The %MktBSize Macro

Introduction

The %MktBSize autocall macro suggests sizes for balanced incomplete block designs (BIBDs). The sizes that it reports are sizes that meet necessary, but not sufficient, conditions for the existence of a BIBD, so a BIBD might not exist for every reported size.

NOTE: The version of the %MktBSize macro that is documented here requires SAS 9.01 or any subsequent release. An enhanced version of the %MktBSize macro is included in the SAS 940m3 maintenance release. The enhanced version requires SAS 940m1 or any subsequent release. The documentation for the enhanced version of the macro is published at http://support.sas.com/rnd/app/macros/MktBSize/mktbsize.htm.

BIBD Parameters

The parameters of a BIBD are as follows:

- *b* specifies the number of blocks. In a partial-profile design, this is the number of profiles. In a MaxDiff design, this is the number of sets.
- *t* specifies the number of treatments. In a partial-profile or MaxDiff design, this is the total number of attributes or messages.
- *k* specifies the block size, which is the number of treatments in each block. In a partial-profile or MaxDiff design, this is the number of attributes or messages that are shown at one time.

If $r = b \times k/t$ and $l = r \times (k-1)/(t-1)$ are integers, and k = t and $b \ge t$, then a complete block design might be possible. This is a necessary but not sufficient condition for the existence of a complete block design. If $r = b \times k/t$ and $l = r \times (k-1)/(t-1)$ are integers, and k < t and $b \ge t$, then a balanced incomplete block design might be possible. This is a necessary but not sufficient condition for the existence of a BIBD.

%MktBSize Macro Syntax

%MktBSize(K=do-list, T=do-list <, optional arguments>)

Required Arguments

K=do-list

SETSIZE=do-list

specifies the block size, or the number of treatments in each block. In a partial-profile or MaxDiff design, this is the number of attributes or messages that are shown at one time in each set. Specify either an integer or a list of integers in the SAS *do-list* syntax.

T=do-list

NATTRS=do-list

specifies the number of treatments. In a partial-profile or MaxDiff design, this is the total number of attributes or messages. Specify either an integer or a list of integers in the SAS *do-list* syntax. When you specify the NATTRS= argument, the output uses the word "Attribute" rather than "Treatment" and the word "Set" rather than "Block."

Optional Arguments

B=do-list

NSETS=do-list

specifies the number of blocks. In a partial-profile design, this is the number of profiles. In a MaxDiff design, this is the number of sets. Specify either an integer or a list of integers in the SAS *do-list* syntax. By default, B=2 to 500.

MAXREPS=n

specifies the maximum number of replications. By default, MAXREPS=1. By default, this argument prevents the %MktBSize macro from reporting designs of size 2b, 3b, and so on, after it has found a size that has b blocks.

OPTIONS=options-list

specifies binary arguments. You can specify one or both of the following values:

NOCHECK

turns off certain checks that are performed on b, t, and k by default. This lets you make some creative expressions that otherwise are not permitted.

UBD

lifts the balance restriction on the design. Results are reported when $r = b \times k/t$ is an integer but $l = r \times (k-1)/(t-1)$

might or might not be an integer. Use this argument when you want to see sizes where every treatment can occur equally often but the pairwise frequencies can be unequal. The listing can contain both sizes where a BIBD might be possible (λ , the expected pairwise frequency, is an integer) and sizes where a BIBD is not possible (λ is not an integer). For example, you might use this argument when the block design is being used to make a partial-profile design.

By default, neither of these arguments is specified.

ORDER=TKB | TBK | BTK | BKT | KBT | KTB

specifies the order of the loops; by default, ORDER=TKB. If you specify expressions in the T=, B=, or K= argument, you might need an ordering other than the default. For example, if you specify

something like t = 2 to $0.5 \star b$, then you must specify ORDER=BKT or any other ordering that defines *b* before *t*. Alternatively, you can specify this argument to change the default ordering of the results.

OUT=SAS-data-set

specifies the output data set to contain the list of potential design sizes. By default, OUT=BIBD.

Help Option

You can specify either of the following to display the option names and simple examples of the macro syntax:

%mktbsize(help)
%mktbsize(?)

%MktBSize Macro Notes

This macro specifies **options nonotes** throughout most of its execution. If you want to see all the notes, submit the following statement before running the macro:

%let mktopts = notes;

To see the macro version, submit the following statement before running the macro:

%let mktopts = version;

Examples

The following invocation of the %MktBSize macro requests a list of designs that have 12 treatments, between 4 and 8 treatments per block, and between 12 and 30 blocks:

```
%mktbsize(t=12, k=4 to 8, b=12 to 30)
```

The results are shown in Figure 1.

