## **Overview: MIANALYZE Procedure**

The MIANALYZE procedure combines the results of the analyses of imputations and generates valid statistical inferences. Multiple imputation provides a useful strategy for analyzing data sets with missing values. Instead of filling in a single value for each missing value, Rubin's (1976, 1987) multiple imputation strategy replaces each missing value with a set of plausible values that represent the uncertainty about the right value to impute.

Multiple imputation inference involves three distinct phases:

- 1. The missing data are filled in m times to generate m complete data sets.
- 2. The *m* complete data sets are analyzed using standard statistical analyses.
- 3. The results from the m complete data sets are combined to produce inferential results.

A companion procedure, PROC MI, creates multiply imputed data sets for incomplete multivariate data. It uses methods that incorporate appropriate variability across the *m* imputations.

The analyses of imputations are obtained by using standard SAS procedures (such as PROC REG) for complete data. No matter which complete-data analysis is used, the process of combining results from different imputed data sets is essentially the same and results in valid statistical inferences that properly reflect the uncertainty due to missing values. These results of analyses are combined in the MIANALYZE procedure to derive valid inferences.

The MIANALYZE procedure reads parameter estimates and associated standard errors or covariance matrix that are computed by the standard statistical procedure for each imputed data set. The MIANALYZE procedure then derives valid univariate inference for these parameters. With an additional assumption about the population between and within imputation covariance matrices, multivariate inference based on Wald tests can also be derived.

The MODELEFFECTS statement lists the effects to be analyzed, and the CLASS statement lists the classification variables in the MODELEFFECTS statement. The variables in the MODELEFFECTS statement that are not specified in a CLASS statement are assumed to be continuous.

When each effect in the MODELEFFECTS statement is a continuous variable by itself, a STDERR statement specifies the standard errors when both parameter estimates and associated standard errors are stored as variables in the same data set.

For some parameters of interest, you can use TEST statements to test linear hypotheses about the parameters. For others, it is not straightforward to compute estimates and associated covariance matrices with standard statistical SAS procedures. Examples include correlation coefficients between two variables and ratios of variable means. These special cases are described in the section "Examples of the Complete-Data Inferences" on page 6010.

# **Getting Started: MIANALYZE Procedure**

The Fitness data described in the REG procedure are measurements of 31 individuals in a physical fitness course. See Chapter 97, "The REG Procedure," for more information. The Fitness1 data set is constructed from the Fitness data set and contains three variables: Oxygen, RunTime, and RunPulse. Some values have been set to missing, and the resulting data set has an arbitrary pattern of missingness in these three variables.

```
*----*
| These measurements were made on men involved in a physical |
| fitness course at N.C. State University.
| Only selected variables of
| Oxygen (oxygen intake, ml per kg body weight per minute),
| Runtime (time to run 1.5 miles in minutes), and
| RunPulse (heart rate while running) are used.
| Certain values were changed to missing for the analysis.

```

Suppose that the data are multivariate normally distributed and that the missing data are missing at random (see the section "Statistical Assumptions for Multiple Imputation" on page 5890 in Chapter 75, "The MI Procedure," for more information about these assumptions). The following statements use the MI procedure to impute missing values for the Fitness1 data set:

```
proc mi data=Fitness1 seed=3237851 noprint out=outmi;
  var Oxygen RunTime RunPulse;
run;
```

The MI procedure creates imputed data sets, which are stored in the Outmi data set. A variable named \_Imputation\_ indicates the imputation numbers. Based on m imputations, m different sets of the point and variance estimates for a parameter can be computed. In PROC MI, m = 25 is the default.

The following statements generate regression coefficients for each of the 25 imputed data sets:

```
proc reg data=outmi outest=outreg covout noprint;
  model Oxygen= RunTime RunPulse;
  by _Imputation_;
run:
```

The following statements display (in Figure 76.1) output parameter estimates and covariance matrices from PROC REG for the first two imputed data sets:

```
proc print data=outreg(obs=8);
   var _Imputation_ _Type_ _Name_
        Intercept RunTime RunPulse;
   title 'Parameter Estimates from Imputed Data Sets';
run;
```

Figure 76.1 Parameter Estimates

#### **Parameter Estimates from Imputed Data Sets**

Obs	_Imputation_	_TYPE_	_NAME_	Intercept	RunTime	RunPulse
1	1	PARMS		86.544	-2.82231	-0.05873
2	1	COV	Intercept	100.145	-0.53519	-0.55077
3	1	COV	RunTime	-0.535	0.10774	-0.00345
4	1	COV	RunPulse	-0.551	-0.00345	0.00343
5	2	PARMS		83.021	-3.00023	-0.02491
6	2	COV	Intercept	79.032	-0.66765	-0.41918
7	2	COV	RunTime	-0.668	0.11456	-0.00313
8	2	COV	RunPulse	-0.419	-0.00313	0.00264

The following statements combine the 25 sets of regression coefficients:

```
proc mianalyze data=outreg;
  modeleffects Intercept RunTime RunPulse;
run;
```

The "Model Information" table in Figure 76.2 lists the input data set(s) and the number of imputations.

Figure 76.2 Model Information Table

#### The MIANALYZE Procedure

Model Information					
Data Set	WORK.OUTREG				
Number of Imputations	25				

The "Variance Information" table in Figure 76.3 displays the between-imputation, within-imputation, and total variances for combining complete-data inferences. It also displays the degrees of freedom for the total variance, the relative increase in variance due to missing values, the fraction of missing information, and the relative efficiency for each parameter estimate.

Figure 76.3 Variance Information Table

Variance Information (25 Imputations)								
		Variance						
Parameter	Datus	varial- t			Relative Increase	3	Relative	
	Between	Within	Total	DF	in Variance	Information	Efficiency	
Intercept		75.413875			0.310092	0.240234	0.990482	
		75.413875		428.38				

The "Parameter Estimates" table in Figure 76.4 displays a combined estimate and standard error for each regression coefficient (parameter). Inferences are based on *t* distributions. The table displays a 95% confidence interval and a *t* test with the associated *p*-value for the hypothesis that the parameter is equal to the value specified with the THETA0= option (in this case, zero by default). The minimum and maximum parameter estimates from the imputed data sets are also displayed.

Figure 76.4 Parameter Estimates

# Syntax: MIANALYZE Procedure

The following statements are available in the MIANALYZE procedure:

```
PROC MIANALYZE < options>;
BY variables;
CLASS variables;
MODELEFFECTS effects;
< label:> TEST equation1 <, ..., < equationk>> </ options>;
STDERR variables;
```

The BY statement specifies groups in which separate analyses are performed.

The CLASS statement lists the classification variables in the MODELEFFECTS statement. Classification variables can be either character or numeric.

The required MODELEFFECTS statement lists the effects to be analyzed. The variables in the statement that are not specified in a CLASS statement are assumed to be continuous.

The STDERR statement lists the standard errors associated with the effects in the MODELEFFECTS statement when both parameter estimates and standard errors are saved as variables in the same DATA= data set. The STDERR statement can be used only when each effect in the MODELEFFECTS statement is a continuous variable by itself.

The TEST statement tests linear hypotheses about the parameters. An F statistic is used to jointly test the null hypothesis ( $H_0 : \mathbf{L}_{\mathbf{z}} = \mathbf{c}$ ) specified in a single TEST statement. Several TEST statements can be used.

The PROC MIANALYZE and MODELEFFECTS statements are required for the MIANALYZE procedure. The rest of this section provides detailed syntax information for each of these statements, beginning with the PROC MIANALYZE statement. The remaining statements are in alphabetical order.

#### **PROC MIANALYZE Statement**

#### **PROC MIANALYZE** < options>;

The PROC MIANALYZE statement invokes the MIANALYZE procedure. Table 76.1 summarizes the options available in the PROC MIANALYZE statement.

OptionDescriptionInput Data SetsDATA=Specifies the COV, CORR, or EST type data setDATA=Specifies the data set for parameter estimates and standard errorsPARMS=Specifies the data set for parameter estimatesPARMINFO=Specifies the data set for parameter informationCOVB=Specifies the data set for covariance matricesXPXI=Specifies the data set for (X'X)^{-1} matrices

Table 76.1 Summary of PROC MIANALYZE Options

# Statistical Analysis

THETA0= Specifies parameters under the null hypothesis
ALPHA= Specifies the level for the confidence interval
EDF= Specifies the complete-data degrees of freedom

#### **Printed Output**

WCOV	Displays the within-imputation covariance matrix
BCOV	Displays the between-imputation covariance matrix
TCOV	Displays the total covariance matrix
MULT	Displays multivariate inferences

The following options can be used in the PROC MIANALYZE statement. They are listed in alphabetical order.

#### $ALPHA=\alpha$

specifies that confidence limits are to be constructed for the parameter estimates with confidence level  $100(1-\alpha)\%$ , where  $0<\alpha<1$ . The default is ALPHA=0.05.

#### **BCOV**

displays the between-imputation covariance matrix.

#### **COVB** < (**EFFECTVAR=STACKING** | **ROWCOL**) > = *SAS-data-set*

names an input SAS data set that contains covariance matrices of the parameter estimates from imputed data sets. If you provide a COVB= data set, you must also provide a PARMS= data set.

The EFFECTVAR= option identifies the variables for parameters displayed in the covariance matrix and is used only when the PARMINFO= option is not specified. The default is EFFECTVAR= STACKING.

See the section "Input Data Sets" on page 6002 for a detailed description of the COVB= option.

#### DATA=SAS-data-set

names an input SAS data set.

If the input DATA= data set is not a specially structured SAS data set, the data set contains both the parameter estimates and associated standard errors. The parameter estimates are specified in the MODELEFFECTS statement and the standard errors are specified in the STDERR statement.

If the data set is a specially structured input SAS data set, it must have a TYPE of EST, COV, or CORR that contains estimates from imputed data sets:

- If TYPE=EST, the data set contains the parameter estimates and associated covariance matrices.
- If TYPE=COV, the data set contains the sample means, sample sizes, and covariance matrices. Each covariance matrix for variables is divided by the sample size *n* to create the covariance matrix for parameter estimates.
- If TYPE=CORR, the data set contains the sample means, sample sizes, standard errors, and correlation matrices. The covariance matrices are computed from the correlation matrices and associated standard errors. Each covariance matrix for variables is divided by the sample size *n* to create the covariance matrix for parameter estimates.

If you do not specify an input data set with the DATA= or PARMS= option, then the most recently created SAS data set is used as an input DATA= data set. See the section "Input Data Sets" on page 6002 for a detailed description of the input data sets.

#### **EDF**=*number*

specifies the complete-data degrees of freedom for the parameter estimates. This is used to compute an adjusted degrees of freedom for each parameter estimate. By default, EDF= $\infty$  and the degrees of freedom for each parameter estimate are not adjusted.

#### **MULT**

#### **MULTIVARIATE**

requests multivariate inference for the parameters. It is based on Wald tests and is a generalization of the univariate inference. See the section "Multivariate Inferences" on page 6008 for a detailed description of the multivariate inference.

#### PARMINFO=SAS-data-set

names an input SAS data set that contains parameter information associated with variables PRM1, PRM2,..., and so on. These variables are used as variables for parameters in a COVB= data set. See the section "Input Data Sets" on page 6002 for a detailed description of the PARMINFO= option.

