

**Virtual Globe Mapping Output and ZIP Files**

When you specify the FORMAT=KMZ option, the SASENOAA interface engine requests the SWDI data in KMZ format. This results in the retrieval of a zipped KML file, which is then unzipped, saved with the .kml extension, and named by the OUTKMZ= option. In addition, the corresponding KMZ file is saved in the location specified by the fully qualified filename given in the KMZMAP= option. You can then use virtual globe software provided by Google Maps to import your KML data so that you can visualize the results both geospatially and timewise by holding the mouse pointer over each data point to see the variable values that correspond to the requested NOAA data set.

When you specify the FORMAT=SHP option, the SASENOAA engine requests the SWDI data in SHP format. This results in the retrieval of a zipped SHP file, which is then unzipped; the four resulting files are saved with the extensions .dbf, .prj, .shp, and .shx and named by the OUTSHP= option. In addition, the corresponding SHP ZIP file is saved in the location that is specified by the fully qualified filename given in the SHPMAP= option. You can then use virtual globe software such as SAS Bridge for Esri or use PROC MAPIMPORT and PROC GMAP to map your results.
SAS KMZ Map File

The KMZ map (by default) is automatically created and placed in the file that is named by the fully qualified filename specified in the KMZMAP= option of the LIBNAME libref SASENOAA statement. The SASENOAA interface engine invokes PROC HTTP to create the map and to read the KMZ data into SAS.

SAS OUTKMZ File

The SAS KMZ (zipped KML format) data that are returned by the NOAA SWDI web service are placed in a file that is named by the OUTKMZ= option. The SASENOAA interface engine unzips the KMZ file and creates a separate KML file for each SASENOAA engine libref. The SAS KML data file is given the name specified by the OUTKMZ= option and is placed in the location that is specified by the physical-name in your LIBNAME libref SASENOAA statement, which is described in the section “The LIBNAME libref SASENOAA Statement” on page 3631.

SAS OUTSHP File

The SAS SHP (zipped Esri shapefiles format) data that are returned by the NOAA SWDI web service are placed in a file that is named by the OUTSHP= option. The SASENOAA interface engine creates a separate SHP ZIP file for each SASENOAA engine libref. The SASENOAA engine unzips the SHP data file, creating four files that are given the name specified by the OUTSHP= option plus the four file extensions (.dbf, .prj, .shp, and .shx). The four files are saved in the location that is specified by the physical-name in your LIBNAME libref SASENOAA statement, which is described in the section “The LIBNAME libref SASENOAA Statement” on page 3631.

SAS SHP Map File

The SHP map (by default) is automatically created and placed in the file that is named by the fully qualified filename specified in the SHPMAP= option of the LIBNAME libref SASENOAA statement. The SASENOAA interface engine invokes PROC HTTP to create the map and to read the SHP data into SAS.

Examples: SASENOAA Interface Engine

Example 51.1: Retrieving Severe Storm Warning Data with ID= Option for a Specific Date

This example shows how to use the RANGE= option to retrieve severe storm warning data for a specific date. It also shows how to use the ID= option to read the message text for one ID (ID=’397190’). When the ID= option is used, there are two output data sets. The first data set consists of the warning results data (named C1nco in the OUTXML= option), which contain the actual list of storm warnings for the date range that is specified in the RANGE= option. The second data set, C1nco_M, contains the text of the message ID specified in the ID= option, which in this example is 397190.

The output of the PRINT procedure for the MyC1nco data set is shown in Output 51.1.1.
Example 51.1: Retrieving Severe Storm Warning Data with ID= Option for a Specific Date

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Warning Data with ID= Option for May 5, 2006';
libname _all_ clear;
libname mylib "/sasusr/playpens/saskff/noaa/doc/"
   noaaset=warn
   id='397190' / * create c1nco_m data set */
   range='20060505:20060506'
   outXml=c1nco / * create c1nco data set */
   automap=replace
   mapref=MyMap
   xmlmap="/sasusr/playpens/saskff/noaa/test/c1nco.map"
   format=xml;

data mylib.myclnco;
   set noaa.c1nco;
run;
proc contents data=mylib.myclnco; run;
proc print data=mylib.myclnco(obs=5); run;
```

**Output 51.1.1** NOAA Severe Storm Warnings with ID= Option for May 5, 2006

**Retrieve Warning Data with ID= Option for May 5, 2006**

3 POLYGON((-90.06 29.34, -89.8 29.15, -89.6 29.27, -89.6 29.35, -89.6 29.35, -89.77 29.33, -89.75 29.41, -89.81 29.43, -89.83 29.49, -89.93 29.51, -89.94 29.48, -90.07 29.55, -90.18 29.51, -91.06 29.43, -90.06 29.34))

4 POLYGON((-90.06 29.34, -89.8 29.15, -89.6 29.27, -89.6 29.35, -89.77 29.33, -89.75 29.41, -89.81 29.43, -89.83 29.49, -89.93 29.51, -89.94 29.48, -90.07 29.55, -90.18 29.51, -91.06 29.43, -90.06 29.34))

5 POLYGON((-91.57 33.33, -91.73 33.01, -91.17 33.02, -91.14 33.07, -91.2 33.14, -91.09 33.16, -91.14 33.29, -91.57 33.33))
The data sets, C1nco and C1nco_M, reside in the test folder, because that is the physical path given in the SASENOAA LIBNAME statement inside the double quotes:

```
libname noaa sasenoaa "\sasusr\palypens\saskff\noaa\test/"
```

**NOTE:** The DATA step that creates the Mylib.Myc1nco data set reads only the C1nco data into the document folder that is specified by the Mylib libref:

```
libname mylib "\sasusr\playpnes\saskff\noaa\doc/";
```

But the other data set, which contains the message text data set, C1nco_M, is not copied into the document folder; instead it remains in the test folder where it was originally created by the SASENOAA engine. You could also copy it into the document folder using the following code:

```
libname myMes "U:\noaa940\test\"

data mylib.myc1nco_M;
  set myMes.c1nco_M;
run;
```

You should not use the SASENOAA engine libref (NOAA) to access the already created SAS data set C1nco_M, because the message results were already placed in that data set automatically when you ran the example code to download the XML from the SWDI web service. The ID= option causes the SASENOAA engine to create the second data set, C1nco_M. After you read the data into SAS, you should use the normal Base SAS engine to access the resulting SAS data sets, by using the myMes libref in the SET statement that invokes the Base SAS engine.
Example 51.2: Retrieving a Preliminary Local Storm Report by Using a Bounding Box

This example shows how to use a bounding box (by specifying the BBOX= option) to define the geographic area to retrieve a preliminary local storm report (PLSR) starting May 5 and ending May 10 (not including May 10). The output is shown in Output 51.2.1 for the data set My8bb and in Output 51.2.2 for the data set My8bb_M.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve the NOAA SWDI PLSR Data for a Bounding Box';
libname _all_ clear;
libname mylib "/sasusr/playpens/saskff/noaa/doc/";
libname noaa sasenoaa "/sasusr/playpens/saskff/noaa/test/
   noaaset=plsr
   range='20060505:20060510'
   bbox='91,30,-90,31'
   id='427200'
   outXml=my8BB
   automap=replace
   mapref=MyMap
   xmlmap="/sasusr/playpens/saskff/noaa/test/my8BB.map"
   format=xml
   ;

data mylib.PLSRbb;
   set noaa.my8BB;
run;

proc contents data=mylib.PLSRbb; run;
proc print data=mylib.PLSRbb; run;
```

The RANGE= option selects only the storm reports for dates from May 5 to May 10, 2006 (not including May 10), and the BBOX= option limits the data returned to the geographic area defined by the intersection of the specified coordinates: minimum longitude, minimum latitude, maximum longitude, and maximum latitude. The ID='427200' option returns additional data in the SAS data set my8bb_M for the storm event that has that ID, and the results can be viewed using the following sample code. **NOTE:** The SASENOAA engine appends _M to the name specified in the OUTXML= option for these additional data.

```sas
libname myreport '/sasusr/playpens/saskff/noaa/test/';
proc contents data=myreport.my8bb_m; run;
proc print data=myreport.my8bb_m; run;
```

**Output 51.2.2** Preliminary Local Storm Report for Tornado Event, ID=427200

</table>

The results are sorted by the ztime variable, along with WSR_ID, which is a BY variable that can be referenced in the STAT= option (such as STAT='COUNTGROUPBY:WSR_ID') or in the FILTERBY= option (such as FILTERBY='WSR_ID:KBLX'). For a list of possible values for WSR_ID, see the ICAO Location Identifiers column in Table 51.2.
Example 51.4: Retrieving Hail Data for One Weather Station

This example shows how to use the FILTERBY= and FILTERBYCONDITION= options to retrieve the data for one weather station (WSR_ID=KFWS) by using the hail storm data from the NX3HAIL database for May 21, 2011. The output is shown in Output 51.4.1.

```sas
options validvarname=any
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve NX3HAIL Data for WSR_ID=KFWS on May 21, 2011';
libname _all_ clear;
libname mylib "'/sasusr/playpens/saskff/noaa/doc/";

libname noaa sasenoaa "'/sasusr/playpens/saskff/noaa/test/"
    noaaset=nx3hail
    range='20110521:20110522'
    filterBy='WSR_ID:=KFWS'
    filterByCondition='WSR_ID:=or'
    outXml=myCby
    automap=replace
    mapref=MyMap
    xmlmap="/sasusr/playpens/saskff/noaa/myCby.map"
    format=XML;

data mylib.HAILbyC;
    set noaa.myCby;
run;

proc contents data=mylib.HAILbyC; run;
proc print data=mylib.HAILbyC(obs=10); run;
```

**Output 51.4.1** Severe Hail Storm Data Using FILTERBY= Option for Weather Station KFWS on May 21, 2011

</table>

You can see that the output data set, myCby, returns only the data for WSR_ID='KFWS' because of the FILTERBY= and FILTERBYCONDITION= options.
Example 51.5: Retrieving Tornado Vortex Signature Data within a Distance Specified by a Center and a Radius

When you specify NOAASET=NX3TVS, you retrieve data that show an intense gate-to-gate azimuthal shear associated with tornadic-scale rotation. This example shows how to search the NX3TVS database by using the RADIUS= and CENTER= options to retrieve tornado vortex signature data for the date range from May 5 to May 16, 2006. The output is shown in Output 51.5.1.

**Example 51.6: Retrieving Digital Mesocyclone Detection Algorithm Data for a Specific Date**

The digital mesocyclone detection algorithm data (NX3MDA) are the successor to the legacy mesocyclone data (NX3MESO) and are designed to display information about the existence and nature of rotations associated with thunderstorms. Numerical output includes the azimuth, range, and height of the mesocyclone. This example retrieves these data for June 8, 2016. The first 10 observations are shown in Output 51.6.1.

```sas
%include 'c9nco.sas ';
options validvarname=any;

*title 'Digital Mesocyclone Detection Algorithm Data for June 8, 2016';
libname _all_ clear;
libname mylib '/sasusr/playpens/saskff/noaa/doc/';

The SASENOAA engine creates a temporary data set named OUTTP1 that shows the recorded feature (mesocyclone detection algorithm) count for each BY group by WSR_ID. The count represents the number of mesocyclones detected by that weather station. This information can be helpful for determining which geographic area to focus on and is generated automatically by the engine when you specify STAT='COUNTGROUPBY:WSR_ID'. The SASENOAA engine does not save this data set unless the STAT= option is specified; this results in a saved statistics data set that is named by appending _S to the name specified in the OUTXML= option, as shown by the following statements:

```sas
libname mystats "/sasusr/playpens/saskff/noaa/test/";
proc contents data=mystats.c9nco_S; run;
proc print data=mystats.c9nco_S(obs=20); run;
```

For brevity, only the first 10 out of 525 observations are printed by using the OBS= option in the PROC PRINT statement for Output 51.6.1. The first 20 observations of the statistics data set c9nco_S are shown in Output 51.6.2.

In Example 51.8, another method is used to subset results by location when you use the TILE= option. In Example 51.7, the STAT= option is used to collect statistics based on a tile summary in a data set (Mytile_S).

---

Example 51.7: Retrieving Tornado Vortex Signature Data Statistics by Using Tile Summary Statistics

This example retrieves tornado vortex signature data statistics for the range from May 5 to May 16, 2009, but only returns the actual NX3TVS data for 11 days starting on May 5, 2006. **Note:** The NOAA SWDI web service allows a range longer than one year for statistics reporting, but it allows only up to a year for the range of data that you retrieve. The SASENOAA engine uses the specified start and end dates unless the range exceeds one year (of data retrieval). When the range exceeds one year, the SASENOAA engine issues an invalid range warning and defaults to a different end date. The new end date uses an end year that matches the start date’s year. Sometimes this default behavior might generate an end date that precedes the start date, resulting in only one day (corresponding to the start date) of data retrieved for the OUTXML= options results file.
This example generates an 11-day default range when the end year is changed to 2006 (from 2009); the results in the Mytile data set are shown in Output 51.7.1. The Mytile_S data set shows the recorded feature (tornado vortex signature) count for the specified tile in the tile summary specification, and it includes the centerlat, centerlon, day (date), fcoun (feature count for that day), and shapefile. The count represents the number of tornado vortex signatures detected within the tile summary coordinates. This information can be helpful for determining which geographic area and dates to focus on.

**NOTE:** The date range that is specified in the RANGE= option is invalid for the OUTXML data because it spans more than one year, but the STAT= option can use the longer range (as specified) to report the tile summary statistics. For the file specified in the OUTXML= option, the SASENOAA engine issues a warning that the range is invalid, and it changes the end year to the same year as the start year in an attempt to keep the range under one year. In this example, for brevity, OBS=10 is specified in the PROC PRINT statement. You can use the following statements to generate the statistics results, which are shown in Output 51.7.2.