Figure 1	%MktBSize	Output
----------	-----------	--------

					n
t	k	b	r	Lambda	Total
Number of	Block	Number	Treatment	Pairwise	Sample
Treatments	Size	of Blocks	Frequency	Frequencies	Size
12	6	22	11	5	132

You can use this information to create a BIBD by using the %MktBIBD macro as follows:

%mktbibd(t=12, k=6, b=22, seed=104)

There is no guarantee that the %MktBIBD macro will find a BIBD for any specification, but in this case it does, and it finds the design shown in Figure 2.

Figure 2 BIBD with T=12, K=6, B=22

Balanced Incomplete Block Design

x1	x2	x3	x4	x5	x6
7	9	3	10	12	2
5	2	4	6	10	7
5	10	12	9	11	8
7	9	11	12	1	4
12	3	4	5	9	10
10	6	9	11	2	1
3	8	7	1	9	6
2	10	12	6	8	1
9	7	6	4	8	5
1	12	5	7	6	11
12	1	2	3	5	7
8	4	1	10	7	12
6	2	9	8	12	4
4	7	11	3	10	6
11	5	1	2	4	9
11	3	2	8	7	9
6	11	8	5	3	12
3	6	10	9	1	5
2	4	6	12	11	3
1	8	10	11	4	3
4	1	3	2	5	8
10	5	8	7	2	11

The design has B=22 blocks (rows), K=6 treatments per block (columns), and T=12 treatments (the entries are the integers 1 to 12). Each of the T=12 treatments occurs R=11 times, and each treatment occurs in a block with every other treatment λ =5 times.

The following invocation of the %MktBSize macro creates a list of more than 50 designs:

%mktbsize(t=5 to 20, k=3 to t - 1, b=t to 30)

Figure 3 shows a partial listing of the results.

t Number of Treatments			r Treatment Frequency	Lambda Pairwise Frequencies	n Total Sample Size
5	3	10	6	3	30
5	4	5	4	3	20
6	3	10	5	2	30
6	4	15	10	6	60
6	5	6	5	4	30

Figure 3 %MktBSize Output

By default, the maximum number of replications is 1 (MAXREPS=1). Therefore, the design in which T=5, K=3, and B=20 is not listed because it consists of two replications of the design in which T=5, K=3, and B=10, which is listed. Also, the number of blocks (b=t to 30) is specified so that it is never less than the number of treatments. Furthermore, the number of treatments per block (k=3 to t-1) is specified to always be less than the number of treatments. Even more complicated expressions are permitted. For example, to limit the number of treatments per block to no more than half of the number of treatments, you could specify

%mktbsize(t=2 to 10, k=2 to 0.5 * t, b=t to 10)

To limit the number of blocks as a function of the number of treatments, you could specify

mktbsize(t=2 to 10, k=2 to t - 1, b=t to 2 * t)

However, if you want to limit the number of treatments as a function of the number of blocks, you need to use the ORDER= argument to ensure that the number of blocks loop comes first, as in the following specification:

%mktbsize(b=2 to 10, t=2 to 0.5 * b, k=2 to t - 1, order=btk)

The macro reports sizes in which $r = b \times k/t$ and $l = r \times (k-1)/(t-1)$ are integers, $2 \le k < t$, and $b \ge t$. If $r = b \times k/t$ and $l = r \times (k-1)/(t-1)$ are integers, and k = t and $b \ge t$, then a complete block design might be possible. This is a necessary, but not sufficient, condition for the existence of a complete block design. If $r = b \times k/t$ and $l = r \times (k-1)/(t-1)$ are integers, and k < t and $b \ge t$, then a balanced incomplete block design might be possible. This is a necessary, but not sufficient, condition for the existence of a Blanced incomplete block design might be possible. This is a necessary, but not sufficient, condition for the existence of a Blanced incomplete block design might be possible. This is a necessary, but not sufficient, condition for the existence of a Blanced block design sizes along with Blanced block design for the the %MktBSize macro reports unbalanced block design sizes along with BlBD sizes. For example, if you want a design that has 20 treatments and a block size of 6, you can use the following invocation of the %MktBSize macro to find out how many blocks you need:

%mktbsize(t=20, k=6, options=ubd)

Figure 4 displays the results.

Figure 4 %MktBSize Output

					n
t	k	b	r	Lambda	Total
Number of	Block	Number	Treatment	Pairwise	Sample
Treatments	Size	of Blocks	Frequency	Frequencies	Size
20	6	10	3	0.79	60

You can then use the %MktBIBD macro to find a design in which each treatment occurs three times but the treatments do not appear together an equal number of times, as in the following example:

%mktbibd(t=20, k=6, b=10, seed=104)

Figure 5 shows the treatment by treatment frequencies and the design.

Figure 5 %MktBIBD Output

Treatment by Treatment Frequencies
