ABSTRACT
SAS® formats can be used for more than just making your data look nice. Formats can be used as in memory look up tables as well as help you to create data driven code. This paper will show you, with code examples, how to build a format from a dataset; write a format out as a dataset; and how to use formats to help to make programs data driven.

INTRODUCTION
Formats (and informats) are stored in SAS catalogs – a SAS catalog is a special SAS file that contains catalog entries, while formats are a type of catalog entry. Formats can be stored in a permanent library, if for example they are being shared across an organization or in the work library if they are only needed during the execution of a single process or job. A process or job can point to multiple libraries containing formats and the user can specify the order of libraries that SAS should search for the formats using the FMTSEARCH = System Option. Informats are typically used as a way to instruct SAS on how to read data into SAS variables. Formats are typically used as instruction for outputting data. This paper demonstrates how formats can be created from datasets; how they can be viewed as dataset; rules around creating formats; using formats as lookup tables and how formats can help you build data driven processes.

CREATING FORMATS FROM DATASETS
A format dataset must contain, at a minimum, format name, start value, label and format type:
- Format name is the name of the format
- Start is the value in your data
- Label is the value you want to retrieve to assign to your data
- Type determines format/informat, character/numeric

In the example below the dataset contains gender and gender description. To create a format that converts the gender mnemonic into a description, the data needs to be formatted in a way that SAS can recognize and write to the format catalog.

1. Create some data:
   ```sas
   DATA indata;
   FORMAT Gender $4. Gender_DSC $30.;
   INFILE DATALINES delimiter=',';
   INPUT Gender $ Gender_DSC $;
   DATALINES;
   F,Female
   M,Male
   ;
   RUN;
   ```
2. **Format the data to be uploaded to the catalog:**

```plaintext
DATA fmtdata(keep=fmtname start label type);
SET indata;
  fmtname = 'Gender';
  type = 'C';
  start=Gender;
  label=Gender_DSC;
RUN;
```

3. **Write the format to the catalog:**

```plaintext
PROC FORMAT LIB=work CNTLIN=fmtdata;
RUN;
```

Multiple formats can be created in a single dataset; in this case the dataset must be sorted by the fmtname value prior to writing to the catalog.

This simple format example converts a single value to a description, formats containing ranges, where multiple values resolve to a single value, can be controlled with the additional variables:

- **END** (used with start when a range is used)
- **SEXCL** (Start Exclude – useful when setting ranges)
- **EEXCL** (End Exclude – useful when setting ranges)
- **HLO** (High Low Other – useful when setting extremes and defaults)
  - see Table 1 in Appendix for full list of output control data set variables.

## WRITE A FORMAT OUT TO A DATASET

Format or formats can be selected from a SAS catalogue and written out to a dataset called a control dataset.

1. **Select a character format called “gender” and write it out to a dataset called fmtout:**

```plaintext
PROC FORMAT LIB=work CNTLOUT=fmtout;
  SELECT $Gender;
RUN;
```
RULES ABOUT FORMATS

- Formats cannot start or end with a number
- Format names can be up to 32 characters long.
- Character formats must start with a dollar sign ($) - this counts towards the 32 characters.
- You cannot create a format name with the same name as a SAS supplied format

USING FORMATS AS LOOKUP TABLES

**Scenario:** Our data includes cumulative scores for a class of students; we want to weight the scores by a factor that depends on age.

1. **Create some test data that contains score:**

   ```
   DATA Indata(DROP=I seed Height Weight);
   SET sashelp.class;
   FORMAT score 8.2;
   RETAIN seed 1298573062;
   DO I = 1 TO 100;
   SCORE=100.00*I* RANUNI(seed);
   OUTPUT;
   END;
   RUN;
   ```

2. **Create the factor table that maps the age range to the weight:**

   ```
   DATA Factor;
   FORMAT START 8. END 8. FACTOR 8.2;
   INFILE DATALINES delimiter =',';
   INPUT start end factor;
   DATALINES;
   , 11, 1.5
   11, 12, 1.4
   12, 13, 1.3
   13, 14, 1.2
   14, 15, 1.1
   15, , 1.0
   ;
   RUN;
   ```
3. Create a format from the factor table:

```sas
DATA fmtchar(KEEP=fmtname start end label hlo type);
  LENGTH fmtname $30 start end label 8;
SET Factor;
RETAIN type 'I';
fmtname = 'FACTOR';
  start = start;
  end = end;
  label = FACTOR;
IF start = . THEN hlo = 'L';
ELSE hlo = '';
IF end = . THEN hlo = 'H';
RUN;
```

```sas
PROC FORMAT LIB=WORK CNTLIN=fmtchar;
RUN;
```

4. Apply the format to the data:

```sas
DATA new_score;
SET INDATA;
  ** apply the format to the age to determine the FACTOR **;
  FACTOR        = INPUT(age,FACTOR.);
  ** apply the FACTOR to the score **;
  new_SCORE     = SUM(score*FACTOR);
RUN;
```

OR

```sas
DATA new_score_alt;
SET INDATA;
  ** apply the format to the age to determine the FACTOR then **;
  ** apply the FACTOR to the score **;
  new_SCORE     = SUM(score*INPUT(age,FACTOR.));
RUN;
```
USING YOUR DATA TO DRIVE THE LOOKUP

Scenario: Our data includes cumulative scores for a class of students; we want to weight the scores by a factor that depends on age and gender.

