About This Book

Syntax Conventions for the SAS Language

 Overview of Syntax Conventions for the SAS Language

SAS uses standard conventions in the documentation of syntax for SAS language elements. These conventions enable you to easily identify the components of SAS syntax. The conventions can be divided into these parts:

• syntax components
• style conventions
• special characters
• references to SAS libraries and external files

Syntax Components

The components of the syntax for most language elements include a keyword and arguments. For some language elements, only a keyword is necessary. For other language elements, the keyword is followed by an equal sign (=).

keyword
specifies the name of the SAS language element that you use when you write your program. Keyword is a literal that is usually the first word in the syntax. In a CALL routine, the first two words are keywords.

In the following examples of SAS syntax, the keywords are the first words in the syntax:

CHAR (string, position)
CALL RANBIN (seed, n, p, x);
ALTER (alter-password)
BEST w.
REMOVE <data-set-name>

In the following example, the first two words of the CALL routine are the keywords:

CALL RANBIN(seed, n, p, x)

The syntax of some SAS statements consists of a single keyword without arguments:

DO;
... SAS code ...

v
Some system options require that one of two keyword values be specified:

**DUPLEX | NODUPILEX**

argument specifies a numeric or character constant, variable, or expression. Arguments follow the keyword or an equal sign after the keyword. The arguments are used by SAS to process the language element. Arguments can be required or optional. In the syntax, optional arguments are enclosed between angle brackets.

In the following example, *string* and *position* follow the keyword CHAR. These arguments are required arguments for the CHAR function:

```
CHAR (string, position)
```

Each argument has a value. In the following example of SAS code, the argument *string* has a value of 'summer', and the argument *position* has a value of 4:

```
x=char('summer', 4);
```

In the following example, *string* and *substring* are required arguments, while *modifiers* and *startpos* are optional.

```
FIND(string, substring <,modifiers>, <startpos>)
```

**Note:** In most cases, example code in SAS documentation is written in lowercase with a monospace font. You can use uppercase, lowercase, or mixed case in the code that you write.

**Style Conventions**

The style conventions that are used in documenting SAS syntax include uppercase bold, uppercase, and italic:

**UPPERCASE BOLD**

identifies SAS keywords such as the names of functions or statements. In the following example, the keyword ERROR is written in uppercase bold:

```
ERROR <message>;
```

**UPPERCASE**

identifies arguments that are literals.

In the following example of the CMPMODEL= system option, the literals include BOTH, CATALOG, and XML:

```
CMPMODEL = BOTH | CATALOG | XML
```

**italics**

identifies arguments or values that you supply. Items in italics represent user-supplied values that are either one of the following:

- nonliteral arguments In the following example of the LINK statement, the argument *label* is a user-supplied value and is therefore written in italics:

  ```sas
  LINK label;
  ```

- nonliteral values that are assigned to an argument

  In the following example of the FORMAT statement, the argument DEFAULT is assigned the variable *default-format*:

  ```sas
  FORMAT = variable-1 <, ..., variable-nformat><DEFAULT = default-format>;
  ```
Items in italics can also be the generic name for a list of arguments from which you can choose (for example, attribute-list). If more than one of an item in italics can be used, the items are expressed as item-1, ..., item-n.

Special Characters

The syntax of SAS language elements can contain the following special characters:

=  an equal sign identifies a value for a literal in some language elements such as system options.

In the following example of the MAPS system option, the equal sign sets the value of MAPS:

MAPS = location-of-maps

< >  angle brackets identify optional arguments. Any argument that is not enclosed in angle brackets is required.

In the following example of the CAT function, at least one item is required:

CAT (item-1 <, ..., item-n>)

|  a vertical bar indicates that you can choose one value from a group of values. Values that are separated by the vertical bar are mutually exclusive.

In the following example of the CMPMODEL= system option, you can choose only one of the arguments:

CMPMODEL = BOTH | CATALOG | XML

...  an ellipsis indicates that the argument or group of arguments following the ellipsis can be repeated. If the ellipsis and the following argument are enclosed in angle brackets, then the argument is optional.

In the following example of the CAT function, the ellipsis indicates that you can have multiple optional items:

CAT (item-1 <, ..., item-n>)

'value' or “value”

indicates that an argument enclosed in single or double quotation marks must have a value that is also enclosed in single or double quotation marks.

In the following example of the FOOTNOTE statement, the argument text is enclosed in quotation marks:

FOOTNOTE <n> <ods-format-options "text" | "text">;

;  a semicolon indicates the end of a statement or CALL routine.

In the following example each statement ends with a semicolon: data namegame;
length color name $8; color = 'black'; name = 'jack'; game = trim(color) || name; run;
References to SAS Libraries and External Files

Many SAS statements and other language elements refer to SAS libraries and external files. You can choose whether to make the reference through a logical name (a libref or fileref) or use the physical filename enclosed in quotation marks. If you use a logical name, you usually have a choice of using a SAS statement (LIBNAME or FILENAME) or the operating environment's control language to make the association. Several methods of referring to SAS libraries and external files are available, and some of these methods depend on your operating environment.

In the examples that use external files, SAS documentation uses the italicized phrase `file-specification`. In the examples that use SAS libraries, SAS documentation uses the italicized phrase `SAS-library`. Note that `SAS-library` is enclosed in quotation marks:

```plaintext
infile file-specification obs = 100;
libname libref 'SAS-library';
```
What's New in SAS 9.3
Statements

Overview

The SAS statements documentation is no longer part of *SAS Language Reference: Dictionary*. See “Changes to SAS Language Reference: Dictionary” on page x. The SAS statements that were previously documented in *SAS Language Reference: Dictionary* are now documented here, in *SAS Statements: Reference*.

The following enhancements are made for the second maintenance release of SAS 9.3.

- A new `FILENAME` statement that enables you to access files on a Hadoop Distributed File System (HDFS).
- A new `LIBNAME` option that specifies whether an administrator can access a metadata-bound library for which corresponding metadata is corrupted, misconfigured, or missing.

New SAS Statements

The following SAS statements are new:

- **FILENAME, Hadoop Access Method** (p. 128)
  enables you to access files on a Hadoop Distributed File System (HDFS) whose location is specified.

- **LIBNAME JMP** (p. 251)
  associates a libref with a JMP data table and enables you to read and write JMP data tables.

- **RESETLINE** (p. 335)
  restarts the program line numbering in the SAS log to 1.

Enhanced SAS Statements

The following SAS statements have been enhanced:
ABORT (p. 19)
   If you do not specify a value for \( n \), the error code that is returned by SAS is ERROR. The value of ERROR depends on the operating system. The condition code \( n \) is returned to the operating system as the final SAS system exit code.

FILE (p. 76)
   A new device type, JMS, has been added. This device type is supported on all host operating systems.

FILENAME (p. 93)
   A new device type, JMS, has been added. This device type is supported on all host operating systems.

FILENAME, EMAIL Access Method (p. 106)
   • E-mail addresses can be separated with a comma as well as a space.
   • Two new e-mail options enable you to specify an expiration date for the e-mail message and specify that a notification be sent when the e-mail message is delivered to the recipient.

FILENAME, FTP Access Method (p. 117)
   A new FTP option has been added that specifies that an attempt is made for passive mode FTP.

FILENAME, WebDAV Access Method (p. 147)
   A new option has been added that enables you to prompt for a login password if necessary.

INFILE (p. 171)
   A new device type, JMS, has been added. This device type is supported on all host operating systems.

LIBNAME (p. 239)
   • The new option EXTENDOBScontador= enables you to extend the maximum observation count in all output SAS data files in the SAS library.
   • In the second maintenance release of 9.3, the new option AUTHADMIN= specifies whether an administrator can access a metadata-bound library for which corresponding metadata is corrupted, misconfigured, or missing.

Changes to SAS Language Reference: Dictionary

Prior to SAS 9.3, this document was part of SAS Language Reference: Dictionary. Starting with SAS 9.3, SAS Language Reference: Dictionary has been divided into seven documents:

• SAS Data Set Options: Reference
• SAS Formats and Informats: Reference
• SAS Functions and CALL Routines: Reference
• SAS Statements: Reference
• SAS System Options: Reference
• SAS Component Objects: Reference (contains the documentation for the hash, hash iterator, and Java objects)
• *Base SAS Utilities: Reference* (contains the documentation for the SAS DATA step debugger and the SAS Utility macro %DS2CSV)
Recommended Reading

Here is the recommended reading list for this title:

• Base SAS Procedures Guide
• Base SAS Utilities: Reference
• SAS Companion for UNIX Environments
• SAS Companion for Windows
• SAS Companion for z/OS
• SAS Component Objects: Reference
• SAS Data Set Options: Reference
• SAS Formats and Informats: Reference
• SAS Functions and CALL Routines: Reference
• SAS Language Interfaces to Metadata
• SAS Language Reference: Concepts
• SAS Output Delivery System: User's Guide
• SAS Scalable Performance Data Engine: Reference
• SAS System Options: Reference
• SAS XML LIBNAME Engine: User's Guide

Chapter 1
SAS Statements

Definition of Statements
A SAS statement is a string of SAS keywords, SAS names, special characters, and operators that instructs SAS to perform an operation or that gives information to SAS. Each SAS statement ends with a semicolon.

This documentation covers two types of SAS statements:
• statements that are used in DATA step programming
• statements that are global in scope and can be used anywhere in a SAS program.

In addition to the statements documented in SAS Statements: Reference, statements are also documented in the following publications:
• Base SAS Procedures Guide
• SAS Companion for Windows
• SAS Companion for UNIX Environments
• SAS Companion for z/OS
• SAS Language Interfaces to Metadata
• SAS Macro Language: Reference
• SAS Output Delivery System: User's Guide
• SAS Scalable Performance Data Engine: Reference
• SAS XML LIBNAME Engine: User's Guide
• SAS/ACCESS for Relational Databases: Reference
• SAS/CONNECT User's Guide
• SAS/SHARE User's Guide
DATA Step Statements

Executable and Declarative Statements

DATA step statements are executable or declarative statements that can appear in the DATA step. **Executable statements** result in some action during individual iterations of the DATA step; **declarative statements** supply information to SAS and take effect when the system compiles program statements.

The following tables show the SAS executable and declarative statements that you can use in the DATA step.

**Table 1.1  Executable Statements in the DATA Step**

<table>
<thead>
<tr>
<th>Executable Statements</th>
<th>IF, Subsetting</th>

DATA step statements can be grouped into six functional categories. For a list of DATA step statements by category, see “DATA Step Statements by Category” on page 7.

Global Statements

Global statements generally provide information to SAS, request information or data, move between different modes of execution, or set values for system options. Other global statements (ODS statements) deliver output in a variety of formats, such as in Hypertext Markup Language (HTML). You can use global statements anywhere in a SAS program. Global statements are not executable; they take effect as soon as SAS compiles program statements.

Global statements can be divided into eight functional categories. For a list of global statements by category, see “Global Statements by Category” on page 13.

Other SAS software products have additional global statements that are used with those products. For information, see the SAS documentation for those products.

SAS Statements Documented in Other SAS Publications

Some statements are documented with related subject matter in other SAS publications.

- Application Messaging with SAS
- SAS Companion for Windows
- SAS Companion for UNIX Environments
- SAS Companion for z/OS
- SAS Language Interfaces to Metadata
- SAS Macro Language: Reference
- SAS Scalable Performance Data Engine: Reference
- SAS/ACCESS for Relational Databases: Reference
- SAS/CONNECT User’s Guide
- SAS/SHARE User’s Guide

DATA Step Statements by Category

In addition to being either executable or declarative, SAS DATA step statements can be grouped into five functional categories:

Table 2.1 Categories of DATA Step Statements

<table>
<thead>
<tr>
<th>Statements Category</th>
<th>Functionality</th>
</tr>
</thead>
</table>
| Action              | • create and modify variables  
|                     | • select only certain observations to process in the DATA step  
|                     | • look for errors in the input data  
|                     | • work with observations as they are being created |
### Statements Category

<table>
<thead>
<tr>
<th>Statements Category</th>
<th>Functionality</th>
</tr>
</thead>
</table>
| Control             | • skip statements for certain observations  
|                     | • change the order that statements are executed  
|                     | • transfer control from one part of a program to another |
| File-handling       | • work with files used as input to the data set  
|                     | • work with files to be written by the DATA step |
| Information         | • give SAS additional information about the program data vector  
|                     | • give SAS additional information about the data set or data sets that are being created. |
| Window Display      | • display and customize windows. |

The following table lists and briefly describes the DATA step statements by category.

<table>
<thead>
<tr>
<th>Category</th>
<th>Language Elements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td><strong>Action</strong></td>
<td></td>

<tr>
<td>REPLACE Statement (p. 333)</td>
<td>Replaces an observation in the same location.</td>
<td></td>
</tr>
<tr>
<td>STOP Statement (p. 365)</td>
<td>Stops execution of the current DATA step.</td>
<td></td>
</tr>
<tr>
<td>Sum Statement (p. 367)</td>
<td>Adds the result of an expression to an accumulator variable.</td>
<td></td>
</tr>
<tr>
<td>WHERE Statement (p. 382)</td>
<td>Selects observations from SAS data sets that meet a particular condition.</td>
<td></td>
</tr>
<tr>
<td>CONTINUE Statement (p. 47)</td>
<td>Stops processing the current DO-loop iteration and resumes processing the next iteration.</td>
<td></td>
</tr>
<tr>
<td>DO Statement (p. 64)</td>
<td>Specifies a group of statements to be executed as a unit.</td>
<td></td>
</tr>
<tr>
<td>DO Statement, Iterative (p. 65)</td>
<td>Executes statements between the DO and END statements repetitively, based on the value of an index variable.</td>
<td></td>
</tr>
<tr>
<td>DO UNTIL Statement (p. 69)</td>
<td>Executes statements in a DO loop repetitively until a condition is true.</td>
<td></td>
</tr>
<tr>
<td>DO WHILE Statement (p. 70)</td>
<td>Executes statements in a DO-loop repetitively while a condition is true.</td>
<td></td>
</tr>
<tr>
<td>END Statement (p. 73)</td>
<td>Ends a DO group or SELECT group processing.</td>
<td></td>
</tr>
<tr>
<td>GO TO Statement (p. 159)</td>
<td>Directs program execution immediately to the statement label that is specified and, if followed by a RETURN statement, returns execution to the beginning of the DATA step.</td>
<td></td>
</tr>
<tr>
<td>IF-THEN/ELSE Statement (p. 163)</td>
<td>Executes a SAS statement for observations that meet specific conditions.</td>
<td></td>
</tr>
<tr>
<td>label: Statement (p. 234)</td>
<td>Identifies a statement that is referred to by another statement.</td>
<td></td>
</tr>
<tr>
<td>LEAVE Statement (p. 235)</td>
<td>Stops processing the current loop and resumes with the next statement in the sequence.</td>
<td></td>
</tr>
<tr>
<td>LINK Statement (p. 256)</td>
<td>Directs program execution immediately to the statement label that is specified and, if followed by a RETURN statement, returns execution to the statement that follows the LINK statement.</td>
<td></td>
</tr>
<tr>
<td>RETURN Statement (p. 341)</td>
<td>Stops executing statements at the current point in the DATA step and returns to a predetermined point in the step.</td>
<td></td>
</tr>
<tr>
<td>SELECT Statement (p. 350)</td>
<td>Executes one of several statements or groups of statements.</td>
<td></td>
</tr>
<tr>

<td></td>
<td><strong>Enables you to access remote files by using the SFTP protocol.</strong></td>
<td>FILENAME Statement, SFTP Access Method (p. 133)</td>
</tr>
<tr>
<td></td>
<td><strong>Enables you to read from or write to a TCP/IP socket.</strong></td>
<td>FILENAME Statement, SOCKET Access Method (p. 138)</td>
</tr>
<tr>
<td></td>
<td><strong>Enables you to access remote files by using the URL access method.</strong></td>
<td>FILENAME Statement, URL Access Method (p. 142)</td>
</tr>
<tr>
<td></td>
<td><strong>Enables you to access remote files by using the WebDAV protocol.</strong></td>
<td>FILENAME Statement, WebDAV Access Method (p. 147)</td>
</tr>
<tr>
<td></td>
<td><strong>Associates or disassociates a SAS library with a libref (a shortcut name), clears one or all librefs, lists the characteristics of a SAS library, concatenates SAS libraries, or concatenates SAS catalogs.</strong></td>
<td>LIBNAME Statement (p. 239)</td>
</tr>
<tr>
<td></td>
<td><strong>Associates a libref with a JMP data table and enables you to read and write JMP data tables.</strong></td>
<td>LIBNAME Statement for the JMP Engine (p. 251)</td>
</tr>
<tr>
<td></td>
<td><strong>Associates a libref with a SAS library and enables access to a WebDAV (Web-based Distributed Authoring And Versioning) server.</strong></td>
<td>LIBNAME Statement for WebDAV Server Access (p. 252)</td>
</tr>
<tr>
<td></td>
<td><strong>Controls the operation of a SET, MERGE, MODIFY, or UPDATE statement in the DATA step and sets up special grouping variables.</strong></td>
<td>BY Statement (p. 35)</td>
</tr>
<tr>
<td></td>
<td><strong>Specifies that data lines follow.</strong></td>
<td>CARDS Statement (p. 41)</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>------------------</td>
<td>-------------</td>
</tr>
<tr>
<td>CARDS4 Statement (p. 41)</td>
<td>Specifies that data lines that contain semicolons follow.</td>
<td></td>
</tr>
<tr>
<td>DATA Statement (p. 48)</td>
<td>Begins a DATA step and provides names for any output SAS data sets, views, or programs.</td>
<td></td>
</tr>
<tr>
<td>DATALINES Statement (p. 56)</td>
<td>Specifies that data lines follow.</td>
<td></td>
</tr>
<tr>
<td>DATALINES4 Statement (p. 58)</td>
<td>Indicates that data lines that contain semicolons follow.</td>
<td></td>
</tr>
<tr>
<td>FILE Statement (p. 76)</td>
<td>Specifies the current output file for PUT statements.</td>
<td></td>
</tr>
<tr>
<td>INFILE Statement (p. 171)</td>
<td>Specifies an external file to read with an INPUT statement.</td>
<td></td>
</tr>
<tr>
<td>INPUT Statement (p. 199)</td>
<td>Describes the arrangement of values in the input data record and assigns input values to the corresponding SAS variables.</td>
<td></td>
</tr>
<tr>
<td>INPUT Statement, Column (p. 214)</td>
<td>Reads input values from specified columns and assigns them to the corresponding SAS variables.</td>
<td></td>
</tr>
<tr>
<td>INPUT Statement, Formatted (p. 217)</td>
<td>Reads input values with specified informats and assigns them to the corresponding SAS variables.</td>
<td></td>
</tr>
<tr>
<td>INPUT Statement, List (p. 221)</td>
<td>Scans the input data record for input values and assigns them to the corresponding SAS variables.</td>
<td></td>
</tr>
<tr>
<td>INPUT Statement, Named (p. 228)</td>
<td>Reads data values that appear after a variable name that is followed by an equal sign and assigns them to corresponding SAS variables.</td>
<td></td>
</tr>
<tr>
<td>MERGE Statement (p. 266)</td>
<td>Joins observations from two or more SAS data sets into a single observation.</td>
<td></td>
</tr>
<tr>
<td>MODIFY Statement (p. 271)</td>
<td>Replaces, deletes, and appends observations in an existing SAS data set in place but does not create an additional copy.</td>
<td></td>
</tr>
<tr>
<td>PUT Statement (p. 296)</td>
<td>Writes lines to the SAS log, to the SAS output window, or to an external location that is specified in the most recent FILE statement.</td>
<td></td>
</tr>
<tr>
<td>PUT Statement, Column (p. 314)</td>
<td>Writes variable values in the specified columns in the output line.</td>
<td></td>
</tr>
<tr>
<td>PUT Statement, Formatted (p. 316)</td>
<td>Writes variable values with the specified format in the output line.</td>
<td></td>
</tr>
<tr>
<td>PUT Statement, List (p. 319)</td>
<td>Writes variable values and the specified character strings in the output line.</td>
<td></td>
</tr>
<tr>
<td>PUT Statement, Named (p. 324)</td>
<td>Writes variable values after the variable name and an equal sign.</td>
<td></td>
</tr>
<tr>
<td>SET Statement (p. 353)</td>
<td>Reads an observation from one or more SAS data sets.</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>UPDATE Statement (p. 377)</td>
<td>Updates a master file by applying transactions.</td>
</tr>
<tr>
<td>Information</td>
<td>ARRAY Statement (p. 23)</td>
<td>Defines the elements of an array.</td>
</tr>
<tr>
<td></td>
<td>Array Reference Statement (p. 27)</td>
<td>Describes the elements in an array to be processed.</td>
</tr>
<tr>
<td></td>
<td>ATTRIB Statement (p. 31)</td>
<td>Associates a format, informat, label, and length with one or more variables.</td>
</tr>
<tr>
<td></td>
<td>DROP Statement (p. 71)</td>
<td>Excludes variables from output SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>FORMAT Statement (p. 156)</td>
<td>Associates formats with variables.</td>
</tr>
<tr>
<td></td>
<td>INFORMAT Statement (p. 196)</td>
<td>Associates informats with variables.</td>
</tr>
<tr>
<td></td>
<td>KEEP Statement (p. 231)</td>
<td>Specifies the variables to include in output SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>LABEL Statement (p. 233)</td>
<td>Assigns descriptive labels to variables.</td>
</tr>
<tr>
<td></td>
<td>LENGTH Statement (p. 237)</td>
<td>Specifies the number of bytes for storing variables.</td>
</tr>
<tr>
<td></td>
<td>MISSING Statement (p. 270)</td>
<td>Assigns characters in your input data to represent special missing values for numeric data.</td>
</tr>
<tr>
<td></td>
<td>RENAME Statement (p. 331)</td>
<td>Specifies new names for variables in output SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>RETAIN Statement (p. 337)</td>
<td>Causes a variable that is created by an INPUT or assignment statement to retain its value from one iteration of the DATA step to the next.</td>
</tr>
<tr>
<td>Log Control</td>
<td>Comment Statement (p. 45)</td>
<td>Specifies the purpose of the statement or program.</td>
</tr>
<tr>
<td></td>
<td>PAGE Statement (p. 296)</td>
<td>Skips to a new page in the SAS log.</td>
</tr>
<tr>
<td></td>
<td>RESETLINE Statement (p. 335)</td>
<td>Restarts the program line numbers in the SAS log to 1.</td>
</tr>
<tr>
<td></td>
<td>SKIP Statement (p. 365)</td>
<td>Creates a blank line in the SAS log.</td>
</tr>
<tr>
<td>Operating Environment</td>
<td>X Statement (p. 399)</td>
<td>Issues an operating-environment command from within a SAS session.</td>
</tr>
<tr>
<td>Output Control</td>
<td>FOOTNOTE Statement (p. 152)</td>
<td>Writes up to 10 lines of text at the bottom of the procedure or DATA step output.</td>
</tr>
<tr>
<td></td>
<td>TITLE Statement (p. 368)</td>
<td>Specifies title lines for SAS output.</td>
</tr>
<tr>
<td>Program Control</td>
<td>CHECKPOINT EXECUTE_ALWAYS Statement (p. 44)</td>
<td>Indicates to execute the DATA step or PROC step that immediately follows without considering the checkpoint-restart data.</td>
</tr>
</tbody>
</table>
Global Statements by Category

The following table lists and describes SAS global statements, organized by function into eight categories:

<table>
<thead>
<tr>
<th>Statements Category</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>Data Access</td>
<td>associate reference names with SAS libraries, SAS catalogs, external files and output devices, and access remote files.</td>
</tr>
<tr>
<td>Log Control</td>
<td>alter the appearance of the SAS log.</td>
</tr>
<tr>
<td>ODS: Output Control</td>
<td>choose objects to send to output destinations; edit the output format.</td>
</tr>
</tbody>
</table>

**Table 2.2  Global Statements by Category**
<table>
<thead>
<tr>
<th>Statements Category</th>
<th>Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>ODS: SAS Formatted</td>
<td>apply default styles to SAS specific entities such as a SAS data set, SAS output listing, or a SAS document.</td>
</tr>
<tr>
<td>ODS: Third-Party Formatted</td>
<td>apply styles to the output objects that are used by applications outside of SAS.</td>
</tr>
<tr>
<td>Operating Environment</td>
<td>access the operating environment directly.</td>
</tr>
<tr>
<td>Output Control</td>
<td>add titles and footnotes to your SAS output; deliver output in a variety of formats.</td>
</tr>
<tr>
<td>Program Control</td>
<td>govern the way SAS processes your SAS program.</td>
</tr>
</tbody>
</table>

The following table provides brief descriptions of SAS global statements. For more detailed information, see the individual statements.

<table>
<thead>
<tr>
<th>Category</th>
<th>Language Elements</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>Action</td>
<td>ABORT Statement</td>
<td>Stops executing the current DATA step, SAS job, or SAS session.</td>
</tr>
<tr>
<td></td>
<td>(p. 19)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Assignment Statement</td>
<td>Evaluates an expression and stores the result in a variable.</td>
</tr>
<tr>
<td></td>
<td>(p. 30)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>CALL Statement</td>
<td>Invokes a SAS CALL routine.</td>
</tr>
<tr>
<td></td>
<td>(p. 40)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DELETE Statement</td>
<td>Stops processing the current observation.</td>
</tr>
<tr>
<td></td>
<td>(p. 59)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>DESCRIBE Statement</td>
<td>Retrieves source code from a stored compiled DATA step program or a DATA step view.</td>
</tr>
<tr>
<td></td>
<td>(p. 60)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>ERROR Statement</td>
<td>Sets <em>ERROR</em> to 1. A message written to the SAS log is optional.</td>
</tr>
<tr>
<td></td>
<td>(p. 74)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>EXECUTE Statement</td>
<td>Executes a stored compiled DATA step program.</td>
</tr>
<tr>
<td></td>
<td>(p. 75)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>IF Statement, Subsetting</td>
<td>Continues processing only those observations that meet the condition of the specified expression.</td>
</tr>
<tr>
<td></td>
<td>(p. 161)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>LIST Statement</td>
<td>Writes to the SAS log the input data record for the observation that is being processed.</td>
</tr>
<tr>
<td></td>
<td>(p. 258)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>LOSTCARD Statement</td>
<td>Resynchronizes the input data when SAS encounters a missing or invalid record in data that has multiple records per observation.</td>
</tr>
<tr>
<td></td>
<td>(p. 264)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>Null Statement</td>
<td>Signals the end of data lines or acts as a placeholder.</td>
</tr>
<tr>
<td></td>
<td>(p. 290)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>OUTPUT Statement</td>
<td>Writes the current observation to a SAS data set.</td>
</tr>
<tr>
<td></td>
<td>(p. 293)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>PUTLOG Statement</td>
<td>Writes a message to the SAS log.</td>
</tr>
<tr>
<td></td>
<td>(p. 326)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>REDIRECT Statement</td>
<td>Points to different input or output SAS data sets when you execute a stored program.</td>
</tr>
<tr>
<td></td>
<td>(p. 328)</td>
<td></td>
</tr>
<tr>
<td></td>
<td>REMOVE Statement</td>
<td>Deletes an observation from a SAS data set.</td>
</tr>
<tr>
<td></td>
<td>(p. 330)</td>
<td></td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>------------------------------------------</td>
<td>---------------------------------------------------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>REPLACE Statement</td>
<td>REPLACES an observation in the same location.</td>
<td></td>
</tr>
<tr>
<td>STOP Statement</td>
<td>Stops execution of the current DATA step.</td>
<td></td>
</tr>
<tr>
<td>Sum Statement</td>
<td>Adds the result of an expression to an accumulator variable.</td>
<td></td>
</tr>
<tr>
<td>WHERE Statement</td>
<td>Selects observations from SAS data sets that meet a particular condition.</td>
<td></td>
</tr>
<tr>
<td>Control</td>
<td>CONTINUE Statement</td>
<td>Stops processing the current DO-loop iteration and resumes processing the next iteration.</td>
</tr>
<tr>
<td></td>
<td>DO Statement</td>
<td>Specifies a group of statements to be executed as a unit.</td>
</tr>
<tr>
<td></td>
<td>DO Statement, Iterative</td>
<td>Executes statements between the DO and END statements repetitively, based on the value of an index variable.</td>
</tr>
<tr>
<td></td>
<td>DO UNTIL Statement</td>
<td>Executes statements in a DO loop repetitively until a condition is true.</td>
</tr>
<tr>
<td></td>
<td>DO WHILE Statement</td>
<td>Executes statements in a DO-loop repetitively while a condition is true.</td>
</tr>
<tr>
<td></td>
<td>END Statement</td>
<td>Ends a DO group or SELECT group processing.</td>
</tr>
<tr>
<td></td>
<td>GO TO Statement</td>
<td>Directs program execution immediately to the statement label that is specified and, if followed by a RETURN statement, returns execution to the beginning of the DATA step.</td>
</tr>
<tr>
<td></td>
<td>IF-THEN/ELSE Statement</td>
<td>Executes a SAS statement for observations that meet specific conditions.</td>
</tr>
<tr>
<td></td>
<td>label: Statement</td>
<td>Identifies a statement that is referred to by another statement.</td>
</tr>
<tr>
<td></td>
<td>LEAVE Statement</td>
<td>Stops processing the current loop and resumes with the next statement in the sequence.</td>
</tr>
<tr>
<td></td>
<td>LINK Statement</td>
<td>Directs program execution immediately to the statement label that is specified and, if followed by a RETURN statement, returns execution to the statement that follows the LINK statement.</td>
</tr>
<tr>
<td></td>
<td>RETURN Statement</td>
<td>Stops executing statements at the current point in the DATA step and returns to a predetermined point in the step.</td>
</tr>
<tr>
<td></td>
<td>SELECT Statement</td>
<td>Executes one of several statements or groups of statements.</td>
</tr>
<tr>
<td>Data Access</td>
<td>CATNAME Statement</td>
<td>Logically combines two or more catalogs into one by associating them with a catref (a shortcut name); clears one or all catrefs; lists the concatenated catalogs in one concatenation or in all concatenations.</td>
</tr>
<tr>
<td></td>
<td>FILENAME Statement</td>
<td>Associates a SAS fileref with an external file or an output device, disassociates a fileref and external file, or lists attributes of external files.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>-------------------</td>
<td>----------------------------------------------------------------------------------</td>
<td>-------------------------------------------------------------------------------------------------</td>
</tr>
<tr>
<td>FILENAME Statement, CATALOG Access Method (p. 100)</td>
<td>Enables you to reference a SAS catalog as an external file.</td>
<td></td>
</tr>
<tr>
<td>FILENAME, CLIPBOARD Access Method (p. 104)</td>
<td>Enables you to read text data from and write text data to the clipboard on the host computer.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, EMAIL (SMTP) Access Method (p. 106)</td>
<td>Enables you to send electronic mail programmatically from SAS using the SMTP (Simple Mail Transfer Protocol) e-mail interface.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, FTP Access Method (p. 117)</td>
<td>Enables you to access remote files by using the FTP protocol.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, Hadoop Access Method (p. 128)</td>
<td>Enables you to access files on a Hadoop Distributed File System (HDFS) whose location is specified in a configuration file.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, SFTP Access Method (p. 133)</td>
<td>Enables you to access remote files by using the SFTP protocol.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, SOCKET Access Method (p. 138)</td>
<td>Enables you to read from or write to a TCP/IP socket.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, URL Access Method (p. 142)</td>
<td>Enables you to access remote files by using the URL access method.</td>
<td></td>
</tr>
<tr>
<td>FILENAME Statement, WebDAV Access Method (p. 147)</td>
<td>Enables you to access remote files by using the WebDAV protocol.</td>
<td></td>
</tr>
<tr>
<td>LIBNAME Statement (p. 239)</td>
<td>Associates or disassociates a SAS library with a libref (a shortcut name), clears one or all librefs, lists the characteristics of a SAS library, concatenates SAS libraries, or concatenates SAS catalogs.</td>
<td></td>
</tr>
<tr>
<td>LIBNAME Statement for the JMP Engine (p. 251)</td>
<td>Associates a libref with a JMP data table and enables you to read and write JMP data tables.</td>
<td></td>
</tr>
<tr>
<td>LIBNAME Statement for WebDAV Server Access (p. 252)</td>
<td>Associates a libref with a SAS library and enables access to a WebDAV (Web-based Distributed Authoring And Versioning) server.</td>
<td></td>
</tr>
<tr>
<td>File-handling</td>
<td>BY Statement (p. 35)</td>
<td>Controls the operation of a SET, MERGE, MODIFY, or UPDATE statement in the DATA step and sets up special grouping variables.</td>
</tr>
<tr>
<td></td>
<td>CARDS Statement (p. 41)</td>
<td>Specifies that data lines follow.</td>
</tr>
<tr>
<td></td>
<td>CARDS4 Statement (p. 41)</td>
<td>Specifies that data lines that contain semicolons follow.</td>
</tr>
<tr>
<td></td>
<td>DATA Statement (p. 48)</td>
<td>Begins a DATA step and provides names for any output SAS data sets, views, or programs.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>----------</td>
<td>-------------------</td>
<td>-------------</td>
</tr>
<tr>
<td></td>
<td>DATALINES Statement (p. 56)</td>
<td>Specifies that data lines follow.</td>
</tr>
<tr>
<td></td>
<td>DATALINES4 Statement (p. 58)</td>
<td>Indicates that data lines that contain semicolons follow.</td>
</tr>
<tr>
<td></td>
<td>FILE Statement (p. 76)</td>
<td>Specifies the current output file for PUT statements.</td>
</tr>
<tr>
<td></td>
<td>INFILE Statement (p. 171)</td>
<td>Specifies an external file to read with an INPUT statement.</td>
</tr>
<tr>
<td></td>
<td>INPUT Statement (p. 199)</td>
<td>Describes the arrangement of values in the input data record and assigns input values to the corresponding SAS variables.</td>
</tr>
<tr>
<td></td>
<td>INPUT Statement, Column (p. 214)</td>
<td>Reads input values from specified columns and assigns them to the corresponding SAS variables.</td>
</tr>
<tr>
<td></td>
<td>INPUT Statement, Formatted (p. 217)</td>
<td>Reads input values with specified informats and assigns them to the corresponding SAS variables.</td>
</tr>
<tr>
<td></td>
<td>INPUT Statement, List (p. 221)</td>
<td>Scans the input data record for input values and assigns them to the corresponding SAS variables.</td>
</tr>
<tr>
<td></td>
<td>INPUT Statement, Named (p. 228)</td>
<td>Reads data values that appear after a variable name that is followed by an equal sign and assigns them to corresponding SAS variables.</td>
</tr>
<tr>
<td></td>
<td>MERGE Statement (p. 266)</td>
<td>Joins observations from two or more SAS data sets into a single observation.</td>
</tr>
<tr>
<td></td>
<td>MODIFY Statement (p. 271)</td>
<td>Replaces, deletes, and appends observations in an existing SAS data set in place but does not create an additional copy.</td>
</tr>
<tr>
<td></td>
<td>PUT Statement (p. 296)</td>
<td>Writes lines to the SAS log, to the SAS output window, or to an external location that is specified in the most recent FILE statement.</td>
</tr>
<tr>
<td></td>
<td>PUT Statement, Column (p. 314)</td>
<td>Writes variable values in the specified columns in the output line.</td>
</tr>
<tr>
<td></td>
<td>PUT Statement, Formatted (p. 316)</td>
<td>Writes variable values with the specified format in the output line.</td>
</tr>
<tr>
<td></td>
<td>PUT Statement, List (p. 319)</td>
<td>Writes variable values and the specified character strings in the output line.</td>
</tr>
<tr>
<td></td>
<td>PUT Statement, Named (p. 324)</td>
<td>Writes variable values after the variable name and an equal sign.</td>
</tr>
<tr>
<td></td>
<td>SET Statement (p. 353)</td>
<td>Reads an observation from one or more SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>UPDATE Statement (p. 377)</td>
<td>Updates a master file by applying transactions.</td>
</tr>
<tr>
<td>Information</td>
<td>ARRAY Statement (p. 23)</td>
<td>Defines the elements of an array.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>---------------------------</td>
<td>--------------------------------------------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td></td>
<td>Array Reference Statement (p. 27)</td>
<td>Describes the elements in an array to be processed.</td>
</tr>
<tr>
<td></td>
<td>ATTRIB Statement (p. 31)</td>
<td>Associates a format, informat, label, and length with one or more variables.</td>
</tr>
<tr>
<td></td>
<td>DROP Statement (p. 71)</td>
<td>Excludes variables from output SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>FORMAT Statement (p. 156)</td>
<td>Associates formats with variables.</td>
</tr>
<tr>
<td></td>
<td>INFORMAT Statement (p. 196)</td>
<td>Associates informats with variables.</td>
</tr>
<tr>
<td></td>
<td>KEEP Statement (p. 231)</td>
<td>Specifies the variables to include in output SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>LABEL Statement (p. 233)</td>
<td>Assigns descriptive labels to variables.</td>
</tr>
<tr>
<td></td>
<td>LENGTH Statement (p. 237)</td>
<td>Specifies the number of bytes for storing variables.</td>
</tr>
<tr>
<td></td>
<td>MISSING Statement (p. 270)</td>
<td>Assigns characters in your input data to represent special missing values for numeric data.</td>
</tr>
<tr>
<td></td>
<td>RENAME Statement (p. 331)</td>
<td>Specifies new names for variables in output SAS data sets.</td>
</tr>
<tr>
<td></td>
<td>RETAIN Statement (p. 337)</td>
<td>Causes a variable that is created by an INPUT or assignment statement to retain its value from one iteration of the DATA step to the next.</td>
</tr>
<tr>
<td>Log Control</td>
<td>Comment Statement (p. 45)</td>
<td>Specifies the purpose of the statement or program.</td>
</tr>
<tr>
<td></td>
<td>PAGE Statement (p. 296)</td>
<td>Skips to a new page in the SAS log.</td>
</tr>
<tr>
<td></td>
<td>RESETLINE Statement (p. 335)</td>
<td>Restarts the program line numbers in the SAS log to 1.</td>
</tr>
<tr>
<td></td>
<td>SKIP Statement (p. 365)</td>
<td>Creates a blank line in the SAS log.</td>
</tr>
<tr>
<td>Operating Environment</td>
<td>X Statement (p. 399)</td>
<td>Issues an operating-environment command from within a SAS session.</td>
</tr>
<tr>
<td>Output Control</td>
<td>FOOTNOTE Statement (p. 152)</td>
<td>Writes up to 10 lines of text at the bottom of the procedure or DATA step output.</td>
</tr>
<tr>
<td></td>
<td>TITLE Statement (p. 368)</td>
<td>Specifies title lines for SAS output.</td>
</tr>
<tr>
<td>Program Control</td>
<td>CHECKPOINT EXECUTE_ALWAYS Statement (p. 44)</td>
<td>Indicates to execute the DATA step or PROC step that immediately follows without considering the checkpoint-restart data.</td>
</tr>
<tr>
<td></td>
<td>DM Statement (p. 62)</td>
<td>Submits SAS Program Editor, Log, Procedure Output or text editor commands as SAS statements.</td>
</tr>
<tr>
<td>Category</td>
<td>Language Elements</td>
<td>Description</td>
</tr>
<tr>
<td>-----------------------</td>
<td>-----------------------</td>
<td>-----------------------------------------------------------------------------</td>
</tr>
<tr>
<td>END SAS Statement (p. 74)</td>
<td>Terminates a SAS job or session after the current DATA or PROC step executes.</td>
<td></td>
</tr>
<tr>
<td>%INCLUDE Statement (p. 164)</td>
<td>Brings a SAS programming statement, data lines, or both, into a current SAS program.</td>
<td></td>
</tr>
<tr>
<td>%LIST Statement (p. 260)</td>
<td>Displays lines that are entered in the current session.</td>
<td></td>
</tr>
<tr>
<td>LOCK Statement (p. 261)</td>
<td>Acquires and releases an exclusive lock on an existing SAS file.</td>
<td></td>
</tr>
<tr>
<td>OPTIONS Statement (p. 292)</td>
<td>Specifies or changes the value of one or more SAS system options.</td>
<td></td>
</tr>
<tr>
<td>RUN Statement (p. 342)</td>
<td>Executes the previously entered SAS statements.</td>
<td></td>
</tr>
<tr>
<td>%RUN Statement (p. 343)</td>
<td>Ends source statements following a %INCLUDE * statement.</td>
<td></td>
</tr>
<tr>
<td>SASFILE Statement (p. 344)</td>
<td>Opens a SAS data set and allocates enough buffers to hold the entire file in memory.</td>
<td></td>
</tr>
<tr>
<td>SYSECHO Statement (p. 368)</td>
<td>Fires a global statement complete event and passes a text string back to the IOM client.</td>
<td></td>
</tr>
<tr>
<td>Window Display</td>
<td>DISPLAY Statement (p. 61)</td>
<td>Displays a window that is created with the WINDOW statement.</td>
</tr>
<tr>
<td></td>
<td>WINDOW Statement (p. 389)</td>
<td>Creates customized windows for your applications.</td>
</tr>
</tbody>
</table>

**Dictionary**

**ABORT Statement**

Stops executing the current DATA step, SAS job, or SAS session.

- **Valid in:** DATA step
- **Category:** Action
- **Type:** Executable
- **See:** ABORT Statement in the SAS Companion for Windows, SAS Companion for z/OS, and SAS Companion for UNIX Environments

**Syntax**

```
ABORT <ABEND | CANCEL <FILE> | RETURN > <n> <NOLIST>;
```
**Without Arguments**

If you specify no argument, the ABORT statement produces these results under the following methods of operation:

**batch mode and noninteractive mode**

- stops processing the current DATA step and writes an error message to the SAS log. Data sets can contain an incomplete number of observations or no observations, depending on when SAS encountered the ABORT statement.
- sets the OBS= system option to 0.
- continues limited processing of the remainder of the SAS job, including executing macro statements, executing system options statements, and syntax checking of program statements.
- creates output data sets for subsequent DATA and PROC steps with no observations.

**windowing environment**

- stops processing the current DATA step
- creates a data set that contains the observations that are processed before the ABORT statement is encountered
- prints a message to the log that an ABORT statement terminated the DATA step
- continues processing any DATA or PROC steps that follow the ABORT statement

**interactive line mode**

- stops processing the current DATA step. Any further DATA steps or procedures execute normally.

**Arguments**

**ABEND**

causes abnormal termination of the current SAS job or session. Results depend on the method of operation:

- batch mode and noninteractive mode.
  - stops processing immediately.
  - sends an error message to the SAS log that states that execution was terminated by the ABEND option of the ABORT statement.
  - does not execute any subsequent statements or check syntax.
  - returns control to the operating environment; further action is based on how your operating environment and your site treat jobs that end abnormally.

- windowing environment and interactive line mode.
  - causes your windowing environment and interactive line mode to stop processing immediately and return you to your operating environment.

**CANCEL <FILE>**

causes the execution of the submitted statements to be canceled. Results depend on the method of operation:

- batch mode and noninteractive mode.
  - the entire SAS program and SAS system are terminated.
  - an error message is written to the SAS log.
• windowing environment and interactive line mode.
  • clears only the current submitted program.
  • other subsequent submitted programs are not affected.
  • an error message is written to the SAS log.
• workspace server and stored process server.
  • clears only the currently submitted program.
  • other subsequent submit calls are not affected.
  • an error message is written to the SAS log.
• SAS IntrNet application server.
  • creates a separate execution for each request and submits the request code. A CANCEL argument in the request code clears the current submitted code but does not terminate the execution or the SAS session.

FILE
when coded as an option to the CANCEL argument in an autoexec file or in a %INCLUDE file, causes only the contents of the autoexec file or %INCLUDE file to be cleared by the ABORT statement. Other submitted source statements will be executed after the autoexec or %INCLUDE file.

Restriction: The CANCEL argument cannot be submitted using SAS/SHARE, SAS/CONNECT, or SAS/AF.

Note: When the ABORT CANCEL FILE option is executed within a %INCLUDE file, all open macros are closed and execution resumes at the next source line of code.

RETURN
causes the immediate normal termination of the current SAS job or session. Results depend on the method of operation:
• batch mode and noninteractive mode
  • stops processing immediately
  • sends an error message to the SAS log stating that execution was terminated by the RETURN option in the ABORT statement
  • does not execute any subsequent statements or check syntax
  • returns control to your operating environment with a condition code indicating an error
• windowing environment
  • causes your windowing environment and interactive line mode to stop processing immediately and return you to your operating environment.

\( n \)
is an integer value that enables you to specify a condition code:
• when used with the CANCEL argument, the value is placed in the SYSINFO automatic macro variable
• when not used with the CANCEL argument, the error code that is returned by SAS is ERROR. The value of ERROR depends on the operating system. The condition code \( n \) is returned to the operating system as the final SAS system exit code.
NOLIST
suppresses the output of all variables to the SAS log.

**Requirement:** NOLIST must be the last option in the ABORT statement.

**Details**
The ABORT statement causes SAS to stop processing the current DATA step. What happens next depends on

- the method that you use to submit your SAS statements
- the arguments that you use with ABORT
- your operating environment.

The ABORT statement usually appears in a clause of an IF-THEN statement or a SELECT statement that is designed to stop processing when an error condition occurs.

**Note:** The return code generated by the ABORT statement is ignored by SAS if the system option ERRORABEND is in effect.

**Note:** When you execute an ABORT statement in a DATA step, SAS does not use data sets that were created in the step to replace existing data sets with the same name.

**Operating Environment Information**
The only difference between the ABEND and RETURN options is that with ABEND further action is based on how your operating environment and site treat jobs that end abnormally. RETURN simply returns a condition code that indicates an error.

**Comparisons**

- When you use the SAS windowing environment or interactive line mode, the ABORT statement and the STOP statement both stop processing. The ABORT statement sets the value of the automatic variable _ERROR_ to 1, and the STOP statement does not.

- In batch or noninteractive mode, the ABORT and STOP statements also have different effects. Both stop processing, but only ABORT sets the value of the automatic variable _ERROR_ to 1. Use the STOP statement, therefore, when you want to stop only the current DATA step and continue processing with the next step.

**Example: Stopping Execution of SAS**

This example uses the ABORT statement as part of an IF-THEN statement to stop execution of SAS when it encounters a data value that would otherwise cause a division-by-zero condition.

```
if volume=0 then abort 255;
  density=mass/volume;
```

The `n` value causes SAS to return the condition code 255 to the operating environment when the ABORT statement executes.

**Statements:**

- “STOP Statement” on page 365
ARRAY Statement

Defines the elements of an array.

Valid in: DATA step
Category: Information
Type: Declarative

Syntax

ARRAY array-name { subscript } <$> <length> <array-elements> <(initial-value-list)> ;

Arguments

array-name

specifies the name of the array.

Restriction: Array-name must be a SAS name that is not the name of a SAS variable in the same DATA step.

CAUTION: Using the name of a SAS function as an array name can cause unpredictable results. If you inadvertently use a function name as the name of the array, SAS treats parenthetical references that involve the name as array references, not function references, for the duration of the DATA step. A warning message is written to the SAS log.

[subscript]

describes the number and arrangement of elements in the array by using an asterisk, a number, or a range of numbers. Subscript has one of these forms:

dimension-size(s)

specifies the number of elements in each dimension of the array. Dimension-size is a numeric representation of either the number of elements in a one-dimensional array or the number of elements in each dimension of a multidimensional array.

Tip: You can enclose the subscript in braces ({ }), brackets ([ ]) or parentheses ( ()).

Examples:

This ARRAY statement defines a one dimensional array that is named SIMPLE. The SIMPLE array groups together three variables that are named RED, GREEN, and YELLOW:

array simple{3} red green yellow;

An array with more than one dimension is known as a multidimensional array. You can have any number of dimensions in a multidimensional array. For example, a two-dimensional array provides row and column arrangement of array elements. SAS places variables into a two-dimensional array by filling all rows in order, beginning at the upper left corner of the array (known as row-major order). This statement defines a two-dimensional array with five rows and three columns:

array x{5,3} score1-score15;
are the bounds of each dimension of an array, where lower is the lower bound of that dimension and upper is the upper bound.

**Range:** In most explicit arrays, the subscript in each dimension of the array ranges from 1 to \( n \), where \( n \) is the number of elements in that dimension.

**Tips:**
For most arrays, 1 is a convenient lower bound. Thus, you do not need to specify the lower and upper bounds. However, specifying both bounds is useful when the array dimensions have a convenient beginning point other than 1.

To reduce the computational time that is needed for subscript evaluation, specify a lower bound of 0.

**Examples:**
In the following example, the value of each dimension is by default the upper bound of that dimension.

```sas
array x{5,3} score1-score15;
```

As an alternative, the following ARRAY statement is a longhand version of the previous example:

```sas
array x{1:5,1:3} score1-score15;
```

{\*}

specifies that SAS is to determine the subscript by counting the variables in the array. When you specify the asterisk, also include array-elements.

**Restriction:** You cannot use the asterisk with _TEMPORARY_ arrays or when you define a multidimensional array.

$\
specifies that the elements in the array are character elements.

**Tip:** The dollar sign is not necessary if the elements have been previously defined as character elements.

**length**

specifies the length of elements in the array that have not been previously assigned a length.

**array-elements**

specifies the names of the elements that make up the array. *Array-elements* must be either all numeric or all character, and they can be listed in any order. The elements can be

**variables**

lists variable names.

**Range:** The names must be either variables that you define in the ARRAY statement or variables that SAS creates by concatenating the array name and a number. For example, when the subscript is a number (not the asterisk), you do not need to name each variable in the array. Instead, SAS creates variable names by concatenating the array name and the numbers 1, 2, 3, \( \ldots \), \( n \).

**Restriction:** If you use _ALL_, all the previously defined variables must be of the same type.

**Tips:**
These SAS variable lists enable you to reference variables that have been previously defined in the same DATA step:

- `_NUMERIC_` specifies all numeric variables.
- `_CHARACTER_` specifies all character variables.
- `_ALL_` specifies all variables.
Example: “Example 1: Defining Arrays” on page 26

_TEMPORARY_
creates a list of temporary data elements.

Range: Temporary data elements can be numeric or character.

Tips:
Temporary data elements behave like DATA step variables with these exceptions:
They do not have names. Refer to temporary data elements by the array name and dimension.
They do not appear in the output data set.
You cannot use the special subscript asterisk (*) to refer to all the elements.
Temporary data element values are always automatically retained, rather than being reset to missing at the beginning of the next iteration of the DATA step.
Arrays of temporary elements are useful when the only purpose for creating an array is to perform a calculation. To preserve the result of the calculation, assign it to a variable. You can improve performance time by using temporary data elements.

_(initial-value-list)_
gives initial values for the corresponding elements in the array. The values for elements can be numbers or character strings. You must enclose all character strings in quotation marks. To specify one or more initial values directly, use the following format:

_(initial-value(s))_

To specify an iteration factor and nested sublists for the initial values, use the following format:

<constant-iter-value*> <(constant value | constant-sublist)<>

Restriction: If you specify both an _initial-value-list_ and _array-elements_, then _array-elements_ must be listed before _initial-value-list_ in the ARRAY statement.

Tips:
You can assign initial values to both variables and temporary data elements.
Elements and values are matched by position. If there are more array elements than initial values, the remaining array elements receive missing values and SAS issues a warning.
You can separate the values in the initial value list with either a comma or a blank space.
You can also use a shorthand notation for specifying a range of sequential integers. The increment is always +1.
If you have not previously specified the attributes of the array elements (such as length or type), the attributes of any initial values that you specify are automatically assigned to the corresponding array element. Initial values are retained until a new value is assigned to the array element.
When any (or all) elements are assigned initial values, all elements behave as if they were named on a RETAIN statement.

Example: The following examples show how to use the iteration factor and nested sublists. All of these ARRAY statements contain the same initial value list:

ARRAY x{10} x1-x10 (10*5);
ARRAY x{10} x1-x10 (5*(5 5));
ARRAY x{10} x1-x10 (5 5 3*(5 5) 5 5);
ARRAY x[10] x1-x10 (2*(5 5) 5 5 2*(5 5));
ARRAY x[10] x1-x10 (2*(5 2*(5 5)))

**Examples:**
“Example 2: Assigning Initial Numeric Values” on page 26
“Example 3: Defining Initial Character Values” on page 26

**Details**
The ARRAY statement defines a set of elements that you plan to process as a group. You refer to elements of the array by the array name and subscript. Because you usually want to process more than one element in an array, arrays are often referenced within DO groups.

**Comparisons**
- Arrays in the SAS language are different from arrays in many other languages. A SAS array is simply a convenient way of temporarily identifying a group of variables. It is not a data structure, and *array-name* is not a variable.

**Examples**

**Example 1: Defining Arrays**
- array rain {5} janr febr marr aprr mayr;
- array days{7} d1-d7;
- array month{*} jan feb jul oct nov;
- array x{*} _NUMERIC_;
- array qbx{10};
- array meal{3};

**Example 2: Assigning Initial Numeric Values**
- array test{4} t1 t2 t3 t4 (90 80 70 70);
- array test{4} t1-t4 (90 80 2*70);
- array test{4} _TEMPORARY_ (90 80 70 70);

**Example 3: Defining Initial Character Values**
- array test2{*} $ a1 a2 a3 ("a","b","c");

**Example 4: Defining More Advanced Arrays**
- array new{2:5} green jacobs denato fetzer;
- array x{5,3} score1-score15;
- array test{3:4,3:7} test1-test10;
- array temp{0:999} _TEMPORARY_;
- array x{10} (2*1:5);
Example 5: Creating a Range of Variable Names That Have Leading Zeros

The following example shows that you can create a range of variable names that have leading zeros. Each variable name has a length of three characters, and the names sort correctly (A01, A02, … A10). Without leading zeros, the variable names would sort in the following order: A1, A10, A2, … A9.

```
data test (drop=i);
  array a{10} A01-A10;
  do i=1 to 10;
    a{i}=i;
  end;
run;
proc print noobs data=test;
run;
```

Output 2.1  Array Names That Have Leading Zeros

See Also

Statements:

- “Array Reference Statement” on page 27

Array Reference Statement

Describes the elements in an array to be processed.

Valid in: DATA step
Category: Information
Type: Declarative

Syntax

```
array-name { subscript }
```

Arguments

array-name

is the name of an array that was previously defined with an ARRAY statement in the same DATA step.
{subscript}
specifies the subscript. Any of these forms can be used:

{variable-1< , ..., variable-n>}
specifies a variable, or variable list that is usually used with DO-loop processing. For each execution of the DO loop, the current value of this variable becomes the subscript of the array element being processed.

**Tip:** You can enclose a subscript in braces ( { } ), brackets ( [ ] ), or parentheses ( ( ) ).

**Example:** “Example 1: Using Iterative DO-Loop Processing” on page 29

{ * }
forces SAS to treat the elements in the array as a variable list.

**Restriction:** When you define an array that contains temporary array elements, you cannot reference the array elements with an asterisk.

**Tips:**
The asterisk can be used with the INPUT and PUT statements, and with some SAS functions.
This syntax is provided for convenience and is an exception to usual array processing.

**Example:** “Example 4: Using the Asterisk References as a Variable List” on page 30

expression-1< , ..., expression-n>
specifies a SAS expression.

**Range:** The expression must evaluate to a subscript value when the statement that contains the array reference executes. The expression can also be an integer with a value between the lower and upper bounds of the array, inclusive.

**Example:** “Example 3: Specifying the Subscript” on page 29

---

**Details**

- To refer to an array in a program statement, use an array reference. The ARRAY statement that defines the array must appear in the DATA step before any references to that array. An array definition is only in effect for the duration of the DATA step. If you want to use the same array in several DATA steps, redefine the array in each step.

**CAUTION:**

*Using the name of a SAS function as an array name can cause unpredictable results.* If you inadvertently use a function name as the name of the array, SAS treats parenthetical references that involve the name as array references, not function references, for the duration of the DATA step. A warning message is written to the SAS log.

- You can use an array reference anywhere that you can write a SAS expression, including SAS functions and these SAS statements:
  - assignment statement
  - sum statement
  - DO UNTIL(expression)
  - DO WHILE(expression)
  - IF
The DIM function is often used with the iterative DO statement to return the number of elements in a dimension of an array, when the lower bound of the dimension is 1. If you use DIM, you can change the number of array elements without changing the upper bound of the DO statement. For example, because DIM(NEW) returns a value of 4, the following statements process all the elements in the array:

```sas
array new{*} score1-score4;
do i=1 to dim(new);
   new{1}=new{1}+10;
end;
```

### Comparisons

An ARRAY statement defines an array, whereas an array reference defines the members of the array to process.

### Examples

#### Example 1: Using Iterative DO-Loop Processing

In this example, the statements process each element of the array, using the value of variable I as the subscript on the array references for each iteration of the DO loop. If an array element has a value of 99, the IF-THEN statement changes that value to 100.

```sas
array days{7} d1-d7;
do i=1 to 7;
   if days{i}=99 then days{i}=100;
end;
```

#### Example 2: Referencing Many Arrays in One Statement

You can refer to more than one array in a single SAS statement. In this example, you create two arrays, DAYS and HOURS. The statements inside the DO loop substitute the current value of variable I to reference each array element in both arrays.

```sas
array days{7} d1-d7;
array hours{7} h1-h7;
do i=1 to 7;
   if days{i}=99 then days{i}=100;
   hours{i}=days{i}*24;
end;
```

#### Example 3: Specifying the Subscript

In this example, the INPUT statement reads in variables A1, A2, and the third element (A3) of the array named ARR1:

```sas
array arr1{*} a1-a3;
x=1;
input a1 a2 arr1{x+2};
```
Example 4: Using the Asterisk References as a Variable List

- array cost{10} cost1-cost10;
  totcost=sum(of cost {*});
- array days{7} d1-d7;
  input days {*};
- array hours{7} h1-h7;
  put hours {*};

- “DO Statement, Iterative” on page 65

Assignment Statement

Evaluates an expression and stores the result in a variable.

<table>
<thead>
<tr>
<th>Valid in</th>
<th>DATA step</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category:</td>
<td>Action</td>
</tr>
<tr>
<td>Type:</td>
<td>Executable</td>
</tr>
</tbody>
</table>

Syntax

```
variable=expression;
```

Arguments

**variable**

names a new or existing variable.

Range: *variable* can be a variable name, array reference, or SUBSTR function.

Tip: Variables that are created by the Assignment statement are not automatically retained.

**expression**

is any SAS expression.

Tip: *expression* can contain the variable that is used on the left side of the equal sign. When a variable appears on both sides of a statement, the original value on the right side is used to evaluate the expression, and the result is stored in the variable on the left side of the equal sign. For more information, see Chapter 6, “Expressions,” in *SAS Language Reference: Concepts*. 
Details
Assignment statements evaluate the expression on the right side of the equal sign and store the result in the variable that is specified on the left side of the equal sign.

Example: Various Expressions in Assignment Statements
These assignment statements use different types of expressions:
- `name='Amanda Jones';`
- `WholeName='Ms. '||name;`
- `a=a+b;`

See Also
Statements:
- “Sum Statement” on page 367

ATTRIB Statement
Associates a format, informat, label, and length with one or more variables.

Valid in: DATA step
Category: Information
Type: Declarative
See: ATTRIB Statement under Windows, UNIX, and z/OS

Syntax
ATTRIB variable-list(s) attribute-list(s) ;

Arguments
variable-list(s)
names the variables that you want to associate with the attributes.
Tip: List the variables in any form that SAS allows.

attribute-list(s)
specifies one or more attributes to assign to variable-list. Specify one or more of these attributes in the ATTRIB statement:

FORMAT=format
associates a format with variables in variable-list.
Tip: The format can be either a standard SAS format or a format that is defined with the FORMAT procedure.

INFORMAT=informat
associates an informat with variables in variable-list.
Tip: The informat can be either a standard SAS informat or an informat that is defined with the FORMAT procedure.
LABEL='label'
associates a label with variables in variable-list.

LENGTH=<$>length
specifies the length of variables in variable-list.

Range: For character variables, the range is 1 to 32,767 bytes for all operating environments.

Restriction: You cannot change the length of a variable using LENGTH= from PROC DATASETS.

Requirement: Put a dollar sign ($) in front of the length of character variables.

Operating environment: For numeric variables, the minimum length that you can specify with the LENGTH= specification is 2 bytes in some operating environments and 3 bytes in others.

Tip: Use the ATTRIB statement before the SET statement to change the length of variables in an output data set when you use an existing data set as input.

TRANSCODE=YES | NO
specifies whether character variables can be transcoded. Use TRANSCODE=NO to suppress transcoding.

Default: YES

Restrictions:
The TRANSCODE=NO attribute is not supported by some SAS Workspace Server clients. In SAS 9.2, if the attribute is not supported, variable values with TRANSCODE=NO are replaced (masked) with asterisks (*). Prior to SAS 9.2, variables with TRANSCODE=NO were transcoded.

Prior releases of SAS cannot access a SAS 9.1 data set that contains a variable with a TRANSCODE=NO attribute.

Transcode suppression is not supported by the V6TAPE engine.

Interactions:

If the TRANSCODE= attribute is set to NO for any character variable in a data set, then PROC CONTENTS prints a transcode column that contains the TRANSCODE= value for each variable in the data set. If all variables in the data set are set to the default TRANSCODE= value (YES), then no transcode column prints.

Details

The Basics
Using the ATTRIB statement in the DATA step permanently associates attributes with variables by changing the descriptor information of the SAS data set that contains the variables.

You can use ATTRIB in a PROC step, but the rules are different.
How SAS Treats Variables When You Assign Informats with the INFORMAT= Option in the ATTRIB Statement

Informats that are associated with variables by using the INFORMAT= option in the ATTRIB statement behave like informats that are used with modified list input. SAS reads the variables by using the scanning feature of list input, but applies the informat. In modified list input, SAS does the following:

- does not use the value of w in an informat to specify column positions or input field widths in an external file
- uses the value of w in an informat to specify the length of previously undefined character variables
- ignores the value of w in numeric informats
- uses the value of d in an informat in the same way it usually does for numeric informats
- treats blanks that are embedded as input data as delimiters unless you change their status with the DLM= or DLMSTR= option specification in an INFILE statement

If you have coded the INPUT statement to use another style of input, such as formatted input or column input, that style of input is not used when you use the INFORMAT= option in the ATTRIB statement.

How SAS Treats Transcoded Variables When You Use the SET and MERGE Statements

When you use the SET or MERGE statement to create a data set from several data sets, SAS makes the TRANSCODE= attribute of the variable in the output data set equal to the TRANSCODE= value of the variable in the first data set. See “Example 2: Using the SET Statement with Transcoded Variables” on page 34 and “Example 3: Using the MERGE Statement with Transcoded Variables” on page 34.

Note: The TRANSCODE= attribute is set when the variable is first seen on an input data set or in an ATTRIB TRANSCODE= statement. If a SET or MERGE statement comes before an ATTRIB TRANSCODE= statement and the TRANSCODE= attribute contradicts the SET statement, a warning will occur.

Comparisons

You can use either an ATTRIB statement or an individual attribute statement such as FORMAT, INFORMAT, LABEL, and LENGTH to change an attribute that is associated with a variable.

Examples

Example 1: Examples of ATTRIB Statements with Varying Numbers of Variables and Attributes

Here are examples of ATTRIB statements that contain different numbers of variables and attributes:

- single variable and single attribute:
  
  attrib cost length=4;

- single variable with multiple attributes:
  
  attrib solday informat=mmddyy.
  format=worddate.;
• multiple variables with the same multiple attributes:
  `attrib x y length=$4 label='TEST VARIABLE';`

• multiple variables with different multiple attributes:
  `attrib x length=$4 label='TEST VARIABLE'
              y length=$2 label='RESPONSE';`

• variable list with single attribute:
  `attrib month1-month12
       label='MONTHLY SALES';`

**Example 2: Using the SET Statement with Transcoded Variables**
In this example, which uses the SET statement, the variable Z's TRANSCODE= attribute in data set A is NO because B is the first data set and Z's TRANSCODE= attribute in data set B is NO.

```sas
data b;
  length z $4;
  z = 'ice';
  attrib z transcode = no;
data c;
  length z $4;
  z = 'snow';
  attrib z transcode = yes;
data a;
  set b;
  set c;
  /* Check transcode setting for variable Z */
  rc1 = vtranscode(z);
  put rc1=;
run;
```

**Example 3: Using the MERGE Statement with Transcoded Variables**
In this example, which uses the MERGE statement, the variable Z's TRANSCODE= attribute in data set A is YES because C is the first data set and Z's TRANSCODE= attribute in data set C is YES.

```sas
data b;
  length z $4;
  z = 'ice';
  attrib z transcode = no;
data c;
  length z $4;
  z = 'snow';
  attrib z transcode = yes;
data a;
  merge c b;
  /* Check transcode setting for variable Z */
  rc1 = vtranscode(z);
  put rc1=;
run;
```

**See Also**

• “How Many Characters Can I Use When I Measure SAS Name Lengths in Bytes?” in Chapter 3 of *SAS Language Reference: Concepts*
BY Statement

Controls the operation of a SET, MERGE, MODIFY, or UPDATE statement in the DATA step and sets up special grouping variables.

Valid in: DATA step or PROC step
Category: File-handling
Type: Declarative

Syntax

BY <DESCENDING> variable-1
<...<DESCENDING>variable-n> <NOTSORTED> <GROUPFORMAT> ;

Arguments

DESCENDING

specifies that the data sets are sorted in descending order by the variable that is specified. DESCENDING means largest to smallest numerically, or reverse alphabetical for character variables.

Restriction: You cannot use the DESCENDING option with data sets that are indexed because indexes are always stored in ascending order.

Example: “Example 2: Specifying Sort Order” on page 38

GROUPFORMAT

uses the formatted values, instead of the internal values, of the BY variables to determine where BY groups begin and end, and therefore how FIRST.variable and LAST.variable are assigned. Although the GROUPFORMAT option can appear anywhere in the BY statement, the option applies to all variables in the BY statement.

Restrictions:
You must sort the observations in a data set based on the value of the BY variables before using the GROUPFORMAT option in the BY statement.
You can use the GROUPFORMAT option in a BY statement only in a DATA step.
**Interaction:** If you also use the NOTSORTED option, you can group the observations in a data set by the formatted value of the BY variables without requiring that the data set be sorted or indexed.

**Note:** BY-group processing in the DATA step using the GROUPFORMAT option is the same as BY-group processing with formatted values in SAS procedures.

**Tips:**
- Using the GROUPFORMAT option is useful when you define your own formats to display data that is grouped.
- Using the GROUPFORMAT option in the DATA step ensures that BY groups that you use to create a data set match the BY groups in PROC steps that report grouped, formatted data.

**See:** Chapter 20, “BY-Group Processing in the DATA Step,” in *SAS Language Reference: Concepts*

**Example:** “Example 4: Grouping Observations by Using Formatted Values” on page 38

**variable**

names each variable by which the data set is sorted or indexed. These variables are referred to as BY variables for the current DATA or PROC step.

**Requirement:** If you designate a name literal as the BY variable in BY-group processing and you want to refer to the corresponding FIRST. or LAST. temporary variables, you must include the FIRST. or LAST. portion of the two-level variable name within single quotation marks. For example:

```sas
data sedanTypes;
  set cars;
  by 'Sedan Types'n;
  if 'first.Sedan Types'n then type=1;
run;
```

**Tip:** The data set can be sorted or indexed by more than one variable.

**Examples:**
- “Example 1: Specifying One or More BY Variables” on page 38
- “Example 2: Specifying Sort Order” on page 38
- “Example 3: BY-Group Processing with Nonsorted Data” on page 38
- “Example 4: Grouping Observations by Using Formatted Values” on page 38

**NOTSORTED**

specifies that observations with the same BY value are grouped together but are not necessarily sorted in alphabetical or numeric order.

**Restriction:** You cannot use the NOTSORTED option with the MERGE and UPDATE statements.

**Tips:**
- The NOTSORTED option can appear anywhere in the BY statement.
- Using the NOTSORTED option is useful if you have data that falls into other logical groupings such as chronological order or categories.

**Example:** “Example 3: BY-Group Processing with Nonsorted Data” on page 38

**Details**

**How SAS Identifies the Beginning and End of a BY Group**

SAS identifies the beginning and end of a BY group by creating two temporary variables for each BY variable: FIRST.variable and LAST.variable. The value of these variables is either 0 or 1. SAS sets the value of FIRST.variable to 1 when it reads the first
BY Statement

observation in a BY group, and sets the value of LAST.variable to 1 when it reads the last observation in a BY group. These temporary variables are available for DATA step programming but are not added to the output data set.

For a complete explanation of how SAS processes grouped data and of how to prepare your data, see Chapter 20, “BY-Group Processing in the DATA Step,” in SAS Language Reference: Concepts.

In a DATA Step

The BY statement applies only to the SET, MERGE, MODIFY, or UPDATE statement that precedes it in the DATA step, and only one BY statement can accompany each of these statements in a DATA step.

The data sets that are listed in the SET, MERGE, or UPDATE statements must be sorted by the values of the variables that are listed in the BY statement or have an appropriate index. As a default, SAS expects the data sets to be arranged in ascending numeric order or in alphabetical order. The observations can be arranged by one of the following methods:

- sort the data set
- create an index for the variables
- input the observations in order.

Note: MODIFY does not require sorted data, but sorting can improve performance.

Note: The BY statement honors the linguistic collation of data that is sorted by using the SORT procedure with the SORTSEQ=LINGUISTIC option.

For more information, see “How to Prepare Your Data Sets” in Chapter 21 of SAS Language Reference: Concepts.

In a PROC Step

You can specify the BY statement with some SAS procedures to modify their action. Refer to the individual procedure in the Base SAS Procedures Guide for a discussion of how the BY statement affects processing for SAS procedures.

With SAS Views

If you create a DATA step view by reading from a DBMS and the SET, MERGE, UPDATE, or MODIFY statement is followed by a BY statement, the BY statement might cause the DBMS to sort the data in order to return the data in sorted order. Sorting the data could increase execution time.

Processing BY Groups

SAS assigns the following values to FIRST.variable and LAST.variable:

- FIRST.variable has a value of 1 under the following conditions:
  - when the current observation is the first observation that is read from the data set.
  - when you do not use the GROUPFORMAT option and the internal value of the variable in the current observation differs from the internal value in the previous observation.

  If you use the GROUPFORMAT option, FIRST.variable has a value of 1 when the formatted value of the variable in the current observation differs from the formatted value in the previous observation.

- FIRST.variable has a value of 1 for any preceding variable in the BY statement.
In all other cases, FIRST.\textit{variable} has a value of 0.

- \textit{LAST.\textit{variable}} has a value of 1 under the following conditions:
  - when the current observation is the last observation that is read from the data set.
  - when you use the GROUPFORMAT option and the internal value of the variable in the current observation differs from the internal value in the next observation.

If you use the GROUPFORMAT option, LAST.\textit{variable} has a value of 1 when the formatted value of the variable in the current observation differs from the formatted value in the next observation.

- LAST.\textit{variable} has a value of 1 for any preceding variable in the BY statement.
  In all other cases, LAST.\textit{variable} has a value of 0.

### Examples

#### Example 1: Specifying One or More BY Variables

- Observations are in ascending order of the variable DEPT:
  
  ```sas
  by dept;
  ```

- Observations are in alphabetical (ascending) order by CITY and, within each value of CITY, in ascending order by ZIPCODE:
  
  ```sas
  by city zipcode;
  ```

#### Example 2: Specifying Sort Order

- Observations are in ascending order of SALESREP and, within each SALESREP value, in descending order of the values of JANSALES:
  
  ```sas
  by salesrep descending jansales;
  ```

- Observations are in descending order of BEDROOMS, and, within each value of BEDROOMS, in descending order of PRICE:
  
  ```sas
  by descending bedrooms descending price;
  ```

#### Example 3: BY-Group Processing with Nonsorted Data

Observations are ordered by the name of the month in which the expenses were accrued:

```sas
by month notsorted;
```

#### Example 4: Grouping Observations by Using Formatted Values

The following example illustrates the use of the GROUPFORMAT option.

```sas
proc format;
  value range
    low -55 = 'Under 55'
    55-60 = '55 to 60'
    60-65 = '60 to 65'
    65-70 = '65 to 70'
    other = 'Over 70';
run;

proc sort data=sashelp.class out=sorted_class;
  by height;
run;
```
data _null_;  
format height range.;  
set sorted_class;  
  by height groupformat;  
if first.height then  
  put 'Shortest in ' height 'measures ' height:best12.;  
run;

SAS writes the following output to the log:

<table>
<thead>
<tr>
<th>Height Range</th>
<th>Measured Height</th>
</tr>
</thead>
<tbody>
<tr>
<td>Under 55</td>
<td>51.3</td>
</tr>
<tr>
<td>55 to 60</td>
<td>56.3</td>
</tr>
<tr>
<td>60 to 65</td>
<td>62.5</td>
</tr>
<tr>
<td>65 to 70</td>
<td>65.3</td>
</tr>
<tr>
<td>Over 70</td>
<td>72</td>
</tr>
</tbody>
</table>

Example 5: Combining Multiple Observations and Grouping Them Based on One BY Value
The following example shows how to use FIRST.variable and LAST.variable with BY-group processing.

```sas
data Inventory;  
  length RecordID 8 Invoice $ 30 ItemLine $ 50;  
  infile datalines;  
  input RecordID Invoice ItemLine &;  
  drop RecordID;  
  datalines;  
A74  A5296  Highlighters  
A75  A5296  Lot # 7603  
A76  A5296  Yellow Blue Green  
A77  A5296  24 per box  
A78  A5297  Paper Clips  
A79  A5297  Lot # 7423  
A80  A5297  Small Medium Large  
A81  A5298  Gluestick  
A82  A5298  Lot # 4422  
A83  A5298  New item  
A84  A5299  Rubber bands  
A85  A5299  Lot # 7892  
A86  A5299  Wide width, Narrow width  
A87  A5299  1000 per box  
;  
data combined;  
  array Line{4} $ 60 ;  
  retain Line1-Line4;  
  keep Invoice Line1-Line4;  
  set Inventory;  
  by Invoice;  
  if first.Invoice then do;  
    call missing(of Line1-Line4);  
    records = 0;  
  end;  
  records + 1;  
  Line[records]=ItemLine;
```
if last.Invoice then output;
run;
proc print data=combined;
  title 'Office Supply Inventory';
run;

Output 2.2  Output from Combining Multiple Observations

<table>
<thead>
<tr>
<th>Obs</th>
<th>Line1</th>
<th>Line2</th>
<th>Line3</th>
<th>Line4</th>
<th>Invoice</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Highlighters</td>
<td>Lot # 7603</td>
<td>Yellow Blue Green</td>
<td>24 per box</td>
<td>A5296</td>
</tr>
<tr>
<td>2</td>
<td>Paper Clips</td>
<td>Lot # 7423</td>
<td>Small Medium Large</td>
<td></td>
<td>A5297</td>
</tr>
<tr>
<td>3</td>
<td>Gluesick</td>
<td>Lot # 4422</td>
<td>New item</td>
<td></td>
<td>A5298</td>
</tr>
<tr>
<td>4</td>
<td>Rubber bands</td>
<td>Lot # 7892</td>
<td>Wide width, Narrow width</td>
<td>1000 per box</td>
<td>A5299</td>
</tr>
</tbody>
</table>

• “SET Statement” on page 353
• “UPDATE Statement” on page 377

CALL Statement

Invokes a SAS CALL routine.

Valid in: DATA step
Category: Action
Type: Executable

Syntax

CALL routine(parameter-1 <, …parameter-n>);

Arguments

routine

specifies the name of the SAS CALL routine that you want to invoke.

See: For information about available routines, see SAS Functions and CALL Routines: Reference

(parameter)

is a piece of information to be passed to or returned from the routine.
**Requirement:** Enclose this information, which depends on the specific routine, in parentheses.

**Tip:** You can specify additional parameters, separated by commas.

**Details**

SAS CALL routines can assign variable values and perform other system functions.

**See Also**

*SAS Functions and CALL Routines: Reference*

---

### CARDS Statement

Specifies that data lines follow.

**Valid in:** DATA step

**Category:** File-handling

**Type:** Declarative

**Alias:** DATALINES, LINES

**See:** “DATALINES Statement” on page 56

CARDS statement in the *SAS Companion for UNIX Environments*

---

### CARDS4 Statement

Specifies that data lines that contain semicolons follow.

**Valid in:** DATA step

**Category:** File-handling

**Type:** Declarative

**Alias:** DATALINES4, LINES4

**See:** “DATALINES4 Statement” on page 58

---

### CATNAME Statement

Logically combines two or more catalogs into one by associating them with a catref (a shortcut name); clears one or all catrefs; lists the concatenated catalogs in one concatenation or in all concatenations.

**Valid in:** Anywhere

**Category:** Data Access

---

### Syntax

```plaintext
CATNAME <libref.> catref
   <$ (libref-1.catalog-1 <$ (ACCESS=READONLY)>
   <$…libref-n.catalog-n <$ (ACCESS=READONLY)>>>);
```
CATNAME <libref.> catref CLEAR | _ALL_ CLEAR;
CATNAME <libref.> catref LIST | _ALL_ LIST;

**Arguments**

*libref*

is any previously assigned SAS libref. If you do not specify a libref, SAS concatenates the catalog in the Work library, using the catref that you specify.

**Restriction:** The libref must have been previously assigned.

*catref*

is a unique catalog reference name for a catalog or a catalog concatenation that is specified in the statement. Separate the catref from the libref with a period, as in \( \text{libref.catref} \). Any SAS name can be used for this catref.

*catalog*

is the name of a catalog that is available for use in the catalog concatenation.

**Options**

*CLEAR*

disassociates a currently assigned \( \text{catref} \) or \( \text{libref.catref} \).

**Tip:** Specify a specific \( \text{catref} \) or \( \text{libref.catref} \) to disassociate it from a single concatenation. Specify _ALL_ CLEAR to disassociate all currently assigned \( \text{catref} \) or \( \text{libref.catref} \) concatenations.

_ALL_ CLEAR

disassociates all currently assigned \( \text{catref} \) or \( \text{libref.catref} \) concatenations.

*LIST*

writes the catalog names that are included in the specified concatenation to the SAS log.

**Tip:** Specify \( \text{catref} \) or \( \text{libref.catref} \) to list the attributes of a single concatenation. Specify _ALL_ to list the attributes of all catalog concatenations in your current session.

_ALL_ LIST

writes all catalog names that are included in any current catalog concatenation to the SAS log.

*ACCESS=READONLY*

assigns a read-only attribute to the catalog. SAS, therefore, will allow users to read from the catalog entries but not to update information or to write new information.

**Details**

*Why Use CATNAME?*

CATNAME is useful because it enables you to access entries in multiple catalogs by specifying a single catalog reference name (\( \text{libref.catref} \) or \( \text{catref} \)). After you create a catalog concatenation, you can specify the catref in any context that accepts a simple (non-concatenated) catref.

*Rules for Catalog Concatenation*

To use catalog concatenation effectively, you must understand the rules that determine how catalog entries are located among the concatenated catalogs:
When a catalog entry is opened for input or update, the concatenated catalogs are searched and the first occurrence of the specified entry is used.

When a catalog entry is opened for output, it will be created in the first catalog that is listed in the concatenation.

Note: A new catalog entry is created in the first catalog even if there is an entry with the same name in another part of the concatenation.

Note: If the first catalog in a concatenation that is opened for update does not exist, the item will be written to the next catalog that exists in the concatenation.

When you want to delete or rename a catalog entry, only the first occurrence of the entry is affected.

Any time a list of catalog entries is displayed, only one occurrence of a catalog entry name is shown.

Note: Even if the name occurs multiple times in the concatenation, only the first occurrence is shown.

Comparisons

The CATNAME statement is like a LIBNAME statement for catalogs. The LIBNAME statement enables you to assign a shortcut name to a SAS library so that you can use the shortcut name to find the files and use the data that they contain. CATNAME enables you to assign a short name `<libref:catref` (libref is optional) to one or more catalogs so that SAS can find the catalogs and use all or some of the entries in each catalog.

The CATNAME statement explicitly concatenates SAS catalogs. You can use the LIBNAME statement to implicitly concatenate SAS catalogs.

Examples

Example 1: Assigning and Using a Catalog Concatenation

You might need to access entries in several SAS catalogs. The most efficient way to access the information is to logically concatenate the catalogs. Catalog concatenation enables access to the information without actually creating a new, separate, and possibly very large catalog.

Assign librefs to the SAS libraries that contain the catalogs that you want to concatenate:

```
libname mylib1 'data-library-1';
libname mylib2 'data-library-2';
```

Assign a catref, which can be any valid SAS name, to the list of catalogs that you want to logically concatenate:

```
catname allcats {mylib1.catalog1 mylib2.catalog2};
```

The SAS log displays this message:

Log 2.1 Log Output from CATNAME Statement

```
NOTE: Catalog concatenation WORK.ALLCATS has been created.
```

Because no libref is specified, the libref is WORK by default. When you want to access a catalog entry in either of these catalogs, use the libref WORK and the catalog reference
name ALLCATS instead of the original librefs and catalog names. For example, to access a catalog entry named APPKEYS.KEYS in the catalog MYLIB1.CATALOG1, specify
work.allcats.appkeys.keys

Example 2: Creating a Nested Catalog Concatenation
After you create a concatenated catalog, you can use CATNAME to combine your concatenation with other single catalogs or other concatenated catalogs. Nested catalog concatenation is useful, because you can use a single catref to access many different catalog combinations.

libname local 'my_dir';
libname main 'public_dir';
catname private_catalog (local.my_application_code
    local.my_frames
    local.my_formats);
catname combined_catalogs (private_catalog
    main.public_catalog);

In the above example, you could work on private copies of your application entries by using PRIVATE_CATALOG. If you want to see how your entries function when they are combined with the public version of the application, you can use COMBINED_CATALOGS.