#### PARMS < (options) > = SAS-data-set

names an input SAS data set that contains parameter estimates computed from imputed data sets. When a COVB= data set is not specified, the input PARMS= data set also contains standard errors associated with these parameter estimates. If multivariate inference is requested, you must also provide a COVB= or XPXI= data set.

The available *options* are as follows:

#### CLASSVAR=FULL | LEVEL | CLASSVAL

identifies the associated classification variables when reading the classification levels from observations. The CLASSVAR= option is applicable only when the model effects contain classification variables. The default is CLASSVAR= FULL.

#### LINK=NONE | LOGIT | GLOGIT

identifies the type of parameter estimates. The LINK=NONE option (which is the default) indicates the parameter estimates that are derived from a procedure other than the LOGISTIC procedure.

The LINK=LOGIT option indicates the parameter estimates that are derived from the LOGISTIC procedure for ordinal responses. It is applicable only when the variable Intercept is in the MOD-ELEFFECTS statement and the logistic model has more than two response levels. Otherwise, LINK=NONE should be used.

The LINK=GLOGIT option indicates the parameter estimates that are derived from the LOGIS-TIC procedure for nominal responses.

For a detailed description of the PARMS= option, see the section "PARMS < ( parms-options) >= Data Set" on page 6003

#### **TCOV**

displays the total covariance matrix derived by assuming that the population between-imputation and within-imputation covariance matrices are proportional to each other.

#### THETA0=numbers

#### MU0=numbers

specifies the parameter values  $\theta_0$  under the null hypothesis  $\theta = \theta_0$  in the t tests for location for the effects. If only one number  $\theta_0$  is specified, that number is used for all effects. If more than one number is specified, the specified numbers correspond to effects in the MODELEFFECTS statement in the order in which they appear in the statement. When an effect contains classification variables, the corresponding value is not used and the test is not performed.

#### **WCOV**

displays the within-imputation covariance matrices.

#### XPXI=SAS-data-set

names an input SAS data set that contains the  $(X'X)^{-1}$  matrices associated with the parameter estimates computed from imputed data sets. If you provide an XPXI= data set, you must also provide a PARMS= data set. In this case, PROC MIANALYZE reads the standard errors of the estimates from the PARMS= data. The standard errors and  $(X'X)^{-1}$  matrices are used to derive the covariance matrices.

#### **BY Statement**

#### BY variables;

You can specify a BY statement with PROC MIANALYZE to obtain separate analyses of observations in groups that are defined by the BY variables. When a BY statement appears, the procedure expects the input data set to be sorted in order of the BY variables. If you specify more than one BY statement, only the last one specified is used.

If your input data set is not sorted in ascending order, use one of the following alternatives:

- Sort the data by using the SORT procedure with a similar BY statement.
- Specify the NOTSORTED or DESCENDING option in the BY statement for the MIANALYZE procedure. The NOTSORTED option does not mean that the data are unsorted but rather that the data are arranged in groups (according to values of the BY variables) and that these groups are not necessarily in alphabetical or increasing numeric order.
- Create an index on the BY variables by using the DATASETS procedure (in Base SAS software).

For more information about BY-group processing, see the discussion in SAS Language Reference: Concepts. For more information about the DATASETS procedure, see the discussion in the Base SAS Procedures Guide.

#### **CLASS Statement**

#### CLASS variables;

The CLASS statement specifies the classification variables in the MODELEFFECTS statement. Classification variables can be either character or numeric. Classification levels are determined from the formatted values of the classification variables. See "The FORMAT Procedure" in the *Base SAS Procedures Guide* for details.

#### **MODELEFFECTS Statement**

#### **MODELEFFECTS** *effects* ;

The MODELEFFECTS statement lists the effects in the data set to be analyzed. Each effect is a variable or a combination of variables, and is specified with a special notation that uses variable names and operators.

Each variable is either a classification (or CLASS) variable or a continuous variable. If a variable is not declared in the CLASS statement, it is assumed to be continuous. Crossing and nesting operators can be used in an effect to create crossed and nested effects.

One general form of an effect involving several variables is

$$X1 * X2 * A * B * C(DE)$$

where A, B, C, D, and E are classification variables and X1 and X2 are continuous variables.

When the input DATA= data set is not a specially structured SAS data set, you must also specify standard errors of the parameter estimates in an STDERR statement.

#### **STDERR Statement**

```
STDERR variables;
```

The STDERR statement lists standard errors associated with effects in the MODELEFFECTS statement, when the input DATA= data set contains both parameter estimates and standard errors as variables in the data set.

With the STDERR statement, only continuous effects are allowed in the MODELEFFECTS statement. The specified standard errors correspond to parameter estimates in the order in which they appear in the MODELEFFECTS statement.

For example, you can use the following MODELEFFECTS and STDERR statements to identify both the parameter estimates and associated standard errors in a SAS data set:

```
proc mianalyze;
  modeleffects y1 y2;
  stderr sy1 sy2;
run;
```

#### **TEST Statement**

```
< label: > TEST equation1 < , ..., < equationk >> </ options > ;
```

The TEST statement tests linear hypotheses about the parameters  $\beta$ . An F test is used to jointly test the null hypotheses ( $H_0: \mathbf{L}\beta = \mathbf{c}$ ) specified in a single TEST statement in which the MULT option is specified.

Each *equation* specifies a linear hypothesis (a row of the L matrix and the corresponding element of the c vector); multiple *equations* are separated by commas. The label, which must be a valid SAS name, is used to identify the resulting output. You can submit multiple TEST statements. When a label is not included in a TEST statement, a label of "Test j" is used for the jth TEST statement.

The form of an *equation* is as follows:

```
term < \pm term ... > < = \pm term < \pm term ... > >
```

where *term* is a parameter of the model, or a constant, or a constant times a parameter. When no equal sign appears, the expression is set to 0. Only parameters for regressor effects (continuous variables by themselves) are allowed.

For each TEST statement, PROC MIANALYZE displays a "Test Specification" table of the L matrix and the c vector. The procedure also displays a "Variance Information" table of the between-imputation, within-imputation, and total variances for combining complete-data inferences, and a "Parameter Estimates" table of a combined estimate and standard error for each linear component. The linear components are labeled TestPrm1, TestPrm2, ... in the tables.

The following statements illustrate possible uses of the TEST statement:

```
proc mianalyze;
  modeleffects intercept a1 a2 a3;
  test1: test intercept + a2 = 0;
  test2: test intercept + a2;
  test3: test a1=a2=a3;
  test4: test a1=a2, a2=a3;
run:
```

The first and second TEST statements are equivalent and correspond to the specification in Figure 76.5.

Figure 76.5 Test Specification for test1 and test2

# The MIANALYZE Procedure Test: test1 Test Specification

	L Matrix					
Parameter	intercept	a1	a2	a3	С	
TestPrm1	1.000000	0	1.000000	0	0	

The third and fourth TEST statements are also equivalent and correspond to the specification in Figure 76.6.

Figure 76.6 Test Specification for test3 and test4

# The MIANALYZE Procedure Test: test3

Test Specification								
	L Matrix							
Parameter	intercept	a1	a2	a3	С			
TestPrm1	0	1.000000	-1.000000	0	0			
TestPrm2	0	0	1.000000	-1.000000	0			

The ALPHA= and EDF options specified in the PROC MIANALYZE statement are also applied to the TEST statement. You can specify the following options in the TEST statement after a slash(/):

#### **BCOV**

displays the between-imputation covariance matrix.

#### **MULT**

displays the multivariate inference for parameters.

#### **TCOV**

displays the total covariance matrix.

#### **WCOV**

displays the within-imputation covariance matrix.

For more information, see the section "Testing Linear Hypotheses about the Parameters" on page 6009.

# **Details: MIANALYZE Procedure**

## Input Data Sets

You specify input data sets based on the type of inference you requested. For univariate inference, you can use one of the following options:

- a DATA= data set, which provides both parameter estimates and the associated standard errors
- a DATA=EST, COV, or CORR data set, which provides both parameter estimates and the associated standard errors either explicitly (type CORR) or through the covariance matrix (type EST, COV)
- PARMS= data set, which provides both parameter estimates and the associated standard errors

For multivariate inference, which includes the testing of linear hypotheses about parameters, you can use one of the following option combinations:

- a DATA=EST, COV, or CORR data set, which provides parameter estimates and the associated covariance matrix either explicitly (type EST, COV) or through the correlation matrix and standard errors (type CORR) in a single data set
- PARMS= and COVB= data sets, which provide parameter estimates in a PARMS= data set and the associated covariance matrix in a COVB= data set
- PARMS=, COVB=, and PARMINFO= data sets, which provide parameter estimates in a PARMS= data set, the associated covariance matrix in a COVB= data set with variables named PRM1, PRM2, ..., and the effects associated with these variables in a PARMINFO= data set
- PARMS= and XPXI= data sets, which provide parameter estimates and the associated standard errors in a PARMS= data set and the associated  $(X'X)^{-1}$  matrix in an XPXI= data set

The appropriate combination depends on the type of inference and the SAS procedure you used to create the data sets. For instance, if you used PROC REG to create an OUTEST= data set that contains the parameter estimates and covariance matrix, you would use the DATA= option to read the OUTEST= data set.

When the input DATA= data set is a specially structured SAS data set, the data set must contain the variable Imputation to identify the imputation by number. Otherwise, each observation corresponds to an imputation and contains both parameter estimates and associated standard errors.

If you do not specify an input data set with the DATA= or PARMS= option, then the most recently created SAS data set is used as an input DATA= data set. Note that with a DATA= data set, each effect represents a continuous variable; only regressor effects (continuous variables by themselves) are allowed in the MODELEFFECTS statement.

#### **DATA= SAS Data Set**

The DATA= data set provides both parameter estimates and the associated standard errors computed from imputed data sets. Such data sets are typically created with an OUTPUT statement in procedures such as PROC MEANS and PROC UNIVARIATE.

The MIANALYZE procedure reads parameter estimates from observations with variables in the MODEL-EFFECTS statement, and standard errors for parameter estimates from observations with variables in the STDERR statement. The order of the variables for standard errors must match the order of the variables for parameter estimates.

#### DATA=EST, COV, or CORR SAS Data Set

The specially structured DATA= data set provides both parameter estimates and the associated covariance matrix computed from imputed data sets. Such data sets are created by procedures such as PROC CORR (type COV, CORR) and PROC REG (type EST).

With a DATA=EST data set, the MIANALYZE procedure reads parameter estimates from observations with \_TYPE\_='PARM', \_TYPE\_='PARMS', \_TYPE\_='OLS', or \_TYPE\_='FINAL', and covariance matrices for parameter estimates from observations with \_TYPE\_='COV' or \_TYPE\_='COVB'.

With a DATA=COV data set, the procedure reads sample means from observations with \_TYPE\_='MEAN', sample size n from observations with \_TYPE\_='N', and covariance matrices for variables from observations with \_TYPE = 'COV'.

With a DATA=CORR data set, the procedure reads sample means from observations with \_TYPE\_='MEAN', sample size *n* from observations with \_TYPE\_='N', correlation matrices for variables from observations with \_TYPE\_='CORR', and standard errors for variables from observations with \_TYPE\_='STD'. The standard errors and correlation matrix are used to generate a covariance matrix for the variables.

Note that with a DATA=COV or DATA=CORR data set, each covariance matrix for the variables is divided by *n* to create the covariance matrix for the sample means.