```sas
libname mystats "sasusr/playpens/saskff/noaa/test/";

proc contents data=mystats.mytile_S; run;
proc print data=mystats.mytile_S; run;
```

</tr>
</tbody>
</table>

**NOTE:** You can get one day of results for the OUTXML= option by using an end date that is earlier than the start date specified in the RANGE= option. Furthermore, in this example, because both the specified start and end dates are in May, if the specified end date had been May 1, 2009, instead of May 16, 2009, then the statistics results would have been very similar, but the XML file would contain only the results for May 5, 2006. The SASENOAA engine forces the range to use the same year when the specified range exceeds one year. This can sometimes result in an invalid end date that precedes the start date, but the SASENOAA engine then discards the end date so that the range spans only one day, which is the start date.
Example 51.8: Retrieving Tornado Vortex Signature Data by Using Tile Coordinates

This example retrieves the tornado vortex signature (TVS) data for the range May 5 to May 16, 2006, but it selects only the data that fall inside the geographic area defined by the specified tile’s longitude and latitude coordinates (to the nearest tenth of a degree). Output 51.8.1 shows five observations within range of the coordinates specified in the TILE= option.

</tbody>
</table>
NOTE: You could add the option STAT='COUNTGROUPBY:WSR_ID', and the statistics would be stored in a data set named My2TL_S. The statistics results data show all the reporting weather stations by WSR_ID for the specified date range and the summary count of TVS features recorded for each station.

If you want to see a Google map of the same tile’s NX3TVS data, you can rerun this example with the FORMAT=KMZ, KMZMAP=, and OUTKMZ= options to download the corresponding KML file. After you import it to Google My Maps, you see a map like the one shown in Output 51.8.2. When you click on the rightmost data point, you can examine the details of that particular location on the map.

Output 51.8.2 Screen Shot of Google Earth Map of the NX3TVS Data for TILE=-102.12,32.62
Example 51.9: Mapping Hail Data in a Geospatial Framework (KMZ Format) for a Specific Weather Station

This example retrieves the same hail data as in Example 51.4, but instead of requesting the XML format, it requests the KMZ format, so that you can look at the data in a geospatial framework such as that provided by Google Maps.

<td>1</td>
</tr>
</tbody>
</table>

**Note:** The KMZ file shown in Output 51.9.1 is automatically unzipped and renamed MYK2BY.kml by the SASENOAA engine.
Example 51.9: Mapping Hail Data in a Geospatial Framework (KMZ Format) for a Specific Weather Station

Output 51.9.2 shows the Google Earth map for the observations within range of the weather station designated by the filter WSR_ID=KFWS. When you import your KML file (MYK2BY.kml) into Google My Maps, you can examine the details of each set of mapped coordinates on the map by clicking on the data point you want to look at.

Output 51.9.2  Screen Shot of Google Earth Map of the NX3HAIL Data in MYK2BY.kml
Example 51.10: Mapping Hail Data in a Geospatial Framework (SHP Format) for a Specific Weather Station

This example retrieves the same hail data as in Example 51.9, but instead of requesting the KMZ format, it requests the SHP format, so that you can look at the data in a geospatial framework such as that provided by Esri mapping software. Output 51.10.1 shows the retrieved Esri shapefiles that contain the data for the observations within range of the weather station designated by the filter WSR_ID=KFWS.

```sas

Overview: SASEQUAN Interface Engine

The SASEQUAN interface engine enables SAS users to retrieve economic and other time series data from the Quandl website, which is hosted by Quandl. The Quandl website offers access to 8 million time series data sets from 400 sources in finance, economics, society, health, energy, demography, and more. These time series are updated at annual, quarterly, monthly, weekly, and daily intervals. The time series on the Quandl website contain observation or measurement periods that are associated with data values. Although the Quandl API also supports data tables, the SASEQUAN engine does not support data tables at this time.

The SASEQUAN interface engine uses the LIBNAME statement to enable you to specify how to subset your Quandl data and how to collapse the selected time series to the same update frequency. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEQUAN interface engine supports Linux X64 (LAX) and Windows. Although the SASEQUAN engine uses the Quandl API (default is version 3), it is not endorsed or certified by Quandl. By using the SASEQUAN interface engine, you are agreeing to comply with the Quandl terms of use, which are described on the web page at the following URL: https://www.quandl.com/about/terms.

Getting Started: SASEQUAN Interface Engine

You can query the Quandl data set to retrieve the observations or data values for a list of time series by specifying the Quandl code of the data set. The Quandl code consists of a source code and a table code for the data set that contains the time series that you want to read into SAS. You must also specify your unique Quandl API key (authentication token for unlimited access). To obtain your own unique API key, visit the Quandl website at the following URL: https://www.quandl.com/users/sign_up.

The Quandl API key is a 20-character mixed-case alphanumeric string, such as “abCDefghiJKLMn123456,” and is represented by ‘XXXXXXXXXXXXXXXXXXXX’ in the APIKEY= option in the following example. In addition, the example URLs in this section and in the section “Examples: SASEQUAN Interface Engine” on page 3677 use the same Quandl API key as the argument your_quan_apikey.

After you have your assigned Quandl API key and have agreed to the Quandl terms of use, you are almost ready to download Quandl data. Before you download, make sure you have the necessary rights to work with the data.

Now that you are informed about the terms of use of the Quandl data, you can use your Quandl API key to access the Quandl data, as shown in the following example.

In this example, and the ones that follow in “Examples: SASEQUAN Interface Engine” on page 3677, use the SAS option SSLCALISTLOC=<specify the location of your CA certificates here>. The specification that is shown as SSLCALISTLOC=="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem" is for demonstration purposes only. Specify your own location of your trusted certificates inside the double quotes.

The statements that follow enable you to access oil prices from the National Stock Exchange of India’s time series data from September 1, 2013, to November 5, 2013, on a daily basis. The observations are sorted by the time ID variable DATE. The output is shown in Output 52.1.

</tbody>
</table>

The XML data that the Quandl website returns are placed in a file that is named by the OUTXML= option—in this case, OILTD1.xml. Note that the SASEQUAN engine appends a numeral to the XML filename, and the file extension (.xml) is excluded from the filename that appears in the OUTXML= option. This XML data file resides in the current working directory. These data are read into a SAS data set in the folder location that is given inside the string enclosed in double quotation marks in the SASEQUAN LIBNAME statement. So, in the preceding example, if the QUANDL environment variable is set to

/sasusr/playpens/saskff/quan/test/
then the SAS data set (created when the XML file is read into SAS) is located at

```
/sasusr/playpens/saskff/quan/test/OIL_GSA.sas7bdat
```

An equivalent LIBNAME statement that does not use any environment variables could be as follows:

```
libname quan sasequan "'/sasusr/playpens/saskff/fame940/ets/test/'
OUTXML=oiltd
XMLMAP="/sasusr/playpens/saskff/quan/test/oiltd.map"
APIKEY='XXXXXXXXXXXXXXXXXXXX'
IDLIST='NSE/OIL';
```

You could also use either a SAS macro variable or a system environment variable to store the value of your Quandl API key so that the key does not appear explicitly in your SAS code. The XML map that is created is assigned the full pathname that the XMLMAP= option specifies. The SASEQUAN engine appends a numeral to the XML filename to indicate the position of the Quandl code in the IDLIST= option.

The IDLIST= option specifies the list of Quandl data sets (that contain time series) that you want to retrieve. This option accepts a string, enclosed in single quotation marks, that denotes a list of one or more Quandl data sets that you select (keep) in the resulting SAS data set. The result, OILTD, is named in the DATA step and is shown in Figure 52.1. The preceding example uses only one Quandl code, which is in the first position of the IDLIST= option, so the numeral 1 is appended to the name of the XML file, resulting in OILTD1.xml.

It is more efficient to use the DATA step to store your Quandl data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC GPLOT statement. You can also refer to the SASEQUAN libref directly, as in the statement

```
proc print data=quan.oiltd; run;
```

This statement uses the member name, OILTD, in the PROC PRINT statement; this usage corresponds to specifying the OUTXML=OILTD option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASEQUAN libref, the Quandl interface engine reads the entire XML file into SAS again. So it is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly.

---

**Syntax: SASEQUAN Interface Engine**

The SASEQUAN interface engine uses standard engine syntax to read the observations or data values for one or more Quandl data sets that can contain one or more time series in each data set. Table 52.1 summarizes the options that the SASEQUAN engine uses. In addition, there is one required option: `API_KEY='quan_api_key'`. 
### Table 52.1  Summary of LIBNAME `libref` SASEQUAN Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APIKEY=</td>
<td>Specifies the required Quandl access key that enables you to access the data that the Quandl website provides</td>
</tr>
<tr>
<td>AUTOMAP=</td>
<td>Specifies whether or not to overwrite the existing XML map file</td>
</tr>
<tr>
<td>COLLAPSE=</td>
<td>Specifies the reporting frequency (lower frequency to collapse the output results to). The valid reporting frequencies are daily, weekly, monthly, quarterly, annual, and none.</td>
</tr>
<tr>
<td>COLUMN=</td>
<td>Specifies one column (time series) to keep in the output results. The rest of the columns are dropped from the output results. When more than one ID is specified in the IDLIST= option, the specified column index is kept for each ID.</td>
</tr>
<tr>
<td>CONNECT=</td>
<td>Specifies whether or not to use the connect method for a secure connection via a proxy server. You must specify the PROXY= option when you use the CONNECT=ON option. See the PROXY= option.</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not to include diagnostic message logging in the SAS log window</td>
</tr>
<tr>
<td>END=</td>
<td>Specifies the end date (trim_end) for the observation period (&quot;YYYY-MM-DD&quot; formatted string, optional; the default is 1776-07-04 (earliest available))</td>
</tr>
<tr>
<td>FORMAT=</td>
<td>Specifies a file extension that indicates the type of file to retrieve. Only XML is supported for the SASEQUAN interface engine.</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies the frequency of the selected data: daily, weekly, monthly, quarterly, or annual. When the IDLIST= option contains more than one Quandl code, the FREQ= option aggregates higher-frequency data series to lower-frequency time series (such as converting a monthly time series to an annual time series).</td>
</tr>
<tr>
<td>IDLIST=</td>
<td>Specifies a list of Quandl codes for Quandl data set codes for accessing Quandl time series data. To select more than one data set, list the unique Quandl codes, separated by commas. There is a limit of nine Quandl codes in the IDLIST= option.</td>
</tr>
<tr>
<td>MAPREF=</td>
<td>Specifies the fileref used for the map file assignment</td>
</tr>
<tr>
<td>OUTXML=</td>
<td>Specifies the name of the output SAS data set and the XML file(s) requested by the IDLIST= option. When more than one time series ID is listed in the IDLIST= option, the SASEQUAN engine appends the positional integer (1 for the first time series ID, 2 for the second time series ID, and so on) to the name specified by the OUTXML= option.</td>
</tr>
<tr>
<td>PROXY=</td>
<td>Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, use the CONNECT=ON option in addition to the PROXY= option. See the CONNECT= option.</td>
</tr>
<tr>
<td>ROWS=</td>
<td>Specifies the maximum number of observations (rows) to return (integer between 1 and 100,000, optional; the default is 100,000)</td>
</tr>
<tr>
<td>SORT=</td>
<td>Specifies the order of the results in ascending or descending observation-date order. The valid sort arguments are asc and desc; the default is asc.</td>
</tr>
<tr>
<td>START=</td>
<td>Specifies the start date (trim_start) for the observation period (&quot;YYYY-MM-DD&quot; formatted string, optional; the default is 9999-12-31 (latest available))</td>
</tr>
<tr>
<td>TRANS=</td>
<td>Specifies the transformation method to be used for data transformation. The valid transformation arguments are DIFF, RDIFF, RDIFF_FROM, CUMUL, NORMALIZE, and NONE; the default is NONE. See Table 52.2 for formulas.</td>
</tr>
<tr>
<td>XMLMAP=</td>
<td>Specifies the fully qualified name of the location where the XMLmap file is automatically stored. By default, XMLMAP=Quan.map.</td>
</tr>
</tbody>
</table>
The LIBNAME libref SASEQUAN Statement

```
LIBNAME libref SASEQUAN ‘physical-name’ options ;
```