- “LIBNAME Statement” on page 239 for a discussion of implicitly concatenating SAS catalogs

CHECKPOINT EXECUTE_ALWAYS Statement
Indicates to execute the DATA step or PROC step that immediately follows without considering the checkpoint-restart data.

Valid in:    Anywhere
Category:   Program Control

Syntax
CHECKPOINT EXECUTE_ALWAYS;

Without Arguments
The CHECKPOINT EXECUTE_ALWAYS statement indicates to SAS that the DATA step or PROC step that immediately follows is to be executed without considering the checkpoint data.
Details

If checkpoint-restart mode is enabled and a batch program terminates without completing, the program can be rerun beginning with the DATA step or PROC step that was executing when it terminated. DATA or PROC steps that completed before the batch program terminated are not reexecuted. If a DATA step or a PROC step must be reexecuted, you can add the CHECKPOINT EXECUTE_ALWAYS statement before the step. Using the CHECKPOINT EXECUTE_ALWAYS statement ensures that SAS always executes the step without regard to the checkpoint-restart data.

See Also

- “Checkpoint Mode and Restart Mode” in Chapter 8 of *SAS Language Reference: Concepts*

System Options:

- “STEPCHKPT System Option” in *SAS System Options: Reference*
- “STEPCHKPTLIB= System Option” in *SAS System Options: Reference*
- “STEPRESTART System Option” in *SAS System Options: Reference*

---

**Comment Statement**

Specifies the purpose of the statement or program.

**Valid in:** Anywhere

**Category:** Log Control

**Syntax**

```
*message;
```

or

```
/*message*/
```

**Arguments**

*message;

specifies the text that explains or documents the statement or program.

**Range:** These comments can be any length and are terminated with a semicolon.

**Restrictions:**

These comments must be written as separate statements.

These comments cannot contain internal semicolons.

A macro statement or macro variable reference that is contained inside this form of comment is processed by the SAS macro facility. This form of comment cannot be used to hide text from the SAS macro facility.

**Tip:** When using comments within a macro definition or to hide text from the SAS macro facility, use this style comment:

```
/* message */
```

*/message*/

specifies the text that explains or documents the statement or program.
**Range:** These comments can be any length.

**Restriction:** This type of comment cannot be nested.

**Windows specifics:** If you use the Enhanced Editor, you can comment out a block of code by highlighting the block and then pressing CTRL-\- (forward slash). To uncomment a block of code, highlight the block and press CTRL-SHIFT-\- (forward slash).

**Tips:**

These comments can contain semicolons and unmatched quotation marks. You can write these comments within statements or anywhere a single blank can appear in your SAS code.

**Details**

You can use the comment statement anywhere in a SAS program to document the purpose of the program, explain unusual segments of the program, or describe steps in a complex program or calculation. SAS ignores text in comment statements during processing.

**CAUTION:**

Avoid placing the /* comment symbols in columns 1 and 2. In some operating environments, SAS might interpret a /* in columns 1 and 2 as a request to end the SAS program or session.

**Note:** You can add these lines to your code to fix unmatched comment tags, unmatched quotation marks, and missing semicolons.

```sas
/* ' ; " ; */;
quit;
run;
```

**Example: Using the Comment Statement**

These examples illustrate the two types of comments:

- This example uses the *message;* format:

  ```sas
  *This code finds the number in the BY group;
  ```

- This example uses the *message;* format:

  ```sas
  *---------------------------------------*
  | This uses one comment statement      |
  | to draw a box.                      |
  *---------------------------------------*;
  ```

- This example uses the /*message*/ format:

  ```sas
  input @1 name $20. /* last name */
  @200 test 8. /* score test */
  @50 age 3.; /* customer age */
  ```

- This example uses the /*message*/ format:

  ```sas
  /* For example 1 use: x=abc;
  for example 2 use: y=ghi; */
  ```
CONTINUE Statement

Stops processing the current DO-loop iteration and resumes processing the next iteration.

Valid in: DATA step
Category: Control
Type: Executable
Restriction: Can be used only in a DO loop

Syntax
CONTINUE;

Without Arguments
The CONTINUE statement has no arguments. It stops processing statements within the current DO-loop iteration based on a condition. Processing resumes with the next iteration of the DO loop.

Comparisons
- The CONTINUE statement stops the processing of the current iteration of a loop and resumes with the next iteration; the LEAVE statement causes processing of the current loop to end.
- You can use the CONTINUE statement only in a DO loop; you can use the LEAVE statement in a DO loop or a SELECT group.

Example: Preventing Other Statements from Executing
This DATA step creates a report of benefits for new full-time employees. If an employee's status is PT (part-time), the CONTINUE statement prevents the second INPUT statement and the OUTPUT statement from executing.

```plaintext
data new_emp;
  drop i;
  do i=1 to 5;
    input name $ idno status $;
    /* return to top of loop */
    /* when condition is true */
    if status='PT' then continue;
    input benefits $10.;
    output;
  end;
  datalines;
Jones 9011 PT
Thomas 876 PT
Richards 1002 PT
Eye/Dental
Kelly 85111 PT
Smith 433 PT
HMO
;```

DATA Statement

Begins a DATA step and provides names for any output SAS data sets, views, or programs.

Valid in: DATA step
Category: File-handling
Type: Declarative

Syntax

Form 1: `DATA <data-set-name-1><(data-set-options-1)><...><data-set-name-n><(data-set-options-n)></<<DEBUG><NESTING><STACK = stack-size><NOLIST>;;`

Form 2: `DATA _NULL_;</<DEBUG><NESTING><STACK = stack-size><NOLIST>;;`

Form 3: `DATA view-name <data-set-name-1><(data-set-options-1)><...><data-set-name-n><(data-set-options-n)></<VIEW=view-name<(<password-option><SOURCE=source-option> )><NESTING><NOLIST>;;`

Form 4: `DATA data-set-name / PGM=program-name<(<password-option><SOURCE=source-option> )><NESTING><NOLIST>;;`

Form 5: `DATA VIEW=view-name<(<password-option)> <NOLIST>;;
<DESCRIBE>;

Form 6: `DATA PGM=program-name<(<password-option)> <NOLIST>;;
<DESCRIBE>;
<REDIRECT INPUT | OUTPUT old-name-1 = new-name-1<... old-name-n = new-name-n> ;;
<EXECUTE>;

Without Arguments

If you omit the arguments, the DATA step automatically names each successive data set that you create as DATAn, where n is the smallest integer that makes the name unique.

Arguments

data-set-name

names the SAS data file or DATA step view that the DATA step creates. To create a DATA step view, you must specify at least one data-set-name and that data-set-name must match view-name.

Restriction: data-set-name must conform to the rules for SAS names, and additional restrictions might be imposed by your operating environment.

Tips:
Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

You can execute a DATA step without creating a SAS data set. See “Example 5: Creating a Custom Report” on page 54. For more information, see “When Not Creating a Data Set (Form 2)” on page 52.

See: For more information about the types of SAS data set names and when to use each type, see “Names in the SAS Language” in Chapter 3 of SAS Language Reference: Concepts.

(data-set-options)

specifies optional arguments that the DATA step applies when it writes observations to the output data set.

See: SAS Data Set Options: Reference for a definition and list of data set options.

Example: “Example 1: Creating Multiple Data Files and Using Data Set Options” on page 53

/ DEBUG

enables you to debug your program interactively by helping identify logic errors, and sometimes data errors.

/ NESTING

specifies that a note will be printed to the SAS log for the beginning and end of each DO-END and SELECT-END nesting level. This option enables you to debug mismatched DO-END and SELECT-END statements and is particularly useful in large programs where the nesting level is not obvious.

/ STACK=stack-size

specifies the maximum number of nested LINK statements.

_NULL_

specifies that SAS does not create a data set when it executes the DATA step.

VIEW=view-name

names a view that the DATA step uses to store the input DATA step view.

Restrictions:

view-name must match one of the data set names.

SAS creates only one view in a DATA step.

Tips:

If you specify additional data sets in the DATA statement, SAS creates these data sets when the view is processed in a subsequent DATA or PROC step. Views have the capability of generating other data sets at the time the view is executed. SAS macro variables resolve when the view is created. Use the SYMGET function to delay macro variable resolution until the view is processed.

Examples:

“Example 2: Creating Input DATA Step Views” on page 53

“Example 3: Creating a View and a Data File” on page 54

password-option

assigns a password to a stored compiled DATA step program or a DATA step view.

Note: To DESCRIBE a password-protected DATA step program, you must specify its password. If the program has more than one password, you must specify the most restrictive password. ALTER is the most restrictive, and READ is the least restrictive. For more information, see “DESCRIBE Statement” on page 60.

The following password options are available:
ALTER=alter-password
assigns an ALTER password to a SAS data file. The password enables you to protect or replace a stored compiled DATA step program or a DATA step view.

Alias: PROTECT=

Requirements:
If you use an ALTER password in creating a stored compiled DATA step program or a DATA step view, an ALTER password is required to replace the program or view.
If you use an ALTER password in creating a stored compiled DATA step program or a DATA step view, an ALTER password is required to execute a DESCRIBE statement.

READ=read-password
assigns a READ password to a SAS data file. The password enables you to read or execute a stored compiled DATA step program or a DATA step view.

Alias: EXECUTE=

Requirements:
If you use a READ password in creating a stored compiled DATA step program or a DATA step view, a READ password is required to execute the program or view.
If you use a READ password in creating a stored compiled DATA step program or a DATA step view, a READ password is required to execute DESCRIBE and EXECUTE statements. If you use an invalid password, SAS will execute the DESCRIBE statement.

Tip: If you use a READ password in creating a stored compiled DATA step program or a DATA step view, no password is required to replace the program or view.

PW=password
assigns a READ and ALTER password, both having the same value.

SOURCE=source-option
specifies one of the following source options:

SAVE
saves the source code that created a stored compiled DATA step program or a DATA step view.

ENCRYPT
encrypts and saves the source code that created a stored compiled DATA step program or a DATA step view.

Tip: If you encrypt source code, use the ALTER password option as well. SAS issues a warning message if you do not use ALTER.

NOSAVE
does not save the source code.

CAUTION:
If you use the NOSAVE option for a DATA step view, the view cannot be migrated or copied from one version of SAS to another version.

Default: SAVE

PGM=program-name
names the stored compiled program that SAS creates or executes in the DATA step. To create a stored compiled program, specify a slash (/) before the PGM= option. To execute a stored compiled program, specify the PGM= option without a slash (/).
**Tip:** SAS macro variables resolve when the stored program is created. Use the SYMGET function to delay macro variable resolution until the view is processed.

**Example:** “Example 4: Storing and Executing a Compiled Program” on page 54

**NOLIST**
suppresses the output of all variables to the SAS log when the value of _ERROR_ is 1.

**Restriction:** NOLIST must be the last option in the DATA statement.

**Details**

**Using the DATA Statement**
The DATA step begins with the DATA statement. You use the DATA statement to create the following types of output: SAS data sets, data views, and stored programs. You can specify more than one output in a DATA statement. However, only one of the outputs can be a data view. You create a view by specifying the VIEW= option on page 49 and a stored program by specifying the PGM= option on page 50.

**Using Both a READ and an ALTER Password**
If you use both a READ and an ALTER password in creating a stored compiled DATA step program or a DATA step view, the following items apply:

- A READ or ALTER password is required to execute the stored compiled DATA step program or DATA step view.
- A READ or ALTER password is required if the stored compiled DATA step program or DATA step view contains both DESCRIBE and EXECUTE statements.
- If you use an ALTER password with the DESCRIBE and EXECUTE statements, the following items apply:
  - SAS executes both the DESCRIBE and the EXECUTE statements.
  - If you execute a stored compiled DATA step program or DATA step view with an invalid ALTER password:
    - The DESCRIBE statement does not execute.
    - In batch mode, the EXECUTE statement has no effect.
    - In interactive mode, SAS prompts you for a READ password. If the READ password is valid, SAS processes the EXECUTE statement. If it is invalid, SAS does not process the EXECUTE statement.
- If you use a READ password with the DESCRIBE and EXECUTE statements, the following items apply:
  - In interactive mode, SAS prompts you for the ALTER password:
    - If you enter a valid ALTER password, SAS executes both the DESCRIBE and the EXECUTE statements.
    - If you enter an invalid ALTER password, SAS processes the EXECUTE statement but not the DESCRIBE statement.
  - In batch mode, SAS processes the EXECUTE statement but not the DESCRIBE statement.
  - In both interactive and batch modes, if you specify an invalid READ password SAS does not process the EXECUTE statement.
• An ALTER password is required if the stored compiled DATA step program or DATA step view contains a DESCRIBE statement.
• An ALTER password is required to replace the stored compiled DATA step program or DATA step view.

Creating an Output Data Set (Form 1)
Use the DATA statement to create one or more output data sets. You can use data set options to customize the output data set. The following DATA step creates two output data sets, EXAMPLE1 and EXAMPLE2. It uses the data set option DROP to prevent the variable IDNUMBER from being written to the EXAMPLE2 data set.

```sas
data example1 example2 (drop=IDnumber);
  set sample;
  . . .more SAS statements . .
run;
```

When Not Creating a Data Set (Form 2)
Usually, the DATA statement specifies at least one data set name that SAS uses to create an output data set. However, when the purpose of a DATA step is to write a report or to write data to an external file, you might not want to create an output data set. Using the keyword `_NULL_` as the data set name causes SAS to execute the DATA step without writing observations to a data set. This example writes to the SAS log the value of Name for each observation. SAS does not create an output data set.

```sas
data _NULL_;
  set sample;
  put Name ID;
run;
```

Creating a DATA Step View (Form 3)
You can create DATA step views and execute them at a later time. The following DATA step example creates a DATA step view. It uses the SOURCE=ENCRYPT option to both save and encrypt the source code.

```sas
data phone_list / view=phone_list (source=encrypt);
  set customer_list;
  . . .more SAS statements . .
run;
```

For more information, see “DATA Step Views” in Chapter 27 of SAS Language Reference: Concepts.

Creating a Stored Compiled DATA Step Program (Form 4)
The ability to compile and store DATA step programs enables you to execute the stored programs later. Stored compiled DATA step programs can reduce processing costs by eliminating the need to compile DATA step programs repeatedly. The following DATA step example compiles and stores a DATA step program. It uses the ALTER password option, which allows the user to replace an existing stored program, and to protect the stored compiled program from being replaced.

```sas
data testfile / pgm=stored.test_program (alter=sales);
  set sales_data;
  . . .more SAS statements . .
run;
```
For more information, see Chapter 28, “Stored Compiled DATA Step Programs,” in SAS Language Reference: Concepts.

**Describing a DATA Step View (Form 5)**
The following example uses the DESCRIBE statement in a DATA step view to write a copy of the source code to the SAS log.

```sas
data view=inventory;
    describe;
run;
```

For more information, see the “DESCRIBE Statement” on page 60.

**Executing a Stored Compiled DATA Step Program (Form 6)**
The following example executes a stored compiled DATA step program. It uses the DESCRIBE statement to write a copy of the source code to the SAS log.

```sas
libname stored 'SAS library';
data pgm=stored.employee_list;
    describe;
    execute;
run;

libname stored 'SAS library';
data pgm=stored.test_program;
    describe;
    execute;
    ...more SAS statements...
run;
```

For information, see the “DESCRIBE Statement” on page 60 and the “EXECUTE Statement” on page 75.

**Examples**

**Example 1: Creating Multiple Data Files and Using Data Set Options**
This DATA statement creates more than one data set, and it changes the contents of the output data sets:

```sas
data error (keep=subject date weight)
    fitness(label='Exercise Study'
        rename=(weight=pounds));
```

The ERROR data set contains three variables. SAS assigns a label to the FITNESS data set and renames the variable `weight` to `pounds`.

**Example 2: Creating Input DATA Step Views**
This DATA step creates an input DATA step view instead of a SAS data file:

```sas
libname ourlib 'SAS-library';
data ourlib.test / view=ourlib.test;
    set ourlib.fittest;
    tot=sum(of score1-score10);
run;
```
Example 3: Creating a View and a Data File
This DATA step creates an input DATA step view named THEIRLIB.TEST and an additional temporary SAS data set named SCORETOT:

```sas
libname ourlib 'SAS-library-1';
libname theirlib 'SAS-library-2';
data theirlib.test scoretot
  / view=theirlib.test;
  set ourlib.fittest;
  tot=sum(of score1-score10);
run;
```

SAS does not create the data file SCORETOT until a subsequent DATA or PROC step processes the view THEIRLIB.TEST.

Example 4: Storing and Executing a Compiled Program
The first DATA step produces a stored compiled program named STORED.SALESFIG:

```sas
libname in 'SAS-library-1';
libname stored 'SAS-library-2';
data salesdata / pgm=stored.salesfig;
  set in.sales;
  qtr1tot=jan+feb+mar;
run;
```

SAS creates the data set SALESDATA when it executes the stored compiled program STORED.SALESFIG.

```sas
data pgm=stored.salesfig;
run;
```

Example 5: Creating a Custom Report
The second DATA step in this program produces a custom report and uses the _NULL_ keyword to execute the DATA step without creating a SAS data set:

```sas
data sales;
  input dept : $10. jan feb mar;
datalines;
shoes 4344 3555 2666
housewares 3777 4888 7999
appliances 53111 7122 41333
;
data _null_
  set sales;
  qtr1tot=jan+feb+mar;
  put 'Total Quarterly Sales: ' qtr1tot dollar12.;
run;
```

Example 6: Using a Password with a Stored Compiled DATA Step Program
The first DATA step creates a stored compiled DATA step program called STORED.ITEMS. This program includes the ALTER password, which limits access to the program.

```sas
data sample;
  input Name $ TotalItems $;
datalines;
```
Lin 328
Susan 433
Ken 156
Pat 340
;
proc print data=sample;
run;
libname stored 'SAS-library';
data employees / pgm=stored.items (alter=klondike);
set sample;
if TotalItems > 200 then output;
run;

This DATA step executes the stored compiled DATA step program STORED.ITEMS. It uses the DESCRIBE statement to print the source code to the SAS log. Because the program was created with the ALTER password, you must use the password if you use the DESCRIBE statement. If you do not enter the password, SAS will prompt you for it.

data pgm=stored.items (alter=klondike);
describe;
execute;
run;

**Example 7: Displaying Nesting Levels**
The following program has two nesting levels. SAS will generate four log messages, one begin and end message for each nesting level.

data _null_ /nesting;
do i = 1 to 10;
do j = 1 to 5;
   put i= j=;
end;
end;
run;

*Log 2.2  Nesting Level Debug (partial SAS log)*

- “LINK Statement” on page 256

DATALINES Statement

Specifies that data lines follow.

Valid in: DATA step
Category: File-handling
Type: Declarative
Alias: CARDS, LINES
See: Data lines cannot contain semicolons. Use the “DATALINES4 Statement” on page 58 when your data contain semicolons.

Syntax

DATALINES;

Without Arguments

Use the DATALINES statement with an INPUT statement to read data that you enter directly in the program, rather than data stored in an external file.

Details

Using the DATALINES Statement

The DATALINES statement is the last statement in the DATA step and immediately precedes the first data line. Use a null statement (a single semicolon) to indicate the end of the input data.

You can use only one DATALINES statement in a DATA step. Use separate DATA steps to enter multiple sets of data.

Note: If you insert tabs while entering data in the DATALINES statement, you might get unexpected results when using columnar input. This issue exists when you use the SAS Enhanced Editor or SAS Program Editor. To avoid the issue, do one of the following:

- Replace all tabs in the data with single spaces.
- Use the %INCLUDE statement from the SAS editor to submit your code.
- If you are using the SAS Enhanced Editor, select Tools -> Options -> Enhanced Editor to change the tab size from 4 to 1.
**Reading Long Data Lines**
SAS handles data line length with the CARDIMAGE system option. If you use CARDIMAGE, SAS processes data lines exactly like 80-byte punched card images padded with blanks. If you use NOCARDIMAGE, SAS processes data lines longer than 80 columns in their entirety.

**Using Input Options with In-stream Data**
The DATALINES statement does not provide input options for reading data. However, you can access some options by using the DATALINES statement in conjunction with an INFILE statement. Specify DATALINES in the INFILE statement to indicate the source of the data and then use the options that you need. For more information, see “Example 2: Reading In-stream Data with Options” on page 57.

**Comparisons**
- Use the DATALINES statement whenever data do not contain semicolons. If your data contain semicolons, use the DATALINES4 statement.
- The following SAS statements also read data or point to a location where data are stored:
  - The INFILE statement points to raw data lines stored in another file. The INPUT statement reads those data lines.
  - The %INCLUDE statement brings SAS program statements or data lines stored in SAS files or external files into the current program.
  - The SET, MERGE, MODIFY, and UPDATE statements read observations from existing SAS data sets.

**Examples**

**Example 1: Using the DATALINES Statement**
In this example, SAS reads a data line and assigns values to two character variables, NAME and DEPT, for each observation in the DATA step:

```sas
data person;
  input name $ dept $;
  datalines;
  John Sales
  Mary Acctng
;  
```

**Example 2: Reading In-stream Data with Options**
This example takes advantage of options available with the INFILE statement to read in-stream data lines. With the DELIMITER= option, you can use list input to read data values that are delimited by commas instead of blanks.

```sas
data person;
  infile datalines delimiter=',,,'
  input name $ dept $;
  datalines;
  John, Sales
  Mary, Acctng
;  
```

- “INFILE Statement” on page 171

System Options:
- “CARDIMAGE System Option” in SAS System Options: Reference

DATALINES4 Statement
Indicates that data lines that contain semicolons follow.

Valid in: DATA step
Category: File-handling
Type: Declarative
Alias: CARDS4, LINES4

Syntax
DATALINES4;

Without Arguments
Use the DATALINES4 statement together with an INPUT statement to read data that contain semicolons that you enter directly in the program.

Details
The DATALINES4 statement is the last statement in the DATA step and immediately precedes the first data line. Follow the data lines with four consecutive semicolons that are located in columns 1 through 4.

Comparisons
Use the DATALINES4 statement when data contain semicolons. If your data do not contain semicolons, use the DATALINES statement.

Example: Reading Data Lines That Contain Semicolons
In this example, SAS reads data lines that contain internal semicolons until it encounters a line of four semicolons. Execution continues with the rest of the program.

    data biblio;
      input number citation $50.;
      datalines4;
    KIRK, 1988
    2 LIN ET AL., 1995; BRADY, 1993
    3 BERG, 1990; ROA, 1994; WILLIAMS, 1992
    ;;;
DELETE Statement

Stops processing the current observation.

**Valid in:** DATA step

**Category:** Action

**Type:** Executable

**Syntax**

DELETE;

**Without Arguments**
When DELETE executes, the current observation is not written to a data set, and SAS returns immediately to the beginning of the DATA step for the next iteration.

**Details**
The DELETE statement is often used in a THEN clause of an IF-THEN statement or as part of a conditionally executed DO group.

**Comparisons**

- Use the DELETE statement when it is easier to specify a condition that excludes observations from the data set or when there is no need to continue processing the DATA step statements for the current observation.
- Use the subsetting IF statement when it is easier to specify a condition for including observations.
- Do not confuse the DROP statement with the DELETE statement. The DROP statement excludes variables from an output data set; the DELETE statement excludes observations.

**Examples**

**Example 1: Using the DELETE Statement as Part of an IF-THEN Statement**
When the value of LEAFWT is missing, the current observation is deleted:

```
if leafwt=. then delete;
```

**Example 2: Using the DELETE Statement to Subset Raw Data**

```
data topsales;
    infile file-specification;
    input region office product yrsales;
```
if yrsales<100000 then delete;
run;

DESCRIBE Statement

Retrieves source code from a stored compiled DATA step program or a DATA step view.

Valid in: DATA step
Category: Action
Type: Executable
Restriction: Use DESCRIBE only with stored compiled DATA step programs and DATA step views.
Requirement: You must specify the PGM= or the VIEW= option in the DATA statement.

Syntax

DESCRIBE;

Without Arguments

Use the DESCRIBE statement to retrieve program source code from a stored compiled DATA step program or a DATA step view. SAS writes the source statements to the SAS log.

Details

Use the DESCRIBE statement without the EXECUTE statement to retrieve source code from a stored compiled DATA step program or a DATA step view. Use the DESCRIBE statement with the EXECUTE statement to retrieve source code and execute a stored compiled DATA step program. For information about how to use these statements with the DATA statement, see “DATA Statement” on page 48.

Note: To DESCRIBE a password-protected view or DATA step program, you must specify its password. If the view or program was created with more than one password, you must specify the most restrictive password. As with other SAS files, the ALTER password is the most restrictive, and the READ password is the least restrictive. For more information, see “Executing a Stored Compiled DATA Step Program” in Chapter 28 of SAS Language Reference: Concepts and “Using Passwords with Views” in Chapter 34 of SAS Language Reference: Concepts.

Statements:
- “DATA Statement” on page 48
- “EXECUTE Statement” on page 75

DISPLAY Statement
Displays a window that is created with the WINDOW statement.

Valid in: DATA step
Category: Window Display
Type: Executable

Syntax
DISPLAY window.<group> <NOINPUT> <BLANK> <BELL> <DELETE>;

Arguments
window.<group>
names the window and group of fields to be displayed. This field is preceded by a period (.).

Tip: If the window has more than one group of fields, give the complete window.<group> specification. If a window contains a single unnamed group, use only window.

NOINPUT
specifies that you cannot input values into fields that are displayed in the window.
Default: If you omit NOINPUT, you can input values into unprotected fields that are displayed in the window.
Restriction: If you use NOINPUT in all DISPLAY statements in a DATA step, you must include a STOP statement to stop processing the DATA step.
Tip: The NOINPUT option is useful when you want to allow values to be entered into a window at some times but not others. For example, you can display a window once for entering values and a second time for verifying them.

BLANK
clears the window.
Tip: Use the BLANK option when you want to display different groups of fields in a window and you do not want text from the previous group to appear in the current display.

BELL
produces an audible alarm, beep, or bell sound when the window is displayed if your personal computer is equipped with a speaker device that provides sound.

DELETE
deletes the display of the window after processing passes from the DISPLAY statement on which the option appears.
Details

You must create a window in the same DATA step that you use to display it. Once you display a window, the window remains visible until you display another window over it or until the end of the DATA step. When you display a window that contains fields where you enter values, either enter a value or press ENTER at each unprotected field to cause SAS to proceed to the next display. You cannot skip any fields.

While a window is being displayed, use commands and function keys to view other windows, to change the size of the current window, and so on.

A DATA step that contains a DISPLAY statement continues execution until the last observation that is read by a SET, MERGE, UPDATE, MODIFY, or INPUT statement has been processed or until a STOP or ABORT statement is executed. You can also issue the END command on the command line of the window to stop the execution of the DATA step.

You must create a window before you can display it. See the “WINDOW Statement” on page 389 for a description of how to create windows. A window that is displayed with the DISPLAY statement does not become part of the SAS log or output file.

Example

This DATA step creates and displays a window named START. The START window fills the entire screen. Both lines of text are centered.

```
data _null_;  
  window start  
    #5 @28 'WELCOME TO THE SAS SYSTEM'  
    #12 @30 'PRESS ENTER TO CONTINUE';  
  display start;  
  stop;  
run;  
```

Although the START window in this example does not require you to input any values, you must press ENTER to cause the execution to proceed to the STOP statement. If you omit the STOP statement, the DATA step executes endlessly unless you enter END on the command line of the window.

Note: Because this DATA step does not read any observations, SAS cannot detect an end-of-file to cause DATA step execution to cease. If you add the NOINPUT option to the DISPLAY statement, the window displays quickly and is removed.

See Also

Statements:

• “WINDOW Statement” on page 389

DM Statement

Submits SAS Program Editor, Log, Procedure Output or text editor commands as SAS statements.

Valid in: Anywhere
Category: Program Control
Syntax

DM <window> 'command(s)' <window> <CONTINUE> ;

Arguments

window
specifies the active window.

Default: If you omit the window name, SAS uses the Program Editor window as the default.

'command(s)'
can be any windowing command or text editor command and must be enclosed in single quotation marks. If you want to issue several commands, separate them with semicolons.

CONTINUE
causes SAS to execute any SAS statements that follow the DM statement in the Program Editor window and, if a windowing command in the DM statement called a window, makes that window active.

Note: For example, if you specify Log as the active window and have other SAS statements that follow the DM statement (for example, in an autoexec file), those statements are not submitted to SAS until control returns to the SAS interface.

Tip: Any windows that are activated by the SAS statements (such as the Output window) appear before the window that is to be made active.

Details

Execution occurs when the DM statement is submitted to SAS. You can use this statement to modify the windowing environment:

• Change SAS interface features during a SAS session.
• Change SAS interface features at the beginning of each SAS session by placing the DM statement in an autoexec file.
• Perform utility functions in windowing applications, such as saving a file with the FILE command or clearing a window with the CLEAR command.

Window placement affects the outcome of the statement:

• If you name a window before the commands, those commands apply to that window.
• If you name a window after the commands, SAS executes the commands and then makes that window the active window. The active window is opened and contains the cursor.

Examples

Example 1: Using the DM Statement

• dm 'color text cyan; color command red';
  • dm log 'clear; pgm; color numbers green'
    output;
• dm 'caps on';
• dm log 'clear' output;
Example 2: Using the CONTINUE Option with SAS Statements That Do Not Activate a Window
This example causes SAS to display the first window of the SAS/AF application, executes the DATA step, moves the cursor to the first field of the SAS/AF application window, and makes that window active.

dm 'af c=your-program' continue;
data temp;
    . . . more SAS statements . . .
run;

Example 3: Using the CONTINUE Option with SAS Statements That Activate a Window
This example displays the first window of the SAS/AF application and executes the PROC PRINT step, which activates the OUTPUT window. Closing the OUTPUT window moves the cursor to the last active window.

dm 'af c=your-program' continue;
proc print data=temp;
run;

DO Statement
Specifies a group of statements to be executed as a unit.

Valid in: DATA step
Category: Control
Type: Executable

Syntax
DO;
    …more SAS statements…
END;

Without Arguments
Use the DO statement for simple DO group processing.

Details
The DO statement is the simplest form of DO group processing. The statements between the DO and END statements are called a DO group. You can nest DO statements within DO groups.

Note: The memory capabilities of your system can limit the number of nested DO statements that you can use. For details, see the SAS documentation about how many levels of nested DO statements your system's memory can support.

A simple DO statement is often used within IF-THEN/ELSE statements to designate a group of statements to be executed depending on whether the IF condition is true or false.
Comparisons

There are three other forms of the DO statement:

- The iterative DO statement executes statements between DO and END statements repetitively based on the value of an index variable. The iterative DO statement can contain a WHILE or UNTIL clause.
- The DO UNTIL statement executes statements in a DO loop repetitively until a condition is true, checking the condition after each iteration of the DO loop.
- The DO WHILE statement executes statements in a DO loop repetitively while a condition is true, checking the condition before each iteration of the DO loop.

Example: Using the DO Statement

In this simple DO group, the statements between DO and END are performed only when YEARS is greater than 5. If YEARS is less than or equal to 5, statements in the DO group do not execute, and the program continues with the assignment statement that follows the ELSE statement.

```sas
if years>5 then
  do;
    months=years*12;
    put years= months=;
  end;
else yrsleft=5-years;
```

See Also

Statements:
- “DO Statement, Iterative” on page 65
- “DO UNTIL Statement” on page 69
- “DO WHILE Statement” on page 70

DO Statement, Iterative

Executes statements between the DO and END statements repetitively, based on the value of an index variable.

Valid in: DATA step
Category: Control
Type: Executable

Syntax

```
DO index-variable=specification-1 <, …specification-n> ;
…more SAS statements…
END;
```
Arguments

index-variable
names a variable whose value governs execution of the DO group.

Tip: Unless you specify to drop it, the index variable is included in the data set that is being created.

CAUTION: Avoid changing the index variable within the DO group. If you modify the index variable within the iterative DO group, you might cause infinite looping.

specification
denotes an expression or a series of expressions in this form

\[ \text{start <TO stop> <BY increment> <WHILE(expression) | UNTIL(expression)> } \]

The DO group is executed first with index-variable equal to start. The value of start is evaluated before the first execution of the loop.

start
specifies the initial value of the index variable.

When it is used without TO stop or BY increment, the value of start can be a series of items expressed in this form:

\[ \text{item-1 <, ...item-n>} \]

The items can be either all numeric or all character constants, or they can be variables. Enclose character constants in quotation marks. The DO group is executed once for each value in the list. If a WHILE condition is added, it applies only to the item that it immediately follows.

Requirement: When it is used with TO stop or BY increment, start must be a number or an expression that yields a number.

Example: “Example 1: Using Various Forms of the Iterative DO Statement” on page 67

TO stop
specifies the ending value of the index variable.

When both start and stop are present, execution continues (based on the value of increment) until the value of index-variable passes the value of stop. When only start and increment are present, execution continues (based on the value of increment) until a statement directs execution out of the loop, or until a WHILE or UNTIL expression that is specified in the DO statement is satisfied. If neither stop nor increment is specified, the group executes according to the value of start. The value of stop is evaluated before the first execution of the loop.

Requirement: Stop must be a number or an expression that yields a number.

Tip: Any changes to stop made within the DO group do not affect the number of iterations. To stop iteration of a loop before it finishes processing, change the value of index-variable so that it passes the value of stop, or use a LEAVE statement to go to a statement outside the loop.

Example: “Example 1: Using Various Forms of the Iterative DO Statement” on page 67

BY increment
specifies a positive or negative number (or an expression that yields a number) to control the incrementing of index-variable.

The value of increment is evaluated before the execution of the loop. Any changes to the increment that are made within the DO group do not affect the number of iterations. If no increment is specified, the index variable is increased
by 1. When *increment* is positive, *start* must be the lower bound and *stop*, if present, must be the upper bound for the loop. If *increment* is negative, *start* must be the upper bound and *stop*, if present, must be the lower bound for the loop.

**Example:** “Example 1: Using Various Forms of the Iterative DO Statement” on page 67

A WHILE expression is evaluated before each execution of the loop, so that the statements inside the group are executed repetitively while the expression is true. An UNTIL expression is evaluated after each execution of the loop, so that the statements inside the group are executed repetitively until the expression is true.

**Restriction:** A WHILE or UNTIL specification affects only the last item in the clause in which it is located.

**See:** “DO WHILE Statement” on page 70 and “DO UNTIL Statement” on page 69

**Example:** “Example 1: Using Various Forms of the Iterative DO Statement” on page 67

**Requirement:** The iterative DO statement requires at least one *specification* argument.

**Tips:**
The order of the optional TO and BY clauses can be reversed.
When you use more than one *specification*, each one is evaluated before its execution.

**Comparisons**
There are three other forms of the DO statement:

- The DO statement, the simplest form of DO-group processing, designates a group of statements to be executed as a unit, usually as a part of IF-THEN/ELSE statements.
- The DO UNTIL statement executes statements in a DO loop repetitively until a condition is true, checking the condition after each iteration of the DO loop.
- The DO WHILE statement executes statements in a DO loop repetitively while a condition is true, checking the condition before each iteration of the DO loop.

**Examples**

**Example 1: Using Various Forms of the Iterative DO Statement**

- These iterative DO statements use a list of items for the value of *start*:
  - do month='JAN','FEB','MAR';
  - do count=2,3,5,7,11,13,17;
  - do i=5;
  - do i=var1, var2, var3;
  - do i='01JAN2001'd,'25FEB2001'd,'18APR2001'd;
- These iterative DO statements use the *start* TO *stop* syntax:
  - do i=1 to 10;
• do i=1 to exit;
• do i=1 to x-5;
• do i=1 to k-1, k+1 to n;
• do i=k+1 to n-1;

• These iterative DO statements use the BY increment syntax:
  • do i=n to 1 by -1;
  • do i=.1 to .9 by .1, 1 to 10 by 1,
    20 to 100 by 10;
  • do count=2 to 8 by 2;

• These iterative DO statements use WHILE and UNTIL clauses:
  • do i=1 to 10 while(x<y);
  • do i=2 to 20 by 2 until((x/3)>y);
  • do i=10 to 0 by -1 while(month='JAN');

• In this example, the DO loop is executed when I=1 and I=2; the WHILE condition is
  evaluated when I=3, and the DO loop is executed if the WHILE condition is true.
  DO I=1,2,3 WHILE {condition};

**Example 2: Using the Iterative DO Statement without Infinite Looping**

In each of the following examples, the DO group executes ten times. The first example
demonstrates the preferred approach.

```sas
/* correct coding */
do i=1 to 10;
   ...more SAS statements...
end;
```

The next example uses the TO and BY arguments.

```sas
do i=1 to n by m;
   ...more SAS statements...
   if i=10 then leave;
end;
if i=10 then put 'EXITED LOOP';
```

**Example 3: Stopping the Execution of the DO Loop**

In this example, setting the value of the index variable to the current value of EXIT
causes the loop to terminate.

```sas
data iterate1;
   input x;
   exit=10;
do i=1 to exit;
y=x*normal(0);
   /* if y>25,           */
   /* changing i's value */
   /* stops execution */
   if y>25 then i=exit;
output;
end;
```
datalines;
5
000
2500
;

Statements:

• “ARRAY Statement” on page 23
• “Array Reference Statement” on page 27
• “DO Statement” on page 64
• “DO UNTIL Statement” on page 69
• “DO WHILE Statement” on page 70
• “GO TO Statement” on page 159

DO UNTIL Statement

Executes statements in a DO loop repetitively until a condition is true.

Valid in: DATA step
Category: Control
Type: Executable

Syntax

DO UNTIL (expression);
…more SAS statements…
END;

Arguments

(expression)

is any SAS expression, enclosed in parentheses. You must specify at least one
expression.

Details

The expression is evaluated at the bottom of the loop after the statements in the DO loop
have been executed. If the expression is true, the DO loop does not iterate again.

Note: The DO loop always iterates at least once.

Comparisons

There are three other forms of the DO statement:

• The DO statement, the simplest form of DO-group processing, designates a group of
statements to be executed as a unit, usually as a part of IF-THEN/ELSE statements.
• The iterative DO statement executes statements between DO and END statements repetitively based on the value of an index variable.

• The DO WHILE statement executes statements in a DO loop repetitively while a condition is true, checking the condition before each iteration of the DO loop. The DO UNTIL statement evaluates the condition at the bottom of the loop; the DO WHILE statement evaluates the condition at the top of the loop.

  Note: The statements in a DO UNTIL loop always execute at least one time, whereas the statements in a DO WHILE loop do not iterate even once if the condition is false.

**Example: Using a DO UNTIL Statement to Repeat a Loop**

These statements repeat the loop until N is greater than or equal to 5. The expression N>=5 is evaluated at the bottom of the loop. There are five iterations in all (0, 1, 2, 3, 4).

```
n=0;
do until(n>=5);
  put n=;
  n+1;
end;
```

**See Also**

Statements:

• “DO Statement” on page 64
• “DO Statement, Iterative” on page 65
• “DO WHILE Statement” on page 70

---

**DO WHILE Statement**

Executes statements in a DO-loop repetitively while a condition is true.

**Valid in:** DATA step

**Category:** Control

**Type:** Executable

**Syntax**

DO WHILE (expression);
…more SAS statements…
END;

**Arguments**

(expression)

is any SAS expression, enclosed in parentheses. You must specify at least one expression.
Details

The expression is evaluated at the top of the loop before the statements in the DO loop are executed. If the expression is true, the DO loop iterates. If the expression is false the first time it is evaluated, the DO loop does not iterate even once.

Comparisons

There are three other forms of the DO statement:

• The DO statement, the simplest form of DO-group processing, designates a group of statements to be executed as a unit, usually as a part of IF-THEN/ELSE statements.

• The iterative DO statement executes statements between DO and END statements repetitively based on the value of an index variable.

• The DO UNTIL statement executes statements in a DO loop repetitively until a condition is true, checking the condition after each iteration of the DO loop. The DO WHILE statement evaluates the condition at the top of the loop; the DO UNTIL statement evaluates the condition at the bottom of the loop.

Note: If the expression is false, the statements in a DO WHILE loop do not execute. However, because the DO UNTIL expression is evaluated at the bottom of the loop, the statements in the DO UNTIL loop always execute at least once.

Example: Using a DO WHILE Statement

These statements repeat the loop while N is less than 5. The expression N<5 is evaluated at the top of the loop. There are five iterations in all (0, 1, 2, 3, 4).

```sas
n=0;
do while(n<5);
   put n=;
   n+1;
end;
```

Statements:

• “DO Statement” on page 64

• “DO Statement, Iterative” on page 65

• “DO UNTIL Statement” on page 69

DROP Statement

Excludes variables from output SAS data sets.

Valid in: DATA step
Category: Information
Type: Declarative
Syntax

**DROP** `variable-list;`

**Arguments**

`variable-list`

specifies the names of the variables to omit from the output data set.

**Tip:** You can list the variables in any form that SAS allows.

**Details**

The **DROP** statement applies to all the SAS data sets that are created within the same DATA step and can appear anywhere in the step. The variables in the **DROP** statement are available for processing in the DATA step. If no **DROP** or **KEEP** statement appears, all data sets that are created in the DATA step contain all variables. Do not use both **DROP** and **KEEP** statements within the same DATA step.

**Comparisons**

- The **DROP** statement differs from the **DROP=** data set option in the following ways:
  - You cannot use the **DROP** statement in SAS procedure steps.
  - The **DROP** statement applies to all output data sets that are named in the DATA statement. To exclude variables from some data sets but not from others, use the **DROP=** data set option in the DATA statement.
  - The **KEEP** statement is a parallel statement that specifies a list of variables to write to output data sets. Use the **KEEP** statement instead of the **DROP** statement if the number of variables to include is significantly smaller than the number to omit.
  - Do not confuse the **DROP** statement with the **DELETE** statement. The **DROP** statement excludes variables from output data sets; the **DELETE** statement excludes observations.

**Examples**

**Example 1: Basic **DROP** Statement Usage**

These examples show the correct syntax for listing variables with the **DROP** statement:

- `drop time shift batchnum;`
- `drop grade1-grade20;`

**Example 2: **Dropping Variables from the Output Data Set**

In this example, the variables **PURCHASE** and **REPAIR** are used in processing but are not written to the output data set **INVENTORY**:

```sas
data inventory;
    drop purchase repair;
    infile file-specification;
    input unit part purchase repair;
    totcost=sum(purchase,repair);
run;
```
See Also

Data Set Options:
• “DROP= Data Set Option” in SAS Data Set Options: Reference

Statements:
• “DELETE Statement” on page 59
• “KEEP Statement” on page 231

END Statement

Ends a DO group or SELECT group processing.

Valid in: DATA step
Category: Control
Type: Declarative

Syntax
END;

Without Arguments
Use the END statement to end DO group or SELECT group processing.

Details
The END statement must be the last statement in a DO group or a SELECT group.

Example: Using the END Statement
This example shows a simple DO group and a simple SELECT group:

• do;
  ...more SAS statements...
  end;

• select(expression);
  when(expression) SAS statement;
  otherwise SAS statement;
  end;

See Also

Statements:
• “DO Statement” on page 64
• “SELECT Statement” on page 350
ENDSAS Statement
Terminates a SAS job or session after the current DATA or PROC step executes.

Valid in: Anywhere
Category: Program Control

Syntax
ENDSAS;

Without Arguments
The ENDSAS statement terminates a SAS job or session.

Details
ENDSAS is most useful in interactive or windowing sessions.

Note: ENDSAS statements are always executed at the point that they are encountered in a DATA step. Use the ABORT RETURN statement to stop processing when an error condition occurs (for example, in the clause of an IF-THEN statement or a SELECT statement).

Comparisons
You can also terminate a SAS job or session by using the BYE or the ENDSAS command from any SAS window command line. For details, refer to the online Help for SAS windows.

See Also
“SYSSTARTID Automatic Macro Variable” in SAS Macro Language: Reference

ERROR Statement
Sets _ERROR_ to 1. A message written to the SAS log is optional.

Valid in: DATA step
Category: Action
Type: Executable

Syntax
ERROR <message>;

Without Arguments
Using ERROR without an argument sets the automatic variable _ERROR_ to 1 writes a blank message to the log.
Arguments

message
writes a message to the log.

Tip: message can include character literals (enclosed in quotation marks), variable names, formats, and pointer controls.

Details

The ERROR statement sets the automatic variable **_ERROR_** to 1. Writing a message that you specify to the SAS log is optional. When **_ERROR_** = 1, SAS writes the data lines that correspond to the current observation in the SAS log.

Using ERROR is equivalent to using these statements in combination:

- an assignment statement setting **_ERROR_** to 1
- a FILE LOG statement
- a PUT statement (if you specify a message)
- a PUT; statement (if you do not specify a message)
- another FILE statement resetting FILE to any previously specified setting.

Example: Writing Error Messages

In the following examples, SAS writes the error message and the variable name and value to the log for each observation that satisfies the condition in the IF-THEN statement.

- In this example, the ERROR statement automatically resets the FILE statement specification to the previously specified setting.

```sas
file file-specification;
  if type='teen' & age > 19 then
    error 'type and age don’t match ' age=;
```

- This example uses a series of statements to produce the same results.

```sas
file file-specification;
  if type='teen' & age > 19 then
    do;
      file log;
      put 'type and age don’t match ' age=;
      _error_1;
      file file-specification;
    end;
```

Statements:
- “PUT Statement” on page 296

EXECUTE Statement

Executes a stored compiled DATA step program.
Valid in: DATA step
Category: Action
Type: Executable
Restriction: Use EXECUTE with stored compiled DATA step programs only.
Requirement: You must specify the PGM= option in the DATA step.

Syntax
EXECUTE;

Without Arguments
The EXECUTE statement executes a stored compiled DATA step program.

Details
Use the DESCRIBE statement with the EXECUTE statement in the same DATA step to retrieve the source code and execute a stored compiled DATA step program. If you do not specify either statement, EXECUTE is assumed. The order in which you use the statements is interchangeable. The DATA step program executes when it reaches a step boundary. For information about how to use these statements with the DATA statement, see the “DATA Statement” on page 48.

See Also

Statements:
- “DATA Statement” on page 48
- “DESCRIBE Statement” on page 60

FILE Statement
Specifies the current output file for PUT statements.

Syntax
FILE file-specification <device-type> <options> <operating-environment-options>;

Arguments

file-specification
identifies an external file that the DATA step uses to write output from a PUT statement. File-specification can have these forms:
'external-file'
specifies the physical name of an external file, which is enclosed in quotation marks. The physical name is the name by which the operating environment recognizes the file.

fileref
specifies the fileref of an external file.

Requirement: You must have associated fileref with an external file in a FILENAME statement or function in a previous step or in an appropriate operating environment command. The only way to assign the fileref at run time is to use the FILEVAR= option in the FILE statement.

See: “FILENAME Statement” on page 93

fileref(file)
specifies a fileref that is previously assigned to an external file that is an aggregate grouping of files. Follow the fileref with the name of a file or member, which is enclosed in parentheses.

Requirement: You must previously associate fileref with an external file in a FILENAME statement or function, or in an appropriate operating environment command.

Operating environment: Different operating environments call an aggregate grouping of files by different names, such as a directory, a MACLIB, or a partitioned data set. For details, see the SAS documentation for your operating environment.

Note: A file that is located in an aggregate storage location and has a name that is not a valid SAS name must have its name enclosed in quotation marks.

See: “FILENAME Statement” on page 93

LOG
is a reserved fileref that directs the output that is produced by any PUT statements to the SAS log.

At the beginning of each execution of a DATA step, the fileref that indicates where the PUT statements write is automatically set to LOG. Therefore, the first PUT statement in a DATA step always writes to the SAS log, unless it is preceded by a FILE statement that specifies otherwise.

Tip: Because output lines are by default written to the SAS log, use a FILE LOG statement to restore the default action or to specify additional FILE statement options.

PRINT
is a reserved fileref that directs the output that is produced by any PUT statements to the same file as the output that is produced by SAS procedures.

Interaction: When you write to a file, the value of the N= option must be either 1 or PAGESIZE.

Operating environment: The carriage-control characters that are written to a file can be specific to the operating environment. For details, see the SAS documentation for your operating environment.

Tip: When PRINT is the fileref, SAS uses carriage-control characters and writes the output with the characteristics of a print file.

See: A complete discussion of print files in SAS Language Reference: Concepts

Tip: If the file does not exist in the directory that you specify for file-specification, SAS creates the file. If the directory specified in file-specification does not exist, SAS sets the SYSERR macro variable, which can be checked if the ERRORCHECK option is set to STRICT.
**device-type**
specifies the type of device or the access method that is used if the fileref points to an input or output device or a location that is not a physical file:

**CATALOG**
specifies the CATALOG access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

**See:** For a complete list of options that are available with the CATALOG access method, see the “FILENAME Statement, CATALOG Access Method” on page 100.

**CLIPBOARD**
specifies the CLIPBOARD access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

**See:** For a complete list of options that are available with the CLIPBOARD access method, see the “FILENAME, CLIPBOARD Access Method” on page 104.

**DISK**
specifies that the device is a disk drive.

**Tip:** When you assign a fileref to a file on disk, you are not required to specify DISK.

**DUMMY**
specifies that the output to the file is discarded.

**Tip:** Specifying DUMMY can be useful for testing.

**FTP**
specifies the FTP access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

**See:** For a complete list of options that are available with the FTP access method, see the “FILENAME Statement, FTP Access Method” on page 117.

**Example:**
```
infile dummy ftp user='myuid' pass='xxxx' filevar=file_to_read;
```

**GTERM**
indicates that the output device type is a graphics device that will receive graphics data.

**JMS**
specifies a Java Message Service (JMS) destination.

**PIPE**
specifies an unnamed pipe.

**Operating environment:** Some operating environments do not support pipes.

**PLOTTER**
specifies an unbuffered graphics output device.

**PRINTER**
specifies a printer or printer spool file.

**SFTP**
specifies the SFTP access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.
See: For a complete list of options that are available with the SFTP access method, see the “FILENAME Statement, SFTP Access Method” on page 133.

SOCKET
   specifies the SOCKET access method.
   Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.
   See: For a complete list of options that are available with the SOCKET access method, see the “FILENAME Statement, SOCKET Access Method” on page 138.

TAPE
   specifies a tape drive.

TEMP
   creates a temporary file that exists only as long as the filename is assigned. The temporary file can be accessed only through the logical name and is available only while the logical name exists.
   Restriction: Do not specify a physical pathname. If you do, SAS returns an error.
   Tip: Files manipulated by the TEMP device can have the same attributes and behave identically to DISK files.

TERMINAL
   specifies the user's terminal.

UPRINTER
   specifies a Universal Printing printer definition name.
   Tip: If you do not specify the printer name in the FILENAME statement, the PRINTERPATH options control which Universal Printer is used and the destination of the output.

URL
   specifies the URL access method.
   Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.
   See: For a complete list of options that are available with the URL access method, see the “FILENAME Statement, URL Access Method” on page 142.

WEBDAV
   specifies the WEBDAV access method.
   Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.
   See: For a complete list of options that are available with the WEBDAV access method, see the “FILENAME Statement, WebDAV Access Method” on page 147.

Alias: DEVICE=device-type
Default: DISK
Requirement: device-type or DEVICE=device-type must immediately follow file-specification in the statement.

Operating environment: Additional specifications might be required when you specify some devices. See the SAS documentation for your operating environment before specifying a value other than DISK. Values in addition to the ones listed here might be available in some operating environments.
Options

**BLKSIZE=block-size**
specifies the block size of the output file.

**Default:** Dependent on your operating environment. For details, see the FILE Statement in the SAS documentation for your operating environment.

**COLUMN=variable**
specifies a variable that SAS automatically sets to the current column location of the pointer. This variable, like automatic variables, is not written to the data set.

**Alias:** COL=

**See:** LINE= on page 83

**DELIMITER= delimiter(s)**
specifies an alternate delimiter (other than blank) to be used for LIST output where

delimiter is

'list-of-delimiting-characters'
specifies one or more characters to write as delimiters.

**Requirement:** Enclose the list of characters in quotation marks.

**character-variable**
specifies a character variable whose value becomes the delimiter.

**Alias:** DLM=

**Default:** blank space

**Restriction:** Even though a character string or character variable is accepted, only the first character of the string or variable is used as the output delimiter. The FILE DLM= processing differs from INFILE DELIMITER= processing.

**Interaction:** Output that contains embedded delimiters requires the delimiter sensitive data (DSD) option.

**Tips:**

- DELIMITER= can be used with the colon (: ) modifier (modified LIST output).

  The delimiter is case sensitive.

**See:** “DLMSTR= delimiter” on page 80 and “DSD (delimiter sensitive data)” on page 81

**DLMSOPT= 'T' | 't'**
specifies a parsing option for the DLMSTR= T option that removes trailing blanks of the string delimiter.

**Requirement:** The DLMSOPT=T option has an effect only when used with the DLMSTR= option.

**Tip:** The DLMSOPT=T option is useful when you use a variable as the delimiter string

**See:** DLMSTR= on page 80

**DLMSTR= delimiter**
specifies a character string as an alternate delimiter (other than a blank) to be used for LIST output, where delimiter is

'delimiting-string'
specifies a character string to write as a delimiter.

**Requirement:** Enclose the string in quotation marks.

**character-variable**
specifies a character variable whose value becomes the delimiter.

**Default:** blank space
Interactions:
If you specify more than one DLMSTR= option in the FILE statement, the DLMSTR= option that is specified last will be used. If you specify both the DELIMITER= and DLMSTR= options, the option that is specified last will be used.

If you specify RECFM=N, make sure that the LRECL is large enough to hold the largest input item. Otherwise, it might be possible for the delimiter to be split across the record boundary.

See: DELIMITER= on page 80, DLMSOPT= on page 80, and DSD on page 81

DROPOVER
discards data items that exceed the output line length (as specified by the LINESIZE= or LRECL= options in the FILE statement).

By default, data that exceeds the current line length is written on a new line. When you specify DROPOVER, SAS drops (or ignores) an entire item when there is not enough space in the current line to write it. When an entire item is dropped, the column pointer remains positioned after the last value that is written in the current line. Thus, the PUT statement might write other items in the current output line if they fit in the space that remains or if the column pointer is repositioned. When a data item is dropped, the DATA step continues normal execution (_ERROR_ =0). At the end of the DATA step, a message is printed for each file from which data was lost.

Default: FLOWOVER

Tip: Use DROPOVER when you want the DATA step to continue executing if the PUT statement attempts to write past the current line length, but you do not want the data item that exceeds the line length to be written on a new line.

See: “FLOWOVER” on page 83 and “STOPOVER” on page 86

DSD (delimiter sensitive data)
specifies that data values that contain embedded delimiters, such as tabs or commas, be enclosed in quotation marks. The DSD option enables you to write data values that contain embedded delimiters to LIST output. This option is ignored for other types of output (for example, formatted, column, and named). Any double quotation marks that are included in the data value are repeated. When a variable value contains the delimiter and DSD is used in the FILE statement, the variable value will be enclosed in double quotation marks when the output is generated. For example, the following code

```plaintext
DATA _NULL_;  
  FILE log dsd;  
  x="lions, tigers, and bears";  
  put x ' "Oh, my!"';  
run;  
```

will result in the following output:

"""lions, tigers, and bears"", "Oh, my!"

If a quoted (text) string contains the delimiter and DSD is used in the FILE statement, then the quoted string will not be enclosed in double quotation marks when used in a PUT statement. For example, the following code

```plaintext
DATA _NULL_;  
  FILE log dsd;  
  PUT 'lions, tigers, and bears';  
run;  
```

will result in the following output:
lions, tigers, and bears

**Interaction:** If you specify DSD, the default delimiter is assumed to be the comma (,). Specify the DELIMITER= or DLMSTR= option if you want to use a different delimiter.

**Tip:** By default, data values that do not contain the delimiter that you specify are not enclosed in quotation marks. However, you can use the tilde (~) modifier to force any data value, including missing values, to be enclosed in quotation marks, even if it contains no embedded delimiter.

**See:** DELIMITER= on page 80 and DLMSTR= on page 80

**ENCODING= 'encoding-value'**

specifies the encoding to use when writing to the output file. The value for ENCODING= indicates that the output file has a different encoding from the current session encoding.

When you write data to the output file, SAS transcodes the data from the session encoding to the specified encoding.

**Default:** SAS uses the current session encoding.

**See:** “Encoding Values in SAS Language Elements” in Chapter 20 of *SAS National Language Support (NLS)*: Reference Guide

**Example:** “Example 8: Specifying an Encoding When Writing to an Output File” on page 92

**FILENAME=variable**

defines a character variable, whose name you supply, that SAS sets to the value of the physical name of the file currently open for PUT statement output. The physical name is the name by which the operating environment recognizes the file.

**Tips:**
- This variable, like automatic variables, is not written to the data set.
- Use a LENGTH statement to make the variable length long enough to contain the value of the physical filename if the variable length is longer than eight bytes (the default length of a character variable).

**See:** FILEVAR= on page 82

**Example:** “Example 4: Identifying the Current Output File” on page 91

**FILEVAR=variable**

defines a variable whose change in value causes the FILE statement to close the current output file and open a new one the next time the FILE statement executes. The next PUT statement that executes writes to the new file that is specified as the value of the FILEVAR= variable.

**Restriction:** The value of a FILEVAR= variable is expressed as a character string that contains a physical filename.

**Interaction:** When you use the FILEVAR= option, the file-specification is just a placeholder, not an actual filename or a fileref that has been previously assigned to a file. SAS uses this placeholder for reporting processing information to the SAS log. It must conform to the same rules as a fileref.

**Tips:**
- This variable, like automatic variables, is not written to the data set.
- If any of the physical filenames is longer than eight bytes (the default length of a character variable), assign the FILEVAR= variable a longer length with another statement, such as a LENGTH statement or an INPUT statement.

**See:** FILENAME= on page 82

**Example:** “Example 5: Dynamically Changing the Current Output File” on page 91
FLOWOVER
causes data that exceeds the current line length to be written on a new line. When a
PUT statement attempts to write beyond the maximum allowed line length (as
specified by the LINESIZE= option in the FILE statement), the current output line is
written to the file and the data item that exceeds the current line length is written to a
new line.

Default: FLOWOVER

Interaction: If the PUT statement contains a trailing @, the pointer is positioned
after the data item on the new line, and the next PUT statement writes to that
line. This process continues until the end of the input data is reached or until a
PUT statement without a trailing @ causes the current line to be written to the
file.

See: “DROPOVER” on page 81 and “STOPOVER” on page 86

FOOTNOTES | NOFOOTNOTES
controls whether currently defined footnotes are printed.

Alias: FOOTNOTE | NOFOOTNOTE

Default: NOFOOTNOTES

Requirement: In order to print footnotes in a DATA step report, you must set the
FOOTNOTE option in the FILE statement.

HEADER=label
defines a statement label that identifies a group of SAS statements that you want to
execute each time SAS begins a new output page.

Restrictions:
- The first statement after the label must be an executable statement. Thereafter
  you can use any SAS statement.
- Use the HEADER= option only when you write to print files.

Tip: To prevent the statements in this group from executing with each iteration of
the DATA step, use two RETURN statements: one precedes the label and the
other appears as the last statement in the group.

Example: “Example 1: Executing Statements When Beginning a New Page” on
page 89

LINE=variable
defines a variable whose value is the current relative line number within the group of
lines available to the output pointer. You supply the variable name; SAS
automatically assigns the value.

Range: 1 to the value that is specified by the N= option or with the #n line pointer
control. If neither is specified, the LINE= variable has a value of 1.

Tips:
- This variable, like automatic variables, is not written to the data set.
- The value of the LINE= variable is set at the end of PUT statement execution to
the number of the next available line.

LINESIZE=line-size
sets the maximum number of columns per line for reports and the maximum record
length for data files.

Alias: LS=

Default: The default LINESIZE= value is determined by one of two options: 1) the
LINESIZE= system option when you write to file that contains carriage-control
characters or to the SAS log or 2) the LRECL= option in the FILE statement
when you write to a file.
Range: From 64 to the maximum logical record length that is allowed in your operating environment.

Interaction: If a PUT statement tries to write a line that is longer than the value that is specified by the LINESIZE= option, the action that is taken is determined by whether FLOWOVER, DROPOVER, or STOPOVER is in effect. By default (FLOWOVER), SAS writes the line as two or more separate records.

Operating environment: The highest value allowed for LINESIZE= is dependent on your operating environment. For details, see the SAS documentation for your operating environment.

Note: LINESIZE= tells SAS how much of the line to use. LRECL= specifies the physical record length of the file.

See: LRECL= on page 84, “DROPOVER” on page 81, “FLOWOVER” on page 83, and “STOPOVER” on page 86

Example: “Example 6: When the Output Line Exceeds the Line Length of the Output File” on page 92

LINESLEFT=variable
defines a variable whose value is the number of lines left on the current page. You supply the variable name; SAS assigns the value of the number of lines left on the current page to that variable. The value of the LINESLEFT= variable is set at the end of PUT statement execution.

Alias: LL=

Tip: This variable, like automatic variables, is not written to the data set.

LRECL=logical-record-length
specifies the logical record length of the output file.

Default: If you omit the LRECL= option, SAS chooses a value based on the operating environment’s file characteristics.

Interaction: Alternatively, you can specify a global logical record length by using the LRECL system option.

Operating environment: Values for logical-record-length are dependent on the operating environment. For details, see the SAS documentation for your operating environment.

Note: LINESIZE= tells SAS how much of the line to use; LRECL= specifies the physical line length of the file.

See: LINESIZE= on page 83, PAD on page 86, and PAGESIZE= on page 86

MOD
writes the output lines after any existing lines in the file.

Default: OLD

Restrictions: MOD is not accepted under all operating environments. For more information, see the SAS documentation for your operating environment.

Do not use the MOD option with any ODS destination other than the Listing destination. Otherwise, you might receive unexpected output.

See: “OLD” on page 85

N=available-lines
specifies the number of lines that you want available to the output pointer in the current iteration of the DATA step. Available-lines can be expressed as a number (n) or as the keyword PAGESIZE or PS.
n specifies the number of lines that are available to the output pointer. The system can move back and forth between the number of lines that are specified while composing them before moving on to the next set.

PAGESIZE specifies that the entire page is available to the output pointer.

Alias: PS

Restrictions:

N=PAGESIZE is valid only when output is printed.
If the current output file is a file that is to be printed, available-lines must have a value of either 1 or PAGESIZE.

Interactions:
In addition to use in the N= option to control the number of lines available to the output pointer, you can also use the #n line pointer control in a PUT statement.
If you omit the N= option and no # pointer controls are used, one line is available; that is, by default, N=1. If N= is not used but there are # pointer controls, N= is assigned the highest value that is specified for a # pointer control in any PUT statement in the current DATA step.

Tip: Setting N=PAGESIZE enables you to compose a page of multiple columns one column at a time.

Example: “Example 3: Arranging the Contents of an Entire Page” on page 90

ODS < = (ODS-suboptions) >
specifies to use the Output Delivery System to format the output from a DATA step. It defines the structure of the data component and holds the results of the DATA step and binds that component to a table definition to produce an output object. ODS sends this object to all open ODS destinations, each of which formats the output appropriately. For information about the ODS-suboptions and the Output Delivery System, see the “FILE Statement for ODS” in SAS Output Delivery System: User's Guide.

Default: If you omit the ODS suboptions, the DATA step uses a default table definition (base.datastep.table) that is stored in the SASHELP.TMPLMST template store. This definition defines two generic columns: one for character variables, and one for numeric variables. ODS associates each variable in the DATA step with one of these columns and displays the variables in the order in which they are defined in the DATA step.
Without suboptions, the default table definition uses the variable's label as its column heading. If no label exists, the definition uses the variable's name as the column heading.

Restriction: You cannot use _FILE_=, FILEVAR=, HEADER=, and PAD with the ODS option.

Requirement: The ODS option is valid only when you use the fileref PRINT in the FILE statement.

Interaction: The DELIMITER= and DSD options have no effect on the ODS option. The FOOTNOTES|NOFOOTNOTES, LINESIZE, PAGESIZE, and TITLES | NOTITLES options have an effect only on the LISTING destination.

OLD replaces the previous contents of the file.

Default: OLD

Restriction: OLD is not accepted under all operating environments. For details, see the SAS documentation for your operating environment.
PAD | NOPAD
controls whether records written to an external file are padded with blanks to the
length that is specified in the LRECL= option.

Default: NOPAD is the default when writing to a variable-length file; PAD is the
default when writing to a fixed-length file.

Tip: PAD provides a quick way to create fixed-length records in a variable-length
file.

See: LRECL= on page 84

PAGESIZE=value
sets the number of lines per page for your reports.

Alias: PS=

Default: the value of the PAGESIZE= system option.

Range: The value can range from 15 to 32767.

Interaction: If any TITLE statements are currently defined, the lines that they
occupy are included in counting the number of lines for each page.

Tips:
After the value of the PAGESIZE= option is reached, the output pointer advances
to line 1 of a new page.
If you specify FILE LOG, the number of lines that are output on the first page is
reduced by the number of lines in the SAS start-up notes. For example, if
PAGESIZE=20 and there are nine lines of SAS start-up notes, only 11 lines are
available for output on the first page.

See: “PAGESIZE= System Option” in SAS System Options: Reference

PRINT | NOPRINT
controls whether carriage-control characters are placed in the output lines.

Restriction: When you write to a file, the value of the N= option must be either 1 or
PAGESIZE.

Operating environment: The carriage-control characters that are written to a file
can be specific to the operating environment. For details, see the SAS
documentation for your operating environment.

Tips:
The PRINT option is not necessary if you are using fileref PRINT.
If you specify FILE PRINT in an interactive SAS session, then the Output
window interprets the form-feed control characters as page breaks, and blank
lines that are output before the form feed are removed from the output. Writing
the results from the Output window to a flat file produces a file without page
break characters. If a file needs to contain the form-feed characters, then the
FILE statement should include a physical file location and the PRINT option.

RECFM=record-format
specifies the record format of the output file.

Range: Values are dependent on the operating environment. For details, see the
SAS documentation for your operating environment.

STOPOVER
stops processing the DATA step immediately if a PUT statement attempts to write a
data item that exceeds the current line length. In such a case, SAS discards the data
item that exceeds the current line length, writes the portion of the line that was built
before the error occurred, and issues an error message.

Default: FLOWOVER
**TITLES | NOTITLES**

controls the printing of the current title lines on the pages of files. When NOTITLES is omitted, or when TITLES is specified, SAS prints any titles that are currently defined.

**Alias:** TITLE | NOTITLE

**Default:** TITLES

_**FILE_=variable

names a character variable that references the current output buffer of this FILE statement. You can use the variable in the same way as any other variable, even as the target of an assignment. The variable is automatically retained and initialized to blanks. Like automatic variables, the _FILE_= variable is not written to the data set.

**Restriction:** variable cannot be a previously defined variable. Make sure that the _FILE_= specification is the first occurrence of this variable in the DATA step. Do not set or change the length of _FILE_= variable with the LENGTH or ATTRIB statements. However, you can attach a format to this variable with the ATTRIB or FORMAT statement.

**Interaction:** The maximum length of this character variable is the logical record length (LRECL) for the specified FILE statement. However, SAS does not open the file to know the LRECL until before the execution phase. Therefore, the designated size for this variable during the compilation phase is 32,767 bytes.

**Tips:**

Modification of this variable directly modifies the FILE statement's current output buffer. Any subsequent PUT statement for this FILE statement outputs the contents of the modified buffer. The _FILE_= variable accesses only the current output buffer of the specified FILE statement even if you use the N= option to specify multiple output buffers.

To access the contents of the output buffer in another statement without using the _FILE_= option, use the automatic variable _FILE_.

**See:** “Updating the _FILE_ Variable” on page 88

---

**Operating Environment Options**

For descriptions of operating-environment-specific options in the FILE statement, see the SAS documentation for your operating environment.

---

**Details**

**Overview**

By default, PUT statement output is written to the SAS log. Use the FILE statement to route this output to either the same external file to which procedure output is written or to a different external file. You can indicate whether carriage-control characters should be added to the file. See the PRINT | NOPRINT option on page 86.

You can use the FILE statement in conditional (IF-THEN) processing because it is executable. You can also use multiple FILE statements to write to more than one external file in a single DATA step.

**Operating Environment Information**

Using the FILE statement requires operating-environment-specific information. See the SAS documentation for your operating environment before you use this statement.
You can use the Output Delivery System with the FILE statement to write DATA step results. For details, see the “FILE Statement for ODS” in SAS Output Delivery System: User's Guide.

**Updating an External File in Place**

You can use the FILE statement with the INFILE and PUT statements to update an external file in place, updating either an entire record or only selected fields within a record. Follow these guidelines:

- Always place the INFILE statement first.
- Specify the same fileref or physical filename in the INFILE and FILE statements.
- Use options that are common to both the INFILE and FILE statements in the INFILE statement. (Any such options that are used in the FILE statement are ignored.)
- Use the SHAREBUFFERS option in the INFILE statement to allow the INFILE and FILE statements to use the same buffer, which saves CPU time and enables you to update individual fields instead of entire records.

**Accessing the Contents of the Output Buffer**

In addition to the _FILE_ = variable, you can use the automatic _FILE_ variable to reference the contents of the current output buffer for the most recent execution of the FILE statement. This character variable is automatically retained and initialized to blanks. Like other automatic variables, _FILE_ is not written to the data set.

When you specify the _FILE_ = option in a FILE statement, this variable is also indirectly referenced by the automatic _FILE_ variable. If the automatic _FILE_ variable is present and you omit _FILE_ = in a particular FILE statement, then SAS creates an internal _FILE_ = variable for that FILE statement. Otherwise, SAS does not create the _FILE_ = variable for a particular FILE.

During execution and at the point of reference, the maximum length of this character variable is the maximum length of the current _FILE_ variable. However, because _FILE_ only references other variables whose lengths are not known until before the execution phase, the designated length is 32,767 bytes during the compilation phase. For example, if you assign _FILE_ to a new variable whose length is undefined, the default length of the new variable is 32,767 bytes. You cannot use the LENGTH statement and the ATTRIB statement to set or override the length of _FILE_. You can use the FORMAT statement and the ATTRIB statement to assign a format to _FILE_.

**Updating the _FILE_ Variable**

Like other SAS variables, you can update the _FILE_ variable. The following two methods are available:

- Use _FILE_ in an assignment statement.
- Use a PUT statement.

You can update the _FILE_ variable by using an assignment statement that has the following form.

_\_FILE\_ = "<\string-in-quotation-marks\> | character-expression">

The assignment statement updates the contents of the current output buffer and sets the buffer length to the length of 'string-in-quotation-marks' or character-expression. However, using an assignment statement does not affect the current column pointer of the PUT statement. The next PUT statement for this FILE statement begins to update the buffer at column 1 or at the last known location when you use the trailing @ in the PUT statement.
In the following example, the assignment statement updates the contents of the current output buffer. The column pointer of the PUT statement is not affected:

```sas
file print;
  _file_ = '_FILE_';
put 'This is PUT';
```

SAS creates the following output: **This is PUT**

In this example,

```sas
file print;
  _file_ = 'This is from FILE, sir.';
put @14 'both';
```

SAS creates the following output: **This is from both, sir.**

You can also update the _FILE_ variable by using a PUT statement. The PUT statement updates the _FILE_ variable because the PUT statement formats data in the output buffer and _FILE_ points to that buffer. However, by default SAS clears the output buffers after a PUT statement executes and outputs the current record (or N= block of records). Therefore, if you want to examine or further modify the contents of _FILE_ before it is output, include a trailing @ or @@ in any PUT statement (when N=1). For other values of N=, use a trailing @ or @@ in any PUT statement where the last line pointer location is on the last record of the record block. In the following example, when N=1

```sas
file ABC;
  put 'Something' @;
  Y = _file_ || 'is here';
file ABC;
  put 'Nothing' ;
  Y = _file_ || 'is here';
```

Y is first assigned **Something is here** then Y is assigned **is here**.

Any modification of _FILE_ directly modifies the current output buffer for the current FILE statement. The execution of any subsequent PUT statements for this FILE statement will output the contents of the modified buffer.

_FILE_ only accesses the contents of the current output buffer for a FILE statement, even when you use the N= option to specify multiple buffers. You can access all the N= buffers, but you must use a PUT statement with the # line pointer control to make the desired buffer the current output buffer.

### Comparisons

- The FILE statement specifies the output file for PUT statements. The INFILE statement specifies the input file for INPUT statements.
- Both the FILE and INFILE statements enable you to use options that provide SAS with additional information about the external file being used.
- In the Program Editor, Log, and Output windows, the FILE command specifies an external file and writes the contents of the window to the file.

### Examples

**Example 1: Executing Statements When Beginning a New Page**

This DATA step illustrates how to use the HEADER= option:
Write a report. Use DATA `_NULL_` to write a report rather than create a data set:

```sas
data _null_;
  set sprint;
  by dept;
```

Route output to the SAS output window. Point to the header information. The PRINT fileref routes output to the same location as procedure output. HEADER= points to the label that precedes the statements that create the header for each page:

```sas
file print header=newpage;
```

Start a new page for each department:

```sas
if first.dept then put _page_;
  put @22 salesrep @34 salesamt;
```

Write a header on each page. These statements execute each time a new page is begun. RETURN is necessary before the label and as the final statement in a labeled group:

```sas
return;
newpage:
  put @20 'Sales for 1989' /
      @20 dept=;
  return;
run;
```

Example 2: Determining New Page by Lines Left on the Current Page
This DATA step demonstrates using the LINESLEFT= option to determine where the page break should occur, according to the number of lines left on the current page.

Write a report. Use DATA `_NULL_` to write a report rather than create a data set:

```sas
data _null_;
  set info;
```

Route output to the standard SAS output window. The PRINT fileref routes output to the same location as procedure output. LINESLEFT indicates that the variable REMAIN contains the number of lines left on the current page:

```sas
file print linesleft=remain pagesize=20;
  put @5 name @30 phone
      @35 bldg @37 room;
```

Begin a new page when there are fewer than seven lines left on the current page. Under this condition, PUT _PAGE_ begins a new page and positions the pointer at line 1:

```sas
if remain<7 then put _page_;
run;
```

Example 3: Arranging the Contents of an Entire Page
This example shows how to use N=PAGESIZE in a DATA step to produce a two-column telephone book listing, each column containing a name and a phone number:

Create a report and write it to a SAS output window. Use DATA `_NULL_` to write a report rather than create a data set. PRINT is the fileref. SAS uses carriage-control characters to write the output with the characteristics of a print file. N=PAGESIZE makes the entire page available to the output pointer:
data _null_;   
   file 'external-file' print n=pagesize;

- Specify the columns for the report. This DO loop iterates twice on each DATA step iteration. The COL value is 1 on the first iteration and 40 on the second:
  
  do col=1, 40;

- Write 20 lines of data. This DO loop iterates 20 times to write 20 lines in column 1. When finished, the outer loop sets COL equal to 40, and this DO loop iterates 20 times again, writing 20 lines of data in the second column. The values of LINE and COL, which are set and incremented by the DO statements, control where the PUT statement writes the values of NAME and PHONE on the page:
  
  do line=1 to 20;
     set info;
     put #line @col name $20. +1 phone 4.;
  end;

- After composing two columns of data, write the page. This END statement ends the outer DO loop. The PUT _PAGE_ writes the current page and moves the pointer to the top of a new page:
  
  end;
  
  put _page_;   
  run;

Example 4: Identifying the Current Output File

This DATA step causes a file identification message to print in the log and assigns the value of the current output file to the variable MYOUT. The PUT statement, demonstrating the assignment of the proper value to MYOUT, writes the value of that variable to the output file:

```sas
data _null_;   
   length myout $ 200;   
   file file-specification filename=myout;   
   put myout=;   
   stop;   
run;
```

The PUT statement writes a line to the current output file that contains the physical name of the file:

MYOUT=your-output-file

Example 5: Dynamically Changing the Current Output File

This DATA step uses the FILEVAR= option to dynamically change the currently opened output file to a new physical file.

- Write a report. Create a long character variable. Use DATA _NULL_ to write a report rather than create a data set. The LENGTH statement creates a variable with length long enough to contain the name of an external file:
  
  data _null_;   
     length name $ 200;

- Read an in-stream data line and assign a value to the NAME variable:
  
  input name $;

- Close the current output file and open a new one when the NAME variable changes. The file-specification is just a place holder; it can be any valid SAS name:
file file-specification filevar=name mod;
date = date();

• Append a log record to currently open output file:
  put 'records updated ' date date.;

• Supply the names of the external files:
  datalines;
  external-file-1
  external-file-2
  external-file-3
  ;

Example 6: When the Output Line Exceeds the Line Length of the Output File
Because the combined lengths of the variables are longer than the output line (80 characters), this PUT statement automatically writes three separate records:

file file-specification linesize=80;
  put name $ 1-50 city $ 71-90 state $ 91-104;

The value of NAME appears in the first record, CITY begins in the first column of the second record, and STATE in the first column of the third record.

Example 7: Reading Data and Writing Text through a TCP/IP Socket
This example shows reading raw data from a file through a TCP/IP socket. The NBYTE= option is used in the INFILE statement:

/* Start this first as the server */
filename serve socket ':5205' server
  recfm=s
  lrecl=25 blocksize=2500;
data _null_
  nb=25;
  infile serve nbyte=nb;
  input text $char25.;
  put _all_
run;

This example shows writing text to a file through a TCP/IP socket:

/* While the server test is running, */
/*continue with this as the client. */
filename client socket "&hstname:5205"
  recfm=s
  lrecl=25 blocksize=2500;
data _null_
  file client;
  put 'Some text to length 25...';
run;

Example 8: Specifying an Encoding When Writing to an Output File
This example creates an external file from a SAS data set. The current session encoding is WLatin1, but the external file's encoding needs to be UTF-8. By default, SAS writes the external file using the current session encoding.
To tell SAS what encoding to use when writing data to the external file, specify the ENCODING= option. When you tell SAS that the external file is to be in UTF-8 encoding, SAS then transcodes the data from WLatin1 to the specified UTF-8 encoding when writing to the external file.

libname myfiles 'SAS-library';
filename outfile 'external-file';
data _null_;  
   set myfiles.cars;
   file outfile encoding="utf-8";
   put Make Model Year;
run;

**Example 9: Using the FTP Access Method to Write Data to an Excel Spreadsheet**
The example uses the FTP access method and the FILEVAR option to write data to several Microsoft Excel worksheets.

data _null_;  
   do i = 1 to 3;
      sheet = cats('excel\[test-sheet.xlsx\]Sheet', i, '!r1c1:r10c2');
      file area ftp filevar=sheet;
      do x = 1 to 10;
         y = 2*x;
         put x y;
      end;
   end;
run;

- “FILENAME Statement, JMS Access Method” in *Application Messaging with SAS*

**FILENAME Statement**
Associates a SAS fileref with an external file or an output device, disassociates a fileref and external file, or lists attributes of external files.

**Valid in:** Anywhere
Syntax

Form 1:  FILENAME fileref <device-type> 'external-file' <ENCODING='encoding-value'> <options> <operating-environment-options> ;  
Form 2:  FILENAME fileref <device-type> <options> <operating-environment-options> ;  
Form 3:  FILENAME fileref CLEAR | _ALL_ CLEAR;  
Form 4:  FILENAME fileref LIST | _ALL_ LIST ;

Arguments

fileref

is any SAS name that you use when you assign a new fileref. When you disassociate
a currently assigned fileref or when you list file attributes with the FILENAME
statement, specify a fileref that was previously assigned with a FILENAME
statement or an operating environment-level command.

Tip: The association between a fileref and an external file lasts only for the duration
of the SAS session or until you change it or discontinue it by using another
FILENAME statement. Change the fileref for a file as often as you want.

device-type

specifies the type of device or the access method that is used if the fileref points to an
input or output device or location that is not a physical file:

DISK

specifies that the device is a disk drive.

Tip: When you assign a fileref to a file on disk, you are not required to specify
DISK.

DUMMY

specifies that the output to the file is discarded.

Tip: Specifying DUMMY can be useful for testing.

GTERM

indicates that the output device type is a graphics device that will receive
graphics data.

JMS

specifies a Java Message Service (JMS) destination.

PIPE

specifies an unnamed pipe.

Note: Some operating environments do not support pipes.

PLOTTER

specifies an unbuffered graphics output device.

PRINTER

specifies a printer or printer spool file.

TAPE

specifies a tape drive.
TEMP
creates a temporary file that exists only as long as the filename is assigned. The temporary file can be accessed only through the logical name and is available only while the logical name exists.

Restriction: Do not specify a physical pathname. If you do, SAS returns an error.

Tip: Files manipulated by the TEMP device can have the same attributes and behave identically to DISK files.

TERMINAL
specifies the user's terminal.

UPRINTER
specifies a Universal Printing printer definition name.

Tip: If you do not specify the printer name in the FILENAME statement, the PRINTERPATH options control which Universal Printer is used and the destination of the output.

Requirement: device-type must immediately follow fileref in the statement.

Operating environment: Additional specifications might be required when you specify some devices. See the SAS documentation for your operating environment before specifying a value other than DISK. Values in addition to the ones listed here might be available in some operating environments.

'external-file'
is the physical name of an external file. The physical name is the name that is recognized by the operating environment.

Operating environment: For details about specifying the physical names of external files, see the SAS documentation for your operating environment.

Tips:
  Specify external-file when you assign a fileref to an external file.
  You can associate a fileref with a single file or with an aggregate file storage location.

ENCODING= 'encoding-value'
specifies the encoding to use when SAS is reading from or writing to an external file. The value for ENCODING= indicates that the external file has a different encoding from the current session encoding.

When you read data from an external file, SAS transcodes the data from the specified encoding to the session encoding. When you write data to an external file, SAS transcodes the data from the session encoding to the specified encoding.

Default: SAS assumes that an external file is in the same encoding as the session encoding.

Restriction: Not all device types support the encoding option. For more information, see the documentation for your operating system.

Examples:
  “Example 5: Specifying an Encoding When Reading an External File” on page 99
  “Example 6: Specifying an Encoding When Writing to an External File” on page 100

CLEAR
  disassociates one or more currently assigned filerefs.
Tip: Specify `fileref` to disassociate a single fileref. Specify `_ALL_` to disassociate all currently assigned filerefs.

_ALL_
specifies that the CLEAR or LIST argument applies to all currently assigned filerefs.

**LIST**
writes the attributes of one or more files to the SAS log.

**Interaction:** Specify `fileref` to list the attributes of a single file. Specify `_ALL_` to list the attributes of all files that have filerefs in your current session.

**Options**

**RECFM=record-format**
specifies the record format of the external file.

**Operating environment:** Values for `record-format` are dependent on the operating environment. For details, see the SAS documentation for your operating environment.

**Operating Environment Options**
Operating environment options specify details, such as file attributes and processing attributes, that are specific to your operating environment.

**Operating Environment Information**
For a list of valid specifications, see the SAS documentation for your operating environment.

**Details**

**Operating Environment Information**
Using the `FILENAME` statement requires operating environment-specific information. See the SAS documentation for your operating environment before using this statement. Note also that commands are available in some operating environments that associate a fileref with a file and that break that association.

**Definitions**

**external file**
is a file that is created and maintained in the operating environment from which you need to read data, SAS programming statements, or autocall macros, or to which you want to write output. An external file can be a single file or an aggregate storage location that contains many individual external files. See “Example 3: Associating a Fileref with an Aggregate Storage Location” on page 98.

**Operating Environment Information**
Different operating environments call an aggregate grouping of files by different names, such as a directory, a MACLIB, or a partitioned data set. For details about specifying external files, see the SAS documentation for your operating environment.

**fileref**
(a file reference name) is a shorthand reference to an external file. After you associate a fileref with an external file, you can use it as a shorthand reference for that file in SAS programming statements (such as INFILE, FILE, and `%INCLUDE`) and in other commands and statements in SAS software that access external files.
Reading Delimited Data from an External File
Any time a text file originates from anywhere other than the local encoding environment, it might be necessary to specify the ENCODING= option in either EBCDIC or ASCII environments.

For example, when you read an EBCDIC text file on an ASCII platform, it is recommended that you specify the ENCODING= option in the FILENAME statement. However, if you use the DSD and DLM options in the FILENAME statement, the ENCODING= option is a requirement because these options require certain characters in the session encoding (such as quotation marks, commas, and blanks).

The use of encoding-specific informats should be reserved for use with true binary files. That is, they contain both character and non-character fields.

Associating a Fileref with an External File (Form 1)
Use this form of the FILENAME statement to associate a fileref with an external file on disk:

FILENAME fileref 'external-file' <operating-environment-options>;

To associate a fileref with a file other than a disk file, you might need to specify a device type, depending on your operating environment, as shown in this form:

FILENAME fileref <device-type> <operating-environment-options>;

The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement. Change the fileref for a file as often as you want.

To specify a character-set encoding, use the following form:

FILENAME fileref <device-type> <operating-environment-options>;

Associating a Fileref with a Terminal, Printer, Universal Printer, or Plotter (Form 2)
To associate a fileref with an output device, use this form:

FILENAME fileref device-type <operating-environment-options>;

Disassociating a Fileref from an External File (Form 3)
To disassociate a fileref from a file, use a FILENAME statement, specifying the fileref and the CLEAR option.

FILENAME fileref CLEAR | _ALL_ CLEAR;

Writing File Attributes to the SAS Log (Form 4)
Use a FILENAME statement to write the attributes of one or more external files to the SAS log. Specify fileref to list the attributes of one file; use _ALL_ to list the attributes of all the files that have been assigned filerefs in your current SAS session.

FILENAME fileref LIST | _ALL_ LIST;

Comparisons
The FILENAME statement assigns a fileref to an external file. The LIBNAME statement assigns a libref to a SAS data set or to a DBMS file that can be accessed like a SAS data set.
Examples

Example 1: Specifying a Fileref or a Physical Filename
You can specify an external file either by associating a fileref with the file and then specifying the fileref or by specifying the physical filename in quotation marks:

```sas
filename sales 'your-input-file';
data jansales;
    /* specifying a fileref */
    infile sales;
    input salesrep $20. +6 jansales febsales marsales;
run;
data jansales;
    /* physical filename in quotation marks */
    infile 'your-input-file';
    input salesrep $20. +6 jansales febsales marsales;
run;
```

Example 2: Using a FILENAME and a LIBNAME Statement
This example reads data from a file that has been associated with the fileref GREEN and creates a permanent SAS data set stored in a SAS library that has been associated with the libref SAVE.