#### PARMS < ( parms-options) >= Data Set

The PARMS= data set contains both parameter estimates and the associated standard errors computed from imputed data sets. Such data sets are typically created with an ODS OUTPUT statement in procedures such as PROC GENMOD, PROC GLM, PROC LOGISTIC, and PROC MIXED.

The MIANALYZE procedure reads effect names from observations with the variable Parameter, Effect, Variable, or Parm. It then reads parameter estimates from observations with the variable Estimate and standard errors for parameter estimates from observations with the variable StdErr.

The available *parms-options* include the CLASSVAR= option to identify classification variables and the LINK= option to input logistic regression results. When the parameter estimates are derived from the LOGISTIC procedure, the LINK= option can be used to identify the variable required when the parameter estimates are read from observations. The available options are as follows:

- LINK=NONE (which is the default), in which each model effect is completely identified from the effect name. This option should be used for all procedures except PROC LOGISTIC.
- LINK=LOGIT, in which the variable ClassVal0 is used to identify response levels for Intercept from PROC LOGISTIC for ordinal responses. This option is applicable only when the variable Intercept is in

the MODELEFFECTS statement and the logistic model has more than two response levels. Otherwise, LINK=NONE should be used.

• LINK=GLOGIT, in which the variable Response is used to identify response levels for the parameters from PROC LOGISTIC for nominal responses.

When the effects contain classification variables, the CLASSVAR= option can be used to identify the variables when reading the classification levels from observations. The available options are:

- CLASSVAR=FULL (which is the default), the data set contains the classification variables explicitly. PROC MIANALYZE reads the classification levels from observations with their corresponding classification variables. PROC MIXED generates this type of table.
- CLASSVAR=LEVEL, PROC MIANALYZE reads the classification levels for the effect from observations with variables Level1, Level2, and so on, where the variable Level1 contains the classification level for the first classification variable in the effect, and the variable Level2 contains the classification level for the second classification variable in the effect. For each effect, the variables in the crossed list are displayed before the variables in the nested list. The variable order in the CLASS statement is used for variables inside each list. PROC GENMOD generates this type of table.

For example, with the following statements, the variable Level1 has the classification level of the variable c2 for the effect c2:

```
proc mianalyze parms(classvar=Level) = dataparm;
  class c1 c2 c3;
  modeleffects c2 c3(c2 c1);
run;
```

For the effect c3(c2 c1), the variable Level1 has the classification level of the variable c3, Level2 has the level of c1, and Level3 has the level of c2.

CLASSVAR=CLASSVAL, PROC MIANALYZE reads the classification levels for the effect from
observations with variables ClassVal0, ClassVal1, and so on, where the variable ClassVal0 contains the
classification level for the first classification variable in the effect, and the variable ClassVal1 contains
the classification level for the second classification variable in the effect. For each effect, the variables
in the crossed list are displayed before the variables in the nested list. The variable order in the CLASS
statement is used for variables inside each list. PROC LOGISTIC generates this type of tables.

### PARMS < ( parms-options) >= and COVB < (EFFECTVAR=etype) >= Data Sets

The PARMS= data set contains parameter estimates, and the COVB= data set contains associated covariance matrices computed from imputed data sets. Such data sets are typically created with an ODS OUTPUT statement in procedures such as PROC LOGISTIC, PROC MIXED, and PROC REG.

When you specify a PARMS= data set, the MIANALYZE procedure reads effect names from observations with the variable Parameter, Effect, Variable, or Parm. It then reads parameter estimates from observations with the variable Estimate.

The available *parms-options* include the CLASSVAR= option to identify classification variables and the LINK= option to input logistic regression results. For a detailed description of the PARMS= option, see the section "PARMS < ( *parms-options*) >= Data Set" on page 6003.

The EFFECTVAR=*etype* option identifies the variables for parameters displayed in the covariance matrix. The available types are STACKING and ROWCOL:

- EFFECTVAR=STACKING (which is the default), each parameter is displayed by stacking variables in the effect. Begin with the variables in the crossed list, followed by the continuous list, then followed by the nested list. Each classification variable is displayed with its classification level attached. PROC LOGISTIC generates this type of table. When each effect is a continuous variable by itself, each stacked parameter name reduces to the effect name. PROC REG generates this type of table.
  - The MIANALYZE procedure reads parameter names from observations with the variable Parameter, Effect, Variable, Parm, or RowName. It then reads covariance matrices from observations with the stacked variables in a COVB= data set.
- EFFECTVAR=ROWCOL, parameters are displayed by the variables Col1, Col2, ... The parameter associated with the variable Col1 is identified by the observation with value 1 for the variable Row. The parameter associated with the variable Col2 is identified by the observation with value 2 for the variable Row. PROC MIXED generates this type of table.

The MIANALYZE procedure reads the parameter indices from observations with the variable Row and the effect names from observations with the variable Parameter, Effect, Variable, Parm, or RowName. It then reads covariance matrices from observations with the variables Col1, Col2, and so on in a COVB= data set.

When the effects contain classification variables, the data set contains the classification variables explicitly and the MIANALYZE procedure also reads the classification levels from their corresponding classification variables.

#### PARMS < (CLASSVAR= ctype) > =, PARMINFO=, and COVB= Data Sets

The input PARMS= data set contains parameter estimates, the PARMINFO= data set identifies parameters with the variables Prm1, Prm2, and so on, and the COVB= data set contains associated covariance matrices with the variables Prm1, Prm2, and so on. Such data sets are typically created with an ODS OUTPUT statement using procedure such as PROC GENMOD.

When you specify a PARMS= data set, the MIANALYZE procedure reads effect names from observations with the variable Parameter, Effect, Variable, or Parm. It then reads parameter estimates from observations with the variable Estimate.

When the effects contain classification variables, the option CLASSVAR= *ctype* can be used to identify the associated classification variables when reading the classification levels from observations. The available types are FULL, LEVEL, and CLASSVAL, and they are described in the section "PARMS <( parms-options) >= Data Set" on page 6003. The default is CLASSVAR= FULL.

When you specify a COVB= data set, the MIANALYZE procedure reads parameter names from observations with the variable Parameter, Effect, Variable, Parm, or RowName. It then reads covariance matrices from observations with the variables Prm1, Prm2, and so on.

The parameters associated with the variables Prm1, Prm2, and so on are identified in the PARMINFO= data set. PROC MIANALYZE reads the parameter names from observations with the variable Parameter and the corresponding effect from observations with the variable Effect. When the effects contain classification variables, the data set contains the classification variables explicitly and the MIANALYZE procedure also reads the classification levels from observations with their corresponding classification variables.

#### PARMS= and XPXI= Data Sets

The input PARMS= data set contains parameter estimates, and the input XPXI= data set contains associated  $(X'X)^{-1}$  matrices computed from imputed data sets. Such data sets are typically created with an ODS OUTPUT statement in a procedure such as PROC GLM.

When you specify a PARMS= data set, the MIANALYZE procedure reads parameter names from observations with the variable Parameter, Effect, Variable, or Parm. It then reads parameter estimates from observations with the variable Estimate and standard errors for parameter estimates from observations with the variable StdErr.

When you specify a XPXI= data set, the MIANALYZE procedure reads parameter names from observations with the variable Parameter and  $(X'X)^{-1}$  matrices from observations with the parameter variables in the data set.

Note that this combination can be used only when each effect is a continuous variable by itself.

## **Combining Inferences from Imputed Data Sets**

With m imputations, m different sets of the point and variance estimates for a parameter Q can be computed. Suppose that  $\hat{Q}_i$  and  $\hat{W}_i$  are the point and variance estimates, respectively, from the ith imputed data set,  $i = 1, 2, \ldots, m$ . Then the combined point estimate for Q from multiple imputation is the average of the m complete-data estimates:

$$\overline{Q} = \frac{1}{m} \sum_{i=1}^{m} \hat{Q}_i$$

Suppose that  $\overline{W}$  is the within-imputation variance, which is the average of the m complete-data estimates:

$$\overline{W} = \frac{1}{m} \sum_{i=1}^{m} \hat{W}_{i}$$

And suppose that *B* is the between-imputation variance:

$$B = \frac{1}{m-1} \sum_{i=1}^{m} (\hat{Q}_i - \overline{Q})^2$$

Then the variance estimate associated with  $\overline{Q}$  is the total variance (Rubin 1987)

$$T = \overline{W} + (1 + \frac{1}{m})B$$

The statistic  $(Q - \overline{Q})T^{-(1/2)}$  is approximately distributed as t with  $v_m$  degrees of freedom (Rubin 1987), where

$$v_m = (m-1) \left[ 1 + \frac{\overline{W}}{(1+m^{-1})B} \right]^2$$

The degrees of freedom  $v_m$  depend on m and the ratio

$$r = \frac{(1 + m^{-1})B}{\overline{W}}$$

The ratio r is called the relative increase in variance due to nonresponse (Rubin 1987). When there is no missing information about Q, the values of r and B are both zero. With a large value of m or a small value of r, the degrees of freedom  $v_m$  will be large and the distribution of  $(Q - \overline{Q})T^{-(1/2)}$  will be approximately normal.

Another useful statistic is the fraction of missing information about Q:

$$\hat{\lambda} = \frac{r + 2/(v_m + 3)}{r + 1}$$

Both statistics r and  $\lambda$  are helpful diagnostics for assessing how the missing data contribute to the uncertainty about Q.

When the complete-data degrees of freedom  $v_0$  are small, and there is only a modest proportion of missing data, the computed degrees of freedom,  $v_m$ , can be much larger than  $v_0$ , which is inappropriate. For example, with m = 5 and r = 10%, the computed degrees of freedom  $v_m = 484$ , which is inappropriate for data sets with complete-data degrees of freedom less than 484.

Barnard and Rubin (1999) recommend the use of adjusted degrees of freedom

$$v_m^* = \left[\frac{1}{v_m} + \frac{1}{\hat{v}_{obs}}\right]^{-1}$$

where  $\hat{v}_{obs} = (1 - \gamma) v_0(v_0 + 1)/(v_0 + 3)$  and  $\gamma = (1 + m^{-1})B/T$ .

If you specify the complete-data degrees of freedom  $v_0$  with the EDF= option, the MIANALYZE procedure uses the adjusted degrees of freedom,  $v_m^*$ , for inference. Otherwise, the degrees of freedom  $v_m$  are used.

# **Multiple Imputation Efficiency**

The relative efficiency (RE) of using the finite m imputation estimator, rather than using an infinite number for the fully efficient imputation, in units of variance, is approximately a function of m and  $\lambda$  (Rubin 1987, p. 114):

$$RE = (1 + \frac{\lambda}{m})^{-1}$$

Table 76.2 shows relative efficiencies with different values of m and  $\lambda$ .

			λ		
m	10%	20%	30%	50%	70%
3	0.9677	0.9375	0.9091	0.8571	0.8108
5	0.9804	0.9615	0.9434	0.9091	0.8772
10	0.9901	0.9804	0.9709	0.9524	0.9346
20	0.9950	0.9901	0.9852	0.9756	0.9662

Table 76.2 Relative Efficiencies

The table shows that for situations with little missing information, only a small number of imputations are necessary. In practice, the number of imputations needed can be informally verified by replicating sets of *m* imputations and checking whether the estimates are stable between sets (Horton and Lipsitz 2001, p. 246).