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory where the SAS data set is stored that contains the downloaded Quandl data. The required `physical-name` argument specifies the location of the folder where your SAS data set resides. It should end with a backslash if you are in a Windows environment and a forward slash if you are in a UNIX environment.

You can specify the following `options` in the LIBNAME `libref SASEQUAN` statement.

**APIKEY=’quan_apikey’**

specifies the Quandl authentication token or access key that enables you to access the data that the Quandl website provides. The Quandl access key is a 20-character mixed-case alphanumeric string, and it is required. It must be enclosed in single quotation marks. You can request your `quan_apikey` by visiting the website at the following URL:

```
https://www.quandl.com/users/sign_up
```

**AUTOMAP=REPLACE | REUSE**

specifies whether or not to overwrite the existing XML map file. You can specify the following values:

- **REPLACE** specifies that the XML map file be overwritten, and ensures that the most current XML map that is generated by the SASEQUAN engine and named by the XMLMAP= option is used.
- **REUSE** specifies that the XML map file not be overwritten, and ensures that a pre-existing XML map file that is named by the XMLMAP= option is used.

By default, AUTOMAP=REPLACE.

**COLLAPSE=DAILY | WEEKLY | MONTHLY | QUARTERLY | ANNUAL | NONE**

specifies the frequency to which you want to collapse the reporting frequency. You can specify the following values:

- **DAILY** collapses the report to a daily frequency.
- **WEEKLY** collapses the report to a weekly frequency.
- **MONTHLY** collapses the report to a monthly frequency.
- **QUARTERLY** collapses the report to a quarterly frequency.
- **ANNUAL** collapses the report to an annual frequency.
- **NONE** does not collapse the report.

This option is not required. By default, COLLAPSE=NONE when IDLIST=option specifies one Quandl code, but when the IDLIST= option specifies more than one Quandl code, the default for the collapse frequency is set to the same frequency that is specified in the FREQ= option.

The Quandl frequency-collapsing feature reports the native (higher-frequency) time series at a lower frequency (the collapse frequency). When you collapse the frequency of a data set, Quandl returns the last observation for the given period. So if you collapse a daily data set to monthly, you get a
sample of the original data set in which the observation for each month is the last data point available for that month. When you specify more than one Quandl code in the IDLIST= option, it is important to check that the from date and to date of every selected series use the same fiscal year, so that the reporting interval of the merged date values from all the data sets aligns to the same date for the first observation in the range. For example, if multiple Quandl codes are listed in the IDLIST= option, some annual time series have from dates that start in January, and some annual time series have from dates that start in June, then the merged data set will have observation dates reported for both January and June (if COLLAPSE=NONE), resulting in a semiannual interval instead of an annual interval in the merged data. To preserve the annual frequency, specify COLLAPSE=ANNUAL so that each annual time series aligns with the appropriate annual date in the merged data set. The COLLAPSE= option is applied to each Quandl data set that is specified in the IDLIST= option, so that when the data sets are merged, the reporting frequency is equal to the COLLAPSE= frequency. The resulting merged SAS data set contains the same data as the Quandl “supersets” that were created from the same Quandl codes in the IDLIST= option. Although Quandl supersets are no longer supported by Quandl, newer Quandl API methods are available for merging multiple time series by using the Quandl Excel Add-In. The SASEQUAN interface engine uses the Quandl data sets API to request each time series in the IDLIST= option, enabling you to seamlessly store the merged time series in one SAS data set. For more information about the various available methods for Quandl data access, see the web page at following URL: https://www.quandl.com/docs/api#data-organization.

**NOTE:** The COLLAPSE=MONTHLY option reports the daily, weekly, and monthly native frequencies of the time series at a monthly frequency (the collapse frequency). If you specify an annual native frequency time series in the IDLIST= option, then it will not be selected when COLLAPSE=MONTHLY is specified. Only the time series that have native frequencies higher than the reporting frequency specified in the COLLAPSE= option are selected.

**NOTE:** It is highly recommended that you use the COLLAPSE= option when you specify more than one Quandl code in the IDLIST= option.

**CAUTION:** If the COLLAPSE=NONE option is specified, then undesirable time intervals can occur when you specify more than one Quandl code in the IDLIST= option.

**COLUMN=quan_column_index**

specifies the column index that you want to keep in the output results. Specify only one column index, and it will be applied to each Quandl code (ID) that is specified in the IDLIST= option. For example, if there are three columns of data, you can specify COLUMN=1 to keep the first column, COLUMN=2 to keep the second column, or COLUMN=3 to keep the third column.

**CONNECT=ON | OFF**

specifies whether or not to use the connect method along with the PROXY= option. **NOTE:** You must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option when you want to use the connect method. For more information about secure connections, see the PROXY= option.

**DEBUG=ON | OFF**

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be very useful for troubleshooting a problem.
**END=’quan_enddate’**
specifies the end date for the time series in the format ’YYYY-MM-DD’. This option is not required, and the default is 9999-12-31 (latest available). The date must be enclosed in single quotation marks.

**FORMAT=XML**
specifies the format of the file to be received from the Quandl website. Although Quandl can report data in many formats, the SASEQUAN engine supports only the XML format.

**FREQ=DAILY | WEEKLY | MONTHLY | QUARTERLY | ANNUAL**
specifies a lower frequency to aggregate values to. The FREQ= option also selects only those time series that aggregate to the specified frequency. In Quandl data, the highest frequency is daily, and the lowest frequency is annual. You can specify the following values:

- **DAILY** selects time series that aggregate to a daily frequency.
- **WEEKLY** selects time series that aggregate to a weekly frequency.
- **MONTHLY** selects time series that aggregate to a monthly frequency.
- **QUARTERLY** selects time series that aggregate to a quarterly frequency.
- **ANNUAL** selects time series that aggregate to an annual frequency.

The FREQ= option is not required, and the default value is the native frequency of the Quandl data set. **NOTE:** An error is returned if you specify a frequency higher than the native frequency of the selected series. For example, if a series has the native frequency “Annual,” it is not possible to aggregate the series to the higher “Monthly” frequency. To find the native frequency of a time series, enter the time series’ Quandl code (in the database_code and dataset_code fields) in the following URL in your web browser:

```
https://www.quandl.com/api/v3/datasets/{database_code}/{dataset_code}/data.xml
```

The output gives you the time series data along with its native frequency, which is given in the “Frequency” field.

**NOTE:** When you specify a single Quandl code in the IDLIST= option and the FREQ= option is not specified or is an empty string, the native frequency of the time series in that data set is used as the reporting frequency unless you specify the reporting frequency in the COLLAPSE= option. When you specify multiple data sets (and time series) in the IDLIST= option, the “Annual” frequency is used as the default frequency unless you specify the reporting frequency in the COLLAPSE= option. If any time series in the IDLIST= option have a lower native frequency than the specified frequency, then those time series are dropped from the list and excluded from the output.

**IDLIST=’quan_idlist’**
specifies the list of Quandl codes for the data sets that contain the time series to be included in the output SAS data set. There is a limit of nine Quandl codes in the IDLIST= option. This list is comma-delimited and must be enclosed in single quotation marks.

**MAPREF=quan_xmlmapref**
specifies the fileref to use for the map assignment. For an example of the SASEQUAN engine that uses the MAPREF= and XMLMAP= options in the FILENAME statement in order to assign a filename, as in the following, see the section “Getting Started: SASEQUAN Interface Engine” on page 3666:
FILENAME MyMap "/sasusr/playpens/saskff/quan/test/oiltd.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file. It is placed in the current working directory. For more information, see the section “SAS OUTXML File” on page 3676. The SET statement (see the section “Getting Started: SASEQUAN Interface Engine” on page 3666) reads observations from the input data set OILTD and stores them in a SAS data set named OIL_GSA.

OUTXML=quan_xmlfile

specifies the name of the file where the XML data that are returned from the Quandl website are stored. Each Quandl code that is listed in the IDLIST= option is given a positional numeral: 1 for the first code in the IDLIST, 2 for the second code in the IDLIST, and so on. The engine appends this numeral to the filename of the XML of each data set that the website returns. When all the XML files are retrieved, the data are merged into a SAS data set. When only one Quandl code is used in the IDLIST= option, the filename has the numeral 1 appended to the OUTXML filename. By default, OUTXML=QUAN, which creates a file named QUAN1.xml in the current working directory. The SAS data set that is created when the XML data are read into SAS is placed in the folder specified by the physical path in the LIBNAME libref SASEQUAN statement.

PROXY="quan_proxyserver"

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused error or a connection-timed-out error occurs. For quan_proxyserver, specify the server’s HTTP address followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY="http://inetgw.unx.sas.com:8118". See also the CONNECT= option.

ROWS=quan_rows
LIMIT=quan_rows

specifies the maximum number of rows (time series observations) to return, which is an integer between 1 and 100,000. This option is not required. By default, ROWS=100000.

SORT=ASC | DESC
ORDER=ASC | DESC

specifies the order in which to sort the date of time series observations. You can specify the following values:

ASC sorts time series observations in ascending date order.
DESC sorts time series observations in descending date order.

This option is not required. By default, SORT=ASC.

START='quan_startdate'

specifies the start date for the time series in the format 'YYYY-MM-DD'. This option is not required, and the default is 1776-07-04 (earliest available). The date must be enclosed in single quotation marks.
TRANS=CUMUL | DIFF | NORMALIZE | RDIFF | RDIFF_FROM | NONE
TRANSFORMATION=CUMUL | DIFF | NORMALIZE | RDIFF | RDIFF_FROM | NONE

specifies the data value transformation. You can specify the following values:

**CUMUL**
performs the cumulative function.

**DIFF**
performs the difference function.

**NORMALIZE**
performs the normalize function.

**RDIFF**
performs the ratio difference function.

**RDIFF_FROM**
gives the latest (nearest to the end date) value as a percentage increment.

**NONE**
performs no transformation on the data.

This option is not required. By default, TRANS=NONE. The details of the arguments and the corresponding function formulas are presented in Table 52.2.