```sas
filename green 'your-input-file';
libname save 'SAS-library';
data save.vegetable;
    infile green;
    input lettuce cabbage broccoli;
run;
```

Example 3: Associating a Fileref with an Aggregate Storage Location
If you associate a fileref with an aggregate storage location, use the fileref, followed in parentheses by an individual filename, to read from or write to any of the individual external files that are stored there.

Operating Environment Information
Some operating environments enable you to read from but not write to members of aggregate storage locations. For details, see the SAS documentation for your operating environment.

In this example, each DATA step reads from an external file (REGION1 and REGION2, respectively) that is stored in the same aggregate storage location and that is referenced by the fileref SALES.

```sas
filename sales 'aggregate-storage-location';
data total1;
    infile sales(region1);
    input machine $ jansales febsales marsales;
    totsale=jansales+febsales+marsales;
run;
data total2;
    infile sales(region2);
    input machine $ jansales febsales marsales;
```
FILENAME Statement

```sas

totsale=jansales+febsales+marsales;
run;
```

**Example 4: Routing PUT Statement Output**

In this example, the FILENAME statement associates the fileref OUT with a printer that is specified with an operating environment-dependent option. The FILE statement directs PUT statement output to that printer.

```sas
filename out printer operating-environment-option;
data sales;
file out print;
input salesrep $20. +6 jansales febsales marsales;
put _infile_;
datalines;
Jones, E. A. 124357 155321 167895
Lee, C. R. 111245 127564 143255
Desmond, R. T. 97631 101345 117865
;
```

You can use the FILENAME and FILE statements to route PUT statement output to several devices during the same session. To route PUT statement output to your display monitor, use the TERMINAL option in the FILENAME statement, as shown here:

```sas
filename show terminal;
data sales;
file show;
input salesrep $20. +6 jansales febsales marsales;
put _infile_;
datalines;
Jones, E. A. 124357 155321 167895
Lee, C. R. 111245 127564 143255
Desmond, R. T. 97631 101345 117865
;
```

**Example 5: Specifying an Encoding When Reading an External File**

This example creates a SAS data set from an external file. The external file is in UTF-8 character-set encoding, and the current SAS session is in the Wlatin1 encoding. By default, SAS assumes that an external file is in the same encoding as the session encoding, which causes the character data to be written to the new SAS data set incorrectly.

To tell SAS what encoding to use when reading the external file, specify the ENCODING= option. When you tell SAS that the external file is in UTF-8, SAS then transcodes the external file from UTF-8 to the current session encoding when writing to the new SAS data set. Therefore, the data is written to the new data set correctly in Wlatin1.

```sas
libname myfiles 'SAS-library';

filename extfile 'external-file' encoding="utf-8";
data myfiles.unicode;
  infile extfile;
  input Make $ Model $ Year;
run;
```
Example 6: Specifying an Encoding When Writing to an External File

This example creates an external file from a SAS data set. The current session encoding is WLatin1, but the external file's encoding needs to be UTF-8. By default, SAS writes the external file using the current session encoding.

To tell SAS what encoding to use when writing data to the external file, specify the ENCODING= option. When you tell SAS that the external file is to be in UTF-8 encoding, SAS then transcodes the data from WLatin1 to the specified UTF-8 encoding when writing to the external file.

```sas
libname myfiles 'SAS-library';
filename outfile 'external-file' encoding="utf-8";

data _null_
  set myfiles.cars;
  file outfile;
  put Make Model Year;
run;
```

SAS Windowing Interface Commands:
- See the FILE and INCLUDE commands in the Base SAS Help and Documentation

FILENAME Statement, CATALOG Access Method

Enables you to reference a SAS catalog as an external file.

Valid in: Anywhere

Category: Data Access
Syntax
FILENAME fileref CATALOG 'catalog' <catalog-options>;

Arguments
fileref
is a valid fileref.

CATALOG
specifies the access method that enables you to reference a SAS catalog as an external file. You can then use any SAS commands, statements, or procedures that can access external files to access a SAS catalog.

Alias: LIBRARY

Tips:
This access method makes it possible for you to invoke an autocall macro directly from a SAS catalog.
With this access method, you can read any type of catalog entry, but you can write only to entries of type LOG, OUTPUT, SOURCE, and CATAMS.
If you want to access an entire catalog (instead of a single entry), you must specify its two-level name in the catalog parameter.

'catalog'
is a valid two-, three-, or four-part SAS catalog name, where the parts represent library.catalog.entry.entrytype.

Default: The default entry type is CATAMS.

Restriction: The CATAMS entry type is used only by the CATALOG access method. The CPORT and CIMPORT procedures do not support this entry type.

Catalog Options
catalog-options can be any of the following:

LRECL=lrecl
where lrecl is the maximum record length for the data in bytes.

Default: For input, the actual LRECL value of the file is the default. For output, the default is 132.

Interaction: Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in SAS System Options: Reference.

RECFM=recfm
where recfm is one of four record formats:

F
is fixed-record format. Data is transferred in image (binary) mode.

P
is print format.

S
is stream-record format. Data is transferred in image (binary) mode.

Interaction: The amount of data that is read is controlled by the value of the NBYTE= variable in the INFILE statement. The NBYTE= option specifies a variable that is equal to the amount of data to be read. This amount must be less than or equal to LRECL.

See: The NBYTE= option on page 179 in the INFILE statement.
V
is variable-record format (the default). In this format, records have varying
lengths, and they are separated by newlines. Data is transferred in image (binary)
mode.

Default: V

DESC=description
where description is a text description of the catalog.

MOD
specifies to append to the file.

Default: If you omit MOD, the file is replaced.

Details
The CATALOG access method in the FILENAME statement enables you to reference a
SAS catalog as an external file. You can then use any SAS commands, statements, or
procedures that can access external files to access a SAS catalog. For example, the
catalog access method makes it possible for you to invoke an autocall macro directly
from a SAS catalog. See “Example 5: Executing an Autocall Macro from a SAS
Catalog” on page 103.

With the CATALOG access method, you can read any type of catalog entry, but you can
write to only entries of type LOG, OUTPUT, SOURCE, and CATAMS. If you want to
access an entire catalog (instead of a single entry), you must specify its two-level name
in the catalog argument.

Examples

Example 1: Using %INCLUDE with a Catalog Entry
This example submits the source program that is contained in
SASUSER.PROFILE.SASINP.SOURCE:

filename fileref1
catalog 'sasuser.profile.sasinp.source';
%include fileref1;

Example 2: Using %INCLUDE with Several Entries in a Single
Catalog
This example submits the source code from three entries in the catalog
MYLIB.INCLUDE. When no entry type is specified, the default is CATAMS.

filename dir catalog 'mylib.include';
%include dir(mem1);
%include dir(mem2);
%include dir(mem3);

Example 3: Reading and Writing a CATAMS Entry
This example uses a DATA step to write data to a CATAMS entry, and another DATA
step to read it back in:

filename mydata
catalog 'sasuser.data.update.catams';
data _null_;
file mydata;
do i=1 to 10;
  put i;
end;
run;
/* read data from catalog entry update.catams */
data _null_;  
  infile mydata;  
  input;  
  put _INFILE_;  
run;

Example 4: Writing to a SOURCE Entry
This example writes code to a catalog SOURCE entry and then submits it for processing:

filename incit  
  catalog 'sasuser.profile.sasinp.source';
data _null_;  
  file incit;  
  put 'proc options; run;';  
run;
%include incit;

Example 5: Executing an Autocall Macro from a SAS Catalog
If you store an autocall macro in a SOURCE entry in a SAS catalog, you can point to that entry and invoke the macro in a SAS job. Use these steps:

1. Store the source code for the macro in a SOURCE entry in a SAS catalog. The name of the entry is the macro name.
2. Use a LIBNAME statement to assign a libref to that SAS library.
3. Use a FILENAME statement with the CATALOG specification to assign a fileref to the catalog: libref.catalog.
4. Use the SASSAUTO= option and specify the fileref so that the system knows where to locate the macro. Also set MAUTOSOURCE to activate the autocall facility.

This example points to a SAS catalog named MYSAS.MYCAT. It then invokes a macro named REPORTS, which is stored as a SAS catalog entry named MYSAS.MYCAT.REPORTS.SOURCE:

libname mysas 'SAS-library';
filename mymacros catalog 'mysas.mycat';  
options sasautos=mymacros mautosource;  
%reports

FILENAME, CLIPBOARD Access Method

Enables you to read text data from and write text data to the clipboard on the host computer.

Valid in: Anywhere
Category: Data Access

Syntax
FILENAME fileref CLIPBRD <BUFFER=paste-buffer-name>;

Arguments
fileref
is a valid fileref.

CLIPBRD
specifies the access method that enables you to read data from or write data to the clipboard on the host computer.

BUFFER=paste-buffer-name
creates and names the paste buffer. You can create any number of paste buffers by naming them with the BUFFER= argument in the STORE command.

Details
The FILENAME statement, CLIPBOARD Access Method enables you to share data within SAS and between SAS and applications other than SAS.

Comparisons
The STORE command copies marked text in the current window and stores the copy in a paste buffer.

You can also copy data to the clipboard by using the Explorer pop-up menu item Copy Contents to Clipboard.

Examples

Example 1: Using ODS to Write a Data Set as HTML to the Clipboard
This example uses the Sashelp.Air data set as the input file. The ODS is used to write the data set in HTML format to the clipboard.

    filename _temp_clipbrd;
    ods noresults;
    ods html file=_temp_ rs=none style=minimal;
    proc print data=Sashelp.'Air'N noobs;
    run;
    ods results;
    filename _temp_;
**Example 2: Using the DATA Step to Write a Data Set as Comma-separated Values to the Clipboard**

This example uses the Sashelp.Air data set as the input file. The data is written in the DATA step as comma-separated values to the clipboard.

```sas
filename _temp1_temp;
filename _temp2_clipbrd;
proc contents data=Sashelp."Air"N out=info noprint;
proc sort data=info;
   by npos;
run;
data _null_
   set info end=eof;
   file _temp1_dsd;
   put name @@;
   if _n_=1 then do;
      call execute("data _null_
         set Sashelp."Air"N;
         file _temp1_dsd mod;
         put");
   end;
   call execute(trim(name));
   if eof then call execute('; run;');
run;
data _null_
   infile _temp1_;
   file _temp2_;
   input;
   put _infile_
run;
filename _temp1_clear;
filename _temp2_clear;
```

**Example 3: Using the DATA Step to Write Text to the Clipboard**

This example writes three lines to the clipboard.

```sas
filename clippy clipbrd;
data _null_
   file clippy;
   put 'Line 1';
   put 'Line 2';
   put 'Line 3';
run;
```

**Example 4: Using the DATA Step to Retrieve Text from the Clipboard**

This example writes three lines to the clipboard and then retrieves them.

```sas
filename clippy clipbrd;
data _null_
   file clippy;
   put 'Line 1';
   put 'Line 2';
   put 'Line 3';
run;
```
FILENAME Statement, EMAIL (SMTP) Access Method

Enables you to send electronic mail programmatically from SAS using the SMTP (Simple Mail Transfer Protocol) e-mail interface.

### Syntax

```
FILENAME fileref EMAIL <'address'> <email-options>
```

### Arguments

- **fileref**
  - is a valid file reference. The fileref is a name that is temporarily assigned to an external file or to a device type. Note that the fileref cannot exceed eight bytes.

- **EMAIL**
  - specifies the EMAIL device type, which provides the access method that enables you to send electronic mail programmatically from SAS. In order to use SAS to send a message to an SMTP server, you must enable SMTP e-mail. For more information, see Chapter 38, “The SMTP E-Mail Interface,” in *SAS Language Reference: Concepts*.

- **'address'**
  - is the e-mail address to which you want to send the message. You must enclose the address in single or double quotation marks. To specify more than one address, you must enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name along with an address, enclose the address in angle brackets (< >). Specifying an address as a FILENAME statement argument is optional if you specify the TO= e-mail option or the PUT statement %EM_TO% directive, which will override an address specification.

### E–Mail Options

You can use any of the following e-mail options in the FILENAME statement to specify attributes for the electronic message. You can also specify these options in the FILE
statement. E-mail options that you specify in the FILE statement override any corresponding e-mail options that you specified in the FILENAME statement.

**ATTACH='filename.ext' | ATTACH=('filename.ext' attachment-options)**

specifies the physical name of the file or files to be attached to the message and any options to modify attachment specifications. The physical name is the name that is recognized by the operating environment. Enclose the physical name in quotation marks. To attach more than one file, enclose the group of files in parentheses, enclose each file in quotation marks, and separate each with a space. Here are examples:

```
attach="/u/userid/opinion.txt"
attach=('C:\Status\June2001.txt' 'C:\Status\July2001.txt')
attach="user.misc.pds (member)"
```

The **attachment-options** include the following:

**CONTENT_TYPE='content/type'**

specifies the content type for the attached file. You must enclose the value in quotation marks. If you do not specify a content type, SAS tries to determine the correct content type based on the filename. For example, if you do not specify a content type, a filename of `home.html` is sent with a content type of text/html.

*Alias:* CT= and TYPE=

*Default:* If SAS cannot determine a content type based on the filename and extension, the default value is text/plain.

**ENCODING='encoding-value'**

specifies the text encoding of the attachment that is read into SAS. You must enclose the value in quotation marks.

**EXTENSION='extension'**

specifies a different file extension to be used for the specified attachment. You must enclose the value in quotation marks. This extension is used by the recipient's e-mail program for selecting the appropriate utility to use for displaying the attachment. The following example results in the attachment `home.html` being received as `index.htm`.

```
attach=("home.html" name="index" ext="htm")
```

*Alias:* EXT=

*Note:* If you specify `extension=""`, the specified attachment will have no file extension.

**NAME='filename'**

specifies a different name to be used for the specified attachment. You must enclose the value in quotation marks. The following example results in the attachment `home.html` being received as `index.html`.

```
attach=("home.html" name="index")
```

**OUTENCODING='encoding-value'**

specifies the resulting text encoding for the attachment to be sent. You must enclose the value in quotation marks.

*Restriction:* Do not specify EBCDIC encoding values, because the SMTP e-mail interface does not support EBCDIC.

BCC='bcc-address'
specifies the recipient or recipients that you want to receive a blind carbon copy of the e-mail. Individuals that are listed in the BCC field will receive a copy of the e-mail. The BCC field does not appear in the e-mail header, so that these e-mail addresses cannot be viewed by other recipients.

If a BCC address contains more than one word, then enclose the address in single or double quotation marks. To specify more than one address, you must enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name as well as an address, enclose the address in angle brackets (<>). Here are examples:

bcc="joe@site.com"
bcc="(*joe@site.com* "jane@home.net")"
bcc="Joe Smith <joe@site.com>"

CC='cc-address'
specifies the recipient or recipients to receive a carbon copy of the e-mail message. You must enclose the address in single or double quotation marks. To specify more than one address, enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name as well as an address, enclose the address in angle brackets (<>). Here are examples:

cc='joe@site.com'
cc="(*joe@site.com* "jane@home.net")"
cc="Joe Smith <joe@site.com>"

CONTENT_TYPE='content/type'
specifies the content type for the message body. If you do not specify a content type, SAS tries to determine the correct content type. You must enclose the value in quotation marks.

Alias: CT= and TYPE=
Default: text/plain

DELIVERYRECEIPT
specifies that a notification be sent when the e-mail message is delivered to the recipient.

Note: If the recipient’s e-mail client does not support or if the recipient does not allow “delivery receipt” requests, the sender will not get a “delivery receipt” notification when the e-mail is delivered.

ENCODING='encoding-value'
specifies the text encoding to use for the message body. For valid encoding values, see “Encoding Values in SAS Language Elements” in Chapter 20 of SAS National Language Support (NLS): Reference Guide.

EXPIRES='dd mon yyyy hh:mm'
specifies the expiration date for the e-mail message.

The format *dd mon yyyy hh:mm* parameters are defined as follows:

- **dd**
  - an integer from 01 to 31 that represents the day of the month.

- **mon**
  - the first three letters of the month name in English.

- **YYYY**
  - a four-digit integer that represents the year.
hh
    is the number of hours that range from 00 through 23.

mm
    is the number of minutes that range from 00 through 59.

Tip:  If the date and time have passed the current date and time, an error message
       occurs and no e-mail is sent.

FROM='from-address'
    specifies the e-mail address of the author of the message that is being sent. The
    default value for FROM= is the e-mail address of the user who is running SAS. For
    example, specify this option when the person who is sending the message from SAS
    is not the author. You must enclose an address in quotation marks. You can specify
    only one e-mail address. To specify the author's real name along with the address,
    enclose the address in angle brackets (<>). Here are examples:

    from='martin@home.com'
    from="Brad Martin <martin@home.com>"

    Requirement:  The FROM option is required if the EMAILFROM system option is
                 set. For more information, see the “EMAILFROM System Option” in SAS
                 System Options: Reference.

IMPORTANCE='LOW' | 'NORMAL' | 'HIGH'
    specifies the priority of the e-mail message. You must enclose the value in quotation
    marks. You can specify the priority in the language that matches your session
    encoding. However, SAS will translate the priority into English because the actual
    message header must contain English in accordance with the RFC-2076 specification
    (Common Internet Message Headers). Here are examples:

    filename inventory email 'name@mycompany.com' importance='high';
    filename inventory email 'name@mycompany.com' importance='hoch';

    Default:  NORMAL

LRECL=lrecl
    where lrecl is the logical record length of the data.

    Default:  256

    Interaction:  Alternatively, you can specify a global logical record length by using
                 the “LRECL= System Option” in SAS System Options: Reference.

READRECEIPT
    specifies that a notification be sent when the e-mail message is read by the recipient.

    Note:  If the recipient’s e-mail client does not support or if the recipient does not
            allow return “read receipt” requests, the sender will not get a “read receipt”
            notification when the recipient reads the e-mail.

REPLYTO='replyto-address'
    specifies the e-mail address or addresses of who will receive replies. You must
    enclose the address in single or double quotation marks. To specify more than one
    address, enclose the group of addresses in parentheses, enclose each address in single
    or double quotation marks, and separate each address with either a comma or a
    space. To specify a real name along with an address, enclose the address in angle
    brackets (<>). Here are examples:

    replyto='hiroshi@home.com'
    replyto=('hiroshi@home.com' 'akiko@site.com')
    replyto="Hiroshi Mori <mori@site.com>"
SUBJECT=subject
specifies the subject of the message. If the subject contains special characters or
more than one word (that is, it contains at least one blank space), you must enclose
the text in quotation marks. Here are examples:

subject=Sales
subject="June Sales Report"

Note: If you do not enclose a one-word subject in quotation marks, it is converted to
uppercase.

TO='to-address'
specifies the primary recipient or recipients of the e-mail message. You must enclose
the address in single or double quotation marks. To specify more than one address,
enclose the group of addresses in parentheses, enclose each address in single or
double quotation marks, and separate each address with either a comma or a space.
To specify a real name as well as an address, enclose the address in angle brackets (<
>). Here are examples:

to='joe@site.com'
to=('joe@site.com" jane@home.net")
to='Joe Smith <joe@site.com>"

Tip: Specifying TO= overrides the " argument.

PUT Statement E-Mail Directives
The directives that you can specify in a PUT statement to change the attributes of a
message are as follows:

"EM_ABORT!"
abnormally end the current message. You can use this directive to stop SAS from
automatically sending the message at the end of the DATA step. By default, SAS
sends a message for each FILE statement.

"EM_ATTACH! 'filename.ext' | ATTACH=( 'filename.ext' attachment-options)'
replaces the physical name of the file or files to be attached to the message and any
options to modify attachment specifications. The physical name is the name that is
recognized by the operating environment. The directive must be enclosed in
quotation marks, and the physical name must be enclosed in quotation marks. To
attach more than one file, enclose the group of files in parentheses, enclose each file
in quotation marks, and separate each with a space. Here are examples:

put '!'em_attach! /u/userid/opinion.txt';
put '!'em_attach! {'C:\Status\June2001.txt" "C:\Status\July2001.txt"'};
put '!'em_attach! user.misc.pds(member)';

The attachment-options include the following:

CONTENT_TYPE='content/type'
specifies the content type for the attached file. You must enclose the value in
quotation marks. If you do not specify a content type, SAS tries to determine the
correct content type based on the filename. For example, if you do not specify a
content type, a filename of home.html is sent with a content type of text/html.

Alias: CT= and TYPE=

Default: If SAS cannot determine a content type based on the filename and
extension, the default value is text/plain.

ENCODING='encoding-value'
specifies the text encoding to use for the attachment as it is read into SAS. You
must enclose the value in quotation marks. For valid encoding values, see
EXTENSION='extension'
specifies a different file extension to be used for the specified attachment. You must enclose the value in quotation marks. This extension is used by the recipient’s e-mail program for selecting the appropriate utility to use for displaying the attachment. The following example results in the attachment home.html being received as index.htm.

```
put '!em_attach! ("home.html" name="index" ext="htm");
```

**Alias:** EXT=

**Default:** TXT

NAME='filename'
specifies a different name to be used for the specified attachment. You must enclose the value in quotation marks. The following example results in the attachment home.html being received as index.html.

```
put '!em_attach! ("home.html" name="index");
```

OUTENCODING='encoding-value'
specifies the resulting text encoding for the attachment to be sent. You must enclose the value in quotation marks.

**Restriction:** Do not specify EBCDIC encoding values, because the SMTP e-mail interface does not support EBCDIC.

"EM_BCC! bcc-address"
specifies the recipient or recipients that you want to receive a blind carbon copy of the e-mail. Individuals that are listed in the bcc field will receive a copy of the e-mail. The BCC field does not appear in the e-mail header, so that these e-mail addresses cannot be viewed by other recipients.

If a BCC address contains more than one word, then enclose the address in single or double quotation marks. To specify more than one address, you must enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name as well as an address, enclose the address in angle brackets (< >).

```
put '!em_bcc! joe@site.com';
put '!em_bcc! ("joe@site.com" "jane@home.net");
put '!em_bcc! Joe Smith <joe@site.com>;
```

"EM_CC! cc-address"
specifies the recipient or recipients to receive a carbon copy of the e-mail message. You must enclose the address in single or double quotation marks. To specify more than one address, you must enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name as well as an address, enclose the address in angle brackets (< >). Here are examples:

```
put '!em_cc! joe@site.com';
put '!em_cc! ("joe@site.com" "jane@home.com");
put '!em_cc! Joe Smith <joe@site.com>;
```

"EM_DELIVERYRECEIPT!"
specifies that a notification be sent when the e-mail message is delivered to the recipient.
Note: If the recipient’s e-mail client does not support or if the recipient does not allow “delivery receipt” requests, the sender will not get a “delivery receipt” notification when the e-mail is delivered.

"!EM_EXPIRES! dd mon yyyy hh:mm"

replaces the current expiration date for the e-mail message. Here are examples:

put '"!em_expires! 15 Aug 2010 08:00"';
put '"!em_expires! 28 Feb 2011 23:00"';

The format \textit{dd mon hh:mm} parameters are defined as follows:

\textbf{dd} \\
\textbf{is} an integer from 01 to 31 that represents the day of the month.

\textbf{mon} \\
\textbf{are} the first three letters of the month name in English.

\textbf{yyyy} \\
\textbf{is} a four-digit integer that represents the year.

\textbf{hh} \\
\textbf{is} the number of hours that range from 00 through 23.

\textbf{mm} \\
\textbf{is} the number of minutes that range from 00 through 59.

\textbf{Tip:} If the date and time have passed the current date and time, an error message occurs and no e-mail is sent.

"!EM_FROM! from-address"

replaces the current address of the author of the message being sent, which could be either the default or the one specified by the FROM= e-mail option. The directive must be enclosed in quotation marks. You can specify only one e-mail address. To specify the author’s real name along with the address, enclose the address in angle brackets (<>). Here are examples:

put '"!em_from! martin@home.com"';
put '"!em_from! Brad Martin <martin@home.com>"';

"!EM_IMPORTANCE! LOW | NORMAL | HIGH"

specifies the priority of the e-mail message. The directive must be enclosed in quotation marks. You can specify the priority in the language that matches your session encoding. However, SAS will translate the priority into English because the actual message header must contain English in accordance with the RFC-2076 specification (Common Internet Message Headers). Here are examples:

put '"!em_importance! high"';
put '"!em_importance! haut"';

\textbf{Default:} NORMAL

"!EM_NEWMSG!"

clears all attributes of the current message that were set using PUT statement directives.

"!EM_READRECEIPT!"

specifies that a notification be sent when the e-mail message is read by the recipient.

\textbf{Note:} If the recipient’s e-mail client does not support or if the recipient does not allow “read receipt” requests, the sender will not get a “read receipt” notification when the recipient reads the e-mail.
"EM_REPLYTO! replyto-address"
specifies the e-mail address or addresses of who will receive replies. You must enclose the address in single or double quotation marks. To specify more than one address, enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name along with an address, enclose the address in angle brackets (<>). Here are examples:

put '!em_replyto! hiroshi@home.com';
put '!em_replyto! ('hiroshi@home.com" "akiko@site.com")';
put '!em_replyto! Hiroshi Mori <mori@site.com>';

"EM_SEND!"
sends the message with the current attributes. By default, SAS sends a message when the fileref is closed. The fileref closes when the next FILE statement is encountered or the DATA step ends. If you use this directive, SAS sends the message when it encounters the directive, and again at the end of the DATA step. This directive is useful for writing DATA step programs that conditionally send messages or use a loop to send multiple messages.

"EM_SUBJECT! subject"
replaces the current subject of the message. The directive must be enclosed in quotation marks. If the subject contains special characters or more than one word (that is, it contains at least one blank space), you must enclose the text in quotation marks. Here are examples:

put '!em_subject! Sales';
put '!em_subject! "June Sales Report"';

"EM_TO! to-address"
specifies the primary recipient or recipients of the e-mail message. You must enclose the address in single or double quotation marks. To specify more than one address, enclose the group of addresses in parentheses, enclose each address in single or double quotation marks, and separate each address with either a comma or a space. To specify a real name as well as an address, enclose the address in angle brackets (<>). Here are examples:

put '!em_to! joe@site.com';
put '!em_to! ('joe@site.com" "jane@home.net")';
put '!em_to! Joe Smith <joesite.com>';

Tip: Specifying !EM_TO! overrides the 'address' argument and the TO= e-mail option.

Details

The Basics
You can send electronic mail programmatically from SAS using the EMAIL (SMTP) access method. To send e-mail to an SMTP server, you first specify the SMTP e-mail interface with the EMAILSYS system option, use the FILENAME statement to specify the EMAIL device type, and then submit SAS statements in a DATA step or in SCL code. The e-mail access method has several advantages:

• You can use the logic of the DATA step or SCL to subset e-mail distribution based on a large data set of e-mail addresses.
• You can automatically send e-mail upon completion of a SAS program that you submitted for batch processing.
• You can direct output through e-mail based on the results of processing.
In general, DATA step or SCL code that sends e-mail has the following components:

- a FILENAME statement with the EMAIL device-type keyword
- e-mail options specified in the FILENAME or FILE statement that indicate e-mail recipients, subject, attached file or files, and so on
- PUT statements that define the body of the message
- PUT statements that specify e-mail directives (of the form !EM_directive!) that override the e-mail options (for example, TO=, CC=, SUBJECT=, ATTACH=) or perform actions such as send, end abnormally, or start a new message.

You can use encoded e-mail passwords. When a password is encoded with PROC PWENCODE, the output string includes a tag that identifies the string as having been encoded. An example of a tag is {sas001}. The tag indicates the encoding method. Encoding a password enables you to avoid e-mail access authentication with a password in plaintext. Passwords that start with "\{sas" trigger an attempt to be decoded. If the decoding succeeds, then that decoded password is used. If the decoding fails, then the password is used as is. For more information, see PROC PWENCODE in the Base SAS Procedures Guide.

For e-mail messages that you send to another time zone, you can use the EMAILUTCOFFSET= system option to ensure that the e-mail message has the UTC offset that represents your local time. You might use this option this if the time on your computer is not set to a time that uses a UTC offset or your computer does not account for daylight savings time. The UTC offset specified in the EMAILUTCOFFSET= system option adds or replaces a UTC offset to the time in the e-mail's Date: header field. For more information, see the “EMAILUTCOFFSET= System Option” in SAS System Options: Reference.

**PUT Statement Syntax for EMAIL (SMTP) Access Method**

In the DATA step, after using the FILE statement to define your e-mail fileref as the output destination, use PUT statements to define the body of the message. Here is an example.

```sas
filename mymail email 'martin@site.com' subject='Sending Email';

data _null_;
   file mymail;
   put 'Hi';
   put 'This message is sent from SAS...';
run;
```

You can also use PUT statements to specify e-mail directives that override the attributes of your message (the e-mail options like TO=, CC=, SUBJECT=, CONTENT_TYPE=, ATTACH=), or to perform actions such as send, end abnormally, or start a new message. Specify only one directive in each PUT statement; each PUT statement can contain only the text that is associated with the directive that it specifies.

For a list of e-mail directives, see “PUT Statement E-Mail Directives” on page 110.

**Examples**

**Example 1: Sending E-mail with an Attachment Using a DATA Step**

In order to share a copy of your SAS configuration file with another user, you could send it by submitting the following program. The e-mail options are specified in the FILENAME statement:
FILENAME Statement, EMAIL (SMTP) Access Method

filename mymail email "JBrown@site.com"
   subject="My SAS Configuration File"
   attach="/u/sas/sasv8.cfg"

data _null_; file mymail;
   put 'Jim,';
   put 'This is my SAS configuration file.';
   put 'I think you might like the';
   put 'new options I added.';
run;

The following program sends a message and two file attachments to multiple recipients. For this example, the e-mail options are specified in the FILE statement instead of the FILENAME statement.

filename outbox email "ron@acme.com";
data _null_; file outbox
   to=("ron@acme.com" "humberto@acme.com")
   /* Overrides value in */
   /* filename statement */
   cc=("miguel@acme.com" "loren@acme.com")
   subject="My SAS Output"
   attach=("C:\sas\results.out" "C:\sas\code.sas")
; 
   put 'Folks,';
   put 'Attached is my output from the SAS';
   put 'program I ran last night.';
   put 'It worked great!';
run;

Example 2: Using Conditional Logic in a DATA Step

You can use conditional logic in a DATA step in order to send multiple messages and control which recipients get which message. For example, in order to send customized reports to members of two different departments, the following program produces an e-mail message and attachments that are dependent on the department to which the recipient belongs. In the program, the following occurs:

- In the first PUT statement, the !EM_TO! directive assigns the TO attribute.
- The second PUT statement assigns the SUBJECT attribute using the !EM_SUBJECT! directive.
- The !EM_SEND! directive sends the message.
- The !EM_NEWMMSG! directive clears the message attributes, which must be used to clear message attributes between recipients.
- The !EM_ABORT! directive abnormally ends the message before the RUN statement causes it to be sent again. The !EM_ABORT! directive prevents the message from being automatically sent at the end of the DATA step.

filename reports email "Jim.Smith@work.com";
data _null_; file reports;
   length name dept $ 21;
   input name dept;
   put '!EM_TO!' ' name;
   put '!EM_SUBJECT! Report for ' dept;
Example 3: Sending Procedure Output in E-mail
You can use e-mail to send procedure output. This example illustrates how to send ODS HTML in the body of an e-mail message. Note that ODS HTML procedure output must be sent with the RECORD_SEPARATOR (RS) option set to NONE.

```sas
filename outbox email
to='susan@site.com'
type='text/html'
subject='Temperature Conversions';
data temperatures;
do centigrade = -40 to 100 by 10;
   fahrenheit = centigrade*9/5+32;
   output;
end;
run;
ods html
   body=outbox /* Mail it! */
   rs=none;
title 'Centigrade to Fahrenheit Conversion Table';
proc print;
id centigrade;
   var fahrenheit;
run;
```

Example 4: Creating and E-mailing an Image
The following example illustrates how to create a GIF image and send it from SAS as an attachment to an e-mail message.

```sas
filename gsasfile email
to='Jim@acme.com'
type='image/gif'
subject="SAS/GRAPH Output";
goptions dev=gif gsfname=gsasfile;
proc gatestit pic=1;
run;
```
FILENAME Statement, FTP Access Method

Enables you to access remote files by using the FTP protocol.

**Valid in:** Anywhere  
**Category:** Data Access

### Syntax

FILENAME fileref FTP 'external-file' <ftp-options>;

### Arguments

**fileref**

is a valid fileref.

**Tip:** The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement. You can change the fileref for a file as often as you want.

**FTP**

specifies the access method that enables you to use File Transfer Protocol (FTP) to read from or write to a file from any host computer that you can connect to on a network with an FTP server running.

**Tip:** Use FILENAME with FTP when you want to connect to the host computer, to log in to the FTP server, to make records in the specified file available for reading or writing, and to disconnect from the host computer.

**'external-file'**

specifies the physical name of an external file that you want to read from or write to. The physical name is the name that is recognized by the operating environment.

If the file has an IBM 370 format and a record format of FB or FBA, and if the ENCODING= option is specified, then you must also specify the LRECL= option. If
the length of a record is shorter than the value of LRECL, then SAS pads the record with blanks until the record length is equal to the value of LRECL.

**Operating environment:** For details about specifying the physical names of external files, see the SAS documentation for your operating environment.

**Tips:**
If you are not transferring a file but performing a task such as retrieving a directory listing, then you do not need to specify a filename. Instead, put empty quotation marks in the statement. See “Example 1: Retrieving a Directory Listing” on page 124.

You can associate a fileref with a single file or with an aggregate file storage location.
If you use the DIR option, specify the directory in this argument.

**ftp-options**
specifies details that are specific to your operating environment such as file attributes and processing attributes.

**Operating environment:** For more information about some of these FTP options, see the SAS documentation for your operating environment.

**See:** “FTP Options” on page 118

### FTP Options

**AUTHDOMAIN="auth-domain"**
specifies the name of an authentication domain metadata object in order to connect to the FTP server. The authentication domain references credentials (user ID and password) without your having to explicitly specify the credentials. The `auth-domain` name is case sensitive, and it must be enclosed in double quotation marks.

An administrator creates authentication domain definitions while creating a user definition with the User Manager in SAS Management Console. The authentication domain is associated with one or more login metadata objects that provide access to the FTP server and is resolved by the BASE engine calling the SAS Metadata Server and returning the authentication credentials.

**Requirement:** The authentication domain and the associated login definition must be stored in a metadata repository, and the metadata server must be running in order to resolve the metadata object specification.

**Interaction:** If you specify AUTHDOMAIN=, you do not need to specify USER= and PASS=.

**See:** For more information about creating and using authentication domains, see the discussion on credential management in the *SAS Intelligence Platform: Security Administration Guide*.

**BINARY**
is fixed-record format. Thus, all records are of size LRECL with no line delimiters. Data is transferred in image (binary) mode.

The BINARY option overrides the value of RECFM= in the FILENAME FTP statement, if specified, and forces a binary transfer.

**Alias:** RECFM=F

**Interaction:** If you specify the BINARY option and the S370V or S370VS option, then SAS ignores the BINARY option.

**BLOCKSIZE=** *blocksize*
where `blocksize` is the size of the data buffer in bytes.

**Default:** 32768
CD='directory'
issues a command that changes the working directory for the file transfer to the
directory that you specify.

**Interaction:** The CD and DIR options are mutually exclusive. If both are specified,
FTP ignores the CD option and SAS writes an informational note to the log.

**DEBUG**
writes to the SAS log informational messages that are sent to and received from the
FTP server.

**DIR**
Enables you to access directory files or PDS/PDSE members. Specify the directory
name in the *external-file* argument. You must use valid directory syntax for the
specified host.

**Interaction:** The CD and DIR options are mutually exclusive. If both are specified,
FTP ignores the CD option and SAS writes an informational note to the log.

**Tips:**
If you want FTP to append a file extension of DATA to the member name that is
specified in the FILE or INFILE statement, then use the FILEEXT option in
conjunction with the DIR option. The FILEEXT option is ignored if you specify
a file extension in the FILE or INFILE statement.

If you want FTP to create the directory, then use the NEW option in conjunction
with the DIR option. The NEW option will be ignored if the directory exists.

If the NEW option is omitted and you specify an invalid directory, then a new
directory will not be created and you will receive an error message.

The maximum number of directory or z/OS PDSE members that can be open
simultaneously is limited by the number of sockets that can be open
simultaneously on an FTP server. The number of sockets that can be open
simultaneously is proportional to the number of connections that are set up
during the installation of the FTP server. You might want to limit the number of
sockets that are open simultaneously to avoid performance degradation.

**Example:** “Example 10: Reading and Writing from Directories” on page 127

**ENCODING=encoding-value**
specifies the encoding to use when reading from or writing to the external file. The
value for ENCODING= indicates that the external file has a different encoding from
the current session encoding.

When you read data from an external file, SAS transcodes the data from the specified
encoding to the session encoding. When you write data to an external file, SAS
transcodes the data from the session encoding to the specified encoding.

**Default:** SAS assumes that an external file is in the same encoding as the session
encoding.

**Tip:** The data is transferred in image or binary format and is in local data format.
Thus, you must use appropriate SAS informats to read the data correctly.

**See:** “Encoding Values in SAS Language Elements” in Chapter 20 of *SAS National
Language Support (NLS): Reference Guide*

**FILEEXT**
specifies that the member type of DATA is automatically appended to the member
name in the FILE or INFILE statement when you use the DIR option.

**Tip:** The FILEEXT option is ignored if you specify a file extension in the FILE or
INFILE statement.

**See:** LOWCASE_MEMNAME option on page 120

**Example:** “Example 10: Reading and Writing from Directories” on page 127
HOST='host'
where host is the network name of the remote host with the FTP server running.

You can specify either the name of the host (for example, server.pc.mydomain.com) or the IP address of the computer (for example, 2001:db8::).

HOSTRESPONSELEN='size'
where size is the length of the FTP server response message.

Default: 2048 bytes
Range: 2048 to 16384 bytes
Restriction: If you specify a size that is less than 2048 or is greater than 16384, the size will be set to 2048.

LIST
issues the LIST command to the FTP server. LIST returns the contents of the working directory as records that contain all of the file attributes that are listed for each file.
Tip: The file attributes that are returned will vary, depending on the FTP server that is being accessed.

LOWCASE_MEMNAME
enables autocall macro retrieval of lowercase directory or member names from FTP servers.
Restriction: SAS autocall macro retrieval always searches for uppercase directory member names. Mixed case directory or member names are not supported.
Interaction: If you access files off FTP servers by using the %INCLUDE, FILE, INFILE, or other DATA step I/O statements, case sensitivity will be preserved.
See: FILEEXT option on page 119

LRECL=lrecl
where lrecl is the logical record length of the data.
Default: 256
Interaction: Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in SAS System Options: Reference.

LS
issues the LS command to the FTP server. LS returns the contents of the working directory as records with no file attributes.
Tips:
The file attributes that are returned will vary, depending on the FTP server that is being accessed.
To return a listing of a subset of files, use the LSFILE= option in addition to LS.

LSFILE='character-string'
in combination with the LS option, specifies a character string that enables you to request a listing of a subset of files from the working directory. Enclose the character string in quotation marks.
Restriction: LSFILE= can be used only if LS is specified.
Tips:
You can specify a wildcard as part of 'character-string'.
The file attributes that are returned will vary, depending on the FTP server that is being accessed.
Example: This statement lists all of the files that start with sales and end with sas:
filename myfile ftp '' ls lsfile='sales*.sas'
other-ftp-options;
MGET
transfers multiple files, similar to the FTP command MGET.

Tips:
The whole transfer is treated as one file. However, as the transfer of each new
file is started, the EOV= variable is set to 1.
Specify MPROMPT to prompt the user before each file is sent.

MPROMPT
specifies whether to prompt for confirmation that a file is to be read, if necessary,
when the user executes the MGET option.
Restriction: The MPROMPT option is not available on z/OS for batch processing.

NEW
specifies that you want FTP to create the directory when you use the DIR option.
Restriction: The NEW option is not available under z/OS.
Tip: The NEW option will be ignored if the directory exists.

PASS='password'
where password is the password to use with the user name specified in the USER=
option.

Tips:
You can specify the PROMPT option instead of the PASS option, which tells the
system to prompt you for the password.
If the user name is anonymous, then the remote host might require that you
specify your e-mail address as the password.
To use an encoded password, use the PWENCODE procedure in order to
disguise the text string, and then enter the encoded password for the PASS=
option. For more information, see the Chapter 3, “PWENCODE Procedure” in
Encryption in SAS.

Example: “Example 6: Using an Encoded Password” on page 126

PASSIVE
specifies that an attempt is made for passive mode FTP.

In passive mode FTP, the client initiates the control and data connections to the
server. This action solves the problem of firewalls filtering the incoming data port
connection to the client from the server.

Note: Not all FTP servers support the passive mode. If an attempt is made by the
FILENAME statement FTP access method to issue the PASV command and the
command fails or the server does not accept the command, then active mode FTP
is used for the connection.

PORT=portno
where portno is the port that the FTP daemon monitors on the respective host.

The portno can be any number between 0 and 65535 that uniquely identifies a
service.

Tip: In the Internet community, there is a list of predefined port numbers for specific
services. For example, the default port for FTP is 21. A partial list of port
numbers is usually available in the /etc/services file on any UNIX computer.

PROMPT
specifies to prompt for the user login password, if necessary.
Restriction: The PROMPT option is not available for batch processing under z/OS.
Interaction: If PROMPT is specified without USER=, then the user is prompted for
an ID, as well as a password.
Tip: You can use the SAVEUSER option on page 123 to save the user ID and password after the user ID and password prompt is successfully executed.

**RCMD= 'command'**
where *command* is the FTP 'SITE' or 'service' command to send to the FTP server.

FTP servers use SITE commands to provide services that are specific to a system and are essential to file transfer but not common enough to be included in the protocol.

For example, `rcmd='site rdw'` preserves the record descriptor word (RDW) of a z/OS variable blocked data set as a part of the data. See S370V and S370VS below.

**Interaction:** Some FTP service commands might not run at a particular client site depending on the security permissions and the availability of the commands.

**Tips:**
- If you transfer a file with the FTP access method and then cannot read the file, you might need to change the FTP server's UMASK setting.
- If the FTP server supports a SITE UMASK setting, you can change the permissions of the file as shown in the following example:
  ```markdown
  filename in ftp '/mydir/accounting/file2.dat'
  host="xxx.fyi.xxx.com"
  user="john"
  rcmd='site umask 022'
  prompt;
  data _null;
  file in;
  put a $80;
  run;
  ```
  You can specify multiple FTP service commands if you separate them by semicolons. Some examples are as follows:
  ```markdown
  rcmd='ascii;site umask 002'
  rcmd='stat;site chmod 0400 ~mydir/abc.txt'
  ```

**RECFM= *recfm***
where *recfm* is one of three record formats:

- **F** is fixed-record format. Thus, all records are of size LRECL with no line delimiters. Data is transferred in image (binary) mode.
  
  **Aliases:**
  - **BINARY**
    
    The BINARY option overrides the value of RECFM= in the FILENAME FTP statement, if specified, and forces a binary transfer.

- **S** is stream-record format. Data is transferred in image (binary) mode.
  
  **Interaction:** The amount of data that is read is controlled by the current LRECL value or by the value of the NBYTE= variable in the INFILE statement. The NBYTE= option specifies a variable that is equal to the amount of data to be read. This amount must be less than or equal to LRECL.
  
  **See:** The NBYTE= option on page 179 in the INFILE statement.

- **V** is variable-record format (the default). In this format, records have varying lengths, and they are transferred in text (stream) mode.
  
  **Interaction:** Any record larger than LRECL is truncated.
Tip: If you are using files with the IBM 370 Variable format or the IBM 370 Spanned Variable format, then you might want to use the S370V or S370VS options instead of the RECFM= option. See S370V and S370VS below.

Default: V

Interaction: If you specify the RECFM= option and the S370V or S370VS option, then SAS ignores the RECFM= option.

RHELP
issues the HELP command to the FTP server. The results of this command are returned as records.

RSTAT
issues the RSTAT command to the FTP server. The results of this command are returned as records.

SAVEUSER
saves the user ID and password after the user ID and password prompt are successfully executed.

Interaction: The user ID and password are saved only for the duration of the SAS session or until you change the association between the fileref and the external file, or discontinue it with another FILENAME statement.

S370V
indicates that the file being read is in IBM 370 variable format.

Interaction: If you specify this option and the RECFM= option, then SAS ignores the RECFM= option.

Tips:
The data is transferred in image or binary format and is in local data format. Thus, you must use appropriate SAS informats to read the data correctly on non-EBCDIC hosts.

Use the rcmd='site rdw' option when you transfer a z/OS data set with a variable-record format to another z/OS data set with a variable-record format to preserve the record descriptor word (rdw) of each record. By default, most FTP servers remove the rdw that exists in each record before it is transferred.

Typically, the 'SITE RDW' command is not necessary when you transfer a data set with a z/OS variable-record format to ASCII, or when you transfer an ASCII file to a z/OS variable-record format.

S370VS
indicates that the file that is being read is in IBM 370 variable-spanned format.

Interaction: If you specify this option and the RECFM= option, then SAS ignores the RECFM= option.

Tips:
The data is transferred in image or binary format and is in local data format. Thus, you must use appropriate SAS informats to read the data correctly on non-EBCDIC hosts.

Use the rcmd='site rdw' option when you transfer a z/OS data set with a variable-record format to another z/OS data set with a variable-record format to preserve the record descriptor word (rdw) of each record. By default, most FTP servers remove the rdw that exists in each record before it is transferred.

Typically, the 'SITE RDW' command is not necessary when you transfer a data set with a z/OS variable-record format to ASCII, or when you transfer an ASCII file to a z/OS variable-record format.
TERMSTR='eol-char'
where eol-char is the line delimiter to use when RECFM=V. There are three valid values:

- CRLF carriage return (CR) followed by line feed (LF).
- LF line feed only (the default).
- NULL NULL character (0x00).

**Default:** LF  
**Restriction:** Use this option only when RECFM=V.

USER='username'
where username is used to log in to the FTP server.

**Restriction:** The FTP access method does not support FTP proxy servers that require user ID authentication.

**Interaction:** If PROMPT is specified, but USER= is not, then the user is prompted for an ID.

**Tip:** You can specify a proxy server and credentials for an FTP server when using the FTP access method. The user ID and password that you need to log in to the FTP server is sent via the proxy server by using the syntax. Both anonymous and user ID validation are supported.

**Example:** “Example 1: Retrieving a Directory Listing” on page 124

WAIT_MILLISECONDS=milliseconds
specifies the FTP response time in milliseconds.

**Default:** 1,000 milliseconds  
**Tip:** If you receive a “connection closed; transfer aborted” or “network name is no longer available” message in the log, use the WAIT_MILLISECONDS option to increase the response time.

Comparisons

As with the FTP get and put commands, the FTP access method lets you download and upload files. However, this method directly reads files into your SAS session without first storing them on your system.

Examples

**Example 1: Retrieving a Directory Listing**
This example retrieves a directory listing from a host named mvshost1 for user smythe, and prompts smythe for a password:

```
filename dir ftp '' is user='smythe'
   host='mvshost1.mvs.sas.com' prompt;
data _null_
   infile dir;
   input;
   put _INFILE_;  
run;
```

**Note:** The quotation marks are empty because no file is being transferred. Because quotation marks are required by the syntax, however, you must include them.
Example 2: Reading a File from a Remote Host
This example reads a file called sales in the directory /u/kudzu/mydata from the remote UNIX host hp720:

```sas
filename myfile ftp 'sales' cd='/u/kudzu/mydata'
   user='guest' host='hp720.hp.sas.com'
   recfm=v prompt;
data mydata / view=mydata; /* Create a view */
   infile myfile;
   input x $10. y 4.;
run;
proc print data=mydata; /* Print the data */
run;
```

Example 3: Creating a File on a Remote Host
This example creates a file called test.dat in a directory called c:\remote for the user bbailey on the host winnt.pc:

```sas
filename create ftp 'c:\remote\test.dat'
   host='winnt.pc'
   user='bbailey' prompt recfm=v;
data _null_; 
   file create;
   do i=1 to 10;
      put i=;
   end;
run;
```

Example 4: Reading an S370V-Format File on z/OS
This example reads an S370V-format file from a z/OS system. See RCMD= option on page 122 for more information about RCMD='site rdw'.

```sas
filename viewdata ftp 'sluggo.stat.data'
   user='sluggo' host='zoshost1'
   s370v prompt rcmd='site rdw';
data mydata / view=mydata; /* Create a view */
   infile viewdata;
   input x $ebcdic8.;
run;
proc print data=mydata; /* Print the data */
run;
```

Example 5: Anonymously Logging In to FTP
This example shows how to log in to FTP anonymously, if the host accepts anonymous logins.

Note: Some anonymous FTP servers require a password. If required, your e-mail address is usually used. See PASS= option on page 121 under “FTP Options.”

```sas
filename anon ftp '' ls host='130.96.6.1'
   user='anonymous';
data _null_; 
   infile anon;
   input;
   list;
run;
```
Note: The quotation marks following the argument FTP are empty. A filename is needed only when transferring a file, not when routing a command. The quotation marks, however, are required.

Example 6: Using an Encoded Password
This example shows you how to use an encoded password in the FILENAME statement.

In a separate SAS session, use the PWENCODE procedure to encode your password and make note of the output.

```sas
proc pwencode in= "MyPass1";
run;
```

The following output appears in the SAS log:

```
(sas001)TX1QYXNzMQ==
```

You can now use the entire encoded password string in your batch program.

```sas
filename myfile ftp 'sales' cd='/u/kudzu/mydata'
    user='tjbarry' host='hp720.hp.mycompany.com'
    pass="(sas001)TX1QYXMZ==";
```

Example 7: Importing a Transport Data Set
This example uses the CIMPORT procedure to import a transport data set from a host named myshost1 for user calvin. The new data set will reside locally in the SASUSER library. Note that user and password can be SAS macro variables. If you specify a fully qualified data set name, then use double quotation marks and single quotation marks. Otherwise, the system will append the profile prefix to the name that you specify.

```sas
%let user=calvin;
%let pw=xxxxx;
filename inp ftp `'calvin.mat1.cpo'" user="&user"
    pass="&pw" rcmd='binary'
    host='mvshost1';
proc cimport library=sasuser infile=inp;
run;
```

Example 8: Transporting a SAS Library
This example uses the CPORT procedure to transport a SAS library to a host named mvshost1 for user calvin. It will create a new sequential file on the host called userid.mat64.cpo with the recfm of fb, lrecl of 80, and blocksize of 8000.

```sas
filename inp ftp 'mat64.cpo' user='calvin'
    lrecl=80 recfm=f blocksize=8000
    rcmd='site blocksize=800 recfm=fb lrecl=80';
proc cport library=mylib file=inp;
run;
```

Example 9: Creating a Transport Library with Transport Engine
This example creates a new SAS library on host mvshost1. The FILENAME statement assigns a fileref to the new data set. Note the use of the RCMDD= option to specify important file attributes. The LIBNAME statement uses a libref that is the same as the fileref and assigns it to the XPORT engine. The PROC COPY step copies all data sets from the SAS library that are referenced by MYLIB to the XPORT engine. Output from the PROC CONTENTS step confirms that the copy was successful:
FILENAME Statement, FTP Access Method

filename inp ftp 'mat65.cpo' user='calvin'
    pass='xxxx' host='mvshost1'
    lrecl=80 recfm=f blocksize=8000
    rcmd='site blocksize=8000 recfm=fb lrecl=80';
libname mylib 'SAS-library';
libname inp xport;
proc copy in=mylib out=inp mt=data;
run;
proc contents data=inp._all_; run;

Note: For more information about the XPORT engine, see “Transport Engine” in Chapter 35 of SAS Language Reference: Concepts and “XPORT Engine Limitations” in Chapter 4 of Moving and Accessing SAS Files.

Example 10: Reading and Writing from Directories

This example reads the file ftpmem1 from a directory on a UNIX host, and writes the file ftpout1 to a different directory on another UNIX host.

filename indir ftp '/usr/proj2/dir1' DIR
    host='host1.mycompany.com'
    user='xxxx' prompt;
filename outdir ftp '/usr/proj2/dir2' DIR FILEEXT
    host='host2.mycompany.com'
    user='xxxx' prompt;
data _null_;
infile indir(ftpmem1) truncover;
input;
file outdir(ftpout1);
put _infile_;
run;
The file ftpout1 is written to /usr/proj2/dir2/ftpout1.DATA. Note that a member type of DATA is appended to the ftpout1 file because the FILEEXT option was specified in the output file's FILENAME statement. For more information, see the FILEEXT option on page 119.

Note: The DIR option is not needed for some ODS destinations.

The following example writes an output file and transfers it to an ODS-specified destination. The DIR option is not needed.

filename output ftp "~user/ftpdir/" host='host.fyi.company.com' user='userid'
    pass='userpass' recfm=s debug;
ods html body='body.html' path=output;
proc print data=sashelp.class;run;

To export multiple graph files to a remote directory location, the DIR option must be specified in the FILENAME statement. Accordingly, when creating external graph files with the ODS HTML destination, two FILENAME statements are needed: one for the HTML files, and one for the graph files. The following example illustrates the need for two FILENAME statements.

filename output1 ftp "~user/dir" fileext host='host.unx.company.com'
    user='userid' pass='userpass' recfm=s debug;
filename output2 ftp "~user/dir" dir fileext host='host.unx.company.com'
    user='userid' pass='userpass' recfm=s debug;
ods html body='body.html' path=output1 gpath=output2
    frame='frames.html' contents='contents.html';
Example 11: Using a Proxy Server

This example uses a proxy server with the FTP access method. The user ID and password are sent via the proxy server.

```sas
filename test ftp '/' ls
    host='proxy.server.xxx.com'
    user='userid@ftpservername'
    pass='xxxxxx'
    cd='pubsadir/';
data _null_;  
    infile test truncover;  
    input a $256.;  
    put a=;  
run;
```

**FILENAME Statement, Hadoop Access Method**

Enables you to access files on a Hadoop Distributed File System (HDFS) whose location is specified in a configuration file.

- **Valid in:** Anywhere
- **Category:** Data Access
- **Restriction:** Access to Hadoop configurations on systems based on UNIX

**Syntax**

```sas
FILENAME fileref HADOOP 'external-file' <hadoop-options>;
```
**Required Arguments**

`fileref`

is a valid fileref.

**Tip:** The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement.

**HADOOP**

specifies the access method that enables you to use Hadoop to read from or write to a file from any host machine that you can connect to on a Hadoop configuration.

'**external-file**'

specifies the physical name of the file that you want to read from or write in an HDFS system. The physical name is the name that is recognized by the operating environment.

**Operating environment:** For details about specifying the physical names of external files, see the SAS documentation for your operating environment.

**Tip:** Specify `external-file` when you assign a fileref to an external file. You can associate a fileref with a single file or with an aggregate file storage location.

**Hadoop Options**

`hadoop-options` can be any of the following values:

**BUFFERLEN=bufferlen**

specifies the maximum buffer length of the data that is passed to Hadoop for its I/O operations.

**Default:** 503808

**Restriction:** The maximum buffer length is 1000000.

**Tip:** Specifying a buffer length that is larger than the default could result in performance improvements.

**CFG="physical-pathname-of-hadoop-configuration-file" | fileref-that-references-a-hadoop-configuration-file**

specifies the configuration file that contains the connections settings for a specific Hadoop cluster.

**CONCAT**

specifies that the HDFS directory name that is specified on the FILENAME HADOOP statement is considered a wildcard specification. The concatenation of all the files in the directory is treated as a single logical file and read as one file.

**Restriction:** This works for input only.

**Tip:** For best results, do not concatenate text and binary files.

**DIR**

enables you to access files in an HDFS directory.

**Requirement:** You must use valid directory syntax for the specified host.

**Interaction:** Specify the HDFS directory name in the `external-file` argument.

**See:** “FILEEXT” on page 130

**ENCODING='encoding-value'**

specifies the encoding to use when SAS is reading from or writing to an external file. The value for ENCODING= indicates that the external file has a different encoding from the current session encoding.

**Default:** SAS assumes that an external file is in the same encoding as the session encoding.
Note: When you read data from an external file, SAS transcodes the data from the specified encoding to the session encoding. When you write data to an external file, SAS transcodes the data from the session encoding to the specified encoding.

FILEEXT

specifies that a file extension is automatically appended to the filename when you use the DIR option

Interaction: The autocall macro facility always passes the extension .SAS to the file access method as the extension to use when opening files in the autocall library. The DATA step always passes the extension .DATA. If you define a fileref for an autocall macro library and the files in that library have a file extension of .SAS, use the FILEEXT option. If the files in that library do not have an extension, do not use the FILEEXT option. For example, if you define a fileref for an input file in the DATA step and the file X has an extension of .DATA, you would use the FILEEXT option to read the file X.DATA. If you use the INFILE or FILE statement, enclose the member name and extension in quotation marks to preserve case.

Tip: The FILEEXT option is ignored if you specify a file extension on the FILE or INFILE statement.

See: “LOWCASE_MEMNAME” on page 130

LOWCASE_MEMNAME

enables autocall macro retrieval of lowercase directory or member names from HDFS systems.

Restriction: SAS autocall macro retrieval always searches for uppercase directory member names. Mixed-case directory or member names are not supported.

See: “FILEEXT” on page 130

LRECL=logical-record-length

specifies the logical record length of the data.

Default: 65536

Interaction: Alternatively, you can specify a global logical record length by using the LRECL= system option. For more information, see SAS System Options: Reference

MOD

places the file in Update mode and appends updates to the bottom of the file.

PASS=password

specifies the password to use with the user name that is specified in the USER option.

Requirement: The password is case sensitive and it must be enclosed in single or double quotation marks.

Tip: To use an encoded password, use the PWENCODE procedure in order to disguise the text string, and then enter the encoded password for the PASS= option. For more information see the PWENCODE procedure in the Base SAS Procedures Guide.

PROMPT

specifies to prompt for the user login, the password, or both, if necessary.

Interaction: The USER= and PASS= options override the PROMPT option if all three options are specified. If you specify the PROMPT option and do not
specify the USER= or PASS= option, you are prompted for a user ID and password.

**RECFM=record-format**
where record-format is one of three record formats:

- **S**
  - is stream-record format. Data is read in binary mode.
  - **Tip:** The amount of data that is read is controlled by the current LRECL value or the value of the NBYTE= variable in the INFILE statement. The NBYTE= option specifies a variable that is equal to the amount of data to be read. This amount must be less than or equal to LRECL. To avoid problems when you read large binary files like PDF or GIF, set NBYTE=1 to read one byte at a time.
  - **See:** The NBYTE= option in the INFILE statement in the SAS Statements: Reference

- **F**
  - is fixed-record format. In this format, records have fixed lengths, and they are read in binary mode.

- **V**
  - is variable-record format (the default). In this format, records have varying lengths, and they are read in text (stream) mode.
  - **Tip:** Any record larger than LRECL is truncated.
  - **Default:** V

**USER='username'**
where username is used to log on to the Hadoop system.

**Requirement:** The user name is case sensitive and it must be enclosed in single or double quotation marks.

### Details

An HDFS system has defined levels of permissions at both the directory and file level. The Hadoop access method honors those permissions. For example, if a file is available as read-only, you cannot modify it.

**Operating Environment Information**

Using the FILENAME statement requires information that is specific to your operating environment. The Hadoop access method is fully documented here. For more information about how to specify filenames, see the SAS documentation for your operating environment.

### Examples

#### Example 1: Writing to a New Member of a Directory

This example writes the file shoes to the directory testing.

```sas
filename out hadoop '/user/testing/' cfg="/path/cfg.xml" user='xxxx' pass='xxxx' recfm=v lrecl=32167 dir ;

data _null_;  
  file out(shoes) ;  
  put 'write data to shoes file';  
run;
```
Example 2: Creating and Using a Configuration File
This example accesses the file `acctdata.dat` at site `xxx.unx.sas.com`. The configuration file is accessed from the “cfg” fileref assignment.

```sas
filename cfg 'U:/test.cfg';

data _null_;
  file cfg;
  input;
  put _infile_;
  datalines4;
  <configuration>
    <property>
      <name>fs.default.name</name>
      <value>hdfs://xxx.unx.sas.com:8020</value>
    </property>
    <property>
      <name>mapred.job.tracker</name>
      <value>xxx.unx.sas.com:8021</value>
    </property>
  </configuration>

filename foo hadoop '/user/xxxx/acctdata.dat' cfg=cfg user='xxxx'
  pass='xxxx' debug recfm=s lrecl=65536 bufferlen=65536;

data _null_;
  infile foo truncover;
  input a $1024.;
  put a;
run;
```

Example 3: Buffering 1MB of Data during a File Read
This example uses the BUFFERLEN option to buffer 1MB of data at time during the file read. The records of length 1024 are read from this buffer.

```sas
filename foo hadoop '/user/xxxx/acctdata.dat' cfg=cfg user='xxxx'
  pass='xxxx' debug recfm=s lrecl=65536 bufferlen=65536;

data _null_;
  infile foo truncover;
  input a $1024.;
  put a;
run;
```

Example 4: Using the CONCAT Option
This example uses the CONCAT option to read all members of DIRECTORY1 as if they are one file.

```sas
filename foo hadoop '/directory1/' cfg='U=/hadoopcfg.xml' user='user' pass='apass' recfm=s lrecl=1024 bufferlen=1000000;

data _null_;
  infile foo truncover;
  input a $1024.;
  put a;
run;
```
FILENAME Statement, SFTP Access Method

Enables you to access remote files by using the SFTP protocol.

Valid in: Anywhere
Category: Data Access

Syntax
FILENAME fileref SFTP 'external-file' <sftp-options>;

Arguments
fileref
is a valid fileref.

Tip: The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement. You can change the fileref for a file as often as you want.

SFTP
specifies the access method that enables you to use Secure File Transfer Protocol (SFTP) to read from or write to a file from any host computer that you can connect to on a network with an OpenSSH SSHD server running.

'external-file'
specifies the physical name of an external file that you want to read from or write to. The physical name is the name that is recognized by the operating environment.

Operating environment: For details about specifying the physical names of external files, see the SAS documentation for your operating environment.

Tips:
If you are not transferring a file but performing a task such as retrieving a directory listing, then you do not need to specify an external filename. Instead, put empty quotation marks in the statement.
You can associate a fileref with a single file or with an aggregate file storage location.

sftp-options
specifies details that are specific to your operating environment such as file attributes and processing attributes.

Operating environment: For more information about some of these SFTP options, see the SAS documentation for your operating environment.

See: “SFTP Options” on page 134

SFTP Options
sftp-options can be any of the following values:

BATCHFILE='path'
specifies the fully qualified pathname and the filename of the batch file that contains the SFTP commands. These commands are submitted when the SFTP access method is executed. After the batch file processing ends, the SFTP connection is closed.

Requirement: The path must be enclosed in quotation marks.

Tip: After the batch file processing ends, the SFTP connection is closed and the filename assignment is no longer available. If subsequent DATA step processing requires the FILENAME SFTP statement, then another FILENAME SFTP statement is required.

Example: “Example 5: Using a Batch File” on page 138

CD='directory'
issues a command that changes the working directory for the file transfer to the directory that you specify.

DEBUG
writes informational messages to the SAS log.

DIR
enables you to access directory files. Specify the directory name in the external-file argument. You must use valid directory syntax for the specified host.

Interaction: The CD and DIR options are mutually exclusive. If both are specified, SFTP ignores the CD option and SAS writes an informational note to the log.

Tips:
If you want SFTP to create the directory, then use the NEW option in conjunction with the DIR option. The NEW option will be ignored if the directory exists.
If the NEW option is omitted and you specify an invalid directory, then a new directory will not be created and you will receive an error message.

HOST='host'
where host is the network name of the remote host with the OpenSSH SSHD server running.

You can specify either the name of the host (for example, server.pc.mydomain.com) or the IP address of the computer (for example, 2001:db8::).

LRECL=lrecl
where lrecl is the logical record length of the data.

Default: 256
Interaction: Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in SAS System Options: Reference.
LS
issues the LS command to the SFTP server. LS returns the contents of the working directory as records with no file attributes.

Restriction: The LS option will not display files with leading periods, for example .xAuthority.

Interaction: The LS and LSA options are mutually exclusive. If you specify both options, the LSA option takes precedence.

Tip: To return a listing of a subset of files, use the LSFILE= option in addition to LS.

LSA
issues the LS command to the SFTP server. LSA returns all the contents of the working directory as records with no file attributes.

Interactions:
The LS and LSA options are mutually exclusive. If you specify both options, the LSA option takes precedence.
To display files without leading periods, for example .xAuthority, use the LS= option.

Tip: To return a listing of a subset of files, use the LSFILE= option in addition to LSA.

LSFILE='character-string'
in combination with the LS option, specifies a character string that enables you to request a listing of a subset of files from the working directory. Enclose the character string in quotation marks.

Restriction: LSFILE= can be used only if LS or LSA is specified.

Tip: You can specify a wildcard as part of 'character-string'.

Example: This statement lists all of the files that start with sales and end with sas:

filename myfile sftp " ls lsfile='sales*.sas'
other-sftp-options;

MGET
transfers multiple files, similar to the SFTP command MGET.

Tip: The whole transfer is treated as one file. However, as the transfer of each new file is started, the EOV= variable is set to 1.

NEW
specifies that you want SFTP to create the directory when you use the DIR option.

Restriction: The NEW option is not available under z/OS.

Tip: The NEW option will be ignored if the directory exists.

OPTIONS=
specifies SFTP configuration options such as port numbers.

PATH
specifies the location of the SFTP executable if it is not installed in the PATH or $PATH search path.

Tip: It is recommended that the OpenSSH “SFTP” executable or PUTTY “PSFTP” executable be installed in a directory that is accessible via the PATH or $PATH search path.

RECFM=recfm
where recfm is one of two record formats:

F
is fixed-record format. Thus, all records are of size LRECL with no line delimiters.
V is variable-record format (the default). In this format, records have varying lengths, and they are separated by newlines. Data is transferred in image (binary) mode.

Default: V

USER='username'
specifies the user name.

Requirement: The username is required by the PUTTY client on the Windows host.

Tips:
The username is not typically required on LINUX or UNIX hosts when using public key authentication.
Public key authentication using an SSH agent is the recommended way to connect to a remote SSHD server.

WAIT_MILLISECONDS=milliseconds
specifies the SFTP response time in milliseconds.

Default: 1,500 milliseconds

Tip: If you receive a time-out message in the log, use the WAIT_MILLISECONDS option to increase the response time.

Details

The Basics
The Secure File Transfer Protocol (SFTP) provides a secure connection and file transfers between two hosts (client and server) over a network. Both commands and data are encrypted. The client machine initiates a connection with the remote host (OpenSSH SSHD server).

With the SFTP access method, you can read from or write to any host computer that you can connect to on a network with an OpenSSH SSHD server running. The client and server applications can reside on the same computer or on different computers that are connected by a network.

Specific implementation details are dependent on the OpenSSH SSHD server version and how that site is configured.

The SFTP access method relies on default send and reply messages to OpenSSH commands. Custom installs of OpenSSH that modify these messages will disable the SFTP access method.

You must have the applicable client software installed to use the SFTP access method. The SFTP access method supports only the following SSH clients.

- OpenSSH – UNIX
- PUTTY – Windows

Note: Password validation is not supported for the SFTP access method.

Note: Public key authentication using an SSH agent is the recommended way to connect to a remote SSHD server.

Note: If you have trouble running the SFTP access method try to manually validate SFTP client access to an OpenSSH SSHD server without involving the SAS system. Manually validating SFTP client access without involving the SAS system will ensure that your SSH/SSHD configuration and key authentication is setup correctly.
**SFTP Access Methods and SFTP Prompts**

The SFTP access method supports only the following prompts. Changing the prompt will disable the SFTP access method.

- For OpenSSH:
  
  - `sftp>`
  - `sftp >`

- For PUTTY:
  
  - `psftp>`

**Comparisons**

As with the SFTP `get` and `put` commands, the SFTP access method lets you download and upload files. However, this method directly reads files into your SAS session without first storing them on your system.

**Examples**

**Example 1: Connecting to an SSHD Server at a Standard Port**

This example reads a file called `test.dat` using the SFTP access method after connecting to the SSHD server a standard port:

```sas
filename myfile sftp '/users/xxxx/test.dat' host="unixhost1";
data _null_;  
infile myfile truncover;  
input a $25.;  
run;
```

**Example 2: Connecting to an SSHD Server at a Nonstandard Port**

This example reads a file called `test.dat` using the SFTP access method after connecting to the SSHD server at port 4117:

```sas
filename myfile sftp '/users/xxxx/test.dat' host="unixhost1" options="-oPort=4117";
data _null_;  
infile myfile truncover;  
input a $25.;  
run;
```

**Example 3: Connecting a Windows PUTTY Client to an SSHD Server**

This example writes a file called `test.dat` using the SFTP access method after connecting a Windows PUTTY client to the SSHD server with a user ID of `userid`:

```sas
filename outfile sftp '/users/xxxx/test.dat' host="unixhost1" user="userid";
data _null_;  
file outfile;  
do i=1 to 10;  
  put i=;  
end;  
run;
```
Example 4: Reading Files from a Directory on the Remote Host
This example reads the files test.dat and test2.dat from a directory on the remote host.

```sas
filename infile sftp '/users/xxxx/' host="unixhost1" dir;
data _null_;
infile infile(test.dat) truncover;
input a $25.;
infile infile(test2.dat) truncover;
input b $25.;
run;
```

Example 5: Using a Batch File
In this example, when the INFILE statement is processed, the batch file associated with the FILENAME SFTP statement, sftpcmds, is executed.