#### **Multivariate Inferences**

Multivariate inference based on Wald tests can be done with m imputed data sets. The approach is a generalization of the approach taken in the univariate case (Rubin 1987, p. 137; Schafer 1997, p. 113). Suppose that  $\hat{\mathbf{Q}}_i$  and  $\hat{\mathbf{W}}_i$  are the point and covariance matrix estimates for a p-dimensional parameter  $\mathbf{Q}$  (such as a multivariate mean) from the ith imputed data set, i = 1, 2, ..., m. Then the combined point estimate for  $\mathbf{Q}$  from the multiple imputation is the average of the m complete-data estimates:

$$\overline{\mathbf{Q}} = \frac{1}{m} \sum_{i=1}^{m} \hat{\mathbf{Q}}_{i}$$

Suppose that  $\overline{\mathbf{W}}$  is the within-imputation covariance matrix, which is the average of the *m* complete-data estimates:

$$\overline{\mathbf{W}} = \frac{1}{m} \sum_{i=1}^{m} \hat{\mathbf{W}}_{i}$$

And suppose that **B** is the between-imputation covariance matrix:

$$\mathbf{B} = \frac{1}{m-1} \sum_{i=1}^{m} (\hat{\mathbf{Q}}_i - \overline{\mathbf{Q}}) (\hat{\mathbf{Q}}_i - \overline{\mathbf{Q}})'$$

Then the covariance matrix associated with  $\overline{\mathbf{Q}}$  is the total covariance matrix

$$\mathbf{T}_0 = \overline{\mathbf{W}} + (1 + \frac{1}{m})\mathbf{B}$$

The natural multivariate extension of the t statistic used in the univariate case is the F statistic

$$F_0 = (\mathbf{Q} - \overline{\mathbf{Q}})' \mathbf{T}_0^{-1} (\mathbf{Q} - \overline{\mathbf{Q}})$$

with degrees of freedom p and

$$v = (m-1)(1+1/r)^2$$

where

$$r = (1 + \frac{1}{m})\operatorname{trace}(\mathbf{B}\overline{\mathbf{W}}^{-1})/p$$

is an average relative increase in variance due to nonresponse (Rubin 1987, p. 137; Schafer 1997, p. 114).

However, the reference distribution of the statistic  $F_0$  is not easily derived. Especially for small m, the between-imputation covariance matrix **B** is unstable and does not have full rank for  $m \le p$  (Schafer 1997, p. 113).

One solution is to make an additional assumption that the population between-imputation and within-imputation covariance matrices are proportional to each other (Schafer 1997, p. 113). This assumption implies that the fractions of missing information for all components of  $\mathbf{Q}$  are equal. Under this assumption, a more stable estimate of the total covariance matrix is

$$T = (1 + r)\overline{W}$$

With the total covariance matrix T, the F statistic (Rubin 1987, p. 137)

$$F = (\mathbf{Q} - \overline{\mathbf{Q}})'\mathbf{T}^{-1}(\mathbf{Q} - \overline{\mathbf{Q}})/p$$

has an F distribution with degrees of freedom p and  $v_1$ , where

$$v_1 = \frac{1}{2}(p+1)(m-1)(1+\frac{1}{r})^2$$

For  $t = p(m-1) \le 4$ , PROC MIANALYZE uses the degrees of freedom  $v_1$  in the analysis. For t = p(m-1) > 4, PROC MIANALYZE uses  $v_2$ , a better approximation of the degrees of freedom given by Li, Raghunathan, and Rubin (1991):

$$v_2 = 4 + (t - 4) \left[ 1 + \frac{1}{r} (1 - \frac{2}{t}) \right]^2$$

# **Testing Linear Hypotheses about the Parameters**

Linear hypotheses for parameters  $\beta$  are expressed in matrix form as

$$H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$$

where L is a matrix of coefficients for the linear hypotheses and c is a vector of constants.

Suppose that  $\hat{\mathbf{Q}}_i$  and  $\hat{\mathbf{U}}_i$  are the point and covariance matrix estimates, respectively, for a *p*-dimensional parameter  $\mathbf{Q}$  from the *i*th imputed data set, i=1, 2, ..., m. Then for a given matrix  $\mathbf{L}$ , the point and covariance matrix estimates for the linear functions  $\mathbf{L}\mathbf{Q}$  in the *i*th imputed data set are, respectively,

$$\mathbf{L}\hat{\mathbf{Q}_i}$$

$$\mathbf{L}\hat{\mathbf{U}_i}\mathbf{L}'$$

The inferences described in the section "Combining Inferences from Imputed Data Sets" on page 6006 and the section "Multivariate Inferences" on page 6008 are applied to these linear estimates for testing the null hypothesis  $H_0: \mathbf{L}\boldsymbol{\beta} = \mathbf{c}$ .

For each TEST statement, the "Test Specification" table displays the **L** matrix and the **c** vector, the "Variance Information" table displays the between-imputation, within-imputation, and total variances for combining complete-data inferences, and the "Parameter Estimates" table displays a combined estimate and standard error for each linear component.

With the WCOV and BCOV options in the TEST statement, the procedure displays the within-imputation and between-imputation covariance matrices, respectively.

With the TCOV option, the procedure displays the total covariance matrix derived under the assumption that the population between-imputation and within-imputation covariance matrices are proportional to each other.

With the MULT option in the TEST statement, the "Multivariate Inference" table displays an F test for the null hypothesis  $\mathbf{L}\boldsymbol{\beta} = \mathbf{c}$  of the linear components.

## **Examples of the Complete-Data Inferences**

For a given parameter of interest, it is not always possible to compute the estimate and associated covariance matrix directly from a SAS procedure. This section describes examples of parameters with their estimates and associated covariance matrices, which provide the input to the MIANALYZE procedure. Some are straightforward, and others require special techniques.

#### **Means**

For a population mean vector  $\mu$ , the usual estimate is the sample mean vector

$$\overline{\mathbf{y}} = \frac{1}{n} \sum \mathbf{y}_i$$

A variance estimate for  $\overline{y}$  is  $\frac{1}{n}S$ , where S is the sample covariance matrix

$$S = \frac{1}{n-1} \sum_{i} (y_i - \overline{y})(y_i - \overline{y})'$$

These statistics can be computed from a procedure such as PROC CORR. This approach is illustrated in Example 76.2.

#### **Regression Coefficients**

Many SAS procedures are available for regression analysis. Among them, PROC REG provides the most general analysis capabilities, and others like PROC LOGISTIC and PROC MIXED provide more specialized analyses.

Some regression procedures, such as REG and LOGISTIC, create an EST type data set that contains both the parameter estimates for the regression coefficients and their associated covariance matrix. You can read an EST type data set in the MIANALYZE procedure with the DATA= option. This approach is illustrated in Example 76.3.

Other procedures, such as GLM, MIXED, and GENMOD, do not generate EST type data sets for regression coefficients. For PROC MIXED and PROC GENMOD, you can use ODS OUTPUT statement to save parameter estimates in a data set and the associated covariance matrix in a separate data set. These data sets are then read in the MIANALYZE procedure with the PARMS= and COVB= options, respectively. This approach is illustrated in Example 76.4 for PROC MIXED and in Example 76.5 for PROC GENMOD.

PROC GLM does not display tables for covariance matrices. However, you can use the ODS OUTPUT statement to save parameter estimates and associated standard errors in a data set and the associated  $(X'X)^{-1}$ matrix in a separate data set. These data sets are then read in the MIANALYZE procedure with the PARMS= and XPXI= options, respectively. This approach is illustrated in Example 76.6.

For univariate inference, only parameter estimates and associated standard errors are needed. You can use the ODS OUTPUT statement to save parameter estimates and associated standard errors in a data set. This data set is then read in the MIANALYZE procedure with the PARMS= option. This approach is illustrated in Example 76.4.

#### **Correlation Coefficients**

For the population correlation coefficient  $\rho$ , a point estimate is the sample correlation coefficient r. However, for nonzero  $\rho$ , the distribution of r is skewed.

The distribution of r can be normalized through Fisher's z transformation

$$z(r) = \frac{1}{2} \log \left( \frac{1+r}{1-r} \right)$$

z(r) is approximately normally distributed with mean  $z(\rho)$  and variance 1/(n-3).

With a point estimate  $\hat{z}$  and an approximate 95% confidence interval  $(z_1, z_2)$  for  $z(\rho)$ , a point estimate  $\hat{r}$  and a 95% confidence interval  $(r_1, r_2)$  for  $\rho$  can be obtained by applying the inverse transformation

$$r = \tanh(z) = \frac{e^{2z} - 1}{e^{2z} + 1}$$

to  $z = \hat{z}, z_1$ , and  $z_2$ .

This approach is illustrated in Example 76.11.

#### **Ratios of Variable Means**

For the ratio  $\mu_1/\mu_2$  of means for variables  $Y_1$  and  $Y_2$ , the point estimate is  $\overline{y}_1/\overline{y}_2$ , the ratio of the sample means. The Taylor expansion and delta method can be applied to the function  $y_1/y_2$  to obtain the variance estimate (Schafer 1997, p. 196)

$$\frac{1}{n} \left[ \left( \frac{\overline{y}_1}{\overline{y}_2^2} \right)^2 s_{22} - 2 \left( \frac{\overline{y}_1}{\overline{y}_2^2} \right) \left( \frac{1}{\overline{y}_2} \right) s_{12} + \left( \frac{1}{\overline{y}_2} \right)^2 s_{11} \right]$$

where  $s_{11}$  and  $s_{22}$  are the sample variances of  $Y_1$  and  $Y_2$ , respectively, and  $s_{12}$  is the sample covariance between  $Y_1$  and  $Y_2$ .

A ratio of sample means will be approximately unbiased and normally distributed if the coefficient of variation of the denominator (the standard error for the mean divided by the estimated mean) is 10% or less (Cochran 1977, p. 166; Schafer 1997, p. 196).

#### **ODS Table Names**

PROC MIANALYZE assigns a name to each table it creates. You must use these names to reference tables when using the Output Delivery System (ODS). These names are listed in Table 76.3. For more information about ODS, see Chapter 20, "Using the Output Delivery System."

ODS Table Name	Description	Statement	Option
BCov	Between-imputation covariance matrix		BCOV
ModelInfo	Model information		
MultStat	Multivariate inference		MULT
ParameterEstimates	Parameter estimates		
TCov	Total covariance matrix		TCOV
TestBCov	Between-imputation covariance matrix for $L\beta$	TEST	BCOV
TestMultStat	Multivariate inference for $L\beta$	TEST	MULT
TestParameterEstimates	Parameter estimates for $L\beta$	TEST	
TestSpec	Test specification, L and c	TEST	
TestTCov	Total covariance matrix for $L\beta$	TEST	TCOV
TestVarianceInfo	Variance information for $L\beta$	TEST	
TestWCov	Within-imputation covariance matrix for $L\beta$	TEST	WCOV
VarianceInfo	Variance information		
WCov	Within-imputation covariance matrix		WCOV

**Table 76.3** ODS Tables Produced by PROC MIANALYZE

# **Examples: MIANALYZE Procedure**

The following statements generate five imputed data sets to be used in this section. The data set Fitness1 was created in the section "Getting Started: MIANALYZE Procedure" on page 5993. For more information about the MI procedure, See Chapter 75, "The MI Procedure."

```
proc mi data=Fitness1 seed=3237851 noprint out=outmi;
  var Oxygen RunTime RunPulse;
run;
```

The Fish data described in the STEPDISC procedure are measurements of 159 fish of seven species caught in Finland's Lake Laengelmaevesi. For each fish, the length, height, and width are measured. See Chapter 108, "The STEPDISC Procedure," for more information.

