Traffic Lighting: The Next Generation

Julie VanBuskirk, Baylor Health Care System, Dallas, TX
Jennifer S. Harper, Baylor Health Care System, Dallas, TX

Abstract:

Traffic lighting is a tool intended to let a reader quickly evaluate data and at-a-glance sort out good versus bad performance. As the name implies, traditional traffic lighting generally separates data into three categories highlighted with red, yellow, and green based on performance. However, if all the cells in a table are boldly colored in primary colors, the reader is unable to achieve their goal of easily sorting between good and bad results. In addition, colorblind users will not be able to even distinguish between colors.

In this paper we will present the visual design changes made to our output and the SAS techniques behind them. We sought to reduce the amount of decoration in our tables and focus on what was important, the data! We employed a more subtle use of cell shading and borders to effectively draw the reader's eye to the results that most need their attention. Typically, traffic lighting is done using PROC FORMAT, however our data cells contained text strings which required a more complex use of style options, COMPUTE blocks, flag variables, and macros to implement. However all this is quite do-able in SAS and the results were a much more effective table delivered to our partners.

Introduction

Effective presentation is a key component of any analytic work. The message of tables and graphs must be clear and concise. The technique of traffic lighting has been used to draw attention to the performance of an individual area on a table so that performance can be assessed at a glance. The idea is a good one – readers should be able to very easily find the values they most need to focus on.

However, we seem to have gotten traffic lighting happy in our report production. Bright red, yellow, and green colors are showing up in graphs, maps, tables, and dashboards. With all this traffic lighting the message in the data itself is getting lost. If everything is highlighted then nothing stands out. This paper discusses our methods as we transformed output from the traditional bold red/yellow/green version of traffic lighting to a new design that is more in line with visualization best practices.

The "before" table shown below is based on the traditional form of traffic lighting where red, yellow and green indicate relative performance. The symbolism is obvious as this is a very literal metaphor of the ubiquitous traffic light. The problem with this method is that it creates a table so bright that it is distracting. It becomes difficult to even read the data contained within the cells, let alone to actually understand the message of the data. Also, we need to consider colorblind readers. Approximately 10 percent of men and 1 percent of women are colorblind. For those users with the most common form, the red and green colors can be difficult to distinguish. To make sure colorblind users are able to discern the important information in a table, make sure information is not communicated with color alone.

Traffic Lighting: The Next Generation continued

Replacing Traffic Lighting with Performance Signals

What we wanted to do was to highlight data in a table that needed attention, but in a more effective way. To do this, we used principles of visual perception as described by Stephen Few in *Information Dashboard Design*. The principles of visual perception educate us on how our audience reads reports and the methods of data presentation that will focus attention on the most important data. For our reports, we chose to use the principles of enclosure and color. We enclosed the data cells in solid borders as well as by using subtle shading. The colors we used were subtle (gray background) when used for enclosure – or separating cells of interest from others. The use of a stronger red color served to alert the user to particularly poor performance.

Using just enclosure and color, we were able to create three levels of performance signals. Since our purpose was to highlight values that need attention, we don't need to do any extra formatting to "good" values so we decided to leave those alone. In an effort to draw attention to mid and low performance, we used a subtle, but visible light gray background. This draws the reader's attention, but doesn't obscure the ability of the reader to read the actual text values. To differentiate low performers from the middle, we used the technique of enclosure and color by putting a red box around each cell. The red draws the users attention to these cells, and because no other cells have strong borders, the use of enclosure ensures even colorblind readers can identify those cells. This design also reproduces well in black-and-white.

In addition to designing more effective highlighting, we made general design changes to make the table more readable. These include lighter border lines and the use of subtle color highlighting to differentiate the summary row from the individual data cells. One other change was to restructure the table. A user will often first want to know the overall score then look at the values that feed into that value. To encourage this reading, we moved the summary row to the top of the table.

Since we have now abandoned the usual red/yellow/green traffic lighting metaphor, we decided we needed a new name. In discussions of how to replace traffic lighting in our language with Kathy Rowell, a proponent of better data visualization in health care data, she suggested the term "**performance signals**". We hope this term catches on as a way to encourage designers to create tables that successfully *signal the performance* shown in the table rather than maintain an ineffective, if catchy-named, metaphor.

For more on data visualization best practices see the references under "[Further Reading](#)".

Before – using conventional red/yellow/green highlighting

Student Grades	Alfred	Alice	Barbara
Assignment 1	28 (5.6/20)	98 (20/20)	56 (11/20)
Assignment 2	58 (17/30)	76 (23/30)	No Work
Assignment 3	62 (62/100)	86 (86/100)	92 (92/100)
Final Grade Average of All Grades	49	87	49

Traffic Lighting: The Next Generation continued

After – using better practices to highlight performance

Student Grades	Alfred	Alice	Barbara
Final Grade Average of All Grades	49	86	49
Assignment1	28 (5.6/20)	98 (20/20)	56 (11/20)
Assignment2	58 (17/30)	76 (23/30)	No Work
Assignment3	62 (62/100)	86 (86/100)	92 (92/100)

Implementing New Performance Signals in SAS

Converting from conventional traffic lighting to our new “performance signals” required a new method of coding. The usual method involves using a PROC FORMAT of ranges that is applied to the usually numeric variable of interest within the PROC REPORT. This method works well for numeric variables, however report requirements often require a text string for the presentation of the value (example: adding the numerator and denominator such as “55% (110/200)”). To create a complex text string we concatenate several variables into a character string. Since these text strings will be complex and vary cell-by-cell, applying a SAS format is not a feasible way to add the desired highlighting to data values. We had to find an automated, data-driven methodology.