```sas
filename process sftp ' ' host="unixhost1" user="userid" batchfile="c:/stfpdir/sftpcmds.bat";
data _null_;
infile process;
run;
```

- “FILENAME Statement, Hadoop Access Method” on page 128
- “FILENAME Statement, JMS Access Method” in Application Messaging with SAS
- “FILENAME Statement, SOCKET Access Method” on page 138
- “FILENAME Statement, URL Access Method” on page 142
- “LIBNAME Statement” on page 239

FILENAME Statement, SOCKET Access Method
Enables you to read from or write to a TCP/IP socket.

Valid in: Anywhere
Category: Data Access

Syntax
Form 1: `FILENAME fileref SOCKET 'hostname:portno' <tcpip-options>`;
FILENAME Statement, SOCKET Access Method

Form 2:  
FILENAME fileref SOCKET ':portno' SERVER
        <tcpip-options>;

**Arguments**

*fileref*  
is a valid fileref.

  **Tip:** The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement. You can change the fileref for a file as often as you want.

*SOCKET*  
specifies the access method that enables you to read from or write to a Transmission Control Protocol/Internet Protocol (TCP/IP) socket.

*hostname:*portno*
  
is the name or IP address of the host and the TCP/IP port number to connect to.

  **Tip:** Use this specification for client access to the socket.

*':portno'*  
is the port number to create for listening.

  **Tips:**
  
  Use this specification for server mode.

  If you specify :0, the system will choose a number.

*SERVER*  
sets the TCP/IP socket to be a listening socket, thereby enabling the system to act as a server that is waiting for a connection.

  **Tip:** The system accepts all connections serially; only one connection is active at any one time.

  **See:** The RECONN= option on page 140 under TCPIP Options.

*tcpip-options*  
specifies details that are specific to your operating system such as the number of connections that the server will accept.

**Operating Environment Information**

For more information about some of these TCP/IP options, see the SAS documentation for your operating environment.

  **See:** “TCP/IP Options” on page 139

**TCP/IP Options**

*tcpip-options* can be any of the following values:

**BLOCKSIZE=**blocksize
  
  where blocksize is the size of the socket data buffer in bytes.

  **Default:** 8192

**ENCODING=**encoding-value
  
specifies the encoding to use when reading from or writing to the socket. The value for ENCODING= indicates that the socket has a different encoding from the current session encoding.

  When you read data from a socket, SAS transcodes the data from the specified encoding to the session encoding. When you write data to a socket, SAS transcodes the data from the session encoding to the specified encoding.

**LRECL=**\( \text{lrecl} \)

where \( \text{lrecl} \) is the logical record length.

**Default:** 256

**Interaction:** Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in *SAS System Options: Reference*.

**RECFM=**\( \text{recfm} \)

where \( \text{recfm} \) is one of three record formats:

- **F** is fixed record format. Thus, all records are of size LRECL with no line delimiters. Data are transferred in image (binary) mode.

- **S** is stream record format.

  **Interaction:** The amount of data that is read is controlled by the current LRECL value or the value of the NBYTE= variable in the INFILE statement. The NBYTE= option specifies a variable equal to the amount of data to be read. This amount must be less than or equal to LRECL.

  **Tip:** Data are transferred in image (binary) mode.

  **See:** The NBYTE= option on page 179 in the INFILE statement.

- **V** is variable record format (the default).

  **Tips:**

  In this format, records have varying lengths, and they are transferred in text (stream) mode.

  Any record larger than LRECL is truncated.

  **Default:** V

**RECONN=**\( \text{conn-limit} \)

where \( \text{conn-limit} \) is the maximum number of connections that the server will accept.

**Note:** Because only one connection can be active at a time, a connection must be disconnected before the server can accept another connection. When a new connection is accepted, the EOV= variable is set to 1. The server will continue to accept connections, one at a time, until \( \text{conn-limit} \) has been reached.

**TERMSTR=’**\( \text{eol-char} \)’

where \( \text{eol-char} \) is the line delimiter to use when RECFM=V. There are three valid values:

- **CRLF**
  carriage return (CR) followed by line feed (LF).

- **LF**
  line feed only (the default).

- **NULL**
  NULL character (0x00).

  **Default:** LF

**Restriction:** Use this option only when RECFM=V.
Details

The Basics
A TCP/IP socket is a communication link between two applications. The server application creates the socket and waits for a connection. The client application connects to the socket. With the SOCKET access method, you can use SAS to communicate with another application over a socket in either client or server mode. The client and server applications can reside on the same computer or on different computers that are connected by a network.

For example, you can develop an application using Microsoft Visual Basic that communicates with a SAS session that uses the TCP/IP sockets. Note that Visual Basic does not provide inherent TCP/IP support. You can obtain a custom control (VBX) from SAS Technical Support (free of charge) that allows a Visual Basic application to communicate through the sockets.

Using the SOCKET Access Method in Client Mode (Form 1)
In client mode, a local SAS application can use the SOCKET access method to communicate with a remote application that acts as a server (and waits for a connection). Before you can connect to a server, you must know:

- the network name or IP address of the host computer running the server.
- the port number that the remote application is listening to for new connections.

The remote application can be another SAS application, but it does not need to be. When the local SAS application connects to the remote application through the TCP/IP socket, the two applications can communicate by reading from and writing to the socket as if it were an external file. If at any time the remote side of the socket is disconnected, the local side will also automatically terminate.

Using the SOCKET Access Method in Server Mode (Form 2)
When the local SAS application is in server mode, it remains in a wait state until a remote application connects to it. To use the SOCKET access method in server mode, you need to know only the port number that you want the server to listen to for a connection. Typically, servers use well-known ports to listen for connections. These port numbers are reserved by the system for specific server applications. For more information about how well-known ports are defined on your system, refer to the documentation for your TCP/IP software or ask your system administrator.

If the server application does not use a well-known port, then the system assigns a port number when it establishes the socket from the local application. However, because any client application that waits to connect to the server must know the port number, you should try to use a well-known port.

While a local SAS server application is waiting for a connection, SAS is in a wait state. Each time a new connection is established, the EOV= variable in the DATA step is set to 1. Because the server accepts only one connection at a time, no new connections can be established until the current connection is closed. The connection closes automatically when the remote client application disconnects. The SOCKET access method continues to accept new connections until it reaches the limit set in the RECONN option.
Example: Communicating between Two SAS Applications over a TCP/IP Socket

This example shows how two SAS applications can talk over a TCP/IP socket. The local application is in server mode; the remote application is the client that connects to the server. This example assumes that the server host name is hp720.unx.sas.com, that the well-known port number is 5000, and that the server allows a maximum of three connections before closing the socket.

Here is the program for the server application:

```sas
filename local socket ':5000' server reconn=3;
   /*The server is using a reserved port number of 5000.*/
   data tcpip;
      infile local eov=v;
      input x $10;
      if v=1 then
         do; /* new connection when v=1 */
            put 'new connection received';
            end;
         output;
      run;
```

Here is the program for the remote client application:

```sas
filename remote socket 'hp720.unx.sas.com:5000';
data _null_;  
file remote;
   do i=1 to 10;
      put i;
   end;
run;
```

FILENAME Statement, URL Access Method

Enables you to access remote files by using the URL access method.

**Valid in:** Anywhere

**Category:** Data Access
Syntax
FILENAME fileref URL 'external-file' <url-options>;

Arguments
fileref

is a valid fileref.

Tip: The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement. You can change the fileref for a file as often as you want.

URL

specifies the access method that enables you to read a file from any host computer that you can connect to on a network with a URL server running.

Alias: HTTP

'external-file'

specifies the name of the file that you want to read from on a URL server. The Secure Socket Layer (SSL) protocol, https, can also be used to access the files. The file must be specified in one of these formats:

• http://hostname/file
• https://hostname/file
• http://hostname:portno/file
• https://hostname:portno/file

Operating environment: For details about specifying the physical names of external files, see the SAS documentation for your operating environment.

URL Options

url-options can be any of the following values:

AUTHDOMAIN="auth-domain"

specifies the name of an authentication domain metadata object in order to connect to the proxy or Web server. The authentication domain references credentials (user ID and password) without your having to explicitly specify the credentials. The auth-domain name is case sensitive, and it must be enclosed in double quotation marks.

An administrator creates authentication domain definitions while creating a user definition with the User Manager in SAS Management Console. The authentication domain is associated with one or more login metadata objects that provide access to the proxy or Web server and is resolved by the BASE engine calling the SAS Metadata Server and returning the authentication credentials.

Requirement: The authentication domain and the associated login definition must be stored in a metadata repository, and the metadata server must be running in order to resolve the metadata object specification.

Interaction: If you specify AUTHDOMAIN=, you do not need to specify USER= and PASS=.

See: For more information about creating and using authentication domains, see the discussion on credential management in the SAS Intelligence Platform: Security Administration Guide.

BLOCKSIZE=blocksize

where blocksize is the size of the URL data buffer in bytes.

Default: 8K
DEBUG
writes debugging information to the SAS log.

Tip: The result of the HELP command is returned as records.

HEADERS=fileref
specifies the fileref to which the header information is written when a file is opened by using the URL access method. The header information is the same information that is written to the SAS log.

Requirement: The fileref must be defined in a previous FILENAME statement.

Interactions:
If you specify the HEADERS= option without specifying the DEBUG option, the DEBUG option is automatically turned on.
By default, log information is overwritten. To append the log information, you must specify the MOD option in the FILENAME statement that creates the fileref.

LRECL=lrecl
where lrecl is the logical record length of the data.

Default: 256

Interaction: Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in SAS System Options: Reference.

PASS='password'
where password is the password to use with the user name that is specified in the USER option.

Tips:
You can specify the PROMPT option instead of the PASS option, which tells the system to prompt you for the password.
To use an encoded password, use the PWENCODE procedure in order to disguise the text string, and then enter the encoded password for the PASS= option. For more information, see Chapter 3, “PWENCODE Procedure” in Encryption in SAS.

PPASS='password'
where password is the password to use with the user name that is specified in the PUSER option. The PPASS option is used to access the proxy server.

Tips:
You can specify the PROMPT option instead of the PPASS option, which tells the system to prompt you for the password.
To use an encoded password, use the PWENCODE procedure to disguise the text string, and then enter the encoded password for the PASS= option. For more information, see Chapter 3, “PWENCODE Procedure” in Encryption in SAS.

PROMPT
specifies to prompt for the user login password if necessary.

Tip: If you specify PROMPT, you do not need to specify PASS= or PPASS=.

PROXY=url
specifies the Uniform Resource Locator (URL) for the proxy server in one of these forms:

http://hostname/
http://hostname:portno/

PUSER='username'
where username is used to log on to the URL proxy server.
Interactions:
If you specify the PUSER option, the USER option goes to the Web server regardless of whether you specify a proxy server.
If PROMPT is specified, but PUSER is not, the user is prompted for an ID as well as a password.

Tip: If you specify user=’*’, then the user is prompted for an ID.

RECFM=recfm
where recfm is one of three record formats:

F
is fixed-record format. Thus, all records are of size LRECL with no line delimiters. Data is transferred in image (binary) mode.

S
is stream-record format. Data is transferred in image (binary) mode.

Alias: N

Tip: The amount of data that is read is controlled by the current LRECL value or the value of the NBYTE= variable in the INFILE statement. The NBYTE= option specifies a variable that is equal to the amount of data to be read. This amount must be less than or equal to LRECL.

See: The NBYTE= option on page 179 in the INFILE statement.

V
is variable-record format (the default). In this format, records have varying lengths, and they are transferred in text (stream) mode.

Tip: Any record larger than LRECL is truncated.

Default: V

TERMSTR='eol-char'
where eol-char is the line delimiter to use when RECFM=V. There are four valid values:

CR carriage return (CR).
CRLF carriage return (CR) followed by line feed (LF).
LF line feed only (the default).
NULL NULL character (0x00).

Default: LF

Restriction: Use this option only when RECFM=V.

USER='username'
where username is used to log on to the URL server.

Interactions:
If you specify the USER option but do not specify the PUSER option, where the USER option goes depends on whether you specify a proxy server. If you do not specify a proxy server, USER goes to the Web server. If you do specify a proxy server, USER will go to the proxy server.

If you specify the PUSER option, the USER option goes to the Web server regardless of whether you specify a proxy server.

If PROMPT is specified, but USER or PUSER is not, the user is prompted for an ID as well as a password.

Tip: If you specify user=’*’, then the user is prompted for an ID.
Details

The Secure Sockets Layer (SSL) protocol is used when the URL begins with “https” instead of “http”. The SSL protocol provides network security and privacy. Developed by Netscape Communications, SSL uses encryption algorithms that include RC2, RC4, DES, tripleDES, IDEA, and MD5. Not limited to providing only encryption services, SSL can also perform client and server authentication and use message authentication codes. SSL is supported by both Netscape Navigator and Internet Explorer. Many Web sites use the protocol to provide confidential user information such as credit card numbers. The SSL protocol is application independent, enabling protocols such as HTTP, FTP, and Telnet to be layered transparently above it. SSL is optimized for HTTP.

Operating Environment Information

Using the FILENAME statement requires information that is specific to your operating environment. The URL access method is fully documented here, but for more information about how to specify filenames, see the SAS documentation for your operating environment.

Examples

Example 1: Accessing a File at a Web Site

This example accesses document test.dat at site www.a.com:

```sas
filename foo url 'http://www.a.com/test.dat'
   proxy='http://www.gt.sas.com';
```

Example 2: Specifying a User ID and a Password

This example accesses document file1.html at site www.b.com using the SSL protocol and requires a user ID and password:

```sas
filename foo url 'https://www.b.com/file1.html'
   user='jones' prompt;
```

Example 3: Reading the First 15 Records from a URL File

This example reads the first 15 records from a URL file and writes them to the SAS log with a PUT statement:

```sas
filename foo url
   'http://support.sas.com/techsup/service_intro.html';

data _null_;
   infile foo length=len;
   input record $varying200. len;
   put record $varying200. len;
   if _n_<=15 then stop;
run;
```

Statements:

- “FILENAME Statement” on page 93
- “FILENAME Statement, CATALOG Access Method” on page 100
FILENAME Statement, WebDAV Access Method

Enables you to access remote files by using the WebDAV protocol.

Valid in: Anywhere
Category: Data Access
Restriction: Access to WebDAV servers is not supported on Open VMS.

Syntax

FILENAME fileref WEBDAV 'external-file' <webdav-options>;

Arguments

fileref
is a valid fileref.

Tip: The association between a fileref and an external file lasts only for the duration of the SAS session or until you change it or discontinue it with another FILENAME statement. You can change the fileref for a file as often as you want.

WEBDAV
specifies the access method that enables you to use WebDAV (Web Distributed Authoring and Versioning) to read from or write to a file from any host machine that you can connect to on a network with a WebDAV server running.

'external-file'
specifies the name of the file that you want to read from or write to a WebDAV server. The external file must be in one of these forms:

http://hostname/path-to-the-file
https://hostname/path-to-the-file
http://hostname:port/path-to-the-file
https://hostname:port/path-to-the-file

Requirement: When using the HTTPS communication protocol, you must use the SSL (Secure Sockets Layer) protocol that provides secure network communications. For more information, see Encryption in SAS.

Operating environment: For details about specifying the physical names of external files, see the SAS documentation for your operating environment.
**WebDAV Options**

*webdav-options* can be any of the following:

**DEBUG**

writes debugging information to the SAS log.

**DIR**

enables you to access directory files. Specify the directory name in the external-file argument. You must use valid directory syntax for the specified host.

**Tip:** See the `FILEEXT` option on page 148 for information about specifying filename extensions.

**ENCODING='encoding-value'**

specifies the encoding to use when SAS is reading from or writing to an external file. The value for ENCODING= indicates that the external file has a different encoding from the current session encoding.

When you read data from an external file, SAS transcodes the data from the specified encoding to the session encoding. When you write data to an external file, SAS transcodes the data from the session encoding to the specified encoding.

**Default:** SAS assumes that an external file is in the same encoding as the session encoding.

**See:** “Encoding Values in SAS Language Elements” in Chapter 20 of *SAS National Language Support (NLS): Reference Guide*

**FILEEXT**

specifies that a file extension is automatically appended to the filename when you use the DIR option.

**Interaction:** The autocall macro facility always passes the extension .SAS to the file access method as the extension to use when opening files in the autocall library. The DATA step always passes the extension .DATA. If you define a fileref for an autocall macro library and the files in that library have a file extension of .SAS, use the FILEEXT option. If the files in that library do not have an extension, do not use the FILEEXT option. For example, if you define a fileref for an input file in the DATA step and the file X has an extension of .DATA, you would use the FILEEXT option to read the file X.DATA. If you use the INFILE or FILE statement, enclose the member name and extension in quotation marks to preserve case.

**Tip:** The FILEEXT option will be ignored if you specify a file extension in the FILE or INFILE statement.

**See:** `LOWCASE_MEMNAME` option on page 148

**LOCALCACHE="directory name"**

specifies a directory where a temporary subdirectory is created to hold local copies of the server files. Each fileref has its own unique subdirectory. If a directory is not specified, then the subdirectories are created in the SAS Work directory. SAS deletes the temporary files when the SAS program completes.

**Default:** SAS Work directory

**LOCKDURATION=n**

specifies the number of minutes that the files that are written through the WebDAV fileref are locked. SAS unlocks the files when the SAS program successfully finishes executing. If the SAS program fails, then the locks expire after the time allotted.

**Default:** 30 minutes

**LOWCASE_MEMNAME**

enables autocall macro retrieval of lowercase directory or member names from WebDAV servers.
Restriction: SAS autocall macro retrieval always searches for uppercase directory member names. Mixed-case directory or member names are not supported.

See: FILEEXT option on page 148

**LRECL=**`lrecl`

where `lrecl` is the logical record length of the data.

Default: 256

Interaction: Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in *SAS System Options: Reference*.

**MOD**

Places the file in Update mode and appends updates to the bottom of the file.

**PASS=**`password`

where `password` is the password to use with the user name that is specified in the USER option. The password is case sensitive and it must be enclosed in single or double quotation marks.

Alias: PASSWORD=, PW=, PWD=

Tip: To use an encoded password, use the PWENCODE procedure in order to disguise the text string, and then enter the encoded password for the PASS= option. For more information, see Chapter 3, “PWENCODE Procedure” in *Encryption in SAS*.

**PROMPT**

specifies to prompt for the user logon password, if necessary.

Interaction: The USER= and PASS= options override the PROMPT option if all three options are specified. If you specify the PROMPT option and do not specify the USER= or PASS= option, you will be prompted for a user ID and password.

**PROXY=**`url`

specifies the Uniform Resource Locator (URL) for the proxy server in one of these forms:

```
http://hostname/
http://hostname:port/
```

**RECFM=**`recm`

where `recm` is one of two record formats:

- **S**
  - is stream-record format. Data is transferred in image (binary) mode.
  - Tip: The amount of data that is read is controlled by the current LRECL value or the value of the NBYTE= variable in the INFILE statement. The NBYTE= option specifies a variable that is equal to the amount of data to be read. This amount must be less than or equal to the LRECL. To avoid problems when you transfer large binary files such as PDF or GIF, set NBYTE=1 to transfer one byte at a time.
  - See: The NBYTE= option on page 179 in the INFILE statement.

- **V**
  - is variable-record format (the default). In this format, records have varying lengths, and they are transferred in text (stream) mode.
  - Tip: Any record larger than LRECL is truncated.

Default: V
USER='username'
where username is used to log on to the URL server. The user ID is case sensitive
and it must be enclosed in single or double quotation marks.

Alias: UID=

Details
When you access a WebDAV server to update a file, the file is pulled from the
WebDAV server to your local disk storage for processing. When this processing is
complete, the file is pushed back to the WebDAV server for storage. The file is removed
from the local disk storage when it is pushed back.

The Secure Sockets Layer (SSL) protocol is used when the URL begins with “https”
instead of “http”. The SSL protocol provides network security and privacy. Developed
by Netscape Communications, SSL uses encryption algorithms that include RC2, RC4,
DES, tripleDES, IDEA, and MD5. Not limited to providing only encryption services,
SSL can also perform client and server authentication and use message authentication
codes. SSL is supported by both Netscape Navigator and Internet Explorer. Many Web
sites use the protocol to provide confidential user information such as credit card
numbers. The SSL protocol is application independent, which enables protocols such as
HTTP, FTP, and Telnet to be layered transparently above it. SSL is optimized for HTTP.

Note: WebDAV servers have defined levels of permissions at both the directory and file
level. The WebDAV access method honors those permissions. For example, if a file
is available as read-only, the user will not be able to modify it.

Operating Environment Information
Using the FILENAME statement requires information that is specific to your
operating environment. The WebDAV access method is fully documented here, but
for more information about how to specify filenames, see the SAS documentation for
your operating environment.

Examples

Example 1: Accessing a File at a Web Site
This example accesses the file rawFile.txt at site www.mycompany.com.

filename foo webdav 'https://www.mycompany.com/production/files/rawFile.txt'
  user='wong' pass='jd751d';
data _null_;
  infile foo;
  input a $80.;
run;

Example 2: Using a Proxy Server
This example accesses the file acctgfile.dat by using the proxy server
otherwebsvr:80.

filename foo webdav 'https://webserver.com/webdav/acctgfile.dat'
  user='sanchez' pass='239sk349exz'
  proxy='http://otherwebsvr.com:80';
data _null_;
  infile foo;
  input a $80.;
run;
Example 3: Writing to a New Member of a Directory
This example writes the file SHOES to the directory TESTING.

```sas
filename writeit webdav
  "https://webserver.com:8443/webdav/testing/"
  dir user="webuser" pass=XXXXXXXXX;
  data _null_
    file writeit(shoes);
    set sashelp.shoes;
    put region $25. product $14.;
  run;
```

Example 4: Reading from a Member of a Directory
This example reads the file SHOES from the directory TESTING1.

```sas
filename readit webdav
  "https://webserver.com:8443/webdav/testing1/"
  dir user="webuser" pass=XXXXXXXXX;
  data shoes;
  length region $25  product $14;
  infile readit(shoes);
  input region $25. product $14.;
  run;
```

Example 5: Using a WebDAV Location as an Autocall Macro Library
By default, the autocall macro facility expects uppercase filenames. This example accesses the file MYTEST in the autocall macro library WRITEIT.

```sas
filename writeit webdav
  "https://webserver.com/webdav/macrolib"
  dir fileext user="webuser" pass=XXXXXXXXX;
  options SASAUTOS=(writeit);
  /* expects a file called MYTEST.SAS */
  %MYTEST;
```

Example 6: Accessing a Lowercased Autocall Macro Member
The following example accesses the file testmem.sas in the autocall macro library LIST. The LOWCASE_MEMNAME option is used to access the file, which is in lowercase.

```sas
filename list webdav "https://t1234.na.fyi.com:8443/accounting/"
  dir fileext user="xxxxx" pass="xxxxx" LOWCASE_MEMNAME;
  options sasautos=(list);
  %testmem;
```

Example 7: Using a %INCLUDE Statement and Macro Invocation to Access a Lowercased Autocall Macro Member
The following example accesses the file testmem.sas in the autocall macro library MYTEST. Because the file is accessed by using the %INCLUDE statement, case sensitivity is preserved.

```sas
filename mytest webdav "https://t1234.na.fyi.com:8443/payroll/"
  dir user="xxxxxx" pass="xxxxx";
  %include mytest(testmem.sas) /source2;
  %testmem;
```
If the filename was in uppercase, the reference to the filename in the `%INCLUDE statement and macro call needs to be uppercase.

```
%include mytest(TESTMEM.SAS) /source2;
%TESTMEM;
```

**Example 8: Accessing a File with a Mixed-Case Name**

The following example accesses the file `fileNOext` from the `production` directory. Because the file is quoted in the INFILE statement, case sensitivity is preserved and the file extension is ignored.

```
filename test webdav "https://t1234.na.fyi.com:8443/production"
   dir user="xxxxxx" pass="xxxxx";
data _null_;
   infile test('fileNOext');
   input;
   list;
run;
```

**Example 9: Using the FILEEXT Option to Automatically Attach a File Extension**

The following example accesses the file `testmem.sas` from the `sales` directory. The FILEEXT option automatically adds `.DATA` as the file extension. The member name that is read is `testmem.DATA`.

```
filename listing webdav "https://t1234.na.fyi.com:8443/sales"
   dir fileext user="xxxxxx" pass="xxxxx";
data _null_;
   infile listing(testmem);
   input;
   list;
run;
```

**FOOTNOTE Statement**

Writes up to 10 lines of text at the bottom of the procedure or DATA step output.
Valid in: Anywhere
Category: Output Control
Requirement: You must specify the FOOTNOTE option if you use a FILE statement.
See: FOOTNOTE Statement under Windows, UNIX, and z/OS

Syntax

FOOTNOTE<n> <ods-format-options> <text | “text”> ;

Without Arguments
Using FOOTNOTE without arguments cancels all existing footnotes.

Arguments

n
specifies the relative line to be occupied by the footnote.
Default: If you omit n, SAS assumes a value of 1.
Range: n can range from 1 to 10.
Tip: For footnotes, lines are pushed up from the bottom. The FOOTNOTE statement with the highest number appears on the bottom line.

ods-format-options
specifies formatting options for the ODS HTML, RTF, and PRINTER(PDF) destinations.

BOLD
specifies that the footnote text is bold font weight.

ODS destination: HTML, RTF, PRINTER

COLOR=color
specifies the footnote text color.

Alias: C

ODS destination: HTML, RTF, PRINTER

Example: “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373

BCOLOR=color
specifies the background color of the footnote block.

ODS destination: HTML, RTF, PRINTER

FONT=font-face
specifies the font to use. If you supply multiple fonts, then the destination device uses the first one that is installed on your system.

Alias: F

ODS destination: HTML, RTF, PRINTER

HEIGHT=size
specifies the point size.

Alias: H

ODS destination: HTML, RTF, PRINTER

Example: “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373
ITALIC
  specifies that the footnote text is in italic style.

**ODS destination**: HTML, RTF, PRINTER

**JUSTIFY**= CENTER | LEFT | RIGHT
  specifies justification.

  **CENTER**
  specifies center justification.

  **Alias**: C

  **LEFT**
  specifies left justification.

  **Alias**: L

  **RIGHT**
  specifies right justification.

  **Alias**: R

  **Alias**: J

  **ODS destination**: HTML, RTF, PRINTER

  **Example**: “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373

**LINK**="url"
  specifies a hyperlink.

**ODS destination**: HTML, RTF, PRINTER

  **Tip**: The visual properties for LINK= always come from the current style.

**UNDERLIN**= 0 | 1 | 2 | 3
  specifies whether the subsequent text is underlined. 0 indicates no underlining. 1, 2, and 3 indicates underlining.

  **Alias**: U

  **ODS destination**: HTML, RTF, PRINTER

  **Tip**: ODS generates the same type of underline for values 1, 2, and 3. However, SAS/GRAPH uses values 1, 2, and 3 to generate increasingly thicker underlines.

**Note**: The defaults for how ODS renders the FOOTNOTE statement come from style elements that relate to system footnotes in the current style. The FOOTNOTE statement syntax with **ods-format-options** is a way to override the settings that are provided by the current style. The current style varies according to the ODS destination. For more information about how to determine the current style, see “Understanding Styles, Style Elements, and Style Attributes” in Chapter 3 of **SAS Output Delivery System: User's Guide** and “Concepts: Styles and the TEMPLATE Procedure ” in Chapter 13 of **SAS Output Delivery System: User's Guide**.

**Tip**: You can specify these options by letter, word, or words by preceding each letter or word of the *text* by the option. For example, this code will make the footnote “Red, White, and Blue” appear in different colors.

```sas
footnote color=red "Red," color=white "White, and" color=blue "Blue";
```

**'text' | “text”**
  specifies the text of the footnote in single or double quotation marks

**Tips:**
For compatibility with previous releases, SAS accepts some text without quotation marks. When you write new programs or update existing programs, *always* enclose text in quotation marks.

If you use an automatic macro variable in the title text, you must enclose the title text in double quotation marks. The SAS macro facility will resolve the macro variable only if the text is in double quotation marks.

If you use single quotation marks (') or double quotation marks ("")) together (with no space in between them) as the string of text, SAS will output a single quotation mark (') or double quotation mark (""), respectively.

**Details**

A FOOTNOTE statement takes effect when the step or RUN group with which it is associated executes. After you specify a footnote for a line, SAS repeats the same footnote on all pages until you cancel or redefine the footnote for that line. When a FOOTNOTE statement is specified for a given line, it cancels the previous FOOTNOTE statement for that line and for all footnote lines with higher numbers.

**Operating Environment Information**

The maximum footnote length that is allowed depends on the operating environment and the value of the LINESIZE= system option. Refer to the SAS documentation for your operating environment for more information.

**Comparisons**

You can also create footnotes with the FOOTNOTES window. For more information, refer to the online Help for the window.

You can modify footnotes with the Output Delivery System. See “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373.

**Example: Using the FOOTNOTE Statement**

These examples of a FOOTNOTE statement result in the same footnote:

- footnote8 "Managers' Meeting";
- footnote8 'Managers'' Meeting';

These are examples of FOOTNOTE statements that use some of the formatting options for the ODS HTML, RTF, and PRINTER(PDF) destinations. For the complete example, see “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373.

footnote j=left height=20pt
color=red "Prepared *
c='#FF9900' "on";
footnote2 j=center color=blue
height=24pt "&SYSDATE9";
footnote3 link='http://support.sas.com' "SAS";

**See Also**

**Statements:**

- “TITLE Statement” on page 368
FORMAT Statement
Associates formats with variables.

Valid in: DATA step or PROC step
Category: Information
Type: Declarative

Syntax
 FORMAT variable-1 <…variable-n> <format> <DEFAULT=default-format>;
 FORMAT variable-1 <…variable-n> format <DEFAULT=default-format>;
 FORMAT variable-1 <…variable-n> format variable-1 <…variable-n> format;

Arguments

variable
  names one or more variables for SAS to associate with a format. You must specify at least one variable.
  Tip: To disassociate a format from a variable, use the variable in a FORMAT statement without specifying a format in a DATA step or in PROC DATASETS. In a DATA step, place this FORMAT statement after the SET statement. See “Example 3: Removing a Format” on page 159. You can also use PROC DATASETS.

format
  specifies the format that is listed for writing the values of the variables.
  Tip: Formats that are associated with variables by using a FORMAT statement behave like formats that are used with a colon modifier in a subsequent PUT statement. For details about using a colon modifier, see “PUT Statement, List” on page 319.

DEFAULT=default-format
  specifies a temporary default format for displaying the values of variables that are not listed in the FORMAT statement. These default formats apply only to the current DATA step; they are not permanently associated with variables in the output data set.
  A DEFAULT= format specification applies to
  • variables that are not named in a FORMAT or ATTRIB statement
  • variables that are not permanently associated with a format within a SAS data set
  • variables that are not written with the explicit use of a format.

Default: If you omit DEFAULT=, SAS uses BESTw. as the default numeric format and $w$. as the default character format.

Restriction: Use this option only in a DATA step.

Tip: A DEFAULT= specification can occur anywhere in a FORMAT statement. It can specify either a numeric default, a character default, or both.

Example: “Example 1: Assigning Formats and Defaults” on page 157
Details

The FORMAT statement can use standard SAS formats or user-written formats that have been previously defined in PROC FORMAT. A single FORMAT statement can associate the same format with several variables, or it can associate different formats with different variables. If a variable appears in multiple FORMAT statements, SAS uses the format that is assigned last.

You use a FORMAT statement in the DATA step to permanently associate a format with a variable. SAS changes the descriptor information of the SAS data set that contains the variable. You can use a FORMAT statement in some PROC steps, but the rules are different. For more information, see Base SAS Procedures Guide.

Comparisons

Both the ATTRIB and FORMAT statements can associate formats with variables, and both statements can change the format that is associated with a variable. You can use the FORMAT statement in PROC DATASETS to change or remove the format that is associated with a variable. You can also associate, change, or disassociate formats and variables in existing SAS data sets through the windowing environment.

Examples

Example 1: Assigning Formats and Defaults
This example uses a FORMAT statement to assign formats and default formats for numeric and character variables. The default formats are not associated with variables in the data set but affect how the PUT statement writes the variables in the current DATA step.

```sas
data tstfmt;
  format W $char3.
  Y 10.3
  default=8.2 $char8.;
  W='Good morning.';
  X=12.1;
  Y=13.2;
  Z='Howdy-doody';
  put W/X/Y/Z;
run;
prow contents data=tstfmt;
run;
prow print data=tstfmt;
run;
```

The following output shows a partial listing from PROC CONTENTS, as well as the report that PROC PRINT generates.
Output 2.3  Partial Listing from PROC CONTENTS and the PROC PRINT Report

<table>
<thead>
<tr>
<th>#</th>
<th>Variable</th>
<th>Type</th>
<th>Len</th>
<th>Format</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>W</td>
<td>Char</td>
<td>3</td>
<td>$CHAR3.</td>
</tr>
<tr>
<td>3</td>
<td>X</td>
<td>Num</td>
<td>8</td>
<td></td>
</tr>
<tr>
<td>2</td>
<td>Y</td>
<td>Num</td>
<td>8</td>
<td>10.3</td>
</tr>
<tr>
<td>4</td>
<td>Z</td>
<td>Char</td>
<td>11</td>
<td></td>
</tr>
</tbody>
</table>

Output 2.4  PROC PRINT Report

The default formats apply to variables X and Z while the assigned formats apply to the variables W and Y.

The PUT statement produces this result:

```
----+----1----+----2
Goo 12.10 13.200
    13.200
    12.1
Howdy-do
```

**Example 2: Associating Multiple Variables with a Single Format**

This example uses the FORMAT statement to assign a single format to multiple variables.

```sas
data report;
  input Item $ 1-6 Material $8-14 Investment 16-22 Profit 24-31;
  format Item Material $upcase9. Investment Profit dollar15.2;
  datalines;
  shirts cotton 2256354 83952175
  ties   silk    498678  2349615
  suits  silk    9482146 69839563
  belts  leather 7693   14893
  shoes  leather 7936712 22964
; run;
```

Options pageno=1 nodate ls=80 ps=64;
```
proc print data=report;
  title 'Profit Summary: Kellam Manufacturing Company';
run;
```
Output 2.5  Results from Associating Multiple Variables with a Single Format

### Profit Summary: Kellam Manufacturing Company

<table>
<thead>
<tr>
<th>Obs</th>
<th>Item</th>
<th>Material</th>
<th>Investment</th>
<th>Profit</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>SHIRTS</td>

<td>$22,964.00</td>
</tr>
</tbody>
</table>

### Example 3: Removing a Format

This example disassociates an existing format from a variable in a SAS data set. The order of the FORMAT and the SET statements is important.

```sas
data rtest;
    set rtest;
    format x;
run;
```

See Also

- Chapter 16, “DATASETS Procedure” in *Base SAS Procedures Guide*

**Statements:**

- “ATTRIB Statement” on page 31

---

**GO TO Statement**

Directs program execution immediately to the statement label that is specified and, if followed by a RETURN statement, returns execution to the beginning of the DATA step.

**Valid in:** DATA step  
**Category:** Control  
**Type:** Executable  
**Alias:** GOTO

**Syntax**

```sas
GO TO label;
```
Arguments

*label*

specifies a statement label that identifies the GO TO destination. The destination must be within the same DATA step. You must specify the *label* argument.

Comparisons

The GO TO statement and the LINK statement are similar. However, a GO TO statement is often used without a RETURN statement, whereas a LINK statement is usually used with an explicit RETURN statement. The action of a subsequent RETURN statement differs between the GO TO and LINK statements. A RETURN statement after a LINK statement returns execution to the statement that follows the LINK statement. A RETURN after a GO TO statement returns execution to the beginning of the DATA step (unless a LINK statement precedes the GO TO statement. In that case, execution continues with the first statement after the LINK statement).

GO TO statements can often be replaced by DO-END and IF-THEN/ELSE programming logic.

Example: Using a RETURN Statement with the GO TO Statement

Use the GO TO statement as shown here.

- In this example, if the condition is true, the GO TO statement instructs SAS to jump to a label called ADD and to continue execution from there. If the condition is false, SAS executes the PUT statement and the statement that is associated with the GO TO label:

  ```sas
  data info;
    input x;
    if 1<=x<=5 then go to add;
    put x=;
    add: sumx+x;
  datalines;
  7
  6
  323
  ;
  
  Because every DATA step contains an implied RETURN at the end of the step, program execution returns to the top of the step after the sum statement is executed. Therefore, an explicit RETURN statement at the bottom of the DATA step is not necessary.

  - If you do not want the Sum statement to execute for observations that do not meet the condition, rewrite the code and include an explicit return statement.

  ```sas
  data info;
    input x;
    if 1<=x<=5 then go to add;
    put x=;
    return;
    /* SUM statement not executed */
    /* if x<1 or x>5 */
    add: sumx+x;
  datalines;
  ```
IF Statement, Subsetting

Continues processing only those observations that meet the condition of the specified expression.

Valid in: DATA step
Category: Action
Type: Executable

Syntax

IF expression;

Arguments

expression

is any SAS expression.

Details

The subsetting IF statement causes the DATA step to continue processing only those raw data records or those observations from a SAS data set that meet the condition of the expression that is specified in the IF statement. That is, if the expression is true for the observation or record (its value is neither 0 nor missing), SAS continues to execute statements in the DATA step and includes the current observation in the data set. The resulting SAS data set or data sets contain a subset of the original external file or SAS data set.

If the expression is false (its value is 0 or missing), no further statements are processed for that observation or record, the current observation is not written to the data set, and the remaining program statements in the DATA step are not executed. SAS immediately returns to the beginning of the DATA step because the subsetting IF statement does not require additional statements to stop processing observations.

Comparisons

• The subsetting IF statement is equivalent to this IF-THEN statement:

```sas
if not (expression)
then delete;
```
When you create SAS data sets, use the subsetting IF statement when it is easier to specify a condition for including observations. When it is easier to specify a condition for excluding observations, use the DELETE statement.

The subsetting IF and the WHERE statements are not equivalent. The two statements work differently and produce different output data sets in some cases. The most important differences are summarized as follows:

- The subsetting IF statement selects observations that have been read into the program data vector. The WHERE statement selects observations before they are brought into the program data vector. The subsetting IF might be less efficient than the WHERE statement because it must read each observation from the input data set into the program data vector.

- The subsetting IF statement and WHERE statement can produce different results in DATA steps that interleave, merge, or update SAS data sets.

- When the subsetting IF statement is used with the MERGE statement, the SAS System selects observations after the current observations are combined. When the WHERE statement is used with the MERGE statement, the SAS System applies the selection criteria to each input data set before combining the current observations.

- The subsetting IF statement can select observations from an existing SAS data set or from raw data that are read with the INPUT statement. The WHERE statement can select observations only from existing SAS data sets.

- The subsetting IF statement is executable; the WHERE statement is not.

**Example: Limiting Observations**

- This example results in a data set that contains only those observations with the value F for the variable SEX:
  
  ```
  if sex='F';
  ```

- This example results in a data set that contains all observations for which the value of the variable AGE is not missing or 0:

  ```
  if age;
  ```

**See Also**

- Chapter 11, “WHERE-Expression Processing,” in *SAS Language Reference: Concepts*

**Data Set Options:**

- “WHERE= Data Set Option” in *SAS Data Set Options: Reference*

**Statements:**

- “DELETE Statement” on page 59
- “IF-THEN/ELSE Statement” on page 163
- “WHERE Statement” on page 382
IF-THEN/ELSE Statement

Executes a SAS statement for observations that meet specific conditions.

**Valid in:** DATA step  
**Category:** Control  
**Type:** Executable

### Syntax

```sas
IF expression THEN statement;
<ELSE statement;>
```

### Arguments

- `expression`  
  is any SAS expression and is a required argument.
- `statement`  
  can be any executable SAS statement or DO group.

### Details

SAS evaluates the expression in an IF-THEN statement to produce a result that is either nonzero, zero, or missing. A nonzero and nonmissing result causes the expression to be true; a result of zero or missing causes the expression to be false.

If the conditions that are specified in the IF clause are met, the IF-THEN statement executes a SAS statement for observations that are read from a SAS data set, for records in an external file, or for computed values. An optional ELSE statement gives an alternative action if the THEN clause is not executed. The ELSE statement, if used, must immediately follow the IF-THEN statement.

Using IF-THEN statements without the ELSE statement causes SAS to evaluate all IF-THEN statements. Using IF-THEN statements with the ELSE statement causes SAS to execute IF-THEN statements until it encounters the first true statement. Subsequent IF-THEN statements are not evaluated.

**Note:** For greater efficiency, construct your IF-THEN/ELSE statement with conditions of decreasing probability.

### Comparisons

- Use a SELECT group rather than a series of IF-THEN statements when you have a long series of mutually exclusive conditions.
- Use subsetting IF statements, without a THEN clause, to continue processing only those observations or records that meet the condition that is specified in the IF clause.

### Example: Different Ways of Specifying the IF-THEN/ELSE Statements

These examples show different ways of specifying the IF-THEN/ELSE statement.
• if x then delete;
• if status='OK' and type=3 then count+1;
• if age ne agecheck then delete;
• if x=0 then
  if y ne 0 then put 'X ZERO, Y NONZERO';
  else put 'X ZERO, Y ZERO';
  else put 'X NONZERO';
• if answer=9 then
  do;
    answer=.;
    put 'INVALID ANSWER FOR ' id=;
  end;
else
  do;
    answer=answer10;
    valid+1;
  end;
• data region;
  input city $ 1-30;
  if city='New York City'
    or city='Miami' then
    region='ATLANTIC COAST';
  else if city='San Francisco'
    or city='Los Angeles' then
    region='PACIFIC COAST';
datalines;
...more data lines...
;

• “SELECT Statement” on page 350

%INCLUDE Statement

Brings a SAS programming statement, data lines, or both, into a current SAS program.

Valid in: Anywhere
Category: Program Control
Alias: %INC
See: %INCLUDE Statement under Windows, UNIX, and z/OS
**Syntax**

```plaintext
%INCLUDE source(s)
</<SOURCE2><S2=length><operating-environment-options>>;
```

**Arguments**

`source(s)`  
describes the location of the information that you want to access with the %INCLUDE statement. There are three possible sources:

<table>
<thead>
<tr>
<th>Source</th>
<th>Definition</th>
</tr>
</thead>
<tbody>
<tr>
<td>file-specification</td>
<td>specifies an external file</td>
</tr>
<tr>
<td>internal-lines</td>
<td>specifies lines that are entered earlier in the same SAS job or session</td>
</tr>
<tr>
<td>keyboard-entry</td>
<td>specifies statements or data lines that you enter directly from the keyboard</td>
</tr>
</tbody>
</table>

`file-specification`  
identifies an entire external file that you want to bring into your program.

*File-specification* can have these forms:

- `'external-file'`  
specifies the physical name of an external file that is enclosed in quotation marks. The physical name is the name by which the operating environment recognizes the file.

- `fileref`  
specifies a fileref that has previously been associated with an external file.  
  **Tip:** You can use a FILENAME statement or function or an operating environment command to make the association.

- `fileref (filename-1 <, "filename–2.xxx", ... filename-n>)`  
specifies a fileref that has previously been associated with an aggregate storage location. Follow the fileref with one or more filenames that reside in that location. Enclose the filenames in one set of parentheses, and separate each filename with a comma, space.

This example instructs SAS to include the files “testcode1.sas”, “testcode2.sas” and “testcode3.txt.” These files are located in aggregate storage location “mylib.” You do not need to specify the file extension for testcode1 and testcode2 because they are the default .SAS extension. You must enclose testcode3.txt in quotation marks with the whole filename specified because it has an extension other than .SAS:

```plaintext
%include mylib(testcode1, testcode2, 
                  "testcode3.txt");
```

**Operating environment:** Different operating environments call an aggregate grouping of files by different names, such as a directory, a MACLIB, a text library, or a partitioned data set. For information about accessing files from a storage location that contains several files, see the SAS documentation for your operating environment.
Note: A file that is located in an aggregate storage location and has a name that is not a valid SAS name must have its name enclosed in quotation marks.

Tip: You can use a FILENAME statement or function or an operating environment command to make the association.

Restriction: You cannot selectively include lines from an external file.

Operating environment: The character length allowed for filenames is operating environment specific. For complete details about specifying the physical names of external files, see the SAS documentation for your operating environment.

Tips:
You can verify the existence of file-specification by using the SYSERR macro variable if the ERRORCHECK option is set to STRICT.
Including external sources is useful in all types of SAS processing: batch, windowing, interactive line, and noninteractive.

internal-lines
includes lines that are entered earlier in the same SAS job or session.

To include internal lines, use any of the following:

\[ n \] includes line \( n \).

\[ n-m \text{ or } n:m \] includes lines \( n \) through \( m \).

Note: The SPOOL system option controls internal access to previously submitted lines when you run SAS in interactive line mode, noninteractive mode, and batch mode. By default, the SPOOL system option is set to NOSPOOL. The SPOOL system option must be in effect in order to use %INCLUDE statements with internal line references. Use the OPTIONS procedure to determine the current setting of the SPOOL system option on your system.

Tips:
Including internal lines is most useful in interactive line mode processing. Use a %LIST statement to determine the line numbers that you want to include.

Although you can use the %INCLUDE statement to access previously submitted lines when you run SAS in a windowing environment, it might be more practical to recall lines in the Program Editor with the RECALL command and then submit the lines with the SUBMIT command.

keyboard-entry
is a method for preparing a program so that you can interrupt the current program's execution, enter statements or data lines from the keyboard, and then resume program processing.

* prompts you to enter data from the keyboard. Place an asterisk (*) after the %INCLUDE statement in your code:

```sas
proc print;
  %include *;
run;
```

To resume processing the original source program, enter a %RUN statement from the keyboard.
Restriction: The asterisk (*) cannot be used to specify keyboard entry if you use
the Enhanced Editor in the Microsoft Windows operating environment.

Note: The fileref SASTERM must have been previously associated with an
external file in a FILENAME statement or function or an operating
environment command.

Tips:
Use this method when you run SAS in noninteractive or interactive line
mode. SAS pauses during processing and prompts you to enter statements
from the keyboard.

Use this argument to include source from the keyboard:
You can use a %INCLUDE * statement in a batch job by creating a file with
the fileref SASTERM that contains the statements that you would otherwise
enter from the keyboard. The %INCLUDE * statement causes SAS to read
from the file that is referenced by SASTERM. Insert a %RUN statement into
the file that is referenced by SASTERM where you want SAS to resume
reading from the original source.

SOURCE2
causes the SAS log to show the source statements that are being included in your
SAS program.

Tips:
The SAS log also displays the fileref and the filename of the source and the level
of nesting (1, 2, 3, and so on).
The SOURCE2 system option produces the same results. When you specify
SOURCE2 in a %INCLUDE statement, it overrides the setting of the SOURCE2
system option for the duration of the include operation.

S2=length
specifies the length of the record to be used for input. Length can have these values:

S sets S2 equal to the current setting of the S= SAS system option.
0 tells SAS to use the setting of the SEQ= system option to determine whether
the line contains a sequence field. If the line does contain a sequence field,
SAS determines line length by excluding the sequence field from the total
length.

n specifies a number greater than zero that corresponds to the length of the
line to be read, when the file contains fixed-length records. When the file
contains variable-length records, n specifies the column in which to begin
reading data.

Interaction: The S2= system option also specifies the length of secondary source
statements that are accessed by the %INCLUDE statement, and it is effective for
the duration of your SAS session. The S2= option in the %INCLUDE statement
affects only the current include operation. If you use the option in the
%INCLUDE statement, it overrides the system option setting for the duration of
the include operation.

Tips:
Text input from the %INCLUDE statement can be either fixed or variable length.
Fixed-length records are either unsequenced or sequenced at the end of each
record. For fixed-length records, the value given in S2= is the ending column of
the data.

Variable-length records are either unsequenced or sequenced at the beginning of
each record. For variable-length records, the value given in S2= is the starting
column of the data.
See: For a detailed discussion of fixed- and variable-length input records, see “S= System Option” in SAS System Options: Reference and “S2= System Option” in SAS System Options: Reference.

operating-environment-options

Operating environment: Operating environments can support various options for the %INCLUDE statement. See the documentation for your operating environment for a list of these options and their functions.

Details

What %INCLUDE Does
When you execute a program that contains the %INCLUDE statement, SAS executes your code, including any statements or data lines that you bring into the program with %INCLUDE.

Operating Environment Information
Use of the %INCLUDE statement is dependent on your operating environment. See the documentation for your operating environment for more information about additional software features and methods of referring to and accessing your files. See your documentation before you run the examples for this statement.

Three Sources of Data
The %INCLUDE statement accesses SAS statements and data lines from three possible sources:

• external files
• lines entered earlier in the same job or session
• lines entered from the keyboard.

When Useful
The %INCLUDE statement is most often used when running SAS in interactive line mode, noninteractive mode, or batch mode. Although you can use the %INCLUDE statement when you run SAS using windows, it might be more practical to use the INCLUDE and RECALL commands to access data lines and program statements, and submit these lines again.

Rules for Using %INCLUDE

• You can specify any number of sources in a %INCLUDE statement, and you can mix the types of included sources. Note, however, that although it is possible to include information from multiple sources in one %INCLUDE statement, it might be easier to understand a program that uses separately coded %INCLUDE statements for each source.

• The %INCLUDE statement must begin at a statement boundary. That is, it must be the first statement in a SAS job or must immediately follow a semicolon ending another statement. A %INCLUDE statement cannot immediately follow a DATALINES, DATALINES4, CARDS, or CARDS4 statement (or PARMCARDS or PARMCARDS4 statement in procedures that use those statements). However, you can include data lines with the %INCLUDE statement using one of these methods:

  • Make the DATALINES, DATALINES4, or CARDS, CARDS4 statement the first line in the file that contains the data.
• Place the DATALINES, DATALINES4, or CARDS, CARDS4 statement in one file, and the data lines in another file. Use both sources in a single %INCLUDE statement.

The %INCLUDE statement can be nested within a file that has been accessed with %INCLUDE. The maximum number of nested %INCLUDE statements that you can use depends on system-specific limitations of your operating environment (such as available memory or the number of files that you can have open concurrently).

• Because %INCLUDE is a global statement and global statements are not executable, the %INCLUDE statement cannot be used in conditional logic.

• The maximum line length is 32K bytes.

Comparisons

The %INCLUDE statement executes statements immediately. The INCLUDE command brings the included lines into the Program Editor window but does not execute them. You must issue the SUBMIT command to execute those lines.

Examples

Example 1: Including an External File

• This example stores a portion of a program in a file and includes it in a program to be written later. This program is stored in a file named MYFILE:

```plaintext
data monthly;
  input x y month $;
datalines;
1 1 January
2 2 February
3 3 March
4 4 April
;
```

This program includes an external file named MYFILE and submits the DATA step that it contains before the PROC PRINT step executes:

```plaintext
%include 'MYFILE';
proc print;
run;
```

• To reference a file by using a fileref rather than the actual filename, you can use the FILENAME statement (or a command recognized by your operating environment) to assign a fileref:

```plaintext
filename in1 'MYFILE';
```

You can later access MYFILE with the fileref IN1:

```plaintext
%inc in1;
```

• If you want to use many files that are stored in a directory, PDS, or MACLIB (or whatever your operating environment calls an aggregate storage location), you can assign the fileref to the larger storage unit and then specify the filename. For example, this FILENAME statement assigns the fileref STORAGE to an aggregate storage location:

```plaintext
filename storage
  'aggregate-storage-location';
```
You can later include a file using this statement:
\[
%\text{inc} \text{ storage(MYFILE);}\
\]
- You can also access several files or members from this storage location by listing them in parentheses after the fileref in a single %INCLUDE statement. Separate filenames with a comma or a blank space. The following %INCLUDE statement demonstrates this method:
\[
%\text{inc} \text{ storage(file-1,file-2,file-3);}\
\]
When the file does not have the default .SAS extension, you can access it using quotation marks around the complete filename listed inside the parentheses.
- %inc storage("file-1.txt","file-2.dat","file-3.cat");

**Example 2: Including Previously Submitted Lines**
This %INCLUDE statement causes SAS to process lines 1, 5, 9 through 12, and 13 through 16 as if you had entered them again from your keyboard:
\[
%\text{include} \ 1\ 5\ 9-12\ 13:16;\]

**Example 3: Including Input from the Keyboard**
The method shown in this example is valid only when you run SAS in noninteractive mode or interactive line mode.

**Restriction:** The asterisk (*) cannot be used to specify keyboard entry if you use the Enhanced Editor in the Microsoft Windows operating environment.

This example uses %INCLUDE to add a customized TITLE statement when PROC PRINT executes:
\[
data \text{ report;}\
\quad \text{infile \ file-specification;}\
\quad \text{input month \$ salesamt \$;}\
\quad \text{run;}\
\quad \text{proc print;}\
\quad \quad \text{%include \*;}\
\quad \text{run;}\
\]
When this DATA step executes, %INCLUDE with the asterisk causes SAS to issue a prompt for statements that are entered at the keyboard. You can enter statements such as
\[
\text{where month= 'January';}\
\text{title 'Data for month of January';}\
\]
After you enter statements, you can use %RUN to resume processing by entering
\[
%\text{run};\
\]
The %RUN statement signals to SAS to leave keyboard-entry mode and resume reading and executing the remaining SAS statements from the original program.

**Example 4: Using %INCLUDE with Several Entries in a Single Catalog**
This example submits the source code from three entries in the catalog MYLIB.INCLUDE. When no entry type is specified, the default is CATAMS.
\[
\text{filename dir catalog 'mylib.include';}\
\text{%include dir(mem1);}\
\]

Statements:

- “%LIST Statement” on page 260
- “%RUN Statement” on page 343

INFILE Statement

Specifies an external file to read with an INPUT statement.

Valid in: DATA Step
Category: File-handling
Type: Executable
Operating environment: The INFILE statement contains operating environment-specific material. See the SAS documentation for your operating environment before using this statement.
See: INFILE Statement under Windows, UNIX, and z/OS

Syntax

INFILE file-specification <device-type> <options> <operating-environment-options>;

INFILE DBMS-specifications;

Arguments

file-specification
identifies the source of the input data records, which is an external file or instream data. File-specification can have these forms:

'external-file'
specifies the physical name of an external file. The physical name is the name that the operating environment uses to access the file.

fileref
specifies the fileref of an external file.

Requirement: You must have previously associated the fileref with an external file in a FILENAME statement, FILENAME function, or an appropriate operating environment command.

See: “FILENAME Statement” on page 93

fileref(file)

specifies a fileref of an aggregate storage location and the name of a file or member, enclosed in parentheses, that resides in that location.

Requirements: A file that is located in an aggregate storage location and has a name that is not a valid SAS name must have its name enclosed in quotation marks.
You must have previously associated the fileref with an external file in a FILENAME statement, a FILENAME function, or an appropriate operating environment command.

**Operating environment:** Different operating environments call an aggregate grouping of files by different names, such as a directory, a MACLIB, or a partitioned data set. For details about how to specify external files, see the SAS documentation for your operating environment.

**See:** “FILENAME Statement” on page 93

CARD | CARDS4  
for a definition, see DATALINES on page 172.

**Alias:** DATALINES | DATALINES4

DATALINES | DATALINES4  
specifies that the input data immediately follows the DATALINES or DATALINES4 statement in the DATA step. Using DATALINES enables you to use the INFILE statement options to control how the INPUT statement reads instream data lines.

**Alias:** CARDS | CARDS4

**Example:** “Example 1: Changing How Delimiters Are Treated” on page 187

**Tip:** You can verify the existence of file-specification by using the SYSERR macro variable if the ERRORCHECK option is set to STRICT.

**device-type**  
specifies the type of device or the access method that is used if the fileref points to an input or output device or location that is not a physical file:

**CATALOG**  
specifies the CATALOG access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

**See:** For a complete list of options that are available with the CATALOG access method, see the “FILENAME Statement, CATALOG Access Method” on page 100.

**CLIPBOARD**  
specifies the CLIPBOARD access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

**See:** For a complete list of options that are available with the CLIPBOARD access method, see the “FILENAME, CLIPBOARD Access Method” on page 104.

**DISK**  
specifies that the device is a disk drive.

**Tip:** When you assign a fileref to a file on disk, you are not required to specify DISK.

**DUMMY**  
specifies that the output to the file is discarded.

**Tip:** Specifying DUMMY can be useful for testing.

**FTP**  
specifies the FTP access method.

**Interaction:** If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.
See: For a complete list of options that are available with the FTP access method, see the “FILENAME Statement, FTP Access Method” on page 117.

Example:
```
infile dummy ftp user='myuid' pass='xxxx' filevar=file_to_read;
```

GTERM
indicates that the output device type is a graphics device that will receive graphics data.

JMS
specifies a Java Message Service (JMS) destination.

PIPE
specifies an unnamed pipe.

Note: Some operating environments do not support pipes.

PLOTTER
specifies an unbuffered graphics output device.

PRINTER
specifies a printer or printer spool file.

SFTP
specifies the SFTP access method.

Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

See: For a complete list of options that are available with the SFTP access method, see the “FILENAME Statement, SFTP Access Method” on page 133.

SOCKET
specifies the SOCKET access method.

Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

See: For a complete list of options that are available with the SOCKET access method, see the “FILENAME Statement, SOCKET Access Method” on page 138.

TAPE
specifies a tape drive.

TEMP
creates a temporary file that exists only as long as the filename is assigned. The temporary file can be accessed only through the logical name and is available only while the logical name exists.

Restriction: Do not specify a physical pathname. If you do, SAS returns an error.

Tip: Files that are manipulated by the TEMP device can have the same attributes and behave identically to DISK files.

TERMINAL
specifies the user's terminal.

UPRINTER
specifies a Universal Printing printer definition name.

Tip: If you do not specify the printer name in the FILENAME statement, the PRINTERPATH options control which Universal Printer is used and the destination of the output.
URL
specifies the URL access method.

Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

See: For a complete list of options that are available with the URL access method, see the “FILENAME Statement, URL Access Method” on page 142.

WEBDAV
specifies the WEBDAV access method.

Interaction: If the DATA step does not recognize the access method option, the DATA step passes the option to the access method for handling.

See: For a complete list of options that are available with the WEBDAV access method, see the “FILENAME Statement, WebDAV Access Method” on page 147.

Alias: DEVICE=device-type
Default: DISK
Requirement: device-type or DEVICE=device-type must immediately follow file-specification in the statement.

Operating environment: Additional specifications might be required when you specify some devices. See the SAS documentation for your operating environment before specifying a value other than DISK. Values in addition to the ones listed here might be available in some operating environments.

INFILE Options

BLKSIZE=block-size
specifies the block size of the input file.

Default: Dependent on the operating environment. For details, see the SAS documentation for your operating environment.

COLUMN=variable
names a variable that SAS uses to assign the current column location of the input pointer. Like automatic variables, the COLUMN= variable is not written to the data set.

Alias: COL=
See: LINE= on page 178
Example: “Example 8: Listing the Pointer Location” on page 192

DELIMITER=delimiter(s)
specifies an alternate delimiter (other than a blank) to be used for LIST input, where delimiter(s) is 'list-of-delimiting-characters'
specifies one or more characters to read as delimiters.

Requirement: Enclose the list of characters in quotation marks.

Example: “Example 1: Changing How Delimiters Are Treated” on page 187

character-variable
specifies a character variable whose value becomes the delimiter.

Alias: DLM=
Default: blank space
Tip: The delimiter is case sensitive.
DLMSTR= **delimiter**
specifies a character string as an alternate delimiter (other than a blank) to be used for LIST input, where **delimiter** is

'**delimiting-string**'  
specifies a character string to read as a delimiter.

**Requirement:** Enclose the string in quotation marks.

**Example:** “Example 1: Changing How Delimiters Are Treated” on page 187

**character-variable**  
specifies a character variable whose value becomes the delimiter.

**Default:** blank space

**Interactions:**
If you specify more than one DLMSTR= option in the INFILE statement, the DLMSTR= option that is specified last will be used. If you specify both the DELIMITER= and DLMSTR= options, the option that is specified last will be used.

If you specify RECFM=N, make sure that the LRECL is large enough to hold the largest input item. Otherwise, it might be possible for the delimiter to be split across the record boundary.

**Tip:** The delimiter is case sensitive. To make the delimiter case insensitive, use the DLMSOPT='I' option.

**See:** “Reading Delimited Data” on page 184, DELIMITER= on page 174, DLMSOPT= on page 175, and DSD on page 175

**Example:** “Example 1: Changing How Delimiters Are Treated” on page 187

DLMSOPT= **'option(s)'**
specifies parsing options for the DLMSTR= option where **option(s)** can be the following:

I  
specifies that case-insensitive comparisons will be done.

T  
specifies that trailing blanks of the string delimiter will be removed.

**Tips:**

The T option is useful when you use a variable as the delimiter string.
You can specify either I, T, or both.

**Requirement:** The DLMSOPT= option has an effect only when used with the DLMSTR= option.

**See:** DLMSTR= on page 175

**Example:** “Example 1: Changing How Delimiters Are Treated” on page 187

**DSD (delimiter-sensitive data)**
specifies that when data values are enclosed in quotation marks, delimiters within the value are treated as character data. The DSD option changes how SAS treats delimiters when you use LIST input and sets the default delimiter to a comma. When you specify DSD, SAS treats two consecutive delimiters as a missing value and removes quotation marks from character values.

**Interaction:** Use the DELIMITER= or DLMSTR= option to change the delimiter.
Tip: Use the DSD option and LIST input to read a character value that contains a
delimiter within a string that is enclosed in quotation marks. The INPUT
statement treats the delimiter as a valid character and removes the quotation
marks from the character string before the value is stored. Use the tilde (~)
format modifier to retain the quotation marks.

See: “Reading Delimited Data” on page 184, DELIMITER= on page 174, and
DLMSTR= on page 175

Examples:
“Example 1: Changing How Delimiters Are Treated” on page 187
“Example 2: Handling Missing Values and Short Records with List Input” on
page 189

ENCODING= 'encoding-value'
specifies the encoding to use when reading from the external file. The value for
ENCODING= indicates that the external file has a different encoding from the
current session encoding.

When you read data from an external file, SAS transcodes the data from the specified
encoding to the session encoding.

Default: SAS assumes that an external file is in the same encoding as the session
encoding.

See: For valid encoding values, see “Encoding Values in SAS Language Elements”

Example: “Example 11: Specifying an Encoding When Reading an External File”
on page 195

END=variable
specifies a variable that SAS sets to 1 when the current input data record is the last in
the input file. Until SAS processes the last data record, the END= variable is set to 0.
Like automatic variables, this variable is not written to the data set.

Restriction: You cannot use the END= option with the UNBUFFERED option, the
DATALINES or DATALINES4 statement, or an INPUT statement that reads
multiple input data records.

Tip: Use the option EOF= on page 176 when END= is invalid.

Example: “Example 5: Reading from Multiple Input Files” on page 191

EOF=label
specifies a statement label that is the object of an implicit GO TO when the INFILE
statement reaches end of file. When an INPUT statement attempts to read from a file
that has no more records, SAS moves execution to the statement label indicated.

Interaction: Use EOF= instead of the END= option with the UNBUFFERED
option, the DATALINES or DATALINES4 statement, an INPUT statement that reads
multiple input data records.

Tip: The EOF= option is useful when you read from multiple input files
sequentially.

See: END= on page 176, EOF= on page 176, and UNBUFFERED on page 181

EOV=variable
specifies a variable that SAS sets to 1 when the first record in a file in a series of
concatenated files is read. The variable is set only after SAS encounters the next file.
Like automatic variables, the EOV= variable is not written to the data set.

Tip: Reset the EOV= variable back to 0 after SAS encounters each boundary.

See: END= on page 176 and EOF= on page 176
EXPANDTABS | NOEXPANDTABS
specifies whether to expand tab characters to the standard tab setting, which is set at
8-column intervals that start at column 9.

Default: NOEXPANDTABS

Tip: EXPANDTABS is useful when you read data that contains the tab character
that is native to your operating environment.

FILENAME=variable
specifies a variable that SAS sets to the physical name of the currently opened input
file. Like automatic variables, the FILENAME= variable is not written to the data
set.

Tip: Use a LENGTH statement to make the variable length long enough to contain
the value of the filename.

See: FILEVAR= on page 177

Example: “Example 5: Reading from Multiple Input Files” on page 191

FILEVAR=variable
specifies a variable whose change in value causes the INFILE statement to close the
current input file and open a new one. When the next INPUT statement executes, it
reads from the new file that the FILEVAR= variable specifies. Like automatic
variables, this variable is not written to the data set.

Restriction: The FILEVAR= variable must contain a character string that is a
physical filename.

Interaction: When you use the FILEVAR= option, the file-specification is just a
placeholder, not an actual filename or a fileref that has been previously assigned
to a file. SAS uses this placeholder for reporting processing information to the
SAS log. It must conform to the same rules as a fileref.

Tips:
Use FILEVAR= to dynamically change the currently opened input file to a new
physical file.

When using FILEVAR=, it is not possible to know whether the input file that is
currently open is the last file or not. When the DATA step comes to an end-of-
file marker or the end of all open data sets, it performs an orderly shutdown. In
addition, if you use FILEVAR with FIRSTOBS, a file with only a header record
in a series of files will trigger a normal shutdown of the DATA step. The
shutdown occurs because SAS reads beyond the end-of-file marker and the
DATA step terminates. You can use the EOF= option to avoid the shutdown.

See: “Updating External Files in Place” on page 183

Example: “Example 5: Reading from Multiple Input Files” on page 191

FIRSTOBS=record-number
specifies a record number that SAS uses to begin reading input data records in the
input file.

Default: 1

Tip: Use FIRSTOBS= with OBS= to read a range of records from the middle of a
file.

Example: This statement processes record 50 through record 100:
infile file-specification firstobs=50 obs=100;

FLOWOVER
causes an INPUT statement to continue to read the next input data record if it does
not find values in the current input line for all the variables in the statement.
FLOWOVER is the default behavior of the INPUT statement.
LENGTH=variable
specifies a variable that SAS sets to the length of the current input line. SAS does not assign the variable a value until an INPUT statement executes. Like automatic variables, the LENGTH= variable is not written to the data set.

Tip: This option in conjunction with the $VARYING informat is useful when the field width varies.

Examples:
“Example 4: Reading Files That Contain Variable-Length Records” on page 190
“Example 7: Truncating Copied Records” on page 192

LINE=variable
specifies a variable that SAS sets to the line location of the input pointer in the input buffer. Like automatic variables, the LINE= variable is not written to the data set.

Range: 1 to the value of the N= option

Interaction: The value of the LINE= variable is the current relative line number within the group of lines that is specified by the N= option or by the #n line pointer control in the INPUT statement.

See: COLUMN= on page 174 and N= on page 179

Example: “Example 8: Listing the Pointer Location” on page 192

LINESIZE=line-size
specifies the record length that is available to the INPUT statement.

Alias: LS=

Range: up to 32767

Interaction: If an INPUT statement attempts to read past the column that is specified by the LINESIZE= option, then the action that is taken depends on whether the FLOWOVER, MISSOVER, SCANOVER, STOPOVER, or TRUNCOVER option is in effect. FLOWOVER is the default.

Operating environment: Values for line-size are dependent on the operating environment record size. For details, see the SAS documentation for your operating environment.

Tip: Use LINESIZE= to limit the record length when you do not want to read the entire record.

Example: If your data lines contain a sequence number in columns 73 through 80, then use this INFILE statement to restrict the INPUT statement to the first 72 columns:
```
infile file-specification linesize=72;
```

LRECL=logical-record-length
specifies the logical record length.

Default: Dependent on the file characteristics of your operating environment

Restriction: LRECL is not valid when you use the DATALINES file specification.

Interaction: Alternatively, you can specify a global logical record length by using the “LRECL= System Option” in SAS System Options: Reference.

Operating environment: Values for logical-record-length are dependent on the operating environment. For details, see the SAS documentation for your operating environment.

Tip: LRECL= specifies the physical line length of the file. LINESIZE= tells the INPUT statement how much of the line to read.
MISSOVER prevents an INPUT statement from reading a new input data record if it does not find values in the current input line for all the variables in the statement. When an INPUT statement reaches the end of the current input data record, variables without any values assigned are set to missing.

**Tip:** Use MISSOVER if the last field or fields might be missing and you want SAS to assign missing values to the corresponding variable.

**See:** “Reading Past the End of a Line” on page 185, FLOWOVER on page 177, SCANOVER on page 180, STOPOVER on page 181, and TRUNCOVER on page 181

**Example:** “Example 2: Handling Missing Values and Short Records with List Input” on page 189

**N=available-lines**

specifies the number of lines that are available to the input pointer at one time.

**Default:** The highest value following a # pointer control in any INPUT statement in the DATA step. If you omit a # pointer control, then the default value is 1.

**Interaction:** This option affects only the number of lines that the pointer can access at a time; it has no effect on the number of lines an INPUT statement reads.

**Tips:**

When you use # pointer controls in an INPUT statement that are less than the value of N=, you might get unexpected results. To prevent unexpected results, include a # pointer control that equals the value of the N= option. Here is an example:

```
infile 'external file' n=5;
input #2 name : $25. #3 job : $25. #5;
```

The INPUT statement includes a #5 pointer control, even though no data is read from that record.

**Example:** “Example 8: Listing the Pointer Location” on page 192

**NBYTE=variable**

specifies the name of a variable that contains the number of bytes to read from a file when you are reading data in stream record format (RECFM=S in the FILENAME statement).

**Default:** The LRECL value of the file

**Interaction:** If the number of bytes to read is set to -1, then the FTP and SOCKET access methods return the number of bytes that are currently available in the input buffer.

**See:** The RECFM= option on page 140 in the FILENAME statement, SOCKET access method, and the RECFM= option on page 122 in the FILENAME statement, FTP access method

**OBS=record-number | MAX**

specifies the record number of the last record to read in an input file that is read sequentially.

**MAX**

specifies the maximum number of observations to process, which will be at least as large as the largest signed, 32-bit integer. The absolute maximum depends on your host operating environment.

**Default:** MAX

**Tip:** Use OBS= with FIRSTOBS= to read a range of records from the middle of a file.

**Example:** This statement processes only the first 100 records in the file:
infile file-specification obs=100;

PAD | NOPAD
controls whether SAS pads the records that are read from an external file with blanks to the length that is specified in the LRECL= option.

Default: NOPAD
See: LRECL= option on page 178

PRINT | NOPRINT
specifies whether the input file contains carriage-control characters.

Tip: To read a file in a DATA step without having to remove the carriage-control characters, specify PRINT. To read the carriage-control characters as data values, specify NOPRINT.

RECFM=record-format
specifies the record format of the input file.

Operating environment: Values for record-format are dependent on the operating environment. For details, see the SAS documentation for your operating environment.

SCANOVER
causes the INPUT statement to scan the input data records until the character string that is specified in the @'character-string' expression is found.

Interaction: The MISSOVER, TRUNCOVER, and STOPOVER options change how the INPUT statement behaves when it scans for the @'character-string' expression and reaches the end of the record. By default (FLOWOVER option), the INPUT statement scans the next record while these other options cause scanning to stop.

Tip: It is redundant to specify both SCANOVER and FLOWOVER.
See: “Reading Past the End of a Line” on page 185, FLOWOVER on page 177, MISSOVER on page 179, STOPOVER on page 181, and TRUNCOVER on page 181

Example: “Example 3: Scanning Variable-Length Records for a Specific Character String” on page 189

SHAREBUFFERS
specifies that the FILE statement and the INFILE statement share the same buffer.

Alias: SHAREBUFS

Tips:
Use SHAREBUFFERS with the INFILE, FILE, and PUT statements to update an external file in place. Updating an external file in place saves CPU time because the PUT statement output is written straight from the input buffer instead of the output buffer.
Use SHAREBUFFERS to update specific fields in an external file instead of an entire record.

Example: “Example 6: Updating an External File” on page 192

CAUTION: When using SHAREBUFFERS, RECFM=V, and _INFILE_, use caution if you read a record with one length and update the file with a record of a different length. The length of the record can change by modifying _INFILE_. One option to avoid this potential problem is to pad or truncate _INFILE_ so that the original record length is maintained.
START=variable
specifies a variable whose value SAS uses as the first column number of the record that the PUT _INFILE_ statement writes. Like automatic variables, the START variable is not written to the data set.

See: _INFILE_ option on page 298 in the PUT statement

STOPOVER
causes the DATA step to stop processing if an INPUT statement reaches the end of the current record without finding values for all variables in the statement. When an input line does not contain the expected number of values, SAS sets _ERROR_ to 1, stops building the data set as if a STOP statement has executed, and prints the incomplete data line.

Tip: Use FLOWOVER to reset the default behavior.

See: “Reading Past the End of a Line” on page 185, FLOWOVER on page 177, MISSOVER on page 179, SCANOVER on page 180, and TRUNCOVER on page 181

Example: “Example 2: Handling Missing Values and Short Records with List Input” on page 189

TRUNCOver
overrides the default behavior of the INPUT statement when an input data record is shorter than the INPUT statement expects. By default, the INPUT statement automatically reads the next input data record. TRUNCOver enables you to read variable-length records when some records are shorter than the INPUT statement expects. Variables without any values assigned are set to missing.

Tip: Use TRUNCover to assign the contents of the input buffer to a variable when the field is shorter than expected.

See: “Reading Past the End of a Line” on page 185, FLOWOVER on page 177, MISSOVER on page 179, SCANOVER on page 180, and STOPOVER on page 181

Example: “Example 3: Scanning Variable-Length Records for a Specific Character String” on page 189

UNBUFFERED
tells SAS not to perform a buffered (“look ahead”) read.

Alias: UNBUF

Interaction: When you use UNBUFFERED, SAS never sets the END= variable to 1.

Tip: When you read instream data with a DATALINES statement, UNBUFFERED is in effect.

_INFILE_=variable
specifies a character variable that references the contents of the current input buffer for this INFILE statement. You can use the variable in the same way as any other variable, even as the target of an assignment. The variable is automatically retained and initialized to blanks. Like automatic variables, the _INFILE_= variable is not written to the data set.

Restriction: variable cannot be a previously defined variable. Ensure that the _INFILE_= specification is the first occurrence of this variable in the DATA step. Do not set or change the length of _INFILE_= variable with the LENGTH or ATTRIB statements. However, you can attach a format to this variable with the ATTRIB or FORMAT statement.

Interaction: The maximum length of this character variable is the logical record length (LRECL= on page 178) for the specified INFILE statement. However, SAS does not open the file to know the LRECL= until before the execution
phase. Therefore, the designated size for this variable during the compilation phase is 32,767 bytes.

Tips:
Modification of this variable directly modifies the INFILE statement's current input buffer. Any PUT _INFILE_ (when this INFILE is current) that follows the buffer modification reflects the modified buffer contents. The _INFILE_ variable accesses only the current input buffer of the specified INFILE statement even if you use the N= option to specify multiple buffers.

To access the contents of the input buffer in another statement without using the _INFILE_= option, use the automatic variable _INFILE_.

The _INFILE_ variable does not have a fixed width. When you assign a value to the _INFILE_ variable, the length of the variable changes to the length of the value that is assigned.

See: “Accessing the Contents of the Input Buffer” on page 183

Examples:
“Example 9: Working with Data in the Input Buffer” on page 193
“Example 10: Accessing the Input Buffers of Multiple Files” on page 194

Operating Environment Options

options | host-options

Operating Environment Information
For descriptions of operating environment-specific options in the INFILE statement, see the SAS documentation for your operating environment.

See: INFILE Statement under Windows, UNIX, and z/OS

DBMS Specifications

DBMS-Specifications
enable you to read records from some DBMS files. You must license SAS/ACCESS software to be able to read from DBMS files. See the SAS/ACCESS documentation for the DBMS that you use.

Details

How to Use the INFILE Statement
Because the INFILE statement identifies the file to read, it must execute before the INPUT statement that reads the input data records. You can use the INFILE statement in conditional processing, such as an IF-THEN statement, because it is executable. The INFILE statement enables you to control the source of the input data records.

Usually, you use an INFILE statement to read data from an external file. When data is read from the job stream, you must use a DATALINES statement. However, to take advantage of certain data-reading options that are available only in the INFILE statement, you can use an INFILE statement with the file-specification DATALINES and a DATALINES statement in the same DATA step. See “Reading Long Instream Data Records” on page 185 for more information.

When you use more than one INFILE statement for the same file specification and you use options in each INFILE statement, the effect is additive. To avoid confusion, use all the options in the first INFILE statement for a given external file.
**Reading Multiple Input Files**
You can read from multiple input files in a single iteration of the DATA step in one of two ways:

- to keep multiple files open and change which file is read, use multiple INFILE statements.
- to dynamically change the current input file within a single DATA step, use the FILEVAR= option in an INFILE statement. The FILEVAR= option enables you to read from one file, close it, and then open another. See “Example 5: Reading from Multiple Input Files” on page 191.

**Updating External Files in Place**
You can use the INFILE statement in combination with the FILE statement to update records in an external file. Follow these steps:

1. Specify the INFILE statement before the FILE statement.
2. Specify the same fileref or physical filename in each statement.
3. Use options that are common to both the INFILE and FILE statements in the INFILE statement instead of the FILE statement. (Any such options that are used in the FILE statement are ignored.)

To update individual fields within a record instead of the entire record, see the SHAREBUFFERS option on page 180.

**Accessing the Contents of the Input Buffer**
In addition to the _INFILE_ variable, you can use the automatic _INFILE_ variable to reference the contents of the current input buffer for the most recent execution of the INFILE statement. This character variable is automatically retained and initialized to blanks. Like other automatic variables, _INFILE_ is not written to the data set.

When you specify the _INFILE_= option in an INFILE statement, this variable is also indirectly referenced by the automatic _INFILE_ variable. If the automatic _INFILE_ variable is present and you omit _INFILE_ in a particular INFILE statement, then SAS creates an internal _INFILE_ variable for that INFILE statement. Otherwise, SAS does not create the _INFILE_ variable for a particular FILE.

During execution and at the point of reference, the maximum length of this character variable is the maximum length of the current _INFILE_ variable. However, because _INFILE_ only references other variables whose lengths are not known until before the execution phase, the designated length is 32,767 bytes during the compilation phase. For example, if you assign _INFILE_ to a new variable whose length is undefined, then the default length of the new variable is 32,767 bytes. You cannot use the LENGTH statement and the ATTRIB statement to set or override the length of _INFILE_. You can use the FORMAT statement and the ATTRIB statement to assign a format to _INFILE_.

Like other SAS variables, you can update the _INFILE_ variable in an assignment statement. You can also use a format with _INFILE_ in a PUT statement. For example, the following PUT statement writes the contents of the input buffer by using a hexadecimal format.

```
put _infile_ $hex100.;
```

Any modification of the _INFILE_ directly modifies the current input buffer for the current INFILE statement. The execution of any PUT _INFILE_ statement that follows this buffer modification will reflect the contents of the modified buffer.
_INFILE_ only accesses the contents of the current input buffer for an INFILE statement, even when you use the N= option to specify multiple buffers. You can access all the N= buffers, but you must use an INPUT statement with the # line pointer control to make the desired buffer the current input buffer.

**Reading Delimited Data**

By default, the delimiter that is used to read input data records with list input is a blank space. The delimiter-sensitive data (DSD) option, the DELIMITER= option, the DLMSTR= option, and the DLMSOPT= option affect how list input handles delimiters. The DELIMITER= or DLMSTR= option specifies that the INPUT statement use a character other than a blank as a delimiter for data values that are read with list input. When the DSD option is in effect, the INPUT statement uses a comma as the default delimiter.

To read a value as missing between two consecutive delimiters, use the DSD option. By default, the INPUT statement treats consecutive delimiters as a unit. When you use DSD, the INPUT statement treats consecutive delimiters separately. Therefore, a value that is missing between consecutive delimiters is read as a missing value. To change the delimiter from a comma to another value, use the DELIMITER= or DLMSTR= option.

For example, this DATA step program uses list input to read data that is separated with commas. The second data line contains a missing value. Because SAS allows consecutive delimiters with list input, the INPUT statement cannot detect the missing value.

```sas
data scores;
    infile datalines delimiter=',';
    input test1 test2 test3;
    datalines;
    91,87,95
    97,,92
    ,,1,1
    ;
```

With the FLOWOVER option in effect, the data set SCORES contains two, not three, observations. The second observation is built incorrectly:

<table>
<thead>
<tr>
<th>OBS</th>
<th>TEST1</th>
<th>TEST2</th>
<th>TEST3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>91</td>
<td>87</td>
<td>95</td>
</tr>
<tr>
<td>2</td>
<td>97</td>
<td>92</td>
<td>1</td>
</tr>
</tbody>
</table>

To correct the problem, use the DSD option in the INFILE statement.

```sas
data scores;
    input test1 test2 test3;
    datalines;
    91,87,95
    97,,92
    ,,1,1
    ;
    infile datalines dsd;
```

Now the INPUT statement detects the two consecutive delimiters and therefore assigns a missing value to variable TEST2 in the second observation.
The DSD option also enables list input to read a character value that contains a delimiter within a quoted string. For example, if data is separated with commas, DSD enables you to place the character string in quotation marks and read a comma as a valid character. SAS does not store the quotation marks as part of the character value. To retain the quotation marks as part of the value, use the tilde (~) format modifier in an INPUT statement. See “Example 1: Changing How Delimiters Are Treated” on page 187.

Note: Any time a text file originates from anywhere other than the local encoding environment, it might be necessary to specify the ENCODING= option on either EBCDIC or ASCII environments. For example, when you read an EBCDIC text file on an ASCII platform, it is recommended that you specify the ENCODING= option in the INFILE statement. However, if you use the DSD and DLM options in the INFILE statement, the ENCODING= option is a requirement because these options require certain characters in the session encoding (such as quotation marks, commas, and blanks). The use of encoding-specific informats should be reserved for use with true binary files. That is, files that contain both character and noncharacter fields.

### Reading Long Instream Data Records
You can use the INFILE statement with the DATALINES file specification to process instream data. An INPUT statement reads the data records that follow the DATALINES statement. If you use the CARDIMAGE system option, or if this option is the default for your system, then SAS processes the data lines exactly like 80-byte punched card images that are padded with blanks. The default FLOWOVER option in the INFILE statement causes the INPUT statement to read the next record if it does not find values in the current record for all of the variables in the statement. To ensure that your data is processed correctly, use an external file for input when record lengths are greater than 80 bytes.

Note: The NOCARDIMAGE system option (see the “CARDIMAGE System Option” in SAS System Options: Reference) specifies that data lines not be treated as if they were 80-byte card images. The end of a data line is always treated as the end of the last token, except for strings that are enclosed in quotation marks.

### Reading Past the End of a Line
By default, if the INPUT statement tries to read past the end of the current input data record, then it moves the input pointer to column 1 of the next record to read the remaining values. This default behavior is specified by the FLOWOVER option. A message is written to the SAS log:

```
NOTE: SAS went to a new line when INPUT statement reached past the end of a line.
```

Several options are available to change the INPUT statement behavior when an end of line is reached. The STOPOVER option treats this condition as an error and stops building the data set. The MISSOVER and TRUNCOVER options do not allow the input pointer to go to the next record when the current INPUT statement is not satisfied. The SCANOVER option, used with @’character-string’ scans the input record until it finds the specified character-string. The FLOWOVER option restores the default behavior.

<table>
<thead>
<tr>
<th>OBS</th>
<th>TEST1</th>
<th>TEST2</th>
<th>TEST3</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>91</td>
<td>87</td>
<td>95</td>
</tr>
<tr>
<td>2</td>
<td>97</td>
<td>.</td>
<td>92</td>
</tr>
<tr>
<td>3</td>
<td>.</td>
<td>1</td>
<td>1</td>
</tr>
</tbody>
</table>
The TRUNCOVER and MISSOVER options are similar. The MISSOVER option causes the INPUT statement to set a value to missing if the statement is unable to read an entire field because the value is shorter than the field length that is specified in the INPUT statement. The TRUNCOVER option writes whatever characters are read to the appropriate variable.

For example, an external file with variable-length records contains these records:

```
1
22
333
4444
55555
```

The following DATA step reads this data to create a SAS data set. Only one of the input records is as long as the informatted length of the variable TESTNUM.

```sas
data numbers;
  infile 'external-file';
  input testnum 5.;
run;
```

This DATA step creates the three observations from the five input records because by default the FLOWOVER option is used to read the input records.

If you use the MISSOVER option in the INFILE statement, then the DATA step creates five observations. All the values that were read from records that were too short are set to missing. Use the TRUNCOVER option in the INFILE statement if you prefer to see what values were present in records that were too short to satisfy the current INPUT statement.

```sas
infile 'external-file' truncover;
```

The DATA step now reads the same input records and creates five observations. See the following table to compare the SAS data sets.

<table>
<thead>
<tr>
<th>OBS</th>
<th>FLOWOVER</th>
<th>MISSOVER</th>
<th>TRUNCOVER</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>22</td>
<td>.</td>
<td>1</td>
</tr>
<tr>
<td>2</td>
<td>4444</td>

**Comparisons**

- The INFILE statement specifies the *input file* for any INPUT statements in the DATA step. The FILE statement specifies the *output file* for any PUT statements in the DATA step.
- An INFILE statement usually identifies data from an external file. A DATALINES statement indicates that data follows in the job stream. You can use the INFILE
statement with the file specification DATALINES to take advantage of certain data-
reading options that affect how the INPUT statement reads instream data.

Examples

**Example 1: Changing How Delimiters Are Treated**
By default, the INPUT statement uses a blank as the delimiter. This DATA step uses a
comma as the delimiter:

```sas
data num;
   infile datalines dsd;
   input x y z;
datalines;
,2,3
4,5,6
7,8,9
;```

The argument DATALINES in the INFILE statement enables you to use an INFILE
statement option to read instream data lines. The DSD option sets the comma as the
default delimiter. Because a comma precedes the first value in the first data line, a
missing value is assigned to variable X in the first observation, and the value 2 is
assigned to variable Y.

If the data uses multiple delimiters or a single delimiter other than a comma, then simply
specify the delimiter values with the DELIMITER= option. In this example, the
characters a and b function as delimiters:

```sas
data nums;
   infile datalines dsd delimiter='ab';
   input X Y Z;
datalines;
1aa2ab3
4b5bab6
7a8b9
;```

The output that PROC PRINT generates shows the resulting NUM data set. Values are
missing for variables in the first and second observations because DSD causes list input
to detect two consecutive delimiters. If you omit DSD, the characters a, b, aa, ab, ba, or
bb function as the delimiter and no variables are assigned missing values.

**Output 2.6  The NUM Data Set**

<table>
<thead>
<tr>
<th>Obs</th>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>.</td>
<td>2</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>5</td>
<td>.</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>
If you want to use a string as the delimiter, specify the delimiter values with the DLMSTR= option. In this example, the string PRD is used as the delimiter. Note that the string contains uppercase characters. By using the DLMSOPT= option, PRD, Prd, PRd, pRD, pRD, prD, and prd are all valid delimiters.

data test;
  infile datalines dsd dlmstr='PRD' dlmsopt='i';
  input X Y Z;
  datalines;
1PRD2PRd3
4PrDSprd6
7pRd8pRD9
;
proc print data=test; run;

The output from PROC PRINT shows all the observations in the TEST data set.

Output 2.7  The TEST Data Set

<table>
<thead>
<tr>
<th>Obs</th>
<th>X</th>
<th>Y</th>
<th>Z</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1</td>
<td>2</td>
<td>3</td>
</tr>
<tr>
<td>2</td>
<td>4</td>
<td>5</td>
<td>6</td>
</tr>
<tr>
<td>3</td>
<td>7</td>
<td>8</td>
<td>9</td>
</tr>
</tbody>
</table>

This DATA step uses modified list input and the DSD option to read data that is separated by commas and that might contain commas as part of a character value:

data scores;
  infile datalines dsd;
  input Name $9. Score
     Team $25. Div $;
  datalines;
Mitchel,82,"Blue Bunnies, Richmond",AAA
Sue Ellen,74,"Green Gazelles, Atlanta",AA
;
proc print; run;

The output that PROC PRINT generates shows the resulting SCORES data set. The delimiter (comma) is stored as part of the value of TEAM while the quotation marks are not.
Example 2: Handling Missing Values and Short Records with List Input
This example demonstrates how to prevent missing values from causing problems when you read the data with list input. Some data lines in this example contain fewer than five temperature values. Use the MISSOVER option so that these values are set to missing.

```
data weather;
  infile datalines missover;
  input temp1-temp5;
  datalines;
97.9 98.1 98.3
98.6 99.2 99.1 98.5 97.5
96.2 97.3 98.3 97.6 96.5
;```

SAS reads the three values on the first data line as the values of TEMP1, TEMP2, and TEMP3. The MISSOVER option causes SAS to set the values of TEMP4 and TEMP5 to missing for the first observation because no values for those variables are in the current input data record.

When you omit the MISSOVER option or use FLOWOVER, SAS moves the input pointer to line 2 and reads values for TEMP4 and TEMP5. The next time the DATA step executes, SAS reads a new line which, in this case, is line 3. This message appears in the SAS log:

```
NOTE: SAS went to a new line when INPUT statement reached past the end of a line.
```

You can also use the STOPOVER option in the INFILE statement. Using the STOPOVER option causes the DATA step to halt execution when an INPUT statement does not find enough values in a record of raw data:

```
infile datalines stopover;
```

Because SAS does not find a TEMP4 value in the first data record, it sets _ERROR_ to 1, stops building the data set, and prints data line 1.

Example 3: Scanning Variable-Length Records for a Specific Character String
This example shows how to use TRUNCOVER in combination with SCANOVER to pull phone numbers from a phone book. The phone number is always preceded by the word “phone:”. Because the phone numbers include international numbers, the maximum length is 32 characters.
filename phonebk host-specific-path;

data _null_;  
    file phonebk;  
    input line $80.;  
    put line;  
    datalines;  
    Jenny's Phone Book  
        Jim Johnson phone: 619-555-9340  
            Jim wants a scarf for the holidays.  
        Jane Jovalley phone: (213) 555-4820  
            Jane started growing cabbage in her garden.  
            Her dog's name is Juniper.  
        J.R. Hauptman phone: (49)12 34-56 78-90  
            J.R. is my brother.  
    ;  
    run;

Use @’phone:’ to scan the lines of the file for a phone number and position the file pointer where the phone number begins. Use TRUNCOVER in combination with SCANOVER to skip the lines that do not contain 'phone:' and write only the phone numbers to the log.

data _null_;  
    infile phonebk truncover scanover;  
    input @'phone:' phone $32.;  
    put phone=;  
    run;

The program writes the following lines to the SAS log:

<table>
<thead>
<tr>
<th>Phone Number</th>
</tr>
</thead>
<tbody>
<tr>
<td>619-555-9340</td>
</tr>
<tr>
<td>(213) 555-4820</td>
</tr>
<tr>
<td>(49)12 34-56 78-90</td>
</tr>
</tbody>
</table>

**Example 4: Reading Files That Contain Variable-Length Records**

This example shows how to use LENGTH=, in combination with the $VARYING. informat, to read a file that contains variable-length records:

data a;  
    infile file-specification length=linelen lrec=510 pad;  
    input firstvar 1-10 @;  /* assign LINELEN */  
    varlen=linelen-10;  /* Calculate VARLEN */  
    input @11 secondvar $varying500. varlen;  
    run;

The following occurs in this DATA step:

- The INFILE statement creates the variable LINELEN but does not assign it a value.
- When the first INPUT statement executes, SAS determines the line length of the record and assigns that value to the variable LINELEN. The single trailing @ holds the record in the input buffer for the next INPUT statement.
- The assignment statement uses the two known lengths (the length of FIRSTVAR and the length of the entire record) to determine the length of VARLEN.
- The second INPUT statement uses the VARLEN value with the informat $VARYING500. to read the variable SECONDVAR.
See the “$VARYINGw. Informat” in SAS Formats and Informats: Reference for more information.

**Example 5: Reading from Multiple Input Files**
The following DATA step reads from two input files during each iteration of the DATA step. As SAS switches from one file to the next, each file remains open. The input pointer remains in place to begin reading from that location the next time an INPUT statement reads from that file.