**Table 52.2** Quandl Transformation Codes

<table>
<thead>
<tr>
<th>Trans Code</th>
<th>Description</th>
<th>Formula</th>
</tr>
</thead>
<tbody>
<tr>
<td>cumul</td>
<td>Cumulative sum</td>
<td>$x_t + x_{t-1} + \cdots + x_{t-N}$</td>
</tr>
<tr>
<td>diff</td>
<td>Row-on-row change</td>
<td>$x_t - x_{t-1}$</td>
</tr>
<tr>
<td>normalize</td>
<td>Scale series to start at 100</td>
<td>$(\frac{x_t}{x_{t-N}}) \times 100$</td>
</tr>
<tr>
<td>rdiff</td>
<td>Row-on-row percentage change</td>
<td>$(\frac{x_t-x_{t-1}}{x_{t-1}})$</td>
</tr>
<tr>
<td>rdiff_from</td>
<td>Latest value as percentage increment</td>
<td>$(\frac{x_{\text{latest}}-x_t}{x_t})$</td>
</tr>
</tbody>
</table>

$x_t$ is the value of series $x$ at time period $t$. $N$ is the number of observations per year, which differs by frequency: Daily ($N = 260$), Annual ($N = 1$), Monthly ($N = 12$), Quarterly ($N = 4$), and Weekly ($N = 52$).

**XMLMAP=quan_xmlmapfile**
specifies the fully qualified name of the location where the XML map file is automatically stored.
Details: SASEQUAN Interface Engine

The SASEQUAN interface engine enables SAS users to access time series data that are stored in Quandl data sets that the Quandl website provides. Every Quandl data set is identified by a unique ID. For example, the Prague Stock Index is uniquely identified by the code PRAGUESE/PX, which you can view by visiting the website at the following URL:

https://www.quandl.com/data/PRAGUESE/PX-Prague-Stock-Index-PX

The unique code for any data set is always visible on the data set page, next to the words “Quandl Code.”

Quandl API Key

The API key that is used in these examples, abCDefghiJKLMn123456, is for demonstration purposes only. To successfully download data from the Quandl website, use your own Quandl API key, which is a 20-character mixed-case alphanumeric string. You can request your own API key by visiting the website at the following URL:

https://www.quandl.com/users/sign_up

Available Sources That Provide Quandl Economic Time Series Data

To obtain a list of the available sources of Quandl economic data, visit the website at the following URL:

https://blog.quandl.com/api-for-economic-data

Useful Lists for Easy Downloading of Quandl Time Series Data

You can use the Quandl data browser to get a list of Quandl codes for the available time series for a specific database. Enter the following URL in your web browser and click on the category or the particular link for that source:

https://www.quandl.com/search?query=

For example, to find the Quandl codes for the Dow Jones Industrial Average Index, you can enter the following URL in your web browser:

https://www.quandl.com/search?query=dow%20jones%20industrial%20average%20index

To see only the free databases, select the free filter in the browser box. The 19 free databases are listed along with each time series Quandl codes.
Available Time Series for Each Quandl Code

To download all the data set codes and data set names available in the FRED (Federal Reserve Economic Data) database, enter the following URL in your web browser:

https://www.quandl.com/api/v3/databases/FRED/codes

SAS Output Data Set

You can use a SAS DATA step to write the selected Quandl data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the SAS User library.

The contents of the SAS data set include the date of each observation and the series name of each series that is read from the Quandl data source.

The SASEQUAN interface engine maintains the sort order, so the time series are sorted in the resulting SAS data set by the order that is specified in the SORT= option, by date (time ID), and by variable (time series item name).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure along with your SASEQUAN libref to create a custom view of your data.

SAS OUTXML File

The SAS XML (XML format) data that are returned from the Quandl website are placed in a file that is named by the OUTXML= option. The SASEQUAN interface engine creates a separate XML file for each Quandl code that is listed in the IDLIST= option. The engine numbers each data set’s XML file in the order in which it appears in the IDLIST= option, so the first data set has a 1 concatenated to the filename, the second data set has a 2 concatenated to the filename, and so on. In instances of the IDLIST= option that contain more than one Quandl code, the variable names also have the same numeral concatenated to them. This naming convention enables the engine to merge all the selected time series into one SAS data set while preserving the identity of each time series. The SAS XML data file is placed in the current working directory, but the SAS data set (created by reading the XML data into SAS) is placed in the folder specified by the physical-name in the LIBNAME libref SASEQUAN statement, which is described in the section “The LIBNAME libref SASEQUAN Statement” on page 3670.

SAS XML Map File

The XML map that (by default) is automatically created is assigned the full pathname that is given by the XMLMAP= option in your LIBNAME libref SASEQUAN statement. The map file is either reused
(not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE (the default). The SASEQUAN interface engine invokes the XMLV2 engine to create the map and to read the data into SAS.

---

**Examples: SASEQUAN Interface Engine**

**Example 52.1: Retrieving Historical Price Data for Oil India Limited**

This example shows how to use one Quandl code, NSE/OIL, to retrieve historical prices for Oil India Limited, starting September 1, 2013, and ending November 5, 2013, with a daily frequency. The output is shown in Output 52.1.1.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Historical Prices for Oil India Limited';
libname _all_ clear;
libname mylib "/sasusr/playpens/saskff/quan/doc/";

/* export QUANDL="/sasusr/playpens/saskff/quan/test/ " */

libname myQoil sasequan "/sasusr/playpens/saskff/quan/test/" apikey='XXXXXXXXXXXXXXXXXXXXXXXX'
   idlist='NSE/OIL'
   format=XML
   outXml=oil
   automap=replace
   mapref=MyMap
   xmlmap="/sasusr/playpens/saskff/quan/test/oil.map"
   start='2013-09-01'
   end='2013-11-05'
   freq='daily'
   collapse='daily'
;

data mylib.oilall;
   set myQoil.oil;
run;

proc contents data=mylib.oilall; run;
proc print data=mylib.oilall; run;
```

Example 52.2: Retrieving Data by Using Three Quandl Codes

This example shows how to use three Quandl codes of different native frequencies to retrieve quarterly data for corporate profits after tax (FRED/CP), gross domestic product (FRED/GDP), and total consumer credit owned and securitized, outstanding (TOTALSL). The output is shown in Output 52.2.1.

```sas
/* Example 52.2: Retrieving Data by Using Three Quandl Codes */

title 'Retrieve Data for Three Time Series: FRED/CP, FRED/GDP, FRED/TOTALSL';
libname _all_ clear;
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

Example 52.3: Retrieving Data for the JASDAQ-TOP20 Exchange Traded Fund (ETF)

This example shows how to use one Quandl code, GOOG/TYO_1551, to retrieve the price and yield performance of the JASDAQ-TOP20 Exchange Traded Fund (ETF) in Japan, starting January 1, 2014, and ending March 26, 2014, with a daily native frequency. The output is shown in Output 52.3.1.

Example 52.4: Collapsing Data for the JASDAQ-TOP20 Exchange Traded Fund (ETF)

This example shows how to collapse daily data to a weekly interval by using the same Quandl code as in Example 52.3, GOOG/TYO_1551, to retrieve the price and yield performance of the JASDAQ-TOP20 Exchange Traded Fund (ETF) in Japan, starting January 1, 2014, and ending March 26, 2014, with a daily native frequency, collapsing to a weekly frequency by using the COLLAPSE= option. The output is shown in Output 52.4.1.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem"

Example 52.5: Transforming Data for the JASDAQ-TOP20 Exchange Traded Fund (ETF)

This example shows how to transform daily data by using the DIFF transformation and the same Quandl code as in Example 52.3 and Example 52.4, GOOG/TYO_1551, to retrieve the price and yield performance of the JASDAQ-TOP20 Exchange Traded Fund (ETF) in Japan. Specify a range by using START=’2014-01-01’ and END=’2014-03-26’, a transformation function by using TRANS=DIFF, and a collapse frequency by using COLLAPSE=WEEKLY. The output is shown on **Output 52.5.1**.

```sas
options validvarname=any;
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

   title 'JASDAQ-TOP20 ETF, TRANS=DIFF Option';
   libname _all_ clear;
   libname mylib "\sasusr\playpens\saskff\quan/doc/";

   /* export QUANDL=/sasusr/playpens/saskff/quan/test/ */

   libname myTOP20 sasequ "\sasusr\playpens\saskff\quan/test/"
      apikey='XXXXXXXXXXXXXXXXXXXXX'
      idlist='GOOG/TYO_1551'
      format=XML
      outXml=jasdaqX
      automap=replace
      mapref=MyMap
      xmlmap="\sasusr\playpens\saskff\quan/test/jasdaqX.map"
      start='2014-01-01'
      end='2014-03-26'
      collapse=weekly
      trans=diff
```

data mylib.jasdaqX;
    set myTOP20.jasdaqX;
run;

proc contents data=mylib.jasdaqX; run;
proc print data=mylib.jasdaqX; run;

Output 52.5.1  JASDAQ-TOP20 ETF, Weekly Data with TRANS=DIFF

Example 52.6: Reading from Multiple Quandl Data Sets to Merge Multiple Time Series

This example shows how to read data from three Quandl data sets by using the Quandl codes DOE/RWTC, BUNDESBANK/BBK01_WT5511, and YAHOO/INDEX_GSPC to retrieve oil, gold, and stock prices. There are eight time series (one for oil, one for gold, and six for the S&P500), taken from three different Quandl data sets: DOE/RWTC, BUNDESBANK/BBK01_WT5511, and YAHOO/INDEX_GSPC, respectively. Because the Oil, Gold, and S&P500 columns are all from daily native frequency data sets, you can use the collapse frequency “Annual” to minimize the missing values in the output. In the following example, specify a range by using START='1968-12-31' and END='2014-03-27', and specify a collapse frequency by using COLLAPSE=ANNUAL. The output is shown in Output 52.6.1.

```sas
options validvarname=any;
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

   title 'Oil, Gold and S&P Index Stock Time Series Using the COLLAPSE= Option';
   libname _all_ clear;
   libname mylib "'/sasusr/playpens/saskff/quan/doc/";

   /* export QUANDL="/sasusr/playpens/saskff/quan/test/" */
   libname mysup sasequan "'/sasusr/playpens/saskff/quan/test/"
      apikey='XXXXXXXXXXXXXXXXXXXX'
      idlist='DOE/RWTC,BUNDESBANK/BBK01_WT5511,YAHOO/INDEX_GSPC'
      format=XML
      outXml=Tsupe
      automap=replace
      mapref=MyMap
      xmlmap="/sasusr/playpens/saskff/quan/test/Tsupe.map"
   start='1968-12-31'
   end='2014-03-27'
   collapse=annual;

   data mylib.Tsupe;
      set mysup.Tsupe;
      label Value_1 = "WTI Crude Oil Spot Price Cushing, OK FOB";
      label Value_2 = "Gold Price (USD)";
      label Open_3 = "S&P 500 Index Open";
      label High_3="S&P 500 Index High";
      label Low_3= "S&P 500 Index Low";
      label Close_3="S&P 500 Index Close";
      label Volume_3="S&P 500 Index Volume";
      label 'Adjusted Close_3'n ="S&P 500 Index Adjusted Close"
      run;

   proc contents data=mylib.Tsupe; run;
   proc print data=mylib.Tsupe(obs=35) label; run;
```

Chapter 53
The SASERAIN Interface Engine

Overview: SASERAIN Interface Engine

The SASERAIN interface engine enables SAS users to retrieve weather data from the World Weather Online website. This website offers access to time series of weather data such as temperature, precipitation (rainfall), weather description, weather icon, and wind speed. These time series are updated at intervals that the user selects. The weather time series on the World Weather Online website contain observation or measurement periods that are associated with data values.

The SASERAIN interface engine uses the LIBNAME statement to enable you to download World Weather Online data and to specify which weather data time series you want to retrieve based on location. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set.

There are two types of major weather application interfaces (APIs) that return World Weather Online data for the SASERAIN engine. The first type is a local weather API that returns forecasting data and current conditions data, which usually start with today and end with tomorrow’s forecast. You can request up to 15 days of premium local weather forecast data. The SASERAIN engine supports only the premium local
weather API because World Weather Online has discontinued the nonpremium API. The default range for the SASERAIN engine is 2 days. You can use the premium local weather forecast API if you subscribe to the premium service and also specify your premium API key. The premium API key provides a maximum date range of 15 days.

The second type of API is a historical weather API that returns past weather. When you have a premium subscription, you can use a range that starts as early as July 1, 2008.

When no dates are specified, the default type of data that the SASERAIN interface engine returns is the local forecast weather data. **Note:** The SASERAIN interface uses the past weather API whenever a range of dates is specified by a start date and an end date.