The Fish2 data set is constructed from the Fish data set and contains two species of fish. Some values have been set to missing, and the resulting data set has a monotone missing pattern in the variables Length, Width, and Species.

The following statements create the Fish2 data set. It contains two species of fish in the Fish data set.

```
*-----*
| The data set contains two species of the fish (Parkki and Perch)
| and two measurements: Length and Width.
| Some values have been set to missing, and the resulting data set |
| has a monotone missing pattern in the variables
| Length, Width, and Species.

```

The following statements generate 25 imputed data sets to be used in this section. The default regression method is used to impute missing values in continuous variable Width, and the discriminant function method is used to impute the variable Species.

```
proc mi data=Fish2 seed=1305417 out=outfish2;
  class Species;
  monotone logistic( Species= Length Width);
  var Length Width Species;
run;
```

The Fish3 data set is constructed from the Fish data set and contains three species of fish. Some values have been set to missing, and the resulting data set has an arbitrary missing pattern in the variables Length, Width, and Species.

The following statements create the Fish3 data set. It contains two species of fish in the Fish data set.

```
*-----*
| The data set contains three species of the fish
| (Parkki, Perch, and Roach) and two measurements: Length and Width. |
| Some values have been set to missing, and the resulting data set
| has an arbitrary missing pattern in the variables
| Length, Width, and Species.

```

The following statements generate 25 imputed data sets to be used in this section. The default regression method is used to impute missing values in continuous variable Width, and the nominal logistic regression method is used to impute the variable Species.

```
proc mi data=Fish3 seed=30535 out=outfish3;
  class Species;
  fcs logistic ( Species= Length Width / link=glogit);
  var Length Width Species;
run;
```

Example 76.1 through Example 76.7 use different input option combinations to combine parameter estimates computed from different procedures. Example 76.8 combines parameter estimates with classification variables, and Example 76.9 combines nominal logistic regression parameter estimates Example 76.10 shows the use of a TEST statement, and Example 76.11 combines statistics that are not directly derived from procedures.

The MI procedure provides sensitivity analysis for the MAR assumption. Example 76.12 illustrate sensitivity analysis by using the pattern-mixture model approach, and Example 76.13 performs sensitivity analysis by searching and examining the tipping point that reverses the study conclusion.

## **Example 76.1: Reading Means and Standard Errors from a DATA= Data Set**

This example creates an ordinary SAS data set that contains sample means and standard errors computed from imputed data sets. These estimates are then combined to generate valid univariate inferences about the population means.

The following statements use the UNIVARIATE procedure to generate sample means and standard errors for the variables in each imputed data set:

The following statements display the output data set from PROC UNIVARIATE shown in Output 76.1.1:

```
proc print data=outuni (obs=10);
   title 'UNIVARIATE Means and Standard Errors (First 10 Imputations)';
run;
```

Output 76.1.1 UNIVARIATE Output Data Set

#### **UNIVARIATE Means and Standard Errors (First 10 Imputations)**

Obs	_Imputation_	Oxygen	RunTime	RunPulse	SOxygen	SRunTime	SRunPulse

10	10	46.9587	10.5518	171.197	0.94270	0.25214	1.89054

The following statements combine the means and standard errors from imputed data sets, The EDF= option requests that the adjusted degrees of freedom be used in the analysis. For sample means based on 31 observations, the complete-data error degrees of freedom is 30.

```
proc mianalyze data=outuni edf=30;
  modeleffects Oxygen RunTime RunPulse;
  stderr SOxygen SRunTime SRunPulse;
  run;
```

The "Model Information" table in Output 76.1.2 lists the input data set(s) and the number of imputations.

Output 76.1.2 Model Information

#### The MIANALYZE Procedure

Model Information							
Data Set	WORK.OUTUNI						
Number of Imputations	25						

The "Variance Information" table in Output 76.1.3 displays the between-imputation variance, within-imputation variance, and total variance for each univariate inference. It also displays the degrees of freedom for the total variance. The relative increase in variance due to missing values, the fraction of missing information, and the relative efficiency for each imputed variable are also displayed. A detailed description of these statistics is provided in the section "Combining Inferences from Imputed Data Sets" on page 6006 and the section "Multiple Imputation Efficiency" on page 6007.

Output 76.1.3 Variance Information

	Variance Information (25 Imputations)									
		Variance								
					Relative Increase	Fraction Missing	Relative			
Parameter	Between	Within	Total	DF	in Variance	Information	Efficiency

RunTime	0.002938	0.068197	0.071253	26.918	0.044810	0.043035	0.998282			
RunPulse	0.598494	3.345356	3.967790	23.196	0.186059	0.158595	0.993696			

The "Parameter Estimates" table in Output 76.1.4 displays the estimated mean and corresponding standard error for each variable. The table also displays a 95% confidence interval for the mean and a *t* statistic with the associated *p*-value for testing the hypothesis that the mean is equal to the value specified. You can use the THETA0= option to specify the value for the null hypothesis, which is zero by default. The table also displays the minimum and maximum parameter estimates from the imputed data sets.

Output 76.1.4 Parameter Estimates

Parameter Estimates (25 Imputations)											
Parameter Estimate Std Error 95% Confidence Limits DF Minimum Maxi											
Oxygen	47.084579	0.976050	45.0831	49.0861	27.354	46.850020	47.499541				
RunTime	10.549499	0.266933	10.0017	11.0973	26.918	10.428848	10.680797				
RunPulse	171.388418	1.991931	167.2697	175.5071	23.196	169.881385	173.125658				

Parameter Estimates (25 Imputations)								
	t for H0:							
Parameter	Theta0	Parameter=Theta0	Pr >  t					
Oxygen	0	48.24	<.0001					
RunTime	0	39.52	<.0001					
RunPulse	0	86.04	<.0001					

Note that the results in this example could also have been obtained with the MI procedure.

# Example 76.2: Reading Means and Covariance Matrices from a DATA= COV Data Set

This example creates a COV-type data set that contains sample means and covariance matrices computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the population means.

The following statements use the CORR procedure to generate sample means and a covariance matrix for the variables in each imputed data set:

```
proc corr data=outmi cov nocorr noprint out=outcov(type=cov);
   var Oxygen RunTime RunPulse;
   by _Imputation_;
run;
```

The following statements display (in Output 76.2.1) output sample means and covariance matrices from PROC CORR for the first two imputed data sets:

Output 76.2.1 COV Data Set **CORR Means and Covariance Matrices (First Two Imputations)** 

Obs	_Imputation_	_TYPE_	_NAME_	Oxygen	RunTime	RunPulse
1	1	COV	Oxygen	28.5603	-7.2652	-11.812
2	1	COV	RunTime	-7.2652	2.5214	2.536
3	1	COV	RunPulse	-11.8121	2.5357	79.271
4	1	MEAN		47.0120	10.4441	171.216
5	1	STD		5.3442	1.5879	8.903
6	1	N		31.0000	31.0000	31.000
7	2	COV	Oxygen	27.1240	-6.6761	-10.217
8	2	COV	RunTime	-6.6761	2.2035	2.611
9	2	COV	RunPulse	-10.2170	2.6114	95.631
10	2	MEAN		47.2407	10.5040	171.244
11	2	STD		5.2081	1.4844	9.779
12	2	N		31.0000	31.0000	31.000

Note that the covariance matrices in the data set Outcov are estimated covariance matrices of variables, V(y). The estimated covariance matrix of the sample means is  $V(\overline{y}) = V(y)/n$ , where n is the sample size, and is not the same as an estimated covariance matrix for variables.

The following statements combine the results for the imputed data sets, and derive both univariate and multivariate inferences about the means. The EDF= option is specified to request that the adjusted degrees of freedom be used in the analysis. For sample means based on 31 observations, the complete-data error degrees of freedom is 30.

```
proc mianalyze data=outcov edf=30;
   modeleffects Oxygen RunTime RunPulse;
run;
```

The "Variance Information" and "Parameter Estimates" tables display the same results as in Output 76.1.2 and Output 76.1.3, respectively, in Example 76.1.

With the WCOV, BCOV, and TCOV options, as in the following statements, the procedure displays the between-imputation covariance matrix, within-imputation covariance matrix, and total covariance matrix assuming that the between-imputation covariance matrix is proportional to the within-imputation covariance matrix in Output 76.2.2.

```
proc mianalyze data=outcov edf=30 wcov bcov tcov mult;
  modeleffects Oxygen RunTime RunPulse;
run;
```

Output 76.2.2 Covariance Matrices

#### The MIANALYZE Procedure

Within-Imputation Covariance Matrix									
Oxygen RunTime RunPuls									
Oxygen	0.925531500	-0.215584249	-0.621865880						
RunTime	-0.215584249	0.068197432	0.116221427						
RunPulse	-0.621865880	0.116221427	3.345355692						

Output 76.2.2 continued

Between-Imputation Covariance Matrix										
	Oxygen	RunTime	RunPulse							
Oxygen	0.0260976444	0.0018582126	0.0215847560							
RunTime	0.0018582126	0.0029383770	0.0064057721							
RunPulse	0.0215847560	0.0064057721	0.5984941329							
	Total Cov	ariance Matrix								
	Oxygen	RunTime	RunPulse							
Oxygen	1.106311852	-0.257693455	-0.743332446							
RunTime	-0.257693455	0.081518163	0.138922492							
RunPulse	-0.743332446	0.138922492	3.998790592							

With the MULT option, the procedure assumes that the between-imputation covariance matrix is proportional to the within-imputation covariance matrix and displays a multivariate inference for all the parameters taken jointly.

Output 76.2.3 Multivariate Inference

Multivariate Inference Assuming Proportionality of Between/Within Covariance Matrices									
Avg Relative Increase in Variance	Num DF	Den DF Par	F for H0: ameter=Theta0	Pr > F					
0.195326	3	2433.6	13296.2	<.0001					

The "Multivariate Inference" table in Output 76.2.3 shows a significant *p*-value for the null hypothesis that the population means are all equal to zero.

# **Example 76.3: Reading Regression Results from a DATA= EST Data Set**

This example creates an EST-type data set that contains regression coefficients and their corresponding covariance matrices computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the regression model.