```sas
data qtrtot(drop=jansale febsale marsale aprsale maysale junsale);
  /* identify location of 1st file */
  infile file-specification-1;
  /* read values from 1st file */
  input name $ jansale febsale marsale;
  qtr1tot=sum(jansale,febsale,marsale);
  /* identify location of 2nd file */
  infile file-specification-2;
  /* read values from 2nd file */
  input @7 aprsale maysale junsale;
  qtr2tot=sum(aprsale,maysale,junsale);
run;
```

The DATA step terminates when SAS reaches an end of file on the shortest input file.

This DATA step uses FILEVAR= to read from a different file during each iteration of the DATA step:

```sas
data allsales;
  length fileloc myinfile $ 300;
  input fileloc $ ; /* read instream data */
  /* The INFILE statement closes the current file and opens a new one if FILELOC changes value when INFILE executes */
  infile file-specification filevar=fileloc
    filename=myinfile end=done;
  /* DONE set to 1 when last input record read */
  do while(not done);
    /* Read all input records from the currently opened input file, write to ALLSALES */
    input name $ jansale febsale marsale;
    output;
  end;
  put 'Finished reading ' myinfile=;
  datalines;
  external-file-1
  external-file-2
  external-file-3
;
```

The FILENAME= option assigns the name of the current input file to the variable MYINFILE. The LENGTH statement ensures that the FILENAME= variable and FILEVAR= variable have a length that is long enough to contain the value of the filename. The PUT statement prints the physical name of the currently open input file to the SAS log.
Example 6: Updating an External File
This example shows how to use the INFILE statement with the SHAREBUFFERS option and the INPUT, FILE, and PUT statements to update an external file in place:

```sas
data _null_; /* The INFILE and FILE statements  */ /* must specify the same file. */ infile file-specification-1 sharebuffers; file file-specification-1; input state $ 1-2 phone $ 5-16; /* Replace area code for NC exchanges */ if state= 'NC' and substr(phone,5,3)='333' then phone='910-'||substr(phone,5,8); put phone 5-16; run;
```

Example 7: Truncating Copied Records
The LENGTH= option is useful when you copy the input file to another file with the PUT _INFILE_ statement. Use LENGTH= to truncate the copied records. For example, these statements truncate the last 20 columns from each input data record before the input data record is written to the output file:

```sas
data _null_; infile file-specification-1 length=a; input; a=a-20; file file-specification-2; put _infile_; run;
```

The START= option is also useful when you want to truncate what the PUT _INFILE_ statement copies. For example, if you do not want to copy the first 10 columns of each record, these statements copy from column 11 to the end of each record in the input buffer:

```sas
data _null_; infile file-specification start=s; input; s=11; file file-specification-2; put _infile_; run;
```

Example 8: Listing the Pointer Location
This DATA step assigns the value of the current pointer location in the input buffer to the variables LINEPT and COLUMNPT:

```sas
data _null_; infile datalines n=2 line=Linept col=Columnpt; input name $ 1-15 #2 @3 id; put linept= columnpt=; datalines;
J. Brooks
40974
T. R. Ansen
4032
;
These statements produce the following line for each execution of the DATA step because the input pointer is on the second line in the input buffer when the PUT statement executes:

```
Linept=2 Columnpt=9
Linept=2 Columnpt=8
```

**Example 9: Working with Data in the Input Buffer**
The `_INFILE_` variable always contains the most recent record that is read from an INPUT statement. This example illustrates the use of the `_INFILE_` variable to

- read an entire record that you want to parse without using the INPUT statement.
- read an entire record that you want to write to the SAS log.
- modify the contents of the input record before parsing the line with an INPUT statement.

The example file contains phone bill information. The numeric data, minutes, and charge are enclosed in angle brackets (`<>`).

```sas
filename phonbill host-specific-filename;
data _null_; file phonbill; input line $80.; put line; datalines;
City Number Minutes Charge
Jackson 415-555-2384 <25> <2.45>
Jefferson 813-555-2356 <15> <1.62>
Joliet 913-555-3223 <65> <10.32>
; run;
```

The following code reads each record and parses the record to extract the minute and charge values.

```sas
data _null_; infile phonbill firstobs=2; input; city = scan(_infile_, 1, ' '); char_min = scan(_infile_, 1, ' '); char_min = substr(char_min, 2, length(char_min)-2); minutes = input(char_min, BEST12.); put city= minutes=; run;
```

The program writes the following lines to the SAS log:

```
city=Jackson minutes=25
city=Jefferson minutes=15
city=Joliet minutes=65
```

The INPUT statement in the following code reads a record from the file. The automatic `_INFILE_` variable is used in the PUT statement to write the record to the log.

```sas
data _null_; infile phonbill; input;
```
put _infile_;  
run;

The program writes the following lines to the SAS log:

<table>
<thead>
<tr>
<th>City</th>
<th>Number</th>
<th>Minutes</th>
<th>Charge</th>
</tr>
</thead>
<tbody>
<tr>
<td>Jackson</td>
<td>415-555-2384</td>
<td>&lt;25&gt;</td>
<td>&lt;2.45&gt;</td>
</tr>
<tr>
<td>Jefferson</td>
<td>813-555-2356</td>
<td>&lt;15&gt;</td>
<td>&lt;1.62&gt;</td>
</tr>
<tr>
<td>Joliet</td>
<td>913-555-3223</td>
<td>&lt;65&gt;</td>
<td>&lt;10.32&gt;</td>
</tr>
</tbody>
</table>

In the following code, the first INPUT statement reads and holds the record in the input buffer. The _INFILE_ = option removes the angle brackets (< >) from the numeric data. The second INPUT statement parses the value in the buffer.

data _null_;  
length city number $16. minutes charge 8.;  
infile phonbill firstobs=2;  
input @;  
(infile = compress(_infile_, '<>'));  
input city number minutes charge;  
put city= number= minutes= charge=;  
run;

The program writes the following lines to the SAS log:

| city=Jackson number=415-555-2384 minutes=25 charge=2.45 |
| city=Jefferson number=813-555-2356 minutes=15 charge=1.62 |
| city=Joliet number=913-555-3223 minutes=65 charge=10.32 |

**Example 10: Accessing the Input Buffers of Multiple Files**

This example uses both the _INFILE_ automatic variable and the _INFILE_ = option to read multiple files and access the input buffers for each of them. The following code creates four files: three data files and one file that contains the names of all the data files. The second DATA step reads the filenames file, opens each data file, and writes the contents to the log. Because the PUT statement needs _INFILE_ for the filenames file and the data file, one of the _INFILE_ variables is referenced with fname.

data _null_;  
do i = 1 to 3;  
    fname='external-data-file' || put(i,1.) || '.dat';  
    file datfiles filevar=fname;  
    do j = 1 to 5;  
        put i j;  
    end;  
    file 'external-filenames-file';  
    put fname;  
    end;  
run;

data _null_;  
infile 'external-filenames-file' _infile=fname;  
input;  
infile datfiles filevar=fname end=eof;  
do while('eof');  
    input;  
    put fname _infile_;  
end;  
run;
The program writes the following lines to the SAS log:

Example 11: Specifying an Encoding When Reading an External File

This example creates a SAS data set from an external file. The external file's encoding is in UTF-8, and the current SAS session encoding is Wlatin1. By default, SAS assumes that the external file is in the same encoding as the session encoding, which causes the character data to be written to the new SAS data set incorrectly.

To tell SAS what encoding to use when reading the external file, specify the ENCODING= option. When you tell SAS that the external file is in UTF-8, SAS then transcodes the external file from UTF-8 to the current session encoding when writing to the new SAS data set. Therefore, the data is written to the new data set correctly in Wlatin1.

libname myfiles 'SAS-library';
filename extfile 'external-file';
data myfiles.unicode;
   infile extfile encoding="utf-8";
   input Make $ Model $ Year;
run;

• “INPUT Statement” on page 199
INFORMAT Statement
Associates informats with variables.

Valid in: DATA step or PROC step
Category: Information
Type: Declarative

Syntax
INFORMAT variable-1 <...variable-n> <informat>;
INFORMAT <variable-1> <... variable-n> <DEFAULT=default-informat>;
INFORMAT variable-1 <...variable-n> informat <DEFAULT=default-informat>;

Arguments
variable
specifies one or more variables to associate with an informat. You must specify at least one variable when specifying an informat or when including no other arguments. Specifying a variable is optional when using a DEFAULT= informat specification.

Tip: To disassociate an informat from a variable, use the variable's name in an INFORMAT statement without specifying an informat. Place the INFORMAT statement after the SET statement. See “Example 3: Removing an Informat” on page 199.

informat
specifies the informat for reading the values of the variables that are listed in the INFORMAT statement.

Tip: If an informat is associated with a variable by using the INFORMAT statement, and that same informat is not associated with that same variable in the INPUT statement, then that informat will behave like informats that you specify with a colon (:) modifier in an INPUT statement. SAS reads the variables by using list input with an informat. For example, you can use the : modifier with an informat to read character values that are longer than eight bytes, or numeric values that contain nonstandard values. For details, see “INPUT Statement, List” on page 221.

See: SAS Formats and Informats: Reference
Example: “Example 2: Specifying Numeric and Character Informats” on page 198

DEFAULT= default-informat
specifies a temporary default informat for reading values of the variables that are listed in the INFORMAT statement. If no variable is specified, then the DEFAULT= informat specification applies a temporary default informat for reading values of all the variables of that type included in the DATA step. Numeric informats are applied to numeric variables, and character informats are applied to character variables. These default informats apply only to the current DATA step.

A DEFAULT= informat specification applies to
• variables that are not named in an INFORMAT or ATTRIB statement
variables that are not permanently associated with an informat within a SAS data set

• variables that are not read with an explicit informat in the current DATA step.

Default: If you omit DEFAULT=, SAS uses $w.d as the default numeric informat and
$w. as the default character informat.

Restriction: Use this argument only in a DATA step.

Tip: A DEFAULT= specification can occur anywhere in an INFORMAT statement.
It can specify either a numeric default, a character default, or both.

Example: “Example 1: Specifying Default Informats” on page 198

Details

The Basics
An INFORMAT statement in a DATA step permanently associates an informat with a variable. You can specify standard SAS informats or user-written informats, previously defined in PROC FORMAT. A single INFORMAT statement can associate the same informat with several variables, or it can associate different informats with different variables. If a variable appears in multiple INFORMAT statements, SAS uses the informat that is assigned last.

CAUTION:
Because an INFORMAT statement defines the length of previously undefined character variables, you can truncate the values of character variables in a DATA step if an INFORMAT statement precedes a SET statement.

How SAS Treats Variables When You Assign Informats with the INFORMAT Statement
Informats that are associated with variables by using the INFORMAT statement behave like informats that are used with modified list input. SAS reads the variables by using the scanning feature of list input, but applies the informat. In modified list input, SAS

• does not use the value of w in an informat to specify column positions or input field
widths in an external file

• uses the value of w in an informat to specify the length of previously undefined character variables

• ignores the value of w in numeric informats

• uses the value of d in an informat in the same way it usually does for numeric informats

• treats blanks that are embedded as input data as delimiters unless you change their status with a DLM= or DLMSTR= option specification in an INFILE statement.

If you have coded the INPUT statement to use another style of input, such as formatted input or column input, that style of input is not used when you use the INFORMAT statement.

Comparisons

• Both the ATTRIB and INFORMAT statements can associate informats with variables, and both statements can change the informat that is associated with a variable. You can also use the INFORMAT statement in PROC DATASETS to change or remove the informat that is associated with a variable. The SAS
windowing environment enables you to associate, change, or disassociate informat
and variables in existing SAS data sets.

- SAS changes the descriptor information of the SAS data set that contains the
  variable. You can use an INFORMAT statement in some PROC steps, but the rules
  are different. For more information, see Chapter 23, “FORMAT Procedure,” in Base
  SAS Procedures Guide.

Examples

**Example 1: Specifying Default Informats**

This example uses an INFORMAT statement to associate a default numeric informat:

```sas
data tstinfmt;
  informat default=3.1;
  input x;
  put x;
  datalines;
111
222
333
;
```

The PUT statement produces these results:

```
11.1
22.2
33.3
```

**Example 2: Specifying Numeric and Character Informats**

This example associates a character informat and a numeric informat with SAS
variables. Although the character variables do not fully occupy 15 column positions, the
INPUT statement reads the data records correctly by using modified list input:

```sas
data name;
  informat FirstName LastName $15. n1 6.2 n2 7.3;
  input firstname lastname n1 n2;
  datalines;
Alexander Robinson 35 11
;
```

The following output shows a partial listing from PROC CONTENTS, as well as the
report PROC PRINT generates.
Output 2.9  Associating Numeric and Character Informats with SAS Variables

<table>
<thead>
<tr>
<th>#</th>
<th>Variable</th>
<th>Type</th>
<th>Len</th>
<th>Informat</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>FirstName</td>
<td>Char</td>
<td>15</td>
<td>$15.</td>
</tr>
<tr>
<td>2</td>
<td>LastName</td>
<td>Char</td>
<td>15</td>
<td>$15.</td>
</tr>
<tr>
<td>3</td>
<td>n1</td>
<td>Num</td>
<td>8</td>
<td>6.2</td>
</tr>
<tr>
<td>4</td>
<td>n2</td>
<td>Num</td>
<td>8</td>
<td>7.3</td>
</tr>
</tbody>
</table>

Output 2.10  PROC PRINT Report

<table>
<thead>
<tr>
<th>Obs</th>
<th>FirstName</th>
<th>LastName</th>
<th>n1</th>
<th>n2</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>Alexander</td>
<td>Robinson</td>
<td>0.35</td>
<td>0.011</td>
</tr>
</tbody>
</table>

Example 3: Removing an Informat
This example disassociates an existing informat. The order of the INFORMAT and SET statements is important.

```sas
data rtest;
  set rtest;
  informat x;
run;
```

Statements:
- “ATTRIB Statement” on page 31
- “INPUT Statement” on page 199
- “INPUT Statement, List” on page 221

INPUT Statement
Describes the arrangement of values in the input data record and assigns input values to the corresponding SAS variables.

Valid in:  DATA step
Category:  File-handling
Type:  Executable
Syntax

\texttt{INPUT <specification(s)> <@ | @@>;} \\

\textbf{Without Arguments}

The \texttt{INPUT} statement with no arguments is called a \textit{null INPUT statement}. The null \texttt{INPUT} statement

\begin{itemize}
  \item brings an input data record into the input buffer without creating any SAS variables
  \item releases an input data record that is held by a trailing @ or a double trailing @.
\end{itemize}

For an example, see “Example 2: Using a Null INPUT Statement” on page 211.

\textbf{Arguments}

\texttt{specification(s)}

\texttt{can include}

\texttt{variable}

names a variable that is assigned input values.

\texttt{(variable-list)}

specifies a list of variables that are assigned input values.

\textbf{Requirement:} The \texttt{(variable-list)} is followed by an \texttt{(informat-list)}.

\textbf{See:} “How to Group Variables and Informats” on page 219

\texttt{$$}

specifies to store the variable value as a character value rather than as a numeric value.

\textbf{Tip:} If the variable is previously defined as character, $$ is not required.

\textbf{Example:} “Example 1: Using Multiple Styles of Input in One INPUT Statement” on page 210

\texttt{pointer-control}

moves the input pointer to a specified line or column in the input buffer.

\textbf{See:} “Column Pointer Controls” on page 201 and “Line Pointer Controls” on page 203

\texttt{column-specifications}

specifies the columns of the input record that contain the value to read.

\textbf{Tip:} Informats are ignored. Only standard character and numeric data can be read correctly with this method.

\textbf{See:} “Column Input” on page 204

\textbf{Example:} “Example 1: Using Multiple Styles of Input in One INPUT Statement” on page 210

\texttt{format-modifier}

allows modified list input or controls the amount of information that is reported in the SAS log when an error in an input value occurs.

\textbf{Tip:} Use modified list input to read data that cannot be read with simple list input.

\textbf{See:} “When to Use List Input” on page 223 and “Format Modifiers for Error Reporting” on page 203

\textbf{Example:} “Example 6: Positioning the Pointer with a Character Variable” on page 213
informat.
specifies an informat to use to read the variable value.

**Tip:** You can use modified list input to read data with informats. Modified list input is useful when the data require informats but cannot be read with formatted input because the values are not aligned in columns.

**See:** “Formatted Input” on page 205 and “List Input” on page 205

**Example:** “Example 2: Using Informat Lists” on page 221

**(informat-list)**
specifies a list of informats to use to read the values for the preceding list of variables.

**Restriction:** The (informat-list) must follow the (variable-list).

**See:** “How to Group Variables and Informats” on page 219

@ holds an input record for the execution of the next INPUT statement within the same iteration of the DATA step. This line-hold specifier is called trailing @.

**Restriction:** The trailing @ must be the last item in the INPUT statement.

**Tip:** The trailing @ prevents the next INPUT statement from automatically releasing the current input record and reading the next record into the input buffer. It is useful when you need to read from a record multiple times.

**See:** “Using Line-Hold Specifiers” on page 207

**Example:** “Example 3: Holding a Record in the Input Buffer” on page 211

@@ holds the input record for the execution of the next INPUT statement across iterations of the DATA step. This line-hold specifier is called double trailing @.

**Restriction:** The double trailing @ must be the last item in the INPUT statement.

**Tip:** The double trailing @ is useful when each input line contains values for several observations, or when a record needs to be reread on the next iteration of the DATA step.

**See:** “Using Line-Hold Specifiers” on page 207

**Example:** “Example 4: Holding a Record across Iterations of the DATA Step” on page 212

**Column Pointer Controls**

@n moves the pointer to column n.

**Range:** a positive integer

**Tip:** If n is not an integer, SAS truncates the decimal value and uses only the integer value. If n is zero or negative, the pointer moves to column 1.

**Example:** @15 moves the pointer to column 15:

```plaintext
input @15 name $10.;
```

**Example:** “Example 7: Moving the Pointer Backward” on page 214

@numeric-variable moves the pointer to the column given by the value of numeric-variable.

**Range:** a positive integer

**Tip:** If numeric-variable is not an integer, SAS truncates the decimal value and only uses the integer value. If numeric-variable is zero or negative, the pointer moves to column 1.

**Example:** The value of the variable A moves the pointer to column 15:
a=15;
    input @a name $10.;

Example: “Example 5: Positioning the Pointer with a Numeric Variable” on page 212

@ (expression)
    moves the pointer to the column that is given by the value of expression.

Restriction: Expression must result in a positive integer.

Tip: If the value of expression is not an integer, SAS truncates the decimal value and only uses the integer value. If it is zero or negative, the pointer moves to column 1.

Example: The result of the expression moves the pointer to column 15:
    b=5;
    input @(b*3) name $10.;

@ 'character-string'
    locates the specified series of characters in the input record and moves the pointer to the first column after character-string.

@ character-variable
    locates the series of characters in the input record that is given by the value of character-variable and moves the pointer to the first column after that series of characters.

Example: The following statement reads in the WEEKDAY character variable. The second @1 moves the pointer to the beginning of the input line. The value for SALES is read from the next non-blank column after the value of WEEKDAY:
    input @1 day 1. @5 weekday $10.
        @1 @weekday sales 8.2;

Example: “Example 6: Positioning the Pointer with a Character Variable” on page 213

@ (character-expression)
    locates the series of characters in the input record that is given by the value of character-expression and moves the pointer to the first column after the series.

Example: “Example 6: Positioning the Pointer with a Character Variable” on page 213

+n
    moves the pointer n columns.

Range: a positive integer or zero

Tip: If n is not an integer, SAS truncates the decimal value and uses only the integer value. If the value is greater than the length of the input buffer, the pointer moves to column 1 of the next record.

Example: This statement moves the pointer to column 23, reads a value for LENGTH from columns 23 through 26, advances the pointer five columns, and reads a value for WIDTH from columns 32 through 35:
    input @23 length 4. +5 width 4.;

Example: “Example 7: Moving the Pointer Backward” on page 214

+numeric-variable
    moves the pointer the number of columns that is given by the value of numeric-variable.

Range: a positive or negative integer or zero

Tip: If numeric-variable is not an integer, SAS truncates the decimal value and uses only the integer value. If numeric-variable is negative, the pointer moves backward. If the current column position becomes less than 1, the pointer moves...
to column 1. If the value is zero, the pointer does not move. If the value is greater
than the length of the input buffer, the pointer moves to column 1 of the next
record.

Example: “Example 7: Moving the Pointer Backward” on page 214

\+(expression)
moves the pointer the number of columns given by expression.

Range: expression must result in a positive or negative integer or zero.

Tip: If expression is not an integer, SAS truncates the decimal value and uses only
the integer value. If expression is negative, the pointer moves backward. If the
current column position becomes less than 1, the pointer moves to column 1. If
the value is zero, the pointer does not move. If the value is greater than the length
of the input buffer, the pointer moves to column 1 of the next record.

**Line Pointer Controls**

\#n
moves the pointer to record \( n \).

Range: a positive integer

Interaction: The \( N= \) option in the INFILE statement can affect the number of
records the INPUT statement reads and the placement of the input pointer after
each iteration of the DATA step. See the option \( N= \) on page 179.

Example: The \#2 moves the pointer to the second record to read the value for ID
from columns 3 and 4:

```sas
input name $10. #2 id 3-4;
```

\#numeric-variable
moves the pointer to the record that is given by the value of numeric-variable.

Range: a positive integer

Tip: If the value of numeric-variable is not an integer, SAS truncates the decimal
value and uses only the integer value.

\#(expression)
moves the pointer to the record that is given by the value of expression.

Range: expression must result in a positive integer.

Tip: If the value of expression is not an integer, SAS truncates the decimal value and
uses only the integer value.

/advanced the pointer to column 1 of the next input record.

Example: The values for NAME and AGE are read from the first input record
before the pointer moves to the second record to read the value of ID from
columns 3 and 4:

```sas
input name age / id 3-4;
```

**Format Modifiers for Error Reporting**

? suppresses printing the invalid data note when SAS encounters invalid data values.

See: “How Invalid Data Is Handled” on page 209

?? suppresses printing the messages and the input lines when SAS encounters invalid
data values. The automatic variable _ERROR_ is not set to 1 for the invalid
observation.
When to Use INPUT
Use the INPUT statement to read raw data from an external file or in-stream data. If your data are stored in an external file, you can specify the file in an INFILE statement. The INFILE statement must execute before the INPUT statement that reads the data records. If your data are in-stream, a DATALINES statement must precede the data lines in the job stream. If your data contain semicolons, use a DATALINES4 statement before the data lines. A DATA step that reads raw data can include multiple INPUT statements.

You can also use the INFILE statement to read in-stream data by specifying a filename of DATALINES in the INFILE statement before the INPUT statement. Using DATALINES in the INFILE statement enables you to use most of the options available in the INFILE statement with in-stream data.

To read data that are already stored in a SAS data set, use a SET statement. To read database or PC file-format data that are created by other software, use the SET statement after you access the data with the LIBNAME statement. See the SAS/ACCESS documentation for more information.

z/OS Specifics
LOG files that are generated under z/OS and captured with PROC PRINTTO contain an ASA control character in column 1. If you are using the INPUT statement to read a LOG file that was generated under z/OS, you must account for this character if you use column input or column pointer controls.

Overview of Input Styles
There are four ways to describe a record's values in the INPUT statement:

- column
- list (simple and modified)
- formatted
- named.

Each variable value is read by using one of these input styles. An INPUT statement can contain any or all of the available input styles, depending on the arrangement of data values in the input records. However, once named input is used in an INPUT statement, you cannot use another input style.

Column Input
With column input, the column numbers follow the variable name in the INPUT statement. These numbers indicate where the variable values are found in the input data records:

```
input name $ 1-8 age 11-12;
```

This INPUT statement can read the following data records:

```
-------+-----+-----
Peterson 21
Morgan  17
```

Because NAME is a character variable, a $ appears between the variable name and column numbers. For more information, see “INPUT Statement, Column” on page 214.
**List Input**

With *list input*, the variable names are simply listed in the INPUT statement. A $ follows the name of each character variable:

```sas
input name $ age;
```

This INPUT statement can read data values that are separated by blanks or aligned in columns (with at least one blank between):

```
Peterson  21
Morgan    17
```

For more information, see “INPUT Statement, List” on page 221.

**Formatted Input**

With *formatted input*, an informat follows the variable name in the INPUT statement. The informat gives the data type and the field width of an input value. Informats also enable you to read data that are stored in nonstandard form, such as packed decimal, or numbers that contain special characters such as commas.

```sas
input name $char8. +2 income comma6.;
```

This INPUT statement reads these data records correctly:

```
Peterson  21,000
Morgan    17,132
```

The pointer control of +2 moves the input pointer to the field that contains the value for the variable INCOME. For more information, see “INPUT Statement, Formatted” on page 217.

**Named Input**

With *named input*, you specify the name of the variable followed by an equal sign. SAS looks for a variable name and an equal sign in the input record:

```sas
input name= $ age=;
```

This INPUT statement reads the following data records correctly:

```
name=Peterson age=21
name=Morgan age=17
```

For more information, see “INPUT Statement, Named” on page 228.

**Multiple Styles in a Single INPUT Statement**

An INPUT statement can contain any or all of the different input styles:

```sas
input idno name $18. team $ 25-30 startwght endwght;
```

This INPUT statement reads the following data records correctly:

```
023 David Shaw         red    189 165
049 Amelia Serrano     yellow 189 165
```

The value of IDNO, STARTWGHT, and ENDWGHT are read with list input, the value of NAME with formatted input, and the value of TEAM with column input.

**Note:** Once named input is used in an INPUT statement, you cannot change input styles.
**Pointer Controls**

**Overview of Pointers**
As SAS reads values from the input data records into the input buffer, it keeps track of its position with a pointer. The INPUT statement provides three ways to control the movement of the pointer:

- **column pointer controls**
  - reset the pointer's column position when the data values in the data records are read.

- **line pointer controls**
  - reset the pointer's line position when the data values in the data records are read.

- **line-hold specifiers**
  - hold an input record in the input buffer so that another INPUT statement can process it. By default, the INPUT statement releases the previous record and reads another record.

With column and line pointer controls, you can specify an absolute line number or column number to move the pointer or you can specify a column or line location relative to the current pointer position. The following table lists the pointer controls that are available with the INPUT statement.

**Table 2.4 Pointer Controls Available in the INPUT Statement**

<table>
<thead>
<tr>
<th>Pointer Controls</th>

</tr>
</tbody>
</table>

*Note:* Always specify pointer controls before the variable to which they apply.

You can use the COLUMN= and LINE= options in the INFILE statement to determine the pointer's current column and line location.

**Using Column and Line Pointer Controls**
Column pointer controls indicate the column in which an input value starts.
Use line pointer controls within the INPUT statement to move to the next input record or to define the number of input records per observation. Line pointer controls specify which input record to read. To read multiple data records into the input buffer, use the N= option in the INFILE statement to specify the number of records. If you omit N=, you need to take special precautions. For more information, see “Reading More than One Record per Observation” on page 208.

**Using Line-Hold Specifiers**

Line-hold specifiers keep the pointer on the current input record when

- a data record is read by more than one INPUT statement (trailing @)
- one input line has values for more than one observation (double trailing @)
- a record needs to be reread on the next iteration of the DATA step (double trailing @).

Use a single trailing @ to allow the next INPUT statement to read from the same record. Use a double trailing @ to hold a record for the next INPUT statement across iterations of the DATA step.

Normally, each INPUT statement in a DATA step reads a new data record into the input buffer. When you use a trailing @, the following occurs:

- The pointer position does not change.
- No new record is read into the input buffer.
- The next INPUT statement for the same iteration of the DATA step continues to read the same record rather than a new one.

SAS releases a record held by a trailing @ when

- a null INPUT statement executes:
  
  ```
  input;
  ```

- an INPUT statement without a trailing @ executes
- the next iteration of the DATA step begins.

Normally, when you use a double trailing @ (@@), the INPUT statement for the next iteration of the DATA step continues to read the same record. SAS releases the record that is held by a double trailing @

- immediately if the pointer moves past the end of the input record
- immediately if a null INPUT statement executes:
  
  ```
  input;
  ```

- when the next iteration of the DATA step begins if an INPUT statement with a single trailing @ executes later in the DATA step:
  
  ```
  input @;
  ```

**Pointer Location After Reading**

Understanding the location of the input pointer after a value is read is important, especially if you combine input styles in a single INPUT statement. With column and formatted input, the pointer reads the columns that are indicated in the INPUT statement and stops in the next column. With list input, however, the pointer scans data records to locate data values and reads a blank to indicate that a value has ended. After reading a value with list input, the pointer stops in the second column after the value.

For example, you can read these data records with list, column, and formatted input:
This INPUT statement uses list input to read the data records:

```sas
input region $ jansales;
```

After reading a value for REGION, the pointer stops in column 9.

These INPUT statements use column and formatted input to read the data records:

- **column input**
  ```sas
  input region $ 1-7 jansales 12-16;
  ```

- **formatted input**
  ```sas
  input region $7. +4 jansales 5.;
  input region $7. @12 jansales 5.;
  ```

To read a value for the variable REGION, the INPUT statements instruct the pointer to read seven columns and stop in column 8.

---

**Reading More than One Record per Observation**

**Using the # Pointer Control**

The highest number that follows the # pointer control in the INPUT statement determines how many input data records are read into the input buffer. Use the N= option in the INFILE statement to change the number of records. For example, in this statement, the highest value after the # is 3:

```sas
input @31 age 3. #3 id 3-4 #2 @6 name $20.;
```

Unless you use N= in the associated INFILE statement, the INPUT statement reads three input records each time the DATA step executes.

When each observation has multiple input records but values from the last record are not read, you must use a # pointer control in the INPUT statement or N= in the INFILE statement to specify the last input record. For example, if there are four records per observation, but only values from the first two input records are read, use this INPUT statement:

```sas
input name $ 1-10 #2 age 13-14 #4;
```

When you have advanced to the next record with the / pointer control, use the # pointer control in the INPUT statement or the N= option in the INFILE statement to set the number of records that are read into the input buffer. To move the pointer back to an earlier record, use a # pointer control. For example, this statement requires the #2 pointer control, unless the INFILE statement uses the N= option, to read two records:

```sas
input a / b #1 @52 c #2;
```

The INPUT statement assigns A a value from the first record. The pointer advances to the next input record to assign B a value. Then the pointer returns from the second
record to column 1 of the first record and moves to column 52 to assign C a value. The #2 pointer control identifies two input records for each observation so that the pointer can return to the first record for the value of C.

If the number of input records per observation varies, use the N= option in the INFILE statement to give the maximum number of records per observation. For more information, see the N= option on page 179.

Reading Past the End of a Line
When you use @ or + pointer controls with a value that moves the pointer to or past the end of the current record and the next value is to be read from the current column, SAS goes to column 1 of the next record to read it. It also writes this message to the SAS log:

NOTE: SAS went to a new line when INPUT statement reached past the end of a line.

You can alter the default behavior (the FLOWOVER option) in the INFILE statement.

Use the STOPOVER option in the INFILE statement to treat this condition as an error and to stop building the data set.

Use the MISSOVER option in the INFILE statement to set the remaining INPUT statement variables to missing values if the pointer reaches the end of a record.

Use the TRUNCOVER option in the INFILE statement to read column input or formatted input when the last variable that is read by the INPUT statement contains varying-length data.

Positioning the Pointer before the Record
When a column pointer control tries to move the pointer to a position before the beginning of the record, the pointer is positioned in column 1. For example, this INPUT statement specifies that the pointer is located in column −2 after the first value is read:

data test;
   input a @(a-3) b;
datalines;
  2;
;
Therefore, SAS moves the pointer to column 1 after the value of A is read. Both variables A and B contain the same value.

How Invalid Data Is Handled
When SAS encounters an invalid character in an input value for the variable indicated, it

- sets the value of the variable that is being read to missing or the value that is specified with the INVALIDDATA= system option. For more information see the “INVALIDDATA= System Option” in SAS System Options: Reference.
- prints an invalid data note in the SAS log.
- prints the input line and column number that contains the invalid value in the SAS log. Unprintable characters appear in hexadecimal. To help determine column numbers, SAS prints a rule line above the input line.
- sets the automatic variable _ERROR_ to 1 for the current observation.

The format modifiers for error reporting control the amount of information that is printed in the SAS log. Both the ? and ?? modifier suppress the invalid data message. However, the ?? modifier also resets the automatic variable _ERROR_ to 0. For example, these two sets of statements are equivalent:
• input x ?? 10-12;
• input x ? 10-12;
  _error_ = 0;

In either case, SAS sets invalid values of X to missing values. For information about the causes of invalid data, see *SAS Language Reference: Concepts*.

**End-of-File**

End-of-file occurs when an INPUT statement reaches the end of the data. If a DATA step tries to read another record after it reaches an end-of-file, then execution stops. If you want the DATA step to continue to execute, use the END= or EOF= option in the INFILE statement. Then you can write SAS program statements to detect the end-of-file, and to stop the execution of the INPUT statement but continue with the DATA step. For more information, see the “INFILE Statement” on page 171.

**Arrays**

The INPUT statement can use array references to read input data values. You can use an array reference in a pointer control if it is enclosed in parentheses. See “Example 6: Positioning the Pointer with a Character Variable” on page 213.

Use the array subscript asterisk (*) to input all elements of a previously defined explicit array. SAS allows single or multidimensional arrays. Enclose the subscript in braces, brackets, or parentheses. The form of this statement is

```
INPUT array-name{*};
```

You can use arrays with list, column, or formatted input. However, you cannot input values to an array that is defined with `_TEMPORARY_` and that uses the asterisk subscript. For example, these statements create variables X1 through X100 and assign data values to the variables using the 2. informat:

```
array x{100};
input x{*} 2.;
```

**Comparisons**

- The INPUT statement reads raw data in external files or data lines that are entered in-stream (following the DATALINES statement) that need to be described to SAS. The SET statement reads a SAS data set, which already contains descriptive information about the data values.
- The INPUT statement reads data while the PUT statement writes data values, text strings, or both to the SAS log or to an external file.
- The INPUT statement can read data from external files; the INFILE statement points to that file and has options that control how that file is read.

**Examples**

**Example 1: Using Multiple Styles of Input in One INPUT Statement**

This example uses several input styles in a single INPUT statement:

```
data club1;
  input Idno Name $18.
    Team $ 25-30 Startwght Endwght;
datalines;
023 David Shaw red 189 165
```
**Example 2: Using a Null INPUT Statement**
This example uses an INPUT statement with no arguments. The DATA step copies records from the input file to the output file without creating any SAS variables:

```sas
data _null_; 
input; 
put _infile_; 
run;
```

**Example 3: Holding a Record in the Input Buffer**
This example reads a file that contains two types of input data records and creates a SAS data set from these records. One type of data record contains information about a particular college course. The second type of record contains information about the students enrolled in the course. You need two INPUT statements to read the two records and to assign the values to different variables that use different formats. Records that contain class information have a C in column 1; records that contain student information have an S in column 1, as shown here:

```
----+----1----+----2----+
C HIST101 Watson
S Williams 0459
S Flores 5423
C MATH202 Sen
S Lee 7085
```

To know which INPUT statement to use, check each record as it is read. Use an INPUT statement that reads only the variable that tells whether the record contains class or student.

```sas
data schedule(drop=type); 
retain Course Professor; 
input type $1. @; 
if type='C' then 
   input course $ professor $; 
else if type='S' then 
do; 
   input Name $10. Id; 
   output schedule; 
end; 
datalines; 
C HIST101 Watson
S Williams 0459
```
The first INPUT statement reads the TYPE value from column 1 of every line. Because this INPUT statement ends with a trailing @, the next INPUT statement in the DATA step reads the same line. The IF-THEN statements that follow check whether the record is a class or student line before another INPUT statement reads the rest of the line. The INPUT statements without a trailing @ release the held line. The RETAIN statement saves the values about the particular college course. The DATA step writes an observation to the SCHEDULE data set after a student record is read.

The following output that PROC PRINT generates shows the resulting data set SCHEDULE.

Output 2.11 Data Set Schedule

<table>
<thead>
<tr>
<th>Obs</th>
<th>Course</th>
<th>Professor</th>

<td>7085</td>
</tr>
</tbody>
</table>

Example 4: Holding a Record across Iterations of the DATA Step
This example shows how to create multiple observations for each input data record. Each record contains several NAME and AGE values. The DATA step reads a NAME value and an AGE value, outputs an observation, and then reads another set of NAME and AGE values to output, and so on, until all the input values in the record are processed.

data test;
  input name $ age @@;
datalines;
John 13 Monica 12 Sue 15 Stephen 10
Marc 22 Lily 17
;

The INPUT statement uses the double trailing @ to control the input pointer across iterations of the DATA step. The SAS data set contains six observations.

Example 5: Positioning the Pointer with a Numeric Variable
This example uses a numeric variable to position the pointer. A raw data file contains records with the employment figures for several offices of a multinational company. The input data records are

---+-+-+-1-+-2-+-3-+-
8    New York  1 USA 14
The first column has the column position for the office location. The next numeric column is the region category. The geographic region occurs before the number of employees in that office.

You determine the office location by combining the @numeric-variable pointer control with a trailing @. To read the records, use two INPUT statements. The first INPUT statement obtains the value for the @numeric-variable pointer control. The second INPUT statement uses this value to determine the column that the pointer moves to.

```
data office (drop=x);
    infile file-specification;
    input x @;
    if 1<=x<=10 then
        input @x City $9.;
    else do;
        put 'Invalid input at line ' _n_;
        delete;
    end;
run;
```

The DATA step writes only five observations to the OFFICE data set. The fourth input data record is invalid because the value of X is greater than 10. Therefore, the second INPUT statement does not execute. Instead, the PUT statement writes a message to the SAS log and the DELETE statement stops processing the observation.

**Example 6: Positioning the Pointer with a Character Variable**

This example uses character variables to position the pointer. The OFFICE data set, created in “Example 5: Positioning the Pointer with a Numeric Variable” on page 212, contains a character variable CITY whose values are the office locations. Suppose you discover that you need to read additional values from the raw data file. By using another DATA step, you can combine the @character-variable pointer control with a trailing @ and the @character-expression pointer control to locate the values.

If the observations in OFFICE are still in the order of the original input data records, you can use this DATA step:

```
data office2;
    set office;
    infile file-specification;
    array region {5} $ _temporary_
       ('USA' 'CANADA' 'SA' 'EUROPE' 'ASIA');
    input @city Location : 2. @;
    input @(trim(region{location})) Population : 4.;
run;
```

The ARRAY statement assigns initial values to the temporary array elements. These elements correspond to the geographic regions of the office locations. The first INPUT statement uses an @character-variable pointer control. Each record is scanned for the series of characters in the value of CITY for that observation. Then the value of LOCATION is read from the next non-blank column. LOCATION is a numeric category for the geographic region of an office. The second INPUT statement uses an array reference in the @character-expression pointer control to determine the location POPULATION in the input records. The expression also uses the TRIM function to trim
trailing blanks from the character value. This way an exact match is found between the character string in the input data and the value of the array element.

The following output that PROC PRINT generates shows the resulting data set OFFICE2.

**Output 2.12  Data Set OFFICE2**

![The SAS System](image)

**Example 7: Moving the Pointer Backward**

This example shows several ways to move the pointer backward.

- This INPUT statement uses the @ pointer control to read a value for BOOK starting at column 26. Then the pointer moves back to column 1 on the same line to read a value for COMPANY:

  ```sas
  input @26 book $ @1 company;
  ```

- These INPUT statements use `+numeric-variable` or `+(expression)` to move the pointer backward one column. These two sets of statements are equivalent.

  ```sas
  m=-1;
  input x 1-10 +m y 2.;
  ```

  ```sas
  input x 1-10 +(-1) y 2.;
  ```

- “INPUT Statement, List” on page 221
- “INPUT Statement, Named” on page 228

**INPUT Statement, Column**

Reads input values from specified columns and assigns them to the corresponding SAS variables.
Valid in: Data step
Category: File-handling
Type: Executable

Syntax

```plaintext
INPUT variable <$ start-column <- end-column>
<decimalals> @ | @@ > ;
```

Arguments

variable

specifies a variable that is assigned input values.

$ indicates that the variable has character values rather than numeric values.

Tip: If the variable is previously defined as character, $ is not required.

start-column

specifies the first column of the input record that contains the value to read.

–end-column

specifies the last column of the input record that contains the value to read.

Tip: If the variable value occupies only one column, omit end-column.

Example: Because end-column is omitted, the values for the character variable GENDER occupy only column 16:

```plaintext
input name $ 1-10 pulse 11-13 waist 14-15 gender $ 16;
```

<decimalals>

specifies the number of digits to the right of the decimal if the input value does not contain an explicit decimal point.

Tip: An explicit decimal point in the input value overrides a decimal specification in the INPUT statement.

Example: “Example 2: Read Input Data Using Decimals” on page 217

@ holds the input record for the execution of the next INPUT statement within the same iteration of the DATA step. This line-hold specifier is called trailing @.

Restriction: The trailing @ must be the last item in the INPUT statement.

Tip: The trailing @ prevents the next INPUT statement from automatically releasing the current input record and reading the next record into the input buffer. It is useful when you need to read from a record multiple times.

See: “Pointer Controls” on page 206

@@ holds the input record for the execution of the next INPUT statement across iterations of the DATA step. This line-hold specifier is called double trailing @.

Restriction: The double trailing @ must be the last item in the INPUT statement.

Tip: The double trailing @ is useful when each input line contains values for several observations.

See: “Using Line-Hold Specifiers” on page 207
When to Use Column Input
With column input, the column numbers that contain the value follow a variable name in
the INPUT statement. To read with column input, data values must be in
• the same columns in all the input data records
• standard numeric form or character form.¹
Useful features of column input are that
• Character values can contain embedded blanks.
• Character values can be from 1 to 32,767 characters long.
• Input values can be read in any order, regardless of their position in the record.
• Values or parts of values can be read multiple times. For example, this INPUT
  statement reads an ID value in columns 10 through 15 and then reads a GROUP
  value from column 13:
    input id 10-15 group 13;
• Both leading and trailing blanks within the field are ignored. Therefore, if numeric
  values contain blanks that represent zeros or if you want to retain leading and trailing
  blanks in character values, read the value with an informat. See the “INPUT
  Statement,Formatted” on page 217.

Missing Values
Missing data do not require a place-holder. The INPUT statement interprets a blank field
as missing and reads other values correctly. If a numeric or character field contains a
single period, the variable value is set to missing.

Reading Data Lines
SAS always pads the data records that follow the DATALINES statement (in-stream
data) to a fixed length in multiples of 80. The CARDIMAGE system option determines
whether to read or to truncate data past the 80th column.

Reading Variable-Length Records
By default, SAS uses the FLOWOVER option to read varying-length data records. If the
record contains fewer values than expected, the INPUT statement reads the values from
the next data record. To read varying-length data, you might need to use the
TRUNCOVER option in the INFILE statement. The TRUNCOVER option is more
efficient than the PAD option, which pads the records to a fixed length. For more
information, see “Reading Past the End of a Line” on page 185.

Examples

Example 1: Read Input Records with Column Input
This DATA step demonstrates how to read input data records with column input:

```
data scores;
  input name $ 1-18 score1 25-27 score2 30-32
      score3 35-37;
```

¹ See SAS Language Reference: Concepts for the definition of standard and nonstandard data values.
Example 2: Read Input Data Using Decimals

This INPUT statement reads the input data for a numeric variable using two decimal places:

<table>
<thead>
<tr>
<th>Input Data</th>
<th>Statement</th>
<th>Results</th>
</tr>
</thead>
<tbody>
<tr>
<td>2314</td>
<td>input number 1-5 .2;</td>
<td>23.14</td>
</tr>
<tr>
<td>2</td>
<td></td>
<td>.02</td>
</tr>
<tr>
<td>400</td>
<td></td>
<td>4.00</td>
</tr>
<tr>
<td>-140</td>
<td></td>
<td>-1.40</td>
</tr>
<tr>
<td>12.234</td>
<td></td>
<td>12.234</td>
</tr>
<tr>
<td>12.2</td>
<td></td>
<td>12.2</td>
</tr>
</tbody>
</table>

* The decimal specification in the INPUT statement is overridden by the input data value.

Statements:
- “INPUT Statement” on page 199

INPUT Statement, Formatted

Reads input values with specified informat and assigns them to the corresponding SAS variables.

Valid in: DATA step
Category: File-handling
Type: Executable

Syntax

INPUT <pointer-control> variable informat. <@ | @@>;  
INPUT <pointer-control> (variable-list) (informat-list)  
<@ | @@>;  
INPUT <pointer-control> (variable-list) (<n*> informat.)  
<@ | @@>;
Arguments

pointer-control
moves the input pointer to a specified line or column in the input buffer.

See: “Column Pointer Controls” on page 201 and “Line Pointer Controls” on page 203

variable
specifies a variable that is assigned input values.

Requirement: The (variable-list) is followed by an (informat-list).

Example: “Example 1: Formatted Input with Pointer Controls” on page 220

(variable-list)
specifies a list of variables that are assigned input values.

See: “How to Group Variables and Informats” on page 219

Example: “Example 2: Using Informat Lists” on page 221

informat.
specifies a SAS informat to use to read the variable values.

Tip: Decimal points in the actual input values override decimal specifications in a numeric informat.

See: SAS Informats in SAS Formats and Informats: Reference

Example: “Example 1: Formatted Input with Pointer Controls” on page 220

(informat-list)
specifies a list of informats to use to read the values for the preceding list of variables

In the INPUT statement, (informat-list) can include

informat.
specifies an informat to use to read the variable values.

pointer-control
specifies one of these pointer controls to use to position a value: @, #, /, or +.

n*
specifies to repeat n times the next informat in an informat list.

Example: This statement uses the 7.2 informat to read GRADES1, GRADES2, and GRADES3 and the 5.2 informat to read GRADES4 and GRADES5:

input (grades1-grades5)(3*7.2, 2*5.2);

Restriction: The (informat-list) must follow the (variable-list).

See: “How to Group Variables and Informats” on page 219

Example: “Example 2: Using Informat Lists” on page 221

@
holds an input record for the execution of the next INPUT statement within the same iteration of the DATA step. This line-hold specifier is called trailing @.

Restriction: The trailing @ must be the last item in the INPUT statement.

Tip: The trailing @ prevents the next INPUT statement from automatically releasing the current input record and reading the next record into the input buffer. It is useful when you need to read from a record multiple times.

See: “Using Line-Hold Specifiers” on page 207

@@
holds an input record for the execution of the next INPUT statement across iterations of the DATA step. This line-hold specifier is called double trailing @.
Restriction: The double trailing @ must be the last item in the INPUT statement.

Tip: The double trailing @ is useful when each input line contains values for several observations.

See: “Using Line-Hold Specifiers” on page 207

Details

When to Use Formatted Input
With formatted input, an informat follows a variable name and defines how SAS reads the values of this variable. An informat gives the data type and the field width of an input value. Informats also read data that are stored in nonstandard form, such as packed decimal, or numbers that contain special characters such as commas. See “Definition of Informats” in Chapter 3 of SAS Formats and Informats: Reference for descriptions of SAS informats.

Simple formatted input requires that the variables be in the same order as their corresponding values in the input data. You can use pointer controls to read variables in any order. For more information, see the “INPUT Statement” on page 199.

Missing Values
Generally, SAS represents missing values in formatted input with a single period for a numeric value and with blanks for a character value. The informat that you use with formatted input determines how SAS interprets a blank. For example, $CHAR. w reads the blanks as part of the value, whereas BZ. w converts a blank to zero.

Reading Variable-Length Records
By default, SAS uses the FLOWOVER option to read varying-length data records. If the record contains fewer values than expected, the INPUT statement reads the values from the next data record. To read varying-length data, you might need to use the TRUNCOVER option in the INFILE statement. For more information, see “Reading Past the End of a Line” on page 185.

How to Group Variables and Informats
When the input values are arranged in a pattern, you can group the informat list. A grouped informat list consists of two lists:

- the names of the variables to read enclosed in parentheses
- the corresponding informats separated by either blanks or commas and enclosed in parentheses.

Informats can make an INPUT statement shorter because the informat list is recycled until all variables are read and the numbered variable names can be used in abbreviated form. Using informat lists avoids listing the individual variables.

For example, if the values for the five variables SCORE1 through SCORE5 are stored as four columns per value without intervening blanks, this INPUT statement reads the values:

```
input (score1-score5) (4. 4. 4. 4. 4.);
```

However, if you specify more variables than informats, the INPUT statement reuses the informat list to read the remaining variables. A shorter version of the previous statement is

```
input (score1-score5) (4. 4. 4. 4. 4.);
```

input {score1-score5} (4.);

You can use as many informat lists as necessary in an INPUT statement, but do not nest the informat lists. After all the values in the variable list are read, the INPUT statement ignores any directions that remain in the informat list. For an example, see “Example 3: Including More Informat Specifications than Necessary” on page 221.

The \textit{n}\* modifier in an informat list specifies to repeat the next informat \textit{n} times. Here is an example.

input {name score1-score5} ($10. \*4.);

\textbf{How to Store Informats}

The informats that you specify in the INPUT statement are not stored with the SAS data set. Informats that you specify with the INFORMAT or ATTRIB statement are permanently stored. Therefore, you can read a data value with a permanently stored informat in a later DATA step without having to specify the informat or use PROC FSEDIT to enter data in the correct format.

\textbf{Comparisons}

When a variable is read with formatted input, the pointer movement is similar to the pointer movement of column input. The pointer moves the length that the informat specifies and stops at the next column. To read data with informats that are not aligned in columns, use \textit{modified list input}. Using modified list input enables you to take advantage of the scanning feature in list input. See “When to Use List Input” on page 223.

\textbf{Examples}

\textbf{Example 1: Formatted Input with Pointer Controls}

This INPUT statement uses informats and pointer controls:

```
data sales;
  infile file-specification;
  input item $10. +5 jan comma5. +5 feb comma5.+5 mar comma5.;
run;
```

It can read these input data records:

```
----+----1----+----2----+----3----+----4
trucks         1,382     2,789     3,556
vans           1,265     2,543     3,987
sedans         2,391     3,011     3,658
```

The value for ITEM is read from the first 10 columns in a record. The pointer stops in column 11. The trailing blanks are discarded and the value of ITEM is written to the program data vector. Next, the pointer moves five columns to the right before the INPUT statement uses the COMMA5. informat to read the value of JAN. This informat uses five as the field width to read numeric values that contain a comma. Once again, the pointer moves five columns to the right before the INPUT statement uses the COMMA5. informat to read the values of FEB and MAR.
**Example 2: Using Informat Lists**
This INPUT statement uses the character informat $10. to read the values of the variable NAME and uses the numeric informat 4. to read the values of the five variables SCORE1 through SCORE5:

```sas
data scores;
  input (name score1-score5) ($10. 5*4.);
datalines;
Whittaker 121 114 137 156 142
Smythe 111 97 122 143 127
;
```

**Example 3: Including More Informat Specifications than Necessary**
This informat list includes more specifications than are necessary when the INPUT statement executes:

```sas
data test;
  input (x y z) (2.,+1);
datalines;
2 24 36
0 20 30
; 
```

The INPUT statement reads the value of X with the 2. informat. Then, the +1 column pointer control moves the pointer forward one column. Next, the value of Y is read with the 2. informat. Again, the +1 column pointer moves the pointer forward one column. Then, the value of Z is read with the 2. informat. For the third iteration, the INPUT statement ignores the +1 pointer control.

**INPUT Statement, List**
Scans the input data record for input values and assigns them to the corresponding SAS variables.

- **Valid in:** DATA step
- **Category:** File-handling
- **Type:** Executable

**Syntax**

```sas
INPUT <pointer-control> variable <$> <&> <@ | @@>;
INPUT <pointer-control> variable <.: | & | -> <informat.> <@ | @@>;
```
Arguments

**pointer-control**

moves the input pointer to a specified line or column in the input buffer.

**See:** “Column Pointer Controls” on page 201 and “Line Pointer Controls” on page 203

**Example:** “Example 2: Reading Character Data That Contains Embedded Blanks” on page 225

**variable**

specifies a variable that is assigned input values.

$ 

indicates to store a variable value as a character value rather than as a numeric value.

**Tip:** If the variable is previously defined as character, $ is not required.

**Example:** “Example 1: Reading Unaligned Data with Simple List Input” on page 225

& 

indicates that a character value can have one or more single embedded blanks. This format modifier reads the value from the next non-blank column until the pointer reaches two consecutive blanks, the defined length of the variable, or the end of the input line, whichever comes first.

**Restriction:** The & modifier must follow the variable name and $ sign that it affects.

**Tip:** If you specify an informat after the & modifier, the terminating condition for the format modifier remains two blanks.

**See:** “Modified List Input” on page 224

**Example:** “Example 2: Reading Character Data That Contains Embedded Blanks” on page 225

: 

enables you to specify an informat that the INPUT statement uses to read the variable value. For a character variable, this format modifier reads the value from the next non-blank column until the pointer reaches the next blank column, the defined length of the variable, or the end of the data line, whichever comes first. For a numeric variable, this format modifier reads the value from the next non-blank column until the pointer reaches the next blank column or the end of the data line, whichever comes first.

**Tips:**

If the length of the variable has not been previously defined, then its value is read and stored with the informat length.

The pointer continues to read until the next blank column is reached. However, if the field is longer than the formatted length, then the value is truncated to the length of variable.

**See:** “Modified List Input” on page 224

**Examples:**

“Example 3: Reading Unaligned Data with Informat” on page 226

“Example 5: Reading Delimited Data with Modified List Input” on page 227

~ 

indicates to treat single quotation marks, double quotation marks, and delimiters in character values in a special way. This format modifier reads delimiters within quoted character values as characters instead of as delimiters and retains the quotation marks when the value is written to a variable.
Restriction: You must use the DSD option in an INFILE statement. Otherwise, the INPUT statement ignores this option.

See: “Modified List Input” on page 224

Example: “Example 5: Reading Delimited Data with Modified List Input” on page 227

informat.

specifies an informat to use to read the variable values.

Tip: Decimal points in the actual input values always override decimal specifications in a numeric informat.

See: SAS Informs in SAS Formats and Informats: Reference

Examples:

“Example 3: Reading Unaligned Data with Informats” on page 226

@

holds an input record for the execution of the next INPUT statement within the same iteration of the DATA step. This line-hold specifier is called trailing @.

Restriction: The trailing @ must be the last item in the INPUT statement.

Tip: The trailing @ prevents the next INPUT statement from automatically releasing the current input record and reading the next record into the input buffer. It is useful when you need to read from a record multiple times.

See: “Using Line-Hold Specifiers” on page 207

@@

holds an input record for the execution of the next INPUT statement across iterations of the DATA step. This line-hold specifier is called double trailing @.

Restriction: The double trailing @ must be the last item in the INPUT statement.

Tip: The double trailing @ is useful when each input line contains values for several observations.

See: “Using Line-Hold Specifiers” on page 207

Details

When to Use List Input

List input requires that you specify the variable names in the INPUT statement in the same order that the fields appear in the input data records. SAS scans the data line to locate the next value but ignores additional intervening blanks. List input does not require that the data are located in specific columns. However, you must separate each value from the next by at least one blank unless the delimiter between values is changed. By default, the delimiter for data values is one blank space or the end of the input record. List input will not skip over any data values to read subsequent values, but it can ignore all values after a given point in the data record. However, pointer controls enable you to change the order that the data values are read.

There are two types of list input:

• simple list input
• modified list input.

Modified list input makes the INPUT statement more versatile because you can use a format modifier to overcome several of the restrictions of simple list input. See “Modified List Input” on page 224.
Simple List Input
Simple list input places several restrictions on the type of data that the INPUT statement can read:

- By default, at least one blank must separate the input values. Use the DLM= or DLMSTR= option or the DSD option in the INFILE statement to specify a delimiter other than a blank.

- Represent each missing value with a period, not a blank, or two adjacent delimiters.

- Character input values cannot be longer than 8 bytes unless the variable is given a longer length in an earlier LENGTH, ATTRIB, or INFORMAT statement.

- Character values cannot contain embedded blanks unless you change the delimiter.

- Data must be in standard numeric or character format.

Modified List Input
List input is more versatile when you use format modifiers. The format modifiers are as follows:

<table>
<thead>
<tr>
<th>Format Modifier</th>
<th>Purpose</th>
</tr>
</thead>
<tbody>
<tr>
<td>&amp;</td>
<td>reads character values that contain embedded blanks.</td>
</tr>
<tr>
<td>:</td>
<td>reads data values that need the additional instructions that informats can provide but that are not aligned in columns.*</td>
</tr>
<tr>
<td>~</td>
<td>reads delimiters within quoted character values as characters and retains the quotation marks.</td>
</tr>
</tbody>
</table>

* Use formatted input and pointer controls to quickly read data values that are aligned in columns.

For example, use the : modifier with an informat to read character values that are longer than 8 bytes or numeric values that contain nonstandard values.

Because list input interprets a blank as a delimiter, use modified list input to read values that contain blanks. The & modifier reads character values that contain single embedded blanks. However, the data values must be separated by two or more blanks. To read values that contain leading, trailing, or embedded blanks with list input, use the DLM= or DLMSTR= option in the INFILE statement to specify another character as the delimiter. See “Example 5: Reading Delimited Data with Modified List Input” on page 227. If your input data use blanks as delimiters and they contain leading, trailing, or embedded blanks, you might need to use either column input or formatted input. If quotation marks surround the delimited values, you can use list input with the DSD option in the INFILE statement.

Comparisons
How Modified List Input and Formatted Input Differ

Modified list input has a scanning feature that can use informats to read data which are not aligned in columns. Formatted input causes the pointer to move like that of column input to read a variable value. The pointer moves the length that is specified in the informat and stops at the next column.

This DATA step uses modified list input to read the first data value and formatted input to read the second:

---

1 See SAS Language Reference: Concepts for the information about standard and nonstandard data values.
data jansales;
  input item $10. amount comma5.;;
datalines;
trucks 1,382
vans 1,235
sedans 2,391
;

The value of ITEM is read with modified list input. The INPUT statement stops reading when the pointer finds a blank space. The pointer then moves to the second column after the end of the field, which is the correct position to read the AMOUNT value with formatted input.

Formatted input, on the other hand, continues to read the entire width of the field. This INPUT statement uses formatted input to read both data values:

input item $10. +1 amount comma5.;;

To read this data correctly with formatted input, the second data value must occur after the 10th column of the first value, as shown here:

```
-------1-------2
trucks 1,382
vans 1,235
sedans 2,391
```

Also, after the value of ITEM is read with formatted input, you must use the pointer control +1 to move the pointer to the column where the value AMOUNT begins.

**When Data Contains Quotation Marks**

When you use the DSD option in an INFILE statement, which sets the delimiter to a comma, the INPUT statement removes quotation marks before a value is written to a variable. When you also use the tilde (~) modifier in an INPUT statement, the INPUT statement maintains quotation marks as part of the value.

**Examples**

**Example 1: Reading Unaligned Data with Simple List Input**

The INPUT statement in this DATA step uses simple list input to read the input data records:

data scores;
  input name $ score1 score2 score3 team $;
datalines;
Joe 11 32 76 red
Mitchel 13 29 82 blue
Susan 14 27 74 green
;

The next INPUT statement reads only the first four fields in the previous data lines, which demonstrates that you are not required to read all the fields in the record:

input name $ score1 score2 score3;

**Example 2: Reading Character Data That Contains Embedded Blanks**

The INPUT statement in this DATA step uses the & format modifier with list input to read character values that contain embedded blanks.
data list;
  infile file-specification;
  input name $ & score;
run;

It can read these input data records:

----+----1----+----2----+----3----+
Joseph  11 Joergensen  red
Mitchel  13 Mc Allister  blue
Su Ellen 14 Fischer-Simon  green

The & modifier follows the variable that it affects in the INPUT statement. Because this format modifier follows NAME, at least two blanks must separate the NAME field from the SCORE field in the input data records.

You can also specify an informat with a format modifier, as shown here:

    input name $ & +3 lastname & $15. team $;

In addition, this INPUT statement reads the same data to demonstrate that you are not required to read all the values in an input record. The +3 column pointer control moves the pointer past the score value in order to read the value for LASTNAME and TEAM.

Example 3: Reading Unaligned Data with Informats
This DATA step uses modified list input to read data values with an informat:

data jansales;
  input item : $10. amount;
  datalines;
  trucks 1382
  vans 1235
  sedans 2391
; 

The $10. informat allows a character variable of up to ten characters to be read.

Example 4: Reading Comma-Delimited Data with List Input and an Informat
This DATA step uses the DELIMITER= option in the INFILE statement to read list input values that are separated by commas instead of blanks. The example uses an informat to read the date, and a format to write the date.

data scores2;
  length Team $ 14;
  infile datalines delimiter=',';
  input Name $ Score1-Score3 Team $ Final_Date:MMDDYY10.:;
  format final_date weekdate17.:;
  datalines;
  Mitchell,13,29,82,Blue Bunnies,4/5/2007
  Susan,14,27,74,Green Gazelles,11/13/2007
; 
  proc print data=scores2;
  var Name Team Score1-Score3 Final_Date;
  title 'Soccer Player Scores';
run;
Output 2.13  Output from Comma-Delimited Data

Example 5: Reading Delimited Data with Modified List Input
This DATA step uses the DSD option in an INFILE statement and the tilde (~) format modifier in an INPUT statement to retain the quotation marks in character data and to read a character in a string that is enclosed in quotation marks as a character instead of as a delimiter.

```sas
data scores;
  infile datalines dsd;
  input Name : $9. Score1-Score3
    Team ~ $25. Div $;
  datalines;
  Mitchel,13,29,82,"Blue Bunnies, Richmond",AAA
  Sue Ellen,14,27,74,"Green Gazelles, Atlanta",AA
; proc print; run;
```

The output that PROC PRINT generates shows the resulting SCORES data set. The values for TEAM contain the quotation marks.

Output 2.14  SCORES Data Set

- “INPUT Statement, Formatted” on page 217
**INPUT Statement, Named**

Reads data values that appear after a variable name that is followed by an equal sign and assigns them to corresponding SAS variables.

- **Valid in:** DATA step
- **Category:** File-handling
- **Type:** Executable

**Syntax**

```
INPUT <pointer-control> variable= <$> <@ | @@> ;
INPUT <pointer-control> variable= informat. <@ | @@> ;
INPUT variable= <$> start-column <end-column> <.decimals> <@ | @@> ;
```

**Arguments**

- **pointer-control**
  moves the input pointer to a specified line or column in the input buffer.
  
  **See:** “Column Pointer Controls” on page 201 and “Line Pointer Controls” on page 203

- **variable=**
  specifies a variable whose value is read by the INPUT statement. In the input data record, the field has the form
  
  variable=value

  **Example:** “Example 3: Using Named Input with Another Input Style” on page 230

- **$**
  indicates to store a variable value as a character value rather than as a numeric value.

  **Tip:** If the variable is previously defined as character, $ is not required.

  **Example:** “Example 3: Using Named Input with Another Input Style” on page 230

- **informat.**
  specifies an informat that indicates the data type of the input values, but not how the values are read.

  **Tip:** Use the INFORMAT statement to associate an informat with a variable.

  **See:** SAS Informats in *SAS Formats and Informats: Reference*

  **Example:** “Example 3: Using Named Input with Another Input Style” on page 230

- **start-column**
  specifies the column that the INPUT statement uses to begin scanning in the input data records for the variable. The variable name does not have to begin here.

- **end-column**
  determines the default length of the variable.

- **.decimals**
  specifies the number of digits to the right of the decimal if the input value does not contain an explicit decimal point.
Tip: An explicit decimal point in the input value overrides a decimal specification in the INPUT statement.

@ holds an input record for the execution of the next INPUT statement within the same iteration of the DATA step. This line-hold specifier is called trailing @.

Restriction: The trailing @ must be the last item in the INPUT statement.

Tip: The trailing @ prevents the next INPUT statement from automatically releasing the current input record and reading the next record into the input buffer. It is useful when you need to read from a record multiple times.

See: “Using Line-Hold Specifiers” on page 207

@@ holds an input record for the execution of the next INPUT statement across iterations of the DATA step. This line-hold specifier is called double trailing @.

Restriction: The double trailing @ must be the last item in the INPUT statement.

Tip: The double trailing @ is useful when each input line contains values for several observations.

See: “Using Line-Hold Specifiers” on page 207

Details

When to Use Named Input

Named input reads the input data records that contain a variable name followed by an equal sign and a value for the variable. The INPUT statement reads the input data record at the current location of the input pointer. If the input data records contain data values at the start of the record that the INPUT statement cannot read with named input, use another input style to read them. However, once the INPUT statement starts to read named input, SAS expects that all the remaining values are in this form. See “Example 3: Using Named Input with Another Input Style” on page 230.

You do not have to specify the variables in the INPUT statement in the same order that they occur in the data records. Also, you do not have to specify a variable for each field in the record. However, if you do not specify a variable in the INPUT statement that another statement uses (for example, ATTRIB, FORMAT, INFORM, LENGTH statement) and it occurs in the input data record, the INPUT statement automatically reads the value. SAS writes a note to the log that the variable is uninitialized.

When you do not specify a variable for all the named input data values, SAS sets _ERROR_ to 1 and writes a note to the log. Here is an example.

```sas
data list;
  input name=$ age=;
datalines;
name=John age=34  gender=M
; 
```

The note that SAS writes to the log states that GENDER is not defined and _ERROR_ is set to 1.

Restrictions

- After you start to read with named input, you cannot switch to another input style or use pointer controls. All the remaining values in the input data record must be in the form variable=value. SAS treats the values that are not in named input form as invalid data.
If named input values continue after the end of the current input line, use a slash (/) at the end of the input line. The slash tells SAS to move the pointer to the next line and to continue to read with named input. For example,

```sas
input name=$ age=;
can read this input data record:
name=John /
age=34
```

If you use named input to read character values that contain embedded blanks, put two blanks before and after the data value, as you would with list input. See “Example 4: Reading Character Variables with Embedded Blanks” on page 231.

You cannot reference an array with an asterisk or an expression subscript.

**Examples**

**Example 1: Using List and Named Input**

This DATA step uses list input with named input to read input data records.

```sas
data list;
  length name $ 20 gender $ 1;
informat dob ddmmyy8.;
input id name= gender= age= dob=;
datalines;
4798 name=COLIN gender=m age=23 dob=16/02/75
2653 name=MICHELE gender=f age=46 dob=17/02/73
;proc print data=list; run;
```

The INPUT statement uses list input to read the ID variable. The remaining variables NAME, GENDER, AGE, and DOB are read with named input. The LENGTH statement prevents the INPUT statement from truncating the character values for the variable name to a length of eight.

**Example 2: Using Named Input with Variables in Random Order**

Using the same data as in the previous example, this DATA step also uses list input and named input to read input data records. However, in this example, the order of the values in the data is different for the two rows, except for the ID value, which must come first.

```sas
data list;
  length name $ 20 gender $ 1;
informat dob ddmmyy8.;
input id dob= name= gender= age=;
datalines;
4798 gender=m name=COLIN age=23 dob=16/02/75
2653 name=MICHELE dob=17/02/73 age=46 gender=f
;proc print data=list; run;
```

**Example 3: Using Named Input with Another Input Style**

This DATA step uses list input and named input to read input data records:

```sas
data list;
input id name=$20. gender=$;
informat dob ddmmyy8.;
```
data list;
4798 gender=m name=COLIN age=23 dob=16/02/75
2653 name=MICHELE age=46 gender=f
;
proc print data=list; run;

The INPUT statement uses list input to read the first variable, ID. The remaining variables NAME, GENDER, and DOB are read with named input. These variables are not read in order. The $20. informat with NAME= prevents the INPUT statement from truncating the character value to a length of eight. The INPUT statement reads the DOB= field because the INFORMAT statement refers to this variable. It skips the AGE= field altogether. SAS writes notes to the log that DOB is uninitialized, AGE is not defined, and _ERROR_ is set to 1.

**Example 4: Reading Character Variables with Embedded Blanks**

This DATA step reads character variables that contain embedded blanks with named input:

data list2;
    informat header $30. name $15.;
    input header= name=;
    datalines;
header= age=60 AND UP name=PHILIP
;

Two spaces precede and follow the value of the variable HEADER, which is AGE=60 AND UP. The field also contains an equal sign.

See Also

Statements:

- “INPUT Statement” on page 199

---

**KEEP Statement**

Specifies the variables to include in output SAS data sets.

**Valid in:** DATA step

**Category:** Information

**Type:** Declarative

**Syntax**

```
KEEP variable-list;
```

**Arguments**

`variable-list`

specifies the names of the variables to write to the output data set.

**Tip:** List the variables in any form that SAS allows.
Details

The KEEP statement causes a DATA step to write only the variables that you specify to one or more SAS data sets. The KEEP statement applies to all SAS data sets that are created within the same DATA step and can appear anywhere in the step. If no KEEP or DROP statement appears, all data sets that are created in the DATA step contain all variables.

*Note:* Do not use both the KEEP and DROP statements within the same DATA step.

Comparisons

- The KEEP statement cannot be used in SAS PROC steps. The KEEP= data set option can.
- The KEEP statement applies to all output data sets that are named in the DATA statement. To write different variables to different data sets, you must use the KEEP= data set option.
- The DROP statement is a parallel statement that specifies variables to omit from the output data set.
- The KEEP and DROP statements select variables to include in or exclude from output data sets. The subsetting IF statement selects observations.
- Do not confuse the KEEP statement with the RETAIN statement. The RETAIN statement causes SAS to hold the value of a variable from one iteration of the DATA step to the next iteration. The KEEP statement does not affect the value of variables but only specifies which variables to include in any output data sets.

Examples

**Example 1: KEEP Statement Basic Usage**

These examples show the correct syntax for listing variables in the KEEP statement:

```sas
keep name address city state zip phone;
keep rep1-rep5;
```

**Example 2: Keeping Variables in the Data Set**

This example uses the KEEP statement to include only the variables NAME and AVG in the output data set. The variables SCORE1 through SCORE20, from which AVG is calculated, are not written to the data set AVERAGE.

```sas
data average;
  keep name avg;
  infile file-specification;
  input name $ score1-score20;
  avg=mean(of score1-score20);
run;
```

See Also

**Data Set Options:**

- “KEEP= Data Set Option” in *SAS Data Set Options: Reference*
LABEL Statement
Assigns descriptive labels to variables.

Valid in: DATA step
Category: Information
Type: Declarative

Syntax
LABEL variable-1=label-1...<variable-n=label-n>;
LABEL variable-1=' '...<variable-n=' '>;

Arguments
variable
specifies the variable that you want to label.
Tip: You can specify additional pairs of labels and variables.

label
specifies a label of up to 256 characters, including blanks.
Restrictions:
If the label includes a semicolon (;) or an equal sign (=), you must enclose the label in either single or double quotation marks.
If the label includes single quotation marks (‘), then you must enclose the label in double quotation marks.

Tips:
You can specify additional pairs of labels and variables.
For more information about including quotation marks as part of the label, see “Character Constants” in Chapter 6 of SAS Language Reference: Concepts.

' '
removes a label from a variable. Enclose a single blank space in quotation marks to remove an existing label.

Details
Using a LABEL statement in a DATA step permanently associates labels with variables by affecting the descriptor information of the SAS data set that contains the variables. You can associate any number of variables with labels in a single LABEL statement.

You can use a LABEL statement in a PROC step, but the rules are different. See the Base SAS Procedures Guide for more information.

Comparisons
Both the ATTRIB and LABEL statements can associate labels with variables and change a label that is associated with a variable.
Examples

**Example 1: Specifying Labels**

Here are several LABEL statements:

- `label compound=Type of Drug;`
- `label date="Today's Date";`
- `label n='Mark's Experiment Number';`
- `label score1="Grade on April 1 Test" score2="Grade on May 1 Test";`

**Example 2: Removing a Label**

This example removes an existing label:

```sas
data rtest;
  set rtest;
  label x=' ';
run;
```

See Also

Statements:

- “ATTRIB Statement” on page 31

---

**label: Statement**

Identifies a statement that is referred to by another statement.

**Valid in:** DATA step  
**Category:** Control  
**Type:** Declarative

**Syntax**

```
label: statement;
```

**Arguments**

- **label**  
  specifies any SAS name, which is followed by a colon (:). You must specify the `label` argument.

- **statement**  
  specifies any executable statement, including a null statement (;). You must specify the `statement` argument.

**Restrictions:**

- No two statements in a DATA step can have the same label.
- If a statement in a DATA step is labeled, it should be referenced by a statement or option in the same step.
**Tip:** A null statement can have a label:

```
ABC:;
```

**Details**

The statement label identifies the destination of either a GO TO statement, a LINK statement, the HEADER= option in a FILE statement, or the EOF= option in an INFILE statement.

**Comparisons**

The LABEL statement assigns a descriptive label to a variable. A statement label identifies a statement or group of statements that are referred to in the same DATA step by another statement, such as a GO TO statement.

**Example: Jumping to Another Statement**

In this example, if `Stock=0`, the GO TO statement causes SAS to jump to the statement that is labeled `reorder`. When `Stock` is not `0`, execution continues to the RETURN statement and then returns to the beginning of the DATA step for the next observation.

```sas
data Inventory Order;
  input Item $ Stock @;
  /* go to label reorder: */
  if Stock=0 then go to reorder;
  output Inventory;
  return;
  /* destination of GO TO statement */
  reorder: input Supplier $;
  put 'ORDER ITEM ' Item ' FROM ' Supplier;
  output Order;
  datalines;
milk  0 A
bread 3 B
```

**See Also**

**Statements:**
- “GO TO Statement” on page 159
- “LINK Statement” on page 256

**Statement Options:**
- “HEADER=label” on page 83 option in the FILE statement
- “EOF=label” on page 176 in the INFILE statement

---

**LEAVE Statement**

Stops processing the current loop and resumes with the next statement in the sequence.

**Valid in:** DATA step
LEAVE;

Without Arguments
The LEAVE statement stops the processing of the current DO loop or SELECT group and continues DATA step processing with the next statement following the DO loop or SELECT group.

Details
You can use the LEAVE statement to exit a DO loop or SELECT group prematurely based on a condition.

Comparisons
- The LEAVE statement causes processing of the current loop to end. The CONTINUE statement stops the processing of the current iteration of a loop and resumes with the next iteration.
- You can use the LEAVE statement in a DO loop or in a SELECT group. You can use the CONTINUE statement only in a DO loop.

Example: Stop Processing a DO Loop under a Given Condition
This DATA step demonstrates using the LEAVE statement to stop the processing of a DO loop under a given condition. In this example, the IF/THEN statement checks the value of BONUS. When the value of BONUS reaches 500, the maximum amount allowed, the LEAVE statement stops the processing of the DO loop.

data week;
  input name $ idno start_yr status $ dept $;
  bonus=0;
  do year= start_yr to 1991;
    if bonus ge 500 then leave;
    bonus+50;
  end;
  datalines;

See Also

Statements:
LENGTH Statement

Specifies the number of bytes for storing variables.

Valid in: DATA step
Category: Information
Type: Declarative
See: LENGTH Statement under Windows, UNIX, and z/OS

CAUTION: Avoid shortening numeric variables that contain fractions. The precision of a numeric variable is closely tied to its length, especially when the variable contains fractional values. You can safely shorten variables that contain integers according to the rules that are given in the SAS documentation for your operating environment, but shortening variables that contain fractions might eliminate important precision.

Syntax

LENGTH variable-specification(s)<DEFAULT=n>;

Arguments

variable-specification
  is a required argument and has the form
  variable(s)$>length
  variable
  specifies one or more variables that are to be assigned a length. This includes any variables in the DATA step, including those dropped from the output data set.
  Restriction: Array references are not allowed.
  Tip: If the variable is character, the length applies to the program data vector and the output data set. If the variable is numeric, the length applies only to the output data set.

$ specifies that the preceding variables are character variables.
  Default: SAS assumes that the variables are numeric.

length
  specifies a numeric constant that is the number of bytes used for storing variable values.
  Range: For numeric variables, 2 to 8 or 3 to 8, depending on your operating environment. For character variables, 1 to 32,767 under all operating environments.

DEFAULT=n
  changes the default number of bytes that SAS uses to store the values of any newly created numeric variables.
  Default: 8
  Range: 2 to 8 or 3 to 8, depending on your operating environment.
Details

In general, the length of a variable depends on the following:

• whether the variable is numeric or character
• how the variable was created
• whether a LENGTH or ATTRIB statement is present.

Subject to the rules for assigning lengths, lengths that are assigned with the LENGTH statement can be changed in the ATTRIB statement and vice versa. See Chapter 4, “SAS Variables,” in SAS Language Reference: Concepts for information about assigning lengths to variables.

Operating Environment Information

Valid variable lengths depend on your operating environment. For details, see the SAS documentation for your operating environment.

Comparisons

The ATTRIB statement can assign the length as well as other attributes of variables.

Example

This example uses a LENGTH statement to set the length of the character variable NAME to 25 bytes. The LENGTH statement also changes the default number of bytes that SAS uses to store the values of newly created numeric variables from 8 to 4 bytes. The TRIM function removes trailing blanks from LASTNAME before it is concatenated with these items:

• a comma (,)
• a blank space
• the value of FIRSTNAME

If you omit the LENGTH statement, SAS sets the length of NAME to 32 bytes.

```
data testlength;
  informat FirstName LastName $15. n1 6.2;
  input firstname lastname n1 n2;
  length name $25 default=4;
  name=trim(lastname)||', '|first
```
Output 2.15  Partial PROC CONTENTS for TESTLENGTH

<table>

Statements:

- “ATTRIB Statement” on page 31

LIBNAME Statement

 Associates or disassociates a SAS library with a libref (a shortcut name), clears one or all librefs, lists the characteristics of a SAS library, concatenates SAS libraries, or concatenates SAS catalogs.

Valid in: Anywhere
Category: Data Access
See: LIBNAME Statement under Windows, UNIX, and z/OS

Syntax

Form 1:  LIBNAME libref <engine> ’SAS-library’ <options> <engine/host-options> ;
Form 2:  LIBNAME libref CLEAR | _ALL_ CLEAR ;
Form 3:  **LIBNAME libref LIST | _ALL_ LIST;**

Form 4:  **LIBNAME libref <engine> (library-specification-1 <…library-specification-n>) <options>;**

**Arguments**

*libref*  
is a shortcut name or a “nickname” for the aggregate storage location where your SAS files are stored. It is any SAS name when you are assigning a new libref. When you are disassociating a libref from a SAS library or when you are listing attributes, specify a libref that was previously assigned.  
**Range:** 1 to 8 bytes  
**Tip:** The association between a libref and a SAS library lasts only for the duration of the SAS session or until you change it or discontinue it with another LIBNAME statement.

*SAS-library*  
must be the physical name for the SAS library. The physical name is the name that is recognized by the operating environment. Enclose the physical name in single or double quotation marks.

**Operating environment:** For details about specifying the physical names of files, see the SAS documentation for your operating environment.

.library-specification*  
is two or more SAS libraries that are specified by physical names, previously assigned librefs, or a combination of the two. Separate each specification with either a blank or a comma and enclose the entire list in parentheses.

*SAS-library*  
is the physical name of a SAS library, enclosed in quotation marks.

*libref*  
is the name of a previously assigned libref.

**Restriction:** When concatenating libraries, you cannot specify options that are specific to an engine or an operating environment.

**See:** “Rules for Library Concatenation” on page 248

**Example:** “Example 2: Logically Concatenating SAS Libraries” on page 249

*engine*  
is an engine name.

**Tip:** Usually, SAS automatically determines the appropriate engine to use for accessing the files in the library. If you want to create a new library with an engine other than the default engine, then you can override the automatic selection.