Flagging Performance without PROC FORMAT

Creating the text string

The specifications for this project required that data be displayed as a character string as shown in the sample table cell shown below. The table has student names across the top, and Assignments as rows with the last row being the Final Grade (the average of the assignments). (*Note: sample data and complete code are in the [appendix](#).*) Creating the displayed cell contents required concatenating several numeric variables so the assignment score could be displayed along with the numerator and denominator. We also had to add other text elements like parentheses and a line break within the cell.

Student Grades	Alfred	Alice
Assignment 1	28 (5.6/20)	98 (19.6/20)
Assignment2	58 (17.4/30)	76 (22.8/30)

To create the necessary text we used the CATS function to the individual rows for each assignment (excluding the final grade data rows).

Traffic Lighting: The Next Generation continued

```

if assignment_name ne 'Final Grade' then
  All_Grades = cats(put(Grade, 3.1),
                    '^n(',
                    (put(Numerator, 3.1),
                    '/',
                    put(Denominator, 3), ')') )

```

Identifying Performance

Because this new variable is a complex character string, it cannot be easily formatted with PROC FORMAT. To identify which cells should be highlighted with a performance signal, we decided to create a new flag variable that could be used within the report as an indicator of the cell's eventual color. The flag variable was created based on the original numeric grade values using a PROC FORMAT. The format allowed for easy separation between the varying degrees of grades, and allowed us to account for any values that occur out of the expected range.

```

proc format;
  value grades
    low -59 = 1 /* low */
    60 - 78 = 2 /* mid */
    79 - high = 3 /* satisfactory */ ;
run;

```

Creating the table

We used PROC REPORT rather than other reporting procedures because we needed to display the complex text rather than automated summaries. In PROC REPORT the table layout involves using student names as an ACROSS variable, the flag and created grade text string compose the columns under the across variable. Below is the generic structure of the COLUMN statement for PROC REPORT. It sets up the assignment names as the row headers and labels the column, then sets up the student names as the column headers. Nested below each column header are the performance flag and the cell text.

```

column ('column1header' column1) ( acrossvar, ( flagvar complextext ) );

```

The flag variable will be used to indicate which color the following grade variable should be. We used a CALL DEFINE because the number of columns in the table would vary by the number of students and we will have hidden flag columns. Since we did not want to manually count the number and names of each column generated by across variable, we used pre-processing data step to feed into a MACRO created by Allison McMahill in her paper 'Beyond the Basics: Advanced PROC REPORT Tips and Tricks'. This macro uses a data step to calculate the number of variables under the across and sets it as a global macro variable. This data step calculates the column number (_c2_, _c3_, etc.) of each value of the across variable. This is done by sorting the data by the across variable, in this case student_names, next a data step is used to create a count +1 of the total number of occurrences of that variable. This will allow for the calculation of the column number (_cn_) that is used in the report macro to automatically move through the columns.

Traffic Lighting: The Next Generation continued

```

proc sort data=class2; by student_name; run;
data class2;
  set sorted_name;
  by student_name;
  if first.student_name then count+1;
  call symput('num', strip(count) ) ;
run;

```

The macro uses %LET to set the values for several macro variables. These include the position of the starting column under the across, the number of variables before the across, and the number of variables under the across. In this case, where the assignment name is the only variable before the across the starting column is two. The varsleft value is the number of variables before the across (in our example, this is example only one – the assignment variable). The varsunder variable is the number of variables that are under the across variable. In this case, this includes the performance and final_grades variables.

```

/*the position of the first computed var under the across*/
%let startcol = 2;
%let varsleft = 1; /*Number of variables before the across*/
%let varsunder = 2; /*Number of variables under the across*/

```

The MACRO then uses the value of the performance flag to highlight the students' grades. This method uses the COMPUTE block to assign the column identifiers for processing. The DO block starts at the created start column value and goes to a calculated end value. The performance signals are created through a series of CALL DEFINE statements based on the formatted values of the grades variable.

```

%macro create ;
  /* highlight all_grades based on value of performance */
  compute All_Grades;
  %do i=&startcol %to %eval((&num*&varsunder)+&varsleft)
    %by &varsunder;
    /* lower student grades - gray with red border */
    if _c%eval(&i)_ = 1 and count ne 1 then
      call define ("_c%eval(&i+1)_" ,
        "style", "style = [background = gainsboro
          bordertopcolor = red
          borderbottomcolor = red
          borderleftcolor = red
          borderrightcolor= red" );
    /* mid-level student grades - gray background */
    if _c%eval(&i)_ = 2 and count ne 1 then
      call define ("_c%eval(&i+1)_" ,
        "style", "style = [background = gainsboro]");
    /* no highlighting for satisfactory performance */
  %end;
  endcomp;
%mend create;
%create ;

```

To create a table that better focuses on the data, we used subtle grey shading (SAS color gainsboro) for all student grades that needed improvement. We emphasized those that need immediate efforts at improvement by adjusting the cell border colors to enclose only those cells in red. To avoid creating signals for the summary grade row, we used count not

Traffic Lighting: The Next Generation continued

equal to avoid any shading on that row because our goal was to monitor individual assignments, not the final score.

A New Way to Traffic Light

Moving beyond the conventional red, yellow, green traffic lighting to a new design that highlights data without hiding the details allows the person reading a table

The challenges in SAS come in two forms – how to flag cells for highlighting if the cell values are complex character strings and how to apply a more complex style to an unknown table layout. This paper demonstrated moderately complex PROC REPORT techniques using a hidden flag variable to signal performance and compute blocks to assign formatting. The macro we used to manage the counting of an unknown number of columns is also complex, but quite extensible to many situations.

Once again we see that SAS can do it all – boldly going where few tables have gone before.