The following statements use the REG procedure to generate regression coefficients for each imputed data set:

```
proc reg data=outmi outest=outreg covout noprint;
  model Oxygen= RunTime RunPulse;
  by _Imputation_;
run;
```

The following statements display (in Output 76.3.1) output regression coefficients and their covariance matrices from PROC REG for the first two imputed data sets:

```
proc print data=outreg(obs=8);
   var _Imputation_ _Type_ _Name_
      Intercept RunTime RunPulse;
   title 'REG Model Coefficients and Covariance Matrices'
         ' (First Two Imputations)';
run;
```

Output 76.3.1 EST-Type Data Set

#### REG Model Coefficients and Covariance Matrices (First Two Imputations)

Obs	_Imputation_	_TYPE_	_NAME_	Intercept	RunTime	RunPulse
1	1	PARMS		86.544	-2.82231	-0.05873
2	1	COV	Intercept	100.145	-0.53519	-0.55077
3	1	COV	RunTime	-0.535	0.10774	-0.00345
4	1	COV	RunPulse	-0.551	-0.00345	0.00343
5	2	PARMS		83.021	-3.00023	-0.02491
6	2	COV	Intercept	79.032	-0.66765	-0.41918

8	2	COV	RunPulse	-0.419	-0.00313	0.00264

The following statements combine the results for the imputed data sets. The EDF= option is specified to request that the adjusted degrees of freedom be used in the analysis. For a regression model with three independent variables (including the Intercept) and 31 observations, the complete-data error degrees of freedom is 28.

```
proc mianalyze data=outreg edf=28;
  modeleffects Intercept RunTime RunPulse;
run;
```

Output 76.3.2 Variance Information

#### The MIANALYZE Procedure

	Variance Information (25 Imputations)										
		Variance									
Parameter	Between	Within	Total	DF	Relative Increase in Variance	Fraction Missing Information	Relative Efficiency				
Intercept	22.485821	75.413875	98.799129	19.102	0.310092	0.240234	0.990482				
RunTime	0.021126	0.124930	0.146902	21.823	0.175870	0.151147	0.993990				

The "Variance Information" table in Output 76.3.2 displays the between-imputation, within-imputation, and total variances for combining complete-data inferences.

The "Parameter Estimates" table in Output 76.3.3 displays the estimated mean and standard error of the regression coefficients. The inferences are based on the t distribution. The table also displays a 95% mean confidence interval and a t test with the associated p-value for the hypothesis that the regression coefficient is equal to zero. Since the p-value for RunPulse is 0.1812, this variable can be removed from the regression model.

Output 76.3.3 Parameter Estimates

Parameter Estimates (25 Imputations)										
t for H0:  Parameter Estimate Std Error 95% Confidence Limits DF Minimum Maximum Theta0 Parameter=Theta0 Pr >  t

# Example 76.4: Reading Mixed Model Results from PARMS= and COVB= Data Sets

This example creates data sets that contains parameter estimates and covariance matrices computed by a mixed model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the parameters.

The following PROC MIXED statements generate the fixed-effect parameter estimates and covariance matrix for each imputed data set:

```
ods select none;
proc mixed data=outmi;
  model Oxygen= RunTime RunPulse RunTime*RunPulse/solution covb;
  by _Imputation_;
  ods output SolutionF=mixparms CovB=mixcovb;
run;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The ODS OUTPUT statement creates two SAS data sets, named mixparms and mixcovb, from the two ODS tables. The following statements display (in Output 76.4.1) output parameter estimates for the first two imputed data sets:

```
proc print data=mixparms (obs=8);
   var _Imputation_ Effect Estimate StdErr;
   title 'MIXED Model Coefficients (First Two Imputations)';
run;
```

Output 76.4.1 PROC MIXED Model Coefficients

#### MIXED Model Coefficients (First Two Imputations)

Obs	_Imputation_	Effect	Estimate	StdErr
1	1	Intercept	148.09	81.5231
2	1	RunTime	-8.8115	7.8794
3	1	RunPulse	-0.4123	0.4684

5	2	Intercept	64.3607	64.6034
6	2	RunTime	-1.1270	6.4307
7	2	RunPulse	0.08160	0.3688
8	2	RunTime*RunPulse	-0.01069	0.03664

The following statements display (in Output 76.4.2) the output covariance matrices associated with the parameter estimates from PROC MIXED for the first two imputed data sets:

```
proc print data=mixcovb (obs=8);
  var _Imputation_ Row Effect Col1 Col2 Col3 Col4;
  title 'Covariance Matrices (First Two Imputations)';
run;
```

Output 76.4.2 PROC MIXED Covariance Matrices

Covariance Ma	trices (First	Two Im	putations)
---------------	---------------	--------	------------

Obs	_Imputation_	Row	Effect	Col1	Col2	Col3	Col4
1	1	1	Intercept	6646.01	-637.40	-38.1515	3.6542
2	1	2	RunTime	-637.40	62.0842	3.6548	-0.3556
3	1	3	RunPulse	-38.1515	3.6548	0.2194	-0.02099
4	1	4	RunTime*RunPulse	3.6542	-0.3556	-0.02099	0.002040
5	2	1	Intercept	4173.59	-411.46	-23.7889	2.3441
6	2	2	RunTime	-411.46	41.3545	2.3414	-0.2353
7	2	3	RunPulse	-23.7889	2.3414	0.1360	-0.01338
8	2	4	RunTime*RunPulse	2.3441	-0.2353	-0.01338	0.001343

Note that the variables Col1, Col2, Col3, and Col4 are used to identify the effects Intercept, RunTime, RunPulse, and RunTime\*RunPulse, respectively, through the variable Row.

For univariate inference, only parameter estimates and their associated standard errors are needed. The following statements use the MIANALYZE procedure with the input PARMS= data set to produce univariate results:

```
proc mianalyze parms=mixparms edf=28;
   modeleffects Intercept RunTime RunPulse RunTime*RunPulse;
run;
```

The "Variance Information" table in Output 76.4.3 displays the between-imputation, within-imputation, and total variances for combining complete-data inferences.

Output 76.4.3 Variance Information

The MIANALYZE Procedure

Since each covariance matrix contains variables Row, Col1, Col2, Col3, and Col4 for parameters, the EFFECTVAR=ROWCOL option is needed when you specify the COVB= option. The following statements illustrate the use of the MIANALYZE procedure with input PARMS= and COVB(EFFECTVAR=ROWCOL)= data sets:

# **Example 76.5: Reading Generalized Linear Model Results**

This example creates data sets that contains parameter estimates and corresponding covariance matrices computed by a generalized linear model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC GENMOD to generate the parameter estimates and covariance matrix for each imputed data set:

Because of the ODS SELECT statements, no output is displayed. The following statements print (in Output 76.5.1) the output parameter estimates and covariance matrix from PROC GENMOD for the first two imputed data sets:

```
proc print data=gmparms (obs=8);
   var _Imputation_ Parameter Estimate StdErr;
   title 'GENMOD Model Coefficients (First Two Imputations)';
run;
```

Output 76.5.1 PROC GENMOD Model Coefficients

#### **GENMOD Model Coefficients (First Two Imputations)**

Obs	_Imputation_	Parameter	Estimate	StdErr
1	1	Intercept	86.5440	9.5107

7	2	RunPulse	-0.0249	0.0488
8	2	Scale	2.5727	0.3267

The following statements display the parameter information table in Output 76.5.2. The table identifies parameter names used in the covariance matrices. The parameters Prm1, Prm2, and Prm3 are used for the effects Intercept, RunTime, and RunPulse, respectively, in each covariance matrix.

```
proc print data=gmpinfo (obs=6);
   title 'GENMOD Parameter Information (First Two Imputations)';
run:
```

Output 76.5.2 PROC GENMOD Model Information

#### **GENMOD Parameter Information (First Two Imputations)**

Obs	_Imputation_	Parameter	Effect
1	1	Prm1	Intercept
2	1	Prm2	RunTime
3	1	Prm3	RunPulse
4	2	Prm1	Intercept
5	2	Prm2	RunTime
6	2	Prm3	RunPulse

The following statements display (in Output 76.5.3) the output covariance matrices from PROC GENMOD for the first two imputed data sets. Note that the GENMOD procedure computes maximum likelihood estimates for each covariance matrix.

```
proc print data=gmcovb (obs=8);
  var _Imputation_ RowName Prm1 Prm2 Prm3;
  title 'GENMOD Covariance Matrices (First Two Imputations)';
run;
```

Output 76.5.3 PROC GENMOD Covariance Matrices

#### **GENMOD Covariance Matrices (First Two Imputations)**

Obs	_Imputation_	RowName	Prm1	Prm2	Prm3
1	1	Prm1	90.453923	-0.483394	-0.497473
2	1	Prm2	-0.483394	0.0973159	-0.003113
3	1	Prm3	-0.497473	-0.003113	0.0030954
4	1	Scale	1.344E-15	-1.09E-17	-6.12E-18
5	2	Prm1	71.383332	-0.603037	-0.378616
6	2	Prm2	-0.603037	0.1034766	-0.002826
7	2	Prm3	-0.378616	-0.002826	0.0023843
8	2	Scale	1.602E-14	1.755E-16	-1.02E-16

The following statements use the MIANALYZE procedure with input PARMS=, PARMINFO=, and COVB= data sets:

```
proc mianalyze parms=gmparms covb=gmcovb parminfo=gmpinfo;
    modeleffects Intercept RunTime RunPulse;
run;
```

Since the GENMOD procedure computes maximum likelihood estimates for the covariance matrix, the EDF= option is not used. The "Parameter Estimates" table in Output 76.5.4 displays the estimated mean and standard error of the regression coefficients.

Output 76.5.4 Parameter Estimates

#### The MIANALYZE Procedure

	Parameter Estimates (25 Imputations)												
t for H0: Parameter Estimate Std Error 95% Confidence Limits DF Minimum Maximum Theta0 Parameter=Theta0													
Parameter	Estimate	Stu Elloi	95% Comine	ince Limits		Willimitum	Maxilliulli	metau	Parameter-metau	P1 /  4			
Intercept	92.700420	9.565616	73.89020	111.5106	367.43	83.020730	100.839807	0	9.69	<.0001			
RunTime	-3.030325	0.367167	-3.75093	-2.3097	903.54	-3.280042	-2.754668	0	-8.25	<.0001			
RunPulse	-0.079621	0.055231	-0.18815	0.0289	479.31	-0.135862	-0.024910	0	-1.44	0.1501			

The resulting parameter estimates are identical to the estimates in Output 76.3.3 in Example 76.3. However, the standard errors are slightly different because in this example, maximum likelihood estimates for the standard errors are combined without the EDF= option, whereas in Example 76.3, unbiased estimates for the standard errors are combined with the EDF= option.

## Example 76.6: Reading GLM Results from PARMS= and XPXI= Data Sets

This example creates data sets that contains parameter estimates and corresponding  $(X'X)^{-1}$  matrices computed by a general linear model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC GLM to generate the parameter estimates and  $(X'X)^{-1}$  matrix for each imputed data set:

```
ods select none;
proc glm data=outmi;
   model Oxygen= RunTime RunPulse/inverse;
   by _Imputation_;
   ods output ParameterEstimates=glmparms
              InvXPX=glmxpxi;
quit;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The following statements display (in Output 76.6.1) the output parameter estimates and standard errors from PROC GLM for the first two imputed data sets:

```
proc print data=glmparms (obs=6);
  var _Imputation_ Parameter Estimate StdErr;
   title 'GLM Model Coefficients (First Two Imputations)';
run;
```

Output 76.6.1 PROC GLM Model Coefficients

#### **GLM Model Coefficients (First Two Imputations)**

Obs	_Imputation_	Parameter	Estimate	StdErr
1	1	Intercept	86.5440339	10.00726811
2	1	RunTime	-2.8223108	0.32824165
3	1	RunPulse	-0.0587292	0.05854109
4	2	Intercept	83.0207303	8.88996885
5	2	RunTime	-3.0002288	0.33847204
6	2	RunPulse	-0.0249103	0.05137859