**See:** For a list of valid engines, see the SAS documentation for your operating environment. For more background information, see Chapter 35, “SAS Engines,” in *SAS Language Reference: Concepts.*

**CLEAR**  
disassociates one or more currently assigned librefs.

**Tip:** Specify *libref* to disassociate a single libref. Specify _ALL_ to disassociate all currently assigned librefs.

_ALL_  
specifies that the CLEAR or LIST argument applies to all currently assigned librefs.
LIST
writes the attributes of one or more SAS libraries to the SAS log.

Tip: Specify libref to list the attributes of a single SAS library. Specify _ALL_ to list the attributes of all SAS libraries that have librefs in your current session.

**LIBNAME Options**

**ACCESS=READONLY|TEMP**

READONLY
assigns a read-only attribute to an entire SAS library. SAS will not allow you to open a data set in the library in order to update information or write new information.

TEMP
specifies that the SAS library be treated as a scratch library. That is, the system will not consume CPU cycles to ensure that the files in a TEMP library do not become corrupted.

Tip: Use ACCESS=TEMP to save resources only when the data is recoverable.

**Operating environment:** Some operating environments support LIBNAME statement options that have similar functions to the ACCESS= option. See the SAS documentation for your operating environment.

**AUTHADMIN= YES | NO**
specifies whether an administrator can access a metadata-bound library for which corresponding metadata is corrupted, misconfigured, or missing.

Default: NO

Restriction: This LIBNAME option can be used only by administrators of metadata-bound libraries.

Interactions:
If the administrator specifies AUTHADMIN=YES in a LIBNAME statement and knows the password (or passwords) for the target data, the administrator can access that data by explicitly supplying the password (or passwords).

An administrator can choose to specify the AUTHPW= option on the LIBNAME statement as an additional method for making the metadata-bound library password available to later requests.

Note: The use of AUTHADMIN=YES is intended for the administrator to correct misaligned location and metadata information. To ensure that the user who is issuing the LIBNAME statement has administrator rights to correct the misalignments, the user must have the same permissions that are needed to run the AUTHLIB procedure statements and must supply the metadata-bound data passwords when accessing the data sets.

Tip: The AUTHLIB REPAIR statement is preproduction. It is recommended that you use AUTHADMIN=YES when performing any AUTHLIB REPAIR action. As a best practice, do not use AUTHADMIN=YES in any other circumstance.

See:

“AUTHPW=password”
“Metadata-Bound Libraries” on page 249
SAS Guide to Metadata-Bound Libraries
PROC AUTHLIB in Base SAS Procedures Guide

**AUTHALTER=alter-password**

Specifies an ALTER password to use only in data access requests where both of these conditions exist:
• AUTHADMIN=YES is specified in the LIBNAME statement that is referenced in the request.

• The correct password for the target metadata-bound data set or library is not otherwise available or is invalid.

**Requirement:** The **AUTHADMIN** option must be set to YES for this option to have an effect.

**Interaction:** You can use the AUTHALTER= option in the same way as the AUTHPW= option if all three of the passwords (ALTER, READ, and WRITE) are the same.

**See:** *SAS Guide to Metadata-Bound Libraries*

**AUTHPW=** *password*

Specifies a password to use only in data access requests where both of these conditions exist:

• AUTHADMIN=YES is specified in the LIBNAME statement that is referenced in the request or is invalid.

• The correct password for the target metadata-bound library is not otherwise available.

**Requirement:** The **AUTHADMIN** option must be set to YES for this option to have an effect. However, the use of AUTHAMDDIN= YES does not require that you use AUTHPW. You are not required to specify metadata-bound library passwords in a LIBNAME statement.

**Interactions:**

If the metadata-bound library has two or three distinct passwords, you must specify each individual password with the AUTHALTER=, AUTHREAD=, and AUTHWRITE= options as appropriate instead of using the AUTHPW= option on its own.

You can use the AUTHALTER= option in the same way as the AUTHPW= option if all three of the passwords (ALTER, READ, and WRITE) are the same and you are in a SAS language context where ALTER= can be used.

**Tip:** An error occurs if the AUTHPW password does not match the password that is within the referenced secured library object.

**See:** *SAS Guide to Metadata-Bound Libraries*

**AUTHREAD=** *read-password*

Specifies a READ password to use only in data access requests where both of these conditions exist:

• AUTHADMIN=YES is specified in the LIBNAME statement that is referenced in the request.

• The correct password for the target metadata-bound library is not otherwise available or is invalid.

**Requirement:** The **AUTHADMIN** option must be set to YES for this option to have an effect.

**See:** *SAS Guide to Metadata-Bound Libraries*

**AUTHWRITE=** *write-password*

Assigns a WRITE password to a metadata-bound library that prevents users from writing to a library, unless they enter the password.

**Requirement:** The **AUTHADMIN** option must be set to YES for this option to have an effect.

**See:** *SAS Guide to Metadata-Bound Libraries*
COMPRESS=NO | YES | CHAR | BINARY
controls the compression of observations in output SAS data sets for a SAS library.

NO
specifies that the observations in a newly created SAS data set be uncompressed (fixed-length records).

YES | CHAR
specifies that the observations in a newly created SAS data set be compressed (variable-length records) by SAS using RLE (Run Length Encoding). RLE compresses observations by reducing repeated consecutive characters (including blanks) to two-byte or three-byte representations.

Tip: Use this compression algorithm for character data.

BINARY
specifies that the observations in a newly created SAS data set be compressed (variable-length records) by SAS using RDC (Ross Data Compression). RDC combines run-length encoding and sliding-window compression to compress the file.

Tip: This method is highly effective for compressing medium to large (several hundred bytes or larger) blocks of binary data (numeric variables). Because the compression function operates on a single record at a time, the record length needs to be several hundred bytes or larger for effective compression.

Interaction: For the COPY procedure, the default value CLONE uses the compression attribute from the input data set for the output data set instead of the value specified in the COMPRESS= option. For more information about CLONE and NOCLONE, see the COPY Statement in the DATASETS procedure. This interaction does not apply when using SAS/SHARE or SAS/CONNECT.

CVPBYTES=bytes
specifies the number of bytes to expand character variable lengths when processing a SAS data file that requires transcoding.

CVPENGINE|CVPENG=engine
specifies the engine to use in order to process a SAS data file that requires transcoding.

CVPMULTIPLIER|CVPMULT=multiplier
specifies a multiplier value in order to expand character variable lengths when processing a SAS data file that requires transcoding.

EXTENDOBSCOUNTER=NO | YES
specifies whether to extend the maximum observation count in output SAS data files for a SAS library.

NO
specifies that the maximum observation count in a newly created SAS data file is determined by the long integer size for the operating environment. In operating environments with a 32-bit-long integer, the maximum number is $2^{31}-1$ or approximately two billion observations $(2,147,483,647)$. In operating environments with a 64-bit-long integer, the number is $2^{63}-1$ or approximately 9.2 quintillion observations.

YES
requests an enhanced file format in newly created SAS data files that counts observations beyond the 32-bit-long limitation. For a SAS data file that is created
for an operating environment that stores the number of observations with a 32-bit-long integer, the file behaves like a 64-bit file with respect to counters.

**Restrictions:**

A SAS data file that is created with `EXTENDOBSCOUNTER=YES` is incompatible with releases prior to SAS 9.3.

Use with the BASE engine only.

Specify `EXTENDOBSCOUNTER=YES` only for an output SAS data file whose internal data representation stores the observation count as a 32-bit-long integer. For a table that lists the operating environments and `OUTREP=` values that are appropriate with `EXTENDOBSCOUNTER=YES`, see “When to Use the EXTENDOBSCOUNTER=YES Option” in Chapter 26 of *SAS Language Reference: Concepts*.

The extended observation count attribute cannot be inherited by a new file. If you want to create a file with an extended observation count from a file that contains the extended observation count attribute, you must specify the `EXTENDOBSCOUNTER=` option for the new file. For more information, see “Extended Observation Count Behavior Considerations” in Chapter 26 of *SAS Language Reference: Concepts*.

**Tip:** Specifying the `EXTENDOBSCOUNTER=` option in a LIBNAME statement is also useful to migrate a library with the MIGRATE procedure, which does not support SAS data set options.

**See:** “Extending the Observation Count in a SAS Data File” in Chapter 26 of *SAS Language Reference: Concepts*

**Alias:** EOC=

**Default:** NO

**INENCODING=**

overrides the encoding when you are reading (input processing) SAS data sets in the SAS library.

**See:** “INENCODING= and OUTENCODING= Options” in *SAS National Language Support (NLS): Reference Guide*

**OUTENCODING=**

overrides the encoding when you are creating (output processing) SAS data sets in the SAS library.

**See:** “INENCODING= and OUTENCODING= Options” in *SAS National Language Support (NLS): Reference Guide*

**OUTREP=**

specifies the data representation for the SAS library, which is the form in which data is stored in a particular operating environment. Different operating environments use different standards or conventions for storing floating-point numbers (for example, IEEE or IBM mainframe); for character encoding (for example, ASCII or EBCDIC); for the ordering of bytes in memory (for example, big Endian or little Endian); for word alignment (for example, 4-byte boundaries or 8-byte boundaries); for integer data-type length (for example, 16-bit, 32-bit, or 64-bit); and for doubles (for example, byte-swapped or not).

By default, SAS creates a new SAS data set by using the data representation of the CPU that is running SAS. Specifying the `OUTREP=` option enables you to create a SAS data set with a different data representation. For example, in a UNIX environment, you can create a SAS data set that uses a Windows data representation. For more information about compatibility and data representation, see Chapter 32,

</table>
OUTREP= Value | Alias* | Environment
---|---|---
WINdows_64 | 64-bit SAS on Microsoft Windows (for both Itanium-based systems and x64)

* It is recommended that you use the current values. The aliases are available for compatibility only.

**Interactions:**

By default, PROC COPY uses the data representation of the file from the source library. If, instead, you want to use the data representation of the current SAS session, specify the NOCLONE option. If you want to use a different data representation, specify the NOCLONE option and the OUTREP= option. When you use PROC COPY with SAS/SHARE or SAS/CONNECT, the default behavior is to use the data representation of the current SAS session. For more information about CLONE and NOCLONE, see the COPY Statement in the *Base SAS Procedures Guide*.

The COPY procedure (with NOCLONE) and the MIGRATE procedure can use the LIBNAME option OUTREP= for DATA, VIEW, ACCESS, MDD, and DMDB member types. Otherwise, only DATA member types are affected by the OUTREP= LIBNAME option.

Transcoding could result in character data loss when encodings are incompatible. For more information, see the *SAS National Language Support (NLS): Reference Guide*.

**REPEMPTY=**YES|NO

controls replacement of like-named temporary or permanent SAS data sets when the new one is empty.

YES

specifies that a new empty data set with a given name replace an existing data set with the same name. This is the default.

**Interaction:** If REPEMPTY=YES and REPLACE=NO, then the data set is not replaced.

NO

specifies that a new empty data set with a given name not replace an existing data set with the same name.

**Tips:**

Use REPEMPTY=NO to prevent the following syntax error from replacing the existing data set MYLIB.B with the new empty data set MYLIB.B that is created by mistake:

```
libname libref SAS-library REPEMPTY=NO;
data mylib.a set mylib.b;
```

For both the convenience of replacing existing data sets with new ones that contain data and the protection of not overwriting existing data sets with new empty ones that are created by mistake, set REPLACE=YES and REPEMPTY=NO.

**Note:** For an individual data set, the REPEMPTY= data set option overrides the setting of the REPEMPTY= option in the LIBNAME statement.

**See:** “REPEMPTY= Data Set Option” in *SAS Data Set Options: Reference*
Engine Host Options

*engine-host-options*

are one or more options that are listed in the general form *keyword* = *value*.

**Restriction:** When concatenating libraries, you cannot specify options that are specific to an engine or an operating environment.

**Operating environment:** For a list of valid specifications, see the SAS documentation for your operating environment.

Details

**Associating a Libref with a SAS Library (Form 1)**
The association between a libref and a SAS library lasts only for the duration of the SAS session or until you change the libref or discontinue it with another LIBNAME statement. The simplest form of the LIBNAME statement specifies only a libref and the physical name of a SAS library:

```sas
LIBNAME libref 'SAS-library';
```

See “Example 1: Assigning and Using a Libref” on page 249.

An engine specification is usually not necessary. If the situation is ambiguous, SAS uses the setting of the ENGINE= system option to determine the default engine. If all data sets in the library are associated with a single engine, then SAS uses that engine as the default. In either situation, you can override the default by specifying another engine with the ENGINE= system option:

```sas
LIBNAME libref engine 'SAS-library' <options> <engine/host-options>;
```

**Operating Environment Information**
Using the LIBNAME statement requires host-specific information. See the SAS documentation for your operating environment before using this statement.

**Disassociating a Libref from a SAS Library (Form 2)**
To disassociate a libref from a SAS library, use a LIBNAME statement by specifying the libref and the CLEAR option. You can clear a single, specified libref or all current librefs.

```sas
LIBNAME libref CLEAR | _ALL_ CLEAR;
```

**Writing SAS Library Attributes to the SAS Log (Form 3)**
Use a LIBNAME statement to write the attributes of one or more SAS libraries to the SAS log. Specify *libref* to list the attributes of one SAS library; use _ALL_ to list the attributes of all SAS libraries that have been assigned librefs in your current SAS session.

```sas
LIBNAME libref LIST | _ALL_ LIST;
```

**Concatenating SAS Libraries (Form 4)**
When you logically concatenate two or more SAS libraries, you can reference them all with one libref. You can specify a library with its physical filename or its previously assigned libref.

```sas
LIBNAME libref <engine> (library-specification–1 <…library-specification-n> ) <options>;
```
In the same LIBNAME statement, you can use any combination of specifications: librefs, physical filenames, or a combination of librefs and physical filenames. See “Example 2: Logically Concatenating SAS Libraries” on page 249.

**Concatenating SAS Catalogs (Form 4)**

When you logically concatenate two or more SAS libraries, you also concatenate the SAS catalogs that have the same name. For example, if three SAS libraries each contain a catalog named CATALOG1, then when you concatenate them, you create a catalog concatenation for the catalogs that have the same name. See “Example 3: Concatenating SAS Catalogs” on page 250.

```
LIBNAME libref <engine> (library–specification–1 <...library-specification-n> ) <options>;
```

**Rules for Library Concatenation**

After you create a library concatenation, you can specify the libref in any context that accepts a simple (non-concatenated) libref. These rules determine how SAS files (that is, members of SAS libraries) are located among the concatenated libraries:

- When a SAS file is opened for input or update, the concatenated libraries are searched and the first occurrence of the specified file is used.
- When a SAS file is opened for output, it is created in the first library that is listed in the concatenation.
  
  *Note:* A new SAS file is created in the first library even if there is a file with the same name in another part of the concatenation.
- When you delete or rename a SAS file, only the first occurrence of the file is affected.
- Anytime a list of SAS files is displayed, only one occurrence of a filename is shown.
  
  *Note:* Even if the name occurs multiple times in the concatenation, only the first occurrence is shown.
- A SAS file that is logically connected to another file (such as an index to a data set) is listed only if the parent file resides in that same library. For example, if library ONE contains A.DATA, and library TWO contains A.DATA and A.INDEX, only A.DATA from library ONE is listed. (See the previous rule.)
- If any library in the concatenation is sequential, then all of the libraries are treated as sequential.
- The attributes of the first library that is specified determine the attributes of the concatenation. For example, if the first SAS library that is listed is “read only,” then the entire concatenated library is “read only.”
- If you specify any options or engines, they apply only to the libraries that you specified with the complete physical name, not to any library that you specified with a libref.
- If you alter a libref after it has been assigned in a concatenation, it will not affect the concatenation.

**Automatically Creating the Library Directory**

You can set the DLCREATEDIR system option to create the directory for the SAS library that is specified in the LIBNAME statement if that directory does not exist. For more information, see the “DLCREATEDIR System Option” in SAS System Options: Reference.
**z/OS Specifics**

For more information, see the “DLCREATEDIR System Option: z/OS” in SAS Companion for z/OS.

**Metadata-Bound Libraries**

In the second maintenance release of SAS 9.3, the Base SAS LIBNAME engine can enforce permissions on a user and group basis to SAS data sets that are bound to secured table objects in the metadata server. Metadata-bound libraries provide enhanced protection for Base SAS data (SAS data sets and SAS views). A connection to the metadata server is required in order to access metadata-bound data.

For more information, see the SAS Guide to Metadata-Bound Libraries and the AUTHLIB procedure in Base SAS Procedures Guide.

If you have questions or need assistance accessing your data, contact your local SAS Administrator.

**Comparisons**

- Use the LIBNAME statement to reference a SAS library. Use the FILENAME statement to reference an external file. Use the LIBNAME, SAS/ACCESS statement to access DBMS tables.

- Use the CATNAME statement to concatenate SAS catalogs. Use the LIBNAME statement to concatenate SAS catalogs. The CATNAME statement enables you to specify the names of the catalogs that you want to concatenate. The LIBNAME statement concatenates all like-named catalogs in the specified SAS libraries.

**Examples**

**Example 1: Assigning and Using a Libref**

This example assigns the libref SALES to an aggregate storage location that is specified in quotation marks as a physical filename. The DATA step creates SALES.QUARTER1 and stores it in that location. The PROC PRINT step references it by its two-level name, SALES.QUARTER1.

```sas
libname sales 'SAS-library';
data sales.quarter1;
infile 'your-input-file';
input salesrep $20. +6 jansales febsales marsales;
run;
proc print data=sales.quarter1;
run;
```

**Example 2: Logically Concatenating SAS Libraries**

- This example concatenates three SAS libraries by specifying the physical filename of each:

  ```sas
  libname allmine (’file-1’ ’file-2’ ’file-3’);
  ```

- This example assigns librefs to two SAS libraries, one that contains SAS 6 files and one that contains SAS 9 files. This technique is useful for updating your files and applications from SAS 6 to SAS 9 and enables you to have convenient access to both sets of files:
libname v6 'v6-SAS-library';
libname v9 'v9-SAS-library';
libname allmine (v9 v6);

• This example shows that you can specify both librefs and physical filenames in the same concatenation specification:

libname allmine (v9 v6 'some-filename');

Example 3: Concatenating SAS Catalogs
This example concatenates three SAS libraries by specifying the physical filename of each and assigns the libref ALLMINE to the concatenated libraries:

libname allmine ('file-1' 'file-2' 'file-3');

If each library contains a SAS catalog named MYCAT, then using ALLMINE.MYCAT as a libref.catref provides access to the catalog entries that are stored in all three catalogs named MYCAT. To logically concatenate SAS catalogs with different names, see the “CATNAME Statement” on page 41.

Example 4: Permanently Storing Data Sets with One-Level Names
If you want the convenience of specifying only a one-level name for permanent, not temporary, SAS files, then use the USER= system option. This example stores the data set QUARTER1 permanently without using a LIBNAME statement first to assign a libref to a storage location:

options user='SAS-library';
data quarter1;
infile 'your-input-file';
input salesrep $20. +6 jansales febsales marsales;
run;
proc print data=quarter1;
run;

LIBNAME Statement for the JMP Engine
Associates a libref with a JMP data table and enables you to read and write JMP data tables.
Valid in:
Category:
See:

Anywhere
Data Access
Base SAS LIBNAME Statement

Syntax
LIBNAME libref JMP ‘path’ <FMTLIB=libref.format-catalog>;

Arguments
libref
is a character constant, variable, or expression that specifies the libref that is assigned
to a SAS library.
Range: 1 to 8 bytes
path
is the physical name for the SAS library. The physical name is the name that is
recognized by the operating environment. Enclose the physical name in single or
double quotation marks.
FMTLIB=libref.format-catalog
specifies where the formats are stored when a JMP data table is read and where the
formats come from when a JMP data table is created.
Requirement: The library that is specified in the FMTLIB argument must be a SAS
data set LIBNAME statement.
Example:
libname inv jmp "." fmtlib=seform.formats;
libname seform '.';
data work.mine;
set inv.suri2011;
run;


Details

A JMP file is a file format that the JMP software program creates. JMP is an interactive statistics package that is available for Microsoft Windows and Macintosh. For more information, see the JMP documentation that is packaged with your system.

A JMP file contains data that is organized in a tabular format of fields and records. Each field can contain one type of data, and each record can hold one data value for each field.

Base SAS supports access to JMP files. You can access JMP files by either of these two methods:

- the IMPORT and EXPORT procedures and the Import and Export Wizard without a license for SAS/ACCESS Interface to PC Files
  For more information, see SAS/ACCESS Interface to PC Files: Reference.
- the LIBNAME statement for the JMP engine

Examples

Example 1: Using the LIBNAME Statement to Read a JMP Data Table
This example reads and prints five observations from the bank JMP data table.

```
libname b jmp 'c:/temp/national';
proc contents data=b.bank(drop=edlevel id age);
run;
proc print data=b.bank(obs=5 drop=edlevel id age);
run;
```

Example 2: Reading and Sorting a JMP Data Table
This example reads a JMP data table, sorts it, and stores it in a SAS data set. The formats stored on the JMP data set are put in a.formats.

```
libname a 'c:/temp/field';
libname b jmp '.' fmtlib=a.formats;
proc sort data=b.cars out=a.sorted;
   by category_ic;
run;
```

LIBNAME Statement for WebDAV Server Access

 Associates a libref with a SAS library and enables access to a WebDAV (Web-based Distributed Authoring And Versioning) server.

 Valid in: Anywhere
 Category: Data Access
 Restriction: Access to WebDAV servers is not supported on OpenVMS or z/OS.
Syntax

LIBNAME libref <engine> 'SAS-library' <options> WEBDAV USER="user-ID" PASSWORD="user-password" WEBDAV options;

LIBNAME libref CLEAR | _ALL_ CLEAR ;

LIBNAME libref LIST | _ALL_ LIST ;

Arguments

libref
specifies a shortcut name for the aggregate storage location where your SAS files are stored.

Tip: The association between a libref and a SAS library lasts only for the duration of the SAS session or until you change it or discontinue it with another LIBNAME statement.

'SAS-library'
specifies the URL location (path) on a WebDAV server. The URL specifies either HTTP or HTTPS communication protocols.

Restriction: Only one data library is supported when using the WebDAV extension to the LIBNAME statement.

Requirement: When using the HTTPS communication protocol, you must use the SSL (Secure Sockets Layer) protocol that provides secure network communications. For more information, see Encryption in SAS.

engine
specifies the name of a valid SAS engine.

Restriction: REMOTE engines are not supported with the WebDAV options.

See: For a list of valid engines, see the SAS documentation for your operating environment.

CLEAR
disassociates one or more currently assigned librefs. When a libref using a WebDAV server is cleared, the cached files stored locally are deleted also.

Tip: Specify libref to disassociate a single libref. Specify _ALL_ to disassociate all currently assigned librefs.

LIST
writes the attributes of one or more SAS libraries to the SAS log.

Tip: Specify libref to list the attributes of a single SAS library. Specify _ALL_ to list the attributes of all SAS libraries that have librefs in your current session.

_ALL_
specifies that the CLEAR or LIST argument applies to all currently assigned librefs.

LIBNAME Options
For valid LIBNAME statement options, see the “LIBNAME Statement” on page 239.

WebDAV Specific Options

WEBDAV
specifies that the libref access a WebDAV server.

USER="user-ID"
specifies the user name for access to the WebDAV server. The user ID is case sensitive and it must be enclosed in single or double quotation marks.
Alias: UID

Tip: If PROMPT is specified, but USER= is not, then the user is prompted for an ID as well as a password.

PASSWORD="user-password"

specifies a password for the user to access the WebDAV server. The password is case sensitive and it must be enclosed in single or double quotation marks.

Alias: PWD=, PW=, PASS=

Tip: You can specify the PROMPT option instead of the PASSWORD= option.

PROMPT

specifies to prompt for the user login password, if necessary.

Interaction: If PROMPT is specified without USER=, then the user is prompted for an ID, as well as a password.

Tip: If you specify the PROMPT option, you do not need to specify the PASSWORD= option.

AUTHDOMAIN="auth-domain"

specifies the name of an authentication domain metadata object in order to connect to the WebDAV server. The authentication domain references credentials (user ID and password) without your having to explicitly specify the credentials. The auth-domain name is case sensitive, and it must be enclosed in double quotation marks.

An administrator creates authentication domain definitions while creating a user definition with the User Manager in SAS Management Console. The authentication domain is associated with one or more login metadata objects that provide access to the WebDAV server and is resolved by the BASE engine calling the SAS Metadata Server and returning the authentication credentials.

Requirement: The authentication domain and the associated login definition must be stored in a metadata repository, and the metadata server must be running in order to resolve the metadata object specification.

Interaction: If you specify AUTHDOMAIN=, you do not need to specify USER= and PASSWORD=.

See: For complete information about creating and using authentication domains, see the discussion on credential management in the SAS Intelligence Platform: Security Administration Guide.

PROXY=url

specifies the Uniform Resource Locator (URL) for the proxy server in one of these forms:

• "http://hostname"
• "http://hostname:port"

LOCALCACHE="directory name"

specifies a directory where a temporary subdirectory is created to hold local copies of the server files. Each libref has its own unique subdirectory. If a directory is not specified, then the subdirectories are created in the SAS WORK directory. SAS deletes the temporary files when the SAS program completes.

Default: SAS WORK directory

LOCKDURATION=n

specifies the number of minutes that the files written through the WebDAV libref are locked. SAS unlocks the files when the SAS program successfully completes. If the SAS program fails, then the locks expire after the time allotted.

Default: 30
Details

**Data Set Options That Function Differently with a WebDAV Server**

The following table lists the data set options that have different functionality when using a WebDAV server. All other data set options will function as described in the *SAS Data Set Options: Reference*.

**Table 2.6 Data Set Option Functionality with a WebDAV Server**

<table>
<thead>
<tr>
<th>Data Set Option</th>
<th>WebDAV Storage Functionality</th>
</tr>
</thead>
<tbody>
<tr>
<td>CNTLLEV=</td>
<td><em>LIB</em> locks all data sets in the library before writing the data into the local cache. All members are unlocked after the DATA step has completed and the data set has been written back to the WebDAV server. <em>MEM</em> locks the member before writing the data into the local cache. Member is unlocked after the DATA step has completed and the data has been written back to the WebDAV server. <em>REC</em> is not supported. WebDAV allows updates to the entire data set only.</td>
</tr>
<tr>
<td>FILECLOSE</td>
<td>The VxTAPE engine is not supported. Therefore, this option is ignored.</td>
</tr>
<tr>
<td>GENMAX=</td>
<td>This functionality is not supported because the maximum number of revisions to keep cannot be specified in the WebDAV server.</td>
</tr>
<tr>
<td>GENNUM=</td>
<td>This functionality is not supported in WebDAV.</td>
</tr>
<tr>
<td>IDXNAME=</td>
<td>Users can specify an index to use if one exists.</td>
</tr>
<tr>
<td>INDEX=</td>
<td>Indexes can be created in the local cache and saved on the WebDAV server.</td>
</tr>
<tr>
<td>TOBSNO=</td>
<td>Remote engines are not supported. Therefore, this option is ignored.</td>
</tr>
</tbody>
</table>

**WebDAV File Processing**

When accessing a WebDAV server, the file is pulled from the WebDAV server to your local disk storage for processing. When you complete the updating, the file is pushed back to the WebDAV server for storage. The file is removed from the local disk storage when it is pushed back.

**Multiple Librefs to a WebDAV Library**

When you assign a libref to a file on a WebDAV server, the path (URL location), user ID, and password are associated with that libref. After the first libref has been assigned, the user ID and password will be validated on subsequent attempts to assign another libref to the same library.
Note: Lock errors that you typically would not see might occur if either a different user ID or the password, or both, are used in the subsequent attempt to assign a libref to the same library.

Locked Files on a WebDAV Server
In local libraries, SAS locks a file when you open it to prevent other users from altering the file while it is being read. WebDAV locks require Write access to a library, and there is no concept of a read lock. In addition, WebDAV servers can go down, come back up, or go offline at any time. Consequently, SAS honors a lock request on a file on a WebDAV server only if the file is already locked by another user.

Example: Associating a Libref with a WebDAV Directory
The following example associates the libref davdata with the WebDAV directory /users/mydir/datadir on the WebDAV server www.webserver.com:

libname davdata v9 "https://www.webserver.com/users/mydir/datadir";
webdav user="mydir" pw="12345";

Statements:
• “FILENAME Statement, WebDAV Access Method” on page 147
• “LIBNAME Statement” on page 239

LINK Statement
Directs program execution immediately to the statement label that is specified and, if followed by a RETURN statement, returns execution to the statement that follows the LINK statement.

Valid in: DATA step
Category: Control
Type: Executable

Syntax
LINK label;

Arguments
label
    specifies a statement label that identifies the LINK destination. You must specify the label argument.

Details
The LINK statement tells SAS to jump immediately to the statement label that is indicated in the LINK statement and to continue executing statements from that point until a RETURN statement is executed. The RETURN statement sends program control to the statement immediately following the LINK statement.
The LINK statement and the destination must be in the same DATA step. The destination is identified by a statement label in the LINK statement.

The LINK statement can branch to a group of statements that contain another LINK statement. This arrangement is known as nesting. To avoid infinite looping, SAS has set a default number of nested LINK statements. You can have up to 10 LINK statements with no intervening RETURN statements. When more than one LINK statement has been executed, a RETURN statement tells SAS to return to the statement that follows the last LINK statement that was executed. However, you can use the /STACK option in the DATA statement to increase the number of nested LINK statements.

**Comparisons**

The difference between the LINK statement and the GO TO statement is in the action of a subsequent RETURN statement. A RETURN statement after a LINK statement returns execution to the statement that follows LINK. A RETURN statement after a GO TO statement returns execution to the beginning of the DATA step, unless a LINK statement precedes GO TO. In that case, execution continues with the first statement after LINK. In addition, a LINK statement is usually used with an explicit RETURN statement, whereas a GO TO statement is often used without a RETURN statement.

When your program executes a group of statements at several points in the program, using the LINK statement simplifies coding and makes program logic easier to follow. If your program executes a group of statements at only one point in the program, using DO-group logic rather than LINK-RETURN logic is simpler.

**Example: Diverting Program Execution**

In this example, when the value of variable TYPE is `aluv`, the LINK statement diverts program execution to the statements that are associated with the label CALCUL. The program executes until it encounters the RETURN statement, which sends program execution back to the first statement that follows LINK. SAS executes the assignment statement, writes the observation, and then returns to the top of the DATA step to read the next record. When the value of TYPE is not `aluv`, SAS executes the assignment statement, writes the observation, and returns to the top of the DATA step.

```sas
data hydro;
  input type $ depth station $;
  /* link to label calcu: */
  if type ='aluv' then link calcu;
  date=today();
  /* return to top of step */
  return;
  calcu: if station='site_1'
    then elevatn=6650-depth;
  else if station='site_2'
    then elevatn=5500-depth;
  /* return to date=today(); */
  return;
  datalines;
  aluv 523 site_1
  uppa 234 site_2
  aluv 666 site_2
  ...more data lines...
`;
LIST Statement

Writes to the SAS log the input data record for the observation that is being processed.

Valid in: DATA step
Category: Action
Type: Executable

Syntax

LIST;

Without Arguments

The LIST statement causes the input data record for the observation being processed to be written to the SAS log.

Details

The LIST statement operates only on data that is read with an INPUT statement; it has no effect on data that is read with a SET, MERGE, MODIFY, or UPDATE statement.

In the SAS log, a ruler that indicates column positions appears before the first record listed.

For variable-length records (RECFM=V), SAS writes the record length at the end of the input line. SAS does not write the length for fixed-length records (RECFM=F), unless the amount of data read does not equal the record length (LRECL).

Comparisons

<table>
<thead>
<tr>
<th>Action</th>
<th>LIST Statement</th>
<th>PUT Statement</th>
</tr>
</thead>
<tbody>
<tr>
<td>Writes when</td>
<td>at the end of each iteration of the DATA step</td>
<td>immediately</td>
</tr>
<tr>
<td>Writes what</td>
<td>the input data records exactly as they appear</td>
<td>the variables or literals specified</td>
</tr>
</tbody>
</table>
### Examples

**Example 1: Listing Records That Contain Missing Data**

This example uses the `LIST` statement to write to the SAS log any input records that contain missing data. Because of the `#3` line pointer control in the `INPUT` statement, SAS reads three input records to create a single observation. Therefore, the `LIST` statement writes the three current input records to the SAS log each time a value for `W2AMT` is missing.

```sas
data employee;
  input ssn 1-9 #3 w2amt 1-6;
  if w2amt=. then list;
  datalines;
  23456789
  JAMES SMITH
  356.79
  345671234
  Jeffrey Thomas
  .
;
```

**Output 2.17  Log Listing of Missing Data**

```
RULE:-------------1-------------2-------------3-------------4-------------5-------------
  9 345671234
 10 Jeffrey Thomas
 11 .
```

The numbers 9, 10, and 11 are line numbers in the SAS log.

**Example 2: Listing the Record Length of Variable-Length Records**

This example uses as input an external file that contains variable-length ID numbers. The `RECFM=V` option is specified in the `INFILE` statement, and the `LIST` statement writes the records to the SAS log. When the file has variable-length records, as indicated by the `RECFM=V` option in this example, SAS writes the record length at the end of each record that is listed in the SAS log.

```sas
data employee;
  infile 'your-external-file' recfm=v;
  input id $;
```
list;
run;

Output 2.18 Log Listing of Variable-Length Records and Record Lengths

<table>
<thead>

Statements:

• “PUT Statement” on page 296

%LIST Statement

Displays lines that are entered in the current session.

Valid in: Anywhere
Category: Program Control

Syntax

%LIST<n:m | −m>;

Without Arguments

In interactive line mode processing, if you use the %LIST statement without arguments, it displays all previously entered program lines.

Arguments

\n
\n
displays line \( n \).

\n
\n
displays lines \( n \) through \( m \).

Alias: \( n:m \)

Details

Where and When to Use

The %LIST statement can be used anywhere in a SAS job except between a
DATALINES or DATALINES4 statement and the matching semicolon (;) or semicolons
(;;;;). This statement is useful mainly in interactive line mode sessions to display SAS
program code on the monitor. It is also useful to determine lines to include when you use
the %INCLUDE statement.
Interactions

CAUTION:
In all modes of execution, the SPOOL system option controls whether SAS statements are saved. When the SPOOL system option is in effect in interactive line mode, all SAS statements and data lines are saved automatically when they are submitted. You can display them by using the %LIST statement. When NOSPOOL is in effect, %LIST cannot display previous lines.

Example: Displaying Lines That Are Entered in the Current Session

This %LIST statement displays lines 10 through 20:

```sas
%list 10-20;
```

Statements:

• “%INCLUDE Statement” on page 164

System Options:

• “SPOOL System Option” in SAS System Options: Reference

---

LOCK Statement

Acquires and releases an exclusive lock on an existing SAS file.

Valid in: Anywhere

Category: Program Control

Restrictions: You cannot lock a SAS file that another SAS session is currently accessing (either from an exclusive lock or because the file is open).

The LOCK statement syntax is the same whether you issue the statement in a single-user environment or in a client/server environment. However, some LOCK statement functionality applies only to a client/server environment.

Syntax

LOCK `libref.<member-name><member-type | .entry-name.entry-type>>`
<LIST | QUERY | SHOW | CLEAR>;

Arguments

`libref`

is a name that is associated with a SAS library. The libref (library reference) must be a valid SAS name. If the libref is SASUSER or WORK, you must specify it.

Tip: In a single-user environment, you typically would not issue the LOCK statement to exclusively lock a library. To lock a library that is accessed via a multiuser SAS/SHARE server, see the LOCK statement in the SAS/SHARE User's Guide.
member-name

is a valid SAS name that specifies a member of the SAS library that is associated with the libref.

Restriction: The SAS file must be created before you can request a lock. For information about locking a member of a SAS library when the member does not exist, see the SAS/SHARE User's Guide.

member-type

is the type of SAS file to be locked. For example, valid values are DATA, VIEW, CATALOG, MDDB, and so on. The default is DATA.

event-name

is the name of the catalog entry to be locked.

Tip: In a single-user environment, if you issue the LOCK statement to lock an individual catalog entry, the entire catalog is locked; you typically would not issue the LOCK statement to exclusively lock a catalog entry. To lock a catalog entry in a library that is accessed via a multiuser SAS/SHARE server, see the LOCK statement in the SAS/SHARE User's Guide.

event-type

is the type of the catalog entry to be locked.

Tip: In a single-user environment, if you issue the LOCK statement to lock an individual catalog entry, the entire catalog is locked; you typically would not issue the LOCK statement to exclusively lock a catalog entry. To lock a catalog entry in a library that is accessed via a multiuser SAS/SHARE server, see the LOCK statement in the SAS/SHARE User's Guide.

LIST | QUERY | SHOW

writes to the SAS log whether you have an exclusive lock on the specified SAS file.

Tip: This option provides more information in a client/server environment. To use this option in a client/server environment, see the LOCK statement in the SAS/SHARE User's Guide.

CLEAR

releases a lock on the specified SAS file that was acquired by using the LOCK statement in your SAS session.

Details

General Information

The LOCK statement enables you to acquire and release an exclusive lock on an existing SAS file. Once an exclusive lock is obtained, no other SAS session can read or write to the file until the lock is released.

To release an exclusive lock, use the CLEAR option. In addition, an exclusive lock on a data set is released when you use the DATASETS procedure DELETE statement to delete the data set.

Acquiring Exclusive Access to a SAS File in a Single-User Environment

Each time you issue a SAS statement or a procedure to process a SAS file, the file is opened for input, update, or output processing. At the end of the step, the file is closed.

In a program with multiple tasks, a file could be opened and closed multiple times. Because multiple SAS sessions in a single-user environment can access the same SAS file, issuing the LOCK statement to acquire an exclusive lock on the file protects data while it is being updated in a multistep program.
For example, consider a nightly update process that consists of a DATA step to remove observations that are no longer useful, a SORT procedure to sort the file, and a DATASETS procedure to rebuild the file's indexes. If another SAS session accesses the file between any of the steps, the SORT and DATASETS procedures would fail, because they require member-level locking (exclusive) access to the file.

Including the LOCK statement before the DATA step provides the needed protection by acquiring exclusive access to the file. If the LOCK statement is successful, a SAS session that attempts to access the file between steps will be denied access, and the nightly update process runs uninterrupted. See “Example: Locking a SAS File” on page 263.

**Return Codes for the LOCK Statement**

The SAS macro variable SYSLCKRC contains the return code from the LOCK statement. The following actions result in a nonzero value in SYSLCKRC:

- You try to lock a file but cannot obtain the lock (for example, the file was in use or is locked by another SAS session).
- You use a LOCK statement with the LIST option to list a lock.
- You use a LOCK statement with the CLEAR option to release a lock that you do not have.

For more information about the SYSLCKRC SAS macro variable, see *SAS Macro Language: Reference*.

**Comparisons**

- With SAS/SHARE software, you can also use the LOCK statement. Some LOCK statement functionality applies only to a client/server environment.
- The CNTLLEV= data set option specifies the level at which shared Update access to a SAS data set is denied.

**Example: Locking a SAS File**

The following SAS program illustrates the process of locking a SAS data set. Including the LOCK statement provides protection for the multistep program by acquiring exclusive access to the file. Any SAS session that attempts to access the file between steps will be denied access, which ensures that the program runs uninterrupted.

```sas
libname mydata 'SAS-library';
lock mydata.census; 1
data mydata.census; 2
   modify mydata.census;
   (statements to remove obsolete observations)
run;
proc sort force data=mydata.census; 3
   by CrimeRate;
run;
proc datasets library=mydata; 4
   modify census;
   index create CrimeRate;
quit;
lock mydata.census clear; 5
```

1. Acquires exclusive access to the SAS data set MYDATA.CENSUS.
2 Opens MYDATA.CENSUS to remove observations that are no longer useful. At the end of the DATA step, the file is closed. However, because of the exclusive lock, any other SAS session that attempts to access the file is denied access.

3 Opens MYDATA.CENSUS to sort the file. At the end of the procedure, the file is closed but not available to another SAS session.

4 Opens MYDATA.CENSUS to rebuild the file's index. At the end of the procedure, the file is closed but still not available to another SAS session.

5 Releases the exclusive lock on MYDATA.CENSUS. The data set is now available to other SAS sessions.

Data Set Options:
• “CNTLLEV= Data Set Option” in SAS Data Set Options: Reference

LOSTCARD Statement
Resynchronizes the input data when SAS encounters a missing or invalid record in data that has multiple records per observation.

Valid in: DATA step
Category: Action
Type: Executable

Syntax
LOSTCARD;

Without Arguments
The LOSTCARD statement prevents SAS from reading a record from the next group when the current group has a missing record.

Details
When to Use LOSTCARD
When SAS reads multiple records to create a single observation, it does not discover that a record is missing until it reaches the end of the data. If there is a missing record in your data, the values for subsequent observations in the SAS data set might be incorrect. Using LOSTCARD prevents SAS from reading a record from the next group when the current group has fewer records than SAS expected.

LOSTCARD is most useful when the input data have a fixed number of records per observation and when each record for an observation contains an identification variable that has the same value. LOSTCARD usually appears in conditional processing such as in the THEN clause of an IF-THEN statement, or in a statement in a SELECT group.
**When LOSTCARD Executes**

When LOSTCARD executes, SAS takes several steps:

1. Writes three items to the SAS log: a lost card message, a ruler, and all the records that it read in its attempt to build the current observation.

2. Discards the first record in the group of records being read, does not write an observation, and returns processing to the beginning of the DATA step.

3. Does not increment the automatic variable _N_ by 1. (Normally, SAS increments _N_ by 1 at the beginning of each DATA step iteration.)

4. Attempts to build an observation by beginning with the second record in the group, and reads the number of records that the INPUT statement specifies.

5. Repeats steps 1 through 4 when the IF condition for a lost card is still true. To make the log more readable, SAS prints the message and ruler only once for a given group of records. In addition, SAS prints each record only once, even if a record is used in successive attempts to build an observation.

6. Builds an observation and writes it to the SAS data set when the IF condition for a lost card is no longer true.

**Example: Resynchronizing Input Data**

This example uses the LOSTCARD statement in a conditional construct to identify missing data records and to resynchronize the input data:

```sas
data inspect;
  input id 1-3 age 8-9 #2 id2 1-3 loc
    #3 id3 1-3 wt;
  if id ne id2 or id ne id3 then
    do;
      put 'DATA RECORD ERROR: ' id= id2= id3=;
      lostcard;
    end;
  datalines;
301    32
301    61432
301    127
302    61
302    83171
400    46
409    23145
400    197
411    53
411    99551
411    139
;
```

The DATA step reads three input records before writing an observation. If the identification number in record 1 (variable ID) does not match the identification number in the second record (ID2) or third record (ID3), a record is incorrectly entered or omitted. The IF-THEN DO statement specifies that if an identification number is invalid, SAS prints the message that is specified in the PUT statement message and executes the LOSTCARD statement.

In this example, the third record for the second observation (ID3=400) is missing. The second record for the third observation is incorrectly entered (ID=400 while ID2=409). Therefore, the data set contains two observations with ID values 301 and 411. There are
no observations for ID=302 or ID=400. The PUT and LOSTCARD statements write
these statements to the SAS log when the DATA step executes:

```
DATA RECORD ERROR: id=302 id2=302 id3=400
NOTE: LOST CARD.
RULE:--------1--------2--------3--------4--------5--------
 14   302    61
 15   302   83171
 16   400    46
DATA RECORD ERROR: id=302 id2=400 id3=409
NOTE: LOST CARD.
 17   409   23145
DATA RECORD ERROR: id=400 id2=409 id3=400
NOTE: LOST CARD.
 18   400    197
DATA RECORD ERROR: id=409 id2=400 id3=411
NOTE: LOST CARD.
 19   411     53
DATA RECORD ERROR: id=400 id2=411 id3=411
NOTE: LOST CARD.
 20   411   99551
```

The numbers 14, 15, 16, 17, 18, 19, and 20 are line numbers in the SAS log.

**See Also**

**Statements:**

- “IF-THEN/ELSE Statement” on page 163

**MERGE Statement**

Joins observations from two or more SAS data sets into a single observation.

<table>
<thead>
<tr>
<th>Valid in:</th>
<th>DATA step</th>
</tr>
</thead>
<tbody>
<tr>
<td>Category:</td>
<td>File-handling</td>
</tr>
<tr>
<td>Type:</td>
<td>Executable</td>
</tr>
</tbody>
</table>

**Syntax**

```
<...SAS-data-set-n<(data-set-options)>> <END=variable>;
```

**Arguments**

**SAS-data-set**

specifies at least two existing SAS data sets from which observations are read. You
can specify individual data sets, data set lists, or a combination of both.

**Tips:**

Instead of using a data set name, you can specify the physical pathname to the
file, using syntax that your operating system understands. The pathname must be
enclosed in single or double quotation marks.
You can specify additional SAS data sets.

**See:** “Using Data Set Lists with MERGE” on page 267

(data-set-options)

specifies one or more SAS data set options in parentheses after a SAS data set name.

**Note:** The data set options specify actions that SAS is to take when it reads observations into the DATA step for processing. For a list of data set options, see the *SAS Data Set Options: Reference*

**Tip:** Data set options that apply to a data set list apply to all of the data sets in the list.

**END=**

variable

names and creates a temporary variable that contains an end-of-file indicator.

**Note:** The variable, which is initialized to 0, is set to 1 when the MERGE statement processes the last observation. If the input data sets have different numbers of observations, the END= variable is set to 1 when MERGE processes the last observation from all data sets.

**Tip:** The END= variable is not added to any SAS data set that is being created.

### Details

#### Overview

The MERGE statement is flexible and has a variety of uses in SAS programming. This section describes basic uses of MERGE. Other applications include using more than one BY variable, merging more than two data sets, and merging a few observations with all observations in another data set.

For more information, see “How to Prepare Your Data Sets” in Chapter 21 of *SAS Language Reference: Concepts*.

#### Using Data Set Lists with MERGE

You can use data set lists with the MERGE statement. Data set lists provide a quick way to reference existing groups of data sets. These data set lists must be either name prefix lists or numbered range lists.

**Name prefix lists** refer to all data sets that begin with a specified character string. For example, `merge SALES1:;` tells SAS to merge all data sets starting with "SALES1" such as SALES1, SALES10, SALES11, and SALES12.

**Numbered range lists** require you to have a series of data sets with the same name, except for the last character or characters, which are consecutive numbers. In a numbered range list, you can begin with any number and end with any number. For example, these lists refer to the same data sets:

- `sales1 sales2 sales3 sales4`
- `sales1-sales4`

**Note:** If the numeric suffix of the first data set name contains leading zeros, the number of digits in the numeric suffix of the last data set name must be greater than or equal to the number of digits in the first data set name. Otherwise, an error will occur. For example, the data set lists `sales001–sales99` and `sales01–sales9` will cause an error. The data set list `sales001–sales999` is valid. If the numeric suffix of the first data set name does not contain leading zeros, the number of digits in the numeric suffix of the first and last data set names do not have to be equal. For example, the data set list `sales1–sales999` is valid.

Some other rules to consider when using numbered data set lists are as follows:
• You can specify groups of ranges.
  
  ```
  merge cost1-cost4 cost11-cost14 cost21-cost24;
  ```

• You can mix numbered range lists with name prefix lists.
  
  ```
  merge cost1-cost4 cost2: cost33-37;
  ```

• You can mix single data sets with data set lists.
  
  ```
  merge cost1 cost10-cost20 cost30;
  ```

• Quotation marks around data set lists are ignored.
  
  ```
  /* these two lines are the same */
  merge sales1-sales4;
  merge 'sales1'n-'sales4'n;
  ```

• Spaces in data set names are invalid. If quotation marks are used, trailing blanks are ignored.
  
  ```
  /* blanks in these statements will cause errors */
  merge sales 1-sales 4;
  merge 'sales 1'n - 'sales 4'n;
  /* trailing blanks in this statement will be ignored */
  merge 'sales1'n - 'sales4'n;
  ```

• The maximum numeric suffix is 2147483647.
  
  ```
  /* this suffix will cause an error */
  merge prod2000000000-prod2934850239;
  ```

• Physical pathnames are not allowed.
  
  ```
  /* physical pathnames will cause an error */
  %let work_path = %sysfunc(pathname(WORK));
  merge '&work_path\dept.sas7bdat' - '&work_path\emp.sas7bdat';
  ```

### One-to-One Merging

One-to-one merging combines observations from two or more SAS data sets into a single observation in a new data set. To perform a one-to-one merge, use the MERGE statement without a BY statement. SAS combines the first observation from all data sets that are named in the MERGE statement into the first observation in the new data set, the second observation from all data sets into the second observation in the new data set, and so on. In a one-to-one merge, the number of observations in the new data set is equal to the number of observations in the largest data set named in the MERGE statement. See Example 1 for an example of a one-to-one merge. For more information, see Chapter 21, “Reading, Combining, and Modifying SAS Data Sets,” in *SAS Language Reference: Concepts.*

**CAUTION:**

*Use care when you combine data sets with a one-to-one merge.* One-to-one merges can sometimes produce undesirable results. Test your program on representative samples of the data sets before you use this method.

### Match-Merging

Match-merging combines observations from two or more SAS data sets into a single observation in a new data set according to the values of a common variable. The number of observations in the new data set is the sum of the largest number of observations in each BY group in all data sets. To perform a match-merge, use a BY statement immediately after the MERGE statement. The variables in the BY statement must be common to all data sets. Only one BY statement can accompany each MERGE statement.
statement in a DATA step. The data sets that are listed in the MERGE statement must be
sorted in order of the values of the variables that are listed in the BY statement, or they
must have an appropriate index. See Example 2 for an example of a match-merge. For
more information, see Chapter 21, “Reading, Combining, and Modifying SAS Data

*Note:* The MERGE statement does not produce a Cartesian product on a many-to-many
match-merge. Instead, it performs a one-to-one merge while there are observations in
the BY group in at least one data set. When all observations in the BY group have
been read from one data set and there are still more observations in another data set,
SAS performs a one-to-many merge until all observations have been read for the BY
group.

**Comparisons**

- MERGE combines observations from two or more SAS data sets. UPDATE
  combines observations from exactly two SAS data sets. UPDATE changes or
  updates the values of selected observations in a master data set as well. UPDATE
  also might add observations.

- Like UPDATE, MODIFY combines observations from two SAS data sets by
  changing or updating values of selected observations in a master data set.

- The results that are obtained by reading observations using two or more SET
  statements are similar to the results that are obtained by using the MERGE statement
  with no BY statement. However, with the SET statements, SAS stops processing
  before all observations are read from all data sets if the number of observations are
  not equal. In contrast, SAS continues processing all observations in all data sets
  named in the MERGE statement.

**Examples**

**Example 1: One-to-One Merging**
This example shows how to combine observations from two data sets into a single
observation in a new data set:

```sas
data benefits.qtr1;
    merge benefits.jan benefits.feb;
run;
```

**Example 2: Match-Merging**
This example shows how to combine observations from two data sets into a single
observation in a new data set according to the values of a variable that is specified in the
BY statement:

```sas
data inventry;
    merge stock orders;
    by partnum;
run;
```

**Example 3: Merging with a Data Set List**
This example uses a data list to define the data sets that are merged.

```sas
data d008; job=3; emp=19; run;
data d009; job=3; sal=50; run;
data d010; job=4; emp=97; run;
data d011; job=4; sal=15; run;
```
data comb;
  merge d008-d011;
  by job;
run;
proc print data=comb;
run;

- Chapter 21, “Reading, Combining, and Modifying SAS Data Sets,” in SAS Language Reference: Concepts

MISSING Statement

Assigns characters in your input data to represent special missing values for numeric data.

Valid in: Anywhere
Category: Information

Syntax

MISSING character(s);

Arguments

character
  is the value in your input data that represents a special missing value.

Range: Special missing values can be any of the 26 letters of the alphabet (uppercase or lowercase) or the underscore (_).
Tip: You can specify more than one character.

Details

The MISSING statement usually appears within a DATA step, but it is global in scope.

Comparisons

The MISSING= system option enables you to specify a character to be printed when numeric variables contain ordinary missing values (.). If your data contain characters that represent special missing values, such as a or z, do not use the MISSING= option to define them; simply define these values in a MISSING statement.
Example: Identifying Certain Types of Missing Data

With survey data, you might want to identify certain types of missing data. For example, in the data, an A can mean that the respondent is not at home at the time of the survey; an R can mean that the respondent refused to answer. Use the MISSING statement to identify to SAS that the values A and R in the input data lines are to be considered special missing values rather than invalid numeric data values:

```sas
data survey;
  missing a r;
  input id answer;
  datalines;
  001 2
  002 R
  003 1
  004 A
  005 2
;
```

The resulting data set SURVEY contains exactly the values that are coded in the input data.

Statements:

- “UPDATE Statement” on page 377

System Options:

- “MISSING= System Option” in SAS System Options: Reference

MODIFY Statement

Replaces, deletes, and appends observations in an existing SAS data set in place but does not create an additional copy.

Valid in: DATA step

Category: File-handling

Type: Executable

Restriction: Cannot modify the descriptor portion of a SAS data set, such as adding a variable

Note: If you modify a password-protected data set, specify the password with the appropriate data set option (ALTER= or PW=) within the MODIFY statement, and not in the DATA statement.

CAUTION: Damage to the SAS data set can occur if the system terminates abnormally during a DATA step that contains the MODIFY statement. Observations in native SAS data files might have incorrect data values, or the data file might become unreadable. DBMS tables that are referenced by views are not affected.
Syntax

Form 1:  \texttt{MODIFY master-data-set <(data-set-options)> transaction-data-set <(data-set-options)> <NOBS=variable> <END=variable> <UPDATEMODE=MISSINGCHECK | NOMISSINGCHECK>;} \texttt{BY by-variable;}  
Form 2:  \texttt{MODIFY master-data-set <(data-set-options)> KEY=index \texttt{}</ UNIQUE> <NOBS=variable> <END=variable>;}  
Form 3:  \texttt{MODIFY master-data-set <(data-set-options)> <NOBS=variable> POINT=variable;}  
Form 4:  \texttt{MODIFY master-data-set <(data-set-options)> <NOBS=variable> <END=variable>;}  

Arguments

\texttt{master-data-set}

specifies the SAS data set that you want to modify.

\textbf{Restrictions:}

This data set must also appear in the DATA statement.

For sequential and matching access, the master data set can be a SAS data file, a SAS/ACCESS view, an SQL view, or a DBMS engine for the LIBNAME statement. It cannot be a DATA step view or a pass-through view.

For random access using POINT=, the master data set must be a SAS data file or an SQL view that references a SAS data file.

For direct access using KEY=, the master data set can be a SAS data file or the DBMS engine for the LIBNAME statement. If it is a SAS file, it must be indexed and the index name must be specified on the KEY= option.

For a DBMS, the KEY= is set to the keyword DBKEY and the column names to use as an index must be specified on the DBKEY= data set option. These column names are used in constructing a WHERE expression that is passed to the DBMS.

\textbf{Tip:} Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

\texttt{(data-set-options)}

specifies one or more SAS data set options in parentheses after a SAS data set name.

\textbf{Note:} The data set options specify actions that SAS is to take when it reads observations into the DATA step for processing. For a list of data set options, see the \textit{SAS Data Set Options: Reference}.

\textbf{Tip:} Data set options that apply to a data set list apply to all of the data sets in the list.

\texttt{transaction-data-set}

specifies the SAS data set that provides the values for matching access. These values are the values that you want to use to update the master data set.

\textbf{Restriction:} Specify this data set only when the DATA step contains a \texttt{BY} statement.

\textbf{Tip:} Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

\texttt{by-variable}

specifies one or more variables by which you identify corresponding observations.
END=variable
creates and names a temporary variable that contains an end-of-file indicator.

Restriction: Do not use this argument in the same MODIFY statement with the POINT= argument. POINT= indicates that MODIFY uses random access. The value of the END= variable is never set to 1 for random access.

Notes:
The variable, which is initialized to zero, is set to 1 when the MODIFY statement reads the last observation of the data set being modified (for sequential access) or the last observation of the transaction data set (for matching access). It is also set to 1 when MODIFY cannot find a match for a KEY= value (random access). This variable is not added to any data set.

KEY=index
specifies a simple or composite index of the SAS data file that is being modified. The KEY= argument retrieves observations from that SAS data file based on index values that are supplied by like-named variables in another source of information.

Default: If the KEY= value is not found, the automatic variable _ERROR_ is set to 1, and the automatic variable _IORC_ receives the value corresponding to the SYSRC autocall macro's mnemonic _DSENOM. See “Automatic Variable _IORC_ and the SYSRC Autocall Macro” on page 277.

Restriction: KEY= processing is different for SAS/ACCESS engines. See the SAS/ACCESS documentation for more information.

Tips:
Examples of sources for index values include a separate SAS data set named in a SET statement and an external file that is read by an INPUT statement.
If duplicates exist in the master file, only the first occurrence is updated unless you use a DO-LOOP to execute a SET statement for the data set that is listed on the KEY=option for all duplicates in the master data set.
If duplicates exist in the transaction data set, and they are consecutive, use the UNIQUE option to force the search for a match in the master data set to begin at the top of the index. Write an accumulation statement to add each duplicate transaction to the observation in master. Without the UNIQUE option, only the first duplicate transaction observation updates the master.
If the duplicates in the transaction data set are not consecutive, the search begins at the beginning of the index each time, so that each duplicate is applied to the master. Write an accumulation statement to add each duplicate to the master.

See: UNIQUE on page 274

Examples:
“Example 5: Modifying Observations Located by an Index” on page 284
“Example 6: Handling Duplicate Index Values” on page 285
“Example 7: Controlling I/O” on page 287

NOBS=variable
creates and names a temporary variable whose value is usually the total number of observations in the input data set. For certain SAS views, SAS cannot determine the number of observations. In these cases, SAS sets the value of the NOBS= variable to the largest positive integer value available in the operating environment.

Note: At compilation time, SAS reads the descriptor portion of the data set and assigns the value of the NOBS= variable automatically. Thus, you can refer to the NOBS= variable before the MODIFY statement. The variable is available in the DATA step but is not added to the new data set.

Tip: The NOBS= and POINT= options are independent of each other.
Example: “Example 4: Modifying Observations Located by Observation Number” on page 283

POINT=variable
reads SAS data sets using random (direct) access by observation number. variable names a variable whose value is the number of the observation to read. The POINT= variable is available anywhere in the DATA step, but it is not added to any SAS data set.

Restrictions:
You cannot use the POINT= option with any of the following:
• BY statement
• WHERE statement
• WHERE= data set option
• transport format data sets
• sequential data sets (on tape or disk)
• a table from another vendor's relational database management system.

You can use POINT= with compressed data sets only if the data set was created with the POINTOBS= data set option set to YES, the default value.

You can use the random access method on compressed files only with SAS version 7 and beyond.

Requirements:
When using the POINT= argument, include one or both of the following programming constructs:
• a STOP statement
• programming logic that checks for an invalid value of the POINT= variable

Because POINT= reads only the specified observations, SAS cannot detect an end-of-file condition as it would if the file were being read sequentially. Because detecting an end-of-file condition terminates a DATA step automatically, failure to substitute another means of terminating the DATA step when you use POINT= can cause the DATA step to go into a continuous loop.

Tip: If the POINT= value does not match an observation number, SAS sets the automatic variable _ERROR_ to 1.

Example: “Example 4: Modifying Observations Located by Observation Number” on page 283

UNIQUE
causes a KEY= search always to begin at the top of the index for the data file being modified.

Restriction: UNIQUE can appear only with the KEY= option.

Tip: Use UNIQUE when there are consecutive duplicate KEY= values in the transaction data set, so that the search for a match in the master data set begins at the top of the index file for each duplicate transaction. You must include an accumulation statement or the duplicate values overwrite each other causing only the last transaction value to be the result in the master observation.

Example: “Example 6: Handling Duplicate Index Values” on page 285

UPDATEMODE=MISSINGCHECK | NOMISSINGCHECK
specifies whether missing variable values in a transaction data set are to be allowed to replace existing variable values in a master data set.

MISSINGCHECK
prevents missing variable values in a transaction data set from replacing values in a master data set.
NOMISSINGCHECK allows missing variable values in a transaction data set to replace values in a master data set by preventing the check from being performed.

Default: NOMISSINGCHECK

Requirement: The UPDATEMODE argument must be accompanied by a BY statement that specifies the variables by which observations are matched.

Tip: However, special missing values are the exception and they replace values in the master data set even when NOMISSINGCHECK is in effect.

Details

Matching Access (Form 1)
The matching access method uses the BY statement to match observations from the transaction data set with observations in the master data set. The BY statement specifies a variable that is in the transaction data set and the master data set. When the MODIFY statement reads an observation from the transaction data set, it uses dynamic WHERE processing to locate the matching observation in the master data set. The observation in the master data set can be either

• replaced in the master data set with the value from the transaction data set
• deleted from the master data set
• appended to the master data set.

“Example 3: Modifying Observations Using a Transaction Data Set” on page 281 shows the matching access method.

Duplicate BY Values (Form 1)
Duplicates in the master and transaction data sets affect processing.

• If duplicates exist in the master data set, only the first occurrence is updated because the generated WHERE statement always finds the first occurrence in the master.

• If duplicates exist in the transaction data set, the duplicates are applied one on top of another unless you write an accumulation statement to add all of them to the master observation. Without the accumulation statement, the values in the duplicates overwrite each other so that only the value in the last transaction is the result in the master observation.

Direct Access by Indexed Values (Form 2)
This method requires that you use the KEY= option in the MODIFY statement to name an indexed variable from the data set that is being modified. Use another data source (typically a SAS data set named in a SET statement or an external file read by an INPUT statement) to provide a like-named variable whose values are supplied to the index. MODIFY uses the index to locate observations in the data set that is being modified.

“Example 5: Modifying Observations Located by an Index” on page 284 shows the direct-access-by-indexed-values method.

Duplicate Index Values (Form 2)

• If there are duplicate values of the indexed variable in the master data set, only the first occurrence is retrieved, modified, or replaced. Use a DO LOOP to execute a SET statement with the KEY= option multiple times to update all duplicates with the transaction value.
• If there are duplicate, nonconsecutive values in the like-named variable in the data source, MODIFY applies each transaction cumulatively to the first observation in the master data set whose index value matches the values from the data source. Therefore, only the value in the last duplicate transaction is the result in the master observation unless you write an accumulation statement to accumulate each duplicate transaction value in the master observation.

• If there are duplicate, consecutive values in the variable in the data source, the values from the first observation in the data source are applied to the master data set, but the DATA step terminates with an error when it tries to locate an observation in the master data set for the second duplicate from the data source. To avoid this error, use the UNIQUE option in the MODIFY statement. The UNIQUE option causes SAS to return to the top of the master data set before retrieving a match for the index value. You must write an accumulation statement to accumulate the values from all the duplicates. If you do not, only the last one applied is the result in the master observation.

“Example 6: Handling Duplicate Index Values” on page 285 shows how to handle duplicate index values.

• If there are duplicate index values in both data sets, you can use SQL to apply the duplicates in the transaction data set to the duplicates in the master data set in a one-to-one correspondence.

**Direct (Random) Access by Observation Number (Form 3)**

You can use the POINT= option in the MODIFY statement to name a variable from another data source (not the master data set), whose value is the number of an observation that you want to modify in the master data set. MODIFY uses the values of the POINT= variable to retrieve observations in the data set that you are modifying. (You can use POINT= on a compressed data set only if the data set was created with the POINTOBS= data set option.)

It is good programming practice to validate the value of the POINT= variable and to check the status of the automatic variable _ERROR_.

“Example 4: Modifying Observations Located by Observation Number” on page 283 shows the direct (random) access by observation number method.

**CAUTION:**

POINT= can result in infinite looping. Be careful when you use POINT=, as failure to terminate the DATA step can cause the DATA step to go into a continuous loop. Use a STOP statement, programming logic that checks for an invalid value of the POINT= variable, or both.

**Sequential Access (Form 4)**

The sequential access method is the simplest form of the MODIFY statement, but it provides less control than the direct access methods. With the sequential access method, you can use the NOBS= and END= options to modify a data set; you do not use the POINT= or KEY= options.

**Preparing Your Data Sets Before Using MODIFY**

There are a number of things that you can do to improve performance and get the results that you want when using the MODIFY statement. For more information, see “Combining SAS Data Sets: Basic Concepts” in Chapter 21 of *SAS Language Reference: Concepts*. 
Automatic Variable _IORC_ and the SYSRC Autocall Macro

The automatic variable _IORC_ contains the return code for each I/O operation that the MODIFY statement attempts to perform. The best way to test for values of _IORC_ is with the mnemonic codes that are provided by the SYSRC autocall macro. Each mnemonic code describes one condition. The mnemonics provide an easy method for testing problems in a DATA step program. These codes are useful:

- **_DSENMR**
  - specifies that the transaction data set observation does not exist on the master data set (used only with MODIFY and BY statements). If consecutive observations with different BY values do not find a match in the master data set, both of them return _DSENMR._

- **_DSEMTR**
  - specifies that multiple transaction data set observations with a given BY value do not exist on the master data set (used only with MODIFY and BY statements). If consecutive observations with the same BY values do not find a match in the master data set, the first observation returns _DSENMR_ and the subsequent observations return _DSEMTR._

- **_DSENOM**
  - specifies that the data set being modified does not contain the observation that is requested by the KEY= option or the POINT= option.

- **_SENOCHN**
  - specifies that SAS is attempting to execute an OUTPUT or REPLACE statement on an observation that contains a key value which duplicates one already existing on an indexed data set that requires unique key values.

- **_SOK**
  - specifies that the observation was located.

*Note:* The IORCMSG function returns a formatted error message associated with the current value of _IORC_.

“Example 7: Controlling I/O” on page 287 shows how to use the automatic variable _IORC_ and the SYSRC autocall macro.

Writing Observations When MODIFY Is Used in a DATA Step

The way SAS writes observations to a SAS data set when the DATA step contains a MODIFY statement depends on whether certain other statements are present. The possibilities are

- no explicit statement
  - writes the current observation to its original place in the SAS data set. The action occurs as the last action in the step (as if a REPLACE statement were the last statement in the step).

- OUTPUT statement
  - if no data set is specified in the OUTPUT statement, writes the current observation to the end of all data sets that are specified in the DATA step. If a data set is specified, the statement writes the current observation to the end of the data set that is indicated. The action occurs at the point in the DATA step where the OUTPUT statement appears.

- REPLACE <data-set-name> statement
  - rewrites the current observation in the specified data set or data sets, or, if no argument is specified, rewrites the current observation in each data set specified in the DATA statement. The action occurs at the point of the REPLACE statement.
REMOVE <data-set-name> statement
deletes the current observation in the specified data set or data sets, or, if no
argument is specified, deletes the current observation in each data set specified in the
DATA statement. The deletion can be a physical or a logical one, depending on
the characteristics of the engine that maintains the data set.

Remember the following as you work with these statements:

• When no OUTPUT, REPLACE, or REMOVE statement is specified, the default
  action is REPLACE.

• The OUTPUT, REPLACE, and REMOVE statements are independent of each other.
  You can code multiple OUTPUT, REPLACE, and REMOVE statements to apply to
  one observation. However, once an OUTPUT, REPLACE, or REMOVE statement
  executes, the MODIFY statement must execute again before the next REPLACE or
  REMOVE statement executes.

You can use OUTPUT and REPLACE in the following example of conditional logic
because only one of the REPLACE or OUTPUT statements executes per
observation:

data master;
  modify master trans; by key;
  if _iorc_=0 then replace;
  else
    output;
run;

But you should not use multiple REPLACE operations on the same observation as in
this example:

data master;
  modify master;
  x=1;
  replace;
  replace;
run;

You can code multiple OUTPUT statements per observation. However, be careful
when you use multiple OUTPUT statements. It is possible to go into an infinite loop
with just one OUTPUT statement.

data master;
  modify master;
  output;
run;

• Using OUTPUT, REPLACE, or REMOVE in a DATA step overrides the default
  replacement of observations. If you use any one of these statements in a DATA step,
  you must explicitly program each action that you want to take.

• If both an OUTPUT statement and a REPLACE or REMOVE statement execute on a
given observation, perform the OUTPUT action last to keep the position of the
observation pointer correct.

“Example 8: Replacing and Removing Observations and Writing Observations to
Different SAS Data Sets” on page 289 shows how to use the OUTPUT, REMOVE, and
REPLACE statements to write observations.
Missing Values and the MODIFY Statement

By default, the UPDATEMODE=MISSINGCHECK option is in effect, so missing values in the transaction data set do not replace existing values in the master data set. Therefore, if you want to update some but not all variables and if the variables that you want to update differ from one observation to the next, set to missing those variables that are not changing. If you want missing values in the transaction data set to replace existing values in the master data set, use UPDATEMODE=NOMISSINGCHECK.

Even when UPDATEMODE=MISSINGCHECK is in effect, you can replace existing values with missing values by using special missing value characters in the transaction data set. To create the transaction data set, use the MISSING statement in the DATA step. If you define one of the special missing values A through Z for the transaction data set, SAS updates numeric variables in the master data set to that value.

If you want the resulting value in the master data set to be a regular missing value, use a single underscore (_) to represent missing values in the transaction data set. The resulting value in the master data set will be a period (.) for missing numeric values and a blank for missing character values.

For more information about defining and using special missing value characters, see the “MISSING Statement” on page 270.

Using MODIFY with Data Set Options

If you use data set options (such as KEEP=) in your program, then use the options in the MODIFY statement for the master data set. Using data set options in the DATA statement might produce unexpected results.

Using MODIFY in a SAS/SHARE Environment

In a SAS/SHARE environment, the MODIFY statement accesses an observation in Update mode. That is, the observation is locked from the time MODIFY reads it until a REPLACE or REMOVE statement executes. At that point the observation is unlocked. It cannot be accessed until it is re-read with the MODIFY statement. The MODIFY statement opens the data set in Update mode, but the control level is based on the statement used. For example, KEY= and POINT= are member-level locking. See the SAS/SHARE User's Guide for more information.

Comparisons

• When you use a MERGE, SET, or UPDATE statement in a DATA step, SAS creates a new SAS data set. The data set descriptor of the new copy can be different from the old one (variables added or deleted, labels changed, and so on). When you use a MODIFY statement in a DATA step, however, SAS does not create a new copy of the data set. As a result, the data set descriptor cannot change.

For information about DBMS replacement rules, see the SAS/ACCESS documentation.

• If you use a BY statement with a MODIFY statement, MODIFY works much like the UPDATE statement, except that

  • neither the master data set nor the transaction data set needs to be sorted or indexed. (The BY statement that is used with MODIFY triggers dynamic WHERE processing.)

  Note: Dynamic WHERE processing can be costly if the MODIFY statement modifies a SAS data set that is not in sorted order or has not been indexed. Having the master data set in sorted order or indexed and having the
transaction data set in sorted order reduces processing overhead, especially for large files.

- both the master data set and the transaction data set can have observations with duplicate values of the BY variables. MODIFY treats the duplicates as described in “Duplicate BY Values (Form 1)” on page 275.
- MODIFY cannot make any changes to the descriptor information of the data set as UPDATE can. Thus, it cannot add or delete variables, change variable labels, and so on.

Examples

Example 1: Input Data Set for Examples
The examples modify the INVTY.STOCK data set. INVTY.STOCK contains these variables:

PARTNO
is a character variable with a unique value identifying each tool number.

DESC
is a character variable with the text description of each tool.

INSTOCK
is a numeric variable with a value describing how many units of each tool the company has in stock.

RECDATE
is a numeric variable containing the SAS date value that is the day for which INSTOCK values are current.

PRICE
is a numeric variable with a value that describes the unit price for each tool.

In addition, INVTY.STOCK contains a simple index on PARTNO. This DATA step creates INVTY.STOCK:

```sas
libname invty 'SAS-library';
data invty.stock(index=(partno));
  input PARTNO $ DESC $ INSTOCK @17
  RECDATE date7. @25 PRICE;
  format recdate date7.;
datalines;
K39R seal  34  27jul95 245.00
M4J7 sander  98  20jun95 45.88
LK43 filter 121  19may96 10.99
MN21 brace  43  10aug96 27.87
BC85 clamp  80  16aug96 9.55
NCF3 valve 198  20mar96 24.50
KJ66 cutter 6  18jun96 19.77
UYN7 rod 211  09sep96 11.55
JD03 switch 383  09jan97 13.99
BV1B timer 26  03jan97 34.50
;```
Example 2: Modifying All Observations

This example replaces the date on all of the records in the data set INVTY.STOCK with the current date. It also replaces the value of the variable RECDATE with the current date for all observations in INVTY.STOCK:

```plaintext
data invty.stock;
  modify invty.stock;
  recdate=today();
run;
proc print data=invty.stock noobs;
  title 'INVTY.STOCK';
run;
```

Output 2.19   Results of Updating the RECDATE Field

```

</tbody>
</table>
```

The MODIFY statement opens INVTY.STOCK for update processing. SAS reads one observation of INVTY.STOCK for each iteration of the DATA step and performs any operations that the code specifies. In this case, the code replaces the value of RECDATE with the result of the TODAY function for every iteration of the DATA step. An implicit REPLACE statement at the end of the step writes each observation to its previous location in INVTY.STOCK.

Example 3: Modifying Observations Using a Transaction Data Set

This example adds the quantity of newly received stock to its data set INVTY.STOCK as well as updating the date on which stock was received. The transaction data set ADDINV in the WORK library contains the new data.

The ADDINV data set is the data set that contains the updated information. ADDINV contains these variables:

PARTNO

is a character variable that corresponds to the indexed variable PARTNO in INVTY.STOCK.
NWSTOCK

is a numeric variable that represents quantities of newly received stock for each tool.

ADDINV is the second data set in the MODIFY statement. SAS uses it as the transaction data set and reads each observation from ADDINV sequentially. Because the BY statement specifies the common variable PARTNO, MODIFY finds the first occurrence of the value of PARTNO in INVTY.STOCK that matches the value of PARTNO in ADDINV. For each observation with a matching value, the DATA step changes the value of RECDATE to today's date and replaces the value of INSTOCK with the sum of INSTOCK and NWSTOCK (from ADDINV). MODIFY does not add NWSTOCK to the INVTY.STOCK data set because that would modify the data set descriptor. Thus, it is not necessary to put NWSTOCK in a DROP statement.

This example specifies ADDINV as the transaction data set that contains information to modify INVTY.STOCK. A BY statement specifies the shared variable whose values locate the observations in INVTY.STOCK.

This DATA step creates ADDINV:

data addinv;
   input PARTNO $ NWSTOCK;
   datalines;
   K39R 55
   M4J7 21
   LK43 43
   MN21 73
   BC85 57
   NCF3 90
   KJ66 2
   UYN7 108
   JD03 55
   BV1E 27
;  

This DATA step uses values from ADDINV to update INVTY.STOCK.

libname invty 'SAS-library';

data invty.stock;
   modify invty.stock addinv;
   by partno;
   RECDATE=today();
   INSTOCK=instock+nwstock;
   if _iorc_=0 then replace;
run;

proc print data=invty.stock noobs;
   title 'INVTY.STOCK';
run;
Example 4: Modifying Observations Located by Observation Number

This example reads the data set NEWP, determines which observation number in INVTY.STOCK to update based on the value of TOOL_OBS, and performs the update. This example explicitly specifies the update activity by using an assignment statement to replace the value of PRICE with the value of NEWP.

The data set NEWP contains two variables:

TOOL_OBS
  contains the observation number of each tool in the tool company's master data set, INVTY.STOCK.

NEWP
  contains the new price for each tool.

This DATA step creates NEWP:

data newp;
  input TOOL_OBS NEWP;
datalines;
1 251.00
2 49.33
3 12.32
4 30.00
5 15.00
6 25.75
7 22.00
8 14.00
9 14.32
10 35.00
;
This DATA step updates INVTY.STOCK:

libname invty 'SAS-library';

data invty.stock;
  set newp;
  modify invty.stock point=tool_obs
     nobs=max_obs;
  if _error_=1 then
    do;
      put 'ERROR occurred for TOOL_OBS=' tool_obs
         / 'during DATA step iteration' _n_
         / 'TOOL_OBS value might be out of range.';
    _error_=0;
    stop;
  end;
  PRICE=newp;
  RECDATE=today();
run;

proc print data=invty.stock noobs;
  title 'INVTY.STOCK';
run;

Output 2.21 Results of Updating the RECDATE and PRICE Fields

Example 5: Modifying Observations Located by an Index

This example uses the KEY= option to identify observations to retrieve by matching the values of PARTNO from ADDINV with the indexed values of PARTNO in INVTY.STOCK. ADDINV is created in “Example 3: Modifying Observations Using a Transaction Data Set” on page 281.

KEY= supplies index values that allow MODIFY to access directly the observations to update. No dynamic WHERE processing occurs. In this example, you specify that the
The value of INSTOCK in the master data set INVTY.STOCK increases by the value of the variable NWSTOCK from the transaction data set ADDINV.

```
libname invty 'SAS-library';

data invty.stock;
  set addinv;
  modify invty.stock key=partno;
  INSTOCK=instock+nwstock;
  RECDATE=today();
  if _iorc_=0 then replace;
run;

proc print data=invty.stock noobs;
  title 'INVTY.STOCK';
run;
```

**Output 2.22**

**Example 6: Handling Duplicate Index Values**

This example shows how MODIFY handles duplicate values of the variable in the SET data set that is supplying values to the index on the master data set.

The NEWINV data set is the data set that contains the updated information. NEWINV contains these variables:

PARTNO  
is a character variable that corresponds to the indexed variable PARTNO in INVTY.STOCK. The NEWINV data set contains duplicate values for PARTNO; M4J7 appears twice.

NWSTOCK  
is a numeric variable that represents quantities of newly received stock for each tool.

This DATA step creates NEWINV:
data newinv;
  input PARTNO $ NWSTOCK;
datalines;
K89R 55
M4J7 21
M4J7 26
LK43 43
MN21 73
BC85 57
NCF3 90
KJ66 2
UYN7 108
JD03 55
BV1E 27;

This DATA step terminates with an error when it tries to locate an observation in INVTY.STOCK to match with the second occurrence of M4J7 in NEWINV:

libname invty 'SAS-library';
/* This DATA step terminates with an error! */
data invty.stock;
  set newinv;
  modify invty.stock key=partno;
  INSTOCK=instock+nwstock;
  RECDATE=today();
run;

This message appears in the SAS log:

ERROR: No matching observation was found in MASTER data set.
PARTNO=M4J7 NWSTOCK=26 DESC=sander INSTOCK=166 RECDATE=08DEC10 PRICE=45.88
_ERROR_=1_IORC_=1238015_N=3
NOTE: The SAS System stopped processing this step because of errors.
NOTE: There were 3 observations read from the data set WORK.NEWINV.
NOTE: The data set INVTY.STOCK has been updated. There were 2 observations rewritten, 0 observations added and 0 observations deleted.

Adding the UNIQUE option to the MODIFY statement avoids the error in the previous DATA step. The UNIQUE option causes the DATA step to return to the top of the index each time it looks for a match for the value from the SET data set. Thus, it finds the M4J7 in the MASTER data set for each occurrence of M4J7 in the SET data set. The updated result for M4J7 in the output shows that both values of NWSTOCK from NEWINV for M4J7 are added to the value of INSTOCK for M4J7 in INVTY.STOCK. An accumulation statement sums the values; without it, only the value of the last instance of M4J7 would be the result in INVTY.STOCK.

data invty.stock;
  set newinv;
  modify invty.stock key=partno / unique;
  INSTOCK=instock+nwstock;
  RECDATE=today();
  if _iorc_=0 then replace;
run;
proc print data=invty.stock noobs;
  title 'Results of Using the UNIQUE Option';
run;
Example 7: Controlling I/O

This example uses the SYSRC autocall macro and the _IORC_ automatic variable to control I/O condition. This technique helps prevent unexpected results that could go undetected. This example uses the direct access method with an index to update INVTY.STOCK. The data in the NEWSHIP data set updates INVTY.STOCK.

This DATA step creates NEWSHIP:

```sas
data newship;
  input PARTNO $ DESC $ NWSTOCK @17 SHPDATE date7. @25 NWPRICE;
  datalines;
  K89R seal 14 14nov96 245.00
  M4J7 sander 24 23aug96 47.98
  LK43 filter 11 29jan97 14.99
  MN21 brace 9 09jan97 27.87
  BC85 clamp 12 09dec96 10.00
  ME34 cutter 8 14nov96 14.50
  ;
```

Each WHEN clause in the SELECT statement specifies actions for each input/output return code that is returned by the SYSRC autocall macro:

- **_SOK_** indicates that the MODIFY statement executed successfully.
- **_DSENOM_** indicates that no matching observation was found in INVTY.STOCK. The OUTPUT statement specifies that the observation be appended to INVTY.STOCK. See the last observation in the output.
- If any other code is returned by SYSRC, the DATA step terminates and the PUT statement writes the message to the log.

```sas
libname invty 'SAS-library';
```
data invty.stock;
  set newship;
  modify invty.stock key=partno;
  select (_iorc_);
    when (%sysrc(_sok)) do;
      INSTOCK=instock+nwstock;
      RECDATE=shpdate;
      PRICE=nwprice;
      replace;
    end;
    when (%sysrc(_dsenom)) do;
      INSTOCK=nwstock;
      RECDATE=shpdate;
      PRICE=nwprice;
      output;
      _error_=0;
    end;
  otherwise do;
    put
      'An unexpected I/O error has occurred.'/
      'Check your data and your program';
    _error_=0;
    stop;
  end;
run;

proc print data=invty.stock noobs;
  title 'INVTY.STOCK Data Set';
run;
Output 2.24  The Updated INVTY.STOCK Data Set

Example 8: Replacing and Removing Observations and Writing Observations to Different SAS Data Sets

This example shows that you can replace and remove (delete) observations and write observations to different data sets. Further, this example shows that if an OUTPUT, REPLACE, or REMOVE statement is present, you must specify explicitly what action to take because no default statement is generated.