You can choose to retrieve the following types of data for a single location or multiple locations:

- current conditions only
- local weather forecast only
- both current conditions and the local weather forecast
- 24-hour weather forecast only (the frequency is auto-set to 3 hours over one 24-hour period)
- historical (past) weather for a specified date range

The SASERAIN interface engine supports Linux X64 (LAX) and Windows. Although the SASERAIN engine uses the World Weather Online API, it is not endorsed or certified by World Weather Online. By using the SASERAIN interface engine, you are agreeing to comply with the World Weather Online terms of use, which are described on the web page at the following URL:

https://www.worldweatheronline.com/terms-and-conditions.aspx

---

**Getting Started: SASERAIN Interface Engine**

You can query the World Weather Online database to retrieve the observations or data values for a list of time series by specifying the World Weather Online code for the location (q-code). The World Weather Online q-code consists of a location code such as one for City and Country, latitude and longitude, IP address, US zip code, UK/Canadian postal code, or airport code (IATA). To specify more than one location, list each q-code in the QUERY= option, and separate the locations with a semicolon. Neither a comma nor a blank can be used as a separator between the q-codes, because one q-code can contain any number of commas or blanks.

You must also specify your unique World Weather Online premium API key (authentication token). To obtain your own unique API key, visit the World Weather Online website at the following URL:

For more information about the web service (including pricing and premium service information), visit the website at the following URL:

The World Weather Online API key is a 31-character mixed-case alphanumeric string, such as “abCDefghi-jklmnopqrstuvwxyz123456789,” and is represented by ‘XXXXXXXXXXXXXXXXXXXXXXXXXXXX’ in the APIKEY= option in the following example. In addition, the example URLs in this section and in the section “Examples: SASERAIN Interface Engine” on page 3703 use the same World Weather Online API key as the argument your_rain_apikey.

After you have your assigned World Weather Online API key and have agreed to the World Weather Online terms of use, you can use your API key to access the World Weather Online data, as shown in the following example.

In the following example, and “Examples: SASERAIN Interface Engine” on page 3703, use the SAS option SSLCALISTLOC=<specify the location of your CA certificates here>. The specification shown as SSLCALISTLOC= ”/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem” is for demonstration purposes only. Specify your own location of your trusted certificates inside the double quotes.

The statements that follow enable you to access the weather for London, Paris, and Dubai. For brevity of output, the request is for only one day (NUM_OF_DAYS=1), which starts with today. The FX24=YES option returns observations at a frequency of every 3 hours with an additional observation for the 24-hour average (the value of the TIME variable is 24), and the observations are sorted in chronological order. For brevity, only the current conditions output is shown in Figure 53.1.

```sas
options validvarname=any;
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

    title 'Retrieve Weather Data for London, Paris, and Dubai';
    libname _all_ clear;
    libname mylib "'/sasusr/playpens/saskff/rain/doc/'";
    libname rain saserain "'/sasusr/playpens/saskff/rain/test/'"
        QUERY='London,United Kingdom;Paris,France;Dubai,United Arab Emirates'
        FX24=yes
        CONDITIONS=yes
        OUTFXML=tricky
        AUTOMAP=replace
        MAPREF=MyMap
        XMLMAP="'/sasusr/playpens/saskff/rain/test/tricky.map'
        APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXX'
        NUM_OF_DAYS=1
        FORMAT=xml;

    data mylib.my24a;
        set rain.tricky;
        run;
    proc contents data=mylib.my24a; run;
    proc print data=mylib.my24a; run;

    libname condo "'/sasusr/playpens/saskff/rain/test/'";
```
data mylib.mycca;
  set condo.cc_tricky;
run;

proc contents data=mylib.mycca; run;
proc print data=mylib.mycca; run;

</table>

The XML data that the World Weather Online website returns are placed in a file that is named by the OUTXML= option—in this case, TRICKY1.xml. **NOTE:** The SASERAIN engine appends a numeral to the XML filename, and the file extension (.xml) is excluded from the filename that appears in the OUTXML= option. When the SET statement is executed, the XML data are read into a SAS data set named TRICKY.sas7bdat, which resides in the location given inside the string enclosed in double quotation marks in the SASERAIN LIBNAME statement.

You could use either a SAS macro variable or a system environment variable to store the value of your World Weather Online API key so that the key does not appear explicitly in your SAS code. The XML map that is created is assigned the full pathname that the XMLMAP= option specifies. The SASERAIN engine appends a numeral to the XML filename to indicate the position of the World Weather Online location code in the QUERY= option.
The QUERY= option specifies the list of World Weather Online locations that you want to retrieve weather data for. This option accepts a string, enclosed in single quotation marks, that denotes a list of one or more World Weather Online locations that you select (keep) in the resulting SAS data set. The result, TRICKY, is named in the DATA step and is shown in Figure 53.1. The preceding example uses three World Weather Online location codes. London, which is in the first position of the QUERY= option, has the numeral 1 appended to the name of the XML file, resulting in TRICKY1.xml. Paris is in the second position of the QUERY= option, so the numeral 2 is appended to the name of the XML file, resulting in TRICKY2.xml. Dubai is in the third position of the QUERY= option, so the numeral 3 is appended to the name of the XML file, resulting in TRICKY3.xml. The SASERAIN engine merges the three XML files to produce one merged output data set named TRICKY.sas7bdat. The current conditions data set is named CC_TRICKY. The second DATA step uses the SET statement to read the current conditions data into a new data set named MYCCA. These data are shown in Figure 53.1.

It is more efficient to use the DATA step to store your World Weather Online data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC GPLOT statement. You can also refer to the SASERAIN libref directly, as in the statement

```sas
proc print data=rain.tricky;
```

This statement uses the member name, TRICKY, in the PROC PRINT statement which invokes the RAIN libref to run the SASERAIN engine. This usage of the member name, TRICKY, corresponds to specifying the OUTXML=TRICKY option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASERAIN libref, the SASERAIN interface engine reads the entire XML file into SAS again. So it is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly. For another example that uses more SASERAIN LIBNAME statement options, see the section “Examples: SASERAIN Interface Engine” on page 3703.

---

**Syntax: SASERAIN Interface Engine**

The SASERAIN interface engine uses standard engine syntax to read the observations or data values for one or more World Weather Online data sets that can each contain one or more time series. Table 53.1 summarizes the options that the SASERAIN engine uses. In addition, there is one required option: APIKEY='rain_api_key'.
## Table 53.1 Summary of LIBNAME libref SASERAIN Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>APIKEY=</td>
<td>Specifies the required World Weather Online access key that enables you to access the data that the World Weather Online website provides.</td>
</tr>
<tr>
<td>AUTOMAP=</td>
<td>Specifies whether or not to overwrite the existing XML map file.</td>
</tr>
<tr>
<td>CONDITIONS=</td>
<td>Specifies whether or not to return only the current weather conditions upon output. CONDITIONS=YES means that variables for both the current conditions and the weather forecast appear in the output. The default (NO) means that only the local weather forecast variables appear in the output.</td>
</tr>
<tr>
<td>CONNECT=</td>
<td>Specifies whether or not you need the connect method for a secure connection via a proxy server. You must specify the PROXY= option when you use the CONNECT=ON option.</td>
</tr>
<tr>
<td>DATE=</td>
<td>Specifies the start date for past weather data for the specified range: specify the start date in 'YYYY-MM-DD' format.</td>
</tr>
<tr>
<td>DAY=</td>
<td>Specifies that the local weather forecast is current weather, not past weather. When you specify either today or tomorrow, you get today’s weather forecast. This is used with the NUM_OF_DAYS= option to specify a range for obtaining local weather forecast data.</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not to include diagnostic message logging in the SAS log window.</td>
</tr>
<tr>
<td>ENDDATE=</td>
<td>Specifies the end date for past weather for the specified range: specify the end date in 'YYYY-MM-DD' format. The end date must have the same month and year as the DATE= option.</td>
</tr>
<tr>
<td>FORECAST=</td>
<td>Specifies whether or not to return the weather forecast for a given postal code, zip code, and latitude/longitude values.</td>
</tr>
<tr>
<td>FORMAT=</td>
<td>Specifies a file extension that indicates the type of file to retrieve. Only XML is supported for the SASERAIN interface engine.</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies the frequency (interval) of the selected weather forecast data as a character string, such as DAILY, 24HOURLY, HOURLY, 3HOURLY, 6HOURLY, 12HOURLY, or DAY/NIGHT.</td>
</tr>
<tr>
<td>FX24=</td>
<td>Specifies whether or not to return the 24-hour weather forecast at a three-hour interval for a given location (city and country, postal code, zip code, or latitude and longitude).</td>
</tr>
<tr>
<td>NUM_OF_DAYS=</td>
<td>Specifies the number of days to report (starting from today). This is used for reading the local weather forecast data. The default for the SASERAIN engine is 2 days of forecast data, and the maximum is 15 days (premium weather API).</td>
</tr>
</tbody>
</table>
Table 53.1 continued

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>OUTCC=</td>
<td>Specifies the name of the current conditions SAS data set, which contains current conditions data returned by the World Weather Online API. This option is ignored when CONDITIONS=NO. For more information, see the CONDITIONS= option.</td>
</tr>
<tr>
<td>OUTXML=</td>
<td>Specifies the name of the SAS data set and the XML file, which usually contains the weather forecast data returned by the World Weather Online API. When you do not specify the OUTCC= option, the SASERAIN interface prepends ‘CC_’ to the name specified in the OUTXML= option to create the name for the current conditions SAS data set. See the OUTCC= option.</td>
</tr>
<tr>
<td>PROXY=</td>
<td>Specifies the proxy server that you want to use (if you have trouble connecting without specifying a proxy). If you also need the connect method for a secure connection, use the CONNECT=ON option in addition to the PROXY= option. See the CONNECT= option.</td>
</tr>
<tr>
<td>QUERY=</td>
<td>Specifies a required list of World Weather Online location codes. To select more than one location, list the World Weather Online query codes (q-codes), separated by semicolons. There is a limit of nine World Weather Online location codes in the QUERY= option. This is a required option.</td>
</tr>
<tr>
<td>TP=</td>
<td>Specifies the time period (interval) of the selected weather forecast data in number of hours: 1, 3, 6 (default), 12, or 24 hours.</td>
</tr>
<tr>
<td>XMLMAP=</td>
<td>Specifies the fully qualified filename for the XML map that the SASERAIN engine creates. This filename is usually the same as the one in the OUTXML= option.</td>
</tr>
</tbody>
</table>

The LIBNAME libref SASERAIN Statement

LIBNAME libref SASERAIN ‘physical-name’ options ;

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of World Weather Online data files in which the downloaded World Weather Online XML data are stored. The required physical-name argument specifies the location of the folder where your World Weather Online XML data reside. It should end with a backslash if you are in a Windows environment and a forward slash if you are in a UNIX environment.
You can specify the following options in the LIBNAME libref SASERAIN statement.

**APIKEY=’rain_apikey’**
specifies the World Weather Online authentication token or access key that enables you to access the data that the World Weather Online website provides. This access key is a 29-character mixed-case alphanumeric string, and it is required. It must be enclosed in single quotation marks. You can request your rain_apikey by visiting the website at the following URL:

https://developer.worldweatheronline.com/auth/register

**AUTOMAP=REPLACE | REUSE**
specifies whether or not to overwrite the existing XML map file.

**REPLACE** specifies that the XML map file be overwritten, and ensures that the most current XML map that is generated by the SASERAIN engine and named by the XMLMAP= option is used.

**REUSE** specifies that the XML map file not be overwritten, and ensures that a pre-existing XML map file that is named by the XMLMAP= option is used.

By default, AUTOMAP=REPLACE.

**CONDITIONS=ONLYCC | YES | NO**
specifies whether or not to return only current conditions data. CONDITIONS=ONLYCC enables the SASERAIN interface to output the current conditions data but not the forecast data. For more about current conditions, see Table 53.2.