The following statements display (in Output 76.6.2)  $(X'X)^{-1}$  matrices from PROC GLM for the first two imputed data sets:

```
proc print data=glmxpxi (obs=8);
  var _Imputation_ Parameter Intercept RunTime RunPulse;
  title 'GLM X''X Inverse Matrices (First Two Imputations)';
run;
```

Output 76.6.2 PROC GLM  $(X'X)^{-1}$  Matrices

#### **GLM X'X Inverse Matrices (First Two Imputations)**

Obs	_Imputation_	Parameter	Intercept	RunTime	RunPulse
1	1	Intercept	12.696250656	-0.067849956	-0.069826009
2	1	RunTime	-0.067849956	0.0136594055	-0.000436938
3	1	RunPulse	-0.069826009	-0.000436938	0.0004344762
4	1	Oxygen	86.544033929	-2.822310769	-0.058729234
5	2	Intercept	10.784620785	-0.091107072	-0.057201387
6	2	RunTime	-0.091107072	0.0156332765	-0.000426902
7	2	RunPulse	-0.057201387	-0.000426902	0.0003602208
8	2	Oxygen	83.020730343	-3.000228818	-0.024910305

The standard errors for the estimates in the output Glmparms data set are needed to create the covariance matrix from the  $(X'X)^{-1}$  matrix. The following statements use the MIANALYZE procedure with input PARMS= and XPXI= data sets to produce the same results as displayed in Output 76.3.2 and Output 76.3.3 in Example 76.3:

```
proc mianalyze parms=glmparms xpxi=glmxpxi edf=28;
    modeleffects Intercept RunTime RunPulse;
run;
```

## Example 76.7: Reading Logistic Model Results from a PARMS= Data Set

This example creates data sets that contains parameter estimates computed by a logistic regression analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC LOGISTIC to generate the parameter estimates for each imputed data set:

```
ods select none;
proc logistic data=outfish2;
   class Species;
   model Species= Length Width / covb;
   by _Imputation_;
   ods output ParameterEstimates=lgsparms;
run;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The following statements display (in Output 76.7.1) the output logistic regression coefficients from PROC LOGISTIC for the first two imputed data sets:

```
proc print data=lgsparms (obs=6);
   title 'LOGISTIC Model Coefficients (First Two Imputations)';
run;
```

Output 76.7.1 PROC LOGISTIC Model Coefficients

#### **LOGISTIC Model Coefficients (First Two Imputations)**

Obs	_Imputation_	Variable	DF	<b>Estimate</b>	StdErr	${\bf WaldChiSq}$	ProbChiSq	_ESTTYPE_

## **Example 76.8: Reading Mixed Model Results with Classification Covariates**

This example creates data sets that contains parameter estimates and corresponding covariance matrices with classification variables computed by a mixed regression model analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC MIXED to generate the parameter estimates and covariance matrix for each imputed data set:

```
ods select none;
proc mixed data=outfish2;
   class Species;
   model Length= Species Width/ solution;
   by _Imputation_;
   ods output SolutionF=mxparms;
run;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The following statements display (in Output 76.8.1) the output mixed model coefficients from PROC MIXED for the first two imputed data sets:

```
proc print data=mxparms (obs=8);
   var _Imputation_ Effect Species Estimate StdErr;
   title 'MIXED Model Coefficients (First Two Imputations)';
run;
```

Output 76.8.1 PROC MIXED Model Coefficients

## **Example 76.9: Reading Nominal Logistic Model Results**

This example creates data sets to contain parameter estimates that are computed by a nominal logistic regression analysis for a set of imputed data sets. These estimates are then combined to generate valid statistical inferences about the model parameters.

The following statements use PROC LOGISTIC to generate the parameter estimates and covariance matrix for each imputed data set:

```
ods select none;
proc logistic data=outfish3;
  class Species;
  model Species= Length Width / link=glogit covb;
  by Imputation;
   ods output ParameterEstimates=lgsparms
              CovB=lqscovb;
run;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The following statements display (in Output 76.9.1) the output logistic regression coefficients from PROC LOGISTIC for the first two imputed data sets:

```
proc print data=lgsparms (obs=12);
  title 'LOGISTIC Model Coefficients (First Two Imputations)';
run;
```

Output 76.9.1 PROC LOGISTIC Model Coefficients

#### **LOGISTIC Model Coefficients (First Two Imputations)**

### **Example 76.10: Using a TEST statement**

This example creates a DATA=EST data set to contain regression coefficients and their corresponding covariance matrices that are computed from imputed data sets. These estimates are then combined to generate valid statistical inferences about the regression model. A TEST statement is used to test linear hypotheses about the parameters.

The following statements use the REG procedure to generate regression coefficients for each imputed data set:

```
proc reg data=outmi outest=outreg covout noprint;
  model Oxygen= RunTime RunPulse;
  by _Imputation_;
run;
```

The following statements combine the results for the imputed data sets. A TEST statement is used to test linear hypotheses of INTERCEPT=0 and RUNTIME=RUNPULSE.

```
proc mianalyze data=outreg edf=28;
  modeleffects Intercept RunTime RunPulse;
  test Intercept, RunTime=RunPulse / mult;
run;
```

The "Test Specification" table in Output 76.10.1 displays the L matrix and the c vector in a TEST statement. Because no label is specified for the TEST statement, "Test 1" is used as the label.

Output 76.10.1 Test Specification

## The MIANALYZE Procedure Test: Test 1

Test Specification								
L Matrix								
Parameter Intercept RunTime RunPulse								
TestPrm1	1.000000	0	0	0				
<b>TestPrm2</b> 0 1.000000 -1.000000								

The "Variance Information" table in Output 76.10.2 displays the between-imputation variance, within-imputation variance, and total variance for each univariate inference. A detailed description of these statistics is provided in the section "Combining Inferences from Imputed Data Sets" on page 6006 and the section "Multiple Imputation Efficiency" on page 6007.

Output 76.10.2 Variance Information

	Variance Information							
		Variance

## **Example 76.11: Combining Correlation Coefficients**

This example combines sample correlation coefficients that are computed from a set of imputed data sets by using Fisher's z transformation.

Fisher's z transformation of the sample correlation r is

$$z = \frac{1}{2} \log \left( \frac{1+r}{1-r} \right)$$

The statistic z is approximately normally distributed, with mean

$$\log\left(\frac{1+\rho}{1-\rho}\right)$$

and variance 1/(n-3), where  $\rho$  is the population correlation coefficient and n is the number of observations.

The following statements use the CORR procedure to compute the correlation r and its associated Fisher's z statistic between the variables Oxygen and RunTime for each imputed data set.

```
ods select none;
proc corr data=outmi fisher(biasadj=no);
   var Oxygen RunTime;
   by Imputation;
   ods output FisherPearsonCorr=outz;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The ODS OUTPUT statement is used to save Fisher's *z* statistic in an output data set. The following statements display the number of observations and Fisher's *z* statistic for each imputed data set in Output 76.11.1:

```
proc print data=outz (obs=10);
   title 'Fisher''s Correlation Statistics (First 10 Imputations)';
   var _Imputation_ NObs ZVal;
run;
```

Output 76.11.1 Output z Statistics

#### Fisher's Correlation Statistics (First 10 Imputations)

Obs	_Imputation_	NObs	ZVal
1	1	31	-1.27869
2	2	31	-1.30715
3	3	31	-1.27922
4	4	31	-1.39243
5	5	31	-1.40146
6	6	31	-1.22323
7	7	31	-1.27163
8	8	31	-1.17783
9	9	31	-1.36075
10	10	31	-1.23652

The following statements generate the standard error associated with the z statistic,  $1/\sqrt{n-3}$ :

```
data outz;
   set outz;
   StdZ= 1. / sqrt(NObs-3);
run;
```

The following statements use the MIANALYZE procedure to generate a combined parameter estimate  $\hat{z}$  and its variance, as shown in Output 76.11.2. The ODS OUTPUT statement is used to save the parameter estimates in an output data set.

```
proc mianalyze data=outz;
  ods output ParameterEstimates=parms;
  modeleffects ZVal;
  stderr StdZ;
run;
```

Output 76.11.2 Combining Fisher's z Statistics

#### The MIANALYZE Procedure

	Parameter Estimates (25 Imputations)									
									t for H0:	
Parameter	Estimate	Std Error	95% Confide	nce Limits	DF	Minimum	Maximum	Theta0	Parameter=Theta0	Pr >  t
ZVal	-1.292006	0.202699	-1.68963	-0.89438	1403.6	-1.401459	-1.098356	0	-6.37	<.0001

In addition to the estimate for z, PROC MIANALYZE also generates 95% confidence limits for z,  $\hat{z}_{.025}$  and  $\hat{z}_{.975}$ . The following statements print the estimate and 95% confidence limits for z in Output 76.11.3:

```
proc print data=parms;
   title 'Parameter Estimates with 95% Confidence Limits';
   var Estimate LCLMean UCLMean;
run;
```

Output 76.11.3 Parameter Estimates with 95% Confidence Limits

#### Parameter Estimates with 95% Confidence Limits

Obs	Estimate	LCLMean	UCLMean
1	-1.292006	-1.68963	-0.89438

An estimate of the correlation coefficient with its corresponding 95% confidence limits is then generated from the following inverse transformation as described in the section "Correlation Coefficients" on page 6011:

$$r = \tanh(z) = \frac{e^{2z} - 1}{e^{2z} + 1}$$

for  $z = \hat{z}$ ,  $\hat{z}_{.025}$ , and  $\hat{z}_{.975}$ .

The following statements generate and display an estimate of the correlation coefficient and its 95% confidence limits, as shown in Output 76.11.4:

Output 76.11.4 Estimated Correlation Coefficient

## **Example 76.12: Sensitivity Analysis with Control-Based Pattern Imputation**

This example illustrates sensitivity analysis in multiple imputation under the MNAR assumption by creating control-based pattern imputation.

Suppose that a pharmaceutical company is conducting a clinical trial to test the efficacy of a new drug. The trial is conducted with two groups that have an equal number of patients: a treatment group that receives the new drug and a placebo control group. The variable Trt is an indicator variable, with a value of 1 for patients in the treatment group and a value of 0 for patients in the control group. The variable Y0 is the baseline efficacy score, and the variable Y1 is the efficacy score at a follow-up visit.

If the data set does not contain any missing values, then you can use a regression model such as the following to test the treatment effect:

```
Y1 = Trt Y0
```

Suppose that the variables Trt and Y0 are fully observed and the variable Y1 contains missing values in both the treatment and control groups, as shown in Table 76.4.

Table 76.4 Variables

Variables				
Trt	Y0	<b>Y1</b>		
0	X	X		
1	X	X		
0	X			
1	X			

Suppose the data set Mono1 contains the data from the trial that have missing values in Y1. Output 76.12.1 lists the first 10 observations.