The parts that were received in 1997 are output to INVTY.STOCK97 and are removed from INVTY.STOCK. Likewise, the parts that were received in 1995 are output to INVTY.STOCK95 and are removed from INVTY.STOCK. Only the parts that were received in 1996 remain in INVTY.STOCK, and the PRICE is updated only in INVTY.STOCK.

```
libname invty 'SAS-library';

data invty.stock invty.stock95 invty.stock97;
  modify invty.stock;
  if recdate>'01jan97'd then do;
    output invty.stock97;
    remove invty.stock;
  end;
  else if recdate<'01jan96'd then do;
    output invty.stock95;
    remove invty.stock;
  end;
  else do;
    price=price*1.1;
    replace invty.stock;
```
end;
run;

proc print data=invty.stock noobs;
  title 'New Prices for Stock Received in 1996';
run;

Output 2.25  Output from Writing Observations to a Specific SAS Data Set

New Prices for Stock Received in 1996

Null Statement

Signals the end of data lines or acts as a placeholder.

Valid in:  Anywhere
Category:  Action
Type:     Executable

Syntax

;
Without Arguments

The Null statement signals the end of the data lines that occur in your program.

Details

The primary use of the Null statement is to signal the end of data lines that follow a DATALINES or CARDS statement. In this case, the Null statement functions as a step boundary. When your data lines contain semicolons, use the DATALINES4 or CARDS4 statement and a Null statement of four semicolons.

Although the Null statement performs no action, it is an executable statement. Therefore, a label can precede the Null statement, or you can use it in conditional processing.

Example: Marking the End of Data Lines

- The Null statement in this program marks the end of data lines and functions as a step boundary.
  ```
  data test;
  input score1 score2 score3;
  datalines;
  55 135 177
  44 132 169
  ;
  ```
- The input data records in this example contain semicolons. Use the Null statement following the DATALINES4 statement to signal the end of the data lines.
  ```
  data test2;
  input code1 $ code2 $ code3 $;
  datalines4;
  55;39;1 135;32;4 177;27;3
  78;29;1 149;22;4 179;37;3
  ;
  ```
- The Null statement is useful while you are developing a program. For example, use it after a statement label to test your program before you code the statements that follow the label.
  ```
  data _null_;
  set dsn;
  file print header=header;
  put 'report text';
  ...more statements...
  return;
  header;:
  run;
  ```

OPTIONS Statement

Specifies or changes the value of one or more SAS system options.

Valid in: Anywhere
Category: Program Control
See: OPTIONS Statement under z/OS

Syntax

OPTIONS option(s);

Arguments

option

specifies one or more SAS system options to be changed.

Details

The change that is made by the OPTIONS statement remains in effect for the rest of the job, session, SAS process, or until you issue another OPTIONS statement to change the options again. You can specify SAS system options through the OPTIONS statement, through the OPTIONS window, at SAS invocation, and at the initiation of a SAS process.

Note: If you want a particular group of options to be in effect for all your SAS jobs or sessions, store an OPTIONS statement in an autoexec file or list the system options in a configuration file or custom_option_set.

Note: For a system option with a null value, the GETOPTION function returns a value of ' ' (single quotation marks with a blank space between them), for example EMAILID=' '. This GETOPTION value can then be used in the OPTIONS statement.

An OPTIONS statement can appear at any place in a SAS program, except within data lines.

Operating Environment Information

The system options that are available depend on your operating environment. Also, the syntax that is used to specify a system option in the OPTIONS statement might be different from the syntax that is used at SAS invocation. For details, see the SAS documentation for your operating environment.

Comparisons

The OPTIONS statement requires you to enter the complete statement including system option name and value, if necessary. The SAS OPTIONS window displays the options’ names and settings in columns. To change a setting, type over the value that is displayed and press ENTER or RETURN.
Example: Changing the Value of a System Option

This example suppresses the date that is normally written to SAS LISTING output and sets a line size of 72:

```sas
options nodate linesize=72;
```

“Definition of System Options” in Chapter 1 of *SAS System Options: Reference*

---

**OUTPUT Statement**

Writes the current observation to a SAS data set.

- **Valid in:** DATA step
- **Category:** Action
- **Type:** Executable

**Syntax**

```
OUTPUT<data-set-name(s)>;
```

**Without Arguments**

Using OUTPUT without arguments causes the current observation to be written to all data sets that are named in the DATA statement.

If a MODIFY statement is present, OUTPUT with no arguments writes the current observation to the end of the data set that is specified in the MODIFY statement.

**Arguments**

`data-set-name`

specifies the name of a data set to which SAS writes the observation.

**Restriction:** All names specified in the OUTPUT statement must also appear in the DATA statement.

**Tips:**

Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

You can specify up to as many data sets in the OUTPUT statement as you specified in the DATA statement for that DATA step.

**Details**

**When and Where the OUTPUT Statement Writes Observations**

The OUTPUT statement tells SAS to write the current observation to a SAS data set immediately, not at the end of the DATA step. If no data set name is specified in the OUTPUT statement, the observation is written to the data set or data sets that are listed in the DATA statement.
Implicit versus Explicit Output
By default, every DATA step contains an implicit OUTPUT statement at the end of each iteration that tells SAS to write observations to the data set or data sets that are being created. Placing an explicit OUTPUT statement in a DATA step overrides the automatic output, and SAS adds an observation to a data set only when an explicit OUTPUT statement is executed. Once you use an OUTPUT statement to write an observation to any one data set, however, there is no implicit OUTPUT statement at the end of the DATA step. In this situation, a DATA step writes an observation to a data set only when an explicit OUTPUT executes. You can use the OUTPUT statement alone or as part of an IF-THEN or SELECT statement or in DO-loop processing.

When Using the MODIFY Statement
When you use the MODIFY statement with the OUTPUT statement, the REMOVE and REPLACE statements override the implicit write action at the end of each DATA step iteration. See “Comparisons ” on page 294 for more information. If both the OUTPUT statement and a REPLACE or REMOVE statement execute on a given observation, perform the output action last to keep the position of the observation pointer correct.

Comparisons
• OUTPUT writes observations to a SAS data set; PUT writes variable values or text strings to an external file or the SAS log.
• To control when an observation is written to a specified output data set, use the OUTPUT statement. To control which variables are written to a specified output data set, use the KEEP= or DROP= data set option in the DATA statement, or use the KEEP or DROP statement.
• When you use the OUTPUT statement with the MODIFY statement, the following items apply.
  • Using an OUTPUT, REPLACE, or REMOVE statement overrides the default write action at the end of a DATA step. (OUTPUT is the default action; REPLACE becomes the default action when a MODIFY statement is used.) If you use any of these statements in a DATA step, you must explicitly program output for the new observations that are added to the data set.
  • The OUTPUT, REPLACE, and REMOVE statements are independent of each other. More than one statement can apply to the same observation, as long as the sequence is logical.
  • If both an OUTPUT and a REPLACE or REMOVE statement execute on a given observation, perform the OUTPUT action last to keep the position of the observation pointer correct.

Examples
Example 1: Sample Uses of OUTPUT
These examples show how you can use an OUTPUT statement:
• This line of code writes the current observation to a SAS data set.

        output;

• This line of code writes the current observation to a SAS data set when a specified condition is true.

        if deptcode gt 2000 then output;
• This line of code writes an observation to the data set MARKUP when the PHONE value is missing.
  
  if phone= then output markup;

**Example 2: Creating Multiple Observations from Each Line of Input**

You can create two or more observations from each line of input data. This SAS program creates three observations in the data set RESPONSE for each observation in the data set SULFA:

```sas
data response(drop=time1-time3);
  set sulfa;
  time=time1;
  output;
  time=time2;
  output;
  time=time3;
  output;
run;
```

**Example 3: Creating Multiple Data Sets from a Single Input File**

You can create more than one SAS data set from one input file. In this example, OUTPUT writes observations to two data sets, OZONE and OXIDES:

```sas
data ozone oxides;
  infile file-specification;
  input city $ 1-15 date date9.
    chemical $ 26-27 ppm 29-30;
  if chemical='O3' then output ozone;
  else output oxides;
run;
```

**Example 4: Creating One Observation from Several Lines of Input**

You can combine several input observations into one observation. In this example, OUTPUT creates one observation that totals the values of DEFECTS in the first ten observations of the input data set:

```sas
data discards;
  set gadgets;
  drop defects;
  reps+1;
  if reps=1 then total=0;
  total+defects;
  if reps=10 then do;
    output;
    stop;
  end;
run;
```

**See Also**

**Statements:**

- “DATA Statement” on page 48
- “MODIFY Statement” on page 271
PAGE Statement

Skips to a new page in the SAS log.

Valid in: Anywhere
Category: Log Control

Syntax

PAGE;

Without Arguments

The PAGE statement skips to a new page in the SAS log.

Details

You can use the PAGE statement when you run SAS in a windowing environment, batch, or noninteractive mode. The PAGE statement itself does not appear in the log. When you run SAS in interactive line mode, PAGE might print blank lines to the display monitor (or to the alternate log file).

PUT Statement

Writes lines to the SAS log, to the SAS output window, or to an external location that is specified in the most recent FILE statement.

Valid in: DATA step
Category: File-handling
Type: Executable

Syntax

PUT <specification(s)> <_ODS_> <@ | @@>;
**Without Arguments**
The PUT statement without arguments is called a null PUT statement. The null PUT statement

- writes the current output line to the current location, even if the current output line is blank
- releases an output line that is being held with a trailing @ by a previous PUT statement.

For an example, see “Example 5: Holding and Releasing Output Lines” on page 311.
For more information, see “Using Line-Hold Specifiers” on page 305.

**Arguments**

*specification(s)*
specifies what is written, how it is written, and where it is written. The specification can include

*variable*
specifies the variable whose value is written.

*Note:* Beginning with Version 7, you can specify column-mapped Output Delivery System variables in the PUT statement. This functionality is described briefly here in _ODS_ on page 298. It is documented more completely in the “PUT Statement for ODS ” in SAS Output Delivery System: User’s Guide.

*(variable-list)*
specifies a list of variables whose values are written.

*Requirement:* The (format-list) must follow the (variable-list).

*See:* “PUT Statement, Formatted” on page 316

*’character-string’*
specifies a string of text, enclosed in quotation marks, to write.

*Tips:*
To write a hexadecimal string in EBCDIC or ASCII, follow the ending quotation mark with an \(x\).
If you use single quotation marks (‘) or double quotation marks ("”) together (with no space in between them) as the string of text, SAS will output a single quotation mark (‘) or double quotation mark ("), respectively.

*See:* “List Output” on page 302

*Example:* This statement writes HELLO when the hexadecimal string is converted to ASCII characters:
```
put '68656C6C6F'x;
```

*n* specifies to repeat \(n\) times the subsequent character string.

*Example:* This statement writes a line of 132 underscores.
```
put 132*'_'
```

*Example:* “Example 4: Underlining Text” on page 310

*pointer-control*
moves the output pointer to a specified line or column in the output buffer.

*See:*
“Column Pointer Controls ” on page 299
“Line Pointer Controls ” on page 300
column Specifications
specifies which columns of the output line the values are written.
See: “Column Output” on page 302
Example: “Example 2: Moving the Pointer within a Page” on page 307

Format.
specifies a format to use when the variable values are written.
See: “Formatted Output” on page 302
Example: “Example 1: Using Multiple Output Styles in One PUT Statement” on page 307

(format-list)
specifies a list of formats to use when the values of the preceding list of variables are written.
Restriction: The (format-list) must follow the (variable-list).
See: “PUT Statement, Formatted” on page 316

_INFILE_
writes the last input data record that is read either from the current input file or from the data lines that follow a DATELINES statement.
Tips:
_INFILE_ is an automatic variable that references the current INPUT buffer. You can use this automatic variable in other SAS statements.
If the most recent INPUT statement uses line-pointer controls to read multiple input data records, PUT_INFILE_ writes only the record that the input pointer is positioned on.
Example: This PUT statement writes all the values of the first input data record:
input #3 score #1 name $ 6-23;
put _infile_
Example: “Example 6: Writing the Current Input Record to the Log” on page 311

_ALL_
writes the values of all variables, which includes automatic variables, that are defined in the current DATA step by using named output.
See: “Named Output” on page 303

_ODS_
moves data values for all columns (as defined by the ODS option in the FILE statement) into a special buffer, from which it is eventually written to the data component. The ODS option in the FILE statement defines the structure of the data component that holds the results of the DATA step.
Restriction: Use _ODS_ only if you have previously specified the ODS option in the FILE statement.
Interaction: _ODS_ writes data to a specific column only if a PUT statement has not already specified a variable for that column with a column pointer. That is, a variable specification for a column overrides the _ODS_ option.
Tip: You can use the _ODS_ specification in conjunction with variable specifications and column pointers, and it can appear anywhere in a PUT statement.
@@@ holds an output line for the execution of the next PUT statement even across iterations of the DATA step. These line-hold specifiers are called trailing @ and double trailing @.

Restriction: The trailing @ or double trailing @ must be the last item in the PUT statement.

Tip: Use an @ or @@ to hold the pointer at its current location. The next PUT statement that executes writes to the same output line rather than to a new output line.

See: “Using Line-Hold Specifiers” on page 305

Example: “Example 5: Holding and Releasing Output Lines” on page 311

Column Pointer Controls

@\( n \) moves the pointer to column \( n \).

Range: a positive integer

Example: @15 moves the pointer to column 15 before the value of NAME is written:

```sas
put @15 name $10.;
```

Examples:

“Example 2: Moving the Pointer within a Page” on page 307 and
“Example 4: Underlining Text” on page 310

@\( \text{numeric-variable} \)

moves the pointer to the column given by the value of \( \text{numeric-variable} \).

Range: a positive integer

Tip: If \( n \) is not an integer, SAS truncates the decimal portion and uses only the integer value. If \( n \) is zero or negative, the pointer moves to column 1.

Example: The value of the variable A moves the pointer to column 15 before the value of NAME is written:

```sas
a=15;
put @a name $10.;
```

Example: “Example 2: Moving the Pointer within a Page” on page 307

@\( (\text{expression}) \)

moves the pointer to the column that is given by the value of \( \text{expression} \).

Range: a positive integer

Tip: If the value of \( \text{expression} \) is not an integer, SAS truncates the decimal value and uses only the integer value. If it is zero, the pointer moves to column 1.

Example: The result of the expression moves the pointer to column 15 before the value of NAME is written:

```sas
b=5;
put @(b*3) name $10.;
```

\(+\ n\)

moves the pointer \( n \) columns.

Range: a positive integer or zero

Tip: If \( n \) is not an integer, SAS truncates the decimal portion and uses only the integer value.

Example: This statement moves the pointer to column 23, writes a value of LENGTH in columns 23 through 26, advances the pointer five columns, and writes the value of WIDTH in columns 32 through 35:
+numeric-variable

moves the pointer the number of columns given by the value of numeric-variable.

Range: a positive or negative integer or zero

Tip: If numeric-variable is not an integer, SAS truncates the decimal value and uses only the integer value. If numeric-variable is negative, the pointer moves backward. If the current column position becomes less than 1, the pointer moves to column 1. If the value is zero, the pointer does not move. If the value is greater than the length of the output buffer, the current line is written out and the pointer moves to column 1 on the next line.

+(expression)

moves the pointer the number of columns given by expression.

Range: expression must result in an integer

Tip: If expression is not an integer, SAS truncates the decimal value and uses only the integer value. If expression is negative, the pointer moves backward. If the current column position becomes less than 1, the pointer moves to column 1. If the value is zero, the pointer does not move. If the value is greater than the length of the output buffer, the current line is written out and the pointer moves to column 1 on the next line.

Example: “Example 2: Moving the Pointer within a Page” on page 307

Line Pointer Controls

#n

moves the pointer to line n and column 1.

Range: a positive integer

Example: The #2 moves the pointer to the second line before the value of ID is written in columns 3 and 4:

```
put @12 name $10. #2 id 3-4;
```

#numeric-variable

moves the pointer to the line given by the value of numeric-variable and to column 1.

Range: a positive integer

Tip: If the value of numeric-variable is not an integer, SAS truncates the decimal value and uses only the integer value.

#(expression)

moves the pointer to the line that is given by the value of expression and to column 1.

Range: Expression must result in a positive integer.

Tip: If the value of expression is not an integer, SAS truncates the decimal value and uses only the integer value.

/

advances the pointer to column 1 of the next line.

Example: The values for NAME and AGE are written on one line, and then the pointer moves to the second line to write the value of ID in columns 3 and 4:

```
put name age / id 3-4;
```

Example: “Example 3: Moving the Pointer to a New Page” on page 309

OVERPRINT

causes the values that follow the keyword OVERPRINT to print on the most recently written output line.
**Requirement:** You must direct the output to a file. Set the N= option in the FILE statement to 1 and direct the PUT statements to a file.

**Tips:**
- OVERPRINT has no effect on lines that are written to a display.
- Use OVERPRINT in combination with column pointer and line pointer controls to overprint text.

**Example:** This statement overprints underscores, starting in column 15, which underlines the title:

```sas
put @15 'Report Title' overprint @15 '__________';
```

**Example:** “Example 4: Underlining Text” on page 310

**_BLANKPAGE_**

advances the pointer to the first line of a new page, even when the pointer is positioned on the first line and the first column of a new page.

**Tip:** If the current output file contains carriage-control characters, _BLANKPAGE_ produces output lines that contain the appropriate carriage-control character.

**Example:** “Example 3: Moving the Pointer to a New Page” on page 309

**_PAGE_**

advances the pointer to the first line of a new page. SAS automatically begins a new page when a line exceeds the current PAGESIZE= value.

**Tips:**
- If the current output file is printed, _PAGE_ produces an output line that contains the appropriate carriage-control character. _PAGE_ has no effect on a file that is not printed.
- If you specify FILE PRINT in an interactive SAS session, then the Output window interprets the form-feed control characters as page breaks, and they are removed from the output. The resulting file is a flat file without page break characters. If a file needs to contain the form-feed characters, then the FILE statement should include a physical file location and the PRINT option.

**Example:** “Example 3: Moving the Pointer to a New Page” on page 309

**Details**

**When to Use PUT**

Use the PUT statement to write lines to the SAS log, to the SAS output window, or to an external location. If you do not execute a FILE statement before the PUT statement in the current iteration of a DATA step, SAS writes the lines to the SAS log. If you specify the PRINT option in the FILE statement, SAS writes the lines to the SAS output window.

The PUT statement can write lines that contain variable values, character strings, and hexadecimal character constants. With specifications in the PUT statement, you specify what to write, where to write it, and how to format it.

**Output Styles**

**Overview of Output Styles**

There are four ways to write variable values with the PUT statement:

- column
- list (simple and modified)
A single PUT statement might contain any or all of the available output styles, depending on how you want to write lines.

**Column Output**

With column output, the column numbers follow the variable in the PUT statement. These numbers indicate where in the line to write the following value:

```
put name 6-15 age 17-19;
```

These lines are written to the SAS log.

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

```
---------1---------2---------
 Peterson   21
 Morgan      17
```

The PUT statement writes values for NAME and AGE in the specified columns. See “PUT Statement, Column” on page 314 for more information.

**List Output**

With list output, list the variables and character strings in the PUT statement in the order in which you want to write them. For example, this PUT statement writes the values for NAME and AGE to the SAS log.

```
put name age;
```

Here is the SAS log.

```
---------1---------2---------
 Peterson   21
 Morgan      17
```

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

See “PUT Statement, List” on page 319 for more information.

**Formatted Output**

With formatted output, specify a SAS format or a user-written format after the variable name. The format gives instructions on how to write the variable value. Formats enable you to write in a nonstandard form, such as packed decimal, or numbers that contain special characters such as commas. You can also override the default alignment of the formatted output by using -L, -C, or -R.

For example, this PUT statement writes the values for NAME, AGE, and DATE to the SAS log.

```
put name $char10. age 2. +1 date mmddyy10.;
```

Here is the SAS log.

```
---------1---------2---------
 Peterson  21 07/18/1999
 Morgan    17 11/12/1999
```

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.
Using a pointer control of +1 inserts a blank space between the values of AGE and DATE. For more information, see “PUT Statement, Formatted” on page 316.

**Named Output**

With *named output*, list the variable name followed by an equal sign. For example, this PUT statement writes the values for NAME and AGE to the SAS log.

```sas
put name= age=;
```

Here is the SAS log.

```
-----+----1----+----2----+
name=Peterson age=21
name=Morgan age=17
```

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

See “PUT Statement, Named” on page 324 for more information.

**Using Multiple Output Styles in a Single PUT Statement**

A PUT statement can combine any or all of the different output styles. Here is an example.

```sas
put name 'on ' date mmddyy8. ' weighs ' startwght +(-1) '. ' idno= 40-45;
```

See “Example 1: Using Multiple Output Styles in One PUT Statement” on page 307 for an explanation of the lines written to the SAS log.

When you combine different output styles, it is important to understand the location of the output pointer after each value is written. For more information about the pointer location, see “Pointer Location After a Value Is Written” on page 305.

**Avoiding a Common Error When Writing Both a Character Constant and a Variable**

When using a PUT statement to write a character constant that is followed by a variable name, always put a blank space between the closing quotation mark and the variable name:

```sas
put 'Player:' name1 'Player:' name2 'Player:' name3;
```

Otherwise, SAS might interpret a character constant that is followed by a variable name as a special SAS constant as illustrated in this table.

<table>
<thead>
<tr>
<th>Starting Letter of Variable</th>
<th>Represents</th>
<th>Examples</th>
</tr>
</thead>
<tbody>
<tr>
<td>b</td>
<td>bit testing constant</td>
<td>'00100000'b</td>
</tr>
<tr>
<td>d</td>
<td>date constant</td>
<td>'01jan04'd</td>
</tr>
<tr>
<td>dt</td>
<td>datetime constant</td>
<td>'18jan2003:9:27:05am'dt</td>
</tr>
<tr>
<td>n</td>
<td>name literal</td>
<td>'My Table'n</td>
</tr>
<tr>
<td>t</td>
<td>time constant</td>
<td>'9:25:19pm't</td>
</tr>
</tbody>
</table>
“Example 7: Avoiding a Common Error When Writing a Character Constant Followed by a Variable” on page 312 shows how to use character constants followed by variables. For more information about SAS name literals and SAS constants in expressions, see *SAS Language Reference: Concepts*.

**Pointer Controls**
As SAS writes values with the PUT statement, it keeps track of its position with a pointer. The PUT statement provides three ways to control the movement of the pointer:

- **column pointer controls**
  reset the pointer's column position when the PUT statement starts to write the value to the output line.

- **line pointer controls**
  reset the pointer's line position when the PUT statement writes the value to the output line.

- **line-hold specifiers**
  hold a line in the output buffer so that another PUT statement can write to it. By default, the PUT statement releases the previous line and writes to a new line.

With column and line pointer controls, you can specify an absolute line number or column number to move the pointer or you can specify a column or line location that is relative to the current pointer position. The following table lists all pointer controls that are available in the PUT statement.

**Table 2.8 Pointer Controls Available in the PUT Statement**

<table>

</tr>
</tbody>
</table>

*Note:* Always specify pointer controls before the variable for which they apply.

See “Pointer Location After a Value Is Written” on page 305 for more information about how SAS determines the pointer position.
**Using Line-Hold Specifiers**

Line-hold specifiers keep the pointer on the current output line when

- more than one PUT statement writes to the same output line
- a PUT statement writes values from more than one observation to the same output line.

Without line-hold specifiers, each PUT statement in a DATA step writes a new output line.

In the PUT statement, trailing @ and double trailing @@ produce the same effect. Unlike the INPUT statement, the PUT statement does not automatically release a line that is held by a trailing @ when the DATA step begins a new iteration. SAS releases the current output line that is held by a trailing @ or double trailing @ when it encounters

- a PUT statement without a trailing @
- a PUT statement that uses _BLANKPAGE_ or _PAGE_
- the end of the current line (determined by the current value of the LRECL= or LINESIZE= option in the FILE statement, if specified, or the LINESIZE= system option)
- the end of the last iteration of the DATA step.

Using a trailing @ or double trailing @ can cause SAS to attempt to write past the current line length because the pointer value is unchanged when the next PUT statement executes. See “When the Pointer Goes Past the End of a Line” on page 305.

**Pointer Location After a Value Is Written**

Understanding the location of the output pointer after a value is written is important, especially if you combine output styles in a single PUT statement. The pointer location after a value is written depends on which output style you use and whether a character string or a variable is written. With column or formatted output, the pointer is located in the first column after the end of the field that is specified in the PUT statement. These two styles write only variable values.

With list output or named output, the pointer is located in the second column after a variable value because PUT skips a column automatically after each value is written. However, when a PUT statement uses list output to write a character string, the pointer is located in the first column after the string. If you do not use a line pointer control or column output after a character string is written, add a blank space to the end of the character string to separate it from the next value.

After an _INFILE_ specification, the pointer is located in the first column after the record is written from the current input file.

When the output pointer is in the upper left corner of a page,

- PUT _BLANKPAGE_ writes a blank page and moves the pointer to the top of the next page.
- PUT _PAGE_ leaves the pointer in the same location.

You can determine the current location of the pointer by examining the variables that are specified with the COLUMN= option and the LINE= option in the FILE statement.

**When the Pointer Goes Past the End of a Line**

SAS does not write an output line that is longer than the current output line length. The line length of the current output file is determined by

- the value of the LINESIZE= option in the current FILE statement
the value of the LINESIZE= system option (for the SAS output window)

the LRECL= option in the current FILE statement (for external files).

You can inadvertently position the pointer beyond the current line length with one or more of these specifications:

• a + pointer control with a value that moves the pointer to a column beyond the current line length

• a column range that exceeds the current line length (for example, PUT X 90 – 100 when the current line length is 80)

• a variable value or character string that does not fit in the space that remains on the current output line.

By default, when PUT attempts to write past the end of the current line, SAS withholds the entire item that overflows the current line, writes the current line, and then writes the overflow item on a new line, starting in column 1. See the FLOWOVER, DROPOVER, and STOPOVER options in the “FILE Statement” on page 76.

Arrays

You can use the PUT statement to write an array element. The subscript is any SAS expression that results in an integer when the PUT statement executes. You can use an array reference in a numeric-variable construction with a pointer control if you enclose the reference in parentheses, as shown here:

• @ (array-name{i})

• + (array-name{i})

• #(array-name{i})

Use the array subscript asterisk (*) to write all elements of a previously defined array to an external location. SAS allows one-dimensional or multidimensional arrays, but it does not allow a _TEMPORARY_ array. Enclose the subscript in braces, brackets, or parentheses, and print the array using list, formatted, column, or named output. With list output, the form of this statement is

PUT array-name{*};

With formatted output, the form of this statement is

PUT array-name{*} (format|format.list)

The format in parentheses follows the array reference.

Comparisons

• The PUT statement writes variable values and character strings to the SAS log or to an external location while the INPUT statement reads raw data in external files or data lines entered instream.

• Both the INPUT and the PUT statements use the trailing @ and double trailing @ line-hold specifiers to hold the current line in the input or output buffer, respectively. In an INPUT statement, a double trailing @ holds a line in the input buffer from one iteration of the DATA step to the next. In a PUT statement, however, a trailing @ has the same effect as a double trailing @; both hold a line across iterations of the DATA step.

• Both the PUT and OUTPUT statements create output in a DATA step. The PUT statement uses an output buffer and writes output lines to an external location, the SAS log, or your monitor. The OUTPUT statement uses the program data vector and writes observations to a SAS data set.
Examples

**Example 1: Using Multiple Output Styles in One PUT Statement**

This example uses several output styles in a single PUT statement:

```sas
data club1;
  input idno name $ startwght date : date7.;
  put name 'on ' date mmddyy8. ' weighs '
    startwght +(-1) '.' idno= 32-40;
  datalines;
  032 David 180 25nov99
  049 Amelia 145 25nov99
  219 Alan 210 12nov99
;
```

The following table shows the output style used for each variable in the example:

<table>
<thead>
<tr>
<th>Variables</th>
<th>Output Style</th>
</tr>
</thead>
<tbody>
<tr>
<td>NAME, STARTWHT</td>
<td>list output</td>
</tr>
<tr>
<td>DATE</td>
<td>formatted output</td>
</tr>
<tr>
<td>IDNO</td>
<td>named output</td>
</tr>
</tbody>
</table>

The PUT statement also uses pointer controls and specifies both character strings and variable names.

The program writes the following lines to the SAS log:

```
----+----1----+----2----+----3----+----4
David on 11/25/99 weighs 180. idno=1032
Amelia on 11/25/99 weighs 145. idno=1049
Alan on 11/12/99 weighs 210. idno=1219
```

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

Blank spaces are inserted at the beginning and the end of the character strings to change the pointer position. These spaces separate the value of a variable from the character string. The +(-1) pointer control moves the pointer backward to remove the unwanted blank that occurs between the value of STARTWHT and the period. For more information about how to position the pointer, see “Pointer Location After a Value Is Written” on page 305.

**Example 2: Moving the Pointer within a Page**

These PUT statements show how to use column and line pointer controls to position the output pointer.

- To move the pointer to a specific column, use @ followed by the column number, variable, or expression whose value is that column number. For example, this statement moves the pointer to column 15 and writes the value of TOTAL SALES using list output:

  ```sas
  put @15 totalsales;
  ```

  This PUT statement moves the pointer to the value that is specified in COLUMN and writes the value of TOTALSALES with the COMMA6 format:
data _null_;  
  set carsales;  
  column=15;  
  put @column totalsales comma6.;  
run;

• This program shows two techniques to move the pointer backward:

data carsales;
  input item $10. jan : comma5.
    feb : comma5. mar : comma5.;
  saleqtr1=sum(jan,feb,mar);
/* an expression moves pointer backward */
  put '1st qtr sales for ' item
    'is ' saleqtr1 : comma6. +(-1) '.');
/* a numeric variable with a negative 
value moves pointer backward. */
  x=-1;
  put '1st qtr sales for ' item
    'is ' saleqtr1 : comma5. +x '.');
datalines;
trucks         1,382     2,789     3,556
vans           1,265     2,543     3,987
sedans         2,391     3,011     3,658
;

Because the value of SALEQTR1 is written with modified list output, the pointer moves automatically two spaces. For more information, see “How Modified List Output and Formatted Output Differ” on page 322. To remove the unwanted blank that occurs between the value and the period, move the pointer backward by one space.

The program writes the following lines to the SAS log:

----+----1----+----2----+----3----+----4
st qtr sales for trucks is 7,727.
st qtr sales for trucks is 7,727.
st qtr sales for vans is 7,795.
st qtr sales for vans is 7,795.
st qtr sales for sedans is 9,060.
st qtr sales for sedans is 9,060.

Note: The ruled line is for illustrative purposes only; the PUT statement does not generate it.

• This program uses a PUT statement with the / line pointer control to advance to the next output line:

data _null_;  
  set carsales end=lastrec;
  totalsales=saleqtr1;
  if lastrec then
    put @2 'Total Sales for 1st Qtr' 
       totalsales 10-15;
run;

After the DATA step calculates TOTALSALES using all the observations in the CARSALES data set, the PUT statement executes. It writes a character string beginning in column 2 and moves to the next line to write the value of TOTALSALES in columns 10 through 15:
**Example 3: Moving the Pointer to a New Page**

This example creates a data set called `STATEPOP`, which contains information from the 1990 U.S. census about the population of metropolitan and non-metropolitan areas. It executes the FORMAT procedure to group the 50 states and the District of Columbia into four regions. It then uses the IF and PUT statements to control the printed output.

```sas
title1;
data statepop;
  input state $ cityp90 ncityp90 region @@;
  label cityp90= '1990 metropolitan population (million)'
         ncityp90='1990 nonmetropolitan population (million)'
         region= 'Geographic region';
  datalines;
   ME    .443    .785  1  NH    .659    .450  1
   VT    .152    .411  1  MA   5.788    .229  1
   RI    .938    .065  1  CT   3.148    .140  1

1990 US CENSUS for Northeast
Total Urban Population: 45.456 million

PUT _PAGE_ advances the pointer to line 1 of the new page when the value of LAST.REGION is 1. The example prints a footer message before exiting the page.

Example 4: Underlining Text
This example uses OVERPRINT to underscore a value written by a previous PUT statement:

data _null_
  input idno name $ startwght;
  file file-specification print;
  put name 1-10 @15 startwght 3.;
  if startwght > 200 then
    put overprint @15 '___';
  datalines;
  032 David 180
  049 Amelia 145
  219 Alan 210
;

The second PUT statement underlines weights above 200 on the output line the first PUT statement prints.

This PUT statement uses OVERPRINT with both a column pointer control and a line pointer control:

put @5 name $8. overprint @5 8*'_'
    / @20 address;
The PUT statement writes a NAME value, underlines it by overprinting eight underscores, and moves the output pointer to the next line to write an ADDRESS value.

**Example 5: Holding and Releasing Output Lines**
This DATA step demonstrates how to hold and release an output line with a PUT statement:

```sas
data _null_;  
  input idno name $ startwght 3.;  
  put name @;  
  if startwght ne . then  
    put @15 startwght;  
  else put;  
  datalines;  
032 David 180  
049 Amelia 145  
126 Monica  
219 Alan 210  
;
```

In this example,
- the trailing @ in the first PUT statement holds the current output line after the value of NAME is written
- if the condition is met in the IF-THEN statement, the second PUT statement writes the value of STARTWGHT and releases the current output line
- if the condition is not met, the second PUT never executes. Instead, the ELSE PUT statement executes. The ELSE PUT statement releases the output line and positions the output pointer at column 1 in the output buffer.

The program writes the following lines to the SAS log:

```
----+----1----+----2
David         180  
Amelia        145  
Monica         
Alan          210  
```

**Note:** The ruled line is for illustrative purposes only; the PUT statement does not generate it.

**Example 6: Writing the Current Input Record to the Log**
When a value for ID is less than 1000, PUT _INFILE_ executes and writes the current input record to the SAS log. The DELETE statement prevents the DATA step from writing the observation to the TEAM data set.

```sas
data team;  
  input id team $ score1 score2;  
  if id le 1000 then  
    do;  
      put _infile_;  
      delete;  
    end;  
  datalines;  
032 red 180 165  
049 yellow 145 124
```
The program writes the following line to the SAS log:

---+---1----+----2
219 red 210 192

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

**Example 7: Avoiding a Common Error When Writing a Character Constant Followed by a Variable**

This example illustrates how to use a PUT statement to write character constants and variable values without causing them to be misinterpreted as SAS name literals. A SAS name literal is a name token that is expressed as a string within quotation marks, followed by the letter n. For more information about SAS name literals, see *SAS Language Reference: Concepts*.

In the program below, the PUT statement writes the constant 'n' followed by the value of the variable NVAR1, and then writes another constant 'n':

```sas
data _null_
   n=5;
   nvvar1=1;
   var1=7;
   put @1 'n' nvvar1 'n';
run;
```

This program writes the following line to the SAS log:

---+---1----+----2
n1 n

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

If all the spaces between the constants and the variables are removed from the previous PUT statement, SAS interprets 'n' as a name literal instead of reading 'n' as a constant. The next variable is read as VAR1 instead of NVAR1. The final 'n' constant is interpreted correctly.

```sas
put @1 'n' nvvar1 'n';
```

This PUT statement writes the following line to the SAS log:

---+---1----+----2
5 7 n

To print character constants and variable values without intervening spaces, and without potential misinterpretation, you can add spaces between them and use pointer controls where necessary. For example, the following PUT statement uses a pointer control to write the correct character constants and variable values but does not insert blank spaces. Note that +(-1) moves the PUT statement pointer backwards by one space.

```sas
put @1 'n' nvvar1 +(-1) 'n';
```

This PUT statement writes the following line to the SAS log:

---+---1----+----2
nln
**Example 8: Creating Multi-Column Output**

This example uses the `#n` and `@n` column and pointer controls to create multi-column output.

```sas
/*
 * Use `#i` and `@j` to position name and weight information into
 * four columns in column-major order. That is print down column 1
 * first, then print down column 2, etc.
 * This example highlights the need to specify `#` before `@` because
 * `#` sets the column pointer to 1.
 */
data _null_;  
  file print n=ps notitles header=hd;  
  do i = 1 to 80 by 20;  
    do j = 1 to ceil(num_students/4);  
      set sashelp.class nobs=num_students;  
      put #(j+3) @i name $8. '-' +1 weight 5.1;  
    end;  
  end;  
  stop;  
hd:  
  put @26 'Student Weight in Pounds' / @26 24*'-';  
  return;  
run;
```

The program creates the following output:

```
Student Weight in Pounds
------------------------
Alfred  - 112.5     James   -  83.0     Joyce   -  50.5     Robert  - 128.0
Alice   -  84.0     Jane    -  84.5     Judy    -  90.0     Ronald  - 133.0
Barbara -  98.0     Janet   - 112.5     Louise  -  77.0     Thomas  -  85.0
Carol   - 102.5     Jeffrey -  84.0     Mary    - 112.0     William - 112.0
Henry   - 102.5     John    -  99.5     Philip  - 150.0
```

PUT Statement, Column

Writes variable values in the specified columns in the output line.

**Valid in:** DATA step  
**Category:** File-handling  
**Type:** Executable

### Syntax

```
PUT variable start-column <- end-column> <.decimal-places> <@ | @@> ;
```

### Arguments

- **variable**
  - specifies the variable whose value is written.

- **start-column**
  - specifies the first column of the field where the value is written in the output line.

- **end-column**
  - specifies the last column of the field for the value.

**Tip:** If the value occupies only one column in the output line, omit *end-column*.

**Example:** Because *end-column* is omitted, the values for the character variable GENDER occupy only column 16:

```
put name 1-10 gender 16;
```

- **.decimal-places**
  - specifies the number of digits to the right of the decimal point in a numeric value.

  **Range:** positive integer

  **Tip:** If you specify 0 for *d* or omit *d*, the value is written without a decimal point.

  **Example:** “Example: Using Column Output in the PUT Statement” on page 315

- **@ | @@**
  - holds an output line for the execution of the next PUT statement even across iterations of the DATA step. These line-hold specifiers are called *trailing @* and *double trailing @*.

  **Requirement:** The trailing @ or double trailing @ must be the last item in the PUT statement.

  **See:** “Using Line-Hold Specifiers” on page 305

### Details

With column output, the column numbers indicate the position that each variable value will occupy in the output line. If a value requires fewer columns than specified, a character variable is left-aligned in the specified columns, and a numeric variable is right-aligned in the specified columns.

There is no limit to the number of column specifications that you can make in a single PUT statement. You can write anywhere in the output line, even if a value overwrites columns that were written earlier in the same statement. You can combine column output with any of the other output styles in a single PUT statement. For more
Example: Using Column Output in the PUT Statement

Use column output in the PUT statement as shown here.

- This PUT statement uses column output:

```sas
data _null_
    input name $ 1-18 score1 score2 score3
    put name 1-20 score1 23-25 score2 28-30
    score3 33-35;
    datalines;
Joseph     11   32   76
Mitchel    13   29   82
Sue Ellen  14   27   74
;
```

The program writes the following lines to the SAS log:

```
-------1-------2-------3-------4
Joseph     11   32   76
Mitchel    13   29   82
Sue Ellen  14   27   74
```

*Note:* The ruled line is for illustrative purposes only; the PUT statement does not generate it.

The values for the character variable NAME begin in column 1, the left boundary of the specified field (columns 1 through 20). The values for the numeric variables SCORE1 through SCORE3 appear flush with the right boundary of their field.

- This statement produces the same output lines, but writes the SCORE1 value first and the NAME value last:

```sas
put score1 23-25 score2 28-30
    score3 33-35 name $ 1-20;
```

- This DATA step specifies decimal points with column output:

```sas
data _null_
    x=11;
    y=15;
    put x 10-18 .1 y 20-28 .1;
    run;
```

This program writes the following line to the SAS log:

```
-------1-------2-------3-------4
  11.0     15.0
```

Statements:

- “PUT Statement” on page 296
PUT Statement, Formatted

Writes variable values with the specified format in the output line.

Valid in: DATA step
Category: File-handling
Type: Executable

Syntax

PUT <pointer-control> variable format. @@;
PUT <pointer-control> (variable-list) (format-list)
@@;

Arguments

pointer-control
moves the output pointer to a specified line or column.

See:
“Column Pointer Controls ” on page 299
“Line Pointer Controls ” on page 300

Example: “Example 1: Writing a Character between Formatted Values” on page 318

variable
specifies the variable whose value is written.

(variable-list)
specifies a list of variables whose values are written.

Requirement: The (format-list) must follow the (variable-list).

See: “How to Group Variables and Formats” on page 318

Example: “Example 1: Writing a Character between Formatted Values” on page 318

format.
specifies a format to use when the variable values are written. To override the default alignment, you can add an alignment specification to a format:

-L left aligns the value.
-C centers the value.
-R right aligns the value.

Tip: Ensure that the format width provides enough space to write the value and any commas, dollar signs, decimal points, or other special characters that the format includes.

Examples:
This PUT statement uses the format dollar7.2 to write the value of X:

put x dollar7.2;

When X is 100, the formatted value uses seven columns:

$100.00
Example: “Example 2: Overriding the Default Alignment of Formatted Values” on page 318

(format-list)
specifies a list of formats to use when the values of the preceding list of variables are written. In a PUT statement, a format-list can include

format.
specifies the format to use to write the variable values.
Tip: You can specify either a SAS format or a user-written format.
See: SAS Formats and Informats: Reference

pointer-control
specifies one of these pointer controls to use to position a value: @, #, /, +, and OVERPRINT.
Example: “Example 1: Writing a Character between Formatted Values” on page 318

character-string
specifies one or more characters to place between formatted values.
Example: This statement places a hyphen between the formatted values of CODE1, CODE2, and CODE3:
put bldg $ (code1 code2 code3) (3. '-');
Example: “Example 1: Writing a Character between Formatted Values” on page 318

n*
specifies to repeat n times the next format in a format list.
Restriction: The (format-list) must follow (variable-list).
See: “How to Group Variables and Formats” on page 318
Example: This statement uses the 7.2 format to write GRADES1, GRADES2, and GRADES3 and the 5.2 format to write GRADES4 and GRADES5:
put (grades1-grades5) (3*7.2, 2*5.2);

@| @@
holds an output line for the execution of the next PUT statement even across iterations of the DATA step. These line-hold specifiers are called trailing @ and double trailing @.
Restriction: The trailing @ or double trailing @ must be the last item in the PUT statement.
See: “Using Line-Hold Specifiers” on page 305

Details

Using Formatted Output
The Formatted output describes the output lines by listing the variable names and the formats to use to write the values. You can use a SAS format or a user-written format to control how SAS prints the variable values. For a complete description of the SAS formats, see “Definition of Formats” in Chapter 1 of SAS Formats and Informats: Reference.

With formatted output, the PUT statement uses the format that follows the variable name to write each value. SAS does not automatically add blanks between values. If the value uses fewer columns than specified, character values are left-aligned and numeric values are right-aligned in the field that is specified by the format width.
Formatted output, combined with pointer controls, makes it possible to specify the exact line and column location to write each variable. For example, this PUT statement uses the dollar7.2 format and centers the value of X starting at column 12:

```sas
put @12 x dollar7.2-c;
```

**How to Group Variables and Formats**

When you want to write values in a pattern on the output lines, use format lists to shorten your coding time. A format list consists of the corresponding formats separated by either blanks or commas and enclosed in parentheses. It must follow the names of the variables enclosed in parentheses.

For example, this statement uses a format list to write the five variables SCORE1 through SCORE5, one after another, using four columns for each value with no blanks in between:

```sas
put (score1-score5) (4. 4. 4. 4. 4.);
```

A shorter version of the previous statement is

```sas
put (score1-score5) (4.);
```

You can include any of the pointer controls (@, #, /, +, and OVERPRINT) in the list of formats, as well as n*, and a character string. You can use as many format lists as necessary in a PUT statement, but do not nest the format lists. After all the values in the variable list are written, the PUT statement ignores any directions that remain in the format list. For an example, see “Example 3: Including More Format Specifications than Necessary” on page 319.

You can also specify a reference to all elements in an array as (array-name {*}), followed by a list of formats. You cannot, however, specify the elements in a _TEMPORARY_ array in this way. This PUT statement specifies an array name and a format list:

```sas
put (array1{*}) (4.);
```

For more information about how to reference an array, see “Arrays” on page 306.

**Examples**

**Example 1: Writing a Character between Formatted Values**

This example formats some values and writes a - (hyphen) between the values of variables BLDG and ROOM:

```sas
data _null_;  
  input name & $15. bldg $ room;  
  put name @20 (bldg room) ($1. "-" 3.);  
datalines;  
Bill Perkins  J 126  
Sydney Riley  C 219  
;  
```

These lines are written to the SAS log:

```
Bill Perkins       J-126  
Sydney Riley       C-219  
```

**Example 2: Overriding the Default Alignment of Formatted Values**

This example includes an alignment specification in the format:
data _null_;  
  input name $ 1-12 score1 score2 score3;  
  put name $12.-r +3 score1 3. score2 3. score3 4.;  
  datalines;  
Joseph          11   32   76  
Mitchel         13   29   82  
Sue Ellen       14   27   74  
;  
 These lines are written to the SAS log:
  1----+----1----+----2----+----3----+----4
  Joseph    11 32  76
  Mitchel    13 29  82
  Sue Ellen    14 27  74
The value of the character variable NAME is right-aligned in the formatted field. (Left
alignment is the default for character variables.)

**Example 3: Including More Format Specifications than Necessary**
This format list includes more specifications than are necessary when the PUT statement
executes:

data _null_;  
  input x y z;  
  put (x y z) (2.,+1);  
  datalines;  
  2 24 36
  0 20 30
;  
The PUT statement writes the value of X using the 2. format. Then, the +1 column
pointer control moves the pointer forward one column. Next, the value of Y is written
with the 2. format. Again, the +1 column pointer moves the pointer forward one column.
Then, the value of Z is written with the 2. format. For the third iteration, the PUT
statement ignores the +1 pointer control.
These lines are written to the SAS log:
  2----+----1----+-
  2 24 36
  0 20 30

**See Also**

**Statements:**

- “PUT Statement” on page 296

---

1 The ruled line is for illustrative purposes only; the PUT statement does not generate it.
2 The ruled line is for illustrative purposes only; the PUT statement does not generate it.
Valid in: DATA step  
Category: File-handling  
Type: Executable

Syntax

PUT <pointer-control> variable <@ | @@>;

PUT <pointer-control> <n*> 'character-string' <@ | @@>;

PUT <pointer-control> variable < : | -> format.<@ | @@>;

Arguments

**pointer-control**

moves the output pointer to a specified line or column.

*See:*

“Column Pointer Controls ” on page 299  
“Line Pointer Controls ” on page 300

**Example:** “Example 2: Writing Character Strings and Variable Values” on page 323

**variable**

specifies the variable whose value is written.

**Example:** “Example 1: Writing Values with List Output” on page 322

**n**

specifies to repeat n times the subsequent character string.

**Example:** This statement writes a line of 132 underscores:

```
put 132*’_’;
```

**'character-string'**

specifies a string of text, enclosed in quotation marks, to write.

**Interaction:** When insufficient space remains on the current line to write the entire text string, SAS withholds the entire string and writes the current line. Then it writes the text string on a new line, starting in column 1. For more information, see “When the Pointer Goes Past the End of a Line” on page 305.

**Tips:**

To avoid misinterpretation, always put a space after a closing quotation mark in a PUT statement.

If you follow a quotation mark with X, SAS interprets the text string as a hexadecimal constant.

If you use single quotation (‘) or double quotation marks (“) together (with no space in between them) as the string of text, SAS will output a single quotation mark (‘) or double quotation mark (“), respectively.

*See:* “How List Output Is Spaced” on page 321

**Example:** “Example 2: Writing Character Strings and Variable Values” on page 323

**format**

enables you to specify a format that the PUT statement uses to write the variable value. All leading and trailing blanks are deleted, and each value is followed by a single blank.
**Requirement:** You must specify a format.

**See:** “How Modified List Output and Formatted Output Differ” on page 322

**Example:** “Example 3: Writing Values with Modified List Output (:)” on page 323

~

enables you to specify a format that the PUT statement uses to write the variable value. SAS displays the formatted value in quotation marks even if the formatted value does not contain the delimiter. SAS deletes all leading and trailing blanks, and each value is followed by a single blank. Missing values for character variables are written as a blank (" ") and, by default, missing values for numeric variables are written as a period (".").

**Requirement:** You must specify the DSD option in the FILE statement.

**Example:** “Example 4: Writing Values with Modified List Output and ~” on page 323

```put
format.
```
specifies a format to use when the data values are written.

**Tip:** You can specify either a SAS format or a user-written format. See *SAS Formats and Informats: Reference*

**Example:** “Example 3: Writing Values with Modified List Output (:)” on page 323

```put
@ | @@
```
holds an output line for the execution of the next PUT statement even across iterations of the DATA step. These line-hold specifiers are called *trailing @* and *double trailing @*.

**Restriction:** The trailing @ or double-trailing @ must be the last item in the PUT statement.

**See:** “Using Line-Hold Specifiers” on page 305

## Details

### Using List Output

With list output, you list the names of the variables whose values you want written, or you specify a character string in quotation marks. The PUT statement writes a variable value, inserts a single blank, and then writes the next value. Missing values for numeric variables are written as a single period. Character values are left-aligned in the field; leading and trailing blanks are removed. To include blanks (in addition to the blank inserted after each value), use formatted or column output instead of list output.

There are two types of list output:

- simple list output
- modified list output.

Modified list output increases the versatility of the PUT statement because you can specify a format to control how the variable values are written. See “Example 3: Writing Values with Modified List Output (:)” on page 323.

### How List Output Is Spaced

List output uses different spacing methods when it writes variable values and character strings. When a variable is written with list output, SAS automatically inserts a blank space. The output pointer stops at the second column that follows the variable value. However, when a character string is written, SAS does not automatically insert a blank space. The output pointer stops at the column that immediately follows the last character in the string.
To avoid spacing problems when both character strings and variable values are written, you might want to use a blank space as the last character in a character string. When a character string that provides punctuation follows a variable value, you need to move the output pointer backward. Moving the output pointer backward prevents an unwanted space from appearing in the output line. See “Example 2: Writing Character Strings and Variable Values” on page 323.

**How Modified List Output and Formatted Output Differ**

List output and formatted output use different methods to determine how far to move the pointer after a variable value is written. Therefore, modified list output, which uses formats, and formatted output produce different results in the output lines. Modified list output writes the value, inserts a blank space, and moves the pointer to the next column. Formatted output moves the pointer the length of the format, even if the value does not fill that length. The pointer moves to the next column; an intervening blank is not inserted.

The following DATA step uses modified list output to write each output line:

```sas
data _null_;
  input x y;
  put x : comma10.2 y : 7.2;
  datalines;
2353.20 7.10
6231 121
;
```

These lines are written to the SAS log:

```
--------1----+----2
2,353.20   7.10
6,231.00 121.00
```

In comparison, the following example uses formatted output:

```sas
put x comma10.2 y 7.2;
```

These lines are written to the SAS log, with the values aligned in columns:

```
--------1----+----2
2,353.20   7.10
6,231.00 121.00
```

**Examples**

**Example 1: Writing Values with List Output**

This DATA step uses a PUT statement with list output to write variable values to the SAS log:

```sas
data _null_;
  input name $ 1-10 sex $ 12 age 15-16;
  put name sex age;
  datalines;
Joseph   M  13
Mitchel  M  14
Sue Ellen F  11
;
```

These lines are written to the SAS log:
By default, the values of the character variable NAME are left-aligned in the field.

**Example 2: Writing Character Strings and Variable Values**

This PUT statement adds a space to the end of a character string and moves the output pointer backward to prevent an unwanted space from appearing in the output line after the variable STARTWGHT:

```sas
data _null_;  
  input idno name $ startwght;  
  put name 'weighs ' startwght +(-1) '.';  
  datalines;  
032 David 180  
049 Amelia 145  
219 Alan 210  ;
```

These lines are written to the SAS log:

David weighs 180.
Amelia weighs 145.
Alan weighs 210.

The blank space at the end of the character string changes the pointer position. This space separates the character string from the value of the variable that follows. The +(-1) pointer control moves the pointer backward to remove the unwanted blank that occurs between the value of STARTWGHT and the period.

**Example 3: Writing Values with Modified List Output (:)**

This DATA step uses modified list output to write several variable values in the output line using the : argument:

```sas
data _null_;  
  input salesrep : $10. tot : comma6. date : date9.;  
  put 'Week of ' date : worddate15.  
    salesrep : $12. 'sales were '  
    tot : dollar9. + (-1) '.';  
  datalines;  
Wong 15,300 12OCT2004  
Hoffman 9,600 12OCT2004  ;
```

These lines are written to the SAS log:

Week of Oct 12, 2004 Wong sales were $15,300.
Week of Oct 12, 2004 Hoffman sales were $9,600.

**Example 4: Writing Values with Modified List Output and ~**

This DATA step uses modified list output to write several variable values in the output line using the ~ argument:

```sas
data _null_;  
  input salesrep : $10. tot : comma6. date : date9.;  
  file log delimiters=" " dsd;  
  put 'Week of ' date ~ worddate15.
```
salesrep = $12. 'sales were ' tot = dollar9. + (-1) '.

datalines;
Wong 15,300 12OCT2004
Hoffman 9,600 12OCT2004
;

These lines are written to the SAS log:
Week of "Oct 12, 2004" "Wong" sales were "$15,300".
Week of "Oct 12, 2004" "Hoffman" sales were "$9,600".

Statements:
• “PUT Statement” on page 296
• “PUT Statement, Formatted” on page 316

PUT Statement, Named

Writes variable values after the variable name and an equal sign.

Valid in: DATA step
Category: File-handling
Type: Executable

Syntax

PUT <pointer-control> variable= <format.> <@ | @@>;
PUT variable= start-column <end-column>
<.decimal-places> <@ | @@>;

Arguments

pointer-control
moves the output pointer to a specified line or column in the output buffer.

See:
“Column Pointer Controls” on page 299
“Line Pointer Controls” on page 300

variable=
specifies the variable whose value is written by the PUT statement in the form variable=value

format.
specifies a format to use when the variable values are written.

Tip: Ensure that the format width provides enough space to write the value and any commas, dollar signs, decimal points, or other special characters that the format includes.

See: “Formatting Named Output” on page 325

Examples:
This PUT statement uses the format DOLLAR7.2 to write the value of X:
    put x= dollar7.2;
When X=100, the formatted value uses seven columns:
    X=$100.00

**start-column**
specifies the first column of the field where the variable name, equal sign, and value are to be written in the output line.

**– end-column**
determines the last column of the field for the value.

**Tip:** If the variable name, equal sign, and value require more space than the columns specified, PUT will write past the end column rather than truncate the value. You must leave enough space before beginning the next value.

**.decimal-places**
specifies the number of digits to the right of the decimal point in a numeric value. If you specify 0 for d or omit d, the value is written without a decimal point.

**Range:** positive integer

@ | @@
holds an output line for the execution of the next PUT statement even across iterations of the DATA step. These line-hold specifiers are called *trailing @* and *double trailing @*.

**Restriction:** The trailing @ or double trailing @ must be the last item in the PUT statement.

**See:** “Using Line-Hold Specifiers” on page 305

**Details**

**Using Named Output**
With named output, follow the variable name with an equal sign in the PUT statement. You can use either list output, column output, or formatted output specifications to indicate how to position the variable name and values. To insert a blank space between each variable value automatically, use list output. To align the output in columns, use pointer controls or column specifications.

**Formatting Named Output**
You can specify either a SAS format or a user-written format to control how SAS prints the variable values. The width of the format does not include the columns required by the variable name and equal sign. To align a formatted value, SAS deletes leading blanks and writes the variable value immediately after the equal sign. SAS does not align on the right side of the formatted length, as in unnamed formatted output.

For a complete description of the SAS formats, see “Definition of Formats” in Chapter 1 of *SAS Formats and Informats: Reference*.

**Example: Using Named Output in the PUT Statement**
Use named output in the PUT statement as shown here.

- This PUT combines named output with column pointer controls to align the output:

```
data _null_
    input name $ 1-18 score1 score2 score3;
    put name = @20 score1= score3= ;
```
### PUTLOG Statement

Writes a message to the SAS log.

**Valid in:** DATA step  
**Category:** Action  
**Type:** Executable

#### Syntax

```
PUTLOG 'message';
```

#### Arguments

`message`

specifies the message that you want to write to the SAS log. *Message* can include character literals (enclosed in quotation marks), variable names, formats, and pointer controls.

**Tip:** You can precede your message text with WARNING, MESSAGE, or NOTE to better identify the output in the log.

#### Details

The PUTLOG statement writes a message that you specify to the SAS log. The PUTLOG statement is also helpful when you use macro-generated code because you can send output to the SAS log without affecting the current file destination.
Comparisons

The PUTLOG statement is similar to the ERROR statement except that PUTLOG does not set _ERROR_ to 1.

Example: Writing Messages to the SAS Log Using the PUTLOG Statement

The following program creates the computeAverage92 macro, which computes the average score, validates input data, and uses the PUTLOG statement to write error messages to the SAS log. The DATA step uses the PUTLOG statement to write a warning message to the log.

```sas
data ExamScores;
  input Name $ 1-16 Score1 Score2 Score3;
  datalines;
  Sullivan, James   86 92 88
  Martinez, Maria   95 91 92
  Guzik, Eugene     99 98 .
  Schultz, John     90 87 93
  van Dyke, Sylvia  98 . 91
  Tan, Carol        93 85 85
 ;
filename outfile 'path-to-your-output-file';
/* Create a macro that computes the average score, validates */
/* input data, and uses PUTLOG to write error messages to the */
/* SAS log.                                                   */
%macro computeAverage92(s1, s2, s3, avg);
  if &s1 < 0 or &s2 < 0 or &s3 < 0 then
    do;
      putlog 'ERROR: Invalid score data ' &s1= &s2= &s3=;
      &avg = .;
    end;
  else
    &avg = mean(&s1, &s2, &s3);
%mend;
data _null_;   /* WARNING: Score below the minimum ' name= AverageScore= 5.2; */
set ExamScores;
  file outfile;
  %computeAverage92(Score1, Score2, Score3, AverageScore);
  put name Score1 Score2 Score3 AverageScore;
  /* Use PUTLOG to write a warning message to the SAS log. */
  if AverageScore < 92 then
    putlog 'WARNING: Score below the minimum ' name= AverageScore= .2;
run;
```

The following lines are written to the SAS log.
SAS creates the following output file.

**Output 2.27  Individual Examination Scores**

<table>

**Statements:**
- “ERROR Statement” on page 74

---

**REDIRECT Statement**

Points to different input or output SAS data sets when you execute a stored program.

**Valid in:** DATA step  
**Category:** Action  
**Type:** Executable  
**Requirement:** You must specify the PGM= option in the DATA statement.

**Syntax**

```
REDIRECT INPUT | OUTPUT old-name-1 = new-name-1 <… old-name-n = new-name-n>;
```

**Arguments**

**INPUT | OUTPUT**  
specifies whether to redirect input or output data sets. When you specify INPUT, the REDIRECT statement associates the name of the input data set in the source
program with the name of another SAS data set. When you specify OUTPUT, the REDIRECT statement associates the name of the output data set with the name of another SAS data set.

`old-name` specifies the name of the input or output data set in the source program.

`new-name` specifies the name of the input or output data set that you want SAS to process for the current execution.

**Details**

The REDIRECT statement is available only when you execute a stored program. For more information about stored programs, see “Stored Compiled DATA Step Programs” in Chapter 28 of *SAS Language Reference: Concepts*.

**CAUTION:**

Use care when you redirect input data sets. The number and attributes of variables in the input data sets that you read with the REDIRECT statement should match the number and attributes of variables in the input data sets in the MERGE, SET, MODIFY, or UPDATE statements of the source code. If the variable type attributes differ, the stored program stops processing and an appropriate error message is written to the SAS log. If the variable length attributes differ, the length of the variable in the source code data set determines the length of the variable in the redirected data set. Extra variables in the redirected data sets cause the stored program to stop processing and an error message is written to the SAS log.

**TIP** The DROP or KEEP data set options can be added in the stored program if the input data set that you read with the REDIRECT statement has more variables than are in the data set used to compile the program.

**Comparisons**

The REDIRECT statement applies only to SAS data sets. To redirect input and output stored in external files, include a FILENAME statement to associate the fileref in the source program with different external files.

**Example: Executing a Stored Program**

This example executes the stored program called STORED.SAMPLE. The REDIRECT statement specifies the source of the input data as BASE.SAMPLE. The output data set from this execution of the program is redirected and stored in a data set named SUMS.SAMPLE.

```
libname stored 'SAS-library';
libname base 'SAS-library';
libname sums 'SAS-library';
data pgm=stored.sample;
   redirect input in.sample=base.sample;
   redirect output out.sample=sums.sample;
run;
```

**See Also**

- “Stored Compiled DATA Step Programs” in Chapter 28 of *SAS Language Reference: Concepts*
Statements:

- “DATA Statement” on page 48

REMOVE Statement

Deletes an observation from a SAS data set.

Valid in: DATA step  
Category: Action  
Type: Executable  
Restriction: Use only with a MODIFY statement.

Syntax

REMOVE <data-set-name(s)>;

Without Arguments

If you specify no argument, the REMOVE statement deletes the current observation from all data sets that are named in the DATA statement.

Arguments

data-set-name

specifies the data set in which the observation is deleted.

Restriction: The data set name must also appear in the DATA statement and in one or more MODIFY statements.

Tip: Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

Details

The deletion of an observation can be physical or logical, depending on the engine that maintains the data set. Using REMOVE overrides the default replacement of observations. If a DATA step contains a REMOVE statement, you must explicitly program all output for the step.

Comparisons

- Using an OUTPUT, REPLACE, or REMOVE statement overrides the default write action at the end of a DATA step. (OUTPUT is the default action; REPLACE becomes the default action when a MODIFY statement is used.) If you use any of these statements in a DATA step, you must explicitly program all output for new observations.

- The OUTPUT, REPLACE, and REMOVE statements are independent of each other. More than one statement can apply to the same observation, as long as the sequence is logical.

- If both an OUTPUT and a REPLACE or REMOVE statement execute on a given observation, perform the OUTPUT action last to keep the position of the observation pointer correct.
Because the REMOVE statement can perform a physical or a logical deletion, REMOVE is available with the MODIFY statement for all SAS data set engines. Both the DELETE and subsetting IF statements perform only physical deletions. Therefore, they are not available with the MODIFY statement for certain engines.

Example: Removing an Observation from a Data Set

This example removes one observation from a SAS data set.

```sas
libname perm 'SAS-library';
data perm.accounts;
  input AcctNumber Credit;
datalines;
1001 1500
1002 4900
1003 3000
;
data perm.accounts;
  modify perm.accounts;
  if AcctNumber=1002 then remove;
run;
proc print data=perm.accounts;
  title 'Edited Data Set';
run;
```

Here are the results of the PROC PRINT statement:

*Output 2.28  Edited Data Set*

<table>
<thead>
<tr>
<th>Obs</th>
<th>AcctNumber</th>
<th>Credit</th>
</tr>
</thead>
<tbody>
<tr>
<td>1</td>
<td>1001</td>
<td>1500</td>
</tr>
<tr>
<td>3</td>
<td>1003</td>
<td>3000</td>
</tr>
</tbody>
</table>

- “OUTPUT Statement” on page 293
- “REPLACE Statement” on page 333
Valid in: DATA step  
Category: Information  
Type: Declarative

Syntax

RENAME old-name-1=new-name-1…<old-name-n=new-name-n>;

Arguments

old-name
    specifies the name of a variable or variable list as it appears in the input data set, or in the current DATA step for newly created variables.

new-name
    specifies the name or list to use in the output data set.

Details

The RENAME statement enables you to change the names of one or more variables, variables in a list, or a combination of variables and variable lists. The new variable names are written to the output data set only. Use the old variable names in programming statements for the current DATA step. RENAME applies to all output data sets.

Note: The RENAME statement has an effect on data sets opened in output mode only.

Comparisons

• RENAME cannot be used in PROC steps, but the RENAME= data set option can.
• The RENAME= data set option enables you to specify the variables that you want to rename for each input or output data set. Use it in input data sets to rename variables before processing.
• If you use the RENAME= data set option in an output data set, you must continue to use the old variable names in programming statements for the current DATA step. After your output data is created, you can use the new variable names.
• The RENAME= data set option in the SET statement renames variables in the input data set. You can use the new names in programming statements for the current DATA step.
• To rename variables as a file management task, use the DATASETS procedure or access the variables through the SAS windowing interface. These methods are simpler and do not require DATA step processing.

Example: Renaming Data Set Variables

• These examples show the correct syntax for renaming variables using the RENAME statement:

    rename street=address;
    rename time1=temp1 time2=temp2 time3=temp3;
    rename name=Firstname score1-score3=Newscore1-Newscore3;
• This example uses the old name of the variable in program statements. The variable Olddept is named Newdept in the output data set, and the variable Oldaccount is named Newaccount.

    rename Olddept=Newdept Oldaccount=Newaccount;
    if Oldaccount>5000;
    keep Olddept Oldaccount items volume;

• This example uses the old name OLDACCNT in the program statements. However, the new name NEWACCNT is used in the DATA statement because SAS applies the RENAME statement before it applies the KEEP= data set option.

    data market(keep=newdept newaccnt items volume);
    rename olddept=newdept oldaccnt=newaccnt;
    set sales;
    if oldaccnt>5000;
    run;

• The following example uses both a variable and a variable list to rename variables. New variable names appear in the output data set.

    data temp;
    input (score1-score3) (2.,+1) name $;
    rename name=Firstname
        score1-score3=Newscore1-Newscore3;
    datalines;
    12 24 36 Lisa
    22 44 66 Fran
    ;

Data Set Options:
• “RENAME= Data Set Option” in SAS Data Set Options: Reference

REPLACE Statement

Replaces an observation in the same location.

Valid in: DATA step
Category: Action
Type: Executable
Restriction: Use only with a MODIFY statement.

Syntax

    REPLACE <data-set-name-1> <…data-set-name-n>;

Without Arguments

If you specify no argument, the REPLACE statement writes the current observation to the same physical location from which it was read in all data sets that are named in the DATA statement.
Arguments
data-set-name

specifies the data set to which the observation is written.

Requirement: The data set name must also appear in the DATA statement and in one or more MODIFY statements.

Tip: Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

Details

Using an explicit REPLACE statement overrides the default replacement of observations. If a DATA step contains a REPLACE statement, explicitly program all output for the step.

Comparisons

- Using an OUTPUT, REPLACE, or REMOVE statement overrides the default write action at the end of a DATA step. (OUTPUT is the default action; REPLACE becomes the default action when a MODIFY statement is used.) If you use any of these statements in a DATA step, you must explicitly program output of a new observation for the step.
  - The OUTPUT, REPLACE, and REMOVE statements are independent of each other. More than one statement can apply to the same observation, as long as the sequence is logical.
  - If both an OUTPUT and a REPLACE or REMOVE statement execute on a given observation, perform the OUTPUT action last to keep the position of the observation pointer correct.
  - REPLACE writes the observation to the same physical location. OUTPUT writes a new observation to the end of the data set.
  - REPLACE can appear only in a DATA step that contains a MODIFY statement. You can use OUTPUT with or without MODIFY.

Example: Replacing Observations

This example updates phone numbers in data set MASTER with values in data set TRANS. It also adds one new observation at the end of data set MASTER. The SYSRC autocall macro tests the value of _IORC_ for each attempted retrieval from MASTER. (SYSRC is part of the SAS autocall macro library.) The resulting SAS data set appears after the code:

data master;
  input FirstName $ id $ PhoneNumber;
datalines;
  Kevin ABCjkh 904
  Sandi defsns 905
  Terry ghitDP 951
  Jason jklJWM 962
; 
data trans;
  input FirstName $ id $ PhoneNumber;
datalines;
. ABCjkh 2904

. defns 2905
Madeline mnombt 2983
;
data master;
modify master trans;
by id;
/* obs found in master */
/* change info, replace */
if _iorc_ = %sysrc(_sok) then replace;
/* obs not in master */
else if _iorc_ = %sysrc(_dsenmr) then
do;
/* reset _error_ */
_error_ = 0;
/* reset _iorc_ */
_iorc_ = 0;
/* output obs to master */
output;
end;
run;
proc print data=master;
title 'MASTER with New Phone Numbers';
run;

Output 2.29  Data Set with Replaced Observations

<table>
<thead>
<tr>

- “REMOVE Statement” on page 330

RESETLINE Statement

Restarts the program line numbers in the SAS log to 1.

Valid in: Anywhere
Syntax
RESETLINE;

Without Arguments
Use the RESETLINE statement to reset the program line numbers in the SAS log to 1.

Details
Program statements are identified by line numbers in the SAS log. The line numbers start with 1 and continue with the sequence of line numbering until the end of the SAS session or batch program.

You use the RESETLINE statement in your program to restart the program line numbering at 1.

Note: If you use the SPOOL system option, you can use only the %INCLUDE statement to resubmit lines of code that were submitted after the most recent RESETLINE statement.

Example: Resetting Line Numbers in the SAS Log
The following example resets the program line numbers between DATA steps.

data a;
   a=1;
run;
resetline;
data b;
   b=2;
run;

The following lines are written to the SAS log:

1    data a;
2       a=1;
3    run;

NOTE: The data set WORK.A has 1 observations and 1 variables.
NOTE: DATA statement used (Total process time):
      real time           4.79 seconds
      cpu time            0.28 seconds

4    resetline;
1
2    data b;
3       b=2;
4    run;

NOTE: The data set WORK.B has 1 observations and 1 variables.
NOTE: DATA statement used (Total process time):
      real time           0.00 seconds
      cpu time            0.00 seconds
RETAIN Statement

Causes a variable that is created by an INPUT or assignment statement to retain its value from one iteration of the DATA step to the next.

Valid in:       DATA step
Category:      Information
Type:          Declarative

Syntax

RETAIN <element-list(s) <initial-value(s) | (initial-value-1) | (initial-value-list-1) > <...element-list-n<initial-value-n | (initial-value-n ) | (initial-value-list-n)>> ;

Without Arguments

If you do not specify an argument, the RETAIN statement causes the values of all variables that are created with INPUT or assignment statements to be retained from one iteration of the DATA step to the next.

Arguments

element-list

specifies variable names, variable lists, or array names whose values you want retained.

Tips:

If you specify _ALL_, _CHAR_, or _NUMERIC_, only the variables that are defined before the RETAIN statement are affected.

If a variable name is specified only in the RETAIN statement and you do not specify an initial value, the variable is not written to the data set, and a note stating that the variable is uninitialized is written to the SAS log. If you specify an initial value, the variable is written to the data set.

initial-value

specifies an initial value, numeric or character, for one or more of the preceding elements.

Tip: If you omit initial-value, the initial value is missing. Initial-value is assigned to all the elements that precede it in the list. All members of a variable list, therefore, are given the same initial value.

See: (initial-value) and (initial-value-list)

(initial-value)

specifies an initial value, numeric or character, for a single preceding element or for the first in a list of preceding elements.

(initial-value-list)

specifies an initial value, numeric or character, for individual elements in the preceding list. SAS matches the first value in the list with the first variable in the list of elements, the second value with the second variable, and so on.

Element values are enclosed in quotation marks. To specify one or more initial values directly, use the following format:

(initial-value(s))
To specify an iteration factor and nested sublists for the initial values, use the following format:

<constant-iter-value*> <(constant value | constant-sublist)>  

**Restriction:** If you specify both an initial-value-list and an element-list, then element-list must be listed before initial-value-list in the RETAIN statement.

**Tips:**
- You can separate initial values by blank spaces or commas.
- You can also use a shorthand notation for specifying a range of sequential integers. The increment is always +1.
- You can assign initial values to both variables and temporary data elements.
- If there are more variables than initial values, the remaining variables are assigned an initial value of missing and SAS issues a warning message.

**Details**

**Default DATA Step Behavior**
Without a RETAIN statement, SAS automatically sets variables that are assigned values by an INPUT or assignment statement to missing before each iteration of the DATA step.

**Assigning Initial Values**
Use a RETAIN statement to specify initial values for individual variables, a list of variables, or members of an array. If a value appears in a RETAIN statement, variables that appear before it in the list are set to that value initially. (If you assign different initial values to the same variable by naming it more than once in a RETAIN statement, SAS uses the last value.) You can also use RETAIN to assign an initial value other than the default value of 0 to a variable whose value is assigned by a sum statement.

**Redundancy**
It is redundant to name any of these items in a RETAIN statement, because their values are automatically retained from one iteration of the DATA step to the next:
- variables that are read with a SET, MERGE, MODIFY or UPDATE statement
- a variable whose value is assigned in a sum statement
- the automatic variables _N_, _ERROR_, _I_, _CMD_, and _MSG_
- variables that are created by the END= or IN= option in the SET, MERGE, MODIFY, or UPDATE statement or by options that create variables in the FILE and INFILE statements
- data elements that are specified in a temporary array
- array elements that are initialized in the ARRAY statement
- elements of an array that have assigned initial values to any or all of the elements in the ARRAY statement.

You can, however, use a RETAIN statement to assign an initial value to any of the previous items, with the exception of _N_ and _ERROR_.

**Comparisons**
The RETAIN statement specifies variables whose values are *not set to missing* at the beginning of each iteration of the DATA step. The KEEP statement specifies variables that are to be included in any data set that is being created.
Examples

Example 1: Basic Usage

- This RETAIN statement retains the values of variables MONTH1 through MONTH5 from one iteration of the DATA step to the next:
  
  ```
  retain month1-month5;
  ```

- This RETAIN statement retains the values of nine variables and sets their initial values:
  
  ```
  retain month1-month5 1 year 0 a b c 'XYZ';
  ```
  
  The values of MONTH1 through MONTH5 are set initially to 1; YEAR is set to 0; variables A, B, and C are each set to the character value 'XYZ'.

- This RETAIN statement assigns the initial value 1 to the variable MONTH1 only:
  
  ```
  retain month1-month5 (1);
  ```
  
  Variables MONTH2 through MONTH5 are set to missing initially.

- This RETAIN statement retains the values of all variables that are defined earlier in the DATA step but not the values that are defined afterwards:
  
  ```
  retain _all_;
  ```

- All of these statements assign initial values of 1 through 4 to VAR1 through VAR4:
  
  ```
  - retain var1-var4 (1 2 3 4);
  - retain var1-var4 (1,2,3,4);
  - retain var1-var4(1:4);
  ```

Example 2: Overview of the RETAIN Operation

This example shows how to use variable names and array names as elements in the RETAIN statement and shows assignment of initial values with and without parentheses:

```
data _null_;
array City{3} $ City1-City3;
array cp{3} Citypop1-Citypop3;
retain Year Taxyear 1999 City ' ' cp (10000,50000,100000);
file file-specification print;
put 'Values at beginning of DATA step:' / @3 _all_/;
input Gain;
do i=1 to 3;
   cp{i}=cp{i}+Gain;
end;
put 'Values after adding Gain to city populations:' / @3 _all_/;
datalines;
5000
10000
;
```

Here are the initial values assigned by RETAIN:

- Year and Taxyear are assigned the initial value 1999.
- City1, City2, and City3 are assigned missing values.
- Citypop1 is assigned the value 10000.
- Citypop2 is assigned 50000.
- Citypop3 is assigned 100000.

Here are the lines written by the PUT statements:

Values at beginning of DATA step:
  City1=  City2=  City3=  Citypop1=10000
  Citypop2=50000  Citypop3=100000
  Year=1999  Taxyear=1999  Gain=.  i=.
  _ERROR_=0  _N_=1

Values after adding GAIN to city populations:
  City1=  City2=  City3=  Citypop1=15000
  Citypop2=55000  Citypop3=105000
  Year=1999  Taxyear=1999  Gain=5000  i=4
  _ERROR_=0  _N_=1

Values at beginning of DATA step:
  City1=  City2=  City3=  Citypop1=15000
  Citypop2=55000  Citypop3=105000
  Year=1999  Taxyear=1999  Gain=5000  i=4
  _ERROR_=0  _N_=2

Values after adding GAIN to city populations:
  City1=  City2=  City3=  Citypop1=20000
  Citypop2=65000  Citypop3=115000
  Year=1999  Taxyear=1999  Gain=10000  i=4
  _ERROR_=0  _N_=2

Values at beginning of DATA step:
  City1=  City2=  City3=  Citypop1=20000
  Citypop2=65000  Citypop3=115000
  Year=1999  Taxyear=1999  Gain=10000  i=4
  _ERROR_=0  _N_=3

The first PUT statement is executed three times, whereas the second PUT statement is executed only twice. The DATA step ceases execution when the INPUT statement executes for the third time and reaches the end of the file.

**Example 3: Selecting One Value from a Series of Observations**

In this example, the data set ALLSCORES contains several observations for each identification number and variable ID. Different observations for a particular ID value might have different values of the variable GRADE. This example creates a new data set, CLASS.BESTSCORES, which contains one observation for each ID value. The observation must have the highest GRADE value of all observations for that ID in BESTSCORES.

```sas
libname class 'SAS-library';
proc sort data=class.allscores;
  by id;
run;
data class.bestscores;
  drop grade;
  set class.allscores;
  by id;
  /* Prevents HIGHEST from being reset*/
  /* to missing for each iteration. */
  retain highest;
  /* Sets HIGHEST to missing for each */
  /* different ID value. */
  if first.id then highest=.;
  /* Compares HIGHEST to GRADE in */
RETURN Statement

Stops executing statements at the current point in the DATA step and returns to a predetermined point in the step.

Valid in: DATA step
Category: Control
Type: Executable

Syntax

RETURN;

Without Arguments

The RETURN statement causes execution to stop at the current point in the DATA step, and returns control to a previous DATA step statement.

Details

The point to which SAS returns depends on the order in which statements are executed in the DATA step.

The RETURN statement is often used with the

• GO TO statement
• HEADER= option in the FILE statement
• LINK statement.

When RETURN causes a return to the beginning of the DATA step, an implicit OUTPUT statement writes the current observation to any new data sets (unless the DATA step contains an explicit OUTPUT statement, or REMOVE or REPLACE statements with MODIFY statements). Every DATA step has an implied RETURN as its last executable statement.
Example: Basic Usage

In this example, when the values of X and Y are the same, SAS executes the RETURN statement and adds the observation to the data set. When the values of X and Y are not equal, SAS executes the remaining statements and then adds the observation to the data set.

```sas
data survey;
  input x y;
  if x=y then return;
  put x= y=;
  datalines;
  21 25
  20 20
  7 17
;```

- “GO TO Statement” on page 159
- “LINK Statement” on page 256

---

RUN Statement

Executes the previously entered SAS statements.

Valid in: Anywhere
Category: Program Control

Syntax

```
RUN <CANCEL>;
```

Without Arguments

Without arguments, the RUN statement executes the previously entered SAS statements.

Arguments

CANCEL

terminates the current step without executing it. SAS prints a message that indicates that the step was not executed.

CAUTION:
The CANCEL option does not prevent execution of a DATA step that contains a DATALINES or DATALINES4 statement.

CAUTION:
The CANCEL option has no effect when you use the KILL option with PROC DATASETS.
Details

Although the RUN statement is not required between steps in a SAS program, using it creates a step boundary and can make the SAS log easier to read.

Examples

**Example 1: Executing SAS Statements**
This RUN statement marks a step boundary and executes this PROC PRINT step:

```
proc print data=report;
  title 'Status Report';
run;
```

**Example 2: Using the CANCEL Option**
This example shows the usefulness of the CANCEL option in a line prompt mode session. The fourth statement in the DATA step contains an invalid value for PI (4.13 instead of 3.14). RUN with CANCEL ends the DATA step and prevents it from executing.

```
data circle;
  infile file-specification;
  input radius;
  c=2*4.13*radius;
run cancel;
```

The following message is written to the SAS log:

```
WARNING: DATA step not executed at user's request.
```

---

**%RUN Statement**

Ends source statements following a %INCLUDE * statement.

- Valid in: Anywhere
- Category: Program Control

**Syntax**

```
%RUN;
```

**Without Arguments**
The %RUN statement causes SAS to stop reading input from the keyboard (including subsequent SAS statements on the same line as %RUN) and resume reading from the previous input source.

**Details**

Using the %INCLUDE statement with an asterisk specifies that you enter source lines from the keyboard.

*Note:* The asterisk (*) cannot be used to specify keyboard entry if you use the Enhanced Editor in the Microsoft Windows operating environment.
Comparisons

The RUN statement executes previously entered DATA or PROC steps. The %RUN statement ends the prompting for source statements and returns program control to the original source program, when you use the %INCLUDE statement to allow data to be entered from the keyboard.

The type of prompt that you use depends on how you run the SAS session. The include operation is most useful in interactive line and noninteractive modes, but it can also be used in windowing and batch mode. When you are running SAS in batch mode, include the %RUN statement in the external file that is referenced by the SASTERM fileref.

Example: Entering Source Lines from the Keyboard

To request keyboard-entry source on a %INCLUDE statement, follow the statement with an asterisk:

```
%include *;
```

Note: The asterisk (*) cannot be used to specify keyboard entry if you use the Enhanced Editor in the Microsoft Windows operating environment.

When it executes this statement, SAS prompts you to enter source lines from the keyboard. When you finish entering code from the keyboard, type the following statement to return processing to the program that contains the %INCLUDE statement.