1. Create a factor table based on age, a different factor for each gender:

```sql
DATA Factor2;
  FORMAT start 8. end 8. factor_F 8.2 factor_M 8.2;
  INFILE DATALINES delimiter =',';
  INPUT start end factor_F factor_M;
DATALINES;
  , 11, 1.5, 1.6
  11, 12, 1.4, 1.5
  12, 13, 1.3, 1.4
  13, 14, 1.2, 1.3
  14, 15, 1.1, 1.2
  15, , 1.0, 1.1
RUN;
```

2. Create formats from the factor table for each gender

```sql
DATA fmtchar(KEEP=fmtname start end label hlo type);
LENGTH fmtname $30 start end label 8;
SET Factor2;
RETAIN type 'i';
fmtname = FACTOR_typ;
  start = start;
  end = end;
  label = FACTOR;
IF start = . THEN hlo = 'L';
ELSE hlo = '';
IF end = . THEN hlo = 'H';
RUN;
```

PROC FORMAT LIB=WORK CNTLIN=fmtchar;
RUN;
3. Create some test data:

```sas
DATA indata(DROP=I seed Height Weight);
SET sashelp.class;
  FORMAT score 8.2;
  RETAIN seed 1298573062;
DO I = 1 TO 100;
  SCORE=100.00*I* RANUNI(seed);
  OUTPUT;
END;
RUN;
```

4. Apply the format to the data:

```sas
DATA NEW_SCORE2;
SET indata;
  ** figure out the format we need to use to resolve the SCORE **;
  FACTOR_TYPE   = UPCASE(compress('FACTOR_'||sex));
  ** apply the format to the SCORE to determine the FACTOR **;
  FACTOR        = INPUTN(age,FACTOR_type);
  ** apply the FACTOR to the SCORE **;
  new_bal     = SUM(SCORE*FACTOR);
RUN;
```

OR

```sas
DATA NEW_SCORE_alt;
SET indata;
  ** figure out the format we need to use to resolve the SCORE **;
  ** apply the format to the SCORE to determine the FACTOR **;
  ** apply the FACTOR to the SCORE **;
  new_bal = SUM(SCORE*INPUTN(age,UPCASE(compress('FACTOR_'||sex))));
RUN;
```
CONCLUSION

Formats can be user defined and stored for permanent or temporary use; they can be used in the traditional way to tell SAS how to read in data or to what the data will look like when written out; or can be used as look up tables to help make programs more data driven.

### Table 1  OUTPUT CONTROL DATA SET

<table>
<thead>
<tr>
<th>Variable</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>DATATYPE</td>
<td>enables the use of directives in a picture as a template to format date, time, or datetime values</td>
</tr>
<tr>
<td>DECAP</td>
<td>specifies the separator character for the fractional part of a number</td>
</tr>
<tr>
<td>DEFAULT</td>
<td>specifies a numeric variable that indicates the default length for format or informat.</td>
</tr>
<tr>
<td>DIG3SEP</td>
<td>specifies the three-digit separator character for a number.</td>
</tr>
<tr>
<td>END</td>
<td>specifies a character variable that gives the range's ending value</td>
</tr>
</tbody>
</table>
| EEXCL        | specifies a character variable that indicates whether the range's ending value is excluded. Valid values are as follows:  
\[ Y \text{- specifies that the range's ending value is excluded.} \]  
\[ N \text{- specifies that the range's ending value is not excluded.} \] |
| FILL         | for picture formats, specifies a numeric variable whose value is the value of the FILL= option. |
| FMTNAME      | specifies a character variable whose value is the format or informat name.  |
| FUZZ         | specifies a numeric variable whose value is the value of the FUZZ= option.   |
| HLO          | specifies a character variable that contains range information about the format or informat. The following valid values can appear in any combination  
\[ F \text{- specifies a standard SAS format or informat that is used with a value} \]  
\[ H \text{- specifies that a range's ending value is HIGH} \]  
\[ I \text{- specifies a numeric informat range} \]  
\[ J \text{- specifies justification for an informat} \]  
\[ L \text{- specifies that a range's starting value is LOW} \]  
\[ M \text{- specifies that the MULTILABEL option is in effect} \]  
\[ N \text{- specifies that the format or informat has no ranges, including no OTHER= range} \]  
\[ O \text{- specifies that the range is OTHER.} \]  
\[ R \text{- specifies that the ROUND option is in effect} \]  
\[ S \text{- specifies that the NOTSORTED option is in effect} \]  
\[ U \text{- specifies that the UPCASE option for an informat be used} \] |
<p>| LABEL        | specifies a character variable whose value is associated with a              |</p>
<table>
<thead>
<tr>
<th><strong>Format or Informat</strong></th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>LANGUAGE</strong></td>
</tr>
<tr>
<td>specifies the language that is used for weekdays and months that you can substitute in a date, time, or datetime picture. If you specify a language that is not supported or is invalid, English is used.</td>
</tr>
<tr>
<td><strong>LENGTH</strong></td>
</tr>
<tr>
<td>specifies a numeric variable whose value is the value of the LENGTH= option</td>