**ONLYCC** specifies that only the current conditions be output.

**YES** specifies that the current conditions be output.

**NO** specifies that the current conditions variables be excluded from the output.

By default, the SASERAIN engine uses CONDITIONS=NO and FORECAST=YES. Specify CONDITIONS=YES to create both the current conditions output data set (named in the OUTCC= option) and the weather forecast output data set (named in the OUTXML= option). When the OUTCC= option is not specified, the prefix ‘CC_’ is added to the name specified in the OUTXML= option. For more information, see the FORECAST= and OUTCC= options. The SASERAIN engine issues a warning when both past weather and current conditions are selected in the same SASERAIN LIBNAME statement.
### Table 53.2 Current Conditions Forecast Variables

</tr>
<tr>
<td>cloudcover</td>
<td>Cloud cover in percentage</td>
</tr>
</tbody>
</table>

**CONNECT=ON | OFF**

specifies whether or not to use the connect method along with the PROXY= option. **NOTE**: You must use the PROXY= option and specify your proxy server in addition to the CONNECT=ON option when you want to use the connect method. For more information about a secure connection, see the PROXY= option.

**DATE=rain_date_start**

specifies the start date for requesting past (historical) weather data: specify 'YYYY-MM-DD' (format for the rain_date_start). The earliest start date for premium users is July 1, 2008.

**DAY=TODAY | TOMORROW**

specifies the start date for the local current weather forecast: specify today or tomorrow, but results are the same—they start today. If you want a start date other than today, then use the DATE= option. Use the NUM_OF_DAYS= option to specify the number of days to report.

**DEBUG=ON | OFF**

specifies whether or not to include diagnostic message logging in the SAS log window. This information can be very useful for troubleshooting a problem.

**ENDDATE=rain_date_enddate**

specifies the end date for the range to report past weather: 'YYYY-MM-DD' (format for the rain_date_enddate). The earliest start date (which you specify in the DATE= option) for premium past weather is July 1, 2008, but the ENDDATE= option must have the same month and year as the start date. The date must be enclosed in single quotation marks. The ENDDATE= option is not required, and the default range is 2 days.
FORECAST=YES | NO

specifies whether or not to return the weather forecast for a given location (city and country, postal code, zip code, or latitude and longitude values). By default, the SASERAIN engine uses FORECAST=YES. For more about weather forecast variables, see Table 53.3. When the type of data is not specified in the LIBNAME statement options, the SASERAIN engine defaults to normal weather forecast data and automatically defaults to the FX=YES option. Use either the FX24= option or the FX= option (but not both). When you specify FX24=YES, you do not need to specify any interval (FREQ= option) or any range specification, because the default is 24 hours of data at an interval of every 3 hours (and an extra observation for the 24-hour average).

</table>
The LIBNAME libref SASERAIN Statement

FORMAT=XML
specifies the format of the file to be retrieved from the World Weather Online website. Although World Weather Online can report data in many formats, the SASERAIN engine supports only the XML format.

FREQ=DAILY | HOURLY | 3HOURLY | 6HOURLY | 12HOURLY | 24HOURLY | DAY/NIGHT
specifies the frequency of the weather data. In World Weather Online weather forecast data, the highest frequency is hourly, and the lowest frequency is daily.

The FREQ= option is not required, and the default interval value is 6 hours.

FX24=YES | NO
specifies whether or not to return the 24-hour weather forecast at a three-hour interval for city/country, postal code, zip code, and latitude/longitude values. By default, the SASERAIN engine uses FX24=NO. When the type of data is not specified in the LIBNAME statement options, the SASERAIN engine defaults to normal weather forecast data and automatically defaults to the FX=YES option. **NOTE:** Use either the FX24= option or the FX= option (but not both). When you specify FX24=YES, you do not need to specify any interval (FREQ= option) or any range specification, because the default is 24 hours of data at an interval of 3 hours, but there is also an extra observation for the 24-hour averages for the reported variables.

MAPREF=rain_xmlmapref
specifies the fileref to use for the map assignment. For an example of the SASERAIN engine that uses the MAPREF= and XMLMAP= options in the FILENAME statement in order to assign a filename, as in the following statement, see the section “Examples: SASERAIN Interface Engine” on page 3703:

FILENAME MyMap "/sasusr/playpens/saskff/rain/test/gstart.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file. It is placed in the current working folder. The SAS data set that is created (when the XML data are read into SAS) is placed in the folder specified by physical-name, and you can reference it by using the myLib libref in your SASERAIN LIBNAME statement. This is shown in the section “Examples: SASERAIN Interface Engine” on page 3703, inside the DATA step in the SET statement. The SET statement reads observations from the input data set myLib.GSTART and stores them in a SAS data set named HowCool.

NUM_OF_DAYS=rain_numdays
specifies the number of days to report local weather (starting from today). The maximum is 15 days.

OUTCC=rain_outcc
specifies the name of the SAS data set where the current conditions data that are returned from the World Weather Online website are stored. When OUTCC= option is not specified, the SASERAIN interface stores the current conditions data in a SAS data set named by adding the prefix ‘CC_’ to the name specified in the OUTXML= option. If there is no request for current conditions data, then the OUTCC= option is ignored.
OUTXML=rain_xmlfile

specifies the name of both the XML file (downloaded) and the SAS data set created when the XML data are read into SAS. Each World Weather Online location code that is listed in the QUERY= option is given a positional numeral: 1 for the first code in the QUERY= option, 2 for the second code, and so on. The SASERAIN engine appends this numeral to the filename of the XML of each data set that the website returns. When all the XML files are retrieved, the data are merged into a SAS data set. When only one World Weather Online location code is specified in the QUERY= option, the filename has the numeral 1 appended to the OUTXML filename. By default, OUTXML=RAIN, which creates a file named RAIN1.xml in the current working directory. The SAS data set that is created when the XML data are read into SAS is placed in the folder specified by the physical path in the LIBNAME libref SASERAIN statement.

PROXY=“rain_proxyserver”

specifies which proxy server to use. This option is not required. The specified proxy server is used only when a connection-refused error or a connection-timed-out error occurs. For rain_proxyserver, specify the server’s HTTP address followed by a colon and the port number, and enclose that string in double quotation marks; for example, PROXY=“http://inetgw.unx.sas.com:8118”. See also the CONNECT= option.

QUERY=’rain_qcode_list’

specifies the list of World Weather Online locations for the data sets that contain the time series to be included in the output SAS data set. There is a limit of nine World Weather Online location codes in the QUERY= option. The argument ’rain_qcode_list’ is semicolon-delimited and must be enclosed in single quotation marks. For example:

    QUERY=’QCODE1;QCODE2;...QcodeN’

Each QCODE specifies a weather data location in one of the following location formats:

- **Latitude,Longitude** specifies the location of the selected weather forecast in decimal degrees (XX.XXX,XX.XXX).
- **UScityName,State** specifies the location of the selected US city and state.
- **cityName,Country** specifies the location of the selected city in the specified country, or if the location is in the United States, you can specify cityName,State.
- **IPaddress** specifies the location by using the Internet Protocol address in XXX.XXX.XXX.XXX format.
- **USzipcode** specifies the location by using the US zip code format.
- **UK_CANpostalcode** specifies the location by using the United Kingdom or Canadian postal code format.

You can specify a maximum of nine q-code locations in the QUERY= option, separated by semicolons. Each q-code can contain commas, blanks, or both. The QUERY= option is required.
TP=1 | 3 | 6 | 12 | 24
specifies the number of hours in a time period. In World Weather Online weather forecast data, the highest frequency is 1 (hourly), and the lowest frequency is 24 (daily).

The TP= option is not required, and the default interval value is 6 hours.

XMLMAP=rain_xmlmapfile
specifies the fully qualified name of the location where the XML map file is automatically stored.

---

**Details: SASERAIN Interface Engine**

The SASERAIN interface engine enables SAS users to access time series data that are stored in World Weather Online data sets that the World Weather Online website provides. Every World Weather Online data set is identified by a unique location code ID (which you specify in the QUERY= option). For example, London (England) is uniquely identified by the latitude and longitude that you obtain by using the search API on the web page with the following URL:

https://api.worldweatheronline.com/premium/v1/search.ashx?query=LONDON,UNITED%20KINGDOM&key=XXXXXXXXXXXXXXXXXXXXXXXXXXXX

When you specify the QUERY= option (for one to nine locations), the SASERAIN engine automatically calls the search API to find the unique latitude and longitude for each location that you want. If the request is ambiguous (too vague), then the SASERAIN engine issues a warning that it is using the best first match, and then lists the three possible matches that were searched. If the wrong latitude and longitude for a location were selected, you can rerun the SASERAIN engine with a different QUERY= option from the list of possibilities that best match your desired location. **NOTE:** It is best to specify latitude and longitude if you are having difficulty pinpointing your desired location.

---

**World Weather Online API Key**

The API key that is used in these examples, "XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX", is for demonstration only. To successfully download data from the World Weather Online website, use your own World Weather Online API key, which is a 29-character mixed-case alphanumeric string. You can request your own API key by visiting the website at the following URL:

SAS Output Data Set

You can use a SAS DATA step to write the selected World Weather Online data to a SAS data set. This enables you to use SAS software to easily analyze the data. If you specify the name of the output data set in the DATA statement, the SAS engine supervisor creates a SAS data set that has the specified name in either the SAS Work library or, if specified, the SAS User library.

The contents of the SAS data set include the date of each observation and the name of each location whose weather data is read from the World Weather Online website.

The SASERAIN interface engine maintains the sort order, so the locations (q-codes) are sorted in the resulting SAS data set by the order that you specify in the QUERY= option, by date (time ID), and by variable (time series item name).

You can use the PRINT and CONTENTS procedures to print your output data set and its contents. Alternatively, you can view your SAS output observations by opening the desired output data set in a SAS Explorer window. You can also use the SQL procedure with your SASERAIN libref to create a custom view of your data.

SAS OUTXML File

The SAS XML (XML format) data that are returned from the World Weather Online website are placed in a file that is named by the OUTXML= option. The SASERAIN interface engine creates a separate XML file for each World Weather Online code that you list in the QUERY= option. The engine numbers each data set’s XML file in the order in which it appears in the QUERY= option, so the first data set has a 1 concatenated to the filename, the second data set has a 2 concatenated to the filename, and so on. When the QUERY= option contains more than one World Weather Online code, the variable names also have the same numeral concatenated to them. This naming convention enables the engine to merge all the selected time series into one SAS data set while preserving the identity of each time series. The SAS XML data are placed in the current working directory. The SAS data set created when the XML data are read into SAS is placed in the location specified by the physical-name in the LIBNAME libref SASERAIN statement, which is described in the section “The LIBNAME libref SASERAIN Statement” on page 3695.

SAS XML Map File

The XML map that (by default) is automatically created is assigned the full pathname that you specify in the XMLMAP= option in your LIBNAME libref SASERAIN statement. The map file is either reused (not overwritten) if you specify AUTOMAP=REUSE or overwritten by a new map if you specify AUTOMAP=REPLACE (the default). The SASERAIN interface engine invokes the XMLV2 engine to create the map and to read the data into SAS.
Example 53.1: Retrieving Weather Forecast Data for One Location

When you are specifying one location by city, it is important to also specify the country. Because spaces are allowed in city names and country names, a comma (without spaces) is required to separate the city name from the country name. The following statements enable you to access the World Weather Online data for Paris. The output is shown in Output 53.1.1.

```sas
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'World Weather Online Data for Paris';
LIBNAME myLib saserain "/sasusr/playpens/saskff/rain/test/
   OUTXML=gstart
   AUTOMAP=replace
   MAPREF=MyMap
   XMLMAP="/sasusr/playpens/saskff/rain/test/gstart.map"
   APIKEY='XXXXXXXXXXXXXXXXXXXX'
   QUERY='Paris,France'
   FORMAT=xml
   NUM_OF_DAYS=1;

data howCool;
   set myLib.gstart ;
run;

proc contents data=howCool; run;
proc print data=howCool(obs=6); run;
```

The SASERAIN interface engine supports the XML format. The XML data that the World Weather Online website returns are placed in a file named by the OUTXML= option (GSTART). The XML map that is automatically created is assigned the full pathname specified by the XMLMAP= option, and the fileref that is used for the map assignment is specified by the MAPREF= option. Because the XMLMAP= option is specified as /sasusr/playpens/saskff/rain/test/, the SASERAIN engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename:

FILENAME MyMap "/sasusr/playpens/saskff/rain/test/gstart.map";

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file; it is described in the section “SAS OUTXML File” on page 3702. The XML data file is placed
Example 53.2: Retrieving the Two-Day Local Weather Forecast for One Location

The statements that follow enable you to access the weather for London for two days (NUM_OF_DAYS=2), which starts with today. The observations are given at a frequency of every 24 hours and are sorted in chronological order. The output is shown in Output 53.2.1.

```sas
options validvarname=any
    sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Two Day Weather Forecast for London';
libname _all_ clear;

libname mylib "/sasusr/playpens/saskff/rain/doc/";

libname rain saserain "/sasusr/playpens/saskff/rain/test/
    QUERY='London,United Kingdom'
    OUTXML=foggy
    XMLMAP="/sasusr/playpens/saskff/rain/test/foggy.map"
    APIKEY='XXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
    NUM_OF_DAYS=2
    TP=24
    FORMAT=xml;
```
data mylib.london_fog;
    set rain.foggy;
run;

proc contents data=mylib.london_fog; run;
proc print data=mylib.london_fog; run;

Output 53.2.1  London Weather for Today and Tomorrow: London_fog

Retrieve Two Day Weather Forecast for London

Example 53.2: Retrieving the Two-Day Local Weather Forecast for One Location

The XML data that the World Weather Online website returns are placed in a file that is named by the OUTXML= option—in this case, FOGGY1.xml. **NOTE:** The SASERAIN engine appends a numeral to the XML filename, and the file extension (.xml) is excluded from the filename that appears in the OUTXML= option. The SAS data set created when the XML data file is read into SAS is placed in the location that is specified inside the string enclosed in double quotation marks in the SASERAIN LIBNAME statement.