```
%run;
```

Statements:

- “%INCLUDE Statement” on page 164
- “RUN Statement” on page 342

SASFILE Statement

Opens a SAS data set and allocates enough buffers to hold the entire file in memory.

Valid in: Anywhere

Category: Program Control

Restriction: A SAS data set opened by the SASFILE statement can be used for subsequent input (read) or update processing but not for output or utility processing.

See: “SASFILE Statement: z/OS” in SAS Companion for z/OS in SAS Companion for z/OS

Syntax

```
SASFILE <libref: member-name<member-type> <password-option(s)>>
OPEN | LOAD | CLOSE;
```
Arguments

libref
a name that is associated with a SAS library. The libref (library reference) must be a valid SAS name. The default libref is either USER (if assigned) or WORK (if USER not assigned).

Restriction: The libref cannot represent a concatenation of SAS libraries that contain a library in sequential format.

member-name
a valid SAS name that is a SAS data file (a SAS data set with the member type DATA) that is a member of the SAS library associated with the libref.

Restriction: The SAS data set must have been created with the V7, V8, or V9 Base SAS engine.

member-type
the type of SAS file to be opened. Valid value is DATA, which is the default.

password-option(s)
specifies one or more of the following password options:

READ=password
enables the SASFILE statement to open a read-protected file. The password must be a valid SAS name.

WRITE=password
enables the SASFILE statement to use the WRITE password to open a file that is both read-protected and write-protected. The password must be a valid SAS name.

ALTER=password
enables the SASFILE statement to use the ALTER password to open a file that is both read-protected and alter-protected. The password must be a valid SAS name.

PW=password
enables the SASFILE statement to use the password to open a file that is assigned for all levels of protection. The password must be a valid SAS name.

Tip: When SASFILE is executed, SAS checks whether the file is read-protected. Therefore, if the file is read-protected, you must include the READ= password in the SASFILE statement. If the file is either write-protected or alter-protected, you can use a WRITE=, ALTER=, or PW= password. However, the file is opened only in input (read) mode. For subsequent processing, you must specify the necessary password or passwords. See “Example 2: Specifying Passwords with the SASFILE Statement” on page 349.

OPEN
opens the file, allocates the buffers, but defers reading the data into memory until a procedure, statement, or application is executed.

LOAD
opens the file, allocates the buffers, and reads the data into memory.

Note: If the total number of allowed buffers is less than the number of buffers required for the file based on the number of data set pages and index file pages, SAS issues a warning to tell you how many pages are read into memory.

CLOSE
frees the buffers and closes the file.
Details

General Information
The SASFILE statement opens a SAS data set and allocates enough buffers to hold the entire file in memory. Once it is read, data is held in memory, available to subsequent DATA and PROC steps or applications, until either a second SASFILE statement closes the file and frees the buffers or the program ends, which automatically closes the file and frees the buffers.

Using the SASFILE statement can improve performance by
• reducing multiple open or close operations (including allocation and freeing of memory for buffers) to process a SAS data set to one open or close operation
• reducing I/O processing by holding the data in memory.

If your SAS program consists of steps that read a SAS data set multiple times and you have an adequate amount of memory so that the entire file can be held in real memory, the program should benefit from using the SASFILE statement. Also, SASFILE is especially useful as part of a program that starts a SAS server such as a SAS/SHARE server. However, as with most performance-improvement features, it is suggested that you set up a test in your environment to measure performance with and without the SASFILE statement.

Processing a SAS Data Set Opened with SASFILE
When the SASFILE statement executes, SAS opens the specified file. Then when subsequent DATA and PROC steps execute, SAS does not have to open the file for each request; the file remains open until a second SASFILE statement closes it or the program or session ends.

When a SAS data set is opened by the SASFILE statement, the file is opened for input processing and can be used for subsequent input or update processing. However, the file cannot be used for subsequent utility or output processing, because utility and output processing requires exclusive access to the file (member-level locking). For example, you cannot replace the file or rename its variables.

The following table provides a list of some SAS procedures and statements and specifies whether they are allowed if the file is opened by the SASFILE statement:

Table 2.9 Processing Requests for a File Opened by SASFILE

<table>
<thead>
<tr>
<th>Processing Request</th>
<th>Open Mode</th>
<th>Allowed</th>
</tr>
</thead>
<tbody>
<tr>
<td>APPEND procedure</td>
<td>update</td>
<td>Yes</td>

</tr>
<tr>
<td>DATASETS procedure with AGE, CHANGE, or DELETE statements</td>
<td>does not open the file but requires exclusive access</td>
<td>No</td>
</tr>
</tbody>
</table>
Buffer Allocation

A buffer is a reserved area of memory that holds a segment of data while it is processed. The number of allocated buffers determines how much data can be held in memory at one time.

The number of buffers is not a permanent attribute of a SAS file. That is, it is valid only for the current SAS session or job. When a SAS file is opened, a default number of buffers for processing the file is set. The default depends on the operating environment but typically is a small number such as one buffer. To specify a different number of buffers, you can use the BUFNO= data set option or system option.

When the SASFILE statement is executed, SAS automatically allocates the number of buffers based on the number of data set pages and index file pages (if an index file exists). For example:

- If the number of data set pages is five and there is not an index file, SAS allocates five buffers.
- If the number of data set pages is 500 and the number of index file pages is 200, SAS allocates 700 buffers.

If a file that is held in memory increases in size during processing, the number of allocated buffers increases to accommodate the file. Note that if SASFILE is executed for a SAS data set, the BUFNO= option is ignored.

I/O Processing

An I/O (input/output) request reads a segment of data from a storage device (such as disk) and transfers the data to memory, or conversely transfers the data from memory and writes it to the storage device. When a SAS data set is opened by the SASFILE statement, data is read once and held in memory, which should reduce the number of I/O requests.

CAUTION:

I/O processing can be reduced only if there is sufficient real memory. If the SAS data set is very large, you might not have sufficient real memory to hold the entire file. If insufficient memory exists, your operating environment can simulate more...
memory than actually exists, which is virtual memory. If virtual memory occurs, data access I/O requests are replaced with swapping I/O requests, which could result in no performance improvement. In addition, both SAS and your operating environment have a maximum amount of memory that can be allocated, which could be exceeded by the needs of your program. If your program needs exceed the memory that is available, the number of allocated buffers might be decreased to the default allocation in order to free memory.

**TIP** To determine how much memory a SAS data set requires, execute the CONTENTS procedure for the file to list its page size, the number of data set pages, the index file size, and the number of index file pages.

**Using the SASFILE Statement in a SAS/SHARE Environment**

The following are considerations for using the SASFILE statement with SAS/SHARE software:

- You must execute the SASFILE statement before you execute the PROC SERVER statement.
- If the client (the computer on which you use a SAS session to access a SAS/SHARE server) executes the SASFILE statement, it is rejected.
- Once the SASFILE statement is executed, all users who subsequently open the file will access the data held in memory instead of data that is stored on the disk.
- Once the SASFILE statement is executed, you cannot close the file and free the buffers until the SAS/SHARE server is terminated.
- You can use the ALLOCATE SASFILE command for the PROC SERVER statement as an alternative that brings part of the file into memory (controlled by the BUFNO= option).
- If the SASFILE statement is executed and you execute ALLOCATE SASFILE specifying a value for BUFNO= that is a larger number of buffers than allocated by SASFILE, performance will not be improved.

**Comparisons**

- Use the BUFNO= system option or data set option to specify a specific number of buffers.
- With SAS/SHARE software, you can use the ALLOCATE SASFILE command for the PROC SERVER statement to bring part of the file into memory (controlled by the BUFNO= option).

**Examples**

**Example 1: Using SASFILE in a Program with Multiple Steps**

The following SAS program illustrates the process of opening a SAS data set, transferring its data to memory, and reading that data held in memory for multiple tasks. The program consists of steps that read the file multiple times.

```sas
libname mydata 'SAS-library';
sasfile mydata.census.data open; 1
data test1;
   set mydata.census; 2
run;
data test2;
```
set mydata.census;
run;
proc summary data=mydata.census print;
run;
data mydata.census;
  modify mydata.census;
  (statements to modify data)
  run;
sasfile mydata.census close;

1 Opens SAS data set MYDATA.CENSUS, and allocates the number of buffers based on the number of data set pages and index file pages.
2 Reads all pages of MYDATA.CENSUS, and transfers all data from disk to memory.
3 Reads MYDATA.CENSUS a second time, but this time from memory without additional I/O requests.
4 Reads MYDATA.CENSUS a third time, again from memory without additional I/O requests.
5 Reads MYDATA.CENSUS a fourth time, again from memory without additional I/O requests. If the MODIFY statement successfully changes data in memory, the changed data is transferred from memory to disk at the end of the DATA step.
6 Closes MYDATA.CENSUS, and frees allocated buffers.

Example 2: Specifying Passwords with the SASFILE Statement
The following SAS program illustrates using the SASFILE statement and specifying passwords for a SAS data set that is both read-protected and alter-protected:

libname mydata 'SAS-data-data-library';
sasfile mydata.census (read=gizmo) open;
proc print data=mydata.census (read=gizmo);
run;
data mydata.census;
  modify mydata.census (alter=luke);
  (statements to modify data)
  run;

1 The SASFILE statement specifies the READ password, which is sufficient to open the file.
2 In the PRINT procedure, the READ password must be specified again.
3 The ALTER password is used in the MODIFY statement, because the data set is being updated.

Note: It is acceptable to use the higher-level ALTER password instead of the READ password in the above example.

- For information about using the SASFILE statement in a SAS/SHARE environment, see “The SERVER Procedure” in Chapter 9 of SAS/SHARE User's Guide.

Data Set Options:
SELECT Statement

Executes one of several statements or groups of statements.

Valid in: DATA step
Category: Control
Type: Executable

Syntax

SELECT <(select-expression)> ;
WHEN-1 (when-expression-1 <..., when-expression-n>) statement;
<...WHEN-n (when-expression-1<...,when-expression-n>) statement;>
<OTHERWISE statement;>
END;

Arguments

(select-expression)
specifies any SAS expression that evaluates to a single value.
See: “Evaluating the when-expression When a select-expression Is Included” on page 351

(when-expression)
specifies any SAS expression, including a compound expression. SELECT requires you to specify at least one when-expression.
Tips: Separating multiple when-expressions with a comma is equivalent to separating them with the logical operator OR.
The way a when-expression is used depends on whether a select-expression is present.
See: “Evaluating the when-expression When a select-expression Is Not Included” on page 351

statement
can be any executable SAS statement, including DO, SELECT, and null statements. You must specify the statement argument.

Details

Using WHEN Statements in a SELECT Group
The SELECT statement begins a SELECT group. SELECT groups contain WHEN statements that identify SAS statements that are executed when a particular condition is true. Use at least one WHEN statement in a SELECT group. An optional OTHERWISE
statement specifies a statement to be executed if no WHEN condition is met. An END statement ends a SELECT group.

Null statements that are used in WHEN statements cause SAS to recognize a condition as true without taking further action. Null statements that are used in OTHERWISE statements prevent SAS from issuing an error message when all WHEN conditions are false.

**Evaluating the when-expression When a select-expression Is Included**

If the select-expression is present, SAS evaluates the select-expression and when-expression. SAS compares the two for equality and returns a value of true or false. If the comparison is true, statement is executed. If the comparison is false, execution proceeds either to the next when-expression in the current WHEN statement, or to the next WHEN statement if no more expressions are present. If no WHEN statements remain, execution proceeds to the OTHERWISE statement, if one is present. If the result of all SELECT-WHEN comparisons is false and no OTHERWISE statement is present, SAS issues an error message and stops executing the DATA step.

**Evaluating the when-expression When a select-expression Is Not Included**

If no select-expression is present, the when-expression is evaluated to produce a result of true or false. If the result is true, statement is executed. If the result is false, SAS proceeds to the next when-expression in the current WHEN statement, or to the next WHEN statement if no more expressions are present, or to the OTHERWISE statement if one is present. (That is, SAS performs the action that is indicated in the first true WHEN statement.) If the result of all when-expressions is false and no OTHERWISE statement is present, SAS issues an error message. If more than one WHEN statement has a true when-expression, only the first WHEN statement is used. Once a when-expression is true, no other when-expressions are evaluated.

**Processing Large Amounts of Data with %INCLUDE Files**

One way to process large amounts of data is to use %INCLUDE statements in your DATA step. Using %INCLUDE statements enables you to perform complex processing while keeping your main program manageable. The %INCLUDE files that you use in your main program can contain WHEN statements and other SAS statements to process your data. See “Example 5: Processing Large Amounts of Data” on page 352 for an example.

**Comparisons**

Use IF-THEN/ELSE statements for programs with few statements. Use subsetting IF statements without a THEN clause to continue processing only those observations or records that meet the condition that is specified in the IF clause.

**Examples**

**Example 1: Using Statements**

```sas
select (a);
  when (1) x=x*10;
  when (2);
  when (3,4,5) x=x*100;
```
Example 2: Using DO Groups

```sas
select (payclass);
    when ('monthly') amt=salary;
    when ('hourly')
        do;
            amt=hrlywage*min(hrs,40);
            if hrs>40 then put 'CHECK TIMECARD';
        end; /* end of do */
    otherwise put 'PROBLEM OBSERVATION';
end; /* end of select */
```

Example 3: Using a Compound Expression

```sas
select;
    when (mon in ('JUN', 'JUL', 'AUG')
        and temp>70) put 'SUMMER ' mon=;
    when (mon in ('MAR', 'APR', 'MAY'))
        put 'SPRING ' mon=;
    otherwise put 'FALL OR WINTER ' mon=;
end;
```

Example 4: Making Comparisons for Equality

```sas
/* INCORRECT usage to select value of 2 */
select (x);
/* evaluates T/F and compares for */
/* equality with x */
    when (x=2) put 'two';
end; /* correct usage */
select(x);
/* compares 2 to x for equality */
    when (2) put 'two';
end; /* correct usage */
select;
/* compares 2 to x for equality */
    when (x=2) put 'two';
end;
```

Example 5: Processing Large Amounts of Data
In the following example, the %INCLUDE statements contain code that includes WHEN statements to process new and old items in the inventory. The main program shows the overall logic of the DATA step.

```sas
data test (keep=ItemNumber);
    set ItemList;
    select;
        %include NewItems;
        %include OldItems;
        otherwise put 'Item ' ItemNumber ' is not in the inventory.';
    end;
run;
```

• “IF-THEN/ELSE Statement” on page 163

SET Statement

Reads an observation from one or more SAS data sets.

Valid in: DATA step
Category: File-handling
Type: Executable

Syntax

SET <SAS-data-set(s)>(data-set-options(s))>>
<options>;

Without Arguments

When you do not specify an argument, the SET statement reads an observation from the most recently created data set.

Arguments

SAS-data-set (s)

specifies a one-level name, a two-level name, or one of the special SAS data set names.

Tips:

You can specify data set lists. For more information, see “Using Data Set Lists with SET” on page 357.

Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

See: See “SAS Data Sets” in Chapter 25 of SAS Language Reference: Concepts for a description of the levels of SAS data set names and when to use each level.

Example: “Example 13: Using Data Set Lists” on page 362

(data-set-options)

specifies actions SAS is to take when it reads variables or observations into the program data vector for processing.

Tip: Data set options that apply to a data set list apply to all of the data sets in the list.

See: Refer to “Definition of Data Set Options” in Chapter 1 of SAS Data Set Options: Reference for a list of the data set options to use with input data sets.
**SET Options**

**END=variable**

creates and names a temporary variable that contains an end-of-file indicator. The variable, which is initialized to zero, is set to 1 when SET reads the last observation of the last data set listed. This variable is not added to any new data set.

**Restriction:** END= cannot be used with POINT=. When random access is used, the END= variable is never set to 1.

**Interaction:** If you use a BY statement, END= is set to 1 when the SET statement reads the last observation of the interleaved data set. For more information, see “BY-Group Processing with SET” on page 358.

**Example:** “Example 11: Writing an Observation Only After All Observations Have Been Read” on page 361

**KEY=index</UNIQUE>**

provides nonsequential access to observations in a SAS data set, which are based on the value of an index variable or a key.

**Range:** Specify the name of a simple or a composite index of the data set that is being read.

**Restriction:** KEY= cannot be used with POINT=.

**Tip:** Using the _IORC_ automatic variable in conjunction with the SYSRC autocall macro provides you with more error-handling information than was previously available. When you use the SET statement with the KEY= option, the new automatic variable _IORC_ is created. This automatic variable is set to a return code that shows the status of the most recent I/O operation that is performed on an observation in a SAS data set. If the KEY= value is not found, the _IORC_ variable returns a value that corresponds to the SYSRC autocall macro's mnemonic _DSENOM and the automatic variable _ERROR_ is set to 1.

**See:**

For more information, see the description of the autocall macro SYSRC in SAS Macro Language: Reference.

**UNIQUE option on page 356**

**Examples:**

“Example 7: Performing a Table Lookup” on page 360

“Example 8: Performing a Table Lookup When the Master File Contains Duplicate Observations” on page 361

**CAUTION: Continuous loops can occur when you use the KEY= option.** If you use the KEY= option without specifying the primary data set, you must include either a STOP statement to stop DATA step processing, or programming logic that uses the _IORC_ automatic variable in conjunction with the SYSRC autocall macro and checks for an invalid value of the _IORC_ variable, or both.

**INDSNAME=variable**

creates and names a variable that stores the name of the SAS data set from which the current observation is read. The stored name can be a data set name or a physical name. The physical name is the name by which the operating environment recognizes the file.

**Tips:**

For data set names, SAS adds the library name to the variable value (for example, WORK.PRICE) and converts the two-level name to uppercase.

Unless previously defined, the length of the variable is set to 41 bytes. Use a LENGTH statement to make the variable length long enough to contain the value of the physical filename if the filename is longer than 41 bytes.
If the variable is previously defined as a character variable with a specific length, that length is not changed. If the value placed into the INDSNAME variable is longer than that length, then the value is truncated.

If the variable is previously defined as a numeric variable, an error will occur. The variable is available in the DATA step, but the variable is not added to any output data set.

**Example:** “Example 12: Retrieving the Name of the Data Set from Which the Current Observation Is Read” on page 362

NOBS=variable

creates and names a temporary variable whose value is usually the total number of observations in the input data set or data sets. If more than one data set is listed in the SET statement, NOBS= the total number of observations in the data sets that are listed. The number of observations includes those observations that are marked for deletion but are not yet deleted.

**Restriction:** For certain SAS views, SAS cannot determine the number of observations. In these cases, SAS sets the value of the NOBS= variable to the largest positive integer value that is available in your operating environment.

**Interaction:** The NOBS= and POINT= options are independent of each other.

**Tip:** At compilation time, SAS reads the descriptor portion of each data set and assigns the value of the NOBS= variable automatically. Thus, you can refer to the NOBS= variable before the SET statement. The variable is available in the DATA step but is not added to any output data set.

**Example:** “Example 10: Performing a Function until the Last Observation Is Reached” on page 361

OPEN=(IMMEDIATE | DEFER)

enables you to delay the opening of any concatenated SAS data sets until they are ready to be processed.

**IMMEDIATE**

during the compilation phase, opens all data sets that are listed in the SET statement.

**Restriction:** When you use the IMMEDIATE option KEY=, POINT=, and BY statement processing are mutually exclusive.

**Tip:** If a variable on a subsequent data set is of a different type (character versus numeric, for example) than the type of the same-named variable on the first data set, the DATA step will stop processing and produce an error message.

**DEFER**

opens the first data set during the compilation phase, and opens subsequent data sets during the execution phase. When the DATA step reads and processes all observations in a data set, it closes the data set and opens the next data set in the list.

**Restriction:** When you specify the DEFER option, you cannot use the KEY= statement option, the POINT= statement option, or the BY statement. These constructs imply either random processing or interleaving of observations from the data sets, which is not possible unless all data sets are open.

**Requirement:** You can use the DROP=, KEEP=, or RENAME= data set options to process a set of variables, but the set of variables that are processed for each data set must be identical. In most cases, if the set of variables defined by any subsequent data set differs from the variables defined by the first data set, SAS prints a warning message to the log but does not stop execution.

- If a variable on a subsequent data set is of a different type (character versus numeric, for example) than the type of the same-named variable
on the first data set, the DATA step will stop processing and produce an error message.

- If a variable on a subsequent data set was not defined by the first data set in the SET statement, but was defined previously in the DATA step program, the DATA step will stop processing and produce an error message. In this case, the value of the variable in previous iterations might be incorrect because the semantic behavior of SET requires this variable to be set to missing when processing the first observation of the first data set.

**Default:** IMMEDIATE

**POINT=** *variable*

specifies a temporary variable whose numeric value determines which observation is read. POINT= causes the SET statement to use random (direct) access to read a SAS data set.

**Restrictions:**

You cannot use POINT= with a BY statement, a WHERE statement, or a WHERE= data set option. In addition, you cannot use it with transport format data sets, data sets in sequential format on tape or disk, and SAS/ACCESS views or the SQL procedure views that read data from external files.

You cannot use POINT= with KEY=.

**Requirement:** a STOP statement

**Tips:**

You must supply the values of the POINT= variable. For example, you can use the POINT= variable as the index variable in some form of the DO statement. The POINT= variable is available anywhere in the DATA step, but it is not added to any new SAS data set.

**Examples:**

“Example 6: Combining One Observation with Many” on page 360

“Example 9: Reading a Subset by Using Direct Access” on page 361

**CAUTION: Continuous loops can occur when you use the POINT= option.**

When you use the POINT= option, you must include a STOP statement to stop DATA step processing, programming logic that checks for an invalid value of the POINT= variable, or both. Because POINT= reads only those observations that are specified in the DO statement, SAS cannot read an end-of-file indicator as it would if the file were being read sequentially. Because reading an end-of-file indicator ends a DATA step automatically, failure to substitute another means of ending the DATA step when you use POINT= can cause the DATA step to go into a continuous loop. If SAS reads an invalid value of the POINT= variable, it sets the automatic variable _ERROR_ to 1. Use this information to check for conditions that cause continuous DO-loop processing, or include a STOP statement at the end of the DATA step, or both.

**UNIQUE**

causes a KEY= search always to begin at the top of the index for the data set that is being read.

**Restriction:** UNIQUE can appear only with the KEY= argument and must be preceded by a slash.

**Notes:**

By default, SET begins searching at the top of the index only when the KEY= value changes.

If the KEY= value does not change on successive executions of the SET statement, the search begins by following the most recently retrieved
observation. In other words, when consecutive duplicate KEY= values appear, the SET statement attempts a one-to-one match with duplicate indexed values in the data set that is being read. If more consecutive duplicate KEY= values are specified than exist in the data set that is being read, the extra duplicates are treated as not found.

When KEY= is a unique value, only the first attempt to read an observation with that key value succeeds; subsequent attempts to read the observation with that value of the key will fail. The _IORC_ variable returns a value that corresponds to the SYSRC autocall macro's mnemonic _DSENOM. If you add the /UNIQUE option, subsequent attempts to read the observation with the unique KEY= value will succeed. The _IORC_ variable returns a 0.

See: For extensive examples, see *Combining and Modifying SAS Data Sets: Examples*

Example: “Example 8: Performing a Table Lookup When the Master File Contains Duplicate Observations” on page 361

Details

**What SET Does**

Each time the SET statement is executed, SAS reads one observation into the program data vector. SET reads all variables and all observations from the input data sets unless you tell SAS to do otherwise. A SET statement can contain multiple data sets; a DATA step can contain multiple SET statements. See *Combining and Modifying SAS Data Sets: Examples*.

Note: When the DATA step comes to an end-of-file marker or the end of all open data sets, it will perform an orderly shutdown. For example, if you use SET with FIRSTOBS, a file with only a header record in a series of files will trigger a normal shutdown of the DATA step. The shutdown occurs because SAS reads beyond the end-of-file marker and the DATA step terminates. You can use the END= option to avoid the shutdown.

**Uses**

The SET statement is flexible and has a variety of uses in SAS programming. These uses are determined by the options and statements that you use with the SET statement:

- reading observations and variables from existing SAS data sets for further processing in the DATA step
- concatenating and interleaving data sets, and performing one-to-one reading of data sets
- reading SAS data sets by using direct access methods.

**Using Data Set Lists with SET**

You can use data set lists with the SET statement. Data set lists provide a quick way to reference existing groups of data sets. These data set lists must be either name prefix lists or numbered range lists.

Name prefix lists refer to all data sets that begin with a specified character string. For example, set SALES1:; tells SAS to read all data sets starting with "SALES1" such as SALES1, SALES10, SALES11, and SALES12.

Numbered range lists require you to have a series of data sets with the same name, except for the last character or characters, which are consecutive numbers. In a
numbered range list, you can begin with any number and end with any number. For example, these lists refer to the same data sets:

```
sales1 sales2 sales3 sales4
sales1-sales4
```

**Note:** If the numeric suffix of the first data set name contains leading zeros, the number of digits in the numeric suffix of the last data set name must be greater than or equal to the number of digits in the first data set name. Otherwise, an error will occur. For example, the data set lists sales001–sales99 and sales01–sales9 will cause an error. The data set list sales001–sales999 is valid. If the numeric suffix of the first data set name does not contain leading zeros, the number of digits in the numeric suffix of the first and last data set names do not have to be equal. For example, the data set list sales1–sales999 is valid.

Some other rules to consider when using numbered data set lists are as follows:

- You can specify groups of ranges.
  ```
  set cost1-cost4 cost11-cost14 cost21-cost24;
  ```

- You can mix numbered range lists with name prefix lists.
  ```
  set cost1-cost4 cost2: cost33-37;
  ```

- You can mix single data sets with data set lists.
  ```
  set cost1 cost10-cost20 cost30;
  ```

- Quotation marks around data set lists are ignored.
  ```
  /* these two lines are the same */
  set sales1 - sales4;
  set 'sales1'n - 'sales4'n;
  ```

- Spaces in data set names are invalid. If quotation marks are used, trailing blanks are ignored.
  ```
  /* blanks in these statements will cause errors */
  set sales 1 - sales 4;
  set 'sales 1'n - 'sales 4'n;
  /* trailing blanks in this statement will be ignored */
  set 'sales1  'n - 'sales4  'n;
  ```

- The maximum numeric suffix is 2147483647.
  ```
  /* this suffix will cause an error */
  set prod2000000000-prod2934850239;
  ```

### BY-Group Processing with SET

Only one BY statement can accompany each SET statement in a DATA step. The BY statement should immediately follow the SET statement to which it applies. The data sets that are listed in the SET statement must be sorted by the values of the variables that are listed in the BY statement, or they must have an appropriate index. SET, when it is used with a BY statement, interleaves data sets. The observations in the new data set are arranged by the values of the BY variable or variables, and within each BY group, by the order of the data sets in which they occur. See “Example 2: Interleaving SAS Data Sets” on page 359 for an example of BY-group processing with the SET statement.

### Combining SAS Data Sets

Use a single SET statement with multiple data sets to concatenate the specified data sets. That is, the number of observations in the new data set is the sum of the number of
observations in the original data sets, and the order of the observations is all the observations from the first data set followed by all the observations from the second data set, and so on. See “Example 1: Concatenating SAS Data Sets” on page 359 for an example of concatenating data sets.

Use a single SET statement with a BY statement to interleave the specified data sets. The observations in the new data set are arranged by the values of the BY variable or variables, and within each BY group, by the order of the data sets in which they occur. See “Example 2: Interleaving SAS Data Sets” on page 359 for an example of interleaving data sets.

Use multiple SET statements to perform one-to-one reading (also called one-to-one matching) of the specified data sets. The new data set contains all the variables from all the input data sets. The number of observations in the new data set is the number of observations in the smallest original data set. If the data sets contain common variables, the values that are read in from the last data set replace the values that were read in from earlier ones. For examples of one-to-one reading of data sets, see

- “Example 6: Combining One Observation with Many” on page 360
- “Example 7: Performing a Table Lookup” on page 360
- “Example 8: Performing a Table Lookup When the Master File Contains Duplicate Observations” on page 361

For extensive examples, see Combining and Modifying SAS Data Sets: Examples.

For more information about how to prepare your data sets, see “Combining SAS Data Sets: Basic Concepts” in Chapter 21 of SAS Language Reference: Concepts.

Comparisons

- SET reads an observation from an existing SAS data set. INPUT reads raw data from an external file or from in-stream data lines in order to create SAS variables and observations.
- Using the KEY= option with SET enables you to access observations nonsequentially in a SAS data set according to a value. Using the POINT= option with SET enables you to access observations nonsequentially in a SAS data set according to the observation number.

Examples

Example 1: Concatenating SAS Data Sets

If more than one data set name appears in the SET statement, the resulting output data set is a concatenation of all the data sets that are listed. SAS reads all observations from the first data set, then all from the second data set, and so on, until all observations from all the data sets have been read. This example concatenates the three SAS data sets into one output data set named FITNESS:

data fitness;
   set health exercise well;
run;

Example 2: Interleaving SAS Data Sets

To interleave two or more SAS data sets, use a BY statement after the SET statement:

data april;
   set payable recvable;

Example 3: Reading a SAS Data Set
In this DATA step, each observation in the data set NC.MEMBERS is read into the program data vector. Only those observations whose value of CITY is Raleigh are output to the new data set RALEIGH.MEMBERS:

```sas
data raleigh.members;
set nc.members;
if city='Raleigh';
run;
```

Example 4: Merging a Single Observation with All Observations in a SAS Data Set
An observation to be merged into an existing data set can be one that is created by a SAS procedure or another DATA step. In this example, the data set AVGSALES has only one observation:

```sas
data national;
if _n_=1 then set avgsales;
set totsales;
run;
```

Example 5: Reading from the Same Data Set More than Once
In this example, SAS treats each SET statement independently. That is, it reads from one data set as if it were reading from two separate data sets:

```sas
data drugxyz;
set trial5(keep=sample);
if sample>2;
set trial5;
run;
```

For each iteration of the DATA step, the first SET statement reads one observation. The next time the first SET statement is executed, it reads the next observation. Each SET statement can read different observations with the same iteration of the DATA step.

Example 6: Combining One Observation with Many
You can subset observations from one data set and combine them with observations from another data set by using direct access methods, as follows:

```sas
data south;
set revenue;
if region=4;
set expense point=_n_;
run;
```

Example 7: Performing a Table Lookup
This example illustrates using the KEY= option to perform a table lookup. The DATA step reads a primary data set that is named INVTORY and a lookup data set that is named PARTCODE. It uses the index PARTNO to read PARTCODE nonsequentially, by looking for a match between the PARTNO value in each data set. The purpose is to obtain the appropriate description, which is available only in the variable DESC in the lookup data set, for each part that is listed in the primary data set:
Example 8: Performing a Table Lookup When the Master File Contains Duplicate Observations
This example uses the KEY= option to perform a table lookup. The DATA step reads a primary data set that is named INVTORY, which is indexed on PARTNO, and a lookup data set named PARTCODE. PARTCODE contains quantities of new stock (variable NEW_STK). The UNIQUE option ensures that, if there are any duplicate observations in INVTORY, values of NEW_STK are added only to the first observation of the group:

data combine;
  set partcode(keep=partno new_stk);
  set invtory(keep=partno instock price)
    key=partno/unique;
  instock=instock+new_stk;
run;

Example 9: Reading a Subset by Using Direct Access
These statements select a subset of 50 observations from the data set DRUGTEST by using the POINT= option to access observations directly by number:

data sample;
  do obsnum=1 to 100 by 2;
    set drugtest point=obsnum;
    if _error_ then abort;
    output;
  end;
  stop;
run;

Example 10: Performing a Function until the Last Observation Is Reached
These statements use NOBS= to set the termination value for DO-loop processing. The value of the temporary variable LAST is the sum of the observations in SURVEY1 and SURVEY2:

do obsnum=1 to last by 100;
  set survey1 survey2 point=obsnum nobs=last;
  output;
end;
stop;

Example 11: Writing an Observation Only After All Observations Have Been Read
This example uses the END= variable LAST to tell SAS to assign a value to the variable REVENUE and write an observation only after the last observation of RENTAL has been read:

set rental end=last;
totdays + days;
if last then
do;
Example 12: Retrieving the Name of the Data Set from Which the Current Observation Is Read

This example creates three data sets and stores the data set name in a variable named *dsn*. The name is split into three parts and the example prints out the results.

```sas
/* Create some data sets to read */
data gas_price_option; value=395; run;
data gas_rbid_option; value=840; run;
data gas_price_forward; value=275; run;
/* Create a data set D */
data d;
  set gas_price_option gas_rbid_option gas_price_forward indsnname=dsn;
  /* split the data set names into 3 parts */
  commodity = scan (dsn, 2, "._");
  type = scan (dsn, 3, "._");
  instrument = scan (dsn, 4, "._");
run;
proc print data=d;
run;
```

**Output 2.30  Data Set Name Split into Three Parts**

<table>
<thead>
<tr>
<th>Obs</th>
<th>value</th>
<th>commodity</th>
<th>type</th>
<th>instrument</th>
</tr>
</thead>
<tbody>

<td>GAS</td>
<td>PRICE</td>
<td>FORWARD</td>
</tr>
</tbody>
</table>

Example 13: Using Data Set Lists

This example uses a numbered range list to input the data sets.

```sas
data dept008; emp=13; run;
data dept009; emp=9; run;
data dept010; emp=4; run;
data dept011; emp=33; run;
data _null_;    
  set dept008-dept010;
  put _all_;    
run;
```

The following lines are written to the SAS log.
In addition, you could use data set lists to find missing data sets. This example uses a numbered range list to locate the missing data sets. An error occurs for each data set that does not exist. Once you know which data sets are missing, you can correct the SET statement to reflect the data sets that actually exist.

data dept008; emp=13; run;
data dept009; emp=9; run;
data dept011; emp=4; run;
data dept014; emp=33; run;
data _null_; set dept008-dept014;
put _all_; run;

The following lines are written to the SAS log.
Log 2.4  Finding Missing Data Sets Using the SET Statement

```
1    data dept008; emp=13; run;
    NOTE: The data set WORK.DEPT008 has 1 observations and 1 variables.
    NOTE: DATA statement used (Total process time):
          real time           0.04 seconds
          cpu time            0.04 seconds

2    data dept009; emp=9; run;
    NOTE: The data set WORK.DEPT009 has 1 observations and 1 variables.
    NOTE: DATA statement used (Total process time):
          real time           0.00 seconds
          cpu time            0.00 seconds

3    data dept011; emp=4; run;
    NOTE: The data set WORK.DEPT011 has 1 observations and 1 variables.
    NOTE: DATA statement used (Total process time):
          real time           0.03 seconds
          cpu time            0.01 seconds

4    data dept014; emp=33; run;
    NOTE: The data set WORK.DEPT014 has 1 observations and 1 variables.
    NOTE: DATA statement used (Total process time):
          real time           0.00 seconds
          cpu time            0.00 seconds

5    data _null_;       
6    set dept008-dept014;
    ERROR: File WORK.DEPT010.DATA does not exist.
    ERROR: File WORK.DEPT012.DATA does not exist.
    ERROR: File WORK.DEPT013.DATA does not exist.
7    put _all_;        
8    run;
    NOTE: The SAS System stopped processing this step because of errors.
    NOTE: DATA statement used (Total process time):
          real time           0.00 seconds
          cpu time            0.00 seconds
```

Statements:

- “BY Statement” on page 35
- “DO Statement” on page 64
- “INPUT Statement” on page 199
- “MERGE Statement” on page 266
- “STOP Statement” on page 365
- “UPDATE Statement” on page 377
**SKIP Statement**

Creates a blank line in the SAS log.

- **Valid in:** Anywhere
- **Category:** Log Control

**Syntax**

```skip
SKIP <n>;
```

**Without Arguments**

Using SKIP without arguments causes SAS to create one blank line in the log.

**Arguments**

- `n` specifies the number of blank lines that you want to create in the log.

**Tip:** If the number specified is greater than the number of lines that remain on the page, SAS goes to the top of the next page.

**Details**

The SKIP statement itself does not appear in the log. You can use this statement in all methods of operation.

**See Also**

**Statements:**
- “PAGE Statement” on page 296

**System Options:**
- “LINESIZE= System Option” in *SAS System Options: Reference*
- “PAGESIZE= System Option” in *SAS System Options: Reference*
Without Arguments
The STOP statement causes SAS to stop processing the current DATA step immediately and resume processing statements after the end of the current DATA step.

Details
SAS outputs a data set for the current DATA step. However, the observation being processed when STOP executes is not added. The STOP statement can be used alone or in an IF-THEN statement or SELECT group.

Use STOP with any features that read SAS data sets using random access methods, such as the POINT= option in the SET statement. Because SAS does not detect an end-of-file with this access method, you must include program statements to prevent continuous processing of the DATA step.

Comparisons
• When you use a windowing environment or other interactive methods of operation, the ABORT statement and the STOP statement both stop processing. The ABORT statement sets the value of the automatic variable _ERROR_ to 1, but the STOP statement does not.
• In batch or noninteractive mode, the two statements also have different effects. Use the STOP statement in batch or noninteractive mode to continue processing with the next DATA or PROC step.

Examples

Example 1: Basic Usage
• stop;
• if idcode=9999 then stop;
• select (a);
  when (0) output;
  otherwise stop;
  end;

Example 2: Avoiding an Infinite Loop
This example shows how to use STOP to avoid an infinite loop within a DATA step when you are using random access methods:

data sample;
  do sampleobs=1 to totalobs by 10;
    set master.research point=sampleobs nobs=totalobs;
    output;
  end;
  stop;
run;

Statements:
• “ABORT Statement” on page 19
• POINT= option in the SET statement on page 356
**Sum Statement**

Adds the result of an expression to an accumulator variable.

**Valid in:** DATA step  
**Category:** Action  
**Type:** Executable

---

**Syntax**

\[ \text{variable} + \text{expression}; \]

**Arguments**

**variable**

specifies the name of the accumulator variable, which contains a numeric value.

**Tips:**

- The variable is automatically set to 0 before SAS reads the first observation. The variable's value is retained from one iteration to the next, as if it had appeared in a RETAIN statement.
- To initialize a sum variable to a value other than 0, include it in a RETAIN statement with an initial value.

**expression**

is any SAS expression.

**Tips:**

- The expression is evaluated and the result added to the accumulator variable.
- SAS treats an expression that produces a missing value as zero.

**Comparisons**

The sum statement is equivalent to using the SUM function and the RETAIN statement, as shown here:

\[
\text{retain variable } 0;  
\text{variable}=\text{sum(}\text{variable,} \text{expression}); 
\]

**Example: Using the Sum Statement**

Here are examples of sum statements that illustrate various expressions:

- `balance+(-debit);`
- `sumxsq+x*x;`
- `nx+{x ne .};`
- `if status='ready' then OK+1;`

**See Also**

**Functions:**

- “SUM Function” in *SAS Functions and CALL Routines: Reference*
Statements:

- “RETAIN Statement” on page 337

---

**SYSECHO Statement**

Fires a global statement complete event and passes a text string back to the IOM client.

**Valid in:** Anywhere
**Category:** Program Control
**Restriction:** Has an effect only in objectserver mode

**Syntax**

```
SYSECHO <"text">;
```

**Without Arguments**

Using SYSECHO without arguments sends a global statement complete event to the IOM client.

**Arguments**

"text"

specifies a text string that is passed back to the IOM client.

- **Range:** 1–64 characters
- **Requirement:** The text string must be enclosed in double quotation marks.

**Details**

The SYSECHO statement enables IOM clients to manually track the progress of a segment of a submitted SAS program.

When the SYSECHO statement is executed, a global statement complete event is generated and, if specified, the text string is passed back to the IOM client.

---

**TITLE Statement**

Specifies title lines for SAS output.

**Valid in:** Anywhere
**Category:** Output Control
**See:** TITLE Statement under Windows, UNIX, or z/OS

**Syntax**

```
TITLE <n> <ods-format-options> <"text" | "text">;
```

**Without Arguments**

Using TITLE without arguments cancels all existing titles.
Arguments

\( n \)

specifies the relative line that contains the title line.

**Range:** 1 - 10

**Tips:**
- The title line with the highest number appears on the bottom line. If you omit \( n \), SAS assumes a value of 1. Therefore, you can specify TITLE or TITLE1 for the first title line.
- You can create titles that contain blank lines between the lines of text. For example, if you specify text with a TITLE statement and a TITLE3 statement, there will be a blank line between the two lines of text.

**ods-format-options**

specifies formatting options for the ODS HTML, RTF, and PRINTER destinations.

**BOLD**

specifies that the title text is bold font weight.

**ODS destination:** HTML, RTF, PRINTER

**COLOR=** `color`

specifies the title text color.

**Alias:** C

**ODS destination:** HTML, RTF, PRINTER

**Example:** “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373

**BCOLOR=** `color`

specifies the background color of the title block.

**ODS destination:** HTML, RTF, PRINTER

**FONT=** `font-face`

specifies the font to use. If you supply multiple fonts, then the destination device uses the first one that is installed on your system.

**Alias:** F

**ODS destination:** HTML, RTF, PRINTER

**HEIGHT=** `dimension` | `size`

specifies size of the font for titles.

**Dimension**

is a nonnegative number.

**Units of Measure for Dimension**

- **cm**  Centimeters
- **em**  Standard typesetting measurement unit for width
- **ex**  Standard typesetting measurement unit for height
- **in**  Inches
- **mm**  Millimeters
- **pt**  A printer’s point

**Restriction:** If you specify \( dimension \), then specify a unit of measure. Without a unit of measure, the number becomes a relative size.
**size**

The value of `size` is relative to all other font sizes in the HTML document.

**Range:** 1 to 7

**Alias:** H

**ODS destination:** HTML, RTF, PRINTER

**Example:** “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373

**ITALIC**

specifies that the title text is in italic style.

**ODS destination:** HTML, RTF, PRINTER

**JUSTIFY= CENTER | LEFT | RIGHT**

specifies justification.

**CENTER**

specifies center justification.

**Alias:** C

**LEFT**

specifies left justification.

**Alias:** L

**RIGHT**

specifies right justification.

**Alias:** R

**Alias:** J

**ODS destination:** HTML, RTF, PRINTER

**Example:** “Example 3: Customizing Titles and Footnotes by Using the Output Delivery System” on page 373

**LINK='url'**

specifies a hyperlink.

**ODS destination:** HTML, RTF, PRINTER

**Tip:** The visual properties for LINK= always come from the current style.

**UNDERLIN= 0 | 1 | 2 | 3**

specifies whether the subsequent text is underlined. 0 indicates no underlining. 1, 2, and 3 indicates underlining.

**Alias:** U

**ODS destination:** HTML, RTF, PRINTER

**Tip:** ODS generates the same type of underline for values 1, 2, and 3. However, SAS/GRAPH uses values 1, 2, and 3 to generate increasingly thicker underlines.

**Note:** The defaults for how ODS renders the TITLE statement come from style elements relating to system titles in the current style. The TITLE statement syntax with `ods-format-options` is a way to override the settings provided by the current style. The current style varies according to the ODS destination. For more information about how to determine the current style, see “Understanding Styles, Style Elements, and Style Attributes” in Chapter 3 of SAS Output Delivery System: User's Guide. Also see “Concepts: Styles and the TEMPLATE Procedure” in Chapter 13 of SAS Output Delivery System: User's Guide.

**Tips:**
You can specify these options by letter, word, or words by preceding each letter or word of the text by the option.

For example, this code will make the title “Red, White, and Blue” appear in different colors.

```
title color=red "Red," color=white "White, and" color=blue "Blue";
```

'text' | “text”
specifies text that is enclosed in single or double quotation marks.

You can customize titles by inserting BY variable values (#BYVALn), BY variable names (#BYVARn), or BY lines (#BYLINE) in titles that are specified in PROC steps. Embed the items in the specified title text string at the position where you want the substitution text to appear.

#BYVALn | #BYVAL(variable-name)
substitutes the current value of the specified BY variable for #BYVAL in the text string and displays the value in the title.

Follow these rules when you use #BYVAL in the TITLE statement of a PROC step:

- Specify the variable that is used by #BYVAL in the BY statement.
- Insert #BYVAL in the specified title text string at the position where you want the substitution text to appear.
- Follow #BYVAL with a delimiting character, either a space or other nonalphanumeric character (for example, a quotation mark) that ends the text string.
- If you want the #BYVAL substitution to be followed immediately by other text, with no delimiter, use a trailing dot (as with macro variables).

Specify the variable with one of the following:

- \( n \)
  specifies which variable in the BY statement #BYVAL should use. The value of \( n \) indicates the position of the variable in the BY statement.

  **Example:** #BYVAL2 specifies the second variable in the BY statement.

- variable-name
  names the BY variable.

  **Tip:** Variable-name is not case sensitive.

  **Example:** #BYVAL(YEAR) specifies the BY variable, YEAR.

#BYVARn | #BYVAR(variable-name)
substitutes the name of the BY variable or label that is associated with the variable (whatever the BY line would normally display) for #BYVAR in the text string and displays the name or label in the title.

Follow these rules when you use #BYVAR in the TITLE statement of a PROC step:

- Specify the variable that is used by #BYVAR in the BY statement.
- Insert #BYVAR in the specified title text string at the position where you want the substitution text to appear.
- Follow #BYVAR with a delimiting character, either a space or other nonalphanumeric character (for example, a quotation mark) that ends the text string.
• If you want the #BYVAR substitution to be followed immediately by other
text, with no delimiter, use a trailing dot (as with macro variables).

Specify the variable with one of the following:

\( n \)
specifies which variable in the BY statement #BYVAR should use. The value
of \( n \) indicates the position of the variable in the BY statement.

**Example**: #BYVAR2 specifies the second variable in the BY statement.

variable-name

names the BY variable.

**Tip**: variable-name is not case sensitive.

**Example**: #BYVAR(SITES) specifies the BY variable SITES.

#BYLINE

substitutes the entire BY line without leading or trailing blanks for #BYLINE in
the text string and displays the BY line in the title.

**Tip**: #BYLINE produces output that contains a BY line at the top of the page
unless you suppress it by using NOBYLINE in an OPTIONS statement.

**See**: For more information about NOBYLINE, see the “BYLINE System
Option” in *SAS System Options: Reference*.

**Tips:**

For compatibility with previous releases, SAS accepts some text without
quotation marks. When writing new programs or updating existing programs,
always enclose text in quotation marks.

If you use single quotation marks (') or double quotation marks ("") together
(with no space in between them) as the string of text, SAS will output a single
quotation mark (') or double quotation marks (""), respectively.

If you use an automatic macro variable in the title text, you must enclose the title
text in double quotation marks. The SAS macro facility will resolve the macro
variable only if the text is in double quotation marks.

**See**: For more information about including quotation marks as part of the title, see

**Details**

A TITLE statement takes effect when the step or RUN group with which it is associated
executes. Once you specify a title for a line, it is used for all subsequent output until you
cancel the title or define another title for that line. A TITLE statement for a given line
cancels the previous TITLE statement for that line and for all lines with larger \( n \)
numbers.

**Operating Environment Information**

The maximum title length that is allowed depends on your operating environment
and the value of the LINESIZE= system option. Refer to the SAS documentation for
your operating environment for more information.

**Comparisons**

You can also create titles with the TITLES window.
Examples

Example 1: Using the TITLE Statement
The following examples show how you can use the TITLE statement:

- This statement suppresses a title on line n and all lines after it:
  ```
  title n;
  ```
- These code lines are examples of TITLE statements:
  ```
  title 'First Draft';
  title2 "Year's End Report";
  title2 'Year''s End Report';
  ```

Example 2: Customizing Titles by Using BY Variable Values
You can customize titles by inserting BY variable values in the titles that you specify in PROC steps. The following examples show how to use #BYVALn, #BYVARn, and #BYLINE:

- title 'Quarterly Sales for #byval(site)';
- title 'Annual Costs for #byvar2';
- title 'Data Group #byline';

Example 3: Customizing Titles and Footnotes by Using the Output Delivery System
You can customize titles and footnotes with ODS. The following example shows you how to use PROC TEMPLATE to change the color, justification, and size of the text for the title and footnote.

```
2010 BRZ  Corn  31975
2010 CHN  Wheat  109000
2010 CHN  Rice  190100
2010 CHN  Corn  119350
2010 IND  Wheat  62620
2010 IND  Rice  120012
2010 IND  Corn  8660
2010 INS  Wheat  
2010 INS  Rice  51165
2010 INS  Corn  8925
2010 USA  Wheat  62099
2010 USA  Rice  7771
2010 USA  Corn  236064
;
run;
proc format;
  value $cntry 'BRZ'='Brazil'
    'CHN'='China'
    'IND'='India'
    'INS'='Indonesia'
    'USA'='United States';
run;
/*****************************/

Prepared on 07DEC2010

SAS
UPDATE Statement

Updates a master file by applying transactions.

Valid in: DATA step
Category: File-handling
Type: Executable

Syntax

END=variable>
<UPDATEMODE= MISSINGCHECK | NOMISSINGCHECK>;
BY by-variable;

Arguments

master-data-set
specifies the SAS data set used as the master file.

Range: The name can be a one-level name (for example, FITNESS), a two-level name (for example, IN.FITNESS), or one of the special SAS data set names.

Tip: Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

See: “Rules for Words and Names in the SAS Language” in Chapter 3 of SAS Language Reference: Concepts

(data-set-options)
specifies actions SAS is to take when it reads variables into the DATA step for processing.

Requirement: Data-set-options must appear within parentheses and follow a SAS data set name.

Tip: Dropping, keeping, and renaming variables is often useful when you update a data set. Renaming like-named variables prevents the second value that is read from over-writing the first one. By renaming one variable, you make the values of both of them available for processing, such as comparing.

See: A list of data set options to use with input data sets in SAS Data Set Options: Reference
Example: “Example 2: Updating by Renaming Variables” on page 379

**transaction-data-set**

specifies the SAS data set that contains the changes to be applied to the master data set.

**Range:** The name can be a one-level name (for example, HEALTH), a two-level name (for example, IN.HEALTH), or one of the special SAS data set names.

**Tip:** Instead of using a data set name, you can specify the physical pathname to the file, using syntax that your operating system understands. The pathname must be enclosed in single or double quotation marks.

**END=variable**

creates and names a temporary variable that contains an end-of-file indicator. This variable is initialized to 0 and is set to 1 when UPDATE processes the last observation. This variable is not added to any data set.

**UPDATEMODE=MISSINGCHECK**

**UPDATEMODE=NOMISSINGCHECK**

specifies whether missing variable values in a transaction data set are to be allowed to replace existing variable values in a master data set.

**MISSINGCHECK**

prevents missing variable values in a transaction data set from replacing values in a master data set.

**NOMISSINGCHECK**

allows missing variable values in a transaction data set to replace values in a master data set.

**Default:** MISSINGCHECK

**Tip:** Special missing values, however, are the exception and will replace values in the master data set even when MISSINGCHECK (the default) is in effect.

**Details**

**Requirements**

- The UPDATE statement must be accompanied by a BY statement that specifies the variables by which observations are matched.
- The BY statement should immediately follow the UPDATE statement to which it applies.
- The data sets listed in the UPDATE statement must be sorted by the values of the variables listed in the BY statement, or they must have an appropriate index.
- Each observation in the master data set should have a unique value of the BY variable or BY variables. If there are multiple values for the BY variable, only the first observation with that value is updated. The transaction data set can contain more than one observation with the same BY value. (Multiple transaction observations are all applied to the master observation before it is written to the output file.)

For more information, see “How to Prepare Your Data Sets” in Chapter 21 of *SAS Language Reference: Concepts*.

**Transaction Data Sets**

Usually, the master data set and the transaction data set contain the same variables. However, to reduce processing time, you can create a transaction data set that contains only those variables that are being updated. The transaction data set can also contain new variables to be added to the output data set.
The output data set contains one observation for each observation in the master data set. If any transaction observations do not match master observations, they become new observations in the output data set. Observations that are not to be updated can be omitted from the transaction data set. See “Reading, Combining, and Modifying SAS Data Sets” in Chapter 21 of *SAS Language Reference: Concepts*.

### Missing Values

By default the UPDATEMODE=MISSINGCHECK option is in effect, so missing values in the transaction data set do not replace existing values in the master data set. Therefore, if you want to update some but not all variables and if the variables that you want to update differ from one observation to the next, set to missing those variables that are not changing. If you want missing values in the transaction data set to replace existing values in the master data set, use UPDATEMODE=NOMISSINGCHECK.

Even when UPDATEMODE=MISSINGCHECK is in effect, you can replace existing values with missing values by using special missing value characters in the transaction data set. To create the transaction data set, use the MISSING statement in the DATA step. If you define one of the special missing values `A` through `Z` for the transaction data set, SAS updates numeric variables in the master data set to that value.

If you want the resulting value in the master data set to be a regular missing value, use a single underscore `_` to represent missing values in the transaction data set. The resulting value in the master data set will be a period `.` for missing numeric values and a blank for missing character values.

For more information about defining and using special missing value characters, see the “MISSING Statement” on page 270.

### Comparisons

- Both UPDATE and MERGE can update observations in a SAS data set.
- MERGE automatically replaces existing values in the first data set with missing values in the second data set. UPDATE, however, does not do so by default. To cause UPDATE to overwrite existing values in the master data set with missing ones in the transaction data set, you must use UPDATEMODE=NOMISSINGCHECK.
- UPDATE changes or updates the values of selected observations in a master file by applying transactions. UPDATE can also add new observations.

### Examples

#### Example 1: Basic Updating

These program statements create a new data set (OHIO.QTR1) by applying transactions to a master data set (OHIO.JAN). The BY variable STORE must appear in both OHIO.JAN and OHIO.WEEK4, and its values in the master data set should be unique:

```sas
data ohio.qtr1;
  update ohio.jan ohio.week4;
  by store;
run;
```

#### Example 2: Updating by Renaming Variables

This example shows renaming a variable in the FITNESS data set so that it will not overwrite the value of the same variable in the program data vector. Also, the WEIGHT variable is renamed in each data set and a new WEIGHT variable is calculated. The
Master Data Set

**Example 3: Updating with Missing Values**

This example illustrates the DATA steps used to create a master data set PAYROLL and a transaction data set INCREASE that contains regular and special missing values. Note the following after the update is made:

- The salary for ID 1026 remains the same.
- The salary for ID 1034 is a special missing value.
- The salary for ID 1057 is a regular missing value.

    /* Create the Master Data Set */
    data payroll;
        input ID SALARY;
    datalines;
    1011 245
    1026 269
    1028 374
    1034 333
    1057 582
    ;

    /* Create the Transaction Data Set */
    data increase;
        input ID SALARY;
        missing A _;

### WHERE Statement

Selects observations from SAS data sets that meet a particular condition.

**Valid in:** DATA step and PROC step  
**Category:** Action

**Type:** Declarative
Syntax

WHERE where-expression-1
<logical-operator where-expression-n>;

Arguments

where-expression
is an arithmetic or logical expression that generally consists of a sequence of
operands and operators.

Tips:
The operands and operators described in the next several sections are also valid
for the WHERE= data set option.
You can specify multiple where-expressions.

logical-operator
can be AND, AND NOT, OR, or OR NOT.

Details

The Basics
Using the WHERE statement might improve the efficiency of your SAS programs
because SAS is not required to read all observations from the input data set.

The WHERE statement cannot be executed conditionally. That is, you cannot use it as
part of an IF-THEN statement.

WHERE statements can contain multiple WHERE expressions that are joined by logical
operators.

Note: Using indexed SAS data sets can significantly improve performance when you
use WHERE expressions to access a subset of the observations in a SAS data set.
See “Understanding SAS Indexes” in Chapter 26 of SAS Language Reference:
Concepts for a complete discussion of WHERE-expression processing with indexed
data sets and a list of guidelines to consider before you index your SAS data sets.

In DATA Steps
The WHERE statement applies to all data sets in the preceding SET, MERGE,
MODIFY, or UPDATE statement, and variables that are used in the WHERE statement
must appear in all of those data sets. You cannot use the WHERE statement with the
POINT= option in the SET and MODIFY statements.

You can apply OBS= and FIRSTOBS= processing to WHERE processing. For more
information, see “Processing a Segment of Data That Is Conditionally Selected” in

You cannot use the WHERE statement to select records from an external file that
contains raw data, nor can you use the WHERE statement within the same DATA step in
which you read in-stream data with a DATALINES statement.

For each iteration of the DATA step, the first operation SAS performs in each execution
of a SET, MERGE, MODIFY, or UPDATE statement is to determine whether the
observation in the input data set meets the condition of the WHERE statement. The
WHERE statement takes effect immediately after the input data set options are applied
and before any other statement in the DATA step is executed. If a DATA step combines
observations using a WHERE statement with a MERGE, MODIFY, or UPDATE
statement, SAS selects observations from each input data set before it combines them.
**WHERE and BY in a DATA Step**

If a DATA step contains both a WHERE statement and a BY statement, the WHERE statement executes before BY groups are created. Therefore, BY groups reflect groups of observations in the subset of observations that are selected by the WHERE statement, not the actual BY groups of observations in the original input data set.

For a complete discussion of BY-group processing, see “By-Group Processing in SAS Programs” in Chapter 10 of *SAS Language Reference: Concepts*.

**In PROC Steps**

You can use the WHERE statement with any SAS procedure that reads a SAS data set. The WHERE statement is useful in order to subset the original data set for processing by the procedure. The *Base SAS Procedures Guide* documents the action of the WHERE statement only in those procedures for which you can specify more than one data set. In all other cases, the WHERE statement performs as documented here.

**Use of Indexes**

A DATA or PROC step attempts to use an available index to optimize the selection of data when an indexed variable is used in combination with one of the following operators and functions:

- the BETWEEN-AND operator
- the comparison operators, with or without the colon modifier
- the CONTAINS operator
- the IS NULL and IS NOT NULL operators
- the LIKE operator
- the TRIM function
- the SUBSTR function, in some cases.

SUBSTR requires the following arguments:

```plaintext
where substr(variable, position, length) = 'character-string';
```

An index is used in processing when the arguments of the SUBSTR function meet all of the following conditions:

- `position` is equal to 1
- `length` is less than or equal to the length of `variable`
- `length` is equal to the length of `character-string`.

**Operands Used in WHERE Expressions**

Operands in WHERE expressions can contain the following values:

- constants
- time and date values
- values of variables that are obtained from the SAS data sets
- values created within the WHERE expression itself.

You cannot use variables that are created within the DATA step (for example, `FIRST.variable`, `LAST.variable`, `_N_`, or variables that are created in assignment statements) in a WHERE expression because the WHERE statement is executed before
the SAS System brings observations into the DATA or PROC step. When WHERE expressions contain comparisons, the unformatted values of variables are compared.

The following are examples of using operands in WHERE expressions:

- where score>50;
- where date>='01jan1999'd and time>='9:00't;
- where state='Mississippi';

As in other SAS expressions, the names of numeric variables can stand alone. SAS treats values of 0 or missing as false; other values are true. These examples are WHERE expressions that contain the numeric variables EMPNUM and SSN:

- where empnum;
- where empnum and ssn;

Character literals or the names of character variables can also stand alone in WHERE expressions. If you use the name of a character variable by itself as a WHERE expression, SAS selects observations where the value of the character variable is not blank.

**Operators Used in the WHERE Expression**

You can include both SAS operators and special WHERE-expression operators in the WHERE statement. For a complete list of the operators, see Table 2.10 on page 385. For the rules that SAS follows when it evaluates WHERE expressions, see “WHERE-Expression Processing” in Chapter 11 of *SAS Language Reference: Concepts*.

**Table 2.10 WHERE Statement Operators**

<table>
<thead>
<tr>

<td>logical not</td>
</tr>
</tbody>
</table>

#### Other

<table>
<thead>
<tr>
<th>Symbol or Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td></td>
<td></td>
</tr>
<tr>
<td>()</td>
<td>indicate order of evaluation</td>
</tr>
<tr>
<td>+ prefix</td>
<td>positive number</td>
</tr>
<tr>
<td>− prefix</td>
<td>negative number</td>
</tr>
</tbody>
</table>

#### WHERE Expression Only

<table>
<thead>
<tr>
<th>Symbol or Mnemonic</th>
<th>Description</th>
</tr>
</thead>
<tbody>
<tr>
<td>BETWEEN–AND</td>
<td>an inclusive range</td>
</tr>
<tr>
<td>? or CONTAINS</td>
<td>a character string</td>
</tr>
<tr>
<td>IS NULL or IS MISSING</td>
<td>missing values</td>
</tr>
<tr>
<td>LIKE</td>
<td>match patterns</td>
</tr>
<tr>
<td>=*</td>
<td>sounds-like</td>
</tr>
<tr>
<td>SAME-AND</td>
<td>add clauses to an existing WHERE statement without retyping original one</td>
</tr>
</tbody>
</table>

* The caret (^), tilde (~), and the not sign (¬) all indicate a logical not. Use the character available on your keyboard, or use the mnemonic equivalent.
** The OR symbol ( | ), broken vertical bar ( | | ), and exclamation point (!) all indicate a logical or. Use the character available on your keyboard, or use the mnemonic equivalent.
*** Two OR symbols (| | ), two broken vertical bars ( | | | | ), or two exclamation points (!!!) indicate concatenation. Use the character available on your keyboard.
† You can use the colon modifier (:) with any of the comparison operators in order to compare only a specified prefix of a character string.

### Comparisons

- You can use the WHERE command in SAS/FSP software to subset data for editing and browsing. You can use both the WHERE statement and WHERE= data set option in windowing procedures and in conjunction with the WHERE command.
• To select observations from individual data sets when a SET, MERGE, MODIFY, or UPDATE statement specifies more than one data set, apply a WHERE= data set option to each data set. In the DATA step, if a WHERE statement and a WHERE= data set option apply to the same data set, SAS uses the data set option and ignores the statement for that data set. Other data sets without a WHERE data set option use the statement.

• The most important differences between the WHERE statement in the DATA step and the subsetting IF statement are as follows:
  • The WHERE statement selects observations before they are brought into the program data vector, making it a more efficient programming technique. The subsetting IF statement works on observations after they are read into the program data vector.
  • The WHERE statement can produce a different data set from the subsetting IF when a BY statement accompanies a SET, MERGE, or UPDATE statement. The different data set occurs because SAS creates BY groups before the subsetting IF statement selects but after the WHERE statement selects.
  • The WHERE statement cannot be executed conditionally as part of an IF statement, but the subsetting IF statement can.
  • The WHERE statement selects observations in SAS data sets only, whereas the subsetting IF statement selects observations from an existing SAS data set or from observations that are created with an INPUT statement.
  • The subsetting IF statement cannot be used in SAS windowing procedures to subset observations for browsing or editing.
  • Do not confuse the WHERE statement with the DROP or KEEP statement. The DROP and KEEP statements select variables for processing. The WHERE statement selects observations.

Examples

Example 1: Basic WHERE Statement Usage
This DATA step produces a SAS data set that contains only observations from data set CUSTOMER in which the value for NAME begins with Mac and the value for CITY is Charleston or Atlanta.

data testmacs;
  set customer;
  where substr(name,1,3)='Mac' and (city='Charleston' or city='Atlanta');
run;

Example 2: Using Operators Available Only in the WHERE Statement
• Using BETWEEN-AND:
  where empnum between 500 and 1000;

• Using CONTAINS:
  where company ? 'bay';
  where company contains 'bay';

• Using IS NULL and IS MISSING:
where name is null;
where name is missing;

• Using LIKE to select all names that start with the letter D:
  where name like 'D%';

• Using LIKE to match patterns from a list of the following names:
  Diana
  Diane
  Dianna
  Dianthus
  Dyan

<table>
<thead>
<tr>
<th>WHERE Statement</th>
<th>Name Selected</th>
</tr>
</thead>
<tbody>
<tr>
<td>where name like 'D_an';</td>
<td>Dyan</td>
</tr>
<tr>
<td>where name like 'D_an.';</td>
<td>Diana, Diane</td>
</tr>
<tr>
<td>where name like 'D_an_';</td>
<td>Dianna</td>
</tr>
<tr>
<td>where name like 'D_an%';</td>
<td>all names from list</td>
</tr>
</tbody>
</table>

• Using the Sounds-like Operator to select names that sound like “Smith”:
  where lastname=*'Smith';

• Using SAME-AND:
  where year>1991;
  ...more SAS statements...
  where same and year<1999;

  In this example, the second WHERE statement is equivalent to the following WHERE statement:
  where year>1991 and year<1999;

Data Set Options:

• “WHERE= Data Set Option” in SAS Data Set Options: Reference
WINDOW Statement

Creates customized windows for your applications.

Valid in: DATA step

Category: Window Display

Type: Declarative

Syntax

WINDOW window <window-options> field-definition(s);
WINDOW window <window-options> group-definition(s);

Arguments

window
specifies the window name.

Restriction: Window names must conform to SAS naming conventions.

window-options
specifies characteristics of the window as a whole. Specify these window-options before any field or GROUP= specifications:

COLOR=color
specifies the color of the window background for operating environments that have this capability. In other operating environments, this option affects the color of the window border. The following colors are available:

BLACK MAGENTA
BLUE ORANGE
BROWN PINK
CYAN RED
GRAY WHITE
GREEN YELLOW

Default: If you do not specify a color with the COLOR= option, the window's background color is device-dependent instead of black, and the color of a field is device-dependent instead of white.

Tip: The representation of colors might vary, depending on the monitor being used. COLOR= has no effect on monochrome monitors.

COLUMNS=columns
specifies the number of columns in the window.

Default: The window fills all remaining columns on the monitor; the number of columns that are available depends on the type of monitor that is being used.

ICOLUMN=column
specifies the initial column within the monitor at which the window is displayed.

Default: SAS displays the window at column 1.
IROW=\textit{row}

specifies the initial row (or line) within the monitor at which the window is displayed.

\textbf{Default: } SAS displays the window at row 1.

KEYS=\langle\text{libref.}\rangle\text{catalog.}\langle\text{keys-entry}\rangle

specifies the name of a KEYS entry that contains the function key definitions for the window.

\textbf{Default: } SAS uses the current function key settings that are defined in the KEYS window.

\textbf{Tips: }

If you specify only an entry name, SAS looks in the SASUSER.PROFILE catalog for a KEYS entry of the name that is specified. You can also specify the three-level name of a KEYS entry, in the form

\texttt{libref.catalog.keys-entry}

To create a set of function key definitions for a window, use the KEYS window. Define the keys as you want, and use the SAVE command to save the definitions in the SASUSER.PROFILE catalog or in a SAS library and catalog that you specify.

MENU=\langle\text{libref.}\rangle\text{catalog.}\langle\text{pmenu-entry}\rangle

specifies the name of a menu (pmenu) you have built with the PMENU procedure.

\textbf{Tip: } If you specify only an entry name, SAS looks in the SASUSER.PROFILE catalog for a PMENU entry of the name specified. You can also specify the three-level name of a PMENU entry in the form

\texttt{libref.catalog.pmenu-entry}

ROWS=\textit{rows}

specifies the number of rows (or lines) in the window.

\textbf{Default: } The window fills all remaining rows on the monitor.

\textbf{Tip: } The number of rows that are available depends on the type of monitor that is being used.

\textbf{field-definition(s) }

specifies and describes a variable or character string to be displayed in a window or within a group of related fields.

\textbf{Tips: }

A window or group can contain any number of fields, and you can define the same field in several groups or windows.

You can specify multiple \textit{field-definition(s)}.

\textbf{See: } “Field Definitions” on page 391

\textbf{group-definition(s) }

specifies a group and defines all fields within a group. A group definition consists of two parts: the \texttt{GROUP=} option and one or more field definitions.

\textbf{GROUP=}\textit{group}

specifies a group of related fields.

\textbf{Default: } A window contains one unnamed group of fields.

\textbf{Restriction: } \textit{group} must be a SAS name.

\textbf{Tips: }

When you refer to a group in a DISPLAY statement, write the name as \texttt{window.group}. 
A group contains all fields in a window that you want to display at the same time. Display various groups of fields within the same window at different times by naming each group. Choose the group to appear by specifying `window.group` in the DISPLAY statement.

Specifying several groups within a window prevents repetition of window options that do not change and helps you keep track of related displays. For example, if you are defining a window to check data values, arrange the display of variables and messages for most data values in the data set in a group that is named STANDARD. Arrange the display of different messages in a group that is named CHECKIT that appears when data values meet the conditions that you want to check.

### Details

#### The Basics

**Operating Environment Information**

The WINDOW statement has some functionality that might be specific to your operating environment. For details, see the SAS documentation for your operating environment.

You can use the WINDOW statement in the SAS windowing environment, in interactive line mode, or in noninteractive mode to create customized windows for your applications. Windows that you create can display text and accept input; they have command and message lines. The window name appears at the top of the window. Use commands and function keys with windows that you create. A window definition remains in effect only for the DATA step that contains the WINDOW statement.

Define a window before you display it. Use the DISPLAY statement to display windows that are created with the WINDOW statement. For more information, see the “DISPLAY Statement” on page 61.

#### Field Definitions

Use a field definition to identify a variable or a character string to be displayed, its position, and its attributes. Enclose character strings in quotation marks. The position of an item is its beginning row (or line) and column. Attributes include color, whether you can enter a value into the field, and characteristics such as highlighting.

You can define a field to contain a variable value or a character string, but not both. The form of a field definition for a variable value is

```
<row column> variable <format> options
```

The form for a character string is

```
<row column> 'character-string' options
```

The elements of a field definition are described here.

**row column**

specifies the position of the variable or character string.

SAS keeps track of its position in the window with a pointer. For example, when you tell SAS to write a variable's value in the third column of the second row of a window, the pointer moves to row 2, column 3 to write the value. Use the pointer controls that are listed here to move the pointer to the appropriate position for a field.

In a field definition, `row` can be one of these row pointer controls:

1. **You cannot use the WINDOW statement in batch mode because no computer is connected to a batch executing process.**
#n
specifies row n within the window.

**Range:** n must be a positive integer.

#numeric-variable
specifies the row within the window that is given by the value of numeric-variable.

**Restriction:** #numeric-variable must be a positive integer. If the value is not an integer, the decimal portion is truncated and only the integer is used.

#(expression)
specifies the row within the window that is given by the value of expression.

**Restrictions:**
expression can contain array references and must evaluate to a positive integer.
Enclose expression in parentheses.

/ moves the pointer to column 1 of the next row.

In a field definition, *column* can be one of these column pointer controls:

@n
specifies column n within the window.

**Restriction:** n must be a positive integer.

@numeric-variable
specifies the column within the window that is given by the value of numeric-variable.

**Restriction:** numeric-variable must be a positive integer. If the value is not an integer, the decimal portion is truncated and only the integer is used.

@(expression)
specifies the column within the window that is given by the value of expression.

**Restrictions:**
expression can contain array references and must evaluate to a positive integer.
Enclose expression in parentheses.

+n
moves the pointer n columns.

**Range:** n must be a positive integer.

+numeric-variable
moves the pointer the number of columns that is given by the numeric-variable.

**Restriction:** +numeric-variable must be a positive or negative integer. If the value is not an integer, the decimal portion is truncated and only the integer is used.

**Default:** If you omit row in the first field of a window or group, SAS uses the first row of the window. If you omit row in a later field specification, SAS continues on the row that contains the previous field. If you omit column, SAS uses column 1 (the left border of the window).

**Tip:** Although you can specify either row or column first, the examples in this documentation show the row first.

*variable*
specifies a variable to be displayed or to be assigned the value that you enter at that position when the window is displayed.
Tips:

variable can be the name of a variable or of an array reference.

To allow a variable value in a field to be displayed but not changed by the user, use the PROTECT= option (described later in this section). You can also protect an entire window or group for the current execution of the DISPLAY statement by specifying the NOINPUT option in the DISPLAY statement.

If a field definition contains the name of a new variable, that variable is added to the data set that is being created (unless you use a KEEP or DROP specification).

format
gives the format for the variable.

Default: If you omit format, SAS uses an informat and format that are specified elsewhere (for example, in an ATTRIB, INFORMAT, or FORMAT statement or permanently stored with the data set) or a SAS default informat and format.

Tips:

If a field displays a variable that cannot be changed (that is, you use the PROTECT=YES option), format can be any SAS format or a format that you define with the FORMAT procedure.

If a field can both display a variable and accept input, you must either specify the informat in an INFORMAT or ATTRIB statement or use a SAS format such as $CHAR. or TIME. that has a corresponding informat.

If a format is specified, the corresponding informat is assigned automatically to fields that can accept input.

A format and an informat in a WINDOW statement override an informat and a format that are specified elsewhere.

'character-string'
contains the text of a character string to be displayed.

Restrictions: The character string must be enclosed in quotation marks.

You cannot enter a value in a field that contains a character string.

options
Specify field definition attributes:

ATTR=highlighting-attribute
controls these highlighting attributes of the field:

BLINK causes the field to blink.
HIGHLIGHT displays the field at high intensity.
REV_VIDEO displays the field in reverse video.
UNDERLINE underlines the field.

Alias: A=

Tips:

To specify more than one highlighting attribute, use the form

ATTR=(highlighting-attribute-1,...)

The highlighting attributes that are available depend on the type of monitor that you use.

AUTOSKIP=YES | NO
controls whether the cursor moves to the next unprotected field of the current window or group when you have entered data in all positions of a field.
YES specifies that the cursor moves automatically to the next unprotected field.

NO specifies that the cursor does not move automatically.

**Alias:** AUTO=

**Default:** NO

**COLOR=**<color>
specifies a color for the variable or character string. You can specify one of the following colors:

- BLACK
- MAGENTA
- BLUE
- ORANGE
- BROWN
- PINK
- CYAN
- RED
- GRAY
- WHITE
- GREEN
- YELLOW

**Alias:** C=

**Default:** WHITE

**Tips:**

The representation of colors might vary, depending on the monitor that you use.

COLOR= has no effect on monochrome monitors.

**DISPLAY=**<yes_no>
controls whether the contents of a field are displayed.

- YES specifies that SAS displays characters in a field as you type them in.
- NO specifies that the entered characters are not displayed.

**Default:** YES

**PERSIST=**<yes_no>
controls whether a field is displayed by all executions of a DISPLAY statement in the same iteration of the DATA step until the DISPLAY statement contains the BLANK option.

- YES specifies that each execution of the DISPLAY statement displays all previously displayed contents of the field as well as the contents that are scheduled for display by the current DISPLAY statement. If the new contents overlap persisting contents, the persisting contents are no longer displayed.
- NO specifies that each execution of a DISPLAY statement displays only the current contents of the field.

**Default:** NO

**Tip:** PERSIST= is most useful when the position of a field changes in each execution of a DISPLAY statement.

**Example:** “Example 3: Persisting and Nonpersisting Fields” on page 398

**PROTECT=**<yes_no>
controls whether information can be entered into a field.

- YES specifies that you cannot enter information.
NO specifies that you can enter information.

**Alias:** P=

**Default:** No

**Tip:** Use PROTECT= only for fields that contain variables; fields that contain text are automatically protected.

REQUIRED=YES | NO

controls whether a field can be left blank.

NO specifies that you can leave the field blank.

YES specifies that you must enter a value in the field.

**Default:** NO

**Tip:** If you try to leave a field blank that was defined with REQUIRED=YES, SAS does not allow you to input values in any subsequent fields in the window.

**Automatic Variables**
The WINDOW statement creates two automatic SAS variables: _CMD_ and _MSG_.

_**CMD**_
contains the last command from the window's command line that was not recognized by the window.

**Tip:** _CMD_ is a character variable with a length of 80 bytes; its value is set to ' ' (blank) before each execution of a DISPLAY statement.

**Example:** “Example 4: Sending a Message” on page 398

_**MSG**_
contains a message that you specify to be displayed in the message area of the window.

**Tip:** _MSG_ is a character variable with a length of 80 bytes; its value is set to ' ' (blank) after each execution of a DISPLAY statement.

**Example:** “Example 4: Sending a Message” on page 398

**Displaying Windows**
The DISPLAY statement enables you to display windows. Once you display a window, the window remains visible until you display another window over it or until the end of the DATA step. When you display a window that contains fields into which you can enter values, either enter a value or press ENTER at each unprotected field to cause SAS to proceed to the next display. While a window is being displayed, you can use commands and function keys to view other windows, change the size of the current window, and so on. The execution proceeds to the next display only after you have pressed ENTER in all unprotected fields.

A DATA step that contains a DISPLAY statement continues execution until

- the last observation that is read by a SET, MERGE, MODIFY, UPDATE, or INPUT statement has been processed
- a STOP or ABORT statement is executed
- an END command executes.

**Comparisons**

- The WINDOW statement creates a window, and the DISPLAY statement displays it.
The %WINDOW and %DISPLAY statements in the macro language create and display windows that are controlled by the macro facility.

Examples

Example 1: Creating a Single Window
This DATA step creates a window with a single group of fields:

```sas
data _null_;
window start
   #9 @26 'WELCOME TO THE SAS SYSTEM'
   color=black
   #12 @19 'THIS PROGRAM CREATES'
   #12 @40 'TWO SAS DATA SETS'
   #14 @26 'AND USES THREE PROCEDURES'
   #18 @27 'Press ENTER to continue';
   display start;
   stop;
run;
```

The START window fills the entire monitor. The first line of text is black. The other three lines are the default for your operating environment. The text begins in the column that you specified in your program. The START window does not require you to input any values. However, to exit the window do one of the following:

• Press ENTER to cause DATA step execution to proceed to the STOP statement.
• Issue the END command.

If you omit the STOP statement from this program, the DATA step executes endlessly until you execute END from the window, either with a function key or from the command line. (Because this DATA step does not read any observations, SAS cannot detect an end-of-file to end DATA step execution.)

Example 2: Displaying Two Windows Simultaneously
The following statements assign news articles to reporters. The list of article topics is stored as variable art in SAS data set category.article. This application enables you to assign each topic to a writer and to view the accumulating assignments. The program creates a new SAS data set named Assignment.
libname category 'SAS-library';
data Assignment;
  set category.article end=final;
  drop a b j s o;
  window Assignment irow=1 rows=12 color=white
    #3 @10 'Article:' +1 art protect=yes
    'Name:' +1 name $14.;
  window Showtotal irow=20 rows=12 color=white
    group=subtotal
      #1 @10 'Adams has' +1 a
      #2 @10 'Brown has' +1 b
      #3 @10 'Johnson has' +1 j
      #4 @10 'Smith has' +1 s
      #5 @10 'Other has' +1 o
    group=lastmessage
      #8 @10
        'ALL ARTICLES ASSIGNED. Press ENTER to stop processing.,'
  display Assignment blank;
  if name='Adams' then a+1;
  else if name='Brown' then b+1;
  else if name='Johnson' then j+1;
  else if name='Smith' then s+1;
  else o+1;
  display Showtotal.subtotal blank noinput;
  if final then display Showtotal.lastmessage;
run;

When you execute the DATA step, the following windows appear.

In the Assignment window (located at the top of the monitor), you see the name of the
article and a field into which you enter a reporter's name. After you type a name and
press ENTER, SAS displays the Showtotal window (located at the bottom of the
monitor) which shows the number of articles that are assigned to each reporter
(including the assignment that you just made). As you continue to make assignments, the
values in the Showtotal window are updated. During the last iteration of the DATA step,
SAS displays the message that all articles are assigned, and instructs you to press
ENTER to stop processing.
Example 3: Persisting and Nonpersisting Fields
This example demonstrates the PERSIST= option. You move from one window to the other by positioning the cursor in the current window and pressing ENTER.

```sas
data _null_;
array row{3} r1-r3;
array col{3} c1-c3;
input row{*} col{*};
window One
   rows=20 columns=36
   #1 @14 'PERSIST=YES' color=black
   #{row{i}} @(col{i}) 'Hello'
   color=black persist=yes;
window Two
   icolumn=43 rows=20 columns=36
   #1 @14 'PERSIST=NO' color=black
   #{row{i}} @(col{i}) 'Hello'
   color=black persist=no;
do i=1 to 3;
display One;
display Two;
end;
datalines;
5 10 15 5 10 15
;
```

The following windows show the results of this DATA step after its third iteration.

Note that window One shows **Hello** in all three positions in which it was displayed. Window Two shows only the third and final position in which **Hello** was displayed.

Example 4: Sending a Message
This example uses the _CMD_ and _MSG_ automatic variables to send a message when you execute an erroneous windowing command in a window that is defined with the WINDOW statement:

```sas
if _cmd ne ' ' then
   _msg_='CAUTION: UNRECOGNIZED COMMAND' || _cmd_;
```

When you enter a command that contains an error, SAS sets the value of _CMD_ to the text of the erroneous command. Because the value of _CMD_ is no longer blank, the IF statement is true. The THEN statement assigns to _MSG_ the value that is created by concatenating CAUTION: UNRECOGNIZED COMMAND and the value of _CMD_.

---

Chapter 2 • Dictionary of SAS Statements
(up to a total of 80 bytes). The next time a DISPLAY statement displays that window, the message line of the window displays the following:

CAUTION: UNRECOGNIZED COMMAND command

Command is the erroneous windowing command.

**Example 5: Creating a SAS Data Set**
The following statements create a SAS data set by using input from the WINDOW statement.

data new;
  length name $20;
  window start
    #3  @20 'Type the variable name'
    #4  @20 'and press the Enter key.'
    #7 'Name:' +1 name attr=underline
    #11 'When you are finished entering variable names, type "end"'
    #12 'at the command line.';
  display start;
run;
proc print;
run;

**Statements:**

- “DISPLAY Statement” on page 61

---

**X Statement**

Issues an operating-environment command from within a SAS session.

**Valid in:** Anywhere
Category: Operating Environment
See: X Statement under Windows, UNIX, or z/OS

Syntax
X <"operating-environment-command">;

Without Arguments
Using X without arguments places you in your operating environment, where you can issue commands that are specific to your environment.

Arguments
'operating-environment-command'
    specifies an operating environment command that is enclosed in quotation marks.

Details
In all operating environments, you can use the X statement when you run SAS in windowing or interactive line mode. In some operating environments, you can use the X statement when you run SAS in batch or noninteractive mode.

Operating Environment Information
The X statement is dependent on your operating environment. See the SAS documentation for your operating environment to determine whether it is a valid statement on your system. Keep in mind that the way you return from operating environment mode to the SAS session is dependent on your operating environment and the commands that you use with the X statement are specific to your operating environment.

You can use the X statement with SAS macros to write a SAS program that can run in multiple operating environments. See the SAS Macro Language: Reference for information.

Comparisons
In a windowing session, the X command works exactly like the X statement except that you issue the command from a command line. You submit the X statement from the Program Editor window.

The X statement is similar to the SYSTEM function, the X command, and the CALL SYSTEM routine. In most cases, the X statement, X command or %SYSEXEC macro statement are preferable because they require less overhead. However, the SYSTEM function can be executed conditionally. The X statement is a global statement and executes as a DATA step is being compiled.