Output 76.12.1 Clinical Trial Data

First 10 Obs in the Trial Data

Obs	Trt	y0	y1
1	0	10.5212	11.3604
2	0	8.5871	8.5178
3	0	9.3274	
4	0	9.7519	
5	0	9.3495	9.4369
6	1	11.5192	13.2344
7	1	10.7841	
8	1	9.7717	10.9407
9	1	10.1455	10.8279
10	1	8.2463	9.6844

Multiple imputation often assumes that missing values are missing at random (MAR), and the following statements use the MI procedure to impute missing values under this assumption:

```
proc mi data=Mono1 seed=14823 nimpute=20 out=outex12a;
   class Trt;
   monotone reg;
   var Trt y0 y1;
run;
```

The following statements generate regression coefficients for each of the 20 imputed data sets:

```
ods select none;
proc reg data=outex12a;
  model y1= Trt y0;
  by _Imputation_;
  ods output parameterestimates=regparms;
run;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The following statements combine the 20 sets of regression coefficients:

```
proc mianalyze parms=regparms;
   modeleffects Trt;
run:
```

The "Parameter Estimates" table in Output 76.12.2 displays a combined estimate and standard error for the regression coefficient for Trt. The table shows a *t* test statistic of 3.39, with the associated *p*-value 0.0008 for the test that the regression coefficient is equal to 0.

#### Output 76.12.2 Parameter Estimates

#### The MIANALYZE Procedure

Parameter Estimates (20 Imputations)										
t for H0: Parameter Estimate Std Error 95% Confidence Limits DF Minimum Maximum Theta0 Parameter=Theta0 Pr >					Dr > HI					
raiaiiietei	LSumate	Ju Elloi	35 /6 Collinae	ice Lillins	DI	wiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiii	Maxilliulli	THELAU	rarameter-metau	F1 /  4
Trt	0.890609	0.262600	0.372745	1.408473	197.29	0.624115	1.228827	0	3.39	0.0008

The conclusion in Output 76.12.2 is based on the MAR assumption. But if missing Y1 values for individuals in the treatment group imply that these individuals no longer receive the treatment, then it is reasonable to assume that the conditional distribution of Y1, given Y0 for individuals who have missing Y1 values in the treatment group, is similar to the corresponding distribution of individuals in the control group.

Ratitch and O'Kelly (2011) describe an implementation of the pattern-mixture model approach that uses a control-based pattern imputation. That is, an imputation model for the missing observations in the treatment group is constructed not from the observed data in the treatment group but rather from the observed data in the control group. This model is also the imputation model that is used to impute missing observations in the control group.

The following statements implement the control-based pattern imputation:

```
proc mi data=Mono1 seed=14823 nimpute=20 out=outex12b;
   class Trt;
   monotone reg;
   mnar model( y1 /modelobs=(Trt='0'));
   var y0 y1;
run;
```

The MNAR statement imputes missing values for scenarios under the MNAR assumption. The MODEL option specifies that only observations where TRT=0 are used to derive the imputation model for the variable Y1. Thus, Y0 and Y1 (but not Trt) are specified in the VAR list.

The following statements generate regression coefficients for each of the 20 imputed data sets:

```
ods select none;
proc reg data=outex12b;
   model y1= Trt y0;
   by _Imputation_;
   ods output parameterestimates=regparms;
run;
ods select all;
```

The following statements combine the 20 sets of regression coefficients:

```
proc mianalyze parms=regparms;
   modeleffects Trt;
run:
```

#### Output 76.12.3 Parameter Estimates

#### The MIANALYZE Procedure

Parameter Estimates (20 Imputations)										
Darameter	Estimate	Std Error	95% Confider	nce Limite	DE	Minimum	Maximum	ThetaN	t for H0: Parameter=Theta0	Dr > Iti
Tarameter	Louinate	Sta Liioi	JJ /0 COIIIIGCI	ice Lillia		wiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiiii	Maximum	THETA	T drameter=Trietao	117  4
Trt	0.708802	0.279447	0.157975	1.259628	213.68	0.329363	0.919297	0	2.54	0.0119

The "Parameter Estimates" table in Output 76.12.3 shows a *t* test statistic of 2.54, with the *p*-value 0.0119 for the test that the parameter is equal to 0. Thus, for a two-sided Type I error level of 0.05, the significance of the treatment effect is not reversed by control-based pattern imputation.

## **Example 76.13: Sensitivity Analysis with the Tipping-Point Approach**

This example illustrates sensitivity analysis in multiple imputation under the MNAR assumption in which you search for a tipping point that reverses the study conclusion.

Suppose that a pharmaceutical company is conducting a clinical trial to test the efficacy of a new drug. The trial is conducted with two groups that have an equal number of patients: a treatment group that receives the new drug and a placebo control group. The variable Trt is an indicator variable, with a value of 1 for patients in the treatment group and a value of 0 for patients in the control group. The variable Y0 is the baseline efficacy score, and the variable Y1 is the efficacy score at a follow-up visit.

If the data set does not contain any missing values, then you can use a regression model such as the following to test the efficacy of the treatment effect:

```
Y1 = Trt Y0
```

Now suppose in a trial that the variables Trt and Y0 are fully observed and the variable Y1 contains missing values in both the treatment and control groups. The data set Mono2 contains the data from the trial and Figure 76.13.1 lists the first 10 observations.

#### First 10 Obs in the Trial Data

Obs	Trt	y0	y1
1	0	11.4826	
2	0	10.0090	10.8667
3	0	11.3643	10.6660
4	0	11.3098	10.8297
5	0	11.3094	
6	1	10.3815	10.5587
7	1	11.2001	13.7616
8	1	9.7002	10.3460
9	1	10.0801	
10	1	11.2667	11.0634

Multiple imputation often assumes that missing values are missing at random (MAR), and the following statements use the MI procedure to impute missing values under this assumption:

```
proc mi data=Mono2 seed=14823 out=outmi;
  class Trt;
  monotone reg;
  var Trt y0 y1;
run:
```

The following statements generate regression coefficients for each of the 25 imputed data sets:

```
ods select none;
proc reg data=outmi;
   model y1= Trt y0;
   by _Imputation_;
   ods output parameterestimates=regparms;
run;
ods select all;
```

Because of the ODS SELECT statements, no output is displayed. The following statements combine the 20 sets of regression coefficients:

```
proc mianalyze parms=regparms;
   modeleffects Trt;
run;
```

The "Parameter Estimates" table in Output 76.13.2 displays a combined estimate and standard error for the regression coefficient for Trt. The table displays a 95% confidence interval (0.3353, 1.3208), which does not contain 0. The table also shows a t statistic of 3.31, with the associated p-value 0.0011 for the test that the regression coefficient is equal to 0.

#### Output 76.13.2 Parameter Estimates

#### The MIANALYZE Procedure

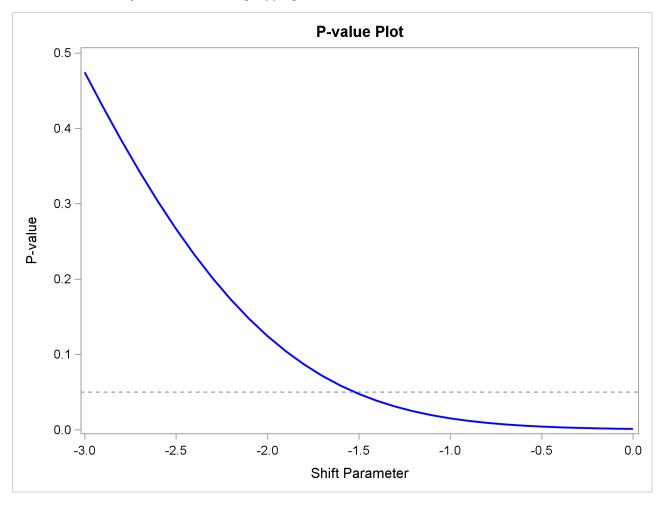

Parameter Estimates (25 Imputations)										
Parameter	Estimate	Std Error	95% Confide	nce l imits	DF	Minimum	Maximum	Theta0	t for H0: Parameter=Theta0	Pr > Itl
Trt		0.249933		1.320842				0		0.0011

The conclusion in Output 76.13.2 is based on the MAR assumption. But if it is plausible that, for the treatment group, the distribution of missing Y1 responses has a lower expected value than that of the corresponding distribution of the observed Y1 responses, the conclusion under the MAR assumption should be examined.

The following macro performs multiple imputation analysis for a specified sequence of shift parameters, which adjust the imputed values for observations in the treatment group (TRT=1):

```
/*----*/
/*--- Performs multiple imputation analysis
/*--- for specified shift parameters:
/*--- data= input data set
/*--- smin= min shift parameter
/*--- smax= max shift parameter
/*--- sinc= increment of the shift parameter
/*--- outparms= output reg parameters
/*-----/
%macro miparms( data=, smin=, smax=, sinc=, outparms=);
ods select none;
data &outparms;
  set _null_;
run:
/*-----# of shift values -----*/
%let ncase= %sysevalf( (&smax-&smin)/&sinc, ceil );
/*--- Multiple imputation analysis for each shift ----*/
%do jc=0 %to &ncase;
  %let sj= %sysevalf( &smin + &jc * &sinc);
 /*--- Generates 25 imputed data sets ----*/
  proc mi data=&data seed=14823 out=outmi;
     class Trt;
     monotone reg;
     mnar adjust( y1 / shift=&sj adjustobs=(Trt='1') );
     var Trt y0 y1;
  run;
 /*----*/
  proc reg data=outmi;
     model y1= Trt y0;
     by _Imputation_;
     ods output parameterestimates=regparm;
  run;
```

```
/*----*/
     proc mianalyze parms=regparm;
         modeleffects Trt;
         ods output parameterestimates=miparm;
     run;
     data miparm;
         set miparm;
         Shift= &sj;
         keep Shift Probt;
     run;
     /*---- Output multiple imputation results ----*/
     data &outparms;
         set &outparms miparm;
     run;
  %end;
  ods select all;
  %mend miparms;
Assume that the tipping point for the shift parameter that reverses the study conclusion is between -3 and 0.
The following statement performs multiple imputation analysis for each of the shift parameters -3.0, -2.9,
..., 0:
  %miparms( data=Mono2, smin=-3, smax=0, sinc=0.1, outparms=parm1);
The following statements display the plot of p-values for shift parameters between -3 and 0:
  title 'P-value Plot';
  proc sqplot data=parm1;
     series x=Shift y=Probt / lineattrs=graphfit(color=blue);
     refline 0.05 / axis=y lineattrs=graphfit(thickness=1px pattern=shortdash);
     xaxis label="Shift Parameter";
     yaxis label="P-value";
  run;
```

Output 76.13.3 Finding Tipping Point for Shift Parameter between -3 and 0

For a two-sided Type I error level of 0.05, the tipping point for the shift parameter is slightly less than -1.5. The following statement performs multiple imputation analysis for shift parameters  $-1.60, -1.59, \dots, -1.50$ :

```
%miparms( data=Mono2, smin=-1.6, smax=-1.5, sinc=0.01, outparms=parm2);
```

The following statements display the p-values that are associated with the shift parameters:

```
proc print label data=parm2;
  var Shift Probt;
  title 'P-values for Shift Parameters';
  label Probt='Pr > |t|';
  format Probt 8.4;
run;
```

Output 76.13.4 Finding Tipping Point for Shift Parameter between -1.6 and -1.5

#### P-values for Shift Parameters

Obs	Shift	Pr >  t
1	-1.60	0.0586
2	-1.59	0.0574
3	-1.58	0.0562
4	-1.57	0.0551
5	-1.56	0.0539
6	-1.55	0.0528
7	-1.54	0.0517
8	-1.53	0.0507
9	-1.52	0.0496
10	-1.51	0.0486
11	-1.50	0.0476

The study conclusion under MAR is reversed when the shift parameter is -1.53. Thus, if the shift parameter -1.53 is plausible, the conclusion under MAR is questionable.