You could use either a SAS macro variable or a system environment variable to store the value of your World Weather Online API key so that the key does not appear explicitly in your SAS code. The XML map that is created is assigned the full pathname that the XMLMAP= option specifies. The SASERAIN engine appends a numeral to the XML filename to indicate the position of the World Weather Online location code in the QUERY= option.

The QUERY= option specifies the list of World Weather Online locations that you want to retrieve weather data for. This option accepts a string, enclosed in single quotation marks, that consists of one or more World Weather Online locations that you select (keep) in the resulting SAS data set. The result, FOGGY, is named in the DATA step and is shown in Figure 53.2.1. The preceding example uses only one World Weather Online code, which is in the first position of the QUERY= option, so the numeral 1 is appended to the name of the XML file, resulting in FOGGY1.xml.

It is more efficient to use the DATA step to store your World Weather Online data in a SAS data set and then refer to the SAS data set directly in your PROC PRINT or PROC GPLOT statement. You can also refer to the SASERAIN libref directly, as in the statement

```sas
proc print data=rain.foggy;
```

This statement uses the member name, FOGGY, in the PROC PRINT statement; this usage corresponds to specifying the OUTXML=FOGGY option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASERAIN libref, the SASERAIN interface engine reads the entire XML file into SAS again. So it is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly.
Example 53.3: Retrieving the Local Weather Forecast for One Location

This example shows how to use one World Weather Online location query to retrieve weather data for Dubai, starting today and ending tomorrow (num_of_days=2), with a 24-hour frequency. The output is shown in Output 53.3.1.

```sas
options validvarname=any
   sslcaлистloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem";

title 'Retrieve Weather Data for Dubai';
libname _all_ clear;
libname mylib "'/sasusr/playpens/saskff/rain/doc/";

libname myplace saserain "'/sasusr/playpens/saskff/rain/test/"
   apikey='XXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXXX'
   query='Dubai,United Arab Emirates'
   format=XML
   outXML=dubhot
   automap=replace
   mapref=MyMap
   xmlmap="/sasusr/playpens/saskff/rain/test/dubhot.map"
   num_of_days=2
   tp=24
;

data mylib.hotdub;
   set myplace.dubhot;
run;

proc contents data=mylib.hotdub; run;
proc print data=mylib.hotdub; run;
```
Output 53.3.1 Local Weather for Dubai

Example 53.6: Retrieving Historical Weather Data for Two Cities for a Date Range

This example shows how to retrieve past weather data for two locations (London and Paris) by using a date range. The historical (past) weather API is invoked because the DATE= and ENDDATE= options are specified. The concept of current conditions does not have any meaning when you specify past dates, so the historical weather data are returned instead of the current conditions. The output is shown in Output 53.6.1. When you specify past dates, the same data are returned whether or not you specify the CC= option. The SAS log shows the following warning:

*****WARNING: Using historical (past) weather API, so current conditions are not reported.

```plaintext
options validvarname=any
   sslcalistloc="/SASSecurityCertificateFramework/1.1/cacerts/trustedcerts.pem"

title 'Historical Weather for Date Range MAY 01, 2017 – MAY 02, 2017 for London and Paris';
libname _all_ clear;
libname mylib "/sasusr/playpens/saskff/rain/doc/"

libname myRain saserain "/sasusr/playpens/saskff/rain/test/"
   apikey='XXXXXXXXXXXXXXXXXXXXX'
   query='London,United Kingdom;Paris,France'
   date='2017-05-01'
   enddate='2017-05-02'
   tp=24
   cc=onlycc
   format=XML
   outXml=rainex05
   automap=replace
   mapref=MyMap
   xmlmap="/sasusr/playpens/saskff/rain/test/rainex05.map"
;

data mylib.cc3day;
   set myRain.rainex05;
run;

proc contents data=mylib.cc3day; run;
proc print data=mylib.cc3day; run;
```
### Output 53.6.1 Historical Weather Data for Date Range for London and Paris

Overview: SASEWBGO Interface Engine

The SASEWBGO interface engine enables SAS programmers to retrieve time series data from the World Bank Group Open (WBGO) data website, hosted by the World Bank Group, which consists of the following five organizations:

**IBRD** International Bank of Reconstruction and Development, which lends to middle-income and creditworthy low-income countries

**IDA** International Development Association, which provides interest-free loans and grants to governments of the poorest countries

**IFC** International Finance Corporation, which focuses exclusively on the private sector by helping developing countries achieve sustainable growth through investment financing, capital mobilization in international financial markets, and advisory services to businesses and governments

**MIGA** Multilateral Investment Guarantee Agency, which offers political risk insurance (guarantees) to investors and lenders to promote foreign direct investment in developing countries to support economic growth, reduce poverty, and improve people’s lives

**ICSID** International Centre for Settlement of Investment Disputes, which provides international facilities for conciliation and arbitration of investment disputes

The first two organizations, the IBRD and the IDA, make up the World Bank.

The World Bank Group Open data catalog contains the databases listed on the web page at the following URL:

http://datacatalog.worldbank.org/

The most popular is the World Development Indicators (WDI) database. This database presents the most current and accurate global development data available, including national, regional, and global estimates. The SASEWBGO interface engine supports access to the WDI database, but it also provides access to time series in other WBGO databases, such as the Global Economic Monitor (GEM) and the Special Data Dissemination Standard (SDDS). For a complete list of WBGO databases, see Table 54.5.

The SASEWBGO interface engine uses the LIBNAME statement to enable you to specify how to retrieve your WBGO data by specifying a country list, a list of time series indicators, a range of years, and an optional page number and number of observations per page to report. You can then use the SAS DATA step to perform further subsetting and to store the resulting time series in a SAS data set. You can perform more analysis (if desired) either in the same SAS session or in a later session.

The SASEWBGO interface engine is supported on SAS running on Linux X64 (LAX) and Windows.

Although the SASEWBGO engine uses the WBGO API, it is not endorsed or certified by the World Bank Group. By using the SASEWBGO interface, you are agreeing to comply with the WBGO terms of use, which are described on the web page at the following URL:

You can query the World Bank Group Open Data (WDI) database to retrieve the observations or data values for a list of economic time series by specifying the series ID (indicator) of each time series that you want to read into SAS and by specifying a list of the countries for which you want to retrieve the time series.

Before downloading any copyright-protected data series, be aware that you are solely responsible for obtaining copyright permissions for any copyright-protected time series that you download (other than for personal use). To obtain a list of the copyright-protected data series, visit the web page at the following URL:

http://data.worldbank.org/restricted-data

Now that you are informed about the terms of use of the WBGO data, you can access these data, as shown in the following example.

The following statements enable you to access the time series data for gross domestic product per capita in current US dollars for Brazil and China for the seven years starting with 2010 and ending with 2016 (on an annual basis). The observations are sorted by the COUNTRY_ID and the time ID variable DATE. Specify the ISO three-letter or ISO two-letter country code for each country for which you want to retrieve time series, separated by a semicolon. In the following LIBNAME statement, you specify the COUNTRYLIST= option by giving the ISO three-letter code for China as ‘chn’ and the ISO three-letter code for Brazil as ‘bra’, separated by a semicolon.

```sas
title 'Retrieve Data for GDP per Capita for Brazil and China';
libname wbgo sasewbgo "<physical pathname>"
  OUTXML=gdpogs
  XMLMAP="<physical filename with file extension .map>"
  COUNTRYLIST='chn;bra'
  IDLIST='NY.GDP.PCAP.CD'
  RANGE='2010:2016';

data gdp_gsa;
  set wbgo.gdpogs ;
run;

proc contents data=gdp_gsa; run;
proc print data=gdp_gsa; run;
```

</tbody>
</table>

The XML data that the WBGO website returns are placed in a file named by the OUTXML= option—in this case, GDPGS.xml. Note that the XML file extension is excluded from the filename specified in the OUTXML= option. When the SET statement is executed, the XML data are read into a SAS data set named Gdp_gsa.sas7bdat, which resides in the location specified by the string enclosed in double quotation marks in the SASEWBGO LIBNAME statement. So, in the preceding example, assume that you use the following SASEWBGO LIBNAME statement:

```
libname wbgo sasewbgo "'/sasusr/playpens/saskff/wbgo/test/"
```

Then, the SAS data set is named by the OUTXML= option specification, created by reading the downloaded XML file, and placed in the location

```
/sasuser/playpens/saskff/wbgo/test/gdpgs.sas7bdat
```

The XML map that is created is assigned the full pathname specified by the XMLMAP= option. The IDLIST= option specifies the list of time series indicators that you want to retrieve. This option accepts a string, enclosed in single quotation marks, that denotes a list of one or more time series that you select (keep) in the resulting SAS data set. The result, Gdp_gsa, is named in the DATA step and shown in Figure 54.1. The Total_count gives the total number of available observation values in the requested range. Example 54.9 demonstrates how to use multiple SASEWBGO LIBNAME statements to access the entire range of data.

It is more efficient to use the DATA step to store your WBGO data in a SAS data set and then refer to the SAS data set directly in later SAS program steps, but you can also refer to the SASEWBGO SAS library reference (libref) directly, as in the following statements:

```
proc print data=wbgo.gdpgs; run;
```

This statement uses the member name, gdpgs, in the PROC PRINT statement; this usage corresponds to specifying the OUTXML=GDPGS option. Although using this statement might seem easier, it is not as efficient, because every time you use the SASEWBGO libref, the SASEWBGO engine reads the entire XML file into SAS. So it is better to refer to the SAS data set repeatedly than to invoke the interface engine repeatedly. See Example 54.1 for sample code that demonstrates how to retrieve multiple time series from one country (China).
The SASEWBGO interface engine uses standard engine syntax to read the observations or data values for one or more time series indicators for one or more countries. Table 54.1 summarizes the options that the SASEWBGO engine uses. Two options are required: COUNTRYLIST= and IDLIST=.

### Table 54.1  Summary of LIBNAME libref SASEWBGO Options

<table>
<thead>
<tr>
<th>Option</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>AUTOMAP=</td>
<td>Specifies whether or not to overwrite the existing XML map file</td>
</tr>
<tr>
<td>COUNTRYLIST=</td>
<td>Specifies the ISO three-letter or two-letter code for each country for which to retrieve time series. When you specify more than one country code, use a semicolon as a delimiter and enclose the country list in single quotes. This option also enables you to specify region IDs or income-level IDs for aggregating your selected time series.</td>
</tr>
<tr>
<td>DEBUG=</td>
<td>Specifies whether or not to include diagnostic messages in the SAS log</td>
</tr>
<tr>
<td>FREQ=</td>
<td>Specifies whether to retrieve quarterly (Q), monthly (M), or yearly (Y) values. The FREQ= option is used only in conjunction with the MRV= option.</td>
</tr>
<tr>
<td>GAPFILL=</td>
<td>Specifies whether or not to backfill missing values: if data are not available, the API backtracks to the next available period. This option is used only with the MRV= option (the maximum number of backtracked periods is limited by the MRV value specified).</td>
</tr>
<tr>
<td>IDLIST=</td>
<td>Specifies a list of time series IDs (indicators) for accessing WBGO data. To select more than one time series, list the unique time series indicators, separated by commas.</td>
</tr>
<tr>
<td>LANG=</td>
<td>Specifies the language to use for text fields returned by the SASEWBGO engine</td>
</tr>
<tr>
<td>MAPREF=</td>
<td>Specifies the fileref used for the map file assignment</td>
</tr>
<tr>
<td>MRV=</td>
<td>Specifies the number of observations retrieved relative to the most recent value</td>
</tr>
<tr>
<td>OUTXML=</td>
<td>Specifies the name of the output SAS data set and the XML file(s) requested by the IDLIST= option. When you specify more than one time series ID in the IDLIST= option, the SASEWBGO engine appends the positional integer (‘1’ for the first time series ID, ‘2’ for the second time series ID, and so on) to the name specified by the OUTXML= option.</td>
</tr>
<tr>
<td>PAGE=</td>
<td>Specifies the page number of the data to retrieve in the returned data</td>
</tr>
<tr>
<td>PER_PAGE=</td>
<td>Specifies the number of observations to view in one page of the retrieved data</td>
</tr>
<tr>
<td>RANGE=</td>
<td>Specifies the range of observations for the retrieved data, such as ‘2000:2001’ for annual data, ‘2009M01:2010M08’ for monthly data, and ‘2009Q1:2010Q3’ for quarterly data</td>
</tr>
<tr>
<td>SORT=</td>
<td>Specifies the order of the results in ascending or descending order by observation date. The valid sort arguments are ‘asc’ and ‘desc’; the default is ‘asc’.</td>
</tr>
<tr>
<td>URL=</td>
<td>Specifies a URL from which to request useful information about countries based on income level, time series indicators based on source ID, or time series indicators based on topic ID. The information is downloaded from the web page at the specified URL and stored in the XWBGOTPU data set (a temporary utility data set), which can then be saved or renamed to a permanent SAS data set.</td>
</tr>
<tr>
<td>XMLMAP=</td>
<td>Specifies the fully qualified name of the location where the XMLmap file is automatically stored. By default, XMLMAP=Wbgo.map.</td>
</tr>
</tbody>
</table>
The LIBNAME libref SASEWBGO Statement

LIBNAME libref SASEWBGO 'physical-name' options;

The LIBNAME statement assigns a SAS library reference (libref) to the physical path of the directory of WBGO data files in which the downloaded WBGO XML data are stored.

You must specify the following arguments:

“physical name”

specifies the location of the folder where your WBGO XML data reside. Enclose the physical name in double quotation marks, and end it with a backslash if the folder is in a Windows environment or a forward slash if it is in a UNIX environment.

COUNTRYLIST='wbgo_countrylist'

specifies the list of country codes, region IDs, or income-level IDs to be included in the output SAS data set. See Table 54.2 and Table 54.3 for the IDs available for each aggregation type. This list is semicolon-delimited and must be enclosed in single quotation marks. To list all countries, specify 'all'. Otherwise, you can use the following information to designate the countries listed in the World Bank API. The World Bank uses the ISO three-letter and two-letter codes to represent most of the countries, with the following exceptions:

- Three-letter code differences: Andorra, Democratic Republic of the Congo, Isle of Man, Romania, Timor-Leste, West Bank and Gaza
- Two-letter code differences: Democratic Republic of the Congo, Serbia, Timor-Leste, Republic of Yemen, West Bank and Gaza
- Countries not using ISO codes: Channel Islands, Kosovo

For more information about country codes, visit the web page at the following URL:

http://www.nationsonline.org/oneworld/country_code_list.htm

IDLIST='wbgo_idlist'

specifies the list of time series indicators to be included in the output SAS data set. This list is comma-delimited and must be enclosed in single quotation marks. The crossproduct of the country list and the ID list defines the cross sections of the resulting SAS output data set. For a complete list of available indicators, visit the web page at the following URL:

http://api.worldbank.org/indicators

You can also specify the following options.

AUTOMAP=REPLACE | REUSE

specifies which XMLmap file to use. You can specify the following values:

REPLACE overwrites the existing XMLmap file and uses the most current XMLmap that is generated by the SASEWBGO engine and specified in the XMLMAP= option.

REUSE uses a preexisting XMLmap file that is specified in the XMLMAP= option.
**DEBUG=ON | OFF**
specifies whether or not to include diagnostic message logging in the SAS log. This information can be very useful for troubleshooting a problem.

**FREQ=M | Q | Y | A**
specifies the frequency of the file to be retrieved from the WBGO website. This option is used only in conjunction with the MRV= option. M is monthly, Q is quarterly, and Y (or A) is yearly (annual). By default, FREQ=Y.

**GAPFILL=Y | N**
specifies whether or not to backfill the unavailable (missing) values in the data retrieved from the WBGO website. This option is used only in conjunction with the MRV= option.

**LANGUAGE=EN | ES | FR**
specifies the language of the text fields for the retrieved data. The following languages are supported: English (EN), Spanish (ES), and French (FR). The SASEWBGO engine does not support Chinese or Arabic. By default, LANGUAGE=EN.

**MAPREF=wbgo_xmlmapfileref**
specifies the fileref used for the map assignment. The SASEWBGO engine uses the MAPREF= and XMLMAP= options in the FILENAME statement to assign a filename, as in the following:

```
FILENAME MyMap "/sasusr/playpens/saskff/wbgo/test/gstart.map";
```

You can use the MAPREF= and XMLMAP= options to control where the map resides, what you name the map, and how you refer to it with a fileref. You can use the OUTXML= option to name your XML data file and to name the SAS data set that you created by reading the XML data into SAS. The resulting SAS data set is placed in the folder designated by ‘physical-name’, and you can reference it by using the myLib libref in your SASEWBGO LIBNAME statement. This is shown in Example 54.1, inside the DATA step in the SET statement. In the example, the SET statement reads observations from the input data set myLib.g2start and stores them in a SAS data set named Gdp2chn.

**MRV=wbgo_mrv**
specifies the number of observations to retrieve relative to the most recent value. You must specify this option when you specify either the GAPFILL= or FREQ= option.

**OUTXML=wbgo_xmfile**
specifies the name of both the XML file (downloaded) and the SAS data set created when the XML data are read into SAS. Each WBGO time series that you list in the IDS= option is given a positional numeral: 1 for the first time series ID listed in the ID= option, 2 for the second time series ID listed, and so on. The SASEWBGO engine appends this numeral to the filename of the XML of each data set that the website returns. When all the XML files are retrieved, the data are merged into a SAS data set. When you specify only one WBGO time series ID in the ID= option, the filename has the numeral 1 appended to the OUTXML= filename. By default, OUTXML=WBGO, which creates a file named WBGO1.xml in the current working directory. The SAS data set that is created when the XML data are read into SAS is placed in the folder specified by the physical path in the LIBNAME libref SASEWBGO statement.
PAGE=wbgo_page
specifies the page number of the data to retrieve. Only one page is retrieved for a request, but the page total can be quite large. By default, the first page is retrieved when the page number is not specified. When you want to see more data than what is retrieved for the first page, make another request by specifying the PAGE= option with the number of the page that you want to retrieve. For the page number, you must specify an integer between 1 and the total page count given by the DATA_PAGES variable in the SAS data set named OUTXML1.sas7bdat, which can be viewed in the SAS listing.

PER_PAGE=wbgo_perpage
specifies the number of observations per page of the data to retrieve. The default is 50 observations per page. You can set the per-page number that you want to retrieve by using this option. The per-page count is given by the DATA_PER_PAGE in the SAS data set named OUTXML1.sas7bdat, which can be viewed in the SAS listing. If you want the entire range of data to be downloaded all at once (in one page), you can specify the PER_PAGE= option to be the value of the TOTAL_COUNT that is given in the output SAS data set named by your OUTXML= option. See Example 54.9 for an example of a SAS macro that enables you to download the entire range of data in one page.

RANGE=’wbgo_range’
specifies the date range of the data that you want to retrieve in the following formats:

’yyyy:yyyy’ designates the start year and end year for the range of annual time series; for example, RANGE=2000:2001.

’yyyyQn:yyyyQn’ designates the start year and quarter (n) and the end year and quarter (n) for the quarterly time series; for example, RANGE=2009Q1:2010Q3.

’yyyyMnn:yyyyMnn’ designates the start year and month (nn) and the end year and month (nn) for the monthly time series; for example, RANGE=2009M01:2010M08.

For quarterly time series, n is an integer between 1 and 4. For monthly time series, nn is an integer between 1 and 12. Most series in the WDI database are annual. For more information about quarterly and monthly data, consult the World Bank data catalog by visiting the website at the following URL:

http://datacatalog.worldbank.org/

See Example 54.7 for sample code that retrieves Quarterly External Debt Statistics data, and see Example 54.8 for sample code that retrieves monthly Global Economic Monitor commodities data.

SORT=ASC | DESC
specifies the order of the time series observations. You can specify the following values:

ASC specifies that the dates for the time series observations be in ascending order (within each country’s cross section of data).

DESC specifies that the dates for the time series observations be in descending order (within each country’s cross section of data).

By default, SORT=’ASC’.

URL="wbgo_url_link/< query_type?>< query_option=value>>< LIMIT=obs_limit>"
queries for useful information, such as listing countries by income level, indicators by source ID, or indicators by topic ID. The SASEWBGO engine stores the information in a temporary utility data set named XWBGOTPU. Specify the following fields in double quotation marks:
wbgo-url-link/
specifies the base WBGO URL that you want to use. The `wbgo-url-link` in the following example is ‘http://api.worldbank.org/’.

```
```

**query_type?query_option**
specifies the type of information that you want to query. You can specify the following `query_types` and `query_options`:

- `countries?incomeLevels=income_level_code`
  retrieves the countries available for a specified income level, such as
  
  ```
  URL="http://api.worldbank.org/countries?incomeLevel=LIC"
  ```

- `source/source_id/indicators?format=xml`
  retrieves the series indicators available for a specified source ID, such as
  
  ```
  URL="http://api.worldbank.org/source/1/indicators?format=xml"
  ```

- `topic/topic_id/indicator?format=xml`
  retrieves the series indicators available for a specified topic ID, such as
  
  ```
  ```

For a list of available sources, topics, and income levels, see Table 54.4, Table 54.5, and Table 54.2, respectively.

**LIMIT=obs_limit**
specifies the maximum number of observations to retrieve.

**XMLMAP=wbgo_xmlmapfile**
specifies the fully qualified name of the location where the XMLmap file is automatically stored. By default, XMLMAP=Wbgo.map.

---

**Details: SASEWBGO Interface Engine**

The SASEWBGO interface engine enables SAS programmers to access time series World Bank Group Open (WBGO) data that the WBGO website provides. Time series selection is provided by the IDLIST= option and the COUNTRYLIST= option. Because both options are required, the SASEWBGO engine issues an error message if either option is not specified. See the Table 54.6 for a list of time series indicators available from the World Development Indicators (WDI) database. For a list of country codes (both the ISO two-letter and three-letter codes), visit the web page at the following URL:

```
http://www.nationsonline.org/oneworld/country_code_list.htm
```

For a list of available time series indicators, see the section “Available Time Series Data Reference: SASEWBGO Interface Engine” on page 3735.
Available Income Levels and Regions to Aggregate WBGO Time Series Data

In addition to aggregating your data based on country ID, you can also aggregate your selected data by specifying income-level IDs or region IDs in the COUNTRYLIST= option. To get a list of the available income levels of WBGO data, enter the following URL in your web browser: http://api.worldbank.org/incomeLevels?format=xml. Table 54.2 shows the income levels that are available.

Table 54.2 Income Levels of the World Bank Group Open Data
